ENVIRONMENTAL PROTECTION AGENCY

ABSTRACT

Several authors have reported that the harmful effects of ammonia are primarily related to the pH and temperature of the water because only the un-ionized ammonia is toxic. The un-ionized fraction increases with rising pH values and with rising temperature.

Other factors such as dissolved oxygen, alkalinity, free carbon dioxide, sodium ions, total dissolved solids, prior exposure to ammonia, physical stress, general physiological status, and the presence of other additive toxins or other mitigating parameters will have a great effect on the overall toxicity of ammonia to aquatic organisms.

The actual reported toxic concentrations of ammonia vary from 0.16 mg/l to 16.5 mg/l NH₃-N. This apparent variability often resulted from the investigator's failure to report pH and temperature values as well as other factors which may have biased their results. It appears that the highest concentration of un-ionized ammonia which apparently will not cause any adverse effects is 0.02 mg/l NH₃-N.

INTRODUCTION

This document summarizes some of the present knowledge on the effect of ammonia on fish and establishes the maximum permissible concentration limit which shall be applicable to those waters classified for fisheries use.

Ammonia is present in most waters at varying concentrations. It appears that several of the reported high concentrations are due primarily to municipal sewage effluents and, to a lesser degree, certain industrial discharges. Some agricultural discharges, such as feedlot runoffs, may also contain high concentrations of ammonia. In some areas, especially in winter, fish rearing facilities may contribute to the total load.

Some investigators, as early as 1913, observed that the toxic effect of ammonia could be related to the pH of a solution. It was not until 1947 that Wuhrmann, et al. (1947) demonstrated that it was the un-ionized ammonia that was the toxic agent and that the ionized ammonia had very little or no toxic effect. Table I summarizes some of the un-ionized ammonia toxicity data reported in the literature.

The terms ammonia, ammonium, ionized and un-ionized ammonia have been a point of confusion within the literature. Lloyd and Herbert (1960) indicated that for purposes of clarity and uniformity, the terms "ionized ammonia" (NH_4^+) and "un-ionized ammonia" (NH_3) should be adopted to describe the two forms of ammonia and that "ammonia" would include both forms (NH_4^+ NH_3). These terms will be used in this document. Reported toxic values for ammonia either as ionized or un-ionized, are normally expressed as either mg/l NH_3 or mg/l $\text{NH}_3\text{-N}$. To be consistent with the current method of reporting ammonia, concentrations of un-ionized and ionized ammonia as well as ammonia will be expressed as mg/l $\text{NH}_3\text{-N}$.

Mosquitofish	14.8 96 hr. LC ₅₀	McKee & Wolf (1963)

From a review of the literature regarding the toxicity of ammonia to aquatic biota, the European Inland Fisheries Advisory Commission (1970) concluded that it was unlikely that concentrations lower than those adversely affecting fish would be toxic to other organisms. Therefore, it appears that fish will be the critical organisms when establishing an in-stream limitation and although it may appear that different species of fish exhibit dissimilar susceptibilities to un-ionized ammonia, such is not the case. Trout and carp are equally susceptible to un-ionized ammonia given time to react; although time-based responses are different, the ultimate response to a given concentration of un-ionized ammonia is the same (Ball, 1967).

Personal communications from Drs. Donald I. Mount and William A. Brungs, National Water Quality Laboratory, Duluth, indicate that the, as yet unpublished, U. S. Environmental Protection Agency's "Criteria for Water Quality" recommends that, for freshwater aquatic life, un-ionized ammonia not exceed 0.025 mg/l as NH₃ (0.02 mg/l NH₃-N). The European Inland Fisheries Advisory Commission (EIFAC) has recommended the same concentration for their inland fisheries. These recommendations have been supported by the National Water Quality Laboratory, Duluth.

CRITICAL VARIABLES AFFECTING AMMONIA TOXICITY

pH Values

Several investigators have reported values for toxic concentrations of ammonia which appear to be at variance. Wuhrmann and Woker (1948) demonstrated that it was the un-ionized ammonia molecule that was the toxic agent and that as the pH of the solution increased, the fraction of un-ionized ammonia increased correspondingly. Later studies by Downing and Merkens (1955) confirmed that the toxicity of ammonia could be directly related to the concentration of un-ionized ammonia present and that the apparent discrepancies which had appeared in some earlier reports were not at variance, but could be compatible when adjusted to concentrations of un-ionized ammonia. In more recent work, Tabata (1962) found that the ionized ammonia fraction could be toxic. He concluded, however, that it was only one-fiftieth as toxic as the un-ionized fraction. Tabata's conclusion is at variance with that of Downing and Merkens who indicated that only the un-ionized fraction was toxic.

Temperature

Generally, the toxicity of ammonia decreases with lower temperatures, due mainly to decreasing fractions of un-ionized ammonia present. However, in addition to its affect on the dissociation of ammonia, temperature extremes also have a demonstrated affect on the performance, survival and toxicant susceptibility of fish. This effect was borne out by studies done by Woker (1949). He demonstrated that, although the survival time of chub (Squalius cephalus) at constant levels of un-ionized ammonia decreased with rising temperatures, the LC₅₀ remained constant. Burrows (1964), in his observations of the toxicity of ammonia to hatchery reared salmonids, demonstrated that the mitigating affects of lower temperatures may hold true only to about 10 C. Burrows reported that un-ionized ammonia was more toxic to chinook salmon below 10 C. Work done by Brown (1969) suggests that at 3 C, the LC₅₀ of un-ionized ammonia for rainbow trout is about half that found at 10 C. It appears, therefore, that the affect which temperature has on the dissociation of ammonia could be negated by the stress induced by lower critical temperatures. The EIFAC (1970) has indicated that for temperatures below 5 C, the maximum permissible concentration of un-ionized ammonia may be less than 0.02 mg/l NH₃-N.

Figure 1 demonstrates the affect which temperature and pH have on the dissociation of ammonia. For practical purposes, the method for calculating the percentages of un-ionized ammonia as suggested by the European Inland Fisheries Advisory Commission (1970) will be used as shown in Table II.

Figure 1. Percentage of Un-ionized Ammonia in Ammonia-Water Solutions
at Various pH and Temperature Values

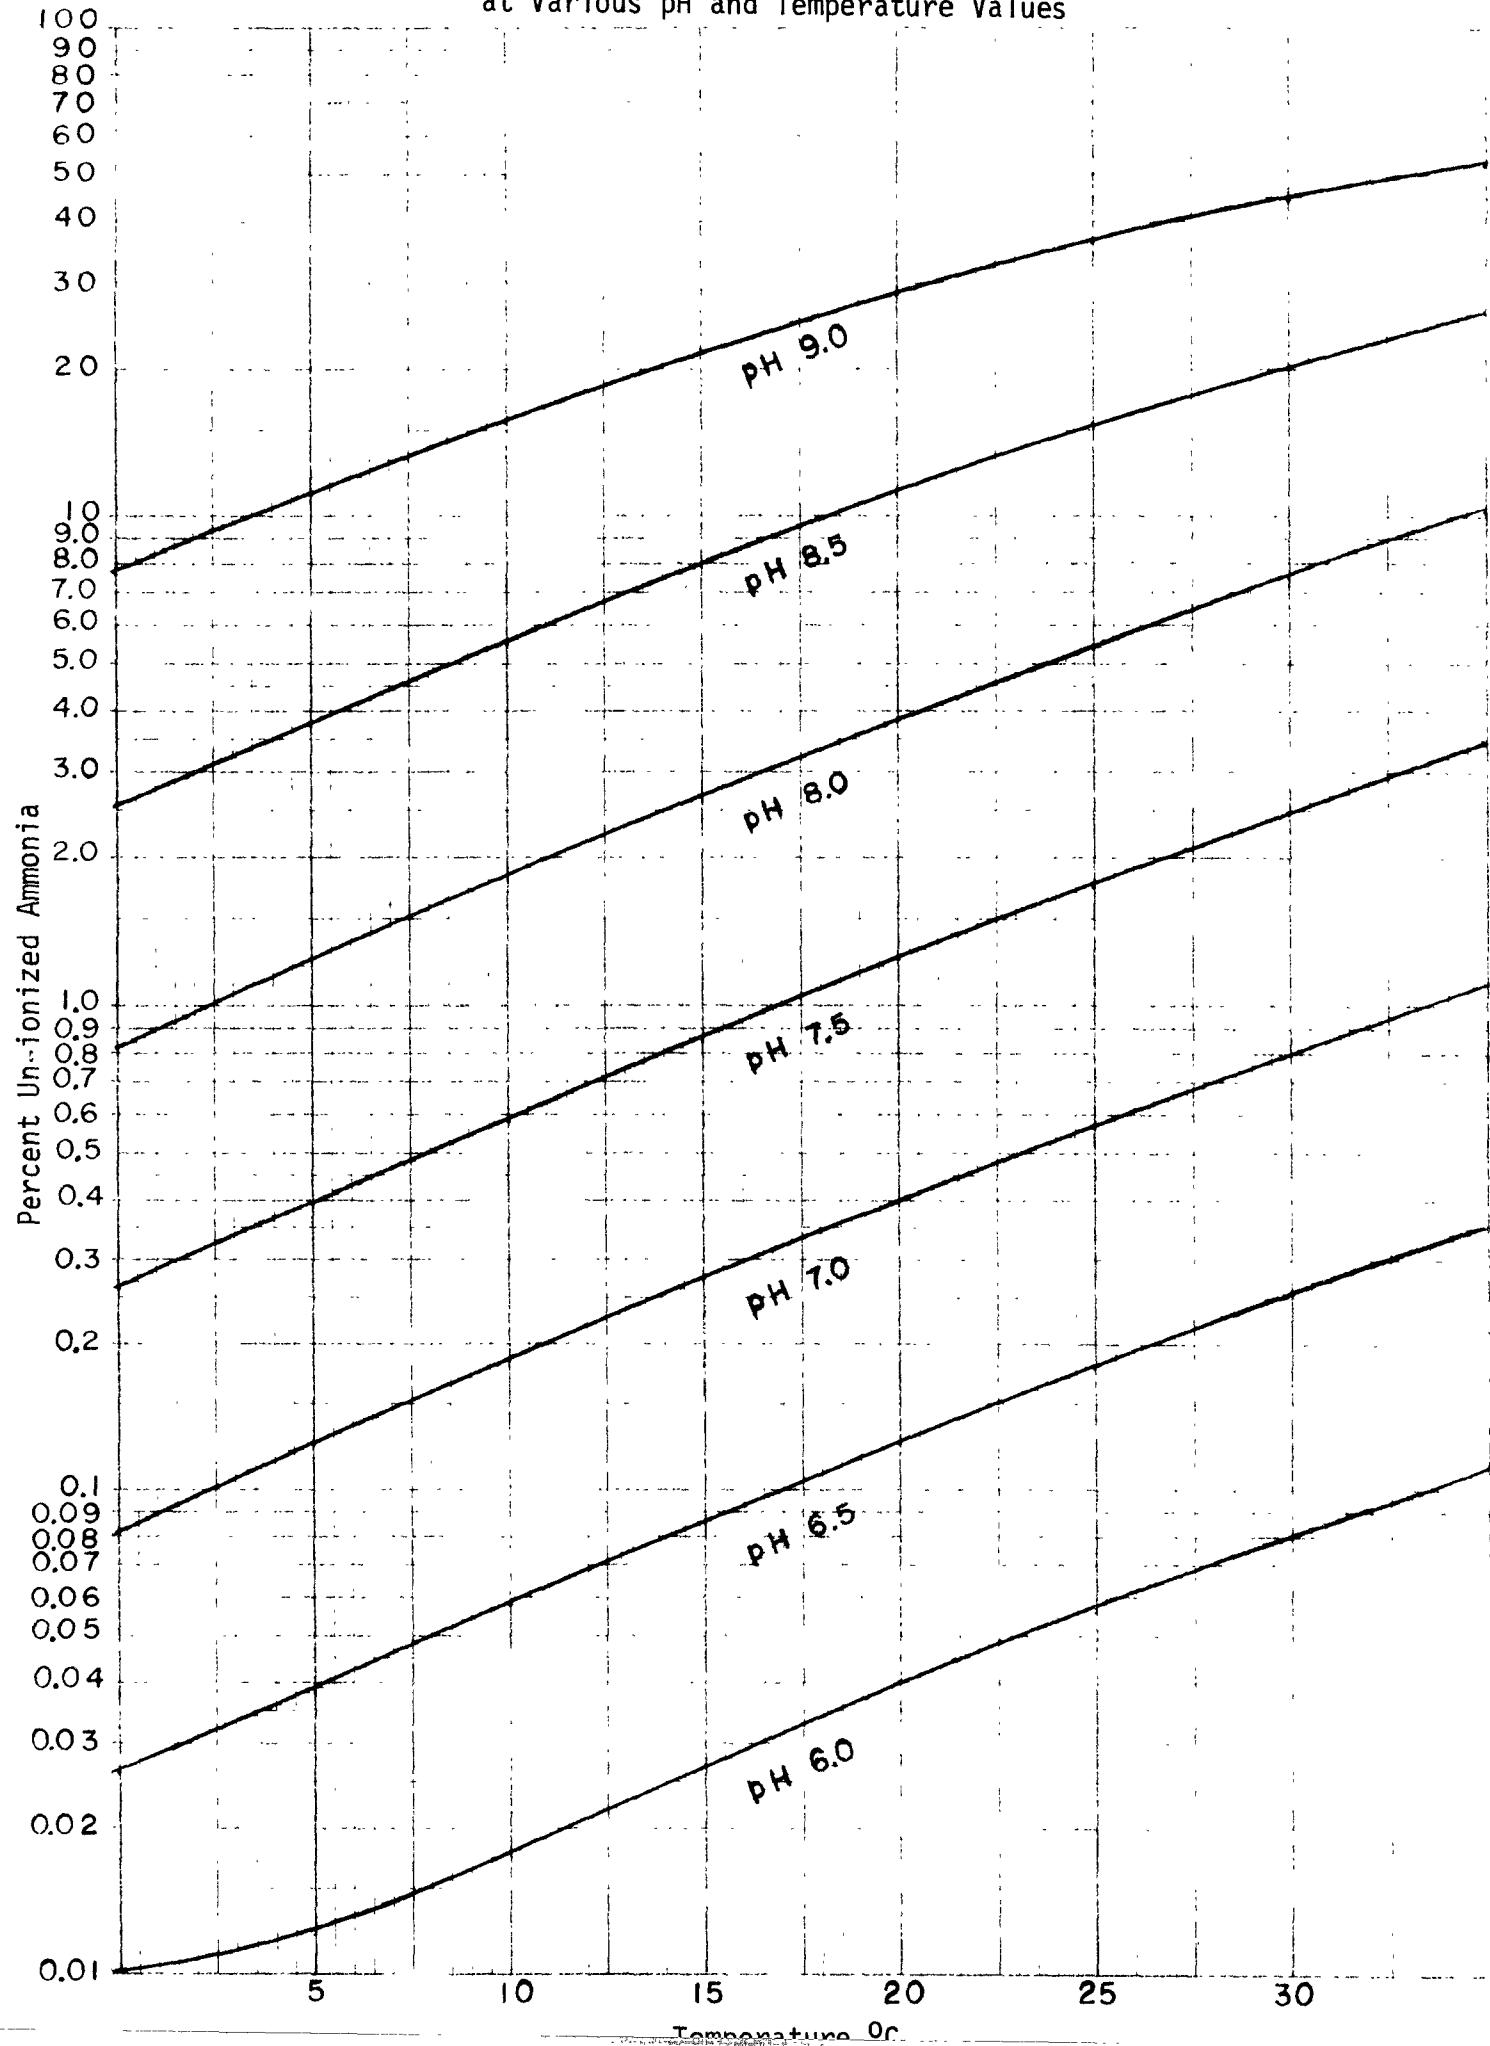

Table II. Method for calculating the percentages of un-ionized ammonia present in ammonia-water solutions.

In ammonia-water solutions, un-ionized ammonia exists in equilibrium with the ammonium ion and hydroxide ion. Butler (1964) shows the equation expressing this equilibrium as:

Derivation formula: $\frac{(\text{NH}_4^+) (\text{OH}^-)}{(\text{NH}_3 \cdot \text{H}_2\text{O})} = K_b$

<u>Temperature</u> $^{\circ}\text{C}$	<u>p</u> _w (a)	<u>p</u> _k _b (b)	<u>p</u> _k _a (c)
0	14.944	4.862	10.082
5	14.734	4.830	9.904
10	14.535	4.804	9.731
15	14.346	4.782	9.564
20	14.167	4.767	9.400
25	13.997	4.751	9.246
30	13.833	4.740	9.093
35	13.680	4.733	8.947

(a) p_w values from the Handbook of Chemistry and Physics 50th edition, 1969, page D-120. The Chemical Rubber Company.

(b) R.G. Bates and G.D. Pinching, J. Am. Chem. Soc., 1950, 72:1393.

(c) Bates and Pinching (1949) critically evaluated the constants for the dissociation of the ammonium ion at five-degree intervals from 0 to 50 C. In determining the constants at intermediate temperatures, the temperature dependence of the pK values must be established. In a recent excellent analysis of the literature data on the ammonia-water equilibrium system, Thurston, Russo, and Emerson (1974) devised such a calculated coefficient utilizing computer techniques which statistically represent a completely adequate fit to the Bates and Pinching data. Thurston, Russo and Emerson have suggested the following equation to calculate p_{Ka} at all temperatures, in ammonia-water solutions of zero salinity:

$$pK_a = 0.09018 + 2729.92/T$$

$$\text{Where } T = ^{\circ}\text{C} + 273.2$$

This equation has been used in this document.

$$(1) \frac{(\text{NH}_4^+) (\text{OH}^-)}{(\text{NH}_3 \cdot \text{H}_2\text{O})} = \text{Kb, where Kb is the dissociation constant for ammonia}$$

$$(2) \frac{(\text{NH}_4^+)}{(\text{NH}_3 \cdot \text{H}_2\text{O})} = \frac{\text{Kb}}{(\text{OH}^-)}$$

$$(3) (\text{NH}_4^+) = \frac{\text{Kb}}{(\text{OH}^-)} (\text{NH}_3 \cdot \text{H}_2\text{O})$$

$$(4) (\text{NH}_4^+) + (\text{NH}_3 \cdot \text{H}_2\text{O}) = \text{ammonia}$$

(5) Substituting the value for (NH_4^+) from equation (3) into equation (4),

$$\frac{\text{Kb} (\text{NH}_3 \cdot \text{H}_2\text{O}) + (\text{NH}_3 \cdot \text{H}_2\text{O})}{(\text{OH}^-)} = \text{ammonia}$$

(6) By factoring out $(\text{NH}_3 \cdot \text{H}_2\text{O})$

$$\text{NH}_3 \cdot \text{H}_2\text{O} \left(1 + \frac{\text{Kb}}{(\text{OH}^-)}\right) = \text{ammonia}$$

$$(7) \frac{\text{NH}_3 \cdot \text{H}_2\text{O} \times 100}{\text{ammonia}} = \frac{100}{1 + \frac{\text{Kb}}{(\text{OH}^-)}} = \text{Percent un-ionized ammonia}$$

$$(a) K_w = K_a K_b$$

$$(b) K_b = \frac{K_w}{K_a}$$

$$(c) \frac{K_b}{(OH^-) K_a(OH^-)} = \frac{(OH^-) (H^+)}{K_a (OH^-)} = \frac{(H^+)}{K_a} = \text{antilog (p}K_a - \text{pH)}$$

$$(8) \text{Percent un-ionized ammonia} = \frac{100}{1 + \text{antilog (p}K_a - \text{pH)}}$$

Given a maximum permissible in-stream concentration of un-ionized ammonia of 0.02 mg/l NH₃-N,

$$(9) \quad \text{Then, } \frac{0.02 \text{ mg/l NH}_3\text{-N} \times 100}{\text{percent un-ionized ammonia}} = \text{ammonia - N}$$

Total Dissolved Solids - Salinity

Herbert and Shurben (1965) reported that, under experimentally controlled conditions of constant pH, the LC₅₀'s of ammonia to rainbow trout in solutions nearly isotonic with fish blood (.9%) were approximately twice those observed in freshwater (.05%). Thurston, Russo and Emerson (1974) indicate that an increase in solution ionic strength results in a concomitant decrease in the un-ionized ammonia fraction of ammonia. This, in part, could rationalize that data reported by Herbert and Shurben. However, further work is needed to clarify the observed mitigating affects of total dissolved solids.

Free Carbon Dioxide

Lloyd and Herbert (1960) showed that the toxicity of ammonia is not entirely dependent on the pH value of the bulk of the solution, but on that of the water at the gill surface. Lloyd (1961) indicated that this value can be readily calculated from the bicarbonate alkalinity, temperature, and free carbon dioxide concentration in the water, and the free carbon dioxide excreted by the gills of the fish. He estimated the concentration of excreted carbon dioxide in the respired water (as mg. carbon dioxide/liter) by using the formula,

$$\text{D.O.} \times \text{R.Q.} \times \frac{\text{mol. wt. CO}_2}{\text{mol. wt. O}_2} \times \frac{P}{100},$$

where D.O. is the dissolved oxygen concentration of the water in

mg/l, R.Q. the respiratory quotient of the fish (assumed to be 0.8), and P the percentage removal of oxygen from the respired water. Lloyd (1961) stated that "as the oxygen concentration of the water is reduced, the concentration of excreted carbon dioxide at the gill surface is also reduced and the pH value of the water at this surface rises, resulting in an apparent increase in the toxicity of ammonia. This increase in toxicity will become greater as the concentration of free carbon dioxide in the bulk of the solution is reduced." However EIFAC (1970) points out that under conditions where dissolved oxygen concentrations are adequate, free carbon dioxide levels very low and pH values high, the level of un-ionized ammonia which is toxic to fish may be about five times greater than those indicated for polluted waters where free carbon dioxide is high and pH lower. This manifest reduction in toxicity is possibly due to an increased pressure gradient across the respiratory membrane, which would facilitate the rapid excretion of carbon dioxide.

Dissolved Oxygen

Several investigators have found that lower concentrations of dissolved oxygen can greatly affect the toxicity of several toxins. Downing and Merkens (1955) and Lloyd (1961) found this effect to be quite evident with ammonia. Lloyd felt that a reduction in dissolved oxygen concentration would be accompanied by an increased rate in ventilation by fish. This could then increase the toxicity of ammonia in two ways. First, the increased rate of ventilation would effect a greater rate of exposure to the un-ionized ammonia molecule. Secondly, increased respiration would effectively reduce the concentration of

carbon dioxide being excreted at the gill surface, thereby increasing the pH at that surface. The effects of varying concentrations of both dissolved oxygen and carbon dioxide are obviously related.

Bicarbonate Alkalinity

The most pronounced effect which bicarbonate alkalinity has on the toxicity of ammonia is associated with the affect which it has on the pH of the solution in conjunction with the concentration of free carbon dioxide present. This effect has been demonstrated by Lloyd (1961).

Prior Exposure

Lloyd and Orr (1969) demonstrated that rainbow trout exposed to sub-lethal concentrations of ammonia could then be exposed to lethal concentrations with no apparent harm. This ability to acclimate was retained for about one day but was lost after about three days. However, no estimates of the maximum concentration in which a fish could survive were given.

TOXICITY OF AMMONIA IN THE PRESENCE OF OTHER POISONS

The European Inland Fisheries Advisory Commission's "Report on Ammonia and Inland Fisheries" (1970) states that "several tests have been made with rainbow trout on the toxicity of mixtures of ammonia with other poisons. Experiments with solutions containing both ammonia and cyanide showed that the combination was more toxic than either substance alone (Wuhrmann and Woker, 1948). Herbert (1962) showed that the threshold LC₅₀ of a mixture of ammonia and phenol was obtained when the sum of the individual concentrations, expressed as the proportion of their separate threshold LC₅₀ values, equalled unity. Further tests with zinc and ammonia (Herbert and Shurben, 1964), and copper and ammonia (Herbert and Van Dyke, 1964) gave similar results, in that the toxicity of the individual poisons could be added together in this manner." However, Brown, Jordan and Tiller (1969) showed that mixtures of zinc, phenol, and ammonia, in which the proportion of the total toxicity contributed by zinc was predominate, were significantly less toxic than the expected values. It may be possible that this method of summing toxicities is not valid for all concentrations of poisons.

Vamos and Tasnadi (1967) reported using copper sulfate to reduce the toxicity of ammonia in carp ponds. It was suggested that, on a short exposure basis, the copper-ammonia compounds formed were not toxic, a finding opposite to that of Herbert and Van Dyke (1964) in laboratory experiments. It is possible, then, that in situ bioassays will have to be conducted to arrive at a more valid acceptable ammonia concentration for a particular situation, especially when other additive toxins are present in relatively high concentrations.

OTHER EFFECTS OF AMMONIA

Indirectly, ammonia can have adverse impacts on fish. Ammonia, either ionized or un-ionized can have a direct influence on the dissolved oxygen concentrations of water.

Under aerobic conditions, ammonia is readily oxidized to nitrite by Nitrosomonas bacteria. Nitrite can be, in turn, oxidized to nitrates by Nitrobacter. Sawyer and McCarty (1967) show the reactions,

and

whereby 2 moles of ammonia will consume 4 moles of oxygen. Ammonia, then, could theoretically have an ultimate oxygen demand of 4.57 mg O₂/mg NH₃-N.

Nitrates, as such, may act to increase the net productivity of aquatic systems. To a certain extent this may be quite beneficial to the entire aquatic community. However, when nitrate levels become excessive, and assuming that the other nutrient factors are present, eutrophication and associated algal blooms can become a severe problem.

MECHANISM OF TOXIC ACTION

Fromm (1970) noted that rainbow trout excrete ninety-four percent of their total nitrogen as ammonia, urea and protein nitrogen. Ammonia is produced endogenously by fish primarily via the degradation of protein, more specifically the deamination of various amino acids. Most authors indicate that teleost fish, unlike mammals, synthesize urea via the purine pathway. Prosser and Brown (1961) indicate that pyrimidine nucleic acids are generally excreted as either ammonia or urea by teleosts.

Of those possible nitrogenous excretory products, ammonia is the smallest and simplest. It is extremely soluble in water and is, normally, easily excreted by fish across the lipid soluble cell membranes of the gills. Except for the toxicity of ammonia, there are advantages over urea as the chief product of nitrogen metabolism. The conversion of protein nitrogen to ammonia requires substantially less energy than urea production. Actually, some deamination reactions lead to the production and capture of free energy (Figure 2).

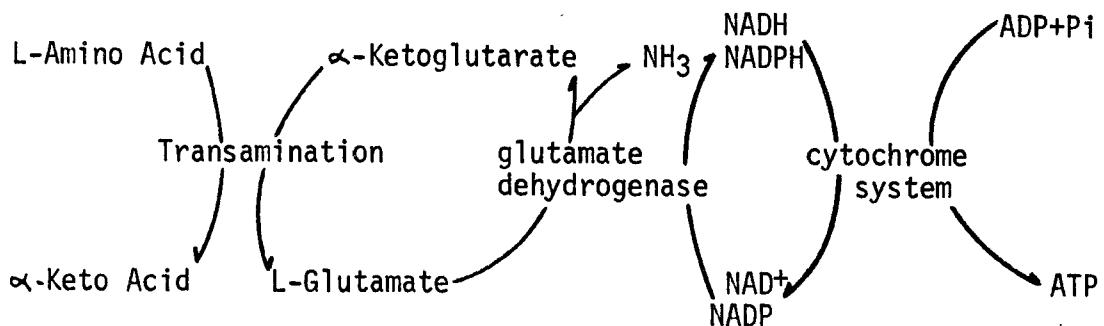

Figure 2. Deamination of amino acids and production of ATP via coupled transamination of glutamate dehydrogenase. (Forster and Goldstein, 1969)

Mammals normally synthesize urea via the ornithine urea cycle (Forster and Goldstein, 1969). However, teleost fish lack two enzymes involved in the first two steps of the ornithine cycle, carbamyl phosphate synthetase and ornithine transcarbamylase. Forster and Goldstein (1969) indicate that urea is probably synthesized from purines and, in some instances, from amino acids by teleosts (Figure 3).

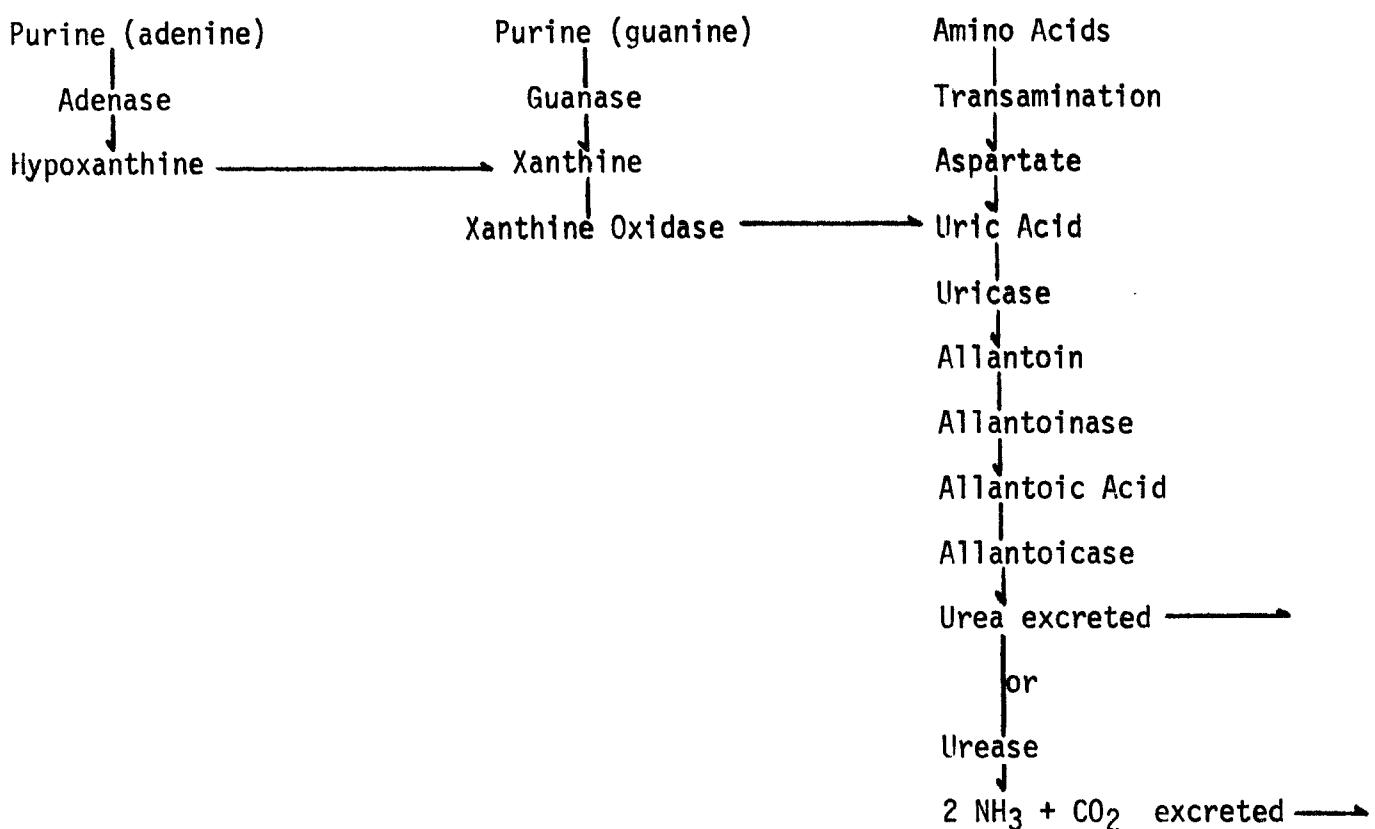

Figure 3. Urea and ammonia production via and purine pathway. (modified from Forster and Goldstein, 1969 and Prosser and Brown, 1961)

Ammonia is a toxic substance. An animal must either excrete it or detoxify it. Most fish, because of their aqueous environment will excrete ammonia rather than detoxify it. Some authors feel that teleost fish are obligated to excrete ammonia rather than detoxify it because they lack the specific enzymes necessary for this process (Forster and Goldstein, 1969).

The excretion of ammonia is extremely dependent upon the pH of both the plasma fluid and water at the gill surface. Normally, only un-ionized ammonia (NH_3) is excreted through the lipid soluble membrane. At the pH of body fluids less than one percent of the ammonia exists as un-ionized ammonia but the conversion of NH_4^+ to NH_3 is instantaneous and hence probably not a rate limiting step in its elimination (Forster and Goldstein, 1969).

Although NH_4^+ probably does not passively diffuse across the gill membrane, it may be possible for NH_4^+ to exchange with Na^+ in the water by cation exchange. Confirmation of the $\text{Na}^+/\text{NH}_4^+$ exchange process was obtained in the freshwater eel where it was shown that injections of ammonium sulfate increased sodium influx sixfold without effecting sodium efflux (Forster and Goldstein, 1969) as shown in Figure 4.

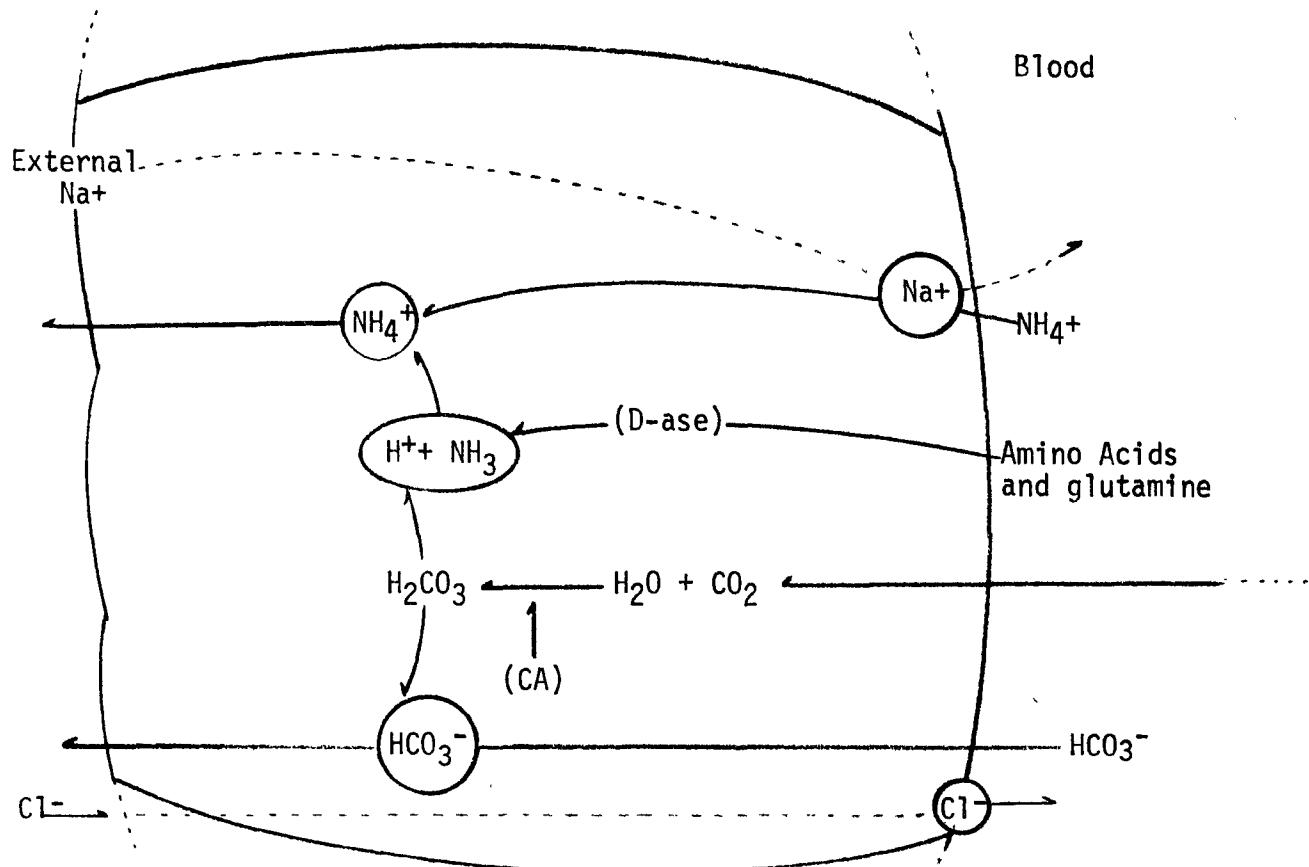

Figure 4. - Schematic representation of ionic exchanges in brachial cells. Deamination and deamination enzymes (D-ase) and carbonic anhydrase (CA). (Forster and Goldstein, 1969)

Fromm (1970) indicated that un-ionized ammonia in water at 1.0 mg/l-N is toxic to trout because it prevents the excretion of normal amounts of ammonia. The toxic action most probably is cytologic, and the nervous system appears to be affected earliest. Contrary to what other investigators have reported, Fromm felt that un-ionized ammonia at 1.0 mg/l-N does not appear

to kill fish by preventing exchange of the respiratory gases at the gill surface or by inhibiting transport of oxygen in combination with hemoglobin.

Studies conducted by Burrows (1964) indicate that continuous exposure to low levels of un-ionized ammonia greatly affected the physiology of salmonids. He noted that exposure to as little as 0.3 mg/l ammonia-NH₄ (0.002 mg/l un-ionized ammonia as N) for six weeks greatly reduced the stamina, performance and growth of salmon. Histological examination of the gill lamella showed extensive hyperplasia of the gill epithelium. Similar examinations of salmon exposed to 0.70 mg/l ammonia-NH₄ (0.005 mg/l un-ionized ammonia as N) for six weeks showed even more extensive hyperplasia, to the extent that there was fusion of the lamella. Obviously, this pathological condition could effectively reduce the surface area of the gills for gas exchange, which would explain the effected physiology. Burrows indicated that this condition would make the fish highly susceptible to gill infections, a problem common to fish rearing units.

Burrows noted that the principal nitrogenous excretory product was greatly dependent upon age, sex, species and stress placed upon fish. Under low loading conditions in the raceways, as well as at night under average loading rates, urea was the primary nitrogenous excretory product. Under higher loading rates and during periods of daylight activity, ammonia became the primary nitrogenous excretory product. Burrows did not offer an explanation for urea suppression, but it appears likely when salmonids are stressed, from either increased physical activity or high hatchery loading rates, they would tend to conserve as much energy as possible and since, as pointed out earlier, urea synthesis requires substantially more energy than ammonia synthesis, the production of ammonia would be favored.

CONCLUSIONS AND RECOMMENDATIONS

1. The effect of ammonia on inland fisheries is an important factor to be considered when establishing water quality criteria.

The presence of ammonia is due primarily to municipal sewage effluents and, to a lesser degree, certain industrial discharges. Certain agricultural discharges, such as feedlot runoffs, may also contain high concentrations of ammonia.

2. The mechanism of toxicity of un-ionized ammonia is highly debatable and should be investigated further. It appears likely to be twofold, depending on the concentration. High concentrations appear to limit the excretion of metabolic ammonia, inducing hyperammonemia and subsequent histologic insult. Continuous exposure to low levels induce histopathologic aberrations of gill epithelia, stressing the animal and making it less resistant to subsequent pathological conditions.

3. Many factors such as pH, temperature, alkalinity, dissolved oxygen, free carbon dioxide, sodium ions, total dissolved solids, presence of other toxins and other factors will greatly affect the toxicity of ammonia. Once a 96-hour LC₅₀ has been determined using the receiving water in question and the most sensitive species, in the most sensitive portion of its life cycle in the locality as the test organisms, a concentration of un-ionized ammonia safe to aquatic life in that water can be estimated by multiplying the 96-hour LC₅₀ by a determined application factor; but, in general, the maximum permissible in-stream concentration of un-ionized ammonia should be 0.02 mg/l NH₃- N for waters classified for fisheries use.

Table III shows the calculated values, based on pH and temperature, for ammonia as N which would give an un-ionized ammonia concentration of 0.02 mg/l NH₃-N. Further, more extensive values are given in Appendix A.

Table III. Concentrations of ammonia ($\text{NH}_4^+ + \text{NH}_3$) which contain an un-ionized ammonia concentration of 0.02 mg/l $\text{NH}_3\text{-N}$.

<u>Temperature</u>	<u>pH Value</u>

*The European Inland Fisheries Advisory Commission (EIFAC), reports that criteria under this heading may be unduly low if there is little free carbon dioxide in the water.

The range of limitations for ammonia are based on pH and temperature variations and assume an activity coefficient of 1.0. For example, at a pH of 7.5 and a temperature of 15 C, the maximum permissible ammonia concentration is 2.41 mg/l as N. This concentration of ammonia would produce an un-ionized ammonia concentration of 0.02 mg/l $\text{NH}_3\text{-N}$. Concentrations of maximum permissible ammonia for pH and temperature values outside of those in Table III are not necessarily valid for reasons explained in the text of this document.

15. SUPPLEMENTARY NOTES			
16. ABSTRACT Several authors have reported that the harmful effects of ammonia are primarily related to the pH and temperature of the water because only the un-ionized ammonia is toxic. The un-ionized fraction increases with rising pH values and with rising temperature. Other factors such as dissolved oxygen, alkalinity, free carbon dioxide, sodium ions, total dissolved solids, prior exposure to ammonia, physical stress, general physiological status, and the presence of other additive toxins or other mitigating parameters will have a great affect on the overall toxicity of ammonia to aquatic organisms. The actual reported toxic concentrations of ammonia vary from 0.16 mg/l to 16.5 mg/l NH ₃ -N. This apparent variability often resulted from the investigator's failure to report pH and temperature values as well as other factors which may have biased their results. It appears that the highest concentration of un-ionized ammonia which apparently will not cause any adverse effects is 0.02 mg/l NH ₃ -N.
