Public Health Service
Bureau of Disease Prevention and Environmental Control
National Center for Air Pollution Control
Cincinnati, Ohio

1967

The ENVIRONMENTAL HEALTH SERIES of reports was established to report the results of scientific and engineering studies of man's environment: The community, whether urban, suburban, or rural, where he lives, works, and plays; the air, water, and earth he uses and re-uses; and the wastes he produces and must dispose of in a way that preserves these natural resources. This SERIES of reports provides for professional users a central source of information on the intramural research activities of the Centers in the Bureau of Disease Prevention and Environmental Control, and on their cooperative activities with state and local agencies, research institutions, and industrial organizations. The general subject area of each report is indicated by the letters that appear in the publication number; the indicators are

AP — Air Pollution

RH — Radiological Health

UIH — Urban and Industrial Health

Reports in the SERIES will be distributed to requesters, as supplies permit. Requests should be directed to the Center identified on the title page.

In 1957 the Air Pollution Medical Program published tables of standardized mortality ratios for deaths occurring during 1949-1951 in 163 metropolitan areas of the United States (Manos, N.E.: *Comparative Mortality among Metropolitan Areas of the United States, 1949-1951,* Public Health Service Publication No. 562, US Government Printing Office, Washington, DC, 1957). The present volume has been prepared to help fill the need for more detailed information about recent variations in mortality among urban areas. Rates for selected causes have been computed for 201 standard metropolitan statistical areas from 1959-1961 mortality data supplied by the National Center for Health Statistics and population data from the 1960 Census of Population.

The bulk of this report contains the age-specific data from which age-adjusted rates were calculated. For persons who do not require the detailed tables of death by age, an Abridged Edition containing Tables 1, 2, 3, and 5 is available on request from the National Center for Air Pollution Control.

UNITED STATES METROPOLITAN MORTALITY

1959 - 1961

INTRODUCTION

CLASSIFICATION OF DATA

Cause of Death Categories

Cause of death coding is based on the International Classification of Diseases as listed in the seventh revision of the *Manual of the International Statistical Classification of Diseases, Injuries, and Causes of Death* (ISC), World Health Organization, Geneva, 1957.

To satisfy all users of a volume such as this, data for all the reported causes of death should be included, but sheer size and cost made some selection of data necessary. An attempt was made to avoid broad, general categories that would have limited usefulness to research workers. Also, disease categories with small numbers of deaths were usually not included. Infectious diseases that are under intensive surveillance by the Public Health Service and for which statistics are already available also were not included (e.g. infectious hepatitis and poliomyelitis). Categories of cancer mortality were made as specific as possible. At times, however, desired specificity could not be achieved because of limitations in the basic data. For example, malignant melanomas could not be separated from other malignant neoplasms of the skin. Whenever possible, all the sub-categories of more general groups have been included so that comparisons can be made with other data sources that are not as detailed.

The causes of death used for tabulation are listed on page xi. This list also indicates those categories that may be combined to recreate categories of the International Statistical Classification's "Intermediate List of 150 Causes" and "Abbreviated List of 50 Causes."

Standard Metropolitan Statistical Areas

The standard metropolitan statistical areas (SMSA's) used in this report are identical to those used by the National Center for Health Statistics (NCHS) in their vital statistics publications for the same years. Thus, except in the New England states, the SMSA's are the same as established by the Bureau of the Budget and used by the Bureau of the Census.

Basically, an SMSA is a county or group of contiguous counties that meets certain criteria of population size, metropolitan character, and economic and social integration with the central city. In the New England states of Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island, and Vermont, however, towns and cities, rather than counties, are the units used by the Bureau of the Budget to define SMSA's. Because vital statistics are not coded to identify all towns, for these New England states the metropolitan state economic areas (MSEA's), which are made up of county units, are used. Because of these changes in the New England states, NCHS has only 201 areas listed instead of the 212 SMSA's of the 1960 census. A list of the 201 areas used in this report and the counties within them follows this introduction (p. xii).

Age Groups

Age classification for the population data is based on age in completed years on April 1, 1960, as reported in the 1960 census. Evidence exists that some age groups, particularly in the nonwhite population, were significantly underenumerated in the census,[1] but specific correction factors were not available when the tables for this volume were prepared. Age for the mortality data is the age of the decedent on his last birthday as reported on the death certificate.

In addition to inaccuracies in original reporting from both sources, the difference in definition of age for deaths and population may produce biased rates. For example, a person dying before April 1, 1960, is not counted in the census. The extent to which these differences affect the rates is not clearly defined, but is usually small. The problem becomes obvious in age groups with small numbers. In a few instances, deaths were reported for

[1]Siegel, J. S. and Zelnik, M.: *An Evaluation of Coverage in the 1960 Census of Population by Techniques of Demographic Analysis and by Composite Methods,* American Statistical Association: Proceedings of the Social Statistics Section, 1966, pp. 71-85.

a group with no census population, for example, the older non-white females of Dubuque, Iowa.

Color

As designated in the 1960 census and vital statistics, the color category "white" includes, in addition to persons reported as "white," those reported as Puerto Rican or Mexican. The color group "non-white" includes the Negro, Indian, Japanese, Chinese, Filipino, Korean, Asian Indian, and Malayan population.

Place of Residence

The tabulated deaths are those allocated to places of residence within the SMSA's. In general, deaths are allocated to the usual place of *residence* as reported on the death certificate. However, if the decedent resided more than 1 year at the place of *occurrence* of death, the death is allocated to the county of occurrence. All institutional deaths are allocated to the usual place of residence before admission, regardless of length of stay.

The definition of usual place of residence for the 1960 census is slightly different. College students and long-term inmates of institutions are counted in the census as residents of the area in which the institution or college is located. Deaths of such persons, however, are usually allocated back to the place of residence before admission. The effect on rates of this difference in definitions is probably very small, but may become important for some diseases in certain areas.

COMPUTATION OF RATES

Table 1 — Observed Deaths and Indirect Age-adjusted Expected Deaths and Yearly Rates per 100,000.

In order to remove the effect of differences in age composition among the cities, age-adjusted rates were calculated for each sex and color group by cause. The adjustment was made by the indirect method to the standard of the age-specific rates for all 201 SMSA's combined for that cause. A list of the standard rates used is on page xiv. The method of calculation is shown below for lung cancer (162-163) in Abilene, Texas.

CALCULATIONS FOR INDIRECT AGE ADJUSTMENT*

		Neoplasm bronchus, trachea, lung			
		Abilene, Texas			
		White Males		White Females	
Age-group, yr	Age-specific standard rate per 100,000 (a)	Population 1960 (b)	Expected deaths using std rates 3 x (a) x (b) / 100,000	Population 1960 (d)	Expected deaths using std rates 3 x (d) x (a) / 100,000
0-4	0.03	6,948	0.01	6,729	0.01
---- ----	----	----	----	----	----
---- ----	----	----	----	----	----
55-64	83.87	3,916	9.85	4,498	11.32
65-74	122.81	2,507	9.24	3,031	11.17
75-84	105.34	1,078	3.41	1,543	4.88
85+	73.66	227	0.50	322	0.71
All ages (i)	22.26	57,137	Sum=30.3	57,371	Sum=35.3
Total observed in 3-year period (ii)			36		8
Ratio of observed to expected (iii) = (ii)/(i)			1.188		0.227
Indirect adjusted rate (iii) x (All age standard)		22.26 x 1.188 = 26.44		22.26 x 0.227 = 5.04	

*Expected deaths printed in Table 1 are rounded numbers and will not produce age-adjusted rates identical to those shown in the table.

CALCULATIONS FOR DIRECT AGE ADJUSTMENT

Age-group, yr	Standard million U.S. 1960 (a)	Neoplasm bronchus, trachea, lung Abilene, Texas, White Males: 1959-1961 Number of deaths (b)	Population 1960 (c)	Age-specific rate (per 100,000) $(d) = \frac{(b)}{3 \times (c)}$	Expected deaths in standard million $\frac{(a) \times (d)}{100,000}$
0-4	113,320	0	6,948	0	0
---- ----	----	----	----	----	----
---- ----	----	----	----	----	----
55-64	86,839	12	3,916	102	88.6
65-74	61,324	10	2,507	133	81.6
75-84	25,839	4	1,078	124	32.0
85+	5,182	1	227	147	7.6
All ages	1,000,000	36	57,137	21*	Sum=268.2
Age 65+	92,345	15	3,812	131*	Sum=121.2

Total age-adjusted rate $= \frac{268.2}{1,000,000} \times 100,000 = \underline{26.8}$

Age 65+ age-adjusted rate $= \frac{121.2}{92,345} \times 100,000 + \underline{131.2}$

*Crude total rates, not shown in Table 4.

Table 2 — SMSA 1960 Live Births and 1960 Census Enumeration by Age, Color, and Sex.

The 1960 live births and population by age, color, and sex for each of the 201 SMSA's are shown as used for calculation of rates in this report. Except for the New England SMSA's as explained above, these figures are identical to those published in the 1960 Census of Population.

Table 3 — Infant and Neonatal Deaths and Mortality Rates per 1,000 Live Births by SMSA, Color, and Sex.

Since the majority of infant and neonatal deaths are attributed to a limited number of causes, they are presented in this separate table. Neonatal mortality is expressed as deaths under 28 days of age per 1,000 live births. It is calculated by dividing the number of deaths for 1959-1961 by three times the number of 1960 live births, and multiplying by 1,000.

Infant mortality rates (deaths under 1 year of age per 1,000 live births) are calculated similarly.

Table 4 — Deaths and Death Rates per 100,000 per Year by SMSA, Cause, and Age.

Age-specific rates are computed by dividing the number of deaths in 1959-1961 by three times the 1960 population for that age group and multiplying by 100,000.

The total rates and those for age 65+ are age-adjusted by the direct method to the standard of the 1960 total U.S. population expressed as a "standard million" (p. xvi). That part of the standard million in the three age groups 65 and over was used as a standard for the age 65+ adjusted rate. The method of calculation is shown above for white males in Abilene, Texas.

Table 5 — Total Deaths and Death Rates per 100,000 by SMSA, Color, and Sex.

Age-specific and direct-adjusted total rates are shown for all causes of death combined. Because all cause categories are not tabulated in Tables 1 and 4, these totals are greater than the sum of the causes listed.

The calculation methods are the same as for Table 4.

The neonatal and infant death rates for all causes are calculated similarly to those in Table 3, except that they are expressed as deaths per 100,000 live births, instead of per 1,000.

INTERPRETATION AND USE OF TABLES

Table 1 — Observed Deaths and Indirect Age-adjusted Expected Deaths and Yearly Rates per 100,000.

The most accurate and detailed analysis of variation in mortality among cities can only be carried out by study of age-, sex-, and color-specific rates. Often, however, summary rates are convenient and desirable for comparison of mortality among areas. Comparison of crude mortality rates (total deaths divided by total population) can be biased if there are differences in the age composition of the communities. Thus, an area with a large proportion of its population in the older age groups would be expected to have a high crude death rate from a cause that increases with age.

Age-adjustment is one method used to improve the comparability of rates. In the "indirect method" used for Table 1, the number of expected deaths is calculated as if the SMSA had for each age group the same rate as all the SMSA's combined. Division of the observed number of deaths by this expected number provides a standardized mortality ratio (SMR), which compares that area's experience with the average for all SMSA's.* To provide an indication of absolute, as well as relative mortality, age-adjusted rates have been computed by multiplying each SMR by the all age standard rate for that cause (See calculation section).

*These SMR's are not comparable to those published for 1949-1951 mortality because different age-specific standard rates were used to compute the expected deaths.

Tabulation in Table 1 of numbers of observed and expected deaths as well as rates allows the user to combine categories in several ways.

Within a single cause, direct comparisons may be made among any of the tabulated rates. Thus, the Abilene, Texas, white male coronary rate (263.52) may be compared with the rate for Akron white females (167.20), as shown below in excerpts from Table 1.

A rate for combinations of sex and color categories within a single cause group may be obtained by finding the ratio of the summed observed and expected numbers and multiplying by the all age standard printed at the bottom of the table.

For example, the Abilene rate for coronary heart disease for all males is:

$$\frac{\text{Sum observed}}{\text{Sum expected}} \times \text{Standard} =$$

$$\frac{360 + 4}{379.1 + 15.4} \times 277.51 = 256.05$$

Since the tabulated cause groups are often very specific, many readers will want age-adjusted rates for several combined causes. Such rates may be calculated in a manner similar to the above by finding the ratio of the sum of observed deaths to the sum of those expected, and multiplying by the sum of the all age standard rates for the several causes.

EXCERPTS FROM TABLE 1

Arteriosclerotic heart disease, including coronary disease (I.S.C. 420)

White male			White female			SMSA	Non-white male			Non-white female		
Exp.	Obs.	Rate	Exp.	Obs.	Rate		Exp.	Obs.	Rate	Exp.	Obs.	Rate
379.1	360	263.52	476.3	199	115.95	Abilene	15.4	4	72.03	16.7	8	133.15
1744.4	2388	379.90	2071.3	1248	167.20	Akron	96.4	99	285.06	100.5	56	154.64
....	....	....	....	....	....		....	....	....	....	....	....

All age standard rate = 277.51

Chronic endocarditis not specified as rheumatic, and other myocardial degeneration (I.S.C. 421, 422)

White male			White female			SMSA	Non-white male			Non-white female		
Exp.	Obs.	Rate	Exp.	Obs.	Rate		Exp.	Obs.	Rate	Exp.	Obs.	Rate
40.0	21	15.18	52.8	17	9.32	Abilene	1.6	1	18.11	1.8	3	47.91
167.3	133	23.00	216.0	143	19.15	Akron	8.7	7	23.31	9.6	9	26.98
....	....	....	....	....	....		....	....	....	....	....	....

All age standard rate = 28.93

For example, the Abilene white male rate for ISC categories 420-422 combined would be:

$$\frac{\text{Sum observed}}{\text{Sum expected}} \times \text{Sum standards} =$$

$$\frac{360 + 21}{379.1 + 40.0} \times (277.51 + 28.93) = 278.58$$

An overall age-adjusted rate for several cities combined might be desired. For example, SMSA's in the Pacific region could be compared to those in the Atlantic states. The computation is the same as given above for combining color and sex groups.

The age-adjusted rates or even the ranking of cities produced by the above methods should not be considered as absolute. A different method of adjustment or a different set of standard rates would undoubtedly produce somewhat different results. Age-adjustment may be considered as one method of deriving a weighted average of the age-specific rates, which are given in Table 4. Different systems of weighting produce different averages. In general, if age-specific rates in all age groups are higher in City A than in City B, any system of adjustment will produce a higher adjusted rate for City A. If, however, a city has higher age-specific rates than another in certain age groups only, then different methods of age-adjustment may change their relative ranking. In this case, one method is really no more correct than another, since the decision as to which city has the higher mortality depends on which age groups are considered.

The age-adjusted rates in Table 1 and Table 4 are not identical, since they are computed by different methods. Linder and Grove[2] have extensively reviewed the problems of different mortality indexes. One approach in comparing the indirect method (Table 1) with the direct method (Table 4) is to consider two hypothetical cities under different situations shown in the figure.

[2]Linder, F. E., and Grove, R. D.: *Techniques of Vital Statistics*, Reprint of Chapters I-IV of *Vital Statistics in the United States 1900-1940*, National Office of Vital Statistics, Washington, D.C., June 1959.

Situation I:

a. The age-specific rates are quite variable from age to age, BUT

b. The percent distributions of the two *populations* are identical, AND

c. The crude death rates are identical.

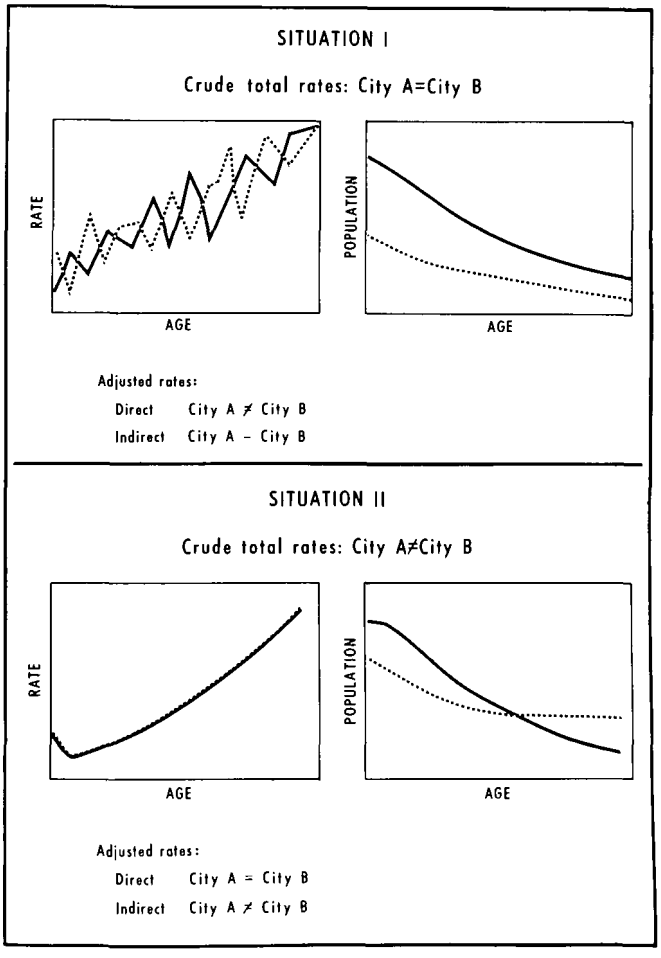
In this situation the two indirect adjusted rates will be identical; however, the direct adjusted rates may not.

Situation II:

a. The age-specific rates are identical at corresponding ages, BUT

b. The percent distributions of the two populations are different.

In this situation the crude rates will usually not be identical. The two indirect adjusted rates will only rarely be identical, but the direct adjusted rates will be equal.



For most of the causes, the age-specific rates, particularly in smaller SMSA's, are based on rather small numbers and are likely to vary as in Situation I. We believe that the population age distribution and crude death rate may provide a more stable index of mortality than the age-specific rates and favor the indirect adjusted rates of Table 1. On the other hand, the user may prefer the direct method, particularly for combinations of disease categories in the larger cities.

Of practical significance is the manner in which the rates may be easily combined for groups other than those tabulated.

The direct adjusted rates for different causes in Table 4 may be directly added, within an SMSA and sex-color group. An adjusted rate for combined sex or color groups cannot be obtained without complete recalculation.

The indirect adjusted rates of Table 1 may be combined into almost any desired grouping by use of the numbers of observed and expected deaths (See formulas above).

Table 3 — Infant and Neonatal Deaths and Mortality Rates per 1,000 Live Births by SMSA, Color, and Sex.

The rates, expressed as deaths per 1,000 live births, need little elaboration. Separate cause groups may be combined by simply adding the rates. In order to combine different sex-color groups or SMSA's, a new rate must be calculated from the number of deaths (Table 3) and live births (Table 2) by the following formula:

Rate (Deaths per 1,000 live births) =

$$\frac{\text{Number deaths 1959-61}}{\text{Number live births 1960 x 3}} \text{ x } 1{,}000$$

Table 4 — Deaths and Death Rates per 100,000 per Year by SMSA, Cause, and Age.

Age-specific rates are given for age 0-4 and subsequent 10 year groups to age 85+. The rate column is left blank when there were no deaths and the rate is a true zero. If there were a few deaths but the rounded rate is less than 1 per 100,000, a zero is printed. For the few instances where there were more deaths than population (e.g. Dubuque, non-white females) the rate is indicated as ———.

Within a city and sex-color group, age-specific rates for a given age group may be added for several causes to obtain an age-specific rate for the combined causes. Rates for different age groups may not be added to obtain a combined age rate.

The total and age 65+ rates are age-adjusted by the direct method, as explained in "Computation of Rates" (p. vi). For a given SMSA these adjusted rates for different causes may be directly added to obtain adjusted rates for combined causes. See the discussion of Table 1 (p. viii) for further comments on the interpretation of these adjusted rates and how they differ from those in Table 1.

Table 5 — Total Deaths and Death Rates per 100,000 by SMSA, Color, and Sex.

See comments for Tables 3 and 4, which apply to this table as well.

CAUSE OF DEATH CATEGORIES
