## DISCLAIMER

This material has been funded wholly or in part by the United States Environmental Protection Agency under Contract No. 68-03-4038. It has been subject to the Agency's review and it has been approved for publication as an EPA document. Mention of trade names or commercial products does not constitute endorsement or recommendation for use.

## FOREWORD

Today's rapidly developing and changing technologies and industrial products and practices frequently carry with them the increased generation of materials that, if improperly dealt with, can threaten both public health and the environment. The U.S. Environmental Protection Agency is charged by Congress with protecting the Nation's land, air, and water systems. Under a mandate of national environmental laws, the agency strives to formulate and implement actions leading to a compatible balance between human activities and the ability of natural systems to support and nurture life. These laws direct the EPA to perform research to define our environmental problems, measure the impacts, and search for solutions.

The Risk Reduction Engineering Laboratory is responsible for planning, implementation, and management of research, development, and demonstration programs to provide an authoritative, defensible engineering basis in support of the policies, programs, and regulations of the EPA with respect to drinking water, wastewater, pesticides, toxic substances, solid and hazardous wastes, and Superfund-related activities.

This publication is one of the products of that research and provides a vital communication link between the researcher and the user community. It contains the results from two pilot scale studies conducted to investigate the removal and fate of 28 RCRA toxic compounds and 19 CERCLA toxics by conventional activated sludge. Related work is underway to measure removals of these and similar toxics by other aerobic and anaerobic processes and results will be presented in subsequent publications.

E. Timothy Oppelt, Director  
Risk Reduction Engineering Laboratory

## ABSTRACT

Two separate studies were conducted to investigate the removal and fate of 28 selected RCRA compounds (0.25 mg/L of each compound) and 19 selected CERCLA compounds (0.5 mg/L of each compound) in conventional activated sludge treatment. In each study, two pilot-scale (35 gpm) activated sludge systems (SRT: 4 days for RCRA study and 8 days for CERCLA study) were operated in parallel at the U.S. EPA Test and Evaluation Facility in Cincinnati, Ohio. One system was spiked continuously with either RCRA or CERCLA toxics to produce an acclimated biomass; the other was spiked intermittently with the same toxics and sampled to determine performance under unacclimated conditions. The selected RCRA or CERCLA compounds did not cause any adverse effects on COD and SS removals. The concentrations of organics (RCRA study) in air emissions indicated that the chlorinated aliphatic solvents were essentially volatilized into the plant air emission stream, whereas the aromatic volatile benzenes were substantially degraded. Additional work is planned to attempt to reduce the analytical variability encountered in these studies.

## INTRODUCTION

The Risk Reduction Engineering Laboratory has evaluated the removal and fate of selected RCRA and CERCLA toxic organic pollutants (Table 1) during pilot-scale primary-activated sludge treatment of municipal wastewater at the Agency's Test and Evaluation Facility in Cincinnati, Ohio. This report summarizes the results of the removal and fate-in-treatment of the selected volatile and semivolatile organic compounds. The pilot treatment systems, chosen as a representative POTW design, consisted of primary clarification followed by conventional plug-flow activated sludge treatment and secondary sedimentation. Two parallel 2.2 liters/second (L/S) (35 gpm) pilot plants were used and are shown in Figure 1. Screened and degritted raw wastewater from the Cincinnati Mill Creek Wastewater Treatment Plant was the wastewater feed for the studies. The selected RCRA and CERCLA toxics were spiked into the raw wastewater in two sequential test periods. The first test (RCRA) period from October 1987 through March 1988 evaluated the removal and fate during treatment of selected volatile and semi-volatile organic toxics. The second test (CERCLA) period from June 1988 through August 1988 evaluated the removal and fate of semivolatile organic toxics.

## EXPERIMENTAL SYSTEM AND TESTING APPROACH

The primary clarifiers in the pilot treatment systems were 2.95 m in diameter and had a sidewater depth (SWD) of 3.6 m. At 2.2 L/S wastewater flow, the overflow rate in the center feed clarifier was  $28 \text{ m}^3/\text{m}^2 \text{ day}$ . The activated sludge aeration basins were 5.4 m long, 3 m wide and had a SWD of 3.6 m. At a flow of 2.2 L/S, the hydraulic residence time in the basins was 7.5 hrs. Conventional coarse bubble diffusers were used in

the basins. The center feed secondary clarifiers were 3.6 m in diameter and had a SWD of 3.6 m. At a 2.2 L/S flow, the overflow rate in the clarifier was  $18.4 \text{ m}^3/\text{m}^2 \text{ day}$ . The nominal operating conditions and design characteristics for the two identical systems used in the study are given in Table 2 in English units. A nominal operational sludge retention time (SRT) of 4 days was employed in the RCRA study period. In the CERCLA study period, the nominal SRT was 8 days.

In order to sample the air space above the primary clarifier, a cover was fabricated with approximately an inch opening around the unit. The cover was vented through a duct to the roof. An air sweep equivalent to a 5 km per hour wind was maintained over the surface of the clarifier by exhausting air at 14,000 liters/min. The aeration basin was fitted with an air tight cover and the offgas was also vented to the roof. Air flow in the aeration basins averaged 5,600 liters/min and maintained a dissolved oxygen level of at least 2.0 mg/L.

#### Operations Approach and Conventional Pollutant Removals

The evaluation of the removal and fate during treatment of the spiked RCRA and CERCLA toxic organics in the large pilot-scale primary-activated sludge treatment systems was performed at two steady-flow operational conditions; operation with a continuous feed of spike toxic cocktail in one pilot train under steady operating conditions and operation of the parallel pilot train under the same steady conditions except with intermittent spiking of the toxic cocktail. The operation with continuous feeding of the spiking cocktail produced "acclimated" biomass. In the operation with intermittent spiking of the cocktail,

spike was added at steady nominal concentrations of toxic organics equal to that in the continuously spiked train for a 24 hour period after every 3 SRT periods of unspiked operation. During the spiking episodes, the intermittently spiked train provided removal and fate-in-treatment data for the toxic organics intermittent loading ("unacclimated") operation. The intermittent spiked treatment train also provided conventional pollutant performance control data during unspiked operation for comparison to the conventional pollutant performance of the continuously spiked train.

The pilot treatment trains were operated at a 4-day (4 +.3) SRT with a nominal spike of 0.25 mg/L of each individual toxic organic during the RCRA study period. The pilot treatment trains were operated at an 8-day (8 ±1 day) SRT with a nominal spike of 0.5 mg/L of each individual toxic organic during the CERCLA spiking period. The overall performance of the parallel treatment systems were characterized for removal of chemical oxygen demand (COD), suspended solids (SS), ammonia (NH<sub>3</sub>-N), and for the removal and fate-in-treatment of the individual toxic organics using automated analytical procedures for the conventional pollutants and Agency GC/MS procedures for the toxic organic compounds.

Average removals of conventional pollutants in the pilot systems during both study periods ranged 81 to 88 percent for the COD and 94 to 97 percent for SS. In the RCRA study period at the nominal 4-day SRT and with a nominal toxic spike of 0.25 mg/L of each individual organic, nitrification occurred in the activated sludge processes with average NH<sub>3</sub>-N reductions ranging 76 to 81 percent for the two spiked pilot treatment trains. In the CERCLA study period at a nominal 8-day SRT and with a nominal spike of 0.5 mg/L of each individual organic, complete nitrification usually occurred in the intermittently spiked activated

sludge process but frequent interference with nitrification was observed in the continuously spiked system. The NH<sub>3</sub>-N reductions during the CERCLA study averaged 98 percent for the intermittently spiked system and 88 percent for the continuously spiked system. Data tables showing removals of the conventional pollutants are included in Appendix 3. As an overview of the operational performance, the pilot treatment represents effective performance for control of conventional pollutants. The presence of the spiked toxic organics in the wastewater produced no significant adverse effects on the treatment of conventional pollutants except on ammonia removal during continuous spiking with the CERCLA compounds.

#### SAMPLING AND ANALYTICAL METHODOLOGY

##### RCRA Offgas Sampling and Analysis

The sampling system used to collect each offgas sample consisted of a 33 liter stainless steel polished canister, a pneumatic flow controller and nickel sample tubing. Previous studies have shown that the canisters are well suited for collecting air samples for VOC analysis and that VOC levels do not deteriorate in the canisters during reasonable holding times.

Canisters and flow controllers were cleaned and prepared for sampling by repeated high-pressure purging with ultrapure zero air. The canisters were then pressurized, and blank checked by gas chromatography/mass spectrometry (GC/MS). After blank checking, clean canisters were evacuated to 28 inches of Hg for sample collection. The nickel tubing was cleaned by heating the tubing to 150°<sup>0</sup>C and flushing with purified nitrogen for 2 hours.

Samples were collected by attaching the nickel tubing to the canister and extending the free end into the offgas duct. The canister vacuum was recorded, the valve opened, and the canister allowed to fill at a constant rate during the sampling event. The canister valve was then closed, sample tubing disconnected, and a final pressure reading recorded at the conclusion of sampling. When the collected samples arrived at the Laboratory they were allowed to equilibrate, then a pressure reading was taken using a mercury manometer before any other manipulations of the sample. The final pressure reading was recorded along with the date, temperature, and barometric pressure. From these data, the sample volume was calculated.

Canister samples were analyzed on a Finnigan Model OWA 1050 GC/MS system with a quadrupole mass spectrometer. This system is equipped with a Tekmar Model 5000 cryogenic concentration and sample introduction system. The GC/MS interface consists of a quartz jet separator. The MS is scanned from 40 to 260 m/z (mass charge ratio) every 2 seconds.

Samples were analyzed by withdrawing 0.1 liter or 0.5 liter from a canister using the system mass flow controller. The volatile organics were concentrated on a cryogenic trap and then desorbed to the GC column for component separation and mass spectral analysis. The GC/MS system was calibrated in units of ng of RCRA organic on column and results were recalculated to yield ug/liter in air sample as collected. From these data, masses of each RCRA organic stripped during the sampling event were calculated. The method used was the contractor's standard operating procedure for canister analysis, SOP No. 09-002-00.

## Quality control

The analytical standard was prepared from the neat compounds and internal audits were analyzed for each test series and the results included with the data. The audit gases were obtained from Scott Speciality Gases as Certified Mixtures in Nitrogen ( $\pm 5$  percent). The audit compounds were 1,1,1-trichloroethane, carbon tetrachloride, trichloroethylene, toluene, and tetrachloroethylene.

Since duplicate field samples were analyzed with good precision and calibration precision was excellent, duplicate analyses on the same canister were not run.

Blanks were analyzed and met the method QC criteria before samples were analyzed on each analysis day. In addition, if a highly concentrated sample was analyzed, blanks were run until the system met the QC blank criteria before proceeding with sample analysis. In all cases, it was found that carry-over was not extensive and this is documented in the Canister QC files. Calibration criteria and other QC procedures follow the SOP.

## RCRA Liquid and Sludge Sample Analysis

Sludge and liquid samples were analyzed by gas chromatography/mass spectrometry (GC/MS) according to the methods outlined in the USEPA Methods for Evaluating Solid Waste, SW846, 3rd edition, November 1986.

### Volatiles

Samples to be analyzed for volatile organic compounds were collected by filling one 40 ml volatile organic analysis (VOA) bottle at each sample interval from each sampling point during the sampling event. The first

step in analyzing these samples involved compositing the individual VOA samples from each sample point into one composite sample for each sample point. Samples to be composited were stored chilled at 4°C. Precleaned glassware were also chilled to this temperature. During the compositing step, the samples were poured down the side of the mixing flask to avoid agitation. After all samples were added, the composite was stirred with a chilled glass stirring rod. Agitation was avoided wherever possible. Two 40 ml composites were then collected and stored at 4°C in headspace-free vials until analysis.

The volatile fractions were analyzed on Finnigan DWA and Extrel ELQ400 GC/MS systems using Method 8240 (Purge and Trap). In this method, 5 ml of sample or an aliquot of sample diluted to 5 ml is purged with an inert gas (helium) in a specially designed purge vessel. Volatile organic compounds are partitioned into the gaseous phase and swept by the purge gas onto a multi-phase sorbent trap. After the purge cycle is complete, the flow of carrier gas is reversed, and the trap is heated rapidly. Volatile organic compounds are thermally desorbed from the trap into the gas chromatograph where the individual components are separated. Identification and quantitation were done by mass spectrometry.

#### Semi-Volatiles

Semi-volatile (extractable) compounds were extracted from the samples according to Method 3520 (continuous liquid-liquid extraction). This method outlines procedures for the isolation of acidic and base/neutral organic compounds from aqueous samples. One liter of

sample, or an aliquot of sample diluted to one liter is pH adjusted to greater than pH 11. It is then mixed with an organic solvent (methylene chloride in this project). Base/neutral organic compounds have greater solubility in the organic phase and are concentrated there. After the base/neutral extract has been removed, the pH of the sample is re-adjusted to less than pH 2. A second extraction is then performed to remove acidic compounds. The organic extracts are then concentrated to one ml. Portions of the acidic and base/neutral extracts from a sample were mixed and an aliquot was injected into the GC/MS for analysis. Samples were analyzed on Finnigan 5100 and Extrel ELQ 400 GC/MS systems in accordance with Method 8270. This method specified GC/MS analysis of organic extracts using a fused silica capillary column, with mass spectrometry for detection and quantitation.

#### CERCLA Liquid and Sludge Sample Analysis

Liquid and sludge samples in the CERCLA study were collected for either 24 or 48 hours and composited for analysis. The CERCLA compounds were all classified as semivolatiles and were analyzed following EPA Extraction Method 1625.

All samples were spiked with a mixture of deuterated or  $^{13}\text{C}$ -labeled priority pollutant organics to represent the priority pollutants spiked into the wastewater feed. Analytical results for the nonlabeled priority pollutant organics were corrected automatically for the recoveries of the labeled priority pollutant organics. The isotopically labeled compounds were used as internal standards for the corresponding priority pollutants. Furthermore, percent recovery of the labeled

compounds, and by inference, of their corresponding natural-isotope analogs, was measured as a function of an internal standard added just before gas chromatography/mass spectrometry (GC/MS) analysis. Anthracene-d<sub>10</sub> was used for Method 1625. A capillary column was used in the GC/MS procedure. Both instruments were attached to a computer data system. To ensure precision, duplicate analyses of individual collected samples and analyses of samples collected and processed in duplicate were performed.

#### REMOVAL AND FATE-IN TREATMENT

Five sample events were performed during the RCRA study period to evaluate the removal and fate-in treatment of the spiked toxic organics. In this study period, the removals and fate of the toxic organics were characterized by GC/MS analyses of the influent to and all discharges from the two treatment systems, i.e., in the raw wastewater, the primary influent, the primary effluent, the secondary effluent, the primary sludge, the waste activated sludge, and the air emissions from both primary clarification and the activated sludge process. In the first two sample events of the RCRA study period, the air samples proved to be too small for the GC/MS sensitivity. With larger samples, precise and quantitatively accurate data were generated on the volatile organic compounds in the primary and activated sludge air emissions from the pilot systems for the last three sample events. In the CERCLA study, eleven sample events on the continuously spiked (acclimated) pilot train and 4 sample events on the intermittently spiked pilot train have been included in the summary tables of average toxic organic removal and toxic organic fate-in-treatment performance of the pilot systems.

The removal and fate-in-treatment performance for the RCRA study period on both volatile and semivolatile organics are summarized in Tables 3 through 10 for "acclimated" and "unacclimated" operation. The performance data for the continuously spiked (acclimated) treatment system are based on 24-hour composite samples with average concentrations reported for the various plant discharges (Tables 3 and 4) including air emissions and removals reported (Tables 5 and 6) across the treatment processes and by treatment mechanism. In the intermittently spiked ("unacclimated") pilot trains, the episodal spiking lasted 24 hours but the sampling composite was extended to 48 hours to permit measurement of the gradual washout of the organic toxics. Thus, the performance data for the unacclimated operation are reported for the toxic organics in the discharges (Tables 7 and 8) as average masses in grams rather than as concentration units. The masses in grams are then used to calculate the removals (Tables 9 and 10) across the treatment processes and in the removal mechanisms. The raw data for the individual sample events are included in the Appendix 1.

The removal and fate-in-treatment performance for the CERCLA study period on semivolatile toxic organics is summarized in Tables 11 through 14. Since only semivolatile organics were employed, air emission sampling was not performed. As in the RCRA study period described above, the performance data for continuously spiked operation ("acclimated") were based on 24-hour composite samples with average toxic organic concentrations reported in the various plant discharges. For intermittently spiked ("unacclimated") operation, the performance data are reported as masses of toxic organics because of the 24-hour spiking episode and the 48-hour composite sampling for organic washout. While air stripping of organics was expected to be an insignificant removal mechanism and air

emissions were not measured for the semivolatile organics, the removal mechanisms during the CERCLA study period are reported in Table 14 as removal in sludge and the combined biodegradation + stripping. The raw data on the individual sample events in the CERCLA study period are also included in Appendix 2.

#### OVERVIEW OF THE RESULTS

Substantial variability occurs in the reported results because some compounds, especially in the RCRA study period, were not satisfactorily identified in the analytical tests. In the RCRA study five spiked toxics, two volatile polar solvents (cyclohexanone and furfural) and three phenols (2,4-dimethyl phenol, 2,4-dinitrophenol, and 4-nitrophenol) were not satisfactorily identified by the analytical methodology. In the CERCLA study, all of the tested toxics were measurable by the analytical procedures, but in the small data base for the unacclimated operation, two compounds, 4-chloroaniline and bis(2-ethylhexyl) phthalate, were not satisfactorily identified by the analytical tests.

The concentrations or masses of the organics in the various samples from the treatment systems revealed good results in the air samples from the RCRA study and reasonable results in the secondary effluents for both studies. The analytical methodology used by the contractor laboratory for the RCRA study period produced poor results on the concentrations or masses of organics in the samples on raw, primary and sludge streams. The contractor laboratory did not use the stable-labelled isotopes in their analytical procedures. In the CERCLA study period, the in-house U.S. EPA laboratory used stable-labelled isotopes in the analytical procedures. The results were generally improved for the raw and primary wastewater

samples compared to the RCRA study period. However, even with the stable-labelled isotopes in the procedure, the amounts of organics found in the complex sludge samples are substantially lower than the measured removals across the primary process. There is a strong indication that organics quantitation by available methods is not reliable in a sludge matrix, and, as a result, mass balance closure in these studies is generally poor.

Appendix 4 provides a quality assurance summary of the RCRA and CERCLA data. Included are analytical recoveries, percent of collected data usable for removal and fate calculations and relative percent differences between collected duplicate samples. There is also a discussion of the process used to retain or exclude data.

The overall organic removals reasonably correspond with overall removals for these organic compounds in other studies. The concentrations of organics in the air emissions generally indicate that the chlorinated aliphatic solvents are essentially volatilized into the plant air emission stream, whereas the aromatic volatile benzenes (toluene, xylenes, chlorobenzenes) are substantially degraded. Pesticides and phthalates are removed by both sorption on sludges and by biodegradation. These air emission results qualitatively confirm results from earlier bench scale studies which had superior analytical reliability but without the real world sampling and wastewater matrix effects. Unfortunately, the variability in the results does not reliably permit calibration of a mechanistic model which is being developed through other treatability studies. Additional work is planned to attempt to reduce the analytical variability encountered in these studies.

# EFFECT OF CERCLA TOXICS ON COD REMOVAL

(Revised)

## EFFECT OF CERCLA TOXICS ON NITRIFICATION

**APPENDIX 4. QUALITY ASSURANCE SUMMARY**

#### Appendix 4. QA/QC Overview

This report combines results from two projects "RCRA Pilot Scale Study of Toxics Removal" and "CERCLA Pilot Scale Study of Toxics Removal." Each project spiked municipal wastewater with mixtures containing multiple organic toxic chemicals having different physical, chemical and biological properties. These properties affected the overall removals and partitioning of the chemicals as well as the reliability of analytical results. Data for each chemical must be evaluated separately since broad generalizations do not apply.

Major changes were necessary in the planned QA for the RCRA project. Analytical work was transferred from in-house to a contractor where different methodology was used in the work assignment. Stable labeled isotopes were not used and measured concentrations could not be corrected for recoveries, although recoveries were measured for samples spiked in the laboratory with surrogate toxics.

Poor closure of material balances around the process units was observed and was caused at least partially by lack of recovery corrections. Fractions of volatile toxics in air emissions had to be based on actual toxics fed to the wastewater rather than on measured influent concentrations. If measured influent concentrations were used, analytical recoveries of essentially 100% from air coupled with the lower recoveries from liquid samples resulted in apparent fractions of some volatile compounds in air approaching 200%.

It was necessary to exclude by inspection some concentration values which did not "fit" the data set. For example, where concentrations of a single chemical in duplicate field samples were quite different, the concentration values were compared to concentrations from preceding and following sample points in the same sample event, to concentrations at the same sample point from other sample events and if necessary to calculated feed concentrations to decide which duplicate to exclude or if all data were highly variable to simply average the two duplicates. If concentrations of all organics in one sample were much higher or lower than in comparable samples, then a decision was made to exclude or retain an entire sample rather than just individual chemical concentrations. In effluent samples where concentrations were generally quite low, large relative differences between samples were generally not significant since the associated masses of chemicals represented only a small fraction of the total mass of chemical added. Therefore most effluent concentrations were retained despite high relative percent differences between duplicates.

Of 29 RCRA toxics in the spike, valid data were reported for only 25 compounds. Table 4-1 shows percent recoveries of laboratory-spiked surrogates and relative percent differences between laboratory-spiked duplicates. Table 4-2 shows the percent of RCRA sampling events providing usable data and Tables 4-3 and 4-4 show a summary of relative percent differences for duplicate field samples.

In the CERCLA project, data collection generally proceeded as planned using the in-house laboratory. Stable labeled isotopes of each spiked chemical were added to every sample and measured analytical values were corrected for recoveries obtained for the labeled compounds. Despite the improved analytical methodology, some chemicals still did not appear to be quantitatively measured in sludge samples, either because of poor separation from the sludge and wastewater matrix or because of degradation before analysis. Where sludge data showed major discrepancies with removal data based on the wastewater analyses, the sludge data were excluded from partitioning calculations.

Of 22 CERCLA toxics in the spike, valid data were reported for 19 compounds. Table 4-5 shows the percent of CERCLA sampling events providing usable data and Tables 4-6 and 4-7 show a summary of relative percent differences for duplicate field samples.

TABLE 4-1. SUMMARY OF RCRA RESULTS - PERCENT RECOVERIES OF LABORATORY - SPIKED SURROGATES AND RELATIVE PERCENT DIFFERENCES (RPD) BETWEEN LABORATORY SPIKED DUPLICATES.

---

<u>Event 3</u>	<u>Recoveries*</u>	<u>RPD Range</u>
Volatiles	19 out of 159: outside of QC limits	3 - 5
Semivolatiles	63 out of 216: outside of QC limits	0 - 39
<u>Event 4</u>	<u>Recoveries</u>	<u>RPD Range</u>
Volatiles	6 out of 165: outside of QC limits	0 - 18
Semivolatiles	34 out of 162: outside of QC limits	0 - 30
<u>Event 5</u>	<u>Recoveries</u>	<u>RPD Range</u>
Volatiles	1 out of 102: outside of QC limits	2 - 5
Semivolatiles	51 out of 192: outside of QC limits	0 - 9
<u>All 3 Events</u>	<u>Recoveries</u>	
Volatiles	26 out of 426: outside of QC limits (6%)	
Semivolatiles	148 out of 570: outside of QC limits (26%)	

---

\*Range of acceptable recoveries was 61% - 145% for volatiles and 9% - 131% for semivolatiles.

TABLE 4-2. PERCENT OF SAMPLING EVENTS PROVIDING DATA USABLE FOR CALCULATION OF TOTAL REMOVAL AND PARTITIONING OF 25 RCRA TOXICS FROM THREE ACCLIMATED EVENTS AND THREE UNACCLIMATED EVENTS

RCRA Toxic	Acclimated		Unacclimated	
	Removal	Partitioning	Removal	Partitioning
