Nonroad Engine and Vehicle Emission Study

List of Appendixes

The following appendixes provide background information for the Nonroad Engine and Vehicle Emission Study - Report. They are presented in their order of first occurrance in the text of the report.

Appendix A. Glossary of Acronyms and Terms

Appendix B. Ozone Formation

Appendix C. Ozone and CO Nonattainment and Air Toxic Risk Estimates

Appendix D. Mobile Source Air Toxics

Appendix E. Manufacturer Association Membership

Appendix F. Technical Review Group Representatives

Appendix G. Emission Inventories Developed Using SIP and CARB Data

Appendix H. List of Equipment Types

Appendix I. Emission Factor Development

Appendix J. Additional Data Submissions

Appendix K. Adjustments to Data in Developing Inventory A

Appendix L. Regional and Seasonal Adjustments to Inventories

Appendix M. Emission Inventory A

Appendix N. EPA Use of Manufacturer Data In Inventory B

Appendix O. Emission Inventory B

Appendix P. Transport and Nonroad Emissions

Appendix Q. Response to Public Comment

Appendix A. Glossary of Acronyms and Terms

Acronyms

The following acronyms have been used in the report or its appendixes.

AIRS	Aeromatic Information Retrieval System
AMS	Area and Mobile Source
ASTM	American Society for Testing and Materials
BY	Base Year
BSFC	Brake Specific Fuel Consumption
CAA or the Act	Clean Air Act
CAAA	Clean Air Act Amendments
CARB	California Air Resources Board
CIMA	Construction Industries Manufacturing Association
CMSA	Consolidated Metropolitan Statistical Area
CNG	Compressed Natural Gas
CO	Carbon Monoxide
CO_2	Carbon Dioxide
CTG	Control Technology Guidelines
EEA	Energy and Environmental Analysis
EMA	Engine Manufacturers Association
EMI	Equipment Manufacturers Institute
EPA	Environmental Protection Agency
HC	Hydrocarbon
hp	Horsepower
IRIS	Integrated Risk Information System
ISIA	International Snowmobile Industry Association
ITA	Industrial Truck Association
LMOS	Lake Michigan Oxidant Study
LPG	Liquified Petroleum Gas
MECA	Manufacturers of Emission Controls Association
MIC	Motorcycle Industry Council
MSA	Metropolitan Statistical Area
NMMA	National Marine Manufacturers Association
NAAQS	National Ambient Air Quality Standards
NAPAP	National Acid Precipitation Assessment Program
NECMA	New England County Metropolitan Areas
NESCAUM	Northeast States for Coordinated Air Use Management
NESHAPS	National Emissions Standards for Hazardous Air Pollutants
NO_2	Nitrogen Dioxide
NO_x	Oxides of Nitrogen
O_3	Ozone
OAR	Office of Air and Radiation
OAQPS	Office of Air Quality and Pollution Standards

ppb	parts per billion
PPEMA	Portable Power Equipment Manufacturers Association
ppm	parts per million
PSR	Power Systems Research
RACT	Reasonably Available Control Technology
ROM	Regional Oxidant Model
ROMNET	Regional Ozone Modeling for NorthEast Transport
rpm	revolutions per minute
RVP	Reid Vapor Pressure
SAE	Society of Automotive Engineers
SIP	State Implementation Plan
SEMA	Specialty Equipment Market Association
SO_2	Sulfur Dioxide
SO_x	Oxides of Sulfur
SwRI	Southwest Research Institute
TPD	Tons per Day
TPSD	Tons per Summer Day
TPWD	Tons per Winter Day
TPY	Tons per Year
TSD	Technical Support Document
TSDF	treatment, storage, and disposal facilities
UAM	Urban Airshed Model
VOC	Volatile Organic Compounds

Glossary of Terms

The following terms are defined as they were used in this report or its appendixes.

Activity level:	Unit indicating the combined effect of population, annual hours of use, average-rated horsepower, and load factor. Determined by multiplying the population x annual hours of use x horsepower x load factor. The activity level is also the product of the population and the per-source usage rate.
Airshed:	A geographical area which, because of topography, meteorology, and climate, shares the same air mass.
Air Toxic:	A compound in the air capable of causing adverse health effects. For the purpose of this report, the air toxics examined were limited to known or suspected carcinogens.
Aldehydes:	A class of fast-reacting organic compounds containing oxygen, hydrogen, and carbon. They contain the group -CHO.
Annual hours of use:	Average number of hours a given equipment type is used in one year.
Attainment area:	A region that meets the National Ambient Air Quality Standards for a criteria pollutant under the Clean Air Act.
Control technology:	A combination of measures designated to achieve the aggregate reduction of emissions.
Crankcase:	The part of the engine that surrounds the crankshaft; usually the lower section of the cylinder block.
Crankcase emissions:	Pollution emitted into the atmosphere from any portion of the engine crankcase ventilating or lubricating system.
Crankcase emission control system:	A system of passages designed to convey gases from and/or to the crankcase of an engine. The system may or may not include means to regulate the flow(s).
Criteria pollutants:	The Clean Air Act requires the Environmental Protection Agency to set air quality standards for common and widespread pollutants after preparing "criteria documents" summarizing scientific knowledge on their health effects. Today there are standards in effect for six "criteria pollutants": sulfur dioxide, carbon monoxide, particulates, nitrogen dioxide, ozone and lead.

Diurnal emissions:	Fuel vapors emitted as a result of a specified increase in fuel tank temperature in a specified time. For the purposes of this report, diurnal losses are those vapor emissions which occur while the equipment is not operating and are attributable to natural changes in ambient conditions (temperature, pressure, etc.).
Duty cycle:	The ratio of the time "on" of a device or system divided by the total cycle time (i.e., "on" plus time "off"). For a device that normally runs intermittently rather than continuously; the amount of time a device operates as opposed to its idle time.
Emission factor:	Measure of the rate at which a particular type of equipment emits a particular pollutant under normal operating conditions. Emission factors are commonly massed-based and expressed in units of mass per unit of work.
Emissions inventory:	A detailed listing of the amounts of pollution generated by different sources in an area during a specific period of time.
Evaporative emissions:	Losses due to evaporation of unburned fuel. For the purposes of this report, evaporative emissions are subdivided into four groups: hot soak, diurnal, resting loss, and running loss emissions.
4-stroke cycle:	The four-piston strokes--intake, compression, power, and exhaust--that make up the complete cycle of events in the 4-stroke-cycle engine. Also called 4-cycle and 4-stroke.
Horsepower, average rated:	The average of the maximum horsepower ratings for the engines in a given type of equipment.
Hot soak emissions:	Emissions which occur after the equipment has been turned off and attributable to the elevated temperature of the equipment (e.g., evaporation from the carburetor bowl).
Load factor:	The ratio of the engine power output during typical operating conditions to the engine rated horsepower.
National Ambient Air Quality Standards (NAAQS):	Section 109 of the Clean Air Act requires EPA to set nationwide standards, the National Ambient Air Quality Standards, for widespread air pollutants. Currently, six pollutants are regulated by primary and secondary NAAQS--carbon monoxide, lead, nitrogen dioxide, ozone, particulate matter (PM-10), and sulfur dioxide. See Criteria Pollutants.

Nonattainment area:	A region that fails to meet Clean Air Act primary ambient air standards are designated as nonattainment areas. Most major cities in the United States are nonattainment areas for one or more of the criteria pollutants. These dirty air regions are subject to strict controls to bring them into compliance with the standards.
Nonroad vehicles:	Vehicles or items of machinery that use an internal combustion engine but are not regulated as motor vehicles or airplanes under the Clean Air Act. Construction equipment is an examples of nonroad vehicles.
Per-source use rate:	Unit indicating the combined effect of annual hours of use, average-rated horsepower, and load factor. Determined by multiplying the annual hours of use by horsepower by load factor.
Population:	Total number of units of a given equipment or engine type at a given point in time.
Refueling emissions:	Hydrocarbon emissions that can occur during filling of the vehicle fuel tank. For the purposes of this report, there are two components of refueling emissions: spillage and vapor displacement.
Reid Vapor Pressure:	The vapor pressure of gasoline at 100°F(37.8°C) determined in a special bomb in the presence of a volume of air which occupies four times the volume of liquid fuel (ASTM procedure D 323).
Running loss emissions:	The emissions which do not pass through the combustion chamber while the source is in operation.
Spillage emissions:	Spillage emissions, or spillage, are those emissions resulting from spilled fuel incurred during the refueling process.
Steady state:	Constant operating conditions with no variation in fuel supply or load. A condition in which circuit values remain essentially constant, occurring after all initial transients or fluctuating conditions have settled down. Steady state exists when periodic (or constant) vehicle responses to periodic (or constant) control and/or disturbance inputs do not change over an arbitrarily long time. The motion responses in steady state are referred to as steady state responses. This definition does not require the vehicle to be operating in a straight line or on a level road surface. It can also be in a turn of constant radius or on a road surface.

Transient:	A phenomenon caused in a system by a sudden change in conditions and which persists for a relatively short time after the change.
Transient state:	Transient state exists when the motion responses, the external forces relative to the vehicle, or the control positions are changing with time.
Vapor displacement:	Vapor displacement emissions, or "displacement", are those emissions which result from displacing fuel vapors in the fuel tank with liquid fuel.
Volatile Organic Compounds (VOC):	Any compound containing carbon and hydrogen or containing carbon and hydrogen in combination with any other element which has a vapor pressure of 1.5 pounds per square inch absolute or greater under actual storage conditions.

Appendix B. Ozone Formation

This appendix provides a brief explanation of the process by which ozone is formed, followed by a list of other sources expanding on the role of NO_X and VOCs.

Description

The prediction of ozone (O_3) levels and the development of control strategies for ozone have been complicated by the fact that ozone is not directly emitted. Rather, it is formed in the lower atmosphere in the presence of sunlight through a complex series of reactions between volatile organic compounds (VOCs), oxides of nitrogen (NO_X), and ambient oxygen. The concentrations of ozone and its precursors are dynamic and nonlinear. Thus, ozone concentrations are not necessarily additive, but depend on the concentrations of all compounds involved in atmospheric chemistry. VOCs are emitted by anthropogenic sources, such as evaporation of gasoline and solvents, and by biogenic sources such as vegetation. Individual VOC species differ widely in their capacity to generate ozone. NO_X is formed primarily by combustion processes and can contribute to either the creation or destruction of ozone, depending on the amount of VOCs present.

Ozone is produced when atomic oxygen (O) reacts with molecular oxygen (O_2) in this reaction:

$$O + O_2 + M \rightarrow O_3 + M$$

where M is a third body that removes the energy of the reaction and stabilizes the O_3 molecule. The atomic oxygen necessary for this reaction is produced primarily from the photodissociation of NO_2, according to this reaction:

$$NO_2 + h\nu \rightarrow NO + O$$

The photon ($h\nu$) in this reaction is in the blue-violet end of the visible spectrum which, when absorbed, produces a brown color. This is why a brown haze is associated with ozone

pollution, even though ozone itself is a colorless gas. In the above reactions, NO_x is involved in creating ozone.

However, in the absence of other reactants, the ozone and nitrogen oxide (NO) produced in these reactions will combine to form nitrogen dioxide and molecular oxygen:

$$NO + O_3 \rightarrow NO_2 + O_2$$

Thus, oxides of nitrogen participate in both the creation of ozone and can retard creation of ozone. Put another way, in isolation equilibrium concentrations of ozone, nitrogen dioxide, and nitrogen oxide coexist. However, in the presence of organic peroxy radicals (RO_2), which are formed by the reaction of hydroxyl radicals (OH) with VOCs, nitrogen dioxide can be regenerated from nitrogen oxide without consuming ozone, as in this reaction:

$$RO_2 + NO \rightarrow NO_2 + RO$$

Thus, the presence of VOCs in the atmosphere is crucial to allowing ozone to accumulate, instead of allowing ozone to stabilize at a relatively low concentration dictated by the equilibrium of NO and NO_2. Generally speaking, the presence of more organic peroxy radicals will allow more ozone molecules to persist in the air. The number of organic peroxy radicals formed from a single VOC varies, and thus the photochemical reactivity of VOCs varies.

Appendix C. Ozone and CO Nonattainment and Air Toxic Risk Estimates

Two of the most persistent air quality problems in the United States are the nonattainment of National Ambient Air Quality Standards for carbon monoxide (CO) and ozone. Table C-01 lists the areas which fail to meet standards for CO and ozone. In addition to these nonattainment problems, concern regarding the risks associated with motor vehicle air toxics is increasing. The cancer risks associated with the motor vehicle pollutants of most concern are shown in Table C-02.[1]

Table C-01. Areas Not Meeting Standards for Carbon Monoxide and Ozone

Metropolitan Area	Pollutant Category	
	CO	Ozone
Albuquerque, NM	Moderate	
Anchorage, AK	Moderate	
Atlanta, GA		Serious
Atlantic City, NJ		Moderate
Bakersfield, CA		Serious
Baltimore, MD	Moderate	Severe
Baton Rouge, LA		Serious

Table C-02. Summary of Risk Estimates*

Motor Vehicle Pollutant	U.S. Cancer Incidences/Year**		
	1986	1995	2005
1,3-Butadiene	236-269	139-172	144-171
Diesel Particulate	178-860	106-662	104-518
Benzene	100-155	60-107	67-114
Formaldehyde	46-86	24-43	27-48
Gasoline Vapors	17-68	24-95	30-119
Asbestos	5-33	ND***	ND
Acetaldehyde	2	1	1
Gasoline Particulate	1-176	1-156	1-146
Ethylene Dibromide	1	<1	<1
Cadmium	<1	<1	<1
Dioxins	ND	ND	ND
Vehicle Interior Emissions	ND	ND	ND

* The risk estimates are 95% upper confidence limits.

** The risk estimates for asbestos, cadmium and ethylene dibromide are for urban exposure only. Risks for the other pollutants include both urban and rural exposure.

*** ND = Not Determined.

Note: The risk estimates are upper bound estimates; therefore, they are not intended to represent actual numbers of cancer cases but rather can be used to rank the mobile source pollutants and to guide further study.

Projections do not account for the 1990 CAAA revisions. Risk estimates are currently being revised as part of the EPA study of "Mobile Source Related Air Toxics" required by Section 206 of the CAAA.

Benzene
Formaldehyde
Acetaldehyde
1,3-Butadiene
Gasoline Vapors
Diesel Particulate
Gasoline Particulate
Iron

*Included in the EPA study of "Mobile Source Related Air Toxics" required by Section 206 of the CAAA.

Table D-03. Other Motor Vehicle Toxics from Title III of the 1990 Clean Air Act Amendments.[†]

Acetonitrile	Hexane
Acrolein	Lead compounds
Acrylic acid	Manganese compounds
Carbon Disulfide	Methanol
Carbonyl sulfide	Methyl ethyl keytone
Catechol	Methyl tert. butyl ether
Chlorine	Naphthalene
Cresols/Cresylic acid	Phenol
Dibenzofurans	Polycyclic organic matter
Diethyl sulfate	Propionaldehyde
Dimethyl sulfate	Styrene
1,4-Dioxane	Toluene
Ethyl benzene	2,2,4-Trimethylpentane
Ethylene dibromide	Xylenes
Ethylene dichloride	

[†] This list compiled by the Office of Mobile Sources in preparing the EPA study required by Section 206 of the CAAA.

Appendix E. Manufacturer Association Membership

This appendix provides a short description for the primary manufacturer associations for nonroad engines and vehicles. Where available, a list of the member companies are also provided.

Industrial Truck Association

The Industrial Truck Association (ITA) is the national, not-for-profit trade association of forklift truck manufacturers and their suppliers. ITA members collectively produce and sell 90 percent of all industrial forklift trucks in the United States.

Regular Members

Baker Material Handling Corp.
Barrett Industrial Trucks
Big Joe Manufacturing Co.
Caterpillar Industrial Inc.
Clark Material Handling, Inc.
Crown Equipment
Drexel Industries, Inc.
Elwell-Parker Electric Co.
Hyster Company
K-D Manitou, Inc.
Kalmar AC
Komatsu Forklift Inc.
  USA
  Canada
Mitsubishi Heavy Industries
  USA
  Canada
Multiton MIC Corp.
Nissan Indust. Equip. Co.
  USA
  Canada
The Prime Mover Company (BT)
The Raymond Corporation
TCM America
  USA
    C. ITOH
    TCM
  Canada
    Delval Handling
Toyota
  USA
  Canada
Yale Materials Handling Corp.

Associate Members

Anderson Power Products
Aquila Corporation
Basiloid Products Corp.
C&D Power Systems
Cascade Corporation
Chloride/Pilot
Curtis Instruments, Inc.
East Penn Mfg. Co., Inc.
Engelhard Corporation
Erectoweld Co., Inc.

ITA Associate Members (continued)

Exide Corporation
GNB Indust. Battery Co.
Hercules Engines, Inc.
Industrial Tires, Ltd.
K W Battery
Kenhar Products Inc.
Kurdziel Industries
Long Reach Mfg. Corp.
Prestolite Electric Inc.
Sevcon
Steel of West Virginia
Swing-Shift Mfg., Inc.
Toyoshima
Vickers, Inc.

Portable Power Equipment Manufacturers Association

The Portable Power Equipment Manufacturers Association (PPEMA) is the national, not-for-profit trade association representing the manufacturers of small engine powered off-road equipment such as chain saws, string trimmers, brush cutters, blowers, hedge trimmers, generators and cut-off saws. PPEMA's members manufacture the engines used in the final products they produce.

Members

Allied Signal
BASF Corporation
Carlton Company
Dolmar U.S.A., Inc.
Echo, Inc.
Homelite Division of Textron, Inc.
Husqvarna Forest & Garden Company
Inertia Dynamics Corporation
Kawasaki Motor Corporation, U.S.A.
Komatsu Zenoah America, Inc.
Oregon Cutting Systems, Division of Blount, Inc.
Poulan/Weed Eater
R.E. Phelon Company, Inc.
Shakespeare Monofilament Company
Shindaiwa, Inc.
Stihl, Inc.
The Toro Company
Walbro Corporation
U.S.A. Zama, Inc.

Outdoor Power Equipment Institute, Inc.

The Outdoor Power Equipment Institute (OPEI) is the national trade association representing manufacturers of consumer and commercial outdoor power equipment and their major components. OPEI members produce the following types of equipment and products: walk-behind lawnmowers; rear engine riding mowers; lawn tractors; garden tractors; walk-behind tillers; walk-behind snow throwers; commercial turf care equipment; engines/

attachments/components; shredders/grinders; lawn vacuums; flexible line trimmers; leaf blowers; log splitters; power brakes and thatchers; and lawn/edger/trimmers. In most cases, the goods manufactured by OPEI members are produced for the consumer market, and represent 86.9 percent of the U.S. market for lawn and garden equipment.

Regular Members

American Yard Products
Ariens Company Consolidated
Atlas Power Equipment
Bunton Company
John Deere Horicon Works
Dixon Industries, Inc.
Exmark Mfg., Inc.
Ferris Industries, Inc.
Garden Way, Inc.
Garden Way, Inc.-PW
Hoffco, Inc.
Homelite Div. of Textron
Honda Power Equip. Mfg., Inc.
Howard Price Turf Equipment
Ingersoll Equip. Co., Inc.
F.D. Kees Mfg. Co.
Kut-Kwick Corporation
Lambert Corporation
Lawn-Boy, Inc.
Maxim Mfg. Co.

Appendix F. Technical Review Group Representatives

The following groups and organizations external to EPA provided a technical reviewer to serve on a technical review panel. This panel provided feedback to staff on technical issues during the study.

California Air Resources Board (CARB)
Construction Industry Manufacturers Association (CIMA)
Engine Manufacturers Association (EMA)
Equipment Manufacturers Institute (EMI)
Industrial Truck Association (ITA)
National Marine Manufacturers Association (NMMA)
Northeast States for Coordinated Air Use Management (NESCAUM)
Outdoor Power Equipment Institute, Inc. (OPEI)
Portable Power Equipment Manufacturers Association (PPEMA)

Appendix G. Emission Inventories Developed Using SIP and CARB Data

As EPA began its study of nonroad emissions, one of the most comprehensive sources of data already available were emission inventories developed for State Implementation Plans (SIPs). EPA considered existing draft emission inventories developed by states in 1987 SIPs and recent inventories developed by the California Air Resources Board (CARB) for their SIPs. SIPs from eighteen geographical areas were used, as were CARB analyses for seven air basins in California. Table G-01 provides a list of these areas.

Table G-01. SIP and CARB Inventories Considered.

SIP Geographical Area	CARB Air Basin
Atlanta, GA MSA	Mountain Counties
Beaumont-Port Arthur, TX MSA	Sacramento Valley
Boston-Lawrence-Salem-Lowell-Brockton, MA NECMA	San Diego
Chicago-Gary-Lake County IL-IN-WI CMSA (IL portion)	San Francisco Bay Area
State of Connecticut	San Joaquin Valley
Dallas-Fort Worth, TX CMSA	South Central Coast
Denver-Boulder CO CMSA	South Coast
Duluth, MN-WI MSA (MN portion)	
El Paso, TX MSA	
Fort Collins-Loveland, CO MSA	
Hartford-New Britain-Middletown-Bristol, CT NECMA	
Houston-Galveston-Brazoria TX CMSA	
Louisville, KY CMSA (KY portion)	
Minneapolis-St. Paul MN-WI MSA (MN portion)	
State of New Jersey	
State of Massachusetts	
Seattle-Tacoma WA CMSA	
Springfield, MA NECMA	

Certain gaps and inconsistencies, as well as outdated emission factors, in the SIP inventories made it difficult to use inventories as available. However, the SIP inventories

considered were developed in enough detail that it was possible to discern how activity levels for nonroad mobile sources were estimated. EPA resolved the inconsistencies where possible and substituted new emission factors in order to generate new inventories based on the SIP data. The emission inventories developed by CARB for nonroad mobile sources were much more detailed than those from the SIPs, and were summarized without revision by EPA.

EPA also contracted for the gathering and compiling of new, comprehensive emission inventories in 24 cities, as described in the body of this report. The SIP inventories categorized nonroad mobile sources in slightly different ways than EPA did in developing new emission inventories. In Table G-02, the SIP and CARB categories are compared with the ten equipment categories developed by EPA for this study.

Table G-02. Different Ways of Categorizing Nonroad Mobile Sources.

SIPs	CARB	New EPA 24-City
Construction Equipment	Heavy-Duty Farm Equipment	Agricultural Equipment
Industrial Equipment	Heavy-Duty Construction Equip.	Logging Equipment
Lawn & Garden Equip.	Utility, Lawn, Garden Equip.	Construction Equipment
Off-Highway Motorcycles	Off-Highway Mobile Equipment	Light Commercial
Snowmobiles	Marine Vessels	Industrial Equipment
Recreational Boats		Airport Service Equipment
Commercial Marine Vessels		Lawn & Garden Equipment
		Recreational Equipment Recreational Marine
		Commercial Marine Vessels

The following section describes in greater detail the data obtained from SIPs and the methodology used in creating the inventories using this data.

SIP-Based Activity Levels

Emission inventories are developed as part of State Implementation Plans, or SIPs, which are submitted periodically to EPA by areas that do not comply with NAAQS. SIPs themselves outline means by which state authorities plan to meet the NAAQS. Generally, this includes a plan for emission reductions, which are projected based on the baseline emission inventory. State air quality planners generally develop emission inventories for nonattainment areas following the methodologies outlined in the existing EPA guidance.[1]

EPA provides information on preparing emission inventories for SIPs in a series of five documents entitled *Procedures for Emission Inventory Preparation* (henceforth simply *Procedures*). The first volume gives an overview of the methodologies and reporting requirements for emission inventories and subsequent volumes give the methodologies whereby activity levels may be estimated at the county level for point sources,[2] nonroad and highway mobile sources,[3] and other area sources.[4] Although all mobile sources are a subcategory of area sources, the term "mobile source" was often used in past SIP emission inventories to refer solely to highway vehicles. Emissions from all other mobile sources are, in such cases, often reported as "off-highway mobile sources" in the area source inventory. This is likely due to the fact that highway vehicles are already regulated and therefore much better characterized than nonroad mobile sources. Also, nonroad mobile source activity is often more similar to that of other area sources than is highway vehicle activity. For example, construction equipment activity can be characterized by considering the construction industry employment during the inventory period. Similarly, fuel consumption (e.g. heating oil) in commercial and industrial applications may be estimated using employment statistics in the applicable industries. Where possible, the emission factors in the EPA guidance document were updated to include more recent data. A full discussion of the development of revised SIP emission factors is contained in Appendix I.

After activity levels for the various source types have been estimated, emission factors* must be applied to calculate emissions in mass per unit time for each of the pollutants being studied in the inventory area.

Inventories developed for SIPs are usually developed for a given base year (BY); hence emissions are expressed in tons per year (tpy). In areas where nonattainment is a seasonal problem, the inventories may also be temporally adjusted. In many areas, ozone nonattainment is predominately a summertime problem; therefore, emissions of ozone precursors are expressed in tons per summer day (tpsd). Similarly, because CO nonattainment is usually a wintertime problem,† CO emissions are often expressed in tons per winter day (tpwd). In its analysis of SIP emission inventories, EPA used those seasonal adjustments that were reported in the SIPs.

For this study, EPA has examined several of the draft SIP inventories developed by states for the 1987 and 1988 BY. Because of the CAAA requirement that states develop emission inventories for the 1990 BY, many of the 1987/1988 draft inventories have not been finalized at this time. However, because the 1990 BY inventories will not be completed in 1991, only the earlier inventories may be considered for this study, despite the fact that they are still in draft form.

In analyzing 1987 base year emission inventories from SIPs, EPA extracted the activity levels calculated for nonroad engines and vehicles. Because the activity levels were separated from the emission factors, it was possible to apply the emission factors developed as part of this study to the activity levels to develop revised emission inventories that have benefitted from improvements to the emission factors.

In adjusting the SIP emission inventories for seasonal activity variations, EPA determined what assumptions had been used in the original inventory and applied only those having to do with seasonal variations. Consequently, these seasonal temporal adjustments are different from those made in inventories that also considered day-to-day activity fluctuations or daily temporal adjustments.

---

* Emission factors for nonroad mobile sources that are currently available from EPA guidance are given in *Compilation of Air Pollutant Emission Factors, Volume II: Mobile Sources*, Fourth Edition and Supplements, AP-42, U.S. Environmental Protection Agency, Research Triangle, Park, NC, September 1985.

† There are notable exceptions, however. The following areas had two or more summertime CO exceedances between 1986 and 1988: Cleveland, Ohio; New York City, New York; St. Louis, Missouri; and Steubenville, Ohio.

Summaries of the analysis of SIP emission inventories are given in the following tables. Detailed results of the SIP emission inventories are given in *State Estimates of Nonroad Engine and Vehicle Emissions*,[5] which documents for each nonattainment area studied the nonroad engine and vehicle activity levels derived, the emissions calculated, and the emissions from other sources (i.e., highway vehicles, other area and point sources).

Emission inventories prepared by the CARB are considered separately because inventories for some nonroad mobile source categories have recently been developed by CARB in support of California's proposed regulations applicable to such sources. These emission inventories are generally more refined than those that have been developed by states following the existing EPA guidance. Furthermore, they use different nonroad mobile source categories and are, therefore, not directly comparable to the draft SIP inventories.

Because of these differences from the SIP-based inventories, data from California's nonroad mobile source emission inventories were used as provided and compared to the highway and other source emissions given in the March 1990 version of the 1987 emission inventory prepared by CARB. The nonroad mobile source categories for which CARB has recently developed emission inventories are: utility and lawn and garden equipment,[6] heavy-duty farm and construction equipment,[7] and commercial marine vessels.[8] [†] These inventories are also summarized in the following tables.

[†]Study continues for other categories. These reports were available for use in this study.

Appendix H. List of Equipment Types

EPA considered over 80 different equipment types in this study of emissions from nonroad sources. Some of these equipment types include more than one kind of equipment. For example, "aerial lifts" includes boom lifts and scissor lifts, and "commercial turf equipment" includes riding turf mowers, walk-behind multi-spindle mowers, and others kinds of equipment.* The equipment types included in each of 10 equipment categories are detailed below.

Lawn and Garden Equipment

trimmers/edgers/brush cutters
lawnmowers
leaf blowers/vacuums
rear engine riding mowers
front mowers
chain saws < 4 hp
shredders < 5 hp
tillers < 5 hp
lawn and garden tractors
wood splitters
snowblowers
chippers/stump grinders
commercial turf equipment
  hydro/seeder mulchers
  riding turf mowers
  thatchers/aerators
  walk-behind multi-spindle mowers
  other miscellaneous equipment
other lawn and garden equipment
  augers
  sickel bar mowers
  pruning towers
  turf cutters

Airport Service Equipment

aircraft support equipment
  aircraft load lifters
  de-icing equipment/heat and start units
  ground power units
  utility service equipment
  baggage conveyors
  airport service vehicles

terminal tractors
  push-back tractors
  tow tractors
  yard spotters

Recreational Equipment

all terrain vehicles (ATVs)
minibikes
off-road motorcycles
golf carts
snowmobiles
specialty vehicles/carts
  snow grooming equipment
  ice maintenance equipment
  go-carts
  industrial ATVs
  industrial personnel carriers

*Note that this appendix contains a slightly more detailed list of equipment than is included in the Energy and Environmental Analysis final report, "Methodology to Estimate Nonroad Equipment Populations by Nonattainment Areas," available in Docket #A-91-24.

Recreational Marine Equipment

vessels with inboard engines
vessels with outboard engines
vessels with sterndrive engines
sailboat auxiliary inboard engines
sailboat auxiliary outboard engines

Light Commercial Equipment

generator sets
- baseload generators
- co-generation generators
- marine generators
- military generators
- peaking generators
- portable generators
- RV generators
- stand-by generators

pumps
- portable pumps
- fire pumps
- industrial pumps
- mud/trash pumps
- concrete pumps

air compressors
gas compressors
welders
pressure washers

Industrial Equipment

aerial lifts
- boom lifts
- scissor lifts
- self propelled elevating platforms

forklifts
sweepers/scrubbers
- municipal sweepers
- industrial sweepers
- scrubbers

other general industrial equipment
- abrasive blasting equipment
- industrial blowers/vacuums
- industrial scrapers/stripers
- marine/industrial winches and hoists
- multipurpose tool carriers
- other miscellaneous industrial equipment
  - strippers
  - floor buffers
  - pipe corers

other material handling equipment
- conveyors
- other miscellaneous material handling equipment
  - speed trucks
  - carriers
  - auto ramps

Construction Equipment

asphalt pavers
tampers/rammers
plate compactors
concrete pavers
rollers
- landfill compactors
- static and vibratory rollers

scrapers
paving equipment
- concrete finishers
- concrete vibrators
- other miscellaneous paving equipment

surfacing equipment
- asphalt/gravel planers
- asphalt mixers/agitators
- crack/joint routers
- pumper kettles/melters
- soil stabilizers
- road reclaimers
- pavement profilers
- roofing equipment
- other misc/surfacing equipment

signal boards
trenchers
- portable/walk-behind trenchers
- riding trenchers
- cable layers
- wheel trenchers

Construction Equipment (continued)

bore/drill rigs
- horizontal boring machines
- self propelled drills
- truck-mounted drills

excavators
- dragline excavators
- hydraulic excavators

concrete/industrial saws
cement and mortar mixers
cranes
- pedestal cranes
- rough terrain cranes
- shovel-type cranes
- straddle cranes
- truck mounted cranes

graders
off-highway trucks
crushing/processing equipment
rough terrain forklifts
rubber tired loaders
rubber tired dozers
tractors/loaders/backhoes
crawler tractors
skid steer loaders
off-highway tractors
dumpers/tenders
other construction equipment
- concrete pumps
- other miscellaneous construction equipment
  - concrete breakers
  - rod benders/cutters
  - highway repair equipment

Agricultural Equipment

2-wheel tractors
agricultural tractors
agricultural mowers
combines
sprayers
- back pack sprayers
- self propelled sprayers
- towable/tractor-mounted sprayers
- fertilizer spreaders

balers
tillers > 5 hp
swathers
hydro power units
other agricultural equipment
- harvesters
- frost/wind mills
- forage harvesters
- leaf harvesters
- fruit/nut harvesters
- orchard pruners
- detasslers
- cotton strippers/pickers
- other miscellaneous agricultural equipment
  - drain augers
  - wind fans
  - bedding chippers

Logging Equipment

chain saws > 4 hp
shredders > 5 hp
skidders
fellers/bunchers
- delimbers

Commercial Marine Vessels

commercial marine vessels

Appendix I. Emission Factor Development

This appendix details the origins of the emission factors used to calculate emission inventories for this study.

For this study, emissions from internal combustion engines are broadly grouped into one of four source categories based on the origin of the emission: tailpipe exhaust, refueling, evaporative, and crankcase emissions. Each of those categories is further divided by pollutant: HC, CO, NO_x, and other toxic pollutants including particulate matter, aldehydes, SO_x, benzene, and 1,3-butadiene. Since refueling and evaporative emissions are not a function of combustion, but are a function of fuel evaporation, only hydrocarbon emissions are considered for refueling and evaporative emissions. For each source category, pollutant, *and* nonroad equipment type (including fuel type and operating cycle), an emission factor is necessary to construct emission inventories. In simple terms, the emission factor is a measure of the rate at which a particular type of equipment emits a particular pollutant under normal operating conditions.

The remainder of this appendix describes how tailpipe exhaust, refueling, evaporative, and crankcase emission factors were developed. Adjustments were made to new engine emission factors to account for in-use effects and test cycle (steady state vs. transient) effects where appropriate. These adjustments are discussed in Chapter 2 of this appendix. Emission factors for particulate matter, aldehydes, and SO_x which were not available from the primary data sources described below were taken from AP-42[1] or from those recommended by Southwest Research Institute (SwRI).[2] Emission rates for nitrosamines, benzene, and 1,3-butadiene are discussed in separate chapters at the end of this appendix. Gasoline vapors are discussed in terms of the refueling and evaporative emissions. The emission factors used for calculating the SIP inventories are presented in Table I-01 and those used for calculating Inventories A and B are in Table I-02.

Tables I-01 through I-17 are located at the end of the appendix.

Chapter 1. Tailpipe Exhaust Emission Factors

A discussion of the development of tailpipe exhaust emission factors used in this study is presented below for the following categories: lawn and garden equipment, agricultural equipment, construction equipment, logging equipment, industrial equipment, light commercial equipment, recreational marine, commercial marine vessels, recreational equipment, and airport service equipment.

1.1. Lawn and Garden Equipment

1.1.1. Gasoline

The primary data source used in deriving the emission factors for gasoline lawn and garden equipment was the California Air Resources Board (CARB) technical support document (TSD) for lawn and garden equipment.[3] The testing done for CARB was performed by manufacturers, Southwest Research Institute (SwRI),[4] and Heiden Associates[5] for the Portable Power Equipment Manufacturers Association (PPEMA). The test results represent the most up-to-date information available for this category which were aggregated into emission factors.

The emission factors for calculating State Implementation Plan (SIP) emission inventories required aggregation of the CARB data into a 4-stroke category and a 2-stroke category. The CARB data was weighted by the population horsepower hours data submitted to EPA by the Outdoor Power Equipment Institute, the Portable Power Equipment Manufacturers Association and by data contained in the Heiden report. Tables I-03 and I-04 show this aggregation for 4-stroke and 2-stroke equipment respectively. To be used in computing SIP emission inventories, it was necessary to convert the emission factors from units of g/hp-hr to g/gallon fuel consumed. Brake specific fuel consumption (BSFC) values shown in Tables I-03 and I-04 were used for the conversion. The origin of these values is also shown in the tables. All aldehyde emission factors were derived from SAE Paper 910560, "Emission Factors for Small Utility Engines."[6]

The emission factors necessary for calculating Inventories A and B also required some aggregation, although not to the extent necessary for the SIP inventory calculation. The derivation of these emission factors is shown in Table I-05.

1.1.2. Diesel

Nearly all lawn and garden equipment is powered by gasoline engines. However, a small population of rear engine riding mowers, lawn and garden tractors, and wood splitters, chippers/stump grinders, and commercial turf equipment are powered by diesel engines. Since no emission data is available for diesel-powered lawn and garden equipment, the emission factors for diesel light commercial equipment (< 50 hp) were assumed to be the best approximation and were used for the study (see "1.5. Light Commercial Equipment < 50 hp").

1.2. Agricultural Equipment & Construction Equipment

1.2.1. Diesel

The most recent, up-to-date published emission factors for agricultural and construction diesel equipment are reported in the CAL/ERT report,[7] and in a recent report to CARB by Energy and Environmental Analysis (EEA)[8] on heavy-duty construction equipment. In general, the emissions for the CAL/ERT report were measured on a 13-mode steady state cycle and emission factors are reported in terms of equipment types. The EEA report presented general emission factors for HC, NO_x and particulate matter by model year.

In addition to these two sources, the Engine Manufacturers Association (EMA) submitted to EPA a list of recommended emission factors for diesel construction and agricultural equipment presented in Table I-06. The emission data was based on individual engine manufacturer submissions of emission data obtained from the 8-Mode Emission Test Procedure (ISO 8178) and related mode weighing factors. The emission factors were EMA's best estimates of in-the-field fleet population weighted factors. For agricultural equipment, EMA provided factors for only three equipment types (i.e. farm tractors, grain combine, and cotton pickers).

In general, the emission factors reported by the three sources are reasonably similar. For agricultural equipment, EPA has selected the factors presented in the CAL/ERT study

since they are presented by specific equipment type. For the SIP inventories, the emission factors were aggregated to tractor and nontractor categories by the energy outputs reported in the CAL/ERT report. The factors were converted from units of g/hp-hr to lb/1000 gallons of fuel consumed by using a BSFC of 0.4 lb/Hp-hr[9] and diesel fuel density of 7.1 lb/gallon.[10] Table I-08 shows the aggregation of the emission factors in terms of g/hp-hr, while Table I-08 shows the lb/1000 gal derivation.

For construction equipment the EMA emission factors were selected to be used to calculate emission inventories. For some equipment types, EMA factors were not available. In these cases, the Fourth Edition of AP-42[11] factors which were derived from CAL/ERT[12] factors were used. Table I-9 compares the AP-42 (CAL/ERT) and EMA emission factors for construction equipment.

The EMA did not report emission factors for particulate matter. The emission factors for particulate matter and aldehydes used in the study for Inventory A are those reported in the Fourth Edition of AP-42. The test results from a recent joint EPA/Industry program to assess test cycles for nonroad equipment are presented in Table I-10. The particulate emissions from the four 1991 diesel nonroad engines tested suggest that these newer engines have considerably lower emission rates than the emission factors reported in AP-42 (which are derived from a 1973 Southwest Research Institute study)[13]. Particulate emission rates for the four new engines tested are two to five times lower than the emission factors used for inventory purposes. Therefore, as the older engine fleet is replaced by the newer engines which emit lower levels of particulate matter, the particulate emission inventory will decrease accordingly. Although, the emission factors reported in AP-42 are assumed by EPA to be more representative of the average engine in the population, the test results on new engines suggest that these emission factors may overestimate particulate emission rates. To some extent, technology improvements in highway engines to meet the particulate emission standards (beginning in 1988) may have been carried into nonroad versions of these engines with the accompanying particulate emission benefit. Also, the data from the EPA/Industry program indicate that engine manufacturers who do not produce engines for highway applications have shown a decrease in particulate levels from 1973 to 1991.

The Engine Manufacturers Association (EMA) expressed concerns regarding the representativeness of the AP-42 data which was generated in 1973. As a result, the

particulate matter emission factors used for Inventory B are the equally weighted average of the AP-42 emission factors and the 1991 EPA/Industry average 8-mode nonroad engine test data.

1.2.2. Gasoline

The emission factors for gasoline agricultural and construction equipment selected to be used in calculating emission inventories are from the Fourth Edition of AP-42. The other sources that reported emission factors for diesel equipment did not report gasoline equipment emission factors. The CAL/ERT report did suggest using 2.8 g/hp-hr HC, 163 g/hp-hr CO, and 7.8 g/hp-hr NO_X for gasoline powered equipment (Tables I-7(c) and I-8(c)). However, the emission factors in AP-42 are more specific to equipment type and will be used for the study.

The particulate emission factors in AP-42 were derived from particulate measurements on gasoline nonroad engines at SwRI in the mid-seventies.[14] Leaded gasolines which generally contained between 1.5 and 2 grams of lead per gallon were used for the emission tests. This high lead fuel is not commercially available today. Even today's leaded fuel contains very little lead. Since particles consisting of lead oxides are the main particulate emission from leaded-gasoline fueled engines, the AP-42 emission factors are not representative of emission rates from equipment operating on currently available gasoline. Therefore, the values reported in AP-42 were not used in this study. Instead, a value of 1.64 lb/1000 gallons was used for the particulate emission factors for gasoline fueled equipment. This value is based on a recommendation from SwRI in the *Nonroad Emission Factors of Air Toxics*[15] report to EPA. Where necessary, the 1.64 lb/1000 gallon was converted to 0.06 g/hp-hr by assuming BSFC 0.5 lb/hp-hr[16] and density of gasoline of 6.2 lb/gallon.[17] Aldehyde emission factors were taken from AP-42.

1.3. Logging Equipment

1.3.1. Chain Saws > 4 hp

The emission factors for commercial chain saws reported in the CARB TSD[18] are used for this category.

1.3.2. Shredders > 5 hp

The emission factors reported in the CARB TSD for 4-stroke commercial shredders/ grinders are used for this category.

1.3.3. Skidders and Feller/Bunchers

The diesel emission factors for log skidders submitted to EPA by EMA (Table N-6) are used for these categories.

1.4. Industrial Equipment

Emission factors for gasoline and diesel industrial equipment used for the study are those reported in Volume I of AP-42. These factors were derived by SwRI in 1973[19] and were based on tests performed on eight diesel engines and four gasoline engines. No emissions data were available for LPG-powered aerial lifts, forklifts, and sweepers/scrubbers. The only emission data found for LPG-powered equipment is from two gasoline engines which were converted to operate on LPG. One engine was a 4.5 hp overhead valve walk behind mower engine tested by Southwest Research Institute.[20] Compared to the emissions when the engine was operated on gasoline, the engine emitted 38% less HC, 55% less CO, 147% more NO_X, 13% less PM, and approximately the same level of aldehydes when operated on LPG. The other engine was a 12.5 hp utility engine tested by Onan.[21] Compared to operation on gasoline, this engine emitted 72% less HC, 80% less CO, and 347% more NO_X when operated on LPG. Since neither of these engines are representative of the larger industrial equipment engines, the emission data cannot directly be used for developing an emission factor. However, the relative differences between the gasoline and LPG emission results for the two engines can be used to approximate the LPG emission factor. The above percentages were averaged resulting in a 55% reduction in HC, a 68% reduction in CO, a 247% increase in NO_X, and a 13% reduction in particulate matter compared to the gasoline baseline emission values when an engine is operated on propane. These percentages were applied to the gasoline emission factors to approximate the LPG emission factors.

1.5. Light Commercial Equipment < 50 hp

Light commercial equipment includes generator sets, pumps, air compressors, gas compressors, welders, and pressure washers. The emission factors recommended by SwRI[22] for the continuous service diesel equipment will be used for the study. These factors are the refrigeration unit emission factors in the Radian report[23]. Emission factors for gasoline light commercial equipment to be used in the study are taken from the CARB technical support document for utility and lawn and garden equipment[24] for *large* engines. Engines tested to develop the *large* engine emission factors included a 16 hp single cylinder side valve engine and two 18 hp 2-cylinder side valve engines. No emissions data were available for LPG powered pumps and gas compressors. Therefore, the gasoline emission factors for these equipment types were decreased by 55% for HC, decreased by 68% for CO, increased by 247% for NO_X, and decreased by 13% for particulate matter to approximate the LPG emission factors. This methodology is discussed in "1.4. Industrial Equipment" above.

1.6. Recreational Marine

1.6.1. Outboard Motors

The emission factors for outboard motors used in the study are derived from data submitted to EPA by the National Marine Manufacturers Association (NMMA). Data were submitted for twenty-five 2-stroke outboard engines and three 4-stroke outboard engines tested using the International Counsel of Marine Industry Associations (ICOMIA) Standard No. 36-88 duty cycle.[25] To aggregate the HC, CO, and NO_X emission factors on a national level for 2-stroke outboard engines, the horsepower distributions for the eight areas of the Broh survey[26] were used. The brake specific emission data supplied by NMMA were grouped into the horsepower ranges consistent with the Broh survey and averaged within each range. These data were then combined as shown in Table I-11a using the survey distributions. The resulting emission factors are in fuel based units (grams/gallon). The 4-stroke outboard emission data supplied by NMMA were aggregated as shown in Table I-11b

Particulate matter, aldehyde, and oxides of sulfur emissions were not measured from the engines tested by NMMA, therefore other data was used to determine the emission factors

for these pollutants. For 4-stroke outboards, the particulate matter and aldehyde (also used for 2-stroke) emission factors for noncatalyst gasoline engines recommended by Southwest Research Institute (SwRI)[27] were used. For 2-stroke outboards, no data on particulate emission rates was available. The particulate emission factors for 2-stroke utility engines of 7.7 g/hp-hr from the CARB technical support document for utility and lawn and garden equipment were used to approximate rates for outboard engines.[28] A brake specific fuel consumption value of 0.16 gallon/hp-hr was calculated from data supplied by NMMA and the Broh study distributions and used to convert the emission factor units to grams/gallon. For SO_X, emission factors for gasoline marine pleasurecraft in AP-42[29] were used.

1.6.2. Inboard Gasoline

The HC, CO, and NO_X emission factors used in the study for gasoline inboard and sterndrive engines were derived from data supplied by NMMA. The NMMA supplied emissions data for three 4-stroke gasoline marine inboard/sterndrive engines which were combined as shown in Table I-11c to determine emission rates in terms of grams/gallon of fuel consumed. The particulate emission factor used was 1.64 lb/1000 gal (0.74 g/gallon) as described in Section 1.2.2. of this appendix. The aldehyde emission factors for noncatalyst gasoline engines recommended by Southwest Research Institute (SwRI) and the SO_X emission factors reported in AP-42 were used for inboard/sterndrive gasoline engines.

1.6.3. Inboard Diesel

The HC, CO, and NO_X emission factors used in the study for diesel inboard engines were derived from data supplied by NMMA. The NMMA supplied data for one small sailboat inboard and three larger diesel inboards. The data were combined as shown in Table 11d to determine emission factors in terms of grams/gallon.

1.7. Commercial Marine Vessels

The AP-42 guidance document subdivides commercial motorships into waterway classifications for the purpose of calculating SIP emission inventories. The classifications are: coastal, great lakes, and river. The vessels operating in each of these waterways have similar characteristics such as size, speed, engine design, and distance traveled. Emission factors for

these classifications are contained in AP-42. These factors are used by states for calculating emission inventories by the fuel sales method described in the *Procedures for Emission Inventory Preparation, Volume IV: Mobile Sources*[30] guidance document published by EPA. Another set of emission factors for calculating emission inventories using a different method (the ship movement data method) is contained in the guidance document. The factors are in terms of size categories (draft). The emission factors used for the SIP inventory calculations are those reported in AP-42 and the guidance document with the exception of the slow speed diesel emission factors. For slow speed diesel marine engines, the emission factor of 550 lb/1000 gallons reported in the recent Booz Allen & Hamilton study[31] for EPA are used. This source is thought to better represent actual NO_x emission factors for the reasons set forth in the report. Emission factors for medium speed diesels were also reported by Radian[32] to CARB in 1988. These factors were based on tests of locomotive engines. The NO_x emission factor reported by Radian is 533 lb/1000 gal which is substantially higher than the factors reported in AP-42 (approx. 300 lb/1000 gal).

The commercial marine vessel inventories used for nonroad inventories A and B were developed by Booz Allen & Hamilton under contract for EPA. The emission factors used are contained in the Booz Allen & Hamilton final report and are reproduced in Tables I-12a and I-12b.

1.8. Recreational Equipment

1.8.1. Off-Road Motorcycles

As part of a recent CARB proposal to control emissions from off-road motorcycles,[33] CARB calculated emission factors for 2-stroke and 4-stroke engines. The factors are shown in Table I-13. To calculate SIP inventories, these factors were aggregated into composite factors by using a 68.5% 2-stroke, 31.5% 4-stroke distribution provided by EEA. The 2-stroke and 4-stroke emission factors for off-road motorcycles were also assumed for all terrain vehicles, minibikes, golf carts, and specialty vehicle carts.

1.8.2. Snowmobiles

Very little data exists on emission rates from snowmobiles. The best currently available published data appears to be contained in AP-42. These emission factors were derived from testing performed by SwRI in 1974[34] and are being considered for the study. The factors in terms of g/hr were converted to g/hp-hr for use in calculating emissions inventories from the activity information provided by EEA. The power reported by SwRI for the various test engines was weighted in the same manner as the emission values to determine a composite power of 5.8 hp over the test cycle. The g/hr value was then divided by 5.8 to determine g/hp hr. In a recent response to CARB mail out #90-70 entitled *A Proposal to Establish Exhaust Emission Standards and Test Procedures for Off-Highway Light-Duty Vehicles and Recreational Vehicles*, the International Snowmobile Industry Association (ISIA) reported snowmobile emission factors of 216 g/hp-hr $HC+NO_x$, and 564 g/hp-hr for CO. These factors are substantially higher than those calculated from the AP-42 factors even though the same SwRI test procedures were used in both cases.

1.9. Airport Service Equipment

The emission factors for industrial equipment were assumed to apply to airport service equipment.

Chapter 2. Adjustments to Tailpipe Emission Factors

2.1. Adjustments for Test Cycle

To develop emission factors representative of in-use nonroad engines, the test cycle that the engines are operated on should simulate typical in-use operation. There is much debate regarding the appropriateness of using a steady state test cycle or a transient test cycle for emission testing nonroad engines. A steady state test is a series of fixed set points of speed and load held for a period of time (usually from two to ten minutes). Emission measurements are made at the end of the period when readings have stabilized. Currently, a transient cycle is used to certify heavy-duty highway engines. It is a continuously varying cycle of speeds and loads which may have brief periods of steady state operation. Emission measurements are made continuously over all points.

The emission factors submitted by EMA for nonroad equipment were based on data generated using a standardized 8-mode steady state test cycle. The 8-mode test cycle does not measure emissions during transition and stabilization between modes. This could understate the emissions of equipment that encounters transient operation in use. This is especially true for particulate emissions, for which the 8-mode cycle does not provide a good measurement for equipment that encounters transient operation. On the other hand, the transient cycle used to simulate highway heavy-duty engine operation may not be as appropriate to simulate nonroad equipment transient operation. However, EPA expects that emission levels of nonroad equipment that encounters transient operation in use will be better represented by levels during the highway transient test.

For diesel powered equipment expected to encounter either transient speed or transient load conditions in-use, EPA adjusted the emission factors that were generated using a steady state cycle. Data from a joint EPA/Industry program to assess test cycles for nonroad equipment was used to determine the ratio of the FTP transient test emissions to the 8-mode steady state test emissions (Table I-10). Based on the currently available data (four engines) these ratios were: 1.4 for HC, 2.0 for CO, 1 for NO_X, and 1.6 for particulates. These ratios were then applied to the emission factors of diesel fueled equipment types that are expected to encounter transient operation in-use. Test cycle adjustments were not made to emission

factors of gasoline fueled equipment types as there was no available data on transient versus steady state test cycle emission comparisons for gasoline fueled engines.

2.2. Adjustments for In-Use Operation

The emission factors contained in Tables I-02a, I-02b, and I-02d were developed using data from testing new engines. Although many of the test procedures used for emission testing required an engine break-in period, the tests performed on new engines do not account for in-use impacts on emissions from engine malfunctions, improper maintenance, and engine wear. To assess the magnitude of these impacts, EPA contracted with Southwest Research Institute (SwRI) to emission test small in-use utility engines. EPA also used existing data on pre-controlled heavy-duty engines to estimate in-use impacts on emission factors.

Southwest Research Institute procured five in-use utility engines (three 4-stroke engines and two 2-stroke engines) and performed emission tests using the SAE J1088 procedure. A description of the engines and the emission test results are shown in Table I-14. The table also shows the emission factors used for the respective equipment types which were derived from new, properly operating engines. The ratio of the in-use engine test emissions to the new engine emission factor is also shown in the table and these values were averaged to determine an in-use adjustment factor which can be applied to new engine emission factors.

2.2.1. 4-Stroke Gasoline Engines Under 20 hp

The 4-stroke engines tested by SwRI showed 2.1 times the HC emissions, 1.9 times the CO emissions, 0.4 times the NO_x emissions, and 3.6 times the particulate emissions of new engine emissions (Table I-14). These engines exhibited problems of low power, head gasket leaks and others which are described in the SwRI report.[35] Although only a very small sample of 4-stroke engines were tested, the trend of high HC, CO, and particulates and low NO_x was consistent. Thus, the adjustment factors were applied to the emission factors of gasoline 4-stroke engines less than 20 hp. The resulting emission factors (Table I-02c) represent a rough approximation of in-use nonroad engine emission levels.

2.2.2. 4-Stroke Gasoline Engines Over 20 hp

In 1983, the Engine Manufacturers Association (EMA) and the EPA conducted a joint in-use test program to develop in-use emission factors for heavy-duty diesel and heavy-duty gasoline engines. The program used 1979 and 1982 model year pre-controlled engines and is the best available source of data for representing in-use nonroad engine emissions. Using this data, a linear regression analysis was performed and the emissions as a function of mileage was plotted. To estimate the in-use adjustment factors some broad assumptions were made. Typical in-use engines were assumed to be have accumulated 55,000 miles, which is half of the useful life of 110,000 miles defined in the regulations for heavy-duty highway gasoline engines. The regression analysis was then used to calculate an in-use factor by dividing the emission value at 55,000 miles by that at 0 miles. The resulting factors of 1.5 for HC and 1.3 for CO were applied to the emission factors of gasoline 4-stroke engines over 20 hp to approximate in-use emission factors (Table I-02c). The NO_X emissions showed no significant change with mileage accumulation and therefore NO_X emission factors were not adjusted. Particulate 4-stroke engine emission factors were not adjusted since no data was available.

2.2.3. 2-Stroke Gasoline Engines

As discussed above, SwRI tested two 2-stroke in-use engines. One was from a walk behind mower (WBM) application and the other was from a string trimmer application. The eleven year old WBM engine exhibited HC, CO, and PM emissions similar to the new engine emission factors shown in Table I-14. This engine produced somewhat higher NO_X emission than the new engine factors show. The string trimmer engine, on the other hand, showed extremely high HC, CO, and PM levels and similar NO_X levels compared to the new engine emission factors. Since only two data points were available for 2-stroke engines and these data were widely divergent, EPA did not estimate in-use adjustment factors based on these points. Instead, the factors used for 4-stroke engines less than 20 hp were used for HC and CO emissions for 2-stroke engines with average horsepower less than 20, as the 2-stroke data bracketed the 4-stroke results for these pollutants (i.e., one data point was much lower and one was much higher). The 4-stroke NO_X adjustment factor of 0.4 did not seem appropriate to apply to 2-strokes since both the 2-stroke engines tested by SwRI showed nearly equal or higher emission levels than new engine emission factors. Therefore, no adjustment was made

to NO_x new engine emission factors. Also, the 4-stroke particulate adjustment factor of 3.6 did not seem appropriate since the new engine emission factor used as numerator of the factor ratio was very small compared to the new emission factor value for 2-stroke engines. Therefore, no adjustment was made to the 2-stroke particulate new engine emission factor. For 2-stroke engines with average horsepower greater than 20, the adjustment factors for 4-strokes greater than 20 hp were used.

For 2-stroke outboard marine engines, these adjustments for HC and CO emissions would likely overstate in-use effects due to the more unique characteristics of these engines. Outboard engines are built to be more durable than the smaller, less expensive utility/lawn and garden engines, and to operate in environments where airborne dust and dirt are less of a problem. Therefore, an adjustment factor of 1.2 was applied to HC and CO for 2-stroke outboard engines.

The National Marine Manufacturer Association suggests that in-use adjustment factors for 2-stroke outboard engines should not be included in the calculation of emission inventories until further investigation can be done. NMMA states that 2-stroke engines do not exhibit the same deterioration in efficiency after extended use as 4-stroke engines and that boaters are more likely to maintain their engines for safety reasons. Also, an NMMA member company recently compiled data on an 8-horsepower, 2-stroke outboard that had accumulated 2,500 hours on the company's durability cycle which showed no increase in specific emission. However, EPA expects that using new engine emission factors for calculating in-use inventories would understate actual in-use emission levels. The in-use adjustment factors for 4-stroke gasoline engines greater than 20 hp were adjusted downward by a factor of about 2 as an estimation of the in-use adjustment for 2-stroke outboard engines. For the in-use estimate, an adjustment factor of 1.2 was applied to HC and CO for 2-stroke outboard engine emission factors.

2.2.4. Diesel Engines

As discussed earlier, EMA and EPA conducted a joint program to assess the emission factors of pre-controlled heavy-duty diesel and gasoline engines. For diesel engines, the data showed no increase in HC, NO_x, and only a slight increase in particulate matter emissions

with vehicle mileage. Therefore, the new engine diesel emission factors were not adjusted for in-use effects.

Chapter 3. Refueling and Evaporative Emission Factors

Hydrocarbon (HC) refueling and evaporative emission factors are presented in this section. A list of nonroad equipment and their evaporative and refueling emission factors may be found in Tables I-01, I-02, I-15 and I-16. Table I-15 and I-16 are also good summaries of how refueling and evaporative emission factors were calculated for gasoline and diesel fueled equipment, respectively.

This chapter is divided into four sections that (1) introduce the concept of refueling and evaporative emissions, (2) present fuel tank volume data, (3) present *refueling* emission factors, and (4) present *evaporative* emission factors. Fuel tank volumes are discussed separately to avoid duplication of discussion in the sections on refueling and evaporative emission factor methodology and data.

3.1. Concepts of Refueling and Evaporative Emissions

The concepts of refueling and evaporative emissions are now presented. These concepts are applicable to both gasoline and diesel fueled equipment (although perhaps more pertinent to gasoline fueled equipment than diesel fueled equipment).

3.1.1. Refueling Emissions

There are two components of refueling emissions: spillage and vapor displacement. Spillage emissions, or simply *spillage*, are those emissions that result from fuel spilled during the refueling process. For example, spillage includes those vapors generated from fuel spilled while filling a storage container from a gas station pump and vapors generated from fuel spilled while transferring the fuel from the storage container to the equipment. Vapor displacement emissions, or *displacement*, are those emissions that result from displacing fuel vapors in the fuel tank or storage container with liquid fuel. For example, if one gallon of gasoline is poured into a container which already contains some gasoline, one gallon of fuel vapor is displaced to the atmosphere by the incoming fuel. For the purposes of this study, *only fuel lost while refueling the equipment is considered*. One would expect, however, that

refueling emissions from the refueling of storage containers would be on the same order of magnitude as the refueling emissions from equipment.

3.1.2. Evaporative Emissions

Evaporative emissions are losses generated by the evaporation of unburned fuel. Evaporative emissions do not pass through the combustion chamber. Rather, the primary sources of evaporative emissions are the carburetor and fuel tank. Similar to their on-road counterparts, evaporative emissions from nonroad sources can be subdivided into four groups: hot soak, diurnal, running loss, and resting loss emissions. Each category accounts for emissions during specific operating conditions of the equipment and specific mechanisms of emission. Hot soak emissions are those emissions which occur after the equipment has been turned off and are attributable to the elevated temperature of the equipment (e.g., evaporation from the carburetor bowl). Diurnal emissions are those fuel vapors which occur while the equipment is not operating and are attributable to natural changes in ambient conditions (temperature, pressure, etc). In addition, diurnal losses occur only during those portions of the year when the equipment is used relatively regularly (every few days).[36] Running loss emissions are those emissions which do not pass through the combustion chamber while the source is in operation. Resting loss emissions are those emissions that are not already identified by another category. For example, emissions which are due to permeation of fuel through fuel lines and fuel tank, and leakage in the fuel system are resting loss emissions. *For the purposes of this study, only diurnal emissions will be considered due to the lack of data for hot soak, resting loss and running loss emissions from nonroad engines.*

3.2. Developing Effective Fuel Tank Volumes

This section will present those data and assumptions which were used to arrive at effective fuel tank volumes for gasoline and diesel equipment. Fuel tank volumes are not discussed with the presentation of other data to avoid tedious duplication of discussion. Both evaporative and refueling emission factors use fuel tank volumes as part of their calculation.

This section, *Developing Effective Fuel Tank Volumes*, is divided into two subchapters. The first subchapter presents effective fuel tank volumes for gasoline equipment and the second subchapter presents effective fuel tank volumes for diesel equipment.

3.2.1. Gasoline Fuel Tank Volumes

Data used to calculate gasoline fuel tank volumes may be broadly categorized into two groups: data supplied by manufacturers and manufacturers' sales brochures, and data generated by EPA. Effective fuel tank volumes derived from each of these sources are discussed below.

Manufacturers' Gasoline Fuel Tank Data -- Manufacturers were asked to supply fuel tank volumes for several pieces of gasoline equipment. However, the fuel tank volumes provided often did not quite match the equipment categories used by EPA in this study and aggregation was required. When possible, a *weighted* average of pertinent fuel tank volumes was used to generate an *effective* fuel tank volume for the particular equipment category and emission source. If the data supplied by manufacturers matched an equipment category exactly, the data were used directly.

Effective fuel tank volumes are not necessarily constant for refueling and evaporative emission factor calculations. Instead, an effective fuel tank volume should be calculated for each emission and equipment type because refueling and evaporative emissions are functions of different factors. A particular weighing factor may be important when aggregating fuel tank volumes for diurnal emission factor calculations, but that same weighing factor may not be important when calculating refueling emissions, or vice-versa. For example, walk behind lawnmowers have a range of fuel tank volumes of 0.37 to 0.68 gallons. It is known that the smaller fuel tank volumes tend to be used by consumers while equipment with larger tanks tend to be used commercially. Furthermore, although there may be fewer commercial lawnmowers (large fuel tanks), their season length is probably longer. The effective fuel tank volume should account for population sizes and length of seasons. Other weighing factors are used when calculating an effective fuel tank volume for refueling emission factors. Refueling emissions are influenced by the amount of fuel consumed, which is a function of population, horsepower, load factor, brake specific fuel consumption and usage rate. The effective fuel

tank volume for refueling emissions should account for these factors. Therefore, the purpose for which the average fuel tank volume is calculated dictates how individual fuel tank volumes are weighted.

The discussion below presents effective gasoline fuel tank volumes for evaporative and refueling emissions. Fuel tank aggregation for calculation of gasoline refueling emission factors are discussed first and fuel tank aggregation for calculation of gasoline evaporative emission factors are discussed afterwards. The aggregations were often reduced to mere population weighings or averages because so many weighing factors were not available (i.e., if a particular weighing factor is not known, then the category is assumed to be homogeneous with respect to that weighing factor). For this reason, gasoline fuel tank volumes used for calculation of evaporative emissions are the same as those used for refueling emission factors unless specifically indicated as different in the section titled *Manufacturer's Data for Calculation of Gasoline Evaporative Emission Factors*. In addition, several fuel tank volumes were taken directly from data supplied by manufacturers but those are not discussed below. Those data are readily identified in Table I-15.

Manufacturer's Data for Calculation of Gasoline Refueling Emission Factors -- Ideally, effective fuel tank volumes for generation of refueling emission factors are weighted by the amount of fuel consumed which is a function of population, horsepower, load factor, brake specific fuel consumption, and usage rate. As will be seen, tank volumes are very seldom weighted ideally.

Trimmers/Edgers/Brush Cutters - a straight average of fuel tank volumes from edge, hedge and string trimmers is used:

$$\frac{0.29\ gal + 0.11\ gal + 0.14\ gal}{3} = 0.18\ gal$$

Lawnmowers - a population[37] and usage* weighted average of consumer and commercial walk behind mowers is used:

Lawnmowers	Pop. (%)	Usage Ratio	Vol. (gal)	Product (hrs-g/yr-gal)
Consumer	95	1	0.37	35.2
Commercial	5	16	0.68	54.4
Totals		175		89.6
Effective Gas Tank Volume =			0.51	

Leaf Blowers/Vacuums - A population, usage, and horsepower weighted average[38] † of consumer and commercial walk behind mowers is used:

Leaf Blowers/ Vacuums	Pop. (%)	Usage (hrs/yr)	HP (hp)	L.F.	Tank Volume (gal)	Product (hrs-g-hp/ yr-gal)
Cons. Hand Held	92.83	9	.8	.47	0.16	50
Comm. Hand Held	1.84	197	.8	.47	0.16	22
Cons. Wk Behind	0.77	12	3.0	.47	0.83	11
Comm. Wk Behind	4.56	293	3.0	.47	0.83	1,564
Totals				2,347.33		1,647
Effective Gas Tank Volume =					0.70	

* Consumer and commercial usage rates were supplied by OPEI in their letter of May 24, 1991, to Clare Ryan of the EPA.

† Walk behind blower populations are assumed to be the same as backpack blower populations.

Lawn and Garden Tractors - a population[39] and usage[40] weighted average of lawn and garden tractors is used:

Lawn and Garden Tractors	Pop. (%)	Usage (hrs/yr)	Volume (gal)	Product (hrs-g/yr-gal)
Lawn	75	40	2.25	6,750.0
Garden	25	50	3.69	4,612.5
Totals		4,250		11,362.5
Effective Gas Tank Volume =			2.67	

Generator Sets - an average of small and portable generators is used:

$$\frac{0.92\ gal + 1.13\ gal}{2} = 1.02\ gal$$

Manufacturer's Data for Calculation of Gasoline Evaporative Emission Factors

Effective fuel tank volumes used for evaporative emission factor development which are different from those shown for refueling emission factor development are listed below. Ideally, when aggregating equipment fuel tank volumes for diurnal emission factor generation, the values would be weighted by population and days of in-use season. However, days of in-use season are not available and, therefore, could not be used. This should not significantly bias the data because the aggregated equipment tend to have similar season lengths.

Walk Behind Lawnmowers - a population weighted[‡] average of values presented for consumer and commercial walk behind mowers is used:

	% Pop.		Vol.	
consumer:	95	*	.37	= .352
commercial:	5	*	.68	= .034
			Total	= .39 gal

[‡] Populations were supplied by OPEL

Leaf Blowers/Vacuums - a population weighted[41] [f] average of consumer and commercial walk behind mowers is used:

	% Pop.		Vol.	
hand held:	93.6	*	0.16	= 0.150
walk behind:	6.4	*	0.83	= 0.053
			Total	= 0.20 gal

Lawn and Garden Tractors - a population weighted[42] average of lawn and garden tractors is used:

	% Pop.		Vol.	
lawn:	75	*	1.94	= 1.455
garden:	25	*	3.69	= 0.923
			Total	= 2.38 gal

EPA Generated Gasoline Fuel Tank Volumes -- Several fuel tank volumes were not provided by industry and alternative methods of approximating the fuel tank volumes were necessary. Three alternatives were identified to approximate missing fuel tank volume data. The first alternative is to substitute fuel tank values from equipment that use similar engines. For example, the fuel tank volume for *Generator Sets* is also used for *Signal Boards* because signal boards use generators. If a substitution is not possible or justifiable, then the second alternative is to calculate fuel tank volumes based on regression analysis. A regression of known tank volumes versus net engine horsepowers was created by EPA and is described in detail later in this subchapter. The third alternative is the use of fuel tank volumes based on the engineering judgement of EPA personnel. For all equipment, manufacturer suggested values were used when available and if not, then the first, second and third alternatives were used, respectively.

Volumes Based on Equipment with Similar Engines -- Effective fuel tank volumes which were assumed based on similar engines are shown below.

[f] Walk behind blower populations are assumed to be the same as backpack blower populations. Consumer and commercial usage rates are assumed identical to those of lawnmowers.

Wood Splitter - assume equivalent to *Lawnmowers*[c] (0.51 gal for refueling emissions and 0.39 gal for evaporative emissions).

Commercial Turf Equipment - Wide area walk behind lawnmowers comprise the majority of this category and therefore, the wide area walk behind lawnmower fuel tank volume is used (5.0 gal). Hydro-seeders/mulchers, although a part of this category, were not incorporated into this number due to unknown weighing factors and relatively insignificant populations.

Other Lawn and Garden Equipment - assume equivalent to *Lawnmowers* (0.51 gal for refueling emissions and 0.39 gal for evaporative emissions).

Specialty Vehicles Carts - assume equivalent to *Golf Carts* (6 gal).

Air Compressors - assume equivalent to small compressors (1.13 gal).

Pressure Washers - assume equivalent to *Pumps* (0.75 gal).

Tampers/Rammers - assume equivalent to *Plate Compactors* (0.94 gal).

Rollers - assume equivalent to vibratory roller compactors (3.0 gal). Note that this is a good assumption for the gasoline portion of rollers only.

Paving Equipment - assume equivalent to vibrators/finishers (1.0 gal). Note that this is a good assumption for the gasoline portion of paving equipment only.

Surfacing Equipment - assume equivalent to *Paving Equipment* (1.0 gal).

Signal Boards - assume equivalent to *Generator Sets* (1.02 gal).

2-Wheel Tractors - assume equivalent to *Lawn and Garden Tractors* (2.67 gal for refueling emissions and 2.38 gal for evaporative emissions).

Agricultural Mowers - assume equivalent to *Lawn and Garden Tractors* (2.67 gal for refueling emissions and 2.38 gal for evaporative emissions).

Sprayers - assume equivalent to crop/turf sprayers (1.5 gal). Fertilizer spreaders were not included in this category because there is not adequate means to weigh their impact.

Volumes Based on Regression Line – A regression of fuel tank volume versus net engine horsepower from John Deere farm, construction and utility engines was created by

[c] The names of equipment types included in this study are italicized to distinguish them from equipment types used by manufacturers in communicating data to EPA.

EPA from John Deere product literature. The regression line is only applicable to equipment with engines of 15 hp or more. The result of that regression is:

$$Fuel\ Tank\ Vol. = 0.51 \times Net\ HP \quad ; \quad R^2 = 0.82$$

Articulated tractors and some feller-bunchers were excluded from the regression due to their exceptionally high fuel tank volumes. A list of equipment type, model, engine, net hp and fuel tank volume for all equipment used in that regression as well as a plot of the data is presented in Table I-17.

As indicated in Table I-17, most of the equipment used to create the above regression line are diesel fueled. There may be some concern that fuel tank volumes of similar diesel and gasoline equipment do not approximate each other because a particular piece of gasoline equipment tends to be smaller and have a smaller fuel tank than its diesel counterpart. This should not be the case when comparing gasoline and diesel equipment of similar horsepower. When the influence of the size of engine is removed, as done by the regression, that difference should be minimal. On the contrary, a larger mass of gasoline is required to do the same amount of work as done by a diesel fueled piece of equipment (i.e., the brake specific fuel consumption of gasoline equipment tends to be higher) and, therefore, gasoline fuel tanks would necessarily be larger to accommodate the same amount of work. Thus, use of this regression may slightly overestimate gasoline spillage emissions but underestimate gasoline diurnal emissions.

Due to the lack of data for much of the equipment, the regression line was used extensively (approximately 25% of all equipment types). The gasoline equipment for which fuel tank volumes were calculated from the regression are shown in the following (hp in parenthesis).

Chippers/Stump Grinders (62)	Cranes (55)
Aircraft Support Equipment (48)	Crushing/Proc. Equipment (60)
Vessels w/Inboard Engines (170)	Rough Terrain Forklifts (88)
Aerial Lifts (36)	Other Construction Equipment (150)
Sweepers/Scrubbers (39)	Asphalt Pavers (31)
Other General Industrial Equipment (19)	Swathers (106)
Tractors/Loaders/Backhoes (63)	Bore Drill Rigs (54)
Excavators (80)	Rubber Tired Loaders (67)
Combines (131)	Agricultural Tractors (87)
Other Material Handling Equipment (51)	Other Agricultural Equipment (55)

Fuel Tank Volumes Based on EPA Assumptions -- EPA was forced to make assumptions regarding the fuel tank size of *Sailboat Auxiliary Inboard Engines* (6 gal.), *Sailboat Auxiliary Outboard Engines* (6 gal.) and *Vessels w/Sterndrive Engines* (21 gal.) because data for those categories was not available. These values were presented to the National Marine Manufacturers Association (NMMA) and deemed to be acceptable estimates based on available data.[43] Estimates for the fuel tank volume of *Dumpers/Tenders*, *Terminal Tractors*, and *Hydro Power Units* were also required. *Dumpers/Tenders* were assumed to have fuel tank volumes of 3.0 gallons. *Terminal Tractors* are assumed to have the same tank volume as their diesel counterparts (5.71 gal) and *Hydro Power Units* are assumed to have fuel tank volumes of 5.0 gallons. Note that these assumptions apply to gasoline versions of the equipment only.

3.2.2. Diesel Fuel Tank Volumes

Fuel tank volumes for most diesel equipment were found from the regression line developed by EPA from John Deere equipment as described above in the section on gasoline fuel tank volumes. Fuel tanks for some equipment were taken from manufacturer supplied data and the reader is referred to Table I-16 for those details.

3.3. Methodology Used to Calculate Refueling Emission Factors

This section will present the methodology and data used to calculate refueling emission factors for gasoline and diesel equipment. The reader is referred to section 3.1, *Concepts of Refueling and Evaporative Emissions*, for a definition of refueling emissions.

3.3.1. Gasoline Refueling Emission Factors

Spillage -- Very little work has been done to quantify the amount of fuel spilled while refueling nonroad engines. The only known spillage values have been presented by Briggs & Stratton and OPEI for lawn and garden equipment (primarily standard walk behind lawnmowers). Briggs & Stratton has presented a value of 45 grams (approximately 1.5 oz.) per refueling and suggested that the value be reduced to 22.5 g/refueling as the user becomes familiar with the equipment.[44] OPEI reported in a study completed in September of 1991 that 17 grams of fuel were spilled during a typical refueling incident. All of these values are much higher than the spillage value which may be *backed out* of Mobile4 for on-highway vehicles which is roughly 3.6 g/refueling (0.31 g/gal x 11.5 gal/refuel).[45]

The discrepancy between the Mobile4 value and the OPEI and Briggs & Stratton value is most likely due to the fact that (1) many nonroad engines are refueled from fuel containers which are more difficult to use than gasoline pumps, (2) fuel containers do not have automatic shut off capability and (3) equipment fuel tanks are not as accessible. Therefore, the numbers provided by OPEI and Briggs & Stratton are probably closer to the true value for nonroad engines which are typically refueled from a portable, hand-held fuel container. When deriving the emission factors presented in this study, EPA has assumed that 17 g of fuel is spilled per refueling when a portable fuel container is used and, for nonroad equipment that is refueled from a gasoline pump, spillage is assumed to be 3.6 g/refueling. EPA chose the OPEI over the Briggs & Stratton value because it is based on substantially more data.

The method of refueling (pump or container) is discerned by equipment type and fuel tank size. Lawn and garden (except chippers/stump grinders), recreational, and light commercial equipment are assumed to be refueled from portable fuel containers. In addition, any other equipment with fuel tank volumes less than 6 gallons[46] ** are assumed to be

** The largest common consumer hand-held fuel container volume is 6 gallons.

refueled primarily from portable fuel containers regardless of category (except baggage tow tractors). All other equipment are assumed to be refueled from a fuel pump. The amount of fuel spilled per gallon of gasoline consumed may be calculated by:

$$Spillage_{portable\ container}\left[\frac{g}{gal}\right] = \frac{17.0\left[\frac{g}{refuel.}\right]}{Tank\ Vol.\left[\frac{gal}{refuel.}\right]}$$

or,

$$Spillage_{fuel\ pump}\left[\frac{g}{gal}\right] = \frac{3.6\left[\frac{g}{refuel.}\right]}{Tank\ Vol.\left[\frac{gal}{refuel.}\right]}$$

where *Tank Vol.* is the effective fuel tank volume. All refuelings are assumed to be *fill-ups* and thus, the spillage estimates are low.

Vapor Displacement -- Vapor displacement emission values were taken from on-highway data because no estimates for vapor displacement emissions from nonroad engines can be found in literature. However, the on-highway and nonroad displacement values should be similar since the gasoline composition for both is the same. EPA has implemented the model proposed by Rothman and Johnson of the EPA for on-highway vehicles to predict displacement emissions[47]:

$$Disp. = -5.909 - 0.0949 \times dT + 0.0884 \times Td + 0.485 \times RVP$$

where: $Disp. = Displacement\left(\frac{g}{gal}\right)$

dT = *Temp of Tank - Temp of Dispensed Fuel* (°F)

Td = *Temp of Dispensed Fuel* (°F)

RVP = *Reid Vapor Pressure*

Rothman and Johnson also recommend seasonal national average values for the model variables. EPA has matched those averages with equipment types for the particular season of the year in which the equipment is most likely to operate. Rothman and Johnson's summer and annual RVP values are not used in anticipation of the new RVP standards which will limit RVP to 10.5 during the summer of 1992. The annual average RVP was recalculated based on the new summer RVP and the current winter RVP as shown below.

$$Annual\ RVP = \frac{5 \times 10.5 + 7 \times 13.9}{12} = 12.5$$

The equipment tank temperature, dispensed fuel temperature (Td) and delta T (dT) values suggested by Rothman and Johnson are shown in the table below (with modifications) for equipment which are refueled from a gas pump.[48] Rothman and Johnson's values have been modified further to estimate displacement emissions from equipment refueled from a portable fuel container. Those values are also shown in the table.

Refueling Method	Season	Equip. Tank Temp.	Dispensed Temp. (Td)	dT (°F)	RVP	DISP (g/gal)
Fuel Pump	Annual Average	73.3	68.9	4.40	12.5	5.83
	Summer Average	85.0	76.2	8.80	10.5	5.08
	Winter Average	59.5	60.3	-0.80	13.9	6.09
Portable Container	Annual Average	73.3	73.3	0.00	12.5	6.63
	Summer Average	85.0	85.0	0.00	10.5	6.70
	Winter Average	59.5	59.5	0.00	13.9	6.09

The temperature differences between the equipment's fuel tank and the dispensed fuel (dT), as well as the actual dispensed fuel temperature (Td), are representative of fuel

dispensed from underground storage tanks. It is unlikely that the temperature of fuel dispensed from a portable fuel container will match that of fuel dispensed from an underground storage tank. Rather, the fuel temperature from a portable container will most likely match that of the fuel in the equipment since both the container and equipment are exposed to the same ambient conditions. Therefore, the "pump dispensed" values suggested by Rothman and Johnson are used only for equipment refueled from gasoline fuel pumps. For equipment refueled from fuel containers, the values Td are assumed equal to the equipment tank temperature. Thus, dT is zero.

It can be correctly argued that the dispensed fuel temperature for many nonattainment areas will be dissimilar to those values presented above--especially the winter time values. While recognizing this deficiency, EPA is unable to incorporate *city-by-city* emission factors due to the immense size of that task. The best available national emission factors are used for all cities. A list of equipment and the associated displacement emission factors as well as total refueling emission factors is located in Table I-15.

To make the refueling emission factors compatible with the populations and usage rates used in the study, the refueling emission factor units were changed from grams per gallon to grams per horsepower hour (except some recreational equipment which are expressed in g/hr and marine vessels which are expressed in g/gal) by multiplying the original value by the brake specific fuel consumption (BSFC). To facilitate that change, assumptions regarding BSFC were necessary. BSFC data provided by SWRI and CARB were used to estimate BSFC's for equipment with average horsepower of 8 hp and less, 8 hp to 20 hp and above 20 hp. The values assumed are 0.219[49] [††], 0.15[50] [‡‡], or 0.0806[51] gal/hp-hr, respectively. After selecting the appropriate BSFC, refueling emission factors were easily

[††] Assume 95% side valve, 5% OHV using 4-4.5 hp engines. Assume 6.2 lb of gasoline per gallon.

[‡‡] Assume 90% side valve, 10% OHV using 11-12 hp engines. Assume 6.2 lb per gallon of gasoline.

transformed to units of grams per brake horsepower hour. For example, if the original spillage value is 49.78 g/gal (walk behind lawnmower; avg hp = 4.0) then,

$$49.78 \frac{g}{gal} \times 0.219 \frac{gal}{hp-hr} = 10.90 \frac{g}{hp-hr}$$

Refueling emission factors for all recreational equipment except snowmobiles are expressed in units of g/hr, instead of g/hp-hr. The conversions were made by multiplying the original value in g/hp-hr by the average horsepower and load factor supplied by EEA. For example, the conversion for minibikes is:

$$11.26 \frac{g}{hp-hr} \times 4\ hp \times 0.62 = 12.92 \frac{g}{hr}$$

3.3.2. Diesel Refueling Emission Factors

Refueling emissions from diesel fueled equipment are not as significant as those from gasoline fueled equipment because diesel fuel has a relatively high initial boiling temperature of 350 °F which impedes its evaporation. Gasoline, on the other hand, has initial boiling temperatures of 60 - 80 °F depending on the season of year (RVP) and, therefore, evaporates more readily.[52] As a result, very little work has been done to quantify diesel refueling emissions. Indeed, EPA is not aware of any studies of emissions from spilled diesel fuel. However, work has been done by F. Peter Hutchins of the EPA to quantify displacement emissions from diesel fuel.[53] Hutchins' work has shown the displacement emissions from diesel fuel to be 0.041 grams per gallon of fuel dispensed and fuel tank temperatures of approximately 80 °F. For the purposes of the present study, all diesel equipment are assumed to emit HC vapors at a rate of 0.041 grams per gallon of fuel dispensed. EPA is not aware of any other data pertaining to refueling or evaporative emissions from diesel fueled equipment and, therefore, other diesel refueling emission sources are not included in this study.

Just as was needed for the gasoline refueling emission factors, the diesel refueling emission factors were adjusted to be compatible with the populations and usage rates used in the study. The units were changed from grams per gallon to grams per horsepower hour

(except some recreational equipment which are expressed in g/hr and marine vessels which are expressed in g/gal). To facilitate that change, assumptions regarding the brake specific fuel consumption (BSFC) were necessary. Recognizing that diesel equipment generally have lower BSFCs than gasoline equipment, the gasoline BSFC values were multiplied by 0.8 to estimate BSFCs for diesel equipment[54]. Therefore, the BSFCs assumed in this report for diesel equipment are 0.175, 0.12, and 0.065 gal/hp-hr, for engines under 8 hp, between 8 and 20 hp, and over 20 hp, respectively. Refueling emission factors for all recreational equipment except snowmobiles are expressed in units of g/hr, instead of g/hp-hr. The conversion was made by multiplying the original value in g/hp-hr by the average horsepower and load factor supplied by EEA.

3.4. Methodology Used to Calculate Evaporative Emission Factors

This section will present the methodology and data used to calculate evaporative emission factors for gasoline and diesel equipment. Evaporative emissions are composed of diurnal, hot soak, resting loss and running loss emissions and this section will present each individually.

3.4.1. Gasoline Evaporative Emission Factors

Diurnal -- The most comprehensive data available for diurnal emissions appears to be contained in two reports written by Charles T. Hare and Karl J. Springer of Southwest Research Institute.[55] [56] Both CARB and AP-42 refer to their work for diurnal emissions. In summary, Southwest developed diurnal emission factors of 2 g/gal/day[11] and 4 g/gal/day for protected (shaded) and unprotected fuel tanks, respectively, during the in-use season. This report will assume the average of the two estimates, 3 g/gal/day, because of the difficulty in determining what percentage of each type of equipment has protected or unprotected fuel tanks. Diurnal emission factors, in units of grams per day of possible use, are calculated from the fuel tank volumes developed in section 3.2 of this appendix and are presented in Table I-15. *Vessels w/Outboard Engines* and *Sailboat Auxiliary Outboard Engines* are assumed to have no diurnal emissions because fuel tanks for those equipment types are not vented.[57]

[11] g/gal/day means grams of HC emissions per gallon of tank volume (not necessarily gallon of fuel) per day

Hot Soak -- After reviewing SAE papers and SwRI reports regarding evaporative emissions and referring with several manufacturers, EPA found no appropriate values for hot soak emission factors for nonroad engines. Hot soak emission values for on-highway engines do exist, but they are not representative of nonroad engines due to the different size, design, packaging and carburetors that each employs. Therefore, this study does not account for hot soak emissions.

Resting Loss -- Resting loss emissions are not included in this study due to the lack of available data. However, to obtain a *feel* for the potential magnitude of this type of emission, one can consider the amount of fuel a plastic storage container is permitted to lose and still meet the standards devised by the American Society for Testing and Materials (ASTM). A nonmetallic fuel container passes the standards set by ASTM if it loses less than 1% of its mass over 30 days at a temperature of 75 °F. The test fuel used is a 70% isooctane, 30% toluene mixture (by volume). Assuming that the test fuel and regular gasoline behave the same, the standard indicates the fuel container could lose up to 28 grams of fuel per month.

Running Loss -- Just as for hot soak emissions, no data on the subject of running loss emissions for nonroad engines was found and on-highway values would not be representative. Therefore, running loss emissions are not accounted for in this study.

3.4.2. Diesel Evaporative Emission Factors

EPA is not aware of any diesel evaporative emission data and therefore, diesel evaporative emissions are not included in this study. On a qualitative basis, however, it can be said that evaporative emissions from diesel equipment should be much less than evaporative emissions from gasoline equipment because diesel fuel has a relatively high initial boiling temperature of 350 °F which impedes its evaporation. Gasoline, on the other hand, has initial boiling temperatures of 60 - 80 °F depending on the season of year (RVP) and, therefore, evaporates more readily.[58]

Chapter 4. Crankcase Emission Factors

Crankcase emission factors are presented in this section for gasoline and diesel nonroad equipment after a brief introduction of crankcase emissions.

Crankcase emissions are those exhaust gases which, upon leaving the combustion chamber, do not pass through the exhaust valve. Rather, the gases discharge into the crankcase via the clearance between the piston and cylinder wall. Eventually, these gases may escape from the crankcase to the atmosphere, hence, they are named *crankcase emissions* and the crankcase is said to be *open*. Some manufacturers produce engines which route crankcase vapors to the air intake system of the equipment. Those crankcases are called *closed* crankcases. Crankcase emissions, together with evaporative, refueling, and tailpipe emissions, constitute the total emissions from an engine.

All gasoline 4-stroke equipment are assumed to have open crankcases except Lawn and Garden Equipment (but not *Chippers/Stump Grinders*--they are assumed 100% open), *Vessels w/Inboard Engines* and *Vessels w/Sterndrive Engines*. Only 21% of Lawn and Garden Equipment are assumed open[39] [tt] and 100% of *Vessels w/Inboard Engines* and *Vessels w/Sterndrive Engines* are assumed to have closed crankcases.

The rest of this chapter is separated into two sections. The first section introduces crankcase emission factors for 4-stroke gasoline fueled engines and the second introduces crankcase emission factors for 4-stroke diesel fueled engines. Crankcase emissions from 2-stroke engines do not exist due to the nature of 2-stroke engines. Thus, for equipment with both 2-stroke and 4-stroke varieties, the crankcase emission factor is applied only to the 4-stroke engines when calculating total emissions.

4.1. Gasoline Crankcase Emission Factors

This section will present crankcase emission factors for nonroad gasoline engines and describe the methodology for developing them. EPA is not aware of any significant nonroad crankcase emission data and has been forced to utilize data from on-highway engines. Even

[tt] Assume B & S engines represent 60% of market and are 99% closed and Tecumseh and others represent 40% of market and are 48% closed.

so, estimates for crankcase carbon monoxide (CO) or oxides of nitrogen (NO_x) could not be found. Therefore, those pollutants are not considered for gasoline nonroad crankcase emissions. The following paragraphs will present crankcase HC emission factors for gasoline nonroad engines.

Probably the most widely accepted values for nonroad crankcase HC emissions are those found in AP-42.[60] AP-42 reports crankcase HC emissions for farm and construction equipment based on work performed by Southwest Research Institute (SwRI) in the early 1970's.[61] The SwRI work on crankcase HC emissions suggests that "crankcase hydrocarbon emissions are equivalent to about 20 percent of those in the exhaust . . ."[62] This generalization is based on work performed by Charles M. Heinen[63] and P. A. Bennett, et al[64] *** for on-highway vehicles. However, when calculating crankcase emissions, Hare and Springer misinterpreted the Heinen report. Heinen actually proposed the value of 33% of exhaust emissions (20% of total HC emissions) which was estimated by Fred W. Bowditch of General Motors.[65] Heinen chose Bowditch's number as the best compromise of competing values supplied by CARB (31% of uncontrolled HC exhaust; 20% of total),[66] the Federal Government (49% of uncontrolled HC exhaust; 26% of total)[67] and Bowditch (see chart below). The origins of the values supplied by the Federal Government and CARB are unknown while the crankcase emission values put forth by Bowditch (33% of uncontrolled HC exhaust emissions and 20% of total emissions) appear to be educated estimates based on General Motors "quality audit data".

	CARB		Federal		Bowditch		Bennett	
Emis. Type	% Tot	% Exh	% Tot	% Exh	% Tot	% Exh	% Tot	% Exh
Crank.	20	31	26	49	20	33	40	70
Evap.	15	23	21	40	20	33	--	--
Exhaust	65	100	53	100	60	100	60	100

After updating AP-42 using Bowditch's number, the values for crankcase emissions for agricultural equipment are 42.2 g/hr and 47.2 g/hr for tractors and nontractors,

*** Bennett estimated crankcase emissions to be approximately 70% of exhaust emissions (40% of total HC emissions) based on testing five cars.

respectively. These corrected AP-42 estimates closely agree with an EPA study of crankcase HC emissions from nine on-highway vehicles with disabled PCV systems and disconnected fresh air hoses on a gram/hour basis.[68] The EPA found that the nine vehicles studied emitted, on average, 1.92 grams of HC per mile (37.6 g/hr based on 3 bag FTP with average speed of 19.6 mph) over the first three bags of the FTP driving schedule with PCV and fresh air hose disconnected. This value, 37.6 g/hr, compares reasonably well with the updated AP-42 estimates of 42.24 and 47.2 g/hr for tractor and nontractor farm equipment, respectively, run over a steady state mode test. For purposes of estimating total emissions from 4-stroke gasoline nonroad engines, EPA accepts Bowditch's value (33% of untreated exhaust) for all gasoline engines with *open* crankcases. Four-stroke engines with closed crankcases and all 2-stroke engines are assumed to have no crankcase emissions.

There may be concerns regarding the reliability of Bowditch's crankcase number (33% of uncontrolled HC exhaust) for use with today's nonroad engines. The relationship between on-highway crankcase emissions and nonroad crankcase emissions has never been documented for current year on-highway and nonroad engines. Differences in operating cycles, machining tolerances, fuel delivery systems, etc., of on-highway and nonroad engines compromise the ability to use existing on-highway engine exhaust and crankcase emissions to generate nonroad emission factors. For instance, technological advances in combustion design for on-highway vehicles may not have been applied to nonroad engines to date. In addition, those advances may decrease exhaust and/or crankcase emissions but perhaps disproportionally. Despite the legitimate concerns mentioned above, EPA believes that the Bowditch number remains the best available estimate for crankcase emissions because it has been corroborated by EPA in Report #460/3-84-011.[69] In addition, it is more conservative than Bennett's number which has not been corroborated by other sources.

4.2. Diesel Crankcase Emission Factors

This section will present the best available HC, CO, and NO_x emission factors for nonroad diesel engines and describe the methodology for developing them.

Data for crankcase emissions from diesel engines is limited. In fact, no studies which explicitly investigate crankcase emissions from nonroad diesel engines have been found.

However, studies have been found for on-highway crankcase emissions. The most recent and comprehensive paper has been published by Charles T. Hare and Thomas M. Baines.[70] Hare and Baines studied three engines of which two were approximately half way between overhauls and the other was relatively new. They found that hydrocarbon crankcase emissions represent approximately 0.3 to 4.0 percent of corresponding exhaust hydrocarbon emissions (0.006 to 0.017 g/kW-hr) when tested over the 13-mode test procedure. These values are consistent with earlier studies conducted by Chevalier[71] (approximate average value = 0.0395 g/kW-hr[111]) of heavily worn diesel engines and Caterpillar (0.017 g/kW-hr).[72] The condition of the Caterpillar engine was not reported. For the purposes of EPA's nonroad study, diesel crankcase HC emissions will be assumed to be 2 percent (the mean of the range found by Hare and Baines) of untreated exhaust hydrocarbon emissions unless a *closed* crankcase is implemented.

CO and NO_x emissions from diesel crankcases have been reported by Hare and Baines, and Caterpillar. Hare and Baines reported CO and NO_x emission rates of 0.015 to 0.43 percent and 0.006 to 0.1 percent of exhaust emissions, respectively. Their numbers are corroborated by Caterpillar who reported CO and NO_x emission rates of 0.23 and 0.076 of exhaust emission rates. For the purposes of EPA's nonroad study, CO and NO_x crankcase emissions from diesel engines will be assumed to be 0.2 percent and 0.05 percent (the mean of the values reported by Hare and Baines) of exhaust emissions, respectively. In cases where the crankcase is closed, EPA assumes zero diesel crankcase emissions.

[111] Assume BSFC of 0.5 lb/hp-hr.

Chapter 5. Benzene

Based on review of the limited available data for toxic emissions of benzene and 1,3-butadiene, EPA found it most appropriate in these cases to calculate emission rates as a weight percentage of the total hydrocarbon emissions. Benzene exhaust emissions are expressed as roughly 3 percent by weight of tailpipe exhaust hydrocarbons and crankcase hydrocarbons for both gasoline and diesel engines. Only four studies of benzene emissions were available for data applicable to nonroad configurations (i.e., noncatalyst).[73] Analysis of the data indicated that while there were large differences in the benzene emissions with power and driving cycle when expressed in milligrams per hour, milligram per horsepower hour, or milligrams per mile, the differences were far less when expressed as a percent of total exhaust hydrocarbon emissions, as presented in the SwRI report.[74] Refueling emissions, which consist of spillage and vapor displacement, were assumed to consist of 1.7% (weight) benzene which is the average summer and winter grade benzene content of in-use gasoline (diesels were assumed to have negligible refueling emissions).

Chapter 6. 1,3-Butadiene

EPA has also chosen to express 1,3-butadiene emissions as a weight percent of tailpipe exhaust hydrocarbons plus crankcase hydrocarbons. The respective percentages used in this study for nonroad diesel and gasoline engines are 1.6% and 1.3%.[75] Emissions of 1,3-butadiene were almost never measured in engine exhaust prior to the late 1980's, because the procedures for doing so are relatively new. Only one study was available with measurement from diesel engines, and one study with measurements from noncatalyst gasoline automobiles tested on unleaded gasoline. None of the studies found involved measurement from nonroad equipment and duty cycles. However, due to the lack of additional information, EPA did apply these emission rates to all categories.

Chapter 7. Nitrosamines

In addition to HC, CO and NO_x emissions, it has been documented that nitrosamines, which have been found to be carcinogenic in animals, are emitted from vented diesel crankcases.[76] While the contribution of motor vehicle emissions to the nitrosamine concentration is not known for certain, Thomas M. Baines of EPA reports[77] that three researchers (Gordon,[78] Shapley[79] and Pellizzari[80]) have identified nitrosamines near roadways and two of the three suspected automobiles as a source. Gordon reported nitrosamine concentrations as high as 1.1 micrograms per cubic meter in the Los Angeles basin. In his technical report, Baines proposes 109 cancer incidents per year if 1.5 million people are exposed to 1.1 micrograms per cubic meter for 2 hours per day. Undoubtedly, crankcase emissions of nitrosamines contribute to those cancer incidents[†††]. The reader is referred to EPA's Integrated Risk Information System (IRIS) for a more complete risk analysis and the technical report written by Thomas M. Baines for a more in depth analysis of nitrosamines from diesel crankcase emissions and car interiors.

[†††] However, because of uncertainties associated with the contribution of diesel crank cases to nitrosomine concentrations, inventories for nitrosomines were not developed.

TABLE I-01
EMISSION FACTORS USED FOR SIP INVENTORIES

TABLE I-12 Emission Factors for Commercial Marine Vessels

a.) AVERAGE EMISSION FACTORS FOR OCEAN-GOING COMMERCIAL VESSELS

POUNDS OF POLLUTANT PER THOUSAND GALLONS OF FUEL CONSUMED

OPERATING PLANT Operating Mode/Rated Output	POLLUTANT NOx	HC	CO	SOx	PM
STEAM PROPULSION					
Full power	63.6	1.72	7.27	159x(%S)	56.5
Maneuver/Cruise	55.8	0.682	3.45	159x(%S)	20
Hotelling					
- Burning residual bunker fuel	36.4	3.2	*	159x(%S)	10
- Burning distillate oil	22.2	3	4	142x(%S)	15
MOTOR PROPULSION					
All underway operating modes	550	24	61	157x(%S)	33
AUXILIARY DIESEL GENERATORS					
- 20 KW (50% Load)	477	144	53.4	27	17
- 40 KW (50% Load)	226	285	67.6	27	17
- 200 KW (50% Load)	140	17.8	62.3	27	17
- 500 KW (50% Load)	293	81.9	48.1	27	17

Notes:
1. Emission factors showing an asterisk (*) are considered negligible for these operating modes.
2. Average sulfur concentrations used are 0.8 percent for marine diesel, and 2.0 percent for bunker fuel oil.

20	Welders	All Diesel													All Diesel						
20	Pavers/Surfacers	All Diesel													All Diesel						

These notes are intended to provide a brief summary of important assumptions. See text for more detailed explanations.

1 Edge, hedge, string trimmers averaged to get "Trimmers/Edgers/Brush Cutters" category
2 Consumer and commercial lawn mower tank volumes were population and usage weighted for refueling emissions and population weighted for evaporative emissions.
3 For evap emissions, walk behind and hand held blower fuel tank volumes were population weighted to get "Leaf Blowers/Vacuums". For Refueling emissions, walk behind and hand held blower fuel tank volumes were population, HP, and usage weighted. Populations were supplied by PPEMA (assume "backpack" blowers are equivalent to "walk behind") and usage was assumed similar to commercial and consumer lawn mowers.
4 Lawn and garden tractor fuel tank volumes were population and usage weighted for refueling emissions and population weighted for evaporative emissions.
5 Assumed equal to walk behind lawn mowers
6 Fuel tank volumes found using regression analysis.
7 Hydro-Seeders/Mulchers were not included in the "Commercial Turf Equipment" category because there is no way to adequately weigh their impact. In addition, their population is small relative to wide area mowers.
8 Aircraft and baggage towing tractor gasoline fuel tank volumes were assumed equal to corresponding diesel fuel tank volumes.
9 Refueling emissions expressed in g/hr for these equipment types.
10 "Specialty Vehicles/Carts" assumed to have same tank volumes as "Golf Carts"
11 Refueling emissions expressed in g/gal for these equipment types.
12 These equipment have unvented fuel tanks and therefore emit no diurnal emissions.
13 "Sailboat Auxiliary Engines" assumed to have fuel tank volumes of 6 gallons.
14 "Vessels w/Sterndrive Engines" assumed to have fuel tank volumes of 21 gal.
15 Fuel tank volumes from portable and small generator sets were averaged to get "Generator Sets <50HP"
16 "Air Compressors" are assumed to be equivalent to Small Compressors.
17 This equipment is LPG or CNG powered only
18 "Pressure Washers" are assumed to be equivalent to "Pumps".
19 "Tampers/Rammers" are assumed equivalent to "Plate Compactors"
20 This equipment is diesel powered only.
21 "Paving Equipment" assumed equivalent to "Vibrators/Finishers"
22 "Surfacing Equipment" assumed equivalent to "Paving Equipment"
23 "Signal Boards" are assumed equivalent to "Generator Sets <50HP".
24 "Dumpers/Tenders" are assumed to have gasoline fuel tank volumes of 3 gal.
25 These equipment are assumed equivalent to "Lawn and Garden Tractors"
26 Fertilizer spreaders were not included in "Sprayers" because there was no reserve
27 "Hydro Power Units" assumed to have 5 gallon gasoline tanks.

Table I-16. Refueling and Evaporative Emission Factors - Diesel

Manufacturer's Data		Equipment List			REFUELING EMISSIONS						EVAPORATIVE EMISSIONS				
	Average Gas Tank Volume			Average Gas Tank Volume	g depled per gal. (g/gal)	Mean HP	Load Factor	BSFC (g/bhp-hr)	Final refuel. (g/hp-hr)	Final refuel. (g/hr)	Diurnal E.F.	Hot Soak	Resting Loss	Run. Loss	Total Evap (g/day)

Note that all fuel tank volumes are generated based on the regression line described in the text except where indicated below.

1 Fuel tank volumes found using regression analysis.
2 This equipment is gasoline powered only.
3 Sales weighted average of aircraft and baggage tow tractor tank volumes used.
4 Refueling emissions expressed in g/hr for these equipment types.
5 Refueling emissions expressed in g/gal for these equipment.
6 "Sailboat Auxiliary Outboard Engines" assumed to have 4 gallon tanks.
7 This equipment is LPG or CNG powered only.
8 "Plate Compactors" assumed to have 2 gallon fuel tanks.
9 "Signal Boards" are assumed equivalent to "Generator Sets <50HP".
10 "Cement and Mortar Mixers" assumed to have 3 gallon tanks.
11 "Tillers >5 HP" assumed to have 2 gallon tanks.
12 "Feller/Bunchers" fuel tank volume taken from the average of John Deere product literature values.

Table I-17. Fuel Tank vs Net Engine HP Regression

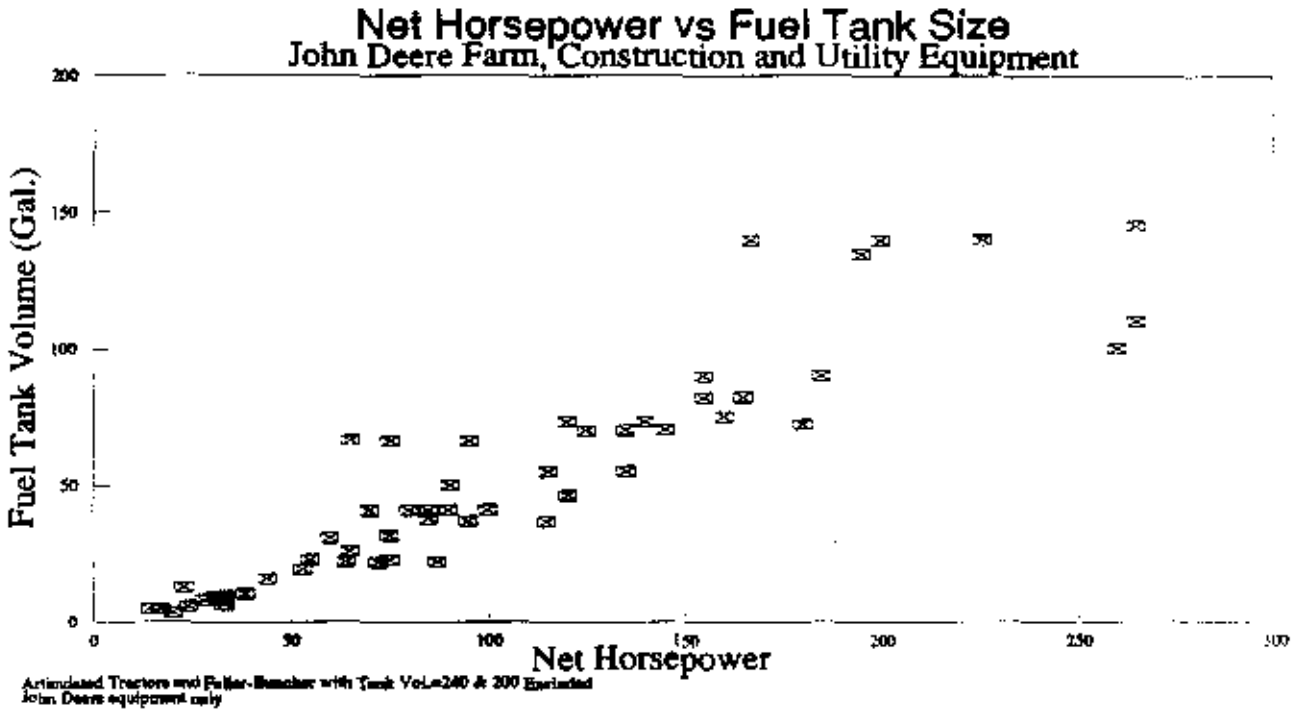

Fuel tank sizes of various John Deere farm, construction and utility engines regressed against gross and net engine power, and displacement. All values taken from 1989-90 sales brochures.

Appendix J. Additional Data Submissions

The following manufacturers, state agencies, and manufacturer associations submitted data to EPA for analysis and review.

Briggs & Stratton
California Air Resources Board
Caterpillar
Engine Manufacturers Association
Equipment Manufacturers Institute
Ford/New Holland
Ford
Gardenway
Homelite
Industrial Truck Association
International Snowmobile Industry Association
John Deere
Kohler
Lawn-Boy
Manufacturers of Emission Controls Association
McCulloch
Motorcycle Industry Council, Inc.
Murray
National Marine Manufacturers Association
Onan
Outdoor Power Equipment Institute, Inc.
Portable Power Equipment Manufacturers Association
Tecumseh Products Company
Weedeaters

Appendix K. Adjustments to Data in Developing Inventory A

In developing Inventory A, EPA made several adjustments to annual hours of use, load factor, population data, and the emissions inventory methodology for recreational marine equipment that are not reflected in the final reports from EPA contractors. These adjustments are detailed below.

1. Annual Hours of Use

Annual hours of use data provided to EPA from the PSR data base were largely based on the assumption that the use of various equipment types is either consumer or commercial. In order to adjust for equipment types with a mixture of consumer and commercial use, EPA adjusted the data by multiplying the regional hours of use reported by the contractor by factors based on data submitted to EPA by OPEI,[1] PPEMA,[2] and CARB:[3]

Equipment Type	Adjustment Factor
Lawnmowers (4-stroke)	1.75 (OPEI)
Lawnmowers (2-stroke)	2.17 (OPEI)
Tillers	1.54 (OPEI)
Trimmers/edgers/brush cutters	1.8 (PPEMA)
Leaf Blowers/vacuums	2.5 (PPEMA)
Snowblowers	1.5 (CARB)

These factors were calculated using the following general equation:

Adjustment Factor = (% consumer) x (consumer hrs) + (% commercial) x (commercial hrs)

In the case of trimmers/edgers/brush cutters, it was necessary to also weight by population the annual hours of use for string and hedge trimmers, for which PPEMA submitted separate estimates. Similarly, the value computed for leaf blowers/vacuums incorporates both

handheld and backpack versions. Detailed information used to derive these adjustments are contained in Appendix N, Part 2.

2. Load Factors

Load factor data provided to EPA from the PSR data base were in some cases too high and in others too low. To correct the data, EPA substituted load factors determined by CARB for the entire lawn and garden equipment category,[4] and data supplied by EMI for crawler tractors and rubber tired loaders.[5]

Equipment Type	Load Factor (%)
Leaf blowers/vacuums (2-stroke)	50
Leaf blowers/vacuums (4-stroke)	36
Trimmers/edgers/Brush cutters (2-stroke)	50
Trimmers/edgers/Brush cutters (4-stroke)	36
Chain saws > 4 hp	50
Chain saws < 4 hp	50
Lawnmowers	36
Rear engine riding mowers	38
Lawn and garden tractors	50*
Front mowers	50
Shredders < 5 hp	36
Tillers < 5 hp	40
Snowblowers	35
Commercial turf equipment	50
Other lawn and garden equipment	50
Crawler tractors	58
Rubber tired loaders	54

* Based on CARB data for consumer and commercial riding mowers and garden tractors, which were weighted by population x hours/yr x rated horsepower.

3. Populations--Chain Saws

In constructing Inventory A, EPA relied on a methodology developed by PPEMA[6] for allocating chain saw populations to the local level. The methodology developed by EEA uses single family housing units (SFHUs) and SIC 078 (landscaping and horticultural services) employment. While this methodology is appropriate for most types of lawn and garden equipment, chain saws are not generally used in major urbanized areas except by horticultural services. One of the four models proposed by PPEMA is based on urban population [human] outside major urbanized areas, rural area population, and SIC 078 employment, which is more appropriate for allocating chain saw use. The national chain saw population estimates reported by EEA were disaggregated to the local level using the local allocations developed with this methodology for Inventory B, as follows:

$$N_A \text{ local} = \frac{N_B \text{ local}}{N_B \text{ national}} \times N_A \text{ national}$$

where N refers to the number of chain saws (all sizes) and A and B refer to Inventories A and B.

4. Populations--Agricultural Equipment

For Inventory A, regional agricultural equipment populations were determined by multiplying PSR national population estimates by the ratio of local over national census data.

Census data exists for some types of agricultural equipment at the local level. However, census counts do not differentiate between equipment that is inoperative or seldom used and equipment used for agricultural activity. National population estimates from the PSR data base are better estimates of equipment used regularly in agricultural activity than the census counts. However, the census counts are accurate indicators of local distribution of the equipment. Thus, the census counts were used as indications to disaggregate the PSR national population estimates to the local level.

5. Populations--Snowmobiles

As recommended by ISIA, EPA assumed that all snowmobiles use 2-stroke gasoline engines, despite the fact that EEA reported a very small number of 4-strokes.

6. Recreational Marine Equipment Emissions Inventory Methodology

Population -- Local boat registration data were used to establish the number of boats of each equipment type in each nonattainment area. However, two adjustments to this information were needed for inventory purposes. The first adjustment was to turn the number of boats into the number of engines. This was necessary to match the horsepower and hours of use estimates, which were derived per engine. The methodology used to calculate the number of engines per boat for this study was developed by EEA and provided to EPA.

The second adjustment was to estimate the number of engines actually used in the nonattainment areas. Unlike most of the equipment contained in this study recreational boats are frequently transported long distances, such that where they are used may be different from where they are owned. Survey results submitted by NMMA for eight nonattainment areas were used as the basis for these adjustments. The survey was conducted for NMMA by Irwin Broh and Associates, Inc. (IB&A).[7] Questionnaires were mailed at random to registered boat owners within and in counties lying within a 50-mile belt of the following nonattainment areas:

Baltimore, MD	Hartford, CT
Boston, MA	Houston, TX
Chicago, IL	Milwaukee, WI
Denver, CO	Seattle, WA

The questionnaire asked a wide variety of questions about the kind of boat(s) owned; engine number, type, and size; amount, location, and time of usage; and fuel used. The

information from the survey was used by EPA in the following formula to calculate the umber of engines used in the nonattainment area:

$$EU = ER \left[\frac{\text{Fuel used in n/a * area}}{\text{Fuel used by boats registered in n/a area}} + \text{\% use from 0-1 mile offshore} \right]$$

*n/a = nonattainment

where:

EU = engines used in nonattainment area
ER = Engines registered in nonattainment area
Fuel used in n/a area = the sum of the reported amount of fuel consumed inside the nonattainment area by boats registered inside the nonattainment area, plus the fuel consumed within the nonattainment area by boats registered outside the nonattainment area
Fuel used by boats registered in the n/a area = The total reported amount of fuel consumed by boats registered inside the nonattainment area without regard to where the fuel was consumed.
% use from 0-1 mile offshore = The survey reported offshore use separately from on-shore use. While offshore emissions have variable effects on nonattainment area air quality, depending on meteorological conditions, it would be inappropriate to totally ignore such emissions. Thus, boat use within one mile offshore of nonattainment areas located on the ocean or the Great Lakes was used as an approximation of the offshore emission contribution. This contributed a relatively small fraction to total boat usage in most nonattainment areas.

While the number of hours of use were also reported by the survey, fuel use was chosen as a better representation of actual boat usage based upon NMMA's stated belief that the reported fuel use was likely to be more accurate than the reported hours (NMMA was concerned that the reported hours were the number of hours the boat was in the water, not the number of hours the engine was being operated).

For the eight areas surveyed by IB&A, the actual survey results for each area were used to calculate individual ratios of engines used to engines registered. For the other 16 areas, the average ratios from the eight surveyed areas were used. For all areas, separate ratios were calculated for the five different equipment types in the recreational marine category.

Because 16 of the areas were not surveyed, the average ratios determined from the eight surveyed areas exceed reasonable maximum boat use in nonattainment areas with relatively little water surface area. To account for this, a calculation of the maximum number of boats that could be operated normally on the available water surface area was made for each nonattainment area according to the following formula:

$$\text{max. boats} = \frac{\text{Water surface area in nonattainment area}}{\text{Area required/boat}}$$

The water surface area in each nonattainment area was supplied by EEA. The area required/boat was supplied by NMMA based on saturation limits determined for a joint study by EPA and marine engine manufacturers in the early 1970's (Grant No. R-801799), plus the IB&A survey results for types of boating activity.

NMMA supplied information suggesting that the available hours of prime boating use are 384 hours/year (12 weeks/year, 4 days per week, 8 hours/day). This figure was multiplied by the maximum number of boats to yield the maximum number of summer boat hours that could be supported within each nonattainment area without hindering boat activity.

This theoretical maximum number of summer boat hours inside the nonattainment area was compared to the amount of summer boat hours inside the nonattainment area calculated from the survey results and the local boat registrations. The calculation of summer boat hours from the survey and registration was made using the following formula:

$$\text{Summer hours} = \left[\sum_i (\#\ \text{n/a boats})(\text{hours})\left(\frac{\text{Fuel used in n/a area}}{\text{Fuel used by boats registered in n/a area}}\right)\right] \times (\text{summer usage})$$

where:

i = each of the five equipment types in the recreational marine category
n/a boats = # boats registered in the nonattainment area
hours = total annual hours of use per boat from the survey for boats registered in the nonattainment area (includes hours operated outside the nonattainment area)

Fuel used ... = Both terms have the same meaning as defined, above, in the formula calculating engines used in nonattainment areas.
Summer usage = reported proportion of summertime operation from the survey.

In cases where the calculated summer boat hours exceeded the theoretical maximum, the calculated number of engines used in the nonattainment area was reduced by the ratio of the theoretical maximum summer boat hours to the calculated summer boat hours. Because this correction ratio does not include offshore boat use, the average offshore use was subtracted prior to applying the correction ratio. For areas on the ocean or on a Great Lake, the average of the offshore usage proportion for the five areas with offshore use was added back after applying the correction ratio.

Annual Fuel Use Estimates -- The load factor, horsepower, and regional hours of use supplied by PSR were multiplied by the following BSFC estimates determined from test data supplied by NMMA for recreational marine engines (the BSFC calculations are discussed in Appendix I):

Diesel - 0.066 gallons/hr-hr
4-stroke gasoline - 0.1 gallons/hp-hr
2-stroke gasoline - 0.16 gallons/hp-hr

Seasonal Adjustment Factors -- Monthly usage reported by the survey respondents were used to directly establish the proportion of boat usage in the summer and the winter for six of the eight regions developed for this study. For the two regions for which no areas were surveyed, the southeast and the west coast, survey results from Houston were used.

Appendix L. Regional and Seasonal Adjustments to Inventories

Annual hours of use data provided to EPA from the PSR data base reflect different usage patterns for different regions of the country.* In developing Inventory A, EPA made several adjustments to this data.

As ozone exceedances are typically a summertime problem and CO exceedances a wintertime problem, EPA developed seasonal adjustment factors to reflect the use of equipment depending on the season of the year.

This appendix describes the assumptions made by EPA in calculating regional hours of use and summertime and wintertime emissions.

1. Regional Adjustments

EPA has allocated the nonattainment areas studied to eight regions. Table L-01 indicates the nonattainment areas that fall into these eight regions, as well as the seasonal designations for each region.

In constructing Inventory A, EPA used annual hours of use data for each region as supplied from the PSR data base, as indicated in the EEA final report, except for the following:

- EPA created a "Mid-Atlantic Coast" region. The annual hours of use rates for equipment in this region are determined by taking the average of the data for the Northeast and Southeast regions.

- EPA created a "Rocky Mountains" region. The annual hours of use rates for equipment in this region are determined by taking the average of the data for the Great Lakes and the Northwest regions.

*This regional annual hours of use data is documented in the Energy and Environmental Analysis final report, "Methodology to Estimate Nonroad Equipment Populations by Nonattainment Areas," available in the public docket.

Table L-01. Regional and Seasonal Designations

Region	Nonattainment Areas	Seasonal Designation
Northeast	Springfield, Hartford, Boston, New York	Cold
Southeast	Atlanta, Baton Rouge, Miami	Warm
Mid-Atlantic Coast	Baltimore, Philadelphia, Washington D.C.	Medium
Great Lakes	Chicago, Cleveland, Milwaukee, Minneapolis, St. Louis	Cold
Southwest	El Paso, Houston	Warm
Rocky Mountains	Denver, Spokane, Provo-Orem	Cold
Northwest	Seattle	Medium
West Coast	South Coast California, San Diego, San Joaquin	Warm

Regional assumptions for commercial marine vessels were not necessary as commercial marine equipment inventories were calculated directly at the regional level.

2. Seasonal Adjustment Factors

Because ozone and CO are largely summertime and wintertime problems, respectively, seasonal adjustment factors were used to determine summertime VOC and NO_x emissions and wintertime CO emissions from nonroad engines and vehicles. Yearly emissions (tons per year) were adjusted according to the following formulas:

$$tpsd = tpy \times SAF_{summer} \qquad tpwd = tpy \times SAF_{winter}$$

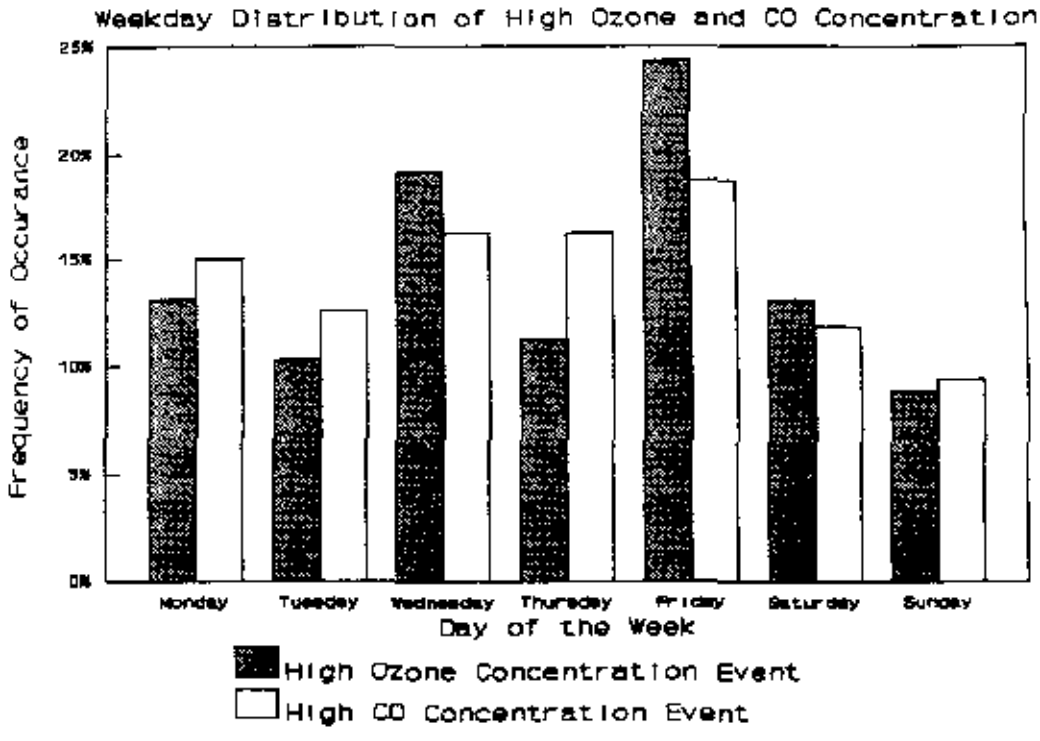

where tpsd and tpwd refer to average daily emissions during the summer and winter and the seasonal adjustment factors (SAFs) are defined as follows:

$$SAF_{summer} = 4 \times \frac{\%\ activity\ during\ summer}{365\ days}$$

$$SAF_{winter} = 4 \times \frac{\%\ activity\ during\ winter}{365\ days}$$

This study did not consider day-to-day (e.g., weekend versus weekday) or hour-to-hour activity level fluctuations. For most of the nonroad engines and vehicles studied, insufficient survey data was available to estimate activity level variations at that level of temporal resolution. Furthermore, ozone and CO exceedances occur with reasonably similar frequency on every day of the week, thus rendering suspect the value of emission inventories that make such distinctions.

The following chart shows the day-to-day distribution of ozone and CO nonattainment in the nonattainment areas included in this study. For both ozone[1] and CO[2] nonattainment, the ten days from 1986-1988 corresponding to the highest ambient concentrations are included.

As this chart shows, high ozone and CO concentrations are only 29% and 35%, respectively, less likely on weekends than on weekdays. It should also be noted that Friday contained the highest number of exceedances, possibly because of a combination of work and recreation activities. If Friday is excluded, high ozone and CO concentrations on the weekend are only 17% and 29%, respectively, less likely than during Monday through Thursday.

For the purposes of determining summer and winter adjustment factors, the nation was divided into three regions based on average January temperatures:

Cold: < 35° F
Medium: 35-44° F
Warm: > 45° F

The cold, medium, and warm regions roughly correspond to northern, central and southern regions as defined in a 1973 report by Hare and Springer[3]:

Northern: 43° north latitude and north
Central: from 37° to 43°
Southern: 37° and south

EPA seasonal adjustment factors have been calculated based on data from Hare and Springer, the CARB Technical Support Document for proposed regulations applicable to lawn and garden equipment,[4] 1987 SIP emission inventories, the Motorcycle Industry Council (MIC),[5] and the NMMA,[6] as detailed below. Seasonal activity percentages were estimated for the 3-month summer and winter periods as shown in Table L-02.

Table L-02. Summer and Winter Percentages of Yearly Activity.

Equipment Category	Cold/Northern		Medium/Central		Warm/Southern	
	Summer (%)	Winter (%)	Summer (%)	Winter (%)	Summer (%)	Winter (%)
Agricultural	50	6	40	6	34	6
Construction	43	10	38	15	33	20
Industrial	30	20	25	25	25	25
Lawn and Garden (excl. chain saws)	50	6	40	6	34	6
Snowblowers/Snowmobiles	0	100	0	100	0	100
Commercial Marine	25	25	25	25	25	25
Airport Service	25	25	25	25	25	25
Logging (including chain saws)	25	25	25	25	25	25
Light Commercial	25	25	25	25	25	25

Hare and Springer reported construction seasons of 7, 8, and 9 months for the north, central, and southern regions, respectively. This corresponds to summer activity percentages of 43%, 38%, and 33% in the same regions. The 1987 SIP emission inventories for Denver and Atlanta reported wintertime activity percentages of 10% and 20%, respectively. These figures were applied to areas in the northern and southern regions. In this study, it was estimated that the wintertime activity percentage in the central region was 15%.

Hare and Springer also reported agricultural seasons of 180, 225, and 270 days for the northern, central, and southern regions, respectively. This corresponds to summer activity percentages of 50%, 40%, and 34% in the same regions. The 1987 SIP emission inventories for both Boston and Atlanta reported that 90% of agricultural equipment activity occurs between April and October, yielding a wintertime activity percentage of 6% in both areas. This figure was herein applied to all nonattainment areas to estimate wintertime agricultural equipment activity.

Because of similarities in the growing seasons, summertime activity percentages for lawn and garden equipment (excluding chain saws and snowblowers) were estimated to be the same as those for agricultural equipment. CARB estimated in the Technical Support Document for its proposed regulations applicable to lawn and garden equipment that wintertime activity accounted for about 6% of yearly activity. This figure was applied to the southern region, and the wintertime activity percentages in the central and northern regions were estimated to be 3% and 0%. However, it was assumed that all snowblower activity occurs during the winter.

The industrial equipment seasonal activity percentages listed above are based on seasonal adjustments used in several 1987 SIP emission inventories. Of those considered in this studied, only that for Chicago reported any nonuniformity of industrial equipment activity - the summer portion of yearly activity was reported to be 30%. This figure was applied to the northern region, and the wintertime activity percentage was consequently estimated to be 20%. Activity in the central and southern regions was estimated to be uniformly distributed across the year.

Due to the year-round nature of equipment use, no seasonal adjustments were made to activity for commercial marine vessels, airport service vehicles, logging equipment (including all chain saws), or light commercial equipment. The survey conducted by NMMA of recreation boat owners included information on seasonal boat usage. These results were used to establish seasonal adjustments for each of the eight regions used for regional hours of use adjustment as shown in Table L-03.

For recreational land-based equipment (e.g., off-highway motorcycles, ATVs, minibikes) other than snowmobiles, survey data submitted to EPA by the Motorcycle Industry

Council (MIC) was used. This survey divided the nation into 12 regions as shown in Table L-04.

Table L-03. Summer and Winter Percentages of Yearly Activity for Recreational Marine Equipment

Region	% During Summer	% During Winter
Northeast	68	1
Southeast	48	7
Mid-Atlantic Coast	57	2
Great Lakes	70	0
Southwest	48	7
Rocky Mountains	69	0
Northwest	57	5
West Coast	48	7

Table L-04. Summer and Winter Percentages of Yearly Activity for Recreational Equipment.*

Region	% During Summer	% During Winter
East	42	12
Midwest	46	8
South	36	15
West	44	11
New England	44	14
Mid-Atlantic Coast	41	12
East Central	48	9
West Central	44	8
Southeast	35	17
Southwest	37	12
Rocky Mountains	44	8
Pacific	43	13
National Average	42	12

The following tables show the seasonal adjustment factors used for each equipment type in each nonattainment area studied by EPA. To ease interpretation, they are expressed as SAF^{-1}. Using this notation, the following percentages of annual use occurring during a three month season would translate into the following factors:

* Excluding snowmobiles.

Table L-05. Examples of Seasonal Activity Percentages and Corresponding Values for SAF and SAF^{-1}

Percent During Season	SAF	SAF^{-1}
10	0.00110	909
25	0.00274	365
35	0.00384	260
50	0.00548	183

Appendix M. Emission Inventory A

Inventory A is presented in two sets of tables which summarize emissions from nonroad engines and vehicles, highway vehicles, and other area and point sources of emissions. Each set of tables summarizes emissions in each of the 24 nonattainment areas included in this study, as well as national emissions.

In the first set of summary tables, nonroad emissions are calculated using new engine emission factors. In the second set of summary tables, nonroad emissions are calculated using in-use emission factors.

Appendix N. EPA Use of Manufacturer Data In Inventory B

In developing activity levels for Inventory B, EPA used data supplied by manufacturers or manufacturer associations where it was available. In some cases, EPA had to adjust data for use in the inventory.

The kinds of data supplied and the adjustments to the data are detailed below. Part 1 is a general overview of the data supplied by manufacturers and used by EPA in constructing Inventory B. Part 2 contains more detailed adjustments made to the data for use in the inventory.

1. General Overview

1.1. Equipment Manufacturers Institute (EMI)

EMI provided population data for several types of agricultural and construction equipment. These equipment types are listed in Table N-01. Estimates of average engine-rated horsepower, annual use, and load factors were also available for these equipment types.

EMI estimates for crawler loaders were considered together with crawler tractors as fitting within the Inventory A estimate for crawler tractors. Because cotton pickers were included in Inventory A under "other agricultural equipment," EMI's cotton picker estimates were only considered in areas where the populations were higher than the Inventory A estimate for other agricultural equipment.

There were several equipment types for which population estimates were not provided by EMI, but for which EPA incorporated horsepower, annual use, and load factor estimates from EMI in developing Inventory B. These included swathers ("windrowers"), mobile elevating work platforms ("aerial lifts"), landfill compactors ("crushing/processing equipment"), and square balers and bale wagons ("balers"). Because of either negligible equipment populations or the absence of any matching equipment type, data for the following equipment types was not considered: leaf loaders, milling machines, horizontal earth borers, forage harvesters, augers, and cranes.

Additional adjustments to EMI data are detailed below in Part 2.

Table N-01. EMI Agricultural and Construction Equipment Data

Equipment Type	EMI Data
Crawler tractors	Crawler tractors Crawler loaders
Rubber tired loaders	Wheeled loaders
Scrapers	Scrapers
Graders	Motor graders
Off-highway trucks	Dumpers
Excavators	Crawler excavators Wheeled excavators
Tractors/loaders/backhoes	Backhoe loaders
Skid steer loaders	Skid steer loaders
Skidder (logging)	Log skidders
Rollers	Rollers and Compactors
Asphalt pavers Concrete pavers	Pavers
Other Agricultural Equip.	Cotton pickers

1.2. Outdoor Power Equipment Institute, Inc. (OPEI)

OPEI provided data on nonhandheld equipment types shown below in Table N-02. EPA combined OPEI's separate estimates for lawn tractors and garden tractors to replace the data for lawn and garden tractors from Inventory A.

OPEI supplied test data which were used to calculate load factors for lawnmowers, rear engine riding mowers, front mowers, and lawn and garden tractors. For other equipment types, EPA used the CARB load factors in Inventory B.

Because OPEI reported separate annual hours of use estimates for commercial and consumer use, EPA used OPEI's reported percentages of such use to construct weighted

average annual hours of use estimates. These and other adjustments to OPEI data are detailed in a later section.

Table N-02. OPEI Nonhandheld Lawn and Garden Equipment Data

Equipment Type	OPEI Data
Lawnmowers	Walk behind mowers
Rear engine riding mowers	Riding mowers
Lawn and garden tractors	Lawn tractors Garden Tractors
Tillers < 5 hp	Walk behind tillers

1.3. Portable Power Equipment Manufacturers Association (PPEMA)

PPEMA provided local and national population data for those types of handheld equipment shown in Table N-03.

Table N-03. PPEMA Handheld Lawn and Garden Equipment Data

Equipment Type	PPEMA Data
Leaf blowers/vacuums (2-stroke)	Backpack blowers Hand blowers
Trimmers/edgers/brush cutters (2-stroke)	Hedge trimmers Trimmer/brush cutter
Chain saws < 4 hp Chain saws > 4 hp	Consumer chain saws Commercial chain saws

PPEMA also provided annual hours of use, horsepower, and load factor data. EPA's use of this data is detailed in a later section.

1.4. Industrial Truck Association (ITA)

ITA provided load factor, annual hours of use, and CMSA-level population estimates for industrial forklifts, which were used in Inventory B as provided.

1.5. International Snowmobile Industry Association (ISIA)

ISIA provided national population and annual hours of use estimates for snowmobiles. To obtain CMSA-level populations, EPA multiplied CMSA-level populations from Inventory A by the ratio of ISIA national populations to Inventory A national populations.

1.6. National Marine Manufacturers Association (NMMA)

Population Data -- Local boat registrations were used to establish the number of boats of each equipment type owned in each nonattainment area, as was done for Inventory A. The same method was also used to calculate the number of engines from the number of boats. However, NMMA requested that the adjustment for the number of engines actually used in the nonattainment areas be handled differently than was done for Inventory A. Rather than directly rely on the ratio of the reported fuel consumed in the nonattainment areas to the reported fuel used by boats registered in the nonattainment area from the IB&A survey, NMMA requested that the adjustment be handled by a formula based upon the water surface area per registered boat in the nonattainment area.

The formula was derived from the relationship between water surface area per registered boat and the reported ratio of fuel consumed in the nonattainment areas to the fuel consumed by boats registered in the nonattainment area for the eight surveyed areas. Equations of the form $Y = 1 - \exp^{(kX))^{**}m}$ provided the best fit to the data, where

Y = ratio of fuel used in the nonattainment area (from boats registered both inside and outside the nonattainment area) to total fuel used by boats registered in nonattainment area (includes fuel used outside the nonattainment area)
X = local water surface area/registered boat in nonattainment area
k and m are coefficients

The value of m was used to calibrate the formula such that the highest r^2 values were obtained without yielding larger values for y in any nonattainment area than the ratio of the theoretical maximum number of summer boat hours inside a nonattainment area to the total summer hours of use calculated for boats registered in a nonattainment area. This ratio was calculated as follows:

$$\frac{\left[\frac{\text{water surface area in n/a area}}{\text{area req/boat}}\right](384)}{(\text{summer usage})\left[\sum_i (\#\text{ n/a boats})(\text{hours})\left(\frac{\text{fuel used in n/a area}}{\text{fuel used by boats registered in n/a area}}\right)\right]}$$

The definition of the above terms and the derivation of this formula are discussed in Appendix K, Section 6.

The value of k was determined by the regression. The final formula developed was:

$$Y = 1 - \exp^{(238x)^{**}.66}$$

This formula was used to develop the basic ratio of fuel used in the nonattainment area to total fuel used by boats registered in the nonattainment area for each of the 24 areas. For those areas located on the ocean or the Great Lakes, the proportion of use within 1 mile offshore reported by the survey for the five areas on the ocean or a Great Lake were added to the basic ratio. The final ratio was multiplied by the number of engines registered in the nonattainment area to calculate the number of engines used in the nonattainment area.

Fuel Use -- For the eight surveyed areas, the average fuel use per engine reported in the survey for boats registered in the nonattainment area were used in the inventory calculations. For the nonsurveyed areas, NMMA submitted a national average fuel use estimate for outboard motors of 91 gallons/year. This estimate was based on the amount of 2-stroke marine motor oil consumed each year. The average fuel use reported in the survey for outboard motors was 142 gallons/year. NMMA requested that EPA use the 91 gallons/year estimate for outboard motors for all of the unsurveyed areas, and scale the

average fuel use reported by the survey for the other equipment types by the outboard motor factor, i.e., 91/142.

Seasonal Adjustment Factors -- As was done for Inventory A, the proportion of boat use in the summer and the winter was based on monthly usage reported by the survey respondents.

1.7. Motorcycle Industry Council, Inc. (MIC)

MIC provided EPA with survey information on the number of miles ridden annually by ATVs and off-highway motorcycles.* An average speed of 25 miles per hour was assumed in order to convert these figures into hours per year. MIC also provided national population figures, which were distributed to the local level using the ratio of the local to national population estimate for Inventory A. The same distribution between 2-stroke and 4-stroke versions as reported by EEA was used in developing Inventory B.

2. Detailed Adjustments

2.1. Equipment Manufacturers Institute (EMI)

EMI supplied load factor, horsepower, annual hours of use, national and CMSA-level population data for various types of construction equipment. The data supplied and the adjustments made to the data are detailed below.

Equipment Type	EMI Data and Adjustment
Crawler Tractor	EMI supplied national horsepower and load factor, as well as national and CMSA level populations and hours/year separately for crawler loaders and tractors. National hours/year were estimated by population weighting the regional values supplied by EMI over all 24 areas. To estimate aggregated hours/year for all crawler loaders and tractors at the regional level, EPA population weighted the regional values for both equipment

* Letter to John German (EPA) from J.C. Delaney, Manager of Technical Programs, MIC, June 6, 1991.

Equipment Type	EMI Data and Adjustment
	types. To estimate aggregated horsepower and load factor at the national level, EPA weighted data for both types by (population) (hours/year) and (population) (hours/year) (horsepower), respectively.
Rubber Tired Loader	For wheel loaders EMI supplied national population, horsepower, and load factor, as well as CMSA level populations and hours/year. EPA estimated national hours of use by population weighting regional values over 23 nonattainment areas.
Scraper	For scrapers, EMI supplied data as for rubber tired loaders.
Graders	For motor graders, EMI supplied data as for rubber tired loaders.
Off-Highway Trucks	For dumpers (off-road haulers), EMI supplied data as for rubber tired loaders.
Excavators	EMI supplied national horsepower and load factor, as well as CMSA level populations and hours/year separately for crawler and wheel excavators. EMI also supplied national populations for all excavators - EPA assumed a uniform national distribution of crawler and wheel versions. National hours/year were estimated by population weighting the regional values supplied by EMI over all 24 areas. To estimate aggregated hours/year for all excavators at the regional level, EPA population weighted the regional values for both types of excavators. To estimate aggregated horsepower and load factor at the national level, EPA weighted crawler and wheel data by (population) (hours/year) and (population) (hours/year) (horsepower), respectively.
Tractor/Loaders/Backhoes	EMI supplied data for backhoe loaders as for rubber tired loaders.
Skid Steer Loaders	EMI supplied data for skid steer loaders as for rubber tired loaders.
Skidder (logging)	EMI supplied data for log skidders as for rubber tired loaders, except that national populations were not provided.
Rollers	EMI supplied data for rollers and compactors as for rubber tired loaders.
Asphalt pavers	EMI supplied data for asphalt pavers as for rubber tired loaders.

Equipment Type	EMI Data and Adjustment
Concrete pavers	EMI supplied only a national population estimate for concrete pavers.
Cranes	EMI supplied only a national population estimate for cranes.
Trenchers	EMI supplied only estimates of the national population, average rated horsepower, and load factor for trenchers.
Rough Terrain Forklifts	EMI supplied data for rough terrain forklifts as for trenchers.
Other Agricultural Equipment	EMI supplied data for cotton pickers as for rubber tired loaders.
Balers	EMI supplied local population and annual use estimates for square balers and bale wagons, as well as national data for horsepower and load factor. To estimate national hours per year for both versions individually, EPA weighted regional values over all 24 areas. EPA estimated aggregated hours per year for all balers at the regional level by population weighting regional values. At the national level, EPA estimated aggregated hours per year, horsepower, and load factor by weighting regional values by population, (population) (hours/year) and (population) (hours/year) (horsepower), respectively.
Aerial Lifts	EMI supplied only horsepower and load factor data for mobile work platforms.

In the draft version of this study, data submitted by EMI for combines and agricultural tractors was used to construct Inventory B. This included population figures developed by the U.S. Bureau of the Census, which EMI has stated may include seldom-used equipment. However, EMI has cautioned that, in constructing an emission inventory, appropriate corrections should be made to either the operative population estimate or the estimate of average annual usage. EMI's submitted data contained no such correction. Consequently, the final version of Inventory B uses the same data as Inventory A for these two types of equipment.

2.2. OPEI Data

Population Data -- CMSA population data for lawnmowers, riding mowers, lawn tractors, garden tractors and tillers were supplied by OPEI[†]. However, because these categories do not fully match those equipment types used in the nonroad study, some aggregation and disaggregation was necessary. Lawn tractors and garden tractors were combined to obtain a value for "Lawn and Garden Tractors". The tiller population was disaggregated into "Tillers < 5 hp" and "Tillers > 5 hp" and the riding mower population was disaggregated into "Front Mowers" and "Rear Engine Riding Mowers". In addition, all equipment populations were disaggregated into 2- and 4-stroke diesel and gasoline equipment types per EEA's methodology for each CMSA[‡] as shown below.

Tillers < 5 hp and Tillers > 5 hp

For each tiller type, the following calculation was made:

$$\left(\frac{Pop_{Stroke\ type,\ Fuel\ type,\ HP\ Range}}{Tiller\ Total\ Pop}\right)_{EEA\ CMSA} \times (Tiller\ Total\ Pop)_{OPEI\ CMSA}$$

$$= (Pop_{Stroke\ type,\ Fuel\ type,\ HP\ Range})_{OPEI\ CMSA}$$

[†] "Information Regarding Selected Outdoor Power Equipment", prepared by OPEI for EPA, April 25, 1991, plus addendum. According to Mary Washburne this data includes diesel as well as gasoline equipment (conversation of Sept. 9, 1991).

[‡] Two EPA CMSAs (i.e., South Coast and San Joaquin) don't match OPEI's regions. For the San Joaquin Valley, EEA population numbers were used and for the South Coast Air Basin CMSA, OPEI's L.A. populations were used.

Lawn and Garden Tractors

$$\left(\frac{(L+G\ Population)_{Stroke,\ Fuel}}{Lawn\ +\ Garden\ total}\right)_{EEA\ CMSA} \times (Lawn\ Pop+\ Garden\ Pop)_{OPEI\ CMSA}$$

$$= ((L+G\ Population)_{Stroke,\ Fuel})_{OPEI\ CMSA}$$

Front Mowers and Rear Engine Riding Mowers

$$\left(\frac{Stroke\ type,\ Fuel\ type,\ Equip.\ Type}{Front+\ Rear\ Engine\ Riding\ Mower\ Tot.}\right)_{EEA\ CMSA} \times (Riding\ Mower\ Tot.)_{OPEI\ CMSA}$$

$$= (Stroke\ type,\ Fuel\ type,\ Equip.\ Type)_{OPEI\ CMSA}$$

In some cases OPEI did not provide data for a particular CMSA, and EPA used data from Inventory A. These cases are identified below:

Walk Behind Lawnmowers	Garden Tractors
Fresno, CA	Bakersfield, CA
Provo-Orem, UT	El Paso, Tx
	Fresno, CA
Riding Mowers	Miami, FL
Bakersfield, CA	Provo-Orem, UT
Fresno, CA	Spokane, WA
Provo-Orem, UT	
San Diego, CA	Walk Behind Tillers
	Bakersfield, CA
Lawn Tractors	Baton Rouge, LA
Bakersfield, CA	Miami, FL
Fresno, CA	Minneapolis-St. Paul, MN
Provo-Orem, UT	Provo-Orem, UT
San Diego, CA	Springfield, MA

Hours of Use -- Hours of use data were taken from the OPEI report to EPA[8]. Additional assumptions specific to the equipment type are described below.

[8] The average of Bakersfield and Fresno values were taken for the San Joaquin Valley and L.A. values were assumed for the South Coast Air Basin CMSA.

Lawn and Garden Tractors

Hours of use for lawn tractors and garden tractors were population weighted based on OPEI CMSA populations to get annual hours of use for "Lawn and Garden Tractors" for each CMSA. For example, the Baltimore CMSA 4-stroke diesel lawn and garden tractor annual usage number is:

$$\frac{40{,}000\ \textit{lawn tractors} \times 41\ \textit{hrs} + 29{,}326\ \textit{garden tractors} \times 56\ \textit{hrs}}{40{,}000 + 29{,}326} = 47.3\ \textit{hrs}$$

Tillers < 5 hp and Tillers > 5 hp

Hours of use for tillers were weighted by commercial and consumer populations provided by OPEI in the addendum to their report. OPEI suggested that 18% of all tillers are used commercially and that 82% are used by consumers. Commercially used tillers are assumed to operate 4 times as much as consumer tillers. Thus, the local consumer hours of use reported by OPEI for each area was multiplied by 1.54 to obtain overall hours of use, as follows:

$$\frac{0.82 \times (\#\ \text{consumer hours}) + 0.18 \times (\#\ \text{consumer hours} \times 4)}{(.82 + (.18 \times 4)\ (\#\ \text{consumer hours})} = (1.54)\ (\#\ \text{consumer hours})$$

Tillers above and below 5 hp were assumed to have the same usage characteristics.

Front Mowers and Rear Engine Riding Mowers

Hours of use for "Front Mowers" and "Rear Engine Riding Mowers" were assumed equal to the riding mower value supplied by OPEI for each CMSA. This assumption will probably underestimate the annual hours of use for "Front Mowers" because they are used commercially while "Rear Engine Riding Mowers" are not.

Lawnmowers

Hours of use for lawnmowers are also weighted by commercial and consumer populations as well as 2-stroke and 4-stroke populations. Based upon sales, useful life, and usage information supplied by OPEI, 94.8% of all lawnmowers are consumer and 5.3% are

commercial, with commercial mowers operating 16 times as much as consumer mowers. Of the consumer lawnmowers, 90% are 4-stroke and 10% are 2-stroke. Of the commercial lawnmowers, 85% are 4-stroke and 15% are 2-stroke. Thus, the local consumer hours reported by OPEI for each area was multiplied by 2.17 to obtain overall average hours of use for 2-stroke lawnmowers, as follows:

$$\frac{\begin{array}{l}0.948 \times 0.10 \times (\text{\# consumer hours}) \\ +0.053 \times 0.15 \times (16 \times \text{\# consumer hours})\end{array}}{(0.948 \times 0.10) + (0.052 \times 0.15)} = (2.170)\ (\text{\# consumer hours})$$

Similarly, the local consumer hours reported by OPEI for each area was multiplied by 1.75 to obtain overall average hours of use for 4-stroke lawnmowers, as follows:

$$\frac{\begin{array}{l}0.948 \times 0.90 \times (\text{\# consumer hours}) \\ +0.053 \times 0.85 \times (16 \times \text{\# consumer hours})\end{array}}{(0.948 \times 0.90) + (0.052 \times 0.85)} = (1.75)\ (\text{\# consumer hours})$$

Horsepower -- Horsepower data for "Lawnmowers", "Rear Engine Riding Mowers", "Lawn and Garden Tractors", and tillers were calculated from the OPEI report by weighting population only, as hours of use were not available. The calculations are shown below:

Walk-Behind Lawnmowers

3.0 (+ *less*)	× 0.08
+ 3.5	× 0.60
+ 4.5	× 0.20
+ 5.0 (+ *more*)	× 0.12
	3.84 *HP*

Rear Engine Riding Mowers and Front Mowers

	8.0 (+ *less*)	× 0.13
+	9.0	× 0.34
+	11.0	× 0.26
+	12.0 (+ *more*)	× 0.27
		10.2 ***HP***

Lawn and Garden Tractors

Garden Tractors:

	12 (+ *less*)	: 12	× 0.19
+	12 - 13.9	: 13	× 0.30
+	14 - 15.9	: 15	× 0.08
+	16 - 17.9	: 17	× 0.11
+	18 - 19.9	: 19	× 0.21
+	20 (+ *more*)	: 20	× 0.11
			15.44 ***HP***

Lawn Tractors:

	12 (+ *less*)	: 8.0	× 0.33
+	12 - 13.9	: 12.3	× 0.42
+	14 - 15.9	: 15.0	× 0.05
+	16 - 17.9	: 17.0	× 0.07
+	18 (+ *more*)	: 19.0	× 0.13
			12.4 ***HP***

Lawn and Garden Tractors	**Population**	**Usage Ratio**	**hp**	
Lawn Tractors	75%	3	12.40	2,790
Garden Tractors	25%	4	15.35	1,535
		325.00		4,325
Average horsepower =			13.31	

Tillers < 5 hp

Tillers below 5 hp had to be disaggregated as follows:

$$\frac{3.9\ (+\ \textit{less}\ ) \times 0.14 \;+\; 4.5 \times \frac{0.77}{2}}{0.14 + \frac{0.77}{2}} = 4.34\ \textit{HP}$$

Tillers > 5 hp

Tillers above 5 hp had to be disaggregated as follows:

$$\frac{6.0\ (+\ \textit{more}\ ) \times 0.09 \;+\; 5.5 \times \frac{0.77}{2}}{0.09 + \frac{0.77}{2}} = 5.59\ \textit{HP}$$

Commercial Turf Equipment

The population weighted average horsepower of multi-spindle walk behind mowers was assumed for the "Commercial Turf Equipment" category:

$$\begin{array}{r} 8.0\ (+\ \textit{less}) \times 0.04 \\ +\ 10.5 \times 0.58 \\ +\ 13.1\ (+\ \textit{more}) \times 0.38 \\ \hline 11.4\ \textit{HP} \end{array}$$

Data for weighting the horsepowers by usage was not available.

Load Factor Data -- In a letter to EPA dated September 9, 1991, OPEI discussed the fact that some types of lawn and garden equipment are fitted with a governor that prevents the engine from reach the RPM at which the rated power (as advertised) is measured. One means of accounting for this discrepancy between the rated and governed maximum power is

to decrease the applicable load factor. Based on data included in this letter, the following load factors were calculated for use in Inventory B:

Lawnmowers - 30%
Rear engine riding mowers - 38%
Front mowers - 38%
Lawn and garden tractors - 38%

In all other cases, the load factors for lawn and garden equipment used in Inventory B were the same as those used in Inventory A.

2.3. PPEMA Data

Population data -- Population data were taken from a Heiden report[£] for 2-stroke gasoline "Trimmers/Edgers/Brush Cutters"**, "Leaf Blowers/Vacuums", "Chain Saws < 4 hp", and "Chain Saws > 4 hp". In an earlier version of this report, Heiden proposed a methodology that relied on urban single family housing units (SFHUs), rural SFHUs, and SIC 078 (landscaping and horticulture services) employment. However, because the regression coefficient for urban SFHUs was negative in the case of chain saws and blowers, Heiden developed on additional model that relies on urban population [human] outside major urbanized areas, rural population, and SIC 078 employment. For these two types of equipment, this additional methodology was used to construct Inventory B. For trimmers, the original methodology proposed by Heiden was used, as no other model was clearly superior on either an econometric or intuitive basis.

The PPEMA chain saw population was distributed to over and under 4 hp ranges based on the distribution reported by EEA.

[£] Heiden Associates, Inc. *Estimates of 24 Nonattainment Area Portable Two-Stroke Power Equipment Populations Based on Actual Industry Shipment Data and Four Alternative Activity Models*, sponsored by the Portable Power Equipment Manufacturers Association. October 30, 1991.

** Quotes (" ") identify equipment types which are included in EEA's final equipment list. Equipment types not written in quotes are manufacturer or otherwise defined.

Usage Data -- Usage data for hand blowers, back blowers, trimmers/brush cutters, hedgetrimmers, chain saws and cut off saws for commercial (professional) and consumer were supplied by PPEMA in an earlier Heiden report.[††] That data was population weighted to obtain average annual hours of use values for "Trimmers/Edgers/Brush Cutters", "Leaf Blowers/Vacuums", "Chain Saws < 4 hp" and "Chain Saws > 4 hp". National population data were provided in the October 30, 1991 Heiden report (see Population Data above). Calculations for each of these equipment types are shown below:

Leaf Blowers/Vacuums

$$\frac{\begin{array}{r}62{,}114\ \textit{Comm Hand Blwrs} \times 197\ \textit{hrs} \\ +\ 3{,}134{,}445\ \textit{Cons Hand Blwrs} \times 9\ \textit{hrs} \\ +\ 154{,}052\ \textit{Comm Back Blwrs} \times 293\ \textit{hrs} \\ +\ 25{,}815\ \textit{Cons Back Blwrs} \times 12\ \textit{hrs}\end{array}}{62{,}114 + 3{,}134{,}445 + 154{,}052 + 25{,}815} = 25.4\ \textit{hrs}$$

Trimmers/Edgers/Brush Cutters

$$\frac{\begin{array}{r}695{,}274\ \textit{Comm L Trimmers/B Cutters} \times 170\ \textit{hrs} \\ +\ 12{,}531{,}475\ \textit{Cons L Trimmers/B Cutters} \times 10\ \textit{hrs} \\ +\ 179{,}259\ \textit{Comm Hedgetrimmers} \times 75\ \textit{hrs} \\ +\ 47{,}649\ \textit{Cons Hedgetrimmers} \times 7\ \textit{hrs}\end{array}}{695{,}274 + 12{,}531{,}475 + 179{,}259 + 47{,}649} = 19.1\ \textit{hrs}$$

Chain Saws > 4 hp

Chain saws over 4 hp are assumed to operate the same number of hours as commercial chain saws (405 hrs/yr).

Chain Saws < 4 hp

The hours of use value for chain saws < 4 hp were obtained by default through the calculation of average horsepower for chain saws < 4 hp. The calculation of average horsepower and subsequent back calculation of hours of use is shown below.

[††] "A 1989 California Baseline Emissions Inventory for Total Hydrocarbon & Carbon Monoxide Emissions from Portable Two-Stroke Power Equipment" prepared by Heiden Associates, Inc. for PPEMA, July 24, 1990.

From PPEMA data:

	Population	Usage	hp	Product
Commercial Chain Saws	344,599	405	4.1	572,206,640
Consumer Chain Saws	7,576,254	7	1.5	79,550,667
		192,596,373		651,757,307
				Average Horsepower = 3.38

From data supplied by EEA:

- 0.32% of chain saws have engines greater than 4 hp.
- 99.68% of chain saws have engines less than 4 hp.
- For those that are > 4 hp, the average horsepower is 6.4 hp.

Therefore, by subtracting the number of hp-hrs attributable to the chain saws > 4 hp from the total number of hp-hrs, average hp and average hours of use for chain saws < 4 hp may be obtained:

$$651{,}757{,}306\ \frac{hp\text{-}hrs}{yr} - 0.0032 \times 7{,}920{,}853 \times 405\ \frac{hrs}{yr} \times 6.4\ hp = 586{,}057{,}882\ \frac{hp\text{-}hrs}{yr}$$

Solving for average horsepower:

$$\frac{586{,}057{,}882\ \frac{hp\text{-}hrs}{yr}}{182{,}330{,}838\ \frac{hrs}{yr}} = 3.21\ hp$$

Solving for average hours of use:

$$\frac{182{,}330{,}838\ unit\text{-}hrs}{0.9968 \times 7{,}920{,}853\ units} = 23.1\ hrs$$

Horsepower Data -- Horsepower data for chain saws, trimmers/brush cutters, hand blowers, back blowers and hedgetrimmers are taken from the 1990 Heiden report (page 18).

The horsepower for chain saws over 4 hp has been provided by EEA (6.4 hp). The average horsepower value used for chain saws less than 4 hp is 3.21 hp and was derived in the discussion earlier regarding the hours of use for chain saws less than 4 hp. The other horsepower values supplied in the Heiden Report have been population and usage weighted to provide average horsepowers for "Trimmers/Edgers/Brush Cutters" and "Leaf Blowers/Vacuums" as shown below:

Trimmers/Edgers/Brush Cutters	Population	Usage	hp	
Comm. Trim/Brush Cut.	695,274	170	1.9	224,573,502
Comm. Hedgetrimmers	179,259	75	1.9	25,544,408
Cons. Trim/Brush Cut.	12,531,475	10	.7	87,720,325
Cons. Hedgetrimmers	47,649	7	.7	233,480
		257,289,298		338,071,715
		Average horsepower =	1.31	

Leaf Blowers/Vacuums	Population	Usage	hp	
Comm. Hand Blowers	62,114	197	.8	9,789,166
Comm. Bkpk Blowers	154,052	293	3.0	135,411,708
Cons. Hand Blowers	3,134,445	9	.8	22,568,004
Cons. Bkpk Blowers	25,815	12	3.0	929,340
		85,893,479		168,698,168
		Average Horsepower =	1.96	

Load Factor Data -- Heiden suggested in the same report[‡‡] that most portable 2-stroke gasoline equipment operated at 50% of rated speed and full load. Therefore, a load factor of 50% is assumed for "Trimmers/Edgers/Brush Cutters", "Leaf Blowers/Vacuums", "Chain Saws < 4 hp" and "Chain Saws > 4 hp".

[‡‡] Ibid. page 6.

2.4. Other Sources of Data

CARB Data -- All CARB data has been taken from the Technical Support Document (TSD) attachment C[55]. Only where OPEI or PPEMA have not submitted values has CARB data been used, when available, for lawn and garden equipment.

Hours of Use

Shredders > 5 hp and Shredders < 5 hp

All shredders are assumed to have the same usage rate, regardless of horsepower. The usage has been weighted by consumer and commercial populations:

Cons:	.64 × 16.5 *hrs*
Comm:	+ .34 × 190 *hrs*
	75.2 *hrs*

Snowblowers

Snowblowers are assumed the same as snowthrowers.

Cons:	.90 × 10 *hrs*
Comm:	+ .10 × 60 *hrs*
	15 *hrs*

Commercial Turf Equipment

The specialized turf care value supplied by CARB is utilized since both categories are predominately wide area walk behind mowers. The value is 800 hours per year.

[55] California Air Resources Board. *Technical Support Documents for California Exhaust Emission Standards and Test Procedures for 1994 and Subsequent Model Year Utility and Lawn and Garden Equipment Engines* Attachment C to CARB Mailout #90-64. El Monte, CA:State of California, December 1991.

Horsepower

Snowblowers

Based on industry suggestions, different horsepowers for 2- and 4-cycle engines are used.

4-Cycle Engines:

CARB reports average horsepowers for consumer and commercial snowthrowers. Those horsepowers have been population and usage rate weighted to find the average 4-cycle horsepower for snowblowers[ff]:

$$\begin{array}{rr} \textit{Cons}: & .90 \times 10\ \textit{hrs} \times 4.5\ \textit{HP} \\ \textit{Comm}: & +\ .10 \times 60\ \textit{hrs} \times 6.0\ \textit{HP} \\ \hline & (.90 \times 10) + (.10 \times 60) \end{array} = 5.1\ \textit{HP}$$

2-Cycle Engines:

The average 2-cycle horsepower for snowblowers was provided by LAWN-BOY[***]:

$$\begin{array}{rr} \textit{Tecumseh Eng}: & .75 \times 3.0\ \textit{HP} \\ \textit{Suzuki Eng} : & +\ .10 \times 4.5\ \textit{HP} \\ \hline & 3.75\ \textit{HP} \end{array}$$

[ff] Note: The CARB data does contain 5% 2-cycle engines. Therefore, the weighing is slightly understated.

[***] Letter to Kevin Green (EPA), from Bob Carlson, Vice-President of Research and Engineering, Briggs & Stratton, October 16, 1991.

Appendix O. Emission Inventory B

Inventory B is presented in two sets of tables which summarize emissions from nonroad engines and vehicles, highway vehicles, and other area and point sources of emissions. Each set of tables summarizes emissions in each of the 24 nonattainment areas included in this study, as well as national emissions.

In the first set of summary tables, nonroad emissions are calculated using new engine emission factors. In the second set of summary tables, nonroad emissions are calculated using in-use emission factors.

Chart P-01. The ROMNET Region and the Northeast Corridor.

To determine the ozone-forming potential of the emission inventory under "real-world" conditions, the model incorporated meteorological data from actual historical ozone episodes. Two recent serious multi-day ozone episodes were chosen for the model based on the presence of "typical" ozone-generating characteristics. Most of the ROMNET results are based on a model of the meteorological conditions during the severe ozone episode of July 4-18, 1988.

In evaluating the impact of various control strategies on reducing ozone in the Northeast Corridor, including the strategy of reducing transported emission, the baseline 1985 emission inventories were projected to the year 2005. The emission from the different source categories were assumed to increase according to predicted growth in highly correlated indicators such as population or employment in the relevant industrial sector. In applying emission control technologies to the source categories, it was generally assumed that the controls could be completely in place and generating 100% of their theoretical effectiveness by 2005, assumptions which are probably quite optimistic. One of the scenarios modeled assessed the impact of relaxing these assumptions.

Three control scenarios were used to assess the impact of transport on the nonattainment areas in the Northeast Corridor. One applied maximum control technology for NO_X and VOC to the 2005 inventories over the entire ROMNET area. Another applied the controls only to sources within the Corridor itself. The third scenario applied maximum control technologies only to sources that were outside the Corridor, yet were inside the U.S. portion of the ROMNET region. As an example of how these scenarios compare to the version modeled in the Clean Air Act, the maximum control technology was assumed to reduce, on average, overall VOC emission by 63% and NO_X emission by 57% from the 2005 baseline level. The CAA version would reduce VOC emission by 32% and NO_X emissions by 32% over the same region. In one scenario where controls were applied only outside the Corridor, a packet of air was tracked from an origin in West Virginia up through the Massachusetts coast. Ozone and ozone precursor levels along its route were modeled and compared to baseline (pre-control) levels. This comparison can be used to suggest the distance over which transported pollutants can be expected to have a measurable impact on ozone levels. The path of the air packet and the difference in pollutant levels between the scenarios along that path are shown in Charts P-02 and P-03. As can be seen from these

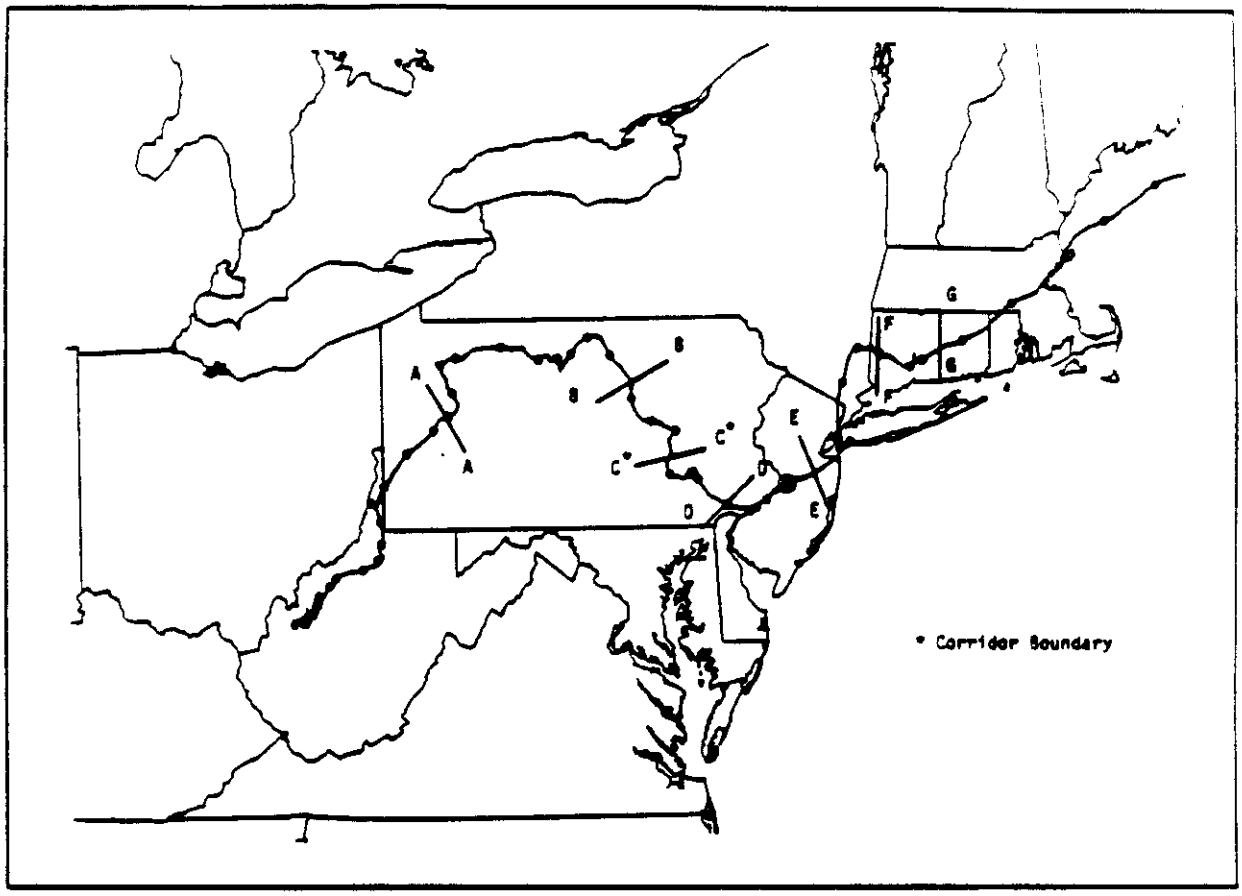

figures, the effect of reducing ozone precursors outside the Northeast Corridor was still noticeable two days after the air packet had passed into the highly polluted Corridor. By the time the air packet reached central Connecticut, it had traveled approximately 340 miles from its point of entry into the Corridor, and yet the reduction in non-Corridor emissions still reduced the predicted ozone level in Connecticut by approximately 5 ppb.

Another assessment of upwind controls on specific nonattainment areas can be made by comparing the ozone levels predicted in the Corridor nonattainment areas under the different scenarios. The effect on these cities of reducing emissions from upwind sources is shown in Tables P-01 and P-02. Table P-01 shows the impact of reducing only non-Corridor emissions on ozone concentrations in Corridor cities. Table P-02 shows the difference in predicted ozone levels for several cities between the scenarios with controls only in the Corridor and controls over the entire ROMNET region. Not surprisingly, the effect is most pronounced for those Corridor cities closest to the Corridor boundary, such as the Washington/Baltimore area and Philadelphia.

The results show that a reduction of 65% of the non-Corridor VOC inventory and 60% of the non-Corridor NO_x inventory resulted in an average peak ozone reduction of 8.6 ppb in the Corridor as a whole and 11.5 ppb average peak ozone reduction in the two western-most nonattainment areas of Washington/Baltimore and Philadelphia. Very roughly, this implies that 1% of the non-Corridor VOC and NO_x inventories account for 0.14 ppb of the peak ozone concentration in the Corridor cities on average and about 0.18 ppb of the peak ozone concentration in the Washington/Baltimore and Philadelphia areas.

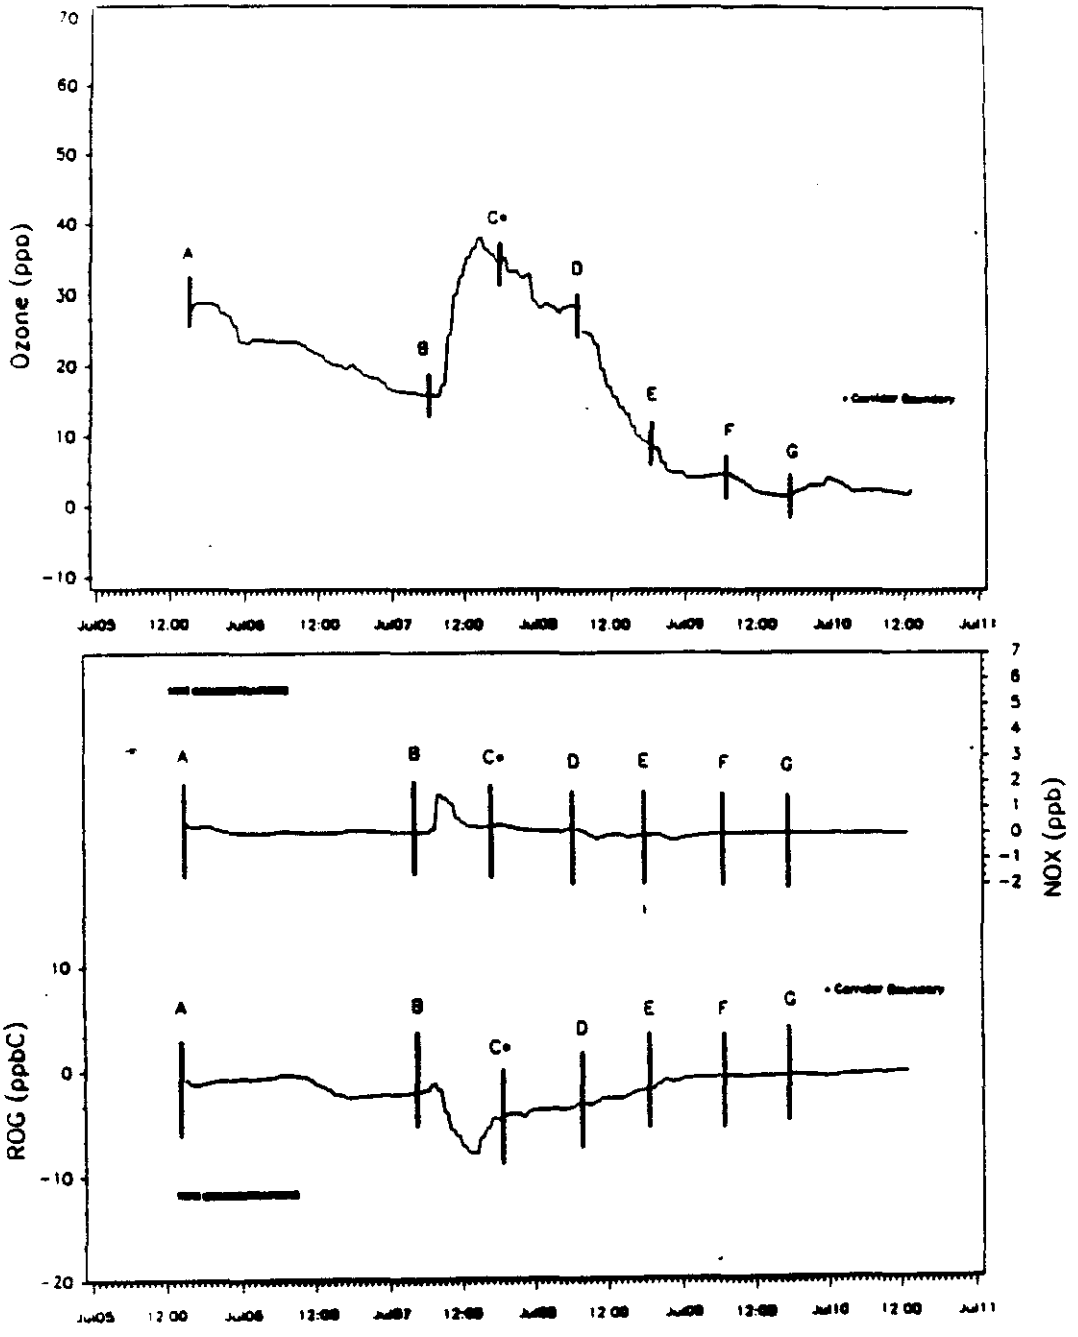

While the reductions in ozone levels due to reduction in transported non-Corridor emissions may not appear large, they should be compared to the reductions predicted for other programs. For example, the ROMNET study also assessed the impact of a control strategy that would convert the entire motor vehicle fleet in the Northeast Corridor to methanol (methanol vehicles have less photochemically reactive emissions) and also reduce the reactivity of solvent emissions throughout the Corridor. Average reductions in ozone levels for the Northeast Corridor cities were approximately 5-8 ppb under this reactivity-based control scenario. These reductions are similar to the reductions predicted for reducing non-Corridor emissions using maximum control technology for VOC and NO_x. Neither measure alone could reduce emissions enough to bring the Corridor into attainment.

Table P-01. Reductions in Corridor Ozone from Uncontrolled 2005 Levels Due to Non-Corridor Controls

City	Ozone Level (ppb)		Reduction (%)
	before control	after	
Baltimore	149	136	9
Philadelphia	148	138	7
New York City	160	152	5
Connecticut	140	133	5
Boston	158	153	3

Note: National Ambient Air Quality Standard (NAAQS) for Ozone = 124 ppb

Table P-02. Reductions in Ozone from Imposing Non-Corridor Controls in Addition to Corridor Controls

City	Ozone Level (ppb)		Reduction (%)
	Corridor-only control	Region-wide	
Baltimore/Washington	139	122	12
Philadelphia	123	115	7
New York City	123	118	4
Boston	113	107	5

Note: National Ambient Air Quality Standard (NAAQS) for Ozone = 124 ppb

According to the ROMNET report, "The results suggest that without stringent upwind controls, ozone levels in parts of the Corridor may not be reduced to below the level specified in the NAAQS even with stringent controls along the entire length of the Corridor." (ES-11) Attainment of the ozone standard across the entire region may require not only maximum control technology across the entire region, but additional substantial across-the-board reductions in VOC emissions in New York City. Again, we should note that the maximum control technologies modeled here were assumed to achieve roughly twice the reduction in VOC and NO_X emissions that are predicted to result from implementation of the minimum requirements of the Clean Air Act. The report goes on to warn: "Considering rule effectiveness and a more realistic representation of control programs, results show predicted episode maximum ozone levels of just above 125 ppb in most sections of the Northeast Corridor with the most stringent VOC/NO_X/reactivity strategy simulated." (ES-11)

1.2. Transport in California

Section 39610(b) of the California Clean Air Act required the CARB to assess the relative contribution of upwind emissions to downwind ozone levels. In June 1990, the Board issued a staff report "Assessment and Mitigation of the Impacts of Transported Pollutants on Ozone Concentrations within California," which assessed the impact of transport for 14 upwind-downwind area pairs.

The California report differs from the ROMNET report in several aspects. For ten of the upwind-downwind area pairs, transport was not assessed using a complete regional air quality model. In these cases, the CARB staff analyzed emission inventories for the upwind and downwind areas, wind patterns that prevailed during nonattainment episodes, the timing of downwind ozone peaks relative to peak precursor-generating periods upwind (e.g., morning and afternoon rush hours), and other available information to determine whether the nonattainment was due primarily to upwind or downwind emissions.

Obviously, this method does not allow for quantitative precision about the impact of upwind emissions on downwind ozone levels. The staff therefore limited its conclusions to categorizing the impact of transport on the downwind area in each transport pair as either overwhelming, significant, or inconsequential. "Overwhelming" impact is defined in the

CARB report as situations in which "ozone exceedances in the downwind area (other than very near the boundary between upwind and downwind areas) occurred without any emission contribution or with only a very small emission contribution from the downwind area." (I.2) "Significant" transport impact was found in cases where "emissions from both the upwind and downwind areas contributed to exceedances of the state standard," (I.2) and "inconsequential" impact was found in areas for which "the staff determined that upwind emissions did not contribute significantly to exceedances of the state ozone standard in the downwind area."(I.2) Some upwind-downwind pairs fell in more than one category; that is, the importance of transport varied substantially depending on meteorology so that transport might be judged substantial under some conditions and inconsequential under others.

The CARB results are shown in Table P-03. For all the transport pairs studied, transport was an "overwhelming" or "significant" contributor under at least some of the meteorological conditions that typically prevailed during ozone exceedances. Transported ozone and ozone precursors have an "overwhelming" impact on nonattainment in five California nonattainment areas under some conditions and a "significant" effect in ten nonattainment areas under some conditions. Some of these areas fall into both the "overwhelming" and "significant" categories due to varying meteorological patterns among ozone exceedance episodes. Most upwind sources of transported pollutants are urban areas, but rural areas also may contribute to downwind nonattainment.

The proportion of VOC and NO_x inventories from nonroad sources in six upwind areas are shown in Tables P-04 - P-09. These tables show what is contributed from each of 5 nonroad categories, as well as the total nonroad contribution and total contribution from all area and point sources. From this, an indication of the proportion of transported pollutants from nonroad sources which impact the downwind area can be drawn.

1.3. Transport in the Lake Michigan Areas

Another area in which transport is believed to have a significant impact on ozone nonattainment is Muskegon, Michigan. Muskegon is a city of 160,000 on the eastern shore of Lake Michigan, approximately 185 km (115 mi) northeast of Chicago. Its persistent nonattainment problems appear to be largely due to emissions from the Chicago area. In July 1988, during a high ozone episode for Muskegon, an instrumented research vessel recorded ozone levels and wind patterns over Lake Michigan to determine if the high ozone levels were being transported over the lake. High ozone levels were observed over the lake and along the shore south of Muskegon. Back trajectories of the air parcels containing the ozone levels showed that these air parcels originated along the heavily industrialized urban southern shore of Lake Michigan. Further evidence of the importance of transport in causing this exceedance is the fact that Grand Rapids, a much larger and more heavily industrialized city than Muskegon approximately 50 km east of Muskegon, approached, but did not exceed, the NAAQS for ozone, although meteorological data were favorable for ozone formation in both Muskegon and Grand Rapids. Back trajectories of the air parcels entering Grand Rapids on this day indicated that they passed over the southern shore of Lake Michigan outside of the urban, industrialized Chicago/Gary area.

EPA's Region V currently is coordinating the development of an Urban Airshed Model that will encompass the greater Lake Michigan area. The Lake Michigan Oxidant Study (LMOS) will assess the transport of ozone precursor emissions and ozone across the lake to better explain the effect of emissions from eastern Wisconsin and the Chicago/Gary area on ozone levels in Michigan. The study will include many new inventories to be developed by EPA and the states bordering Lake Michigan. The Lake Michigan Oxidant Study will be completed in 1993.

2. The Effect of Transported Nonroad Emissions

The fact that ozone is a regional and not a local problem has been demonstrated by studies described previously and is widely understood and accepted. Congress demonstrated their understanding and acceptance of this concept by mandating the creation of regional

transport commissions in the CAAA. Transport work now concentrates on assessing the factors impacting transport and developing a way to model and quantify the transport effect.

For the purposes of this study, EPA has used information gathered in developing ROMNET to tentatively quantify the effect of transported nonroad emissions on air quality in the Northeast Corridor. The impact of nonroad non-Corridor emissions may be roughly assessed by looking at the proportion of the non-Corridor inventory generated by the nonroad source categories. These categories are: nonroad diesel, nonroad gasoline, military aviation, civilian (commercial) aviation, general aviation, gasoline vessels, diesel vessels, and residual-fuel vessels. Their proportions of the inventory are shown in Table P-10.

Table P-10. 1985 Nonroad Proportion of Non-Corridor Base Year Inventories (%)

	VOC	NO_x
Nonroad diesel	0.24	3.01
Nonroad gasoline	1.51	0.94
Vessels		
gasoline	0.46	0.04
diesel	0.04	0.35
residual fuel	----	0.03
Total Nonroad	2.26	4.38

Several caveats should be observed in interpreting these numbers. First, the inventory proportions quoted in Table P-03 are for the base year 1985, not 2005, the year for which the control scenarios were modeled. Inventories for 2005 were not available from the ROMNET calculations because of the way in which inventory numbers were aggregated, speciated, and adjusted by the model during its projections. Also, the myriad meteorological and photochemical assumptions built into the ozone level predictions quoted in the last chapter make quantitative generalizations about the effects of changes in transport on ozone levels somewhat hazardous. Nonetheless, these calculations can help to illustrate the relative

magnitude of the effect of transported pollutants from nonroad sources on several important nonattainment areas. Taken together, the categories of nonroad engines within the scope of this report accounted for 2.3% of the non-Corridor VOC inventory and 4.4% of the non-Corridor NO_x inventory in 1985. Given the correlation of non-Corridor inventory reductions and Corridor peak ozone reductions posited above,* it appears that transported pollutants from nonroad sources account for roughly 0.5 ppb of the peak ozone concentrations in the Corridor cities as a whole and 0.6 ppb of the peak ozone concentration in the Baltimore/Washington and Philadelphia areas. One context for assessing the importance of these impacts on urban ozone would be to compare the magnitude of the effect of transported nonroad sources to the levels of ozone predicted in the major northeastern cities after the implementation of the Clean Air Act mandates modeled by ROMNET. As shown in Table P-11, transported pollutants from non-Corridor nonroad sources would account for roughly 0.3-0.45% of the ozone level along the East Coast during ozone nonattainment episodes.

Table P-11. Clean Air Act Scenario

	Post-CAA Ozone Level	% from Noncorridor Nonroad
Baltimore	134	0.45
Philadelphia	135	0.44
New York City	184	0.27
Boston	131	0.38

* One percent of non-Corridor emissions roughly account for 0.14 ppb of the peak ozone concentration in the corridor cities on average, and about 0.18 ppb of the peak ozone concentration of the Washington/Baltimore and Philadelphia areas.

3. Transport Conclusions

An analysis of ROMNET study finds the following:

1. Transport from all sources from non-Corridor areas into the Northeast Corridor contributes to nonattainment in several cities in the Northeast.

2. Currently, nonroad emissions outside the Corridor area account for approximately 2.3% of the VOC non-Corridor inventory and 4.4% of the NO_x non-Corridor inventory (see Table P-10).

3. In the absence of regulation of nonroad sources, the proportions listed in 2 above will probably increase in the future, as regulations are applied to more of the remaining source categories and are further tightened on categories already subject to emission regulation.

4. Nonroad sources cannot be discounted as insignificant merely because they are outside the boundaries of nonattainment areas.

Again, as the studies quoted in this chapter have demonstrated, ozone is a regional and not a local problem. Airborne transport of ozone and its precursors does not stop at city, county, or state boundaries. Apparently, it is not uncommon for transported pollutants to impact ozone levels 200 miles from the source of the emissions. At this time, it is difficult to quantify precisely the distance ozone and ozone precursors typically travel, but clearly a complete list of sources contributing to urban nonattainment cannot stop at the nonattainment area's border. Thus, nonroad sources outside nonattainment areas may be assumed to contribute to urban nonattainment.

EPA and state officials are continuing to study the role of transport in nonattainment. Therefore, our understanding of transport should be considerably expanded within the next few years. EPA's Office of Air Quality Planning and Standards (OAQPS) is currently working on extensions to the results presented in the ROMNET draft study. These include

applying the regional oxidant model to the Southeast and Midwest, in addition to modeling the effect of the Clean Air Act, as actually passed, on the Northeast. Much of this work will provide support to states containing nonattainment areas in their efforts to comply with the inventory and air quality modeling requirements of the Clean Air Act. OAQPS will also be working with the Northeast transport commission required by the Clean Air Act to help them develop strategies for attainment. These regional models will continue to use existing national emission inventories, which, as discussed above, have some shortcomings in the area of nonroad emissions. Currently, efforts are underway to establish a new national inventory for nonroad engines and other area and mobile sources, called the Aerometric Information Retrieval System/Area and Mobile Source file (AIRS/AMS). The results of these regional models will be re-evaluated using the new inventories as soon as they are available in 1993.

Appendix Q. Response to Public Comment

This appendix summarizes comments EPA received on the October 1991 draft of this report, and the adjustments made to the report in response to comments. A comparison of Charts Q-01 and Q-02 illustrate the effect these changes had on the inventory results for the final report.

Chart Q-01. Median Contributions - Draft Inventory A and B

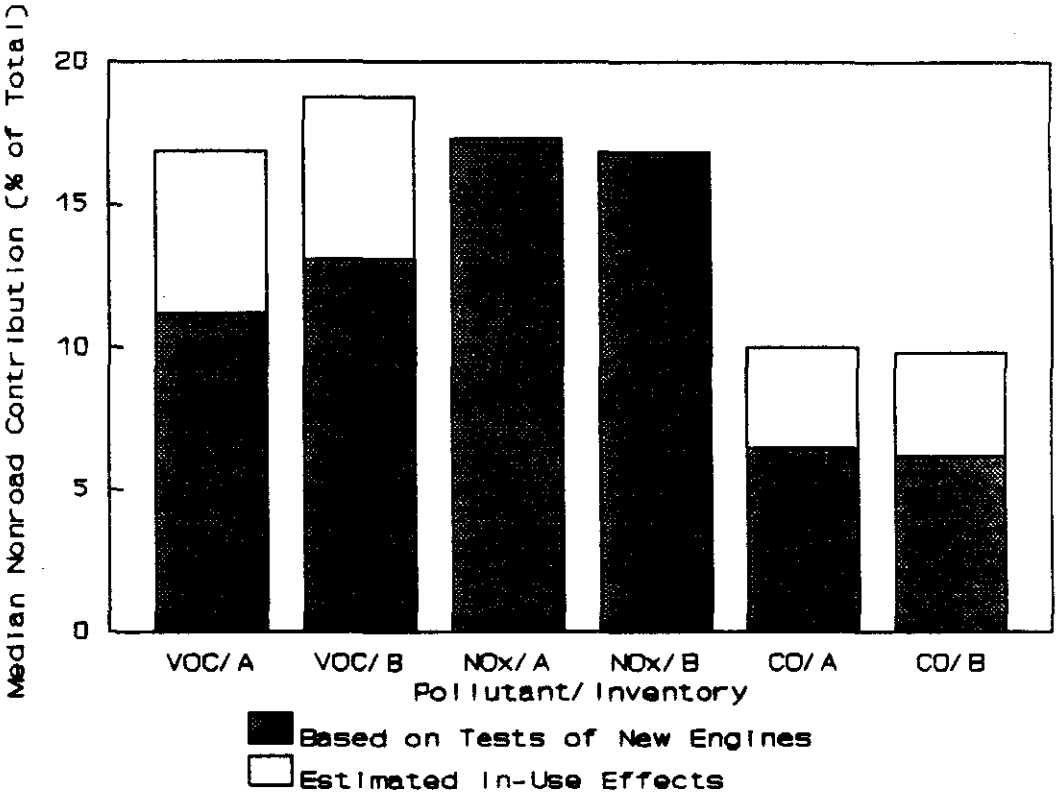

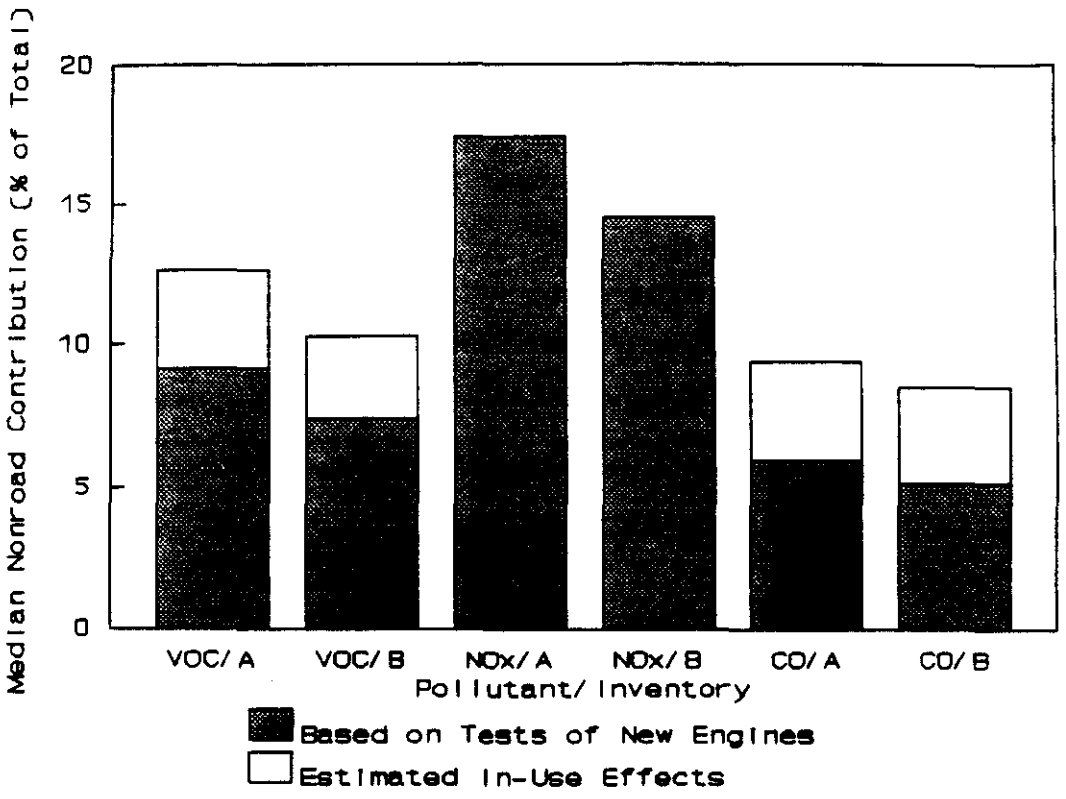

Chart Q-02. Median Contributions - Final Inventory A and B

Comments relating to the development of activity levels, emission factors, and additional considerations are summarized and addressed below. Written comments received from Briggs and Stratton, Engine Manufacturers Association, Equipment Manufacturers Institute, International Snowmobile Industry Association, Industrial Truck Association, OMC, Outboard Power Equipment Institute, National Marine Manufacturers Association, and Payhauler are available in the public docket.

1. Activity Levels

Comments relating to activity levels are discussed by equipment category.

1.1. Recreational Marine Equipment

For the October draft of the nonroad study, EPA relied heavily on data supplied by NMMA from a survey conducted by Irwin Broh and Associates (IB&A) in eight nonattainment areas. The results from this survey were used to adjust local boat registration data to represent actual usage in the nonattainment area (Inventories A and B), determine seasonal adjustment factors (Inventories A and B), and calculate annual hours of use, average horsepower, and load factors for Inventory B.

In comments on the October draft of this report, NMMA requested the following technical revisions be made to activity levels:

1. Use an alternative methodology to determine boat usage based on the concept of "saturation boating".
2. A methodology to extend the saturation boating concept to the 16 unsurveyed areas.
3. Use fuel based activity levels (i.e., gallons/year) and emission factors (i.e., grams/gallon), rather than using horsepower-hour based factors.
4. Use national average fuel usage estimates, based upon the sales of a unique oil formulation used to mix with 2-stroke outboard motor fuel.
5. Correct an error in the calculation of average fuel usage from the survey.

EPA made the following adjustments in response to NMMA's comments:

1. and 2. - Saturation boating methodologies - For Inventory B, a new methodology was developed for the 8 surveyed areas based upon the concept of saturation boating and extended to the 16 unsurveyed areas. Specific equations for allocating boat populations using the concept of saturation boating were developed separately by EPA and NMMA. The equation developed by NMMA was:

$$F = 0.7\ [1 - \exp(-630A)]$$

where:

F = fuel used in the nonattainment area as a fraction of the total fuel used by boats registered in the nonattainment area

A = water surface area available for boating in the nonattainment area divided by the number of registered boats in the nonattainment area.

The equation developed by EPA was slightly different:

$$F = 1 - \exp^{-(238\ A)\ **\ 0.66)}$$

Overall, both formulas yielded similar results (the average ratio for all 24 areas was 39% using NMMA's formula and 39.5% using EPA's). EPA's formula was used in developing Inventory B for the following reasons:

- EPA's formula yielded better r^2 values when regressed against the reported usage ratios from the 8 surveyed areas (.32 vs. .26 for NMMA's formula).
- EPA's formula generated ratios closer to the calculated saturation limits for those areas with high boat densities per nonattainment area water surface area.
- NMMA's formula capped the ratio at a maximum of 70%, which may not be appropriate for areas with very low boat densities per water surface area (although only one of the nonattainment areas studied, Provo-Orem, falls into this category)
- NMMA's actual equation was not submitted until November 7, 1991 (the concept was proposed several weeks earlier).

NMMA specifically requested that this methodology be used for Inventory A, as well as Inventory B. However, EPA was reluctant to totally ignore the survey results from the IB&A survey. Instead, a compromise methodology was used for Inventory A. The IB&A results were used to estimate boat usage in each nonattainment area. This estimate was then compared to the calculated maximum summertime usage based upon saturation boating. In cases where the survey results yielded higher ratios than the calculated saturation ratio, the local estimates were adjusted downward to match the calculated saturation limits. A more complete description of the methodology is contained in Appendix K.

3. Fuel-based activity levels - As recommended by NMMA, both Inventory A and Inventory B were revised from horsepower-hour based calculations to fuel use. Descriptions of how this was done are contained in Appendix I (for emission factors), K (for Inventory A fuel use), and N (for Inventory B fuel use).

4. National average fuel use estimates - The national annual average of 91 gallons per outboard powered boat calculated by NMMA was used for the 16 unsurveyed areas for

Inventory B. The fuel usage for the other recreational marine equipment types was also adjusted for these areas using the outboard ratio of 91 gallons per year to the reported survey results of 142 gallons per year (i.e., 91/142). No adjustments were made to the reported survey results for the eight surveyed areas, or to any areas for Inventory A (fuel usage for Inventory A is based upon information supplied by PSR and BSFC calculations from data supplied by NMMA, not upon IB&A survey results).

5. Error in fuel usage calculations - The error reported by NMMA in calculation of fuel usage from the IB&A survey was corrected and the results recalculated. This primarily affected the calculation of the proportion of boat use in the nonattainment areas for Inventory A (lowering the calculated number of boats used in the nonattainment areas by about 15%).

1.2. Lawn and Garden Equipment

EPA received numerous comments from OPEI and PPEMA. The following comments were all incorporated into Inventory B and, as noted, into Inventory A.

1. Annual hours of use adjustments for commercial use - OPEI commented that the splits between consumer and commercial populations they had supplied for the draft report were erroneously reported as population splits instead of sales splits. The correction roughly halved the commercial populations, with the following impact on the multiplicative adjustments to consumer annual hours of use to reflect the much higher annual usage of commercial equipment:

	Draft	Final
Lawnmower (2-stroke)	x2.5	x2.17
Lawnmower (4-stroke)	x2.5	x1.75
Tiller	x2.2	x1.54

These corrections apply to both Inventory A and Inventory B.

2. Load factors for lawn and garden tractors - OPEI pointed out that load factor adjustments based upon their letter of September 9, 1991 from John F. Linskey to Clare Ryan of EPA had not been incorporated into the draft. This has been corrected in the final report.

dropping the Inventory B load factors from .47 to .38 for lawn and garden tractors, rear engine mowers and front mowers.

3. Horsepower estimates - OPEI commented that errors had been made in their submittal of horsepower ranges for lawn and garden tractors and that 2-stroke snowblowers are smaller than 4-stroke. Based upon new data supplied by OPEI, Inventory B horsepower estimates for lawn and garden tractors dropped from 15.4 to 13.32 and 2-stroke snowblowers from 5.1 to 3.75.

4. Local disaggregation of handheld equipment population - While PPEMA had previously submitted population estimates for hand-held equipment (i.e., chain saws, blowers, trimmers/edgers), for the October draft this equipment was disaggregated to the local level using the general lawn and garden methodology developed for Inventory A. PPEMA subsequently developed a population disaggregation model for hand-held equipment using state-level shipment data and rural, suburban, and urban population splits. PPEMA used this method to directly calculate local equipment populations for chain saws, blowers, and trimmer/edgers. These local population estimates have been incorporated into Inventory B. In addition, as chain saws have very different usage patterns from most lawn and garden equipment (i.e., virtually no individual use by urban residents), the methodology developed by PPEMA was also used to disaggregate local chain saw populations for Inventory A.

EPA received two comments specifically relating to lawn and garden activity levels that have not been incorporated into the final report. First, OPEI commented that the population data for tillers in Inventory A was about 40% higher than in Inventory B, and asked that Inventory A be reduced. Although OPEI certainly knows how many tillers their members sell each year, this is not the same as knowing the population. Engine useful life, annual hours of use, scrappage rates, and consumer/commercial splits all affect equipment populations. PSR uses different methods of estimating populations than OPEI. In most cases, PSR and OPEI generated similar population estimates. There is no available information identifying one population estimate as being clearly superior to the other. Thus, using one method for Inventory A and the other for Inventory B is the most equitable solution.

The second comment that was not incorporated was on tiller load factors. Briggs and Stratton submitted information on the load cycle of several types of equipment. Most of this information either supported the CARB estimates or has been incorporated into Inventory B

load factors. The exception was tiller load factors. CARB estimated a load factor of 40% for tillers. The data submitted by Briggs and Stratton was interpreted to yield a load factor of only 20%. However, the dynamometer test used to determine the load on the engine indicated that the engine used .24 gallon/hour to generate only 0.6-0.7 horsepower. This equates to a BSFC of .34-.4 gallons/horsepower-hour, far higher than expected for these engines. A tiller engine using .24 gallons/hour should generate at least twice this amount of power; which would be in line with a 40% load factor.

1.3. Recreational Equipment

ISIA commented that there are no 4-stroke gasoline snowmobile engines in operation in the United States. In response to this comment, the final report assumes that all snowmobiles use 2-stroke gasoline engines for both Inventory A and Inventory B, despite the fact that EPA contractors reported a very small number of 4-stroke engines.

1.4. Industrial Equipment

The hours of use for forklifts used in the draft report for Inventory B were based on a statement by ITA in its comments concerning the workshop held by EPA on April 3-4, 1991, "A typical light-duty forklift truck may be run for 40 hours per week for an average of 2000 hours per year." In its response to the draft report, ITA commented that by "typical" it did not mean average, and stated that 850 hours is the correct average use rate. EPA adjusted the hours of use for forklifts in Inventory B to 850 hours for the final report.

1.5. Agricultural Equipment

EMI submitted data for combines and agricultural tractors which was used in the draft version of this study to construct Inventory B. This data included population figures developed by the U.S. Bureau of Census, which EMI has stated may include seldom-used equipment. EMI has cautioned that, in constructing an emission inventory, appropriate corrections should be made to either the operative population estimate or the estimate of average annual usage. EMI's submitted data contained no such correction. In comment on the draft version of this study, EMI stated that the Inventory B results for agricultural equipment are significantly overstated because EPA did not apply the downward adjustments

needed. As EPA does not have any information on how to apply such downward adjustments, EPA has used the same data for Inventory B as used for Inventory A for these two types of equipment in this final report.

1.6. Construction Equipment

Payhauler commented that the draft report contains large distortions in the construction equipment/mining category populations in nonattainment areas, in large part as a result of difficulties arising from the use of product sales and/or industry statistical information in estimating equipment populations. Payhauler listed a number of factors which could increase the possibility of error, including confused product descriptions in the sales record, products are frequently short term rental fleets and moved around the country, and the county of sale is not likely to be the county or even state of use.

No adjustments were made to the final report in response to Payhauler's comments for two reasons. First, EPA does not have any data on which to base such adjustments, nor did Payhauler provide any data. Second, product sales were used in this report only to establish state or national level populations. These populations were disaggregated to the local level using local construction activity indices. Thus, the local population figures should reflect the movement of products around the country to actual jobsites.

2. Emission Factors

EPA received comments from several industry associations, including OPEI, NMMA, EMA, PPEMA, and ITA, regarding the emission factors used in the study. One of the common concerns among the industry associations was related to the development and use of adjustment factors which were applied to new engine emission factors to estimate in-use emission rates. The associations were especially concerned with the limited data that were used to develop the adjustment factors for the equipment categories they represented and suggested that in-use factors should not be applied until more data is collected.

EPA realizes that the in-use adjustment factors are based on limited data and could be improved when additional in-use engine testing is completed. However, the in-use adjustments are EPA's best estimates based on existing data, and are clearly superior to the default of zero in-use deterioration, which would result if no in-use factors were applied. In

addition, the inventories in this study are presented two ways, with the in-use adjustment factor applied, and also without the in-use factor applied. This is done by the use of stacked bar charts which readily show the additional contribution of emissions from the in-use adjustment estimates.

The in-use adjustment factors for 2-stroke outboard motors in the draft study report were adjusted downward to 1.2 for HC and CO (from 1.5 for HC and 1.3 for CO) for the final study report. This is discussed in greater detail in Section 2.2.3. of Appendix I. While the arguments presented by NMMA were persuasive as to the superior durability and maintenance of outboard engines, such that these in-use adjustments were made for the final report, they did not support a total lack of in-use engine wear and malmaintenance.

Other comments regarding emission factors were more specific to certain equipment types. OPEI was concerned that the emission factors for snowblowers and commercial turf care equipment should be revised to better represent the horsepower ranges of these equipment. Upon review of the emission factors in the draft study, EPA agreed that these factors warranted adjustment. For snowblowers, the emission factors used for lawn mowers were used for the final study report. For commercial turf care equipment, the emission factors for lawn and garden tractors were used.

OPEI also presented sales data on the proportion of utility engines sold over the last 8 years with open and closed crankcases. Based on this data, the crankcase emission factors for lawn and garden equipment were revised to reflect 22% open crankcases (the draft report assumed 100% open crankcases).

EMA expressed concern that the particulate emission factors used in the draft study report were outdated. The emission factors were derived from AP-42 and based on 1973 tests performed at Southwest Research Institute. EMA suggested that the test results from a recent joint EPA/Industry program to assess test cycles for nonroad equipment be used to revise the particulate emission factors as well as NO_x, HC, and CO emission factors. The particulate emissions from the four 1991 diesel nonroad engines tested suggest that these newer engines have considerably lower particulate emission rates than the emission factors reported in AP-42. To reflect this concern, the particulate emission factors used for Inventory B are the equally weighted average of the AP-42 emission factors and the 1991 EPA/Industry average 8-mode nonroad engine test data. However, because there is no way to determine when

diesel engines began to emit lower amounts of particulates, the particulate emission factors for Inventory A remain those reported in AP-42. A more complete discussion of this is contained in Section 1.2.1. of Appendix I.

Another main area of concern for EMA related to the adjustment factor used to convert from steady state emission factors to in-use (transient) emission factors. EMA suggested that the adjustment factor should be corrected to a value halfway between the steady state and on-highway transient values instead of a correction all the way to the on-highway transient, as was done in the draft study report. However, although the transient cycle used to simulate highway heavy-duty engine operation may not be as appropriate to simulate nonroad equipment transient operation, EPA expects that it is a better representation of nonroad equipment that encounters transient operation in use than the 8-mode steady state test (it should also be noted that no adjustments were made for equipment types expected to primarily, but not exclusively, encounter steady state operation). EPA realizes that different equipment types have varying degrees of transient and/or steady state operating characteristics in-use. However, it was beyond the scope of this study to characterize the in-use operating cycles of the numerous equipment types included in the study. Therefore, the final study report continues to reflect the on-highway transient adjustment for those equipment types expected to encounter transient operation in use and no adjustment for those equipment types expected to primarily encounter steady state operation.

3. Additional Considerations/Other Comments

This section summarizes comments received that were not directly related to activity levels or emission factors.

3.1. Use of Equipment Categories

EPA received comments from EMI and NMMA requesting clarification of EPA's use of equipment categories in constructing emission inventories. Both were concerned that the categories used for this study could be construed as potential regulatory categories.

EPA considered over 80 different types of equipment in this report, many of which are highly specialized and have low sales volumes. EPA grouped the equipment types into 10

equipment categories only to assist the disaggregation of national or state equipment populations to the local level, and to ease analysis and reporting of inventory results. EPA has revised the final report to clarify that these categories are not intended to represent potential regulatory categories.

3.2. Inclusion of Two Sets of Inventories

EPA received a request for clarification of the use of two inventories from EMI, and two manufacturer associations expressed concern about data on which Inventory A is based. ITA expressed concern about lack of access to PSR data and methodology and uncertainty about what is included in Inventory A populations. EMI expressed concern about the method used in Inventory A of estimating equipment populations using engine shipment data.

PSR is a commercially available marketing research data base, and the EEA methodology is based on publicly available indices of commercial activity. Although several manufacturers expressed their belief that PSR was not accurately estimating equipment sales, in every case where manufacturers were willing to divulge equipment sales data to PSR or EEA (12 cases total), PSR's estimates showed excellent agreement with the equipment sales data (usually within 5%). In addition, much of the data used in Inventory A was not available from any other source.

EPA also developed a second set of inventories, Inventory B, which relies on manufacturer-provided data for almost all high usage equipment types. This industry-provided data might not be publicly available to states, but does give EPA a valuable cross check for the first set of inventories. In general, EPA regards both inventories as being equally appropriate estimates of nonroad populations and activity rates, and has learned a great deal from the ways in which they differ and agree.

3.3. Transportable Equipment

EMA commented that EPA should include all transportable equipment (e.g., generator sets, compressors, pumps), as well as self propelled, in the nonroad emissions inventory. It is EMA's position that both fall exclusively within the scope of nonroad mobile engines and vehicles, and that both are within the scope of EPA's authority under Title II of the Clean Air Act. EMA states further that EPA can only make a determination to regulate engines used in

transportable equipment based on the nonroad study, and that by failing to include all transportable equipment in the study, EPA has failed to meet the mandate imposed on it by Congress.

There were several types of equipment that are not included in this study due to lack of data, not just transportable equipment. For example, mining equipment also is not included in the study. Transportable equipment below 50 hp are included in the study, but transportable equipment over 50 hp are not due to lack of data and potential conflict with stationary source requirements.

EPA does not agree that the exclusion of equipment types from the study either prohibits EPA from regulating such equipment as nonroad engines or violates the mandate imposed by Congress. Congress required EPA to regulate nonroad engines if nonroad emissions are determined to be significant based on this study. However, this is a one-way requirement; it does not forbid EPA from regulating nonroad engines under other circumstances. Further, while Congress mandated that the determination of significance be made for nonroad engines as a whole based on this study, the regulatory requirements are for EPA to ". . . promulgate (and from time to time revise) regulations containing standards applicable to emissions from those classes or categories of new nonroad engines and new nonroad vehicles (other than locomotives or engines used in locomotives) which in the Administrator's judgement cause, or contribute to, such air pollutants." Nothing in this language restricts EPA to only those classes or categories included in this study or prohibits EPA from updating the assessment of emission contributions in the future.

3.4. 2-Stroke Marine VOC Emission Reactivity

NMMA submitted the claim that VOC emissions from 2-stroke marine engines are less photochemically reactive than other forms of VOC emissions. However, NMMA did not submit any data substantiating this claim.

VOC reactivity is a very complicated process. While an important consideration is ozone formation, the reactive processes are far from completely understood. Thus, EPA does not have sufficient information to judge the validity of NMMA's claim. Without data substantiating the overall reactivity of unburned fuel, EPA must use the standard assumption that the VOC reactivity of motor vehicle emissions are relatively similar.

3.5. Conclusions Chapter

NMMA commented that the nonroad study is a technical report and, as conclusions are best left for the regulatory process, suggested that EPA remove Chapter 5 from the report.

The purpose of the conclusion chapter is to highlight major points and to identify the points that EPA considers to be most important. No part in the conclusions is intended to be other than a summary of the data presented in the report. Thus, EPA does not agree that it should be removed.

3.6. Consideration of Updated Information

NMMA requested that EPA make a clear statement in the report recognizing the possibility that improved data may result in changes to the inventories, and that such data, if available and credible, will be used by EPA in the determination of significance and any subsequent regulatory process.

Updated data will not necessarily be used in the determination of significance; nor will it be arbitrarily excluded. However, EPA agrees with the statement that any subsequent regulatory activity will incorporate new information. While EPA does not believe this statement needs to be in the body of the report, it is acknowledged here.

3.7. Transport

In their comments, NMMA and OMC brought up several issues that complicate the estimation of the impact of transported VOC emissions on urban nonattainment. For example, NMMA submitted a report compiled by Sierra Research questioning the impact of VOC emissions on ozone transport. EPA does not necessarily agree with all of these comments, however, the issues raised do illustrate the complex nature of transport, and the difficulty of estimating precisely the impact of relatively distant emission sources on any particular nonattainment area. EPA did not include estimates of the impact of transported emissions on urban nonattainment in the final quantitative inventory estimates in recognition of such difficulties. Reliable quantitative estimates of the impact of transported emissions from marine pleasure craft may become available as existing photochemical models such as the Regional Oxidant Model (ROM) and the Urban Airshed Model (UAM) are further refined and applied to individual nonattainment areas in the next several years. EPA is not

attempting to prejudge these results in this report, but merely intends to note that transported ozone or ozone precursors caused by marine pleasure craft used in rural areas and other rural sources may have an impact on urban air quality. The principal conclusions of the impact of all nonroad sources on urban nonattainment contained in this report are based solely on emissions inside the nonattainment areas studied.

In its comments, EMI asserts that transport from more rural areas to urban areas cannot be considered to contribute to urban nonattainment because the concentration of ozone and ozone precursors is generally lower in rural areas. EMI states: The common-sense observation is that if 'Air Mass B' moves into an airshed, then 'Air Mass A', the air already there, has to be moved." To this observation, EPA would add a second observation: that air is not a solid. Elementary principles of physics and meteorology would imply that as Air Mass B enters an area, it mixes with Air Mass A, and that (assuming atmospheric pressure remains constant) some of this mixture exits the area. To the extent that Air Mass B contains air with lower concentrations of ozone and ozone precursors than Air Mass A, this mixing will lower the concentration of ozone in the urban area. However, the effectiveness of this mixing in lowering the concentration of ozone in the urban area is dependent on the concentration of ozone and ozone precursors in the entering Air Mass B, and not merely on the fact that this concentration may be lower than the concentration in the preexisting Air Mass A.

To illustrate this principle, let us assume first that Air Mass B contains no ozone or ozone precursors. Clearly, then, the concentration of ozone and ozone precursors in the mixture of Air Mass A and Air Mass B would be much lower than the concentration in Air Mass A before it was diluted. On the other hand, we could consider a case where Air Mass B has concentrations of ozone and ozone precursors that are only slightly lower than those concentrations in Air Mass A. Under this scenario, the concentrations of ozone and ozone precursors in the mixture would be nearly the same as those concentrations in the urban Air Mass A. Thus, emissions of ozone precursors into a rural air mass can have a deleterious impact on urban air quality by reducing the ability of prevailing winds from rural areas to dilute the pollution in urban air.

These conclusions were borne out by the EPA study entitled "Regional Oxidant Modeling for Northeast Transport", or "ROMNET". This study was based on a detailed

photochemical air quality model (the Regional Oxidant Model or ROM) for the northeastern quadrant of the U.S. EMI has urged elsewhere in their comments that EPA apply this ROM model to the study of emissions from nonroad sources specifically. ROMNET traced the formation of ozone levels in the major northeastern urban areas during specific ozone episodes by incorporating detailed information on emissions and meteorological conditions prevailing during those episodes. The ROMNET study incorporated emissions from nonroad sources along with all other sources of ozone precursors. The study was specifically designed to determine if transport from the western, generally rural part of the ROMNET region (e.g., Ohio, western Pennsylvania) had a negative impact on air quality in the major coastal urban areas (e.g., Philadelphia) during conditions that were known to have produced an actual exceedance of the ozone standard. The study concluded that this transport did, in fact, contribute to nonattainment of the ozone standard in the coastal areas, despite the fact that actual levels of ozone and ozone precursors in an air "packet" as it passed over the more western areas were considerably lower than the levels of ozone and ozone precursors in that air "packet" as it passed through the coastal urban areas.

Elsewhere in the Clean Air Act, Congress apparently concurred with the conclusion that emissions in rural areas can contribute to urban nonattainment. In Section 184 of the Clean Air Act, Congress explicitly created an Ozone Transport Commission comprising 11 northeastern states and the District of Columbia. Congress had concluded that the transport of ozone and ozone precursors in this region was so significant that the air pollution control policies of these states should be coordinated to insure their fairness and effectiveness. Included by law in the Ozone Transport Commission is the State of Vermont, a rural state with no ozone nonattainment areas.

3.8. Determination of Significance/Air Quality Analysis

EMI suggested that the October draft does not provide sufficient information for a determination of significance. EMI believes that:

> "In order to meet the requirements of Section 213(a)(2) the CAA with respect to a determination of significance, an air quality analysis which takes into account heterogeneity in the geographical distribution of nonroad engines/ vehicles, seasonal factors, transport and other atmospheric variables, and which includes photochemical modeling, is required."

As EMI discusses at some length in their comments, EPA does not base the contribution of nonroad engines to ambient air quality problems on photochemical air quality modelling in this study. EPA reiterates its previous position that photochemical modelling is not required to draw valid scientific conclusions about the contribution of nonroad emissions to nonattainment, and that Congress did not intend to require EPA to construct such models.

In the nonroad study, EPA has assumed that the contribution of nonroad sources to the concentration of ozone during a nonattainment episode is proportional to the contribution of nonroad sources to the total amount of VOCs and NO_x emitted in that area by all sources. This is the approach that has historically been taken by EPA in determining the contributions of different sources to nonattainment and in estimating the general effectiveness of nationwide air pollution control measures. It is based on the widely accepted scientific position that urban ozone is formed by the reaction of VOCs and NO_x in the presence of sunlight. Congress in no way indicated that it intended for EPA to digress from this approach; in fact, the legislative history of the CAA clearly shows that Congress conceived of the relative significance of nonroad sources in terms of their contribution to the total inventory of VOCs and NO_x. The Senate Committee Report notes that "[e]missions inventories from EPA estimate that farm and construction equipment emit 3.7 percent of CO nationwide, 4 percent of nationwide NO_x, and 1.3 percent of total hydrocarbons." The Senate Report further states "While inventories of these emissions are not precise, estimates indicate the extent to which they contribute to ozone and other pollution problems." (Senate Report No. 101-228, p. 104) Clearly, the intended mandate of Section 213 is that EPA improve upon existing emissions inventories for nonroad sources and that a conclusion about the significance of nonroad sources could be based on these inventories.

Further, in placing a one-year deadline for the completion of the nonroad study, and an additional one-year deadline for issuing standards based on the results of the study, Congress indicated a certain urgency in addressing this long-neglected category of pollution sources. The one-year deadline is one of only a very few specific requirements for performing the nonroad study; in general, EPA was not told how to perform the study, but rather to complete it quickly. This deadline effectively precludes the time-consuming development of photochemical models. The Regional Oxidant Model for Northeast Transport (ROMNET) study, which covers only the Northeast quadrant of the U.S., took over five years

to complete. An Urban Airshed Model of the Lake Michigan area is also expected to take several years to produce results. Due to the time and expense required to develop photochemical models, Congress has required only states with serious, severe, and extreme nonattainment areas to include them in their State Implementation Plans for attainment of the ozone standard. These areas were given 4 years to complete State Implementation Plans; areas that were not required to include photochemical models were required by Congress to submit State Implementation Plans in 3 years (CAA Section 182).

Finally, it is quite possible that Urban Airshed or Regional Oxidant Modelling would not offer any significant increase in our understanding of the significance of nonroad sources to the nationwide urban nonattainment problem. These models were developed primarily to help individual nonattainment areas determine the effectiveness of specific air pollution control measures, given highly detailed data and assumptions for the unique conditions prevailing in that area. Thus, the models could be used to assess whether a given proposal for reducing emissions from a type of nonroad source would be more effective in a given area than some other measure. However, emission control measures have not yet been proposed for any nonroad source and Congress mandated that the nonroad emission study assess the impact of *current* inventories before EPA issued any such proposals.
