PERFORMANCE EVALUATION OF THE
AERATED LAGOON SYSTEM AT NORTH GULFPORT, MISSISSIPPI

DISCLAIMER

This report has been reviewed by the Municipal Environmental Research Laboratory, U.S. Environmental Protection Agency, and approved for publication. Approval does not signify that the contents necessarily reflect the views and policies of the U.S. Environmental Protection Agency, nor does mention of trade names of commercial products constitute endorsement or recommendation for use.

FOREWORD

The Environmental Protection Agency was created because of increasing public and government concern about the dangers of pollution to the health and welfare of the American people. The complexity of the environment and the interplay between its components require a concentrated and integrated attack on the problem.

Research and development is that necessary first step in problem solution and it involves defining the problem, measuring its impact, and searching for solutions. The Municipal Environmental Research Laboratory develops new and improved technology and systems for the prevention, treatment, and management of wastewater and solid and hazardous waste pollutant discharges from municipal and community sources, for the preservation and treatment of public drinking water supplies, and to minimize the adverse economic, social, health, and aesthetic effects of pollution. This publication is one of the products of that research; a most vital communications link between the researcher and the user community.

As part of these activities, this comprehensive performance evaluation of a two-cell municipal aerated lagoon wastewater treatment system was conducted to determine capabilities of this treatment mode in complying with Federal Secondary Treatment requirements.

Francis T. Mayo, Director
Municipal Environmental Research
Laboratory

ABSTRACT

Municipal aerated wastewater treatment lagoons are extensively employed throughout the United States today. Reliable long-term performance and operational data to evaluate capabilities with respect to Federal Secondary Treatment Standards, however, are generally lacking. This report presents the data collected over a one-year monitoring period at the Orange Grove Lagoon System located in Gulfport, Mississippi.

Results indicate that during the study period, the treatment system did not exceed the federal biochemical oxygen demand average monthly requirement of 30 mg/l nor the seven consecutive day limit of 45 mg/l. The stringent permit level of 15 mg/l set by the Mississippi Air and Water Pollution Control Commission, however, was exceeded in all cases. Performance with respect to federal and state suspended solids criteria was marginal. A yearly average of 30.7 mg/l TSS was reported with secondary treatment quality being exceeded three of the twelve months monitored. The system never exceeded federal or state pH criteria. Fecal coliform standards of 200 colonies/100 ml were met only during the months of January and February. Non-compliance was due to low residual chlorine levels resulting from poor design and operational control.

In addition to the parameters for which Federal Standards have been established, many others were monitored, summarized and discussed. As a result of this study, well-designed and operated, multi-celled aerated lagoons located in climates similar to those of the Gulf Coast should be capable of meeting Federal Secondary Treatment Standards. If more stringent limitations are required due to discharge into water quality limited segments additional polishing of effluent or a different treatment mode may be required.

This report was submitted in fulfillment of Grant No. R803899 by Tulane University under the partial sponsorship of the U.S. Environmental Protection Agency.

LIST OF ABBREVIATIONS

ac	- acre
Alk	- alkalinity as CaCO ₃
BOD ₅	- five day biochemical oxygen demand
cm	- centimeters
°C	- centigrade
COD	- chemical oxygen demand
m ³ /day	- cubic meters per day
DO	- dissolved oxygen concentration
FC	- fecal coliform bacteria
gal	- gallon
ha	- hectare
kg	- kilogram
kg/ha·d	- kilograms per hectare per day
l	- liter
mg	- milligram
mg/l	- milligram per liter
ml	- milliliter
MGD	- million gallons per day
NH ₃ -N	- ammonia-nitrogen
NO ₂ -N	- nitrite-nitrogen
NO ₃ -N	- nitrate-nitrogen
SCOD	- soluble chemical oxygen demand
SBOD ₅	- soluble five day biochemical oxygen demand
TKN	- total Kjeldahl nitrogen
TP	- total phosphorus
TSS	- total suspended solids
VSS	- volatile suspended solids

ACKNOWLEDGMENTS

The cooperation and assistance of Environmental Engineers/Mississippi in sample analysis and data tabulation is greatly appreciated. Particular thanks are expressed to its President, Mr. Clark Malchow, for his assistance during the gear-up and data collection phases of this study.

The cooperation of Mr. Clarence Johnson, President of Orange Grove Utilities, is also greatly appreciated.

SECTION 1

INTRODUCTION

NATURE OF THE PROBLEM

The Federal Water Pollution Control Act Amendments of 1972 established the minimum performance requirements for publicly-owned wastewater treatment facilities. By July, 1977 these treatment works should have complied with effluent limitations based on secondary treatment as defined by the Environmental Protection Agency and as published in the Federal Register. The original imposed regulations state: a) the five-day biochemical oxygen demand (BOD_5) and suspended solids (SS) shall not exceed an arithmetic mean value of 30 mg/l for effluent samples collected over a period of 30 consecutive days nor 45 mg/l for samples collected over seven consecutive days; b) the arithmetic mean of the effluent BOD_5 and SS values determined on samples collected in a period of 30 consecutive days shall not exceed 15 percent of the arithmetic mean of the BOD_5 and SS values determined on influent samples collected at approximately the same time during the same period; and c) the geometric mean of the fecal coliform bacteria in the effluent shall not exceed 200 per 100 milliliters for samples collected over a period of 30 consecutive days nor 400 per 100 milliliters for samples collected during a period of seven consecutive days.

It should be noted that this definition of secondary treatment for municipal waste treatment facilities has been and is being modified. The Federal Register Vol. 41, No. 144, Monday, July 26, 1976, for example, contains proposed changes pertaining to deletion of fecal coliform criteria and pH restrictions. The Federal Register Vol. 42, No. 195, Friday, October 7, 1977, contains changes in the effluent suspended solids limitations for small municipal lagoons (less than 2 MGD).

Because of inherent advantages of lagoon waste treatment systems, more than 4,000 publicly-owned facilities are in operation throughout the United States. Generally, lagoon treatment provides a relatively simple, inexpensive method of wastewater disposal where land costs are low. Consequently, most lagoon systems are located in rural communities where typically little, if any, performance evaluations are conducted. An Environmental Protection Agency (EPA) Task Force Committee, while recently preparing a technical bulletin of design criteria for waste treatment lagoons, uncovered very little evidence of performance evaluation with respect to design. Data obtained appeared to indicate that continuous-discharge facultative lagoons will not conform to secondary treatment requirements without upgrading, due to algal cell content during summer and icing conditions during winter.

It is anticipated that effluent quality from lagoon systems can be improved by the utilization of a mechanical oxygen supply in one or several of the cells. It is, therefore, important to determine how effectively, well-designed series operated aerated waste treatment lagoons perform throughout all seasons of the year in various climatic regions. Collection and evaluation of carefully collected operating and performance data should provide evidence as to whether existing continuous-discharge series operated aerated lagoons can, as presently designed and operated, meet proposed standards. Insight should also be provided as to how design and operational upgrading can effectively be accomplished and how lagoon system design can be optimized.

OBJECTIVES

General Objectives

The primary objective of this investigation is to generate reliable year-round performance and operational data for the Orange Grove Utilities municipal waste treatment lagoon system. The lagoons are located in North Gulfport, Mississippi and consist of two aerated lagoons in series followed by chlorination and final settling.

A secondary objective is to evaluate performance efficiency with respect to actual design criteria and the 1977 Secondary Treatment Standards as established by the Federal Water Pollution Control Act Amendments. Results of data analysis will be of assistance to design engineers and regulatory officials and to EPA in attaining its stated objective of defining performance capabilities of surface aerated lagoons located in the deep south.

Specific Objectives

To accomplish the above general objectives, the following specific objectives were fulfilled:

1. Monitor water quality of: a) lagoon influent, b) between cells-in-series, and c) lagoon effluent preceding and following chlorination over a 12 month period. A sampling frequency of 30 consecutive days, four times during the year (once during each season) and 7 consecutive days, once a month during the other 8 months of data collection was maintained.
2. Analyze performance parameters including: wastewater flow, pH, temperature, dissolved oxygen, alkalinity, total and soluble BOD₅, total suspended solids, volatile suspended solids, algal cell counts, fecal coliform counts, total and soluble COD, total phosphorus, total and soluble Kjeldahl nitrogen (TKN), total and soluble ammonia nitrogen, nitrite nitrogen, and nitrate nitrogen at locations and frequencies noted above.

3. Obtain climatological data (light intensity, air temperature, precipitation, and wind direction and intensity) for the lagoon by on site monitoring.
4. Analyze and evaluate lagoon system performance with respect to (i) criteria employed in system design, (ii) the Water Pollution Control Amendments Act of 1972 (PL 92-500) and (iii) effluent discharge standards established by the State of Mississippi.
5. Determine from data analysis whether all the significant treatment occurs in the first cell or if the second cell is necessary for adequate stabilization.

SECTION 2

CONCLUSIONS

Based on the results of 12 months of monitoring the performance of the Orange Grove Aerated Lagoon System located in Gulfport, Mississippi, the following conclusions can be made:

1. The average influent flow-rate varied from $3,425 \text{ m}^3/\text{day}$ (0.905 MGD) in July to $2,116 \text{ m}^3/\text{day}$ (0.559 MGD) in October. The yearly average influent flow-rate was $2,900 \text{ m}^3/\text{day}$ (0.766 MGD) which exceeded the hydraulic design by 1.53 times. The yearly average per capita hydraulic load to the lagoon system was $0.58 \text{ m}^3/\text{capita/day}$ (153 gal/capita/day).
2. Based on the average influent flow-rate, the average theoretical detention times of the first aeration basin (A1), the second aeration basin (A2), and the settling cell (S2) were respectively 6.8, 10.3 and 5.0 days. Design detention times were 10.4, 15.8, and 2.5 days for A1, A2, and S2 respectively.
3. The organic strength of the raw wastewater was typical of residential wastewater. An average influent biochemical oxygen demand (BOD_5) of 176 mg/l was reported over the study period. This represented a per capita loading of $0.1 \text{ kg BOD}_5/\text{capita/day}$ (0.22 lb $\text{BOD}_5/\text{capita/day}$). The monthly averages of influent BOD_5 concentration ranged from 133 mg/l to 214 mg/l.
4. The actual organic loadings to cells A1 and A2 were 504 and 117 kg $\text{BOD}_5/\text{ha}\cdot\text{d}$ (450 and 104 lb $\text{BOD}_5/\text{ac/day}$) as compared to the design loadings of 374 and 86 kg $\text{BOD}_5/\text{ha}\cdot\text{d}$ (334 and 77 lb $\text{BOD}_5/\text{ac/day}$) respectively. Hence, the system was organically overloaded during the study period.
5. Overall total BOD_5 removal averaged 85.8% through the lagoons system with an average effluent BOD of 25 mg/l. Secondary criteria of 30 mg/l (30 day monitoring) and 45 mg/l (7 consecutive day limit) was met for all months. The stringent permit level of 15 mg/l set by the Mississippi Air and Water Pollution Control Commission owing to discharge into a water quality limited segment, however, was exceeded in all cases.
6. Yearly average effluent BOD_5 from the aeration system was 50 mg/l which represents a 71.6% reduction. Hence, the final settling cell was necessary for compliance with secondary standards.

7. The monthly averages of effluent soluble BOD₅ concentrations for the lagoon system varied from 10 mg/l (February) to 22 mg/l (October), with a yearly mean of 15 mg/l. If total removal of effluent solids were possible, then state discharge limitations of 15 mg/l could be attained. Total influent BOD₅ reductions from A1, A2, and S2 were accumulatively 79.3%, 84.4%, and 91.7%. Approximately 44% of the raw wastewater total BOD₅ was soluble.
8. While most of the BOD₅ was removed in cell A1, the second cell in series provided additional polishing with reserve capacity to handle severe influent organic variation.
9. Chemical oxygen demand (COD) removal performance of the Orange Grove Lagoon System was similar to BOD₅ reduction trends. Monthly averages of final effluent concentrations ranged from 51 mg/l in July to 89 mg/l in November, with a yearly mean level of 66 mg/l. Approximately 62% of the influent COD was removed by the treatment system.
10. Soluble COD removal paralleled that of total COD reduction. Residual effluent soluble COD ranged from 32 to 56 mg/l with a mean level of 40 mg/l. With complete effluent solids separation, 88% of the raw wastewater COD would be stabilized. About 31% of the raw wastewater total COD was soluble.
11. The raw wastewater influent suspended solids (TSS) level was typical of domestic wastewater. Monthly averages of influent suspended solids concentrations ranged from 117 mg/l in October to 291 mg/l in January with a yearly average of 194 mg/l.
12. Final effluent monthly averages of suspended solids concentration varied from 16 mg/l in October to 50 mg/l during February. A yearly average of 31 mg/l TSS was reported which is near the regulatory limit of 30 mg/l. Sampling results for the 30 day monitoring periods were 32 mg/l (January), 34 mg/l (April), 27 mg/l (July), and 19 mg/l (September). Only during the month of February was the 45 mg/l seven day average value exceeded.
13. Effluent solids from the settling pond were primarily algae cells. Algae growth following chlorination was enhanced due to the relatively long retention in cell S2 of 5 days. Effluent BOD₅ associated with the solids content was approximately 0.33 mg BOD₅/mg TSS.
14. Volatile suspended solids (VSS) results were similar to suspended solids removal trends. Both influent and effluent TSS exhibited a 70% volatile content. System volatile solids reduction averaged 84.2% with about 73% being removed in the first cell. Data indicates effluent BOD₅ associated with the volatile suspended solids as approximately 0.5 mg BOD₅/mg VSS.

15. The aerated lagoon system was effective in the removal or conversion of ammonia nitrogen ($\text{NH}_3\text{-N}$). A yearly average reduction of 63% with a mean residual of 5.5 mg/l was reported. During the summer total $\text{NH}_3\text{-N}$ removal averaged 79% with a mean residual of 2.7 mg/l. The soluble $\text{NH}_3\text{-N}$ content represented approximately 92% of the total $\text{NH}_3\text{-N}$ concentration at all sampling locations.
16. Reduction trends of total Kjeldahl Nitrogen (TKN) followed those for ammonia nitrogen. A yearly overall system reduction of 62.4% was observed with an average residual of 9.8 mg/l. Effluent TKN concentrations ranged from 5.8 mg/l in March to 13.2 mg/l during October. Effluent limitations as imposed by the Mississippi Air and Water Pollution Control Commission limit TKN levels to 6.0 mg/l with a maximum of 12.0 mg/l. The system violated the average criteria eleven of the twelve months studied. The soluble fraction accounted for approximately 73-83% of the TKN.
17. The average monthly level of nitrite from the aeration ponds ranged from 0.04 mg/l (November) to 1.73 mg/l (February) with a yearly mean of 0.61 mg/l. The average monthly concentration of nitrate ranged from 0.12 mg/l (September) to 6.50 mg/l (March) with a yearly mean of 2.36 mg/l. Nitrification, however, was inhibited during the period July through November due to low oxygen content (<2 mg/l).
18. Significant removal of the total phosphorous (TP) was not observed during the study period. Approximately 15.4% of the TP was removed within the aeration cells with a total system removal of 30.8%. The yearly mean effluent level was 7.5 mg/l with average monthly ranges of 6.1 mg/l (December) to 10.0 mg/l (November).
19. Federal and state fecal coliform standards of 200 colonies/100 ml were met only during the months of January and February. Non-compliance was due to the low residual chlorine levels maintained. Chlorination was effected prior to the final settling basin with a 5 day retention. A more efficient chlorination chamber and reduced retention in cell S2 along with better operational control should result in compliance to standards.
20. Mean algae cell concentrations for A1, A2, and S2 were 155,600, 220,600, and 119,000 cells/ml respectively. The lower levels found in the effluent are due in part to chlorination prior to the final settling basin. No apparent seasonal trends were noted.
21. Mean yearly alkalinity concentrations indicated a decrease with increased treatment. Average concentrations were 139 mg/l, 116 mg/l, 100 mg/l, and 97 mg/l as CaCO_3 for raw influent, A1 effluent, A2 effluent, and S2 effluent respectively. An overall average system alkalinity reduction of 30% was reported.
22. Measurements of temperature, pH, and dissolved oxygen (DO) were obtained on grab samples in situ and therefore represent instantaneous values which depend on the time of day the analyses were performed.

The value of effluent pH ranged from 6.8-7.5 during the study which falls within the secondary treatment criteria of 6.5 to 9.0 and state limits of 6.0 to 7.8.

23. Seasonal variation in performance for most of the parameters monitored was insignificant due to the mild climatic conditions characteristic of the deep South.
24. For climates similar to those of the Gulf Coast, well-designed and operated, multi-celled aerated lagoons appear capable of providing small municipalities with a treatment method able to comply with Federal Secondary Treatment Standards. If more stringent limitations are required due to discharge into water quality limited segments additional polishing of effluent or a different treatment mode may be required.

SECTION 3

RECOMMENDATIONS

Based on the results of 12 months of intense monitoring of the Orange Grove aerated lagoon facility, the following recommendations are proposed:

1. Secondary treatment standards were consistently exceeded with respect to fecal coliform content. It is recommended that a study be made to determine the most effective chlorination procedure. The relative impact of chlorination prior to and following the settling cell should be assessed as well as the effect of detention time on re-growth.
2. Suspended solids compliance with standards was marginal. The effect of the settling cell detention time on solids removal and algae growth should be investigated.
3. A performance comparison between second cell aeration versus no aeration should be made. A second cell (or cells) acting as a stabilization pond(s) may reduce energy consumption and improve overall treatment.
4. Additional research into simple, cost effective removal of algae cells from lagoon effluent should be conducted.
5. Operational procedures to optimize aerated lagoon system performance should be developed.

SECTION 4

ORANGE GROVE UTILITIES AEROBIC LAGOON SITE DESCRIPTION

The lagoon system studied is owned by Orange Grove Utilities and is located in Harrison County, Mississippi approximately eight miles north of Gulfport. The municipal treatment system services a community consisting of residential homes, shopping centers, etc. from a population of approximately 5,000. The continuous-flow lagoons have been in operation for approximately twelve years. The system was originally designed as multi-celled stabilization lagoons operated in series. Eight years ago the first cell was upgraded to an aerated lagoon. During July, 1975 a change in operation of the lagoon system from a series to parallel flow arrangement was implemented. Additionally, floating aerators were added to the second lagoon and each of the two aerated lagoons was followed by less than a twenty-four hour retention settling basin. The operational change was instituted as an upgrading procedure to meet state requirements when additional house connections were made to the sewer system. During October 1975, prior to the initiation of this study the flow configuration was reverted back to series operation for subsequent testing and evaluation.

A schematic of the existing lagoon system is presented in Figure 1. A brief description of the lagoon system follows:

1. CELL A1---AERATED FACULTATIVE LAGOON

- a. Size: 63 m X 163 m (206 ft X 535 ft)
- b. Area: 1.0 ha (2.5 acres)
- c. Depth: 1.9 m (6.3 ft)
- d. Volume: 19,682 m³ (5.2 MG)
- e. Flow: 1892 m³/day (500,000 GPD) design
- f. Detention time: 10 days (design)
- g. Hydraulic loading: 185 mm/day (7.3 in/day) design
- h. Organic loading: 374 kg/ha·d (334 lbs BOD₅/ac/day) design
- i. Flow pattern: plug flow
- j. Aeration equipment: 8 Welles surface aerators 3.73 kw/aerator (5 hp/aerator)
- k. Power level: 1.5 X 10⁻³ kw/m³ (7.7 hp/MG)
- l. Dikes: unlined with 3:1 slopes
- m. Flow measurement: Martig BHB 1 unit with a 38 cm (15 in) sensing ring calibrated to a Bristal G500 recorder
- n. Inlet: two 25 cm (10 in) diameter C.I. pipes (parallel - 0.61 m) extending 10.7 m (35 ft) into the lagoon (above water)

2. CELL A2---AERATED FACULTATIVE LAGOON

- a. Size: 124 m X 126 m (407 ft X 412 ft)
- b. Area: 1.5 ha (3.8 acres)
- c. Depth: 1.9 m (6.3 ft)
- d. Volume: 29,902 m³ (7.9 MG)
- e. Flow: 1892 m³/day (500,000 GPD) design
- f. Detention time: 15.8 days (design)
- g. Hydraulic loading: 121 mm/day (4.8 in/day) design
- h. Organic loading: 86 kg/ha·d (77 lb BOD₅/ac/day) design
- i. Flow pattern: plug flow
- j. Aeration equipment: 9 Welles surface aerators 5.59 kw/aerator (7.5 hp/aerator)
- k. Power level: 1.67 X 10⁻³ kw/m³ (8.5 hp/MG)

3. CHLORINATION

- a. Chlorinated prior to discharge into settling Cell S2
- b. Chlorination equipment: auto switch over type 45 kg/d-meter (100 lb/d meter)

4. CELL S2---SETTLING BASIN

- a. Size: 29 m X 63 m (95 ft X 205 ft)
- b. Area: 1809 m² (19,475 ft²)
- c. Depth: 1.8 m (6.0 ft)
- d. Volume: 3293 m³ (0.87 MG)
- e. Flow: 1324 m³/day (350,000 GPD) design
- f. Detention time: 2.5 days (design)
- g. Dikes: unlined with 3:1 slopes

As shown in Figure 1, overall system performance was based on the quality of effluent from Cell S2 and hence Cells S1, S3, and S4 were not included in the study evaluation.

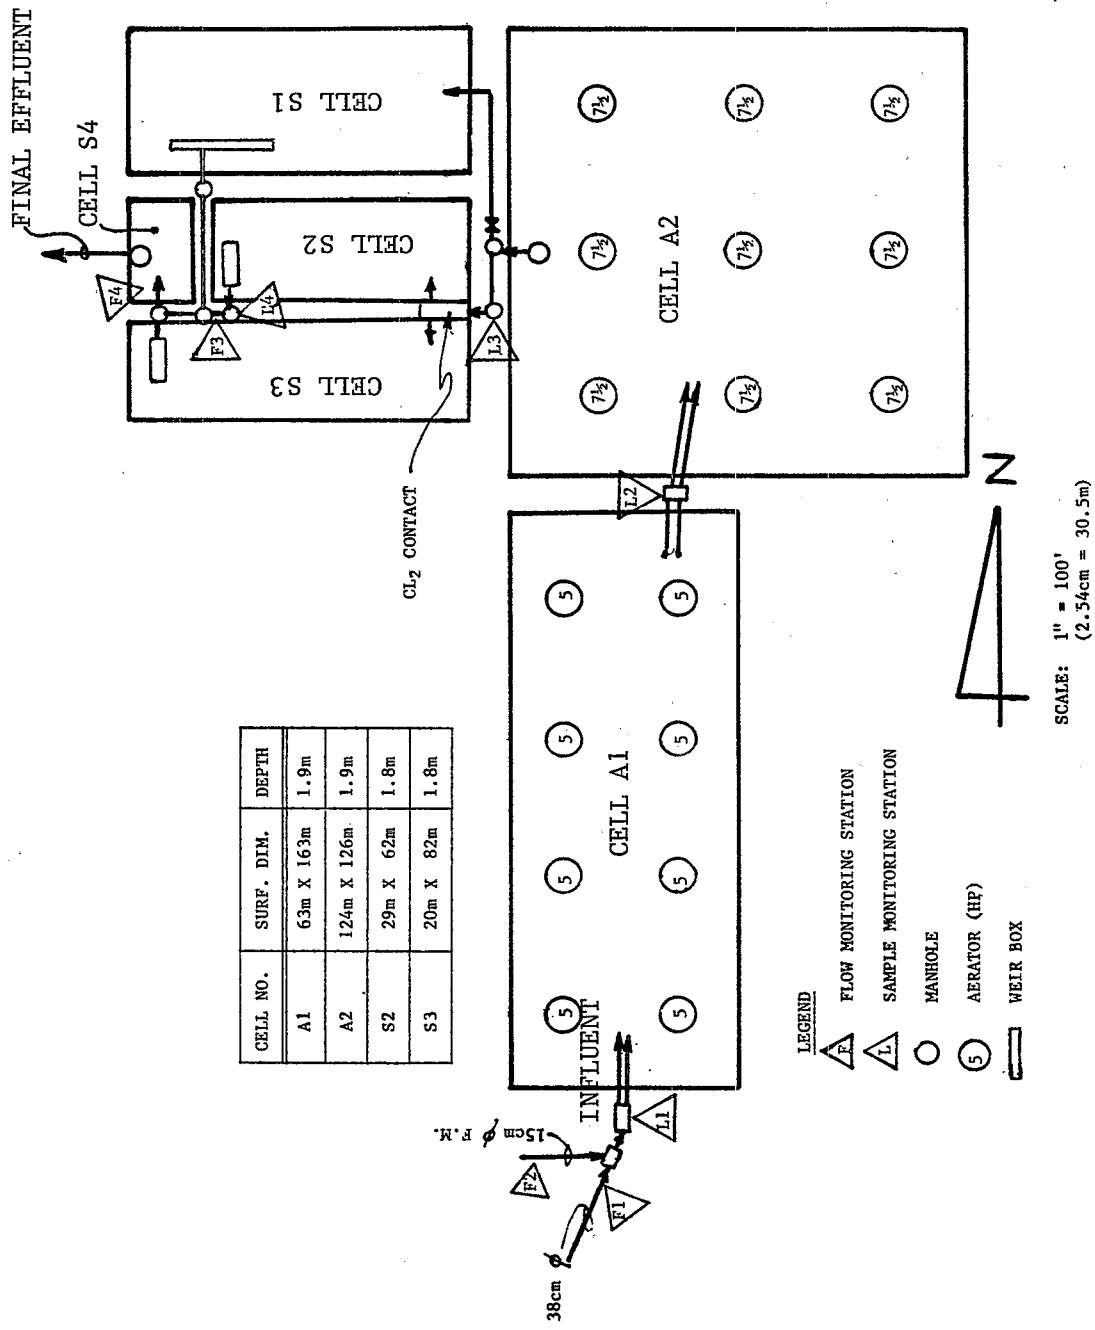

Figure 1. Aerated Lagoon Flow Plan.

SECTION 5

EXPERIMENTAL PROCEDURES

SAMPLE COLLECTION AND ANALYSIS

Performance monitoring of the Orange Grove Lagoon System commenced during the month of December, 1975 and continued over a twelve month period. Monitoring locations for both flow and water quality parameters are shown on Figure 1.

The analytical and sampling program is outlined in Table 1. Testing procedures and sample preservation were in accordance with those outlined in the 13th Edition of Standard Methods for the Examination of Water and Wastewaters¹ or as modified according to EPA techniques².

Water quality parameter sampling locations included: 1) lagoon influent, 2) between cells-in-series, 3) lagoon effluent prior to chlorination, and 4) lagoon effluent after sedimentation. The sampling frequency was 30 consecutive days four times during the year (once during each season) and 7 consecutive days, once a month during the other eight months of data collection. Thirty days sampling reflected performance during the months of January, April, July, and September.

Performance parameters monitored included: wastewater flow, pH, temperature, dissolved oxygen, alkalinity, total and soluble BOD₅, total suspended solids, volatile suspended solids, algal cell counts, fecal coliform counts, total and soluble COD, total phosphorus, total and soluble Kjeldahl nitrogen (TKN), total and soluble ammonia nitrogen, nitrite nitrogen, and nitrate nitrogen. Measurement of wastewater temperature, pH, and dissolved oxygen were made in situ. All other samples (except fecal coliform and algal cell counts) were 24 hour composites. An ISCO Model 1680 sequential sampler was employed at the influent location and samples were composited according to flow. ISCO Model 1580 samplers were used at the other locations (L2, L3, L4). Samplers were iced except when the ambient air temperature was below 7.2°C (45°F).

Hydraulic Data

Influent flow (F1) was measured using a Martig BUB 2 unit with a 38 cm (15 in.) sensing ring calibrated to a Bristol G500 continuous recorder (See Figure 1.). After calibration for pumping rate, the lift station was monitored (F2) for on-off times. Effluent from aeration cell A2 was split between three settling cells. Flow rates percentages for cells S1, S2, and S3 were 8.5%, 23.2% and 68.3% MGD respectively. Total system effluent flow was mea-

sured at Station F4. These latter two flows were monitored with 30.5 cm (12 in.) sensing rings and a Martig BUB 3 unit connected to a Bristol G500 recorder. All flow measurements were recorded as depth of flow and converted to gallons per minute prior to sample compositing.

Auxiliary Monitoring Information

Information on electrical usage for the aeration equipment and maintenance time records during the test period was recorded. Pertinent meteorological data such as air temperatures (high, average, and low), light intensity, rainfall, wind velocity and prevailing direction were recorded daily. Air temperatures and wind data were obtained from the nearby Gulfport, Mississippi airport. Rainfall was measured with a conventional rain gauge located on-site. Solar radiation was also monitored on-site using a R401-Mechanical Pyranograph.

TABLE 1. SAMPLING AND ANALYTICAL SCHEDULE

PARAMETER	SAMPLE LOCATION			
	Lagoon Influent (L1)	Between Cells of Lagoon System (L2)	Lagoon Effluent (L3)	After Chlorination and Clarification (L4)
Daily Flow-Total, Min and Peak	x			x
pH	x	x	x	x
Water Temp	x	x	x	x
DO	x	x	x	x
Alkalinity	x	x	x	x
Total BOD ₅	x	x	x	x
Soluble BOD ₅	x	x	x	x
Total Suspended Solids	x	x	x	x
Volatile Suspended Solids	x	x	x	x
Total COD	x	x	x	x
Soluble COD	x	x	x	x
Total P	x	x	x	x
TKN (Total & Sol)	x	x	x	x
NH ₄ ^{+-N} (Total & Sol)	x	x	x	x
NO ₂ ^{-N}		x	x	x
NO ₃ ^{-N}		x	x	x
Algae Cell Count*	x	x	x	x
Fecal Coliforms		x	x	x
Chlorine Residual			x	x

All parameters monitored daily during stated consecutive sampling program.

*Counted one day during the 7 consecutive day sampling periods and three days each a week apart during the 30-day consecutive sampling periods.

SECTION 6

RESULTS

Performance data collected during this investigation are reported on a monthly basis and tabulated in Appendix A. Auxiliary monitoring information including electrical usage and pertinent meteorological information is presented in Appendix B. Results of the study are shown in Tables 2 through 13 where monthly average, median, and range values for performance parameters are listed. These results will be discussed in Section 7. Characteristics of wastewater influent and effluents from the aeration cells and settling basin were monitored at points L1, L2, L3, and L4 respectively (see Figure 1).

SECTION 7

DISCUSSION OF RESULTS

GENERAL

This section will discuss monitoring results with respect to design criteria and the ability of the system to comply with secondary treatment discharge standards as well as those specified by the Mississippi Air and Water Pollution Control Commission. The influence of seasonal variation on performance will be noted where applicable. Monthly and yearly mean values of parameters are presented to illustrate long term trends and variations.

As illustrated by Figure 1 sampling points L1, L2, L3, and L4 correspond to quality characteristics of raw wastewater influent, effluent from Pond 1, effluent from Pond 2 prior to chlorination, and final effluent from the settling Cell S2, respectively.

Data collected at the Orange Grove Lagoon site reflected performance of a small, series operated aerated lagoon system located in the deep South treating essentially all residential wastewater. A complete listing of all data collected during the study period of December 1975 through November 1976 is contained in Appendix A and Appendix B.

HYDRAULIC PERFORMANCE

The monthly average influent and effluent daily flow-rates are shown in Table 14 and graphically illustrated by Figure 2. Effluent flows were monitored from Cell S2 which received approximately twenty-three percent of the flow from the second aeration basin. During January, 1976 an additional flow meter was installed at location F4 (see Figure 1) to allow for a system flow mass balance. Total effluent flow measurement commenced in February and continued for the remainder of the study. The average monthly daily influent flow-rate varied from 3,425 m³/day (0.905 MGD) in July to 2,116 m³/day (0.559 MGD) in October. The yearly average influent flow-rate was 2,900 m³/day (0.766 MGD). This calculates as a per capita hydraulic load to the lagoon system of approximately 0.58 m³/person/day (153 gal/capita/day). The yearly average influent daily flow-rate exceeded the hydraulic design flow-rate of 0.5 MGD by 1.53 times. During low and high flow months, the design flow was exceeded by 1.12 and 1.81 respectively.

The data indicates significant infiltration and inflow into the sewer system. This is evidenced by Figure 2 showing peak influent flows occurring during the rainy summer period (May-August) which is typical of the Gulf Coast climate. High ground water and sandy soil conditions contribute greatly to

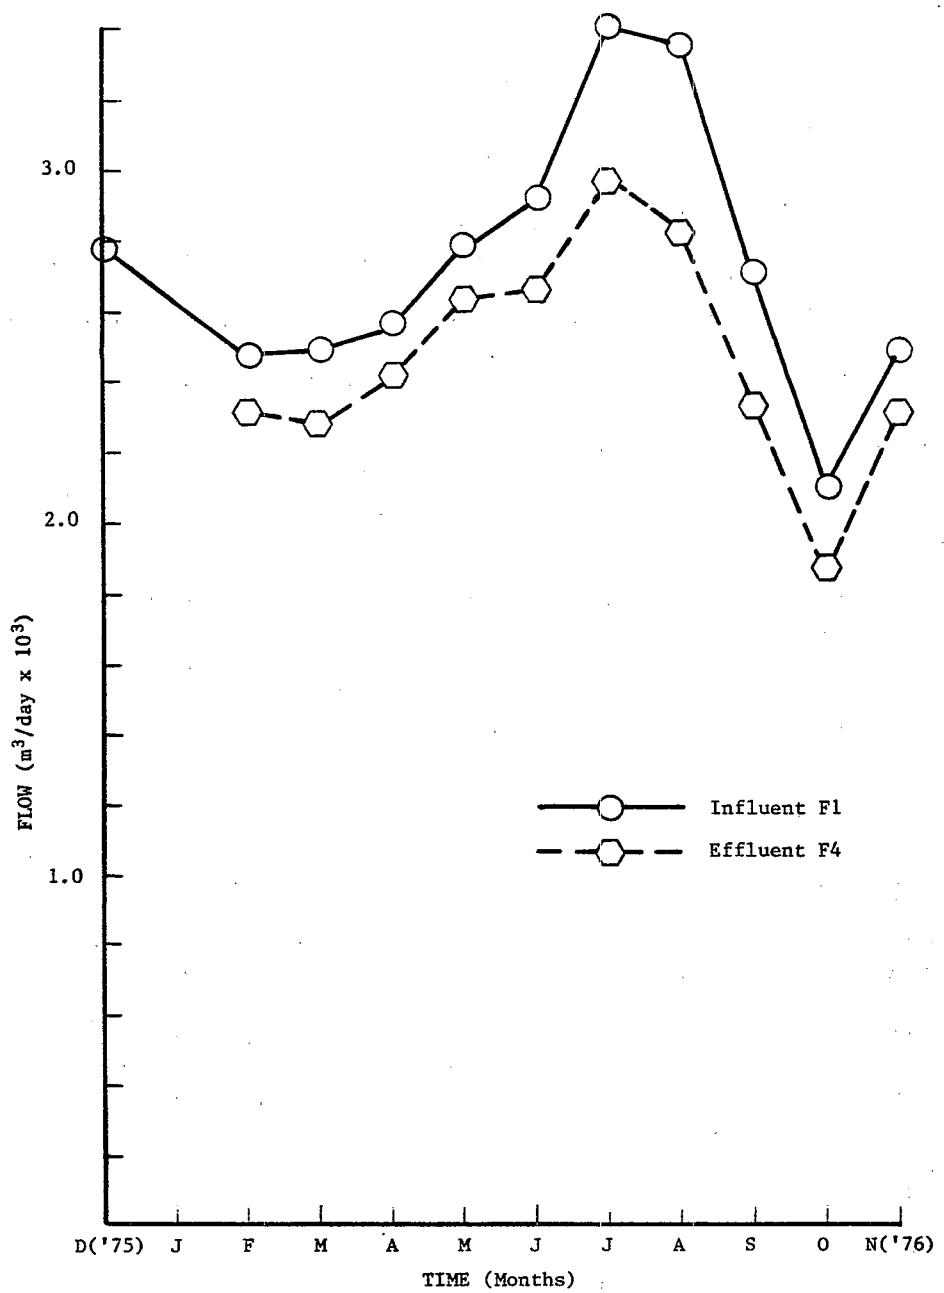

Figure 2. Monthly average influent and effluent daily flowrates.

the problem of infiltration.

TABLE 14. MONTHLY AVERAGE FLOW-RATE OF RAW WASTEWATER INFLUENT AND FINAL EFFLUENT FROM THE ORANGE GROVE AERATED LAGOON SYSTEM

MONTH	INFLUENT	EFFLUENT	Flow-rate ($m^3/day \times 10^3$) - monthly average	PERCENT LOSS
December '75	2.790	-		-
January	3.259	-		-
February	2.483	2.316	6.7	
March	2.509	2.323	7.4	
April	2.574	2.430	5.6	
May	2.800	2.665	4.8	
June	2.926	2.684	8.3	
July	3.425	2.983	12.9	
August	3.369	2.843	15.6	
September	2.737	2.358	13.8	
October	2.116	1.877	11.3	
November '76	2.506	2.332	6.9	
YEARLY MEAN	2.900	2.535	10.0	

Based on the average influent flow-rate, the average theoretical detention times of Cells A1, A2, and S2 are respectively 6.8, 10.3 and 5.0 days. Accounting for losses due to evaporation and seepage retention times were increased approximately five to sixteen percent as shown by Table 14. Design detention times were 10.4, 15.8 and 2.5 days respectively for Basins A1, A2, and S2. Consequently, stabilization time was reduced approximately 35% during average influent flow conditions and 45% during the peak flow period.

ORGANIC REMOVALS

Organic removal efficiency for the lagoon system was assessed in terms of total and soluble BOD_5 and COD reductions.

Total Biochemical Oxygen Demand (BOD_5)

The monthly average total BOD_5 values observed at each sampling location are reported in Table 15 and illustrated in Figure 3.

The influent monthly average total BOD ranged from a maximum of 214 mg/l during January to a minimum of 133 mg/l in July. Low flow months were characterized by higher concentrations as compared to the diluted influent observed during the wet summer months. This trend existed for most performance parameters evaluated.

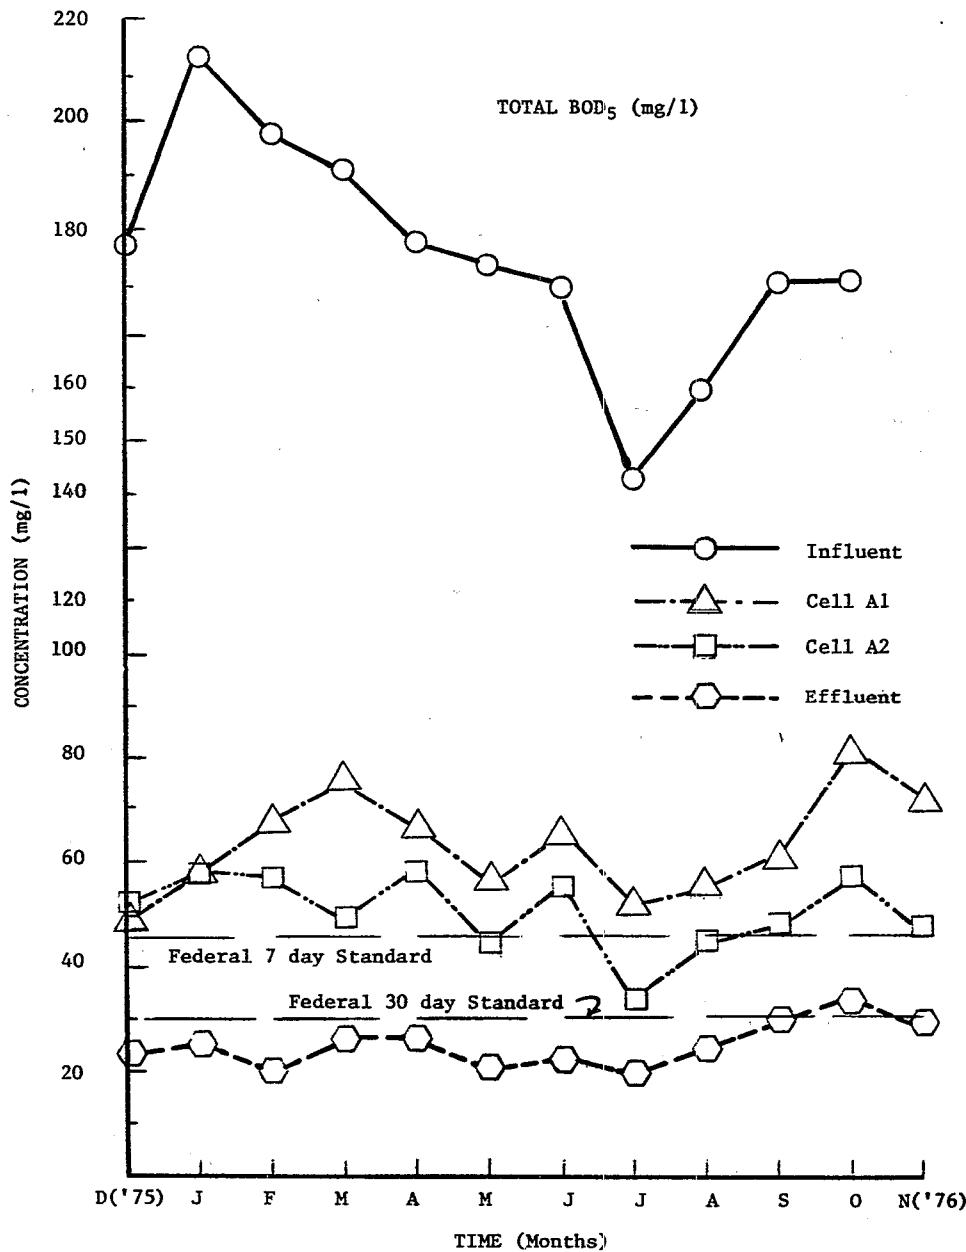

Figure 3. Monthly average total Biochemical Oxygen Demand (BOD_5) removal for the Orange Grove Lagoon System.

TABLE 15. MONTHLY AVERAGE TOTAL BIOCHEMICAL OXYGEN DEMAND CONCENTRATION OF THE RAW WASTEWATER INFLUENT AND THE EFFLUENT FROM EACH CELL IN THE ORANGE GROVE AERATED LAGOON SYSTEM

MONTH	Total biochemical oxygen demand (mg/l) - monthly average			
	INFLUENT	CELL A1	CELL A2	EFFLUENT
December '75	177	49	53	24
January	214	59	59	26
February	198	68	57	20
March	192	76	50	25
April	178	67	59	26
May	175	58	45	21
June	171	66	56	23
July	133	53	34	20
August	151	56	45	25
September	170	62	48	30
October	171	82	58	34
November '76	206	73	47	29
YEARLY MEAN	176	62	50	25

A weighted average influent BOD_5 was calculated as 176 mg/l over the study period. This represents a per capita raw waste loading of 0.1 kg BOD_5 /person/day (0.22 lb BOD_5 /person/day). The actual organic loading to Pond A1 was 504 kg BOD_5 /ha·d (450 lb BOD /ac/day) compared to the design loading of 374 kg BOD_5 /ha·d (334 lb BOD /ac/day). During the study Cell A1 was therefore overloaded by approximately 26%. Cell A2 which was designed for an organic loading of 86 kg BOD_5 /ha·d (76.8 lb/ac/day) experienced an actual loading of 117 kg BOD_5 /ha·d (104 lb/ac/day).

Calculations based on weighted monthly average values indicate a 64.7% reduction in Cell A1 with an additional 18.8% removal in Cell A2. The settling Cell S2 accounted for a 49.6% reduction of its incoming BOD_5 .

Overall total BOD_5 removal averaged 71.4% through the two lagoons with an average effluent total BOD_5 of 25 mg/l. As shown by Table 15 and Figure 3 secondary criteria of 30 mg/l (30 day monitoring) and 45 mg/l (7 consecutive day limit) was met for all months. The stringent permit level of 15 mg/l BOD_5 set by the Mississippi Air and Water Pollution Control Commission owing to discharge into a water quality limited segment, however, was exceeded in all cases. It should be noted that without incorporation of a final settling cell to remove suspended solids, secondary treatment quality effluent would have been unattainable. As shown in Figure 3 effluent organic concentrations were relatively unaffected by seasonal fluctuations. The great buffer capacity of the lagoon system to reduce influent variability is also reflected by

Figure 3. While most of the BOD_5 is removed in Cell A1, the second cell in series provides additional polishing with reserve capacity to handle influent organic variation.

Soluble Biochemical Oxygen Demand

The monthly average effluent soluble BOD_5 concentrations for each sampling location are reported in Table 16 and shown graphically in Figure 4. The monthly average effluent soluble BOD_5 for the entire system varied from 10 mg/l (February) to 22 mg/l (October), with a yearly mean of 15 mg/l. This value is 42.5% less than the total effluent BOD_5 observed. Thus, if total effluent solids were removed by some polishing process an overall BOD_5 removal of 91.7% would be realized over the study period with effluent BOD_5 concentrations less than the state requirement of 15 mg/l being reported for six of the twelve months studied. Total to soluble BOD_5 accumulative removals of 79.3%, 84.4%, and 91.7% were found for Cells A1, A2, and S2 respectively.

The importance of the second aeration cell is better demonstrated by reviewing soluble BOD_5 removals. Approximately 25% of the influent soluble BOD_5 was stabilized by Cell A2 with effluent quality meeting secondary standards 8 out of 12 months (yearly average 28 mg/l). The importance of the settling cell in terms of soluble organic removal is emphasized by Figure 4.

TABLE 16. MONTHLY AVERAGE SOLUBLE BIOCHEMICAL OXYGEN DEMAND CONCENTRATION OF THE RAW WASTEWATER INFLUENT AND THE EFFLUENT FROM EACH CELL IN THE ORANGE GROVE AERATED LAGOON SYSTEM

Soluble biochemical oxygen demand (mg/l) - monthly average

November '76	119	42	28	17
YEARLY MEAN	78	36	28	15

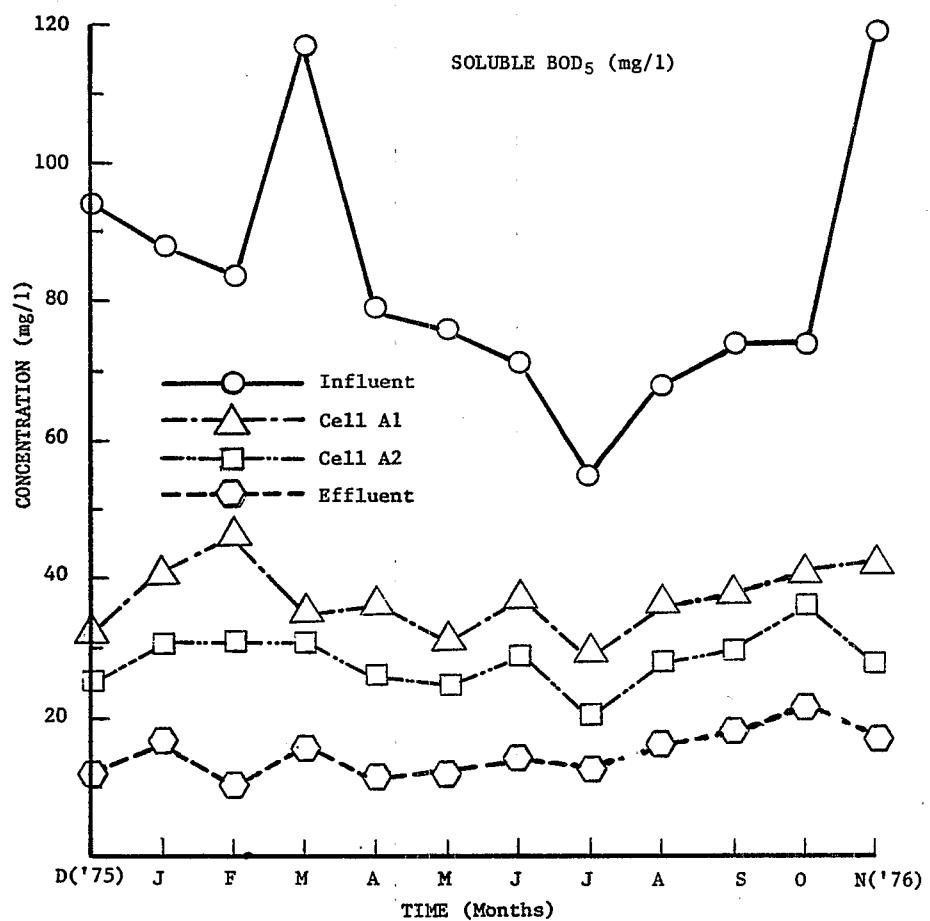

Figure 4. Monthly average soluble BOD₅ removal for the Orange Grove Lagoon System.

Removal trends were similar to those observed for total BOD reductions with little or no seasonal correlation. Soluble influent BOD accounted for approximately 45% of the total. There exists no federal or state discharge standards for soluble BOD₅.

Total Chemical Oxygen Demand (TCOD)

The monthly average total COD values observed at each sampling location are shown in Table 17 and Figure 5. The influent monthly average total COD ranged from a maximum of 510 mg/l in December to a minimum of 164 mg/l during October. Generally, higher concentrations were experienced during the low flow winter months. A weighted average influent total COD of 332 mg/l was reported during the study period. Accumulative total COD reductions were 71.5%, 76.2%, and 80.1%, respectively for Cells A1, A2, and S2. These relatively high COD reductions accounted for an average system effluent concentration of 66 mg/l. As with the BOD₅ data, almost all organic reduction occurs in Cell A1 with Cells A2 and S2 providing some additional polishing and variability reductions. Seasonal fluctuations in effluent quality does not appear significant.

TABLE 17. MONTHLY AVERAGE TOTAL CHEMICAL OXYGEN DEMAND (COD) CONCENTRATION OF THE RAW WASTEWATER INFLUENT AND THE EFFLUENT FROM EACH CELL IN THE ORANGE GROVE AERATED LAGOON SYSTEM

MONTH	Total chemical oxygen demand (mg/l) - monthly average			
	INFLUENT	CELL A1	CELL A2	EFFLUENT

November '76	324	108	86	89
YEARLY MEAN	332	95	79	66

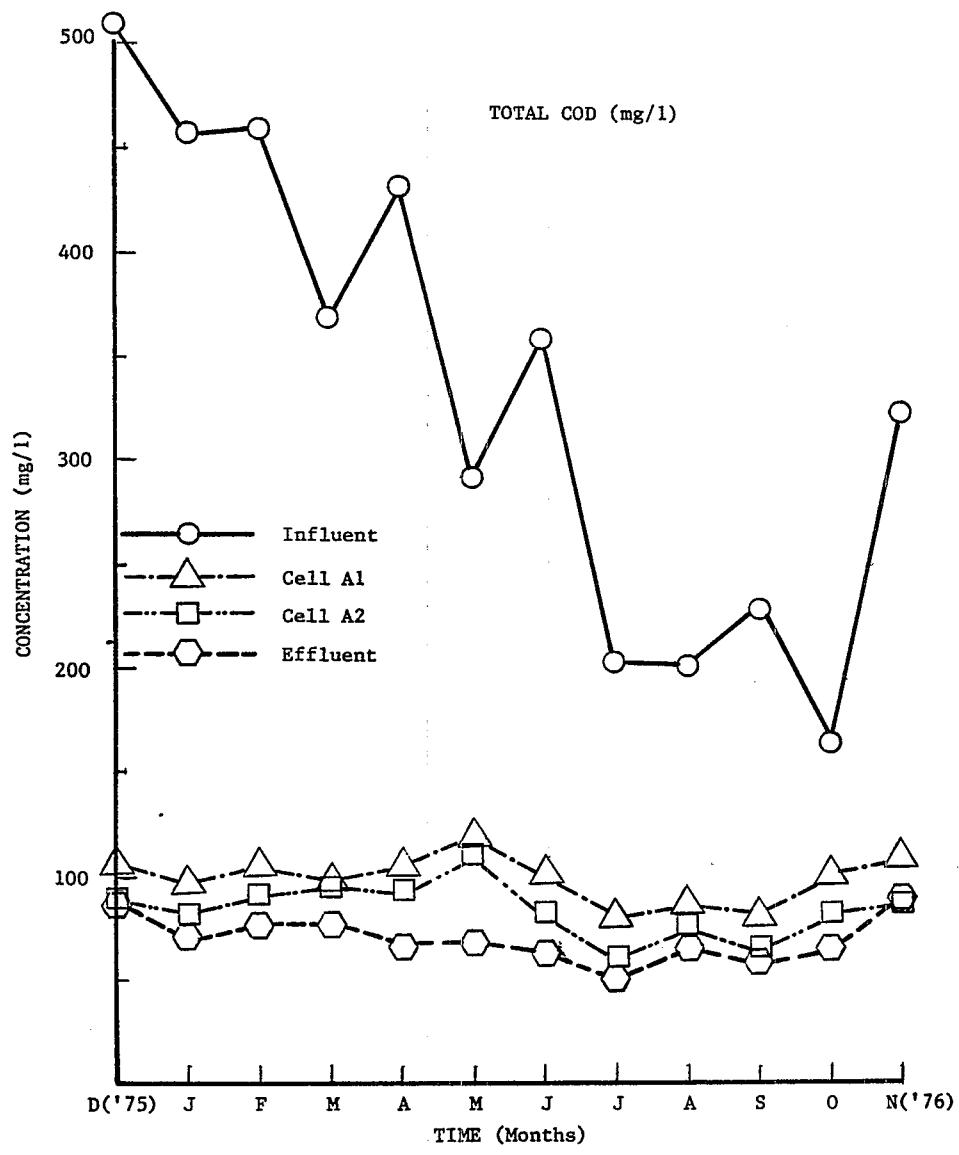

Figure 5. Monthly average total Chemical Oxygen Demand (COD) removal for the Orange Grove Lagoon System.

Soluble Chemical Oxygen Demand (SCOD)

The monthly average effluent soluble COD concentrations for each cell is shown in Table 18 and Figure 6. The average soluble COD influent concentration of 103 mg/l represents 31% of the influent total COD. Removal trends followed those observed for total COD. Accumulative soluble COD reductions for Cells A1, A2, and S2 were 48.8%, 59.5%, and 61.5%, respectively. Residual effluent soluble COD ranged from 32 to 56 mg/l with a mean of 40 mg/l. If complete solids separation was achieved, COD removal (total influent to soluble effluent) would approach 88%. Due to the long residence time employed by the lagoon system higher COD reductions are generally experienced as compared to activated sludge or trickling filter treatment methods. There currently exists no federal or state discharge requirements for COD effluent levels for the Orange Grove Lagoon System.

SOLIDS REMOVAL

Results of total and volatile solids reduction by the lagoon system is discussed as follows.

TABLE 18. MONTHLY AVERAGE SOLUBLE CHEMICAL OXYGEN DEMAND (SCOD)
LEVELS OF THE RAW WASTEWATER INFLUENT AND THE EFFLUENT
FROM EACH CELL IN THE ORANGE GROVE AERATED LAGOON SYSTEM

Soluble chemical oxygen demand (mg/l) - monthly average

YEARLY MEAN	103	53	42	40

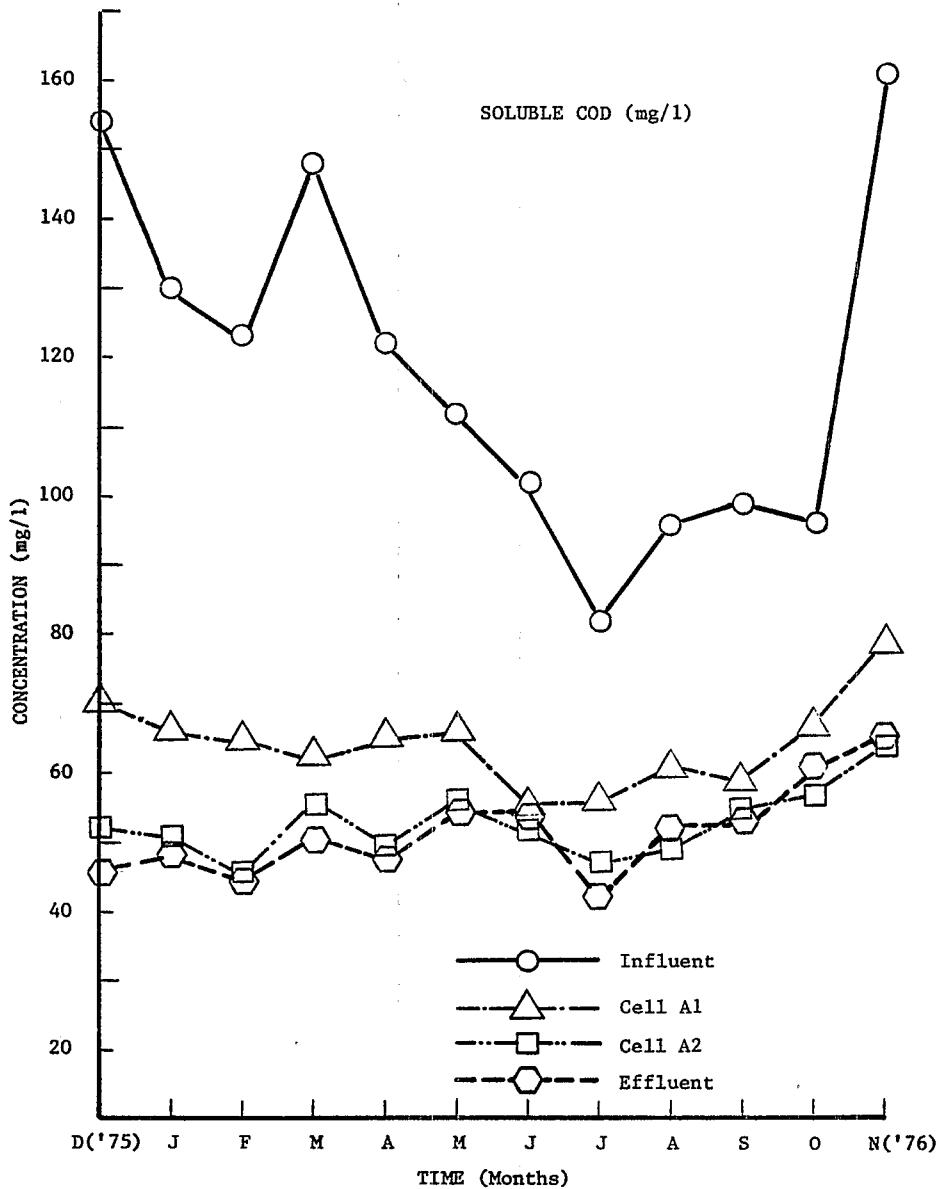

Figure 6. Monthly average soluble COD removal for the Orange Grove Lagoon System.

Total Suspended Solids (TSS)

The monthly average total suspended solids concentrations for raw sewage influent and lagoon effluents are presented in Table 19 and Figure 7.

The monthly average raw sewage influent suspended solids concentration ranged from 291 mg/l in January to 117 mg/l in October. The yearly average level was 194 mg/l which is representative of typical domestic sewage. A wide variation of TSS concentrations was experienced during the study period as shown by Figure 7.

The final effluent monthly average suspended solids concentration varied from 16 mg/l in October to a high of 50 mg/l during February. A yearly average of 31 mg/l TSS was observed which is near the regulatory limit of 30 mg/l. Sampling results for the 30 day monitoring periods indicated 30 day average values of 32, 34, 27, and 19 mg/l for respective months of January, April, July, and September. Only during the month of February was the 45 mg/l seven day average value exceeded.

Data indicates an overall 84.1% reduction of TSS with about 74% removal occurring in the first lagoon. This data is somewhat misleading, however, since effluent solids from the lagoon system were primarily algae cells. The settling pond was effective in reducing the influent TSS by about 31%. While this cell was designed for a 2.5 day detention period at a flow of 1325 m³/day

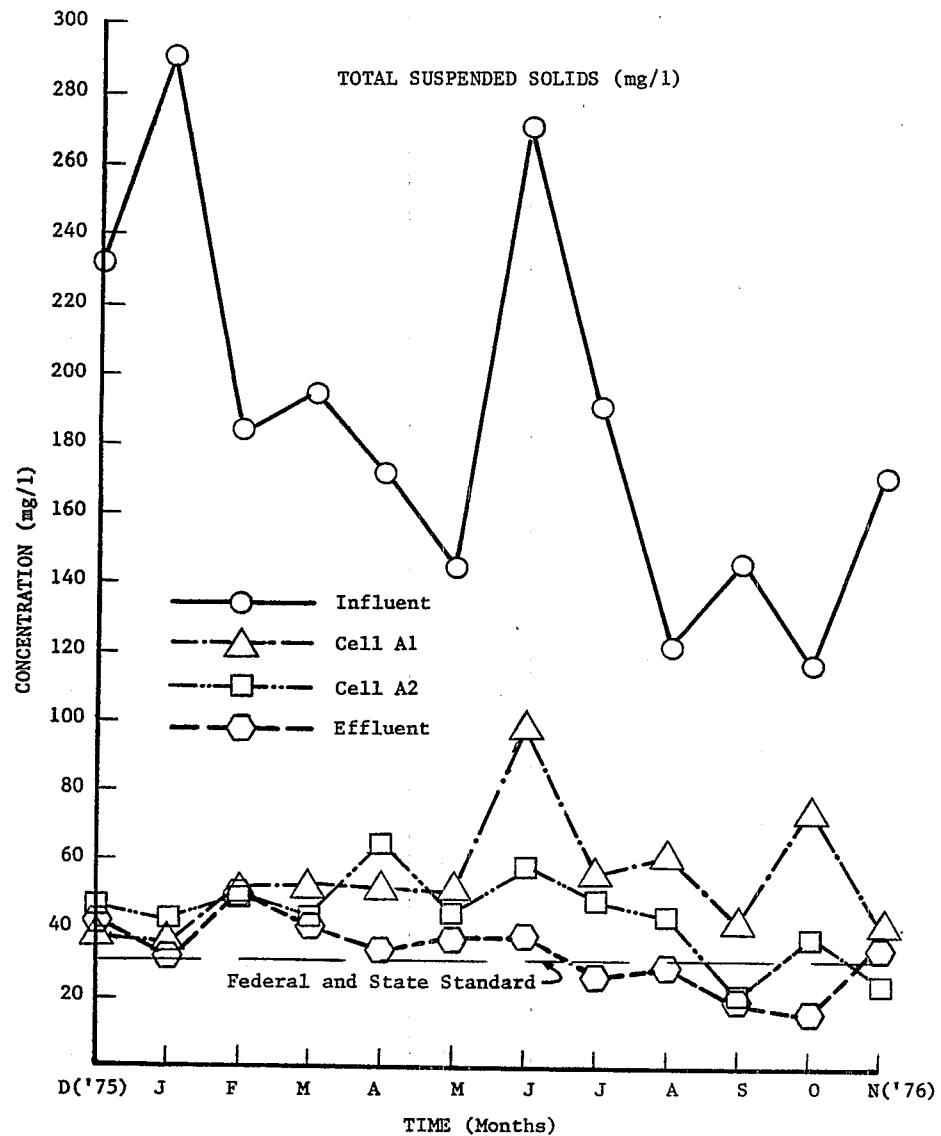

Figure 7. Monthly average total suspended solids removal for the Orange Grove Lagoon System.

(350,000 gpd), operation during the study resulted in an actual flow of about 674 m³/day (178,000 gpd). Actual detention time in settling Cell S2, then was almost 5 days which tended to enhance algae growth.

Volatile Suspended Solids (VSS)

The monthly average effluent volatile suspended solids (VSS) concentrations observed at each sampling station are reported in Table 20 and graphically illustrated in Figure 8. Trends are similar to those for TSS previously discussed. Both influent and effluent TSS exhibited a 70% volatile content. System volatile solids reduction averaged 84.2% with about 73% being removed in the first cell. Data indicates approximately 0.35 mg BOD₅/mg TSS or about 0.5 mg BOD₅/mg VSS. Currently, no state or federal discharge limitations have been established for effluent VSS levels.

NUTRIENT REMOVAL

Lagoon system performance in terms of nutrient removal was assessed by monitoring concentrations of ammonia, total Kjeldahl, nitrite, and nitrate nitrogens and total phosphorus. Results are discussed as follows:

TABLE 20. MONTHLY AVERAGE VOLATILE SUSPENDED SOLIDS CONCENTRATION OF THE RAW WASTEWATER INFLUENT AND THE EFFLUENT FROM EACH CELL IN THE ORANGE GROVE AERATED LAGOON SYSTEM

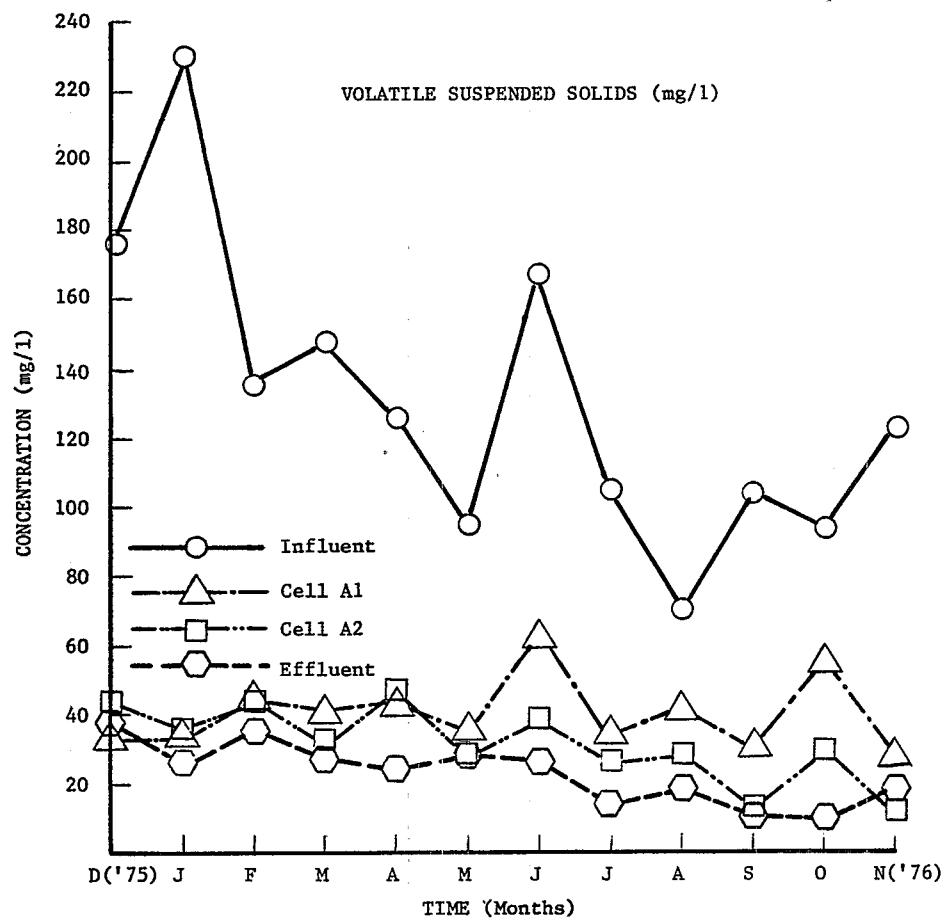

Figure 8. Monthly average volatile suspended solids removal for the Orange Grove Lagoon System.

Ammonia Nitrogen (NH₃-N)

Tables 21 and 22 tabulate respectively average monthly total and soluble ammonia concentrations observed at sampling locations during the study period. Results are also graphically illustrated in Figures 9 and 10.

The total ammonia influent concentration ranged from a high of 20.0 mg/l in November (low flow) to a low of 11.6 mg/l during July (high flow period) with a yearly weighed mean of 15.0 mg/l. The soluble NH₃-N content represented approximately 92% of the total concentrations at all sample locations. Consequently, complete removal of solids would not result in significant additional ammonia reductions. As shown by Figures 9 and 10 very high removals were affected within the first cell during summer months (June through August). NH₃-N assimilation by the biomass during this time was greatest due to temperature influence on metabolic rates. During the summer total NH₃-N removal averaged 79% with an average residual of 2.7 mg/l. Increases in total and soluble NH₃-N levels, however, were noted following both the second aeration cell and settling basin for the months of June through November. This may be attributable to the higher temperatures increasing benthic decomposition rates of settled sludge solids and algae cells with subsequent feedback of ammonia to the overlying waters. Chlorination following sampling location L3 may have resulted in algae cell death with release of NH₃-N into solution.

August	16.3	0.7	2.8	4.6
September	13.1	5.7	5.7	5.6
October	12.6	0.7	5.8	8.8
November '76	17.6	7.0	9.2	8.9
YEARLY MEAN	13.9	7.4	4.7	5.1

Effluent levels of both total and soluble ammonia were lowest during the period from February through August. A low of 0.9 mg/l $\text{NH}_3\text{-N}$ was observed for March and a high of 9.9 mg/l total $\text{NH}_3\text{-N}$ was reported during October. The yearly average system reduction was 63.7% with a residual of 5.5 mg/l. No effluent limits for total or soluble ammonia nitrogen exists for the Orange Grove facility.

Kjeldahl Nitrogen (KN)

Kjeldahl nitrogen is composed of both organic and ammonia nitrogen. The numerical difference between the Kjeldahl nitrogen and $\text{NH}_3\text{-N}$ concentrations yields the organic nitrogen level in a given sample. Both total and soluble average monthly Kjeldahl nitrogen concentrations observed during the study are presented in Tables 23 and 24 respectively. Results are shown graphically in Figures 11 and 12.

The average influent TKN recorded over the twelve months of data collection was 26.2 mg/l with a range of 20.6 mg/l (July) to 30.4 mg/l (April). The soluble fraction accounted for approximately 73% of the TKN at all locations except the final effluent which was characterized by an 83% soluble contribution.

Removal trends followed those for $\text{NH}_3\text{-N}$ with significant reductions in Cell A1 during June, July, and August as expected. Also, as with $\text{NH}_3\text{-N}$ data, slight increases were observed during these months in the effluent from Cell A2. Lowest effluent concentrations were found during the period from February

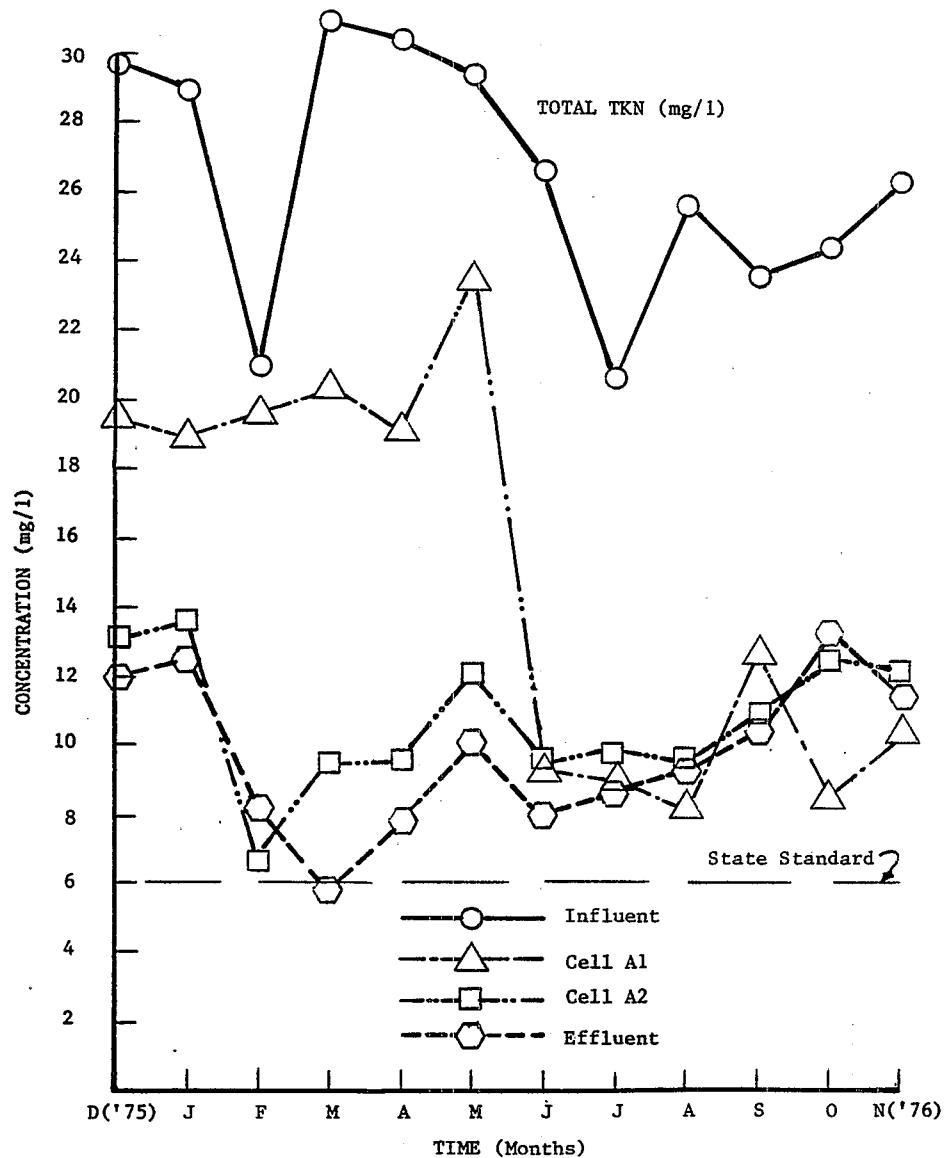

Figure 11. Monthly average total Kjeldahl nitrogen removal for the Orange Grove Lagoon System.

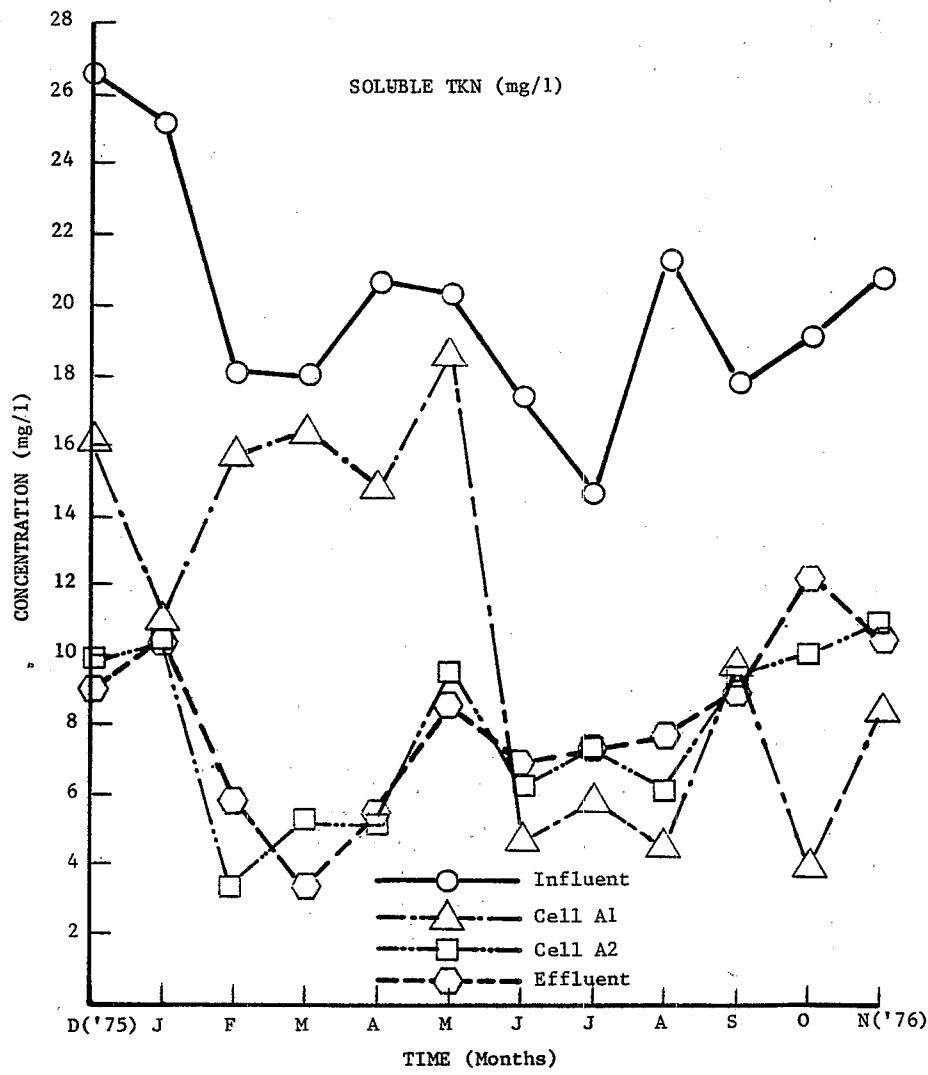

Figure 12. Monthly average soluble Kjeldahl nitrogen removal for the Orange Grove Lagoon System.

through August. Average effluent Kjeldahl nitrogen content was 9.8 and 8.1 mg/l respectively for total and soluble concentrations. These represent overall system reductions of 62.4% and 59.0%. Effluent limitations as imposed by the Mississippi Air and Water Pollution Control Commission limit TKN levels to 6.0 mg/l. Consequently, the system violated this criteria eleven of the twelve months studied.

Nitrite and Nitrate Nitrogen (NO_2 & NO_3 -N)

Lagoon system performance as indicated by nitrite and nitrate levels is summarized in Table 25 and Figure 13. Nitrite nitrogen is an intermediate which is quickly oxidized to the nitrate species. The presence of these forms indicate the activity of specific bacterial population (Nitrosomonas and Nitrobacter respectively) and the relative stability of the effluent. As shown by Figure 13 highest concentrations of both NO_2 and NO_3 were observed from February through March. It would be expected, however, that highest levels would be experienced during summer months when metabolic activity of the nitrifiers is greatest. If one examines the data, one notes oxygen concentrations in Cell A2 to be less than or equal to about 2 mg/l for the months of July through November. Hence nitrification was inhibited during this period due to low oxygen content. If higher dissolved oxygen levels were provided, it is anticipated that nitrite and nitrate levels would have increased with concurrent decreases in TKN and NH_3 -N concentrations.

Total Phosphorus

Mean monthly total phosphorus concentrations, measured as P, recorded during the study period are presented in Table 26 and Figure 14. Influent concentrations ranged from a high of 12.4 mg/l in March to a low of 6.8 mg/l during July. The average yearly influent phosphorus concentration was reported as 9.1 mg/l. Approximately 15.4% of the total phosphorus was removed within the aeration cells with a total system removal of 30.8% being observed. The average effluent level was 7.5 mg/l. Removal efficiencies were relatively unaffected by seasonal variation. Removal is attributable to phosphorus assimilation by micro and macroorganisms within the treatment system.

FECAL COLIFORM

Study results for fecal coliform reductions are listed in Table 27 and graphically illustrated by Figure 15. Fecal coliform concentrations from Cell A2 prior to chlorination were relatively low during the winter period (December-March) and then increase rapidly. Only during January and February did S2 effluent counts indicate compliance with Federal and State standards of 200 colonies/100 ml. Non-compliance was due to low residual chlorine levels maintained.

As previously noted chlorination was affected prior to the final settling basin where residual chlorine was monitored. The actual average detention time during the study in Cell S2 was about five days. Hence maintaining a

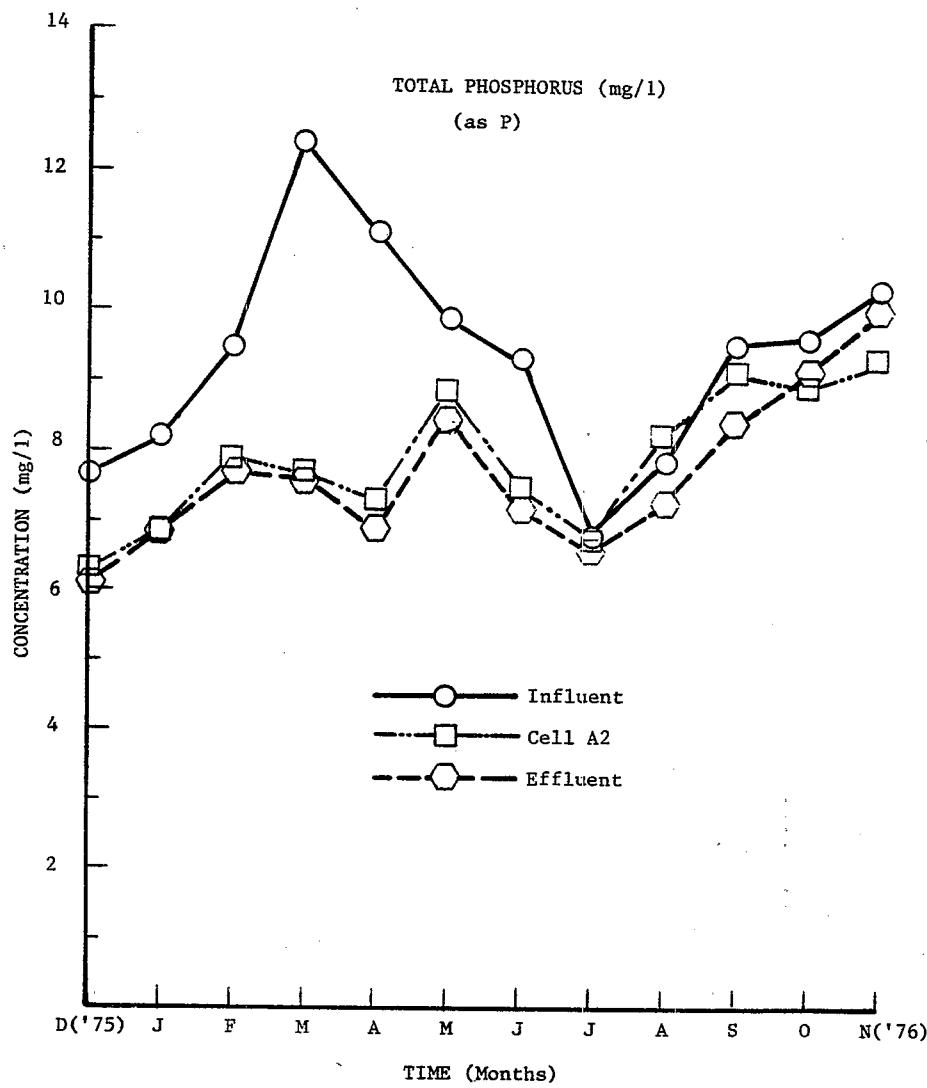

Figure 14. Monthly average total phosphorus removal for the Orange Grove Lagoon System.

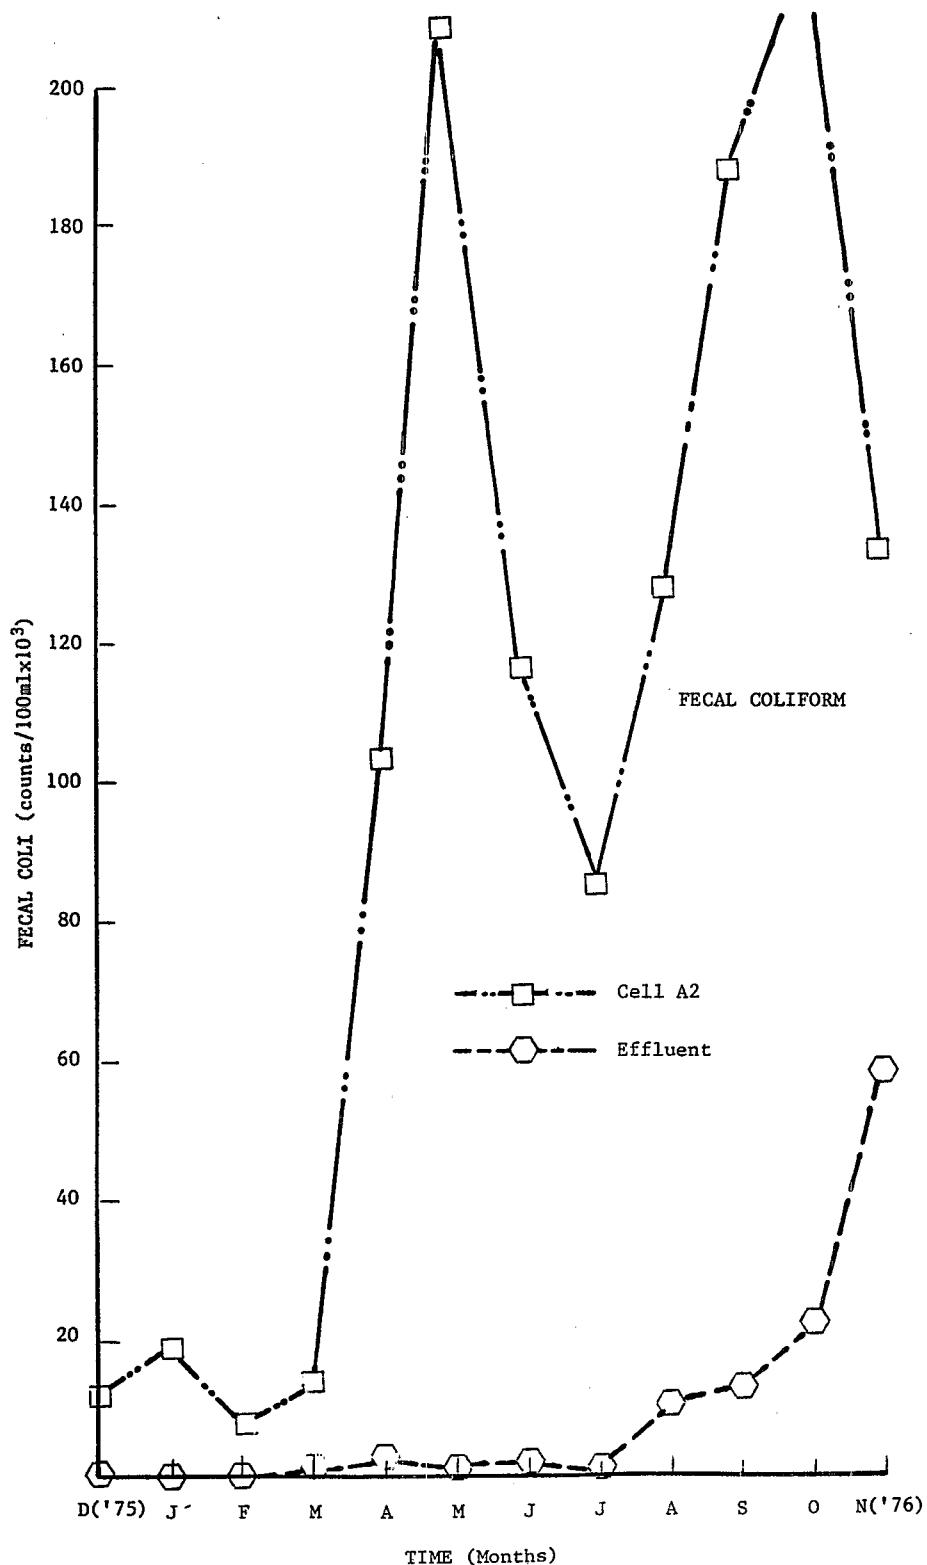

Figure 15. Monthly geometric mean fecal coliform removals for the Orange Grove Lagoon System.

high effluent residual was very difficult. Equipment malfunctions also contributed to these low residuals.

A more efficient chlorination chamber and reduced retention in Cell S2 along with better operational control should result in compliance to fecal coliform standards.

TABLE 27. MONTHLY GEOMETRIC MEAN FECAL COLIFORM COUNT (#/100 ml) OF THE EFFLUENT FROM CELLS A2 AND S2 IN THE ORANGE GROVE AERATED LAGOON SYSTEM

ALGAE

Mean monthly algae cell counts for the effluents from each aeration basin and final settling cell are presented in Table 28 and Figure 16. As indicated the highest counts were recorded in the second aeration cell except during the months of October and November when greater counts were observed in Cell A1. Mean algae cell concentrations for A1, A2, and S2 were 155,600, 202,600, and 119,000 cells/ml respectively. The lower levels found in the effluent are due in part to chlorination prior to the final settling basin. No apparent seasonal trends were noted.

ALKALINITY

The average monthly alkalinity (as CaCO_3) of the raw wastewater influent and effluent from each cell is presented in Table 29 and Figure 17.

Alkalinity is a measure of the buffer capacity of a given water. It consists of carbonate, bicarbonate, and hydroxide components. The amount and forms present will be a function of bacterial and algae activity, pH, and the

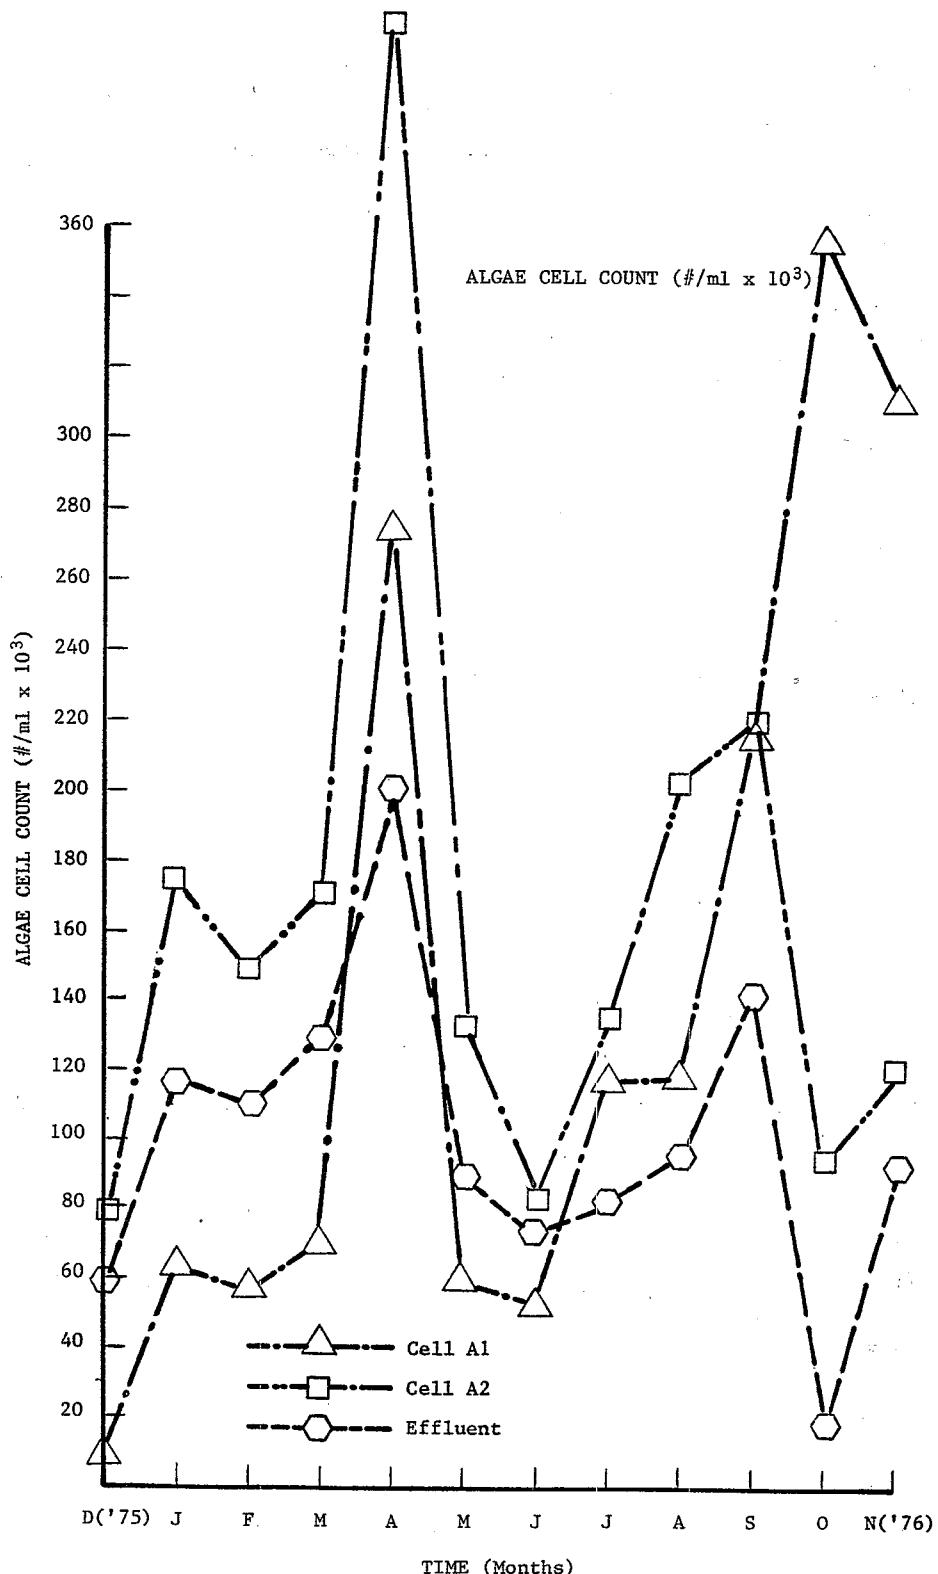

Figure 16. Monthly average algae cell count for the Orange Grove Lagoon System.

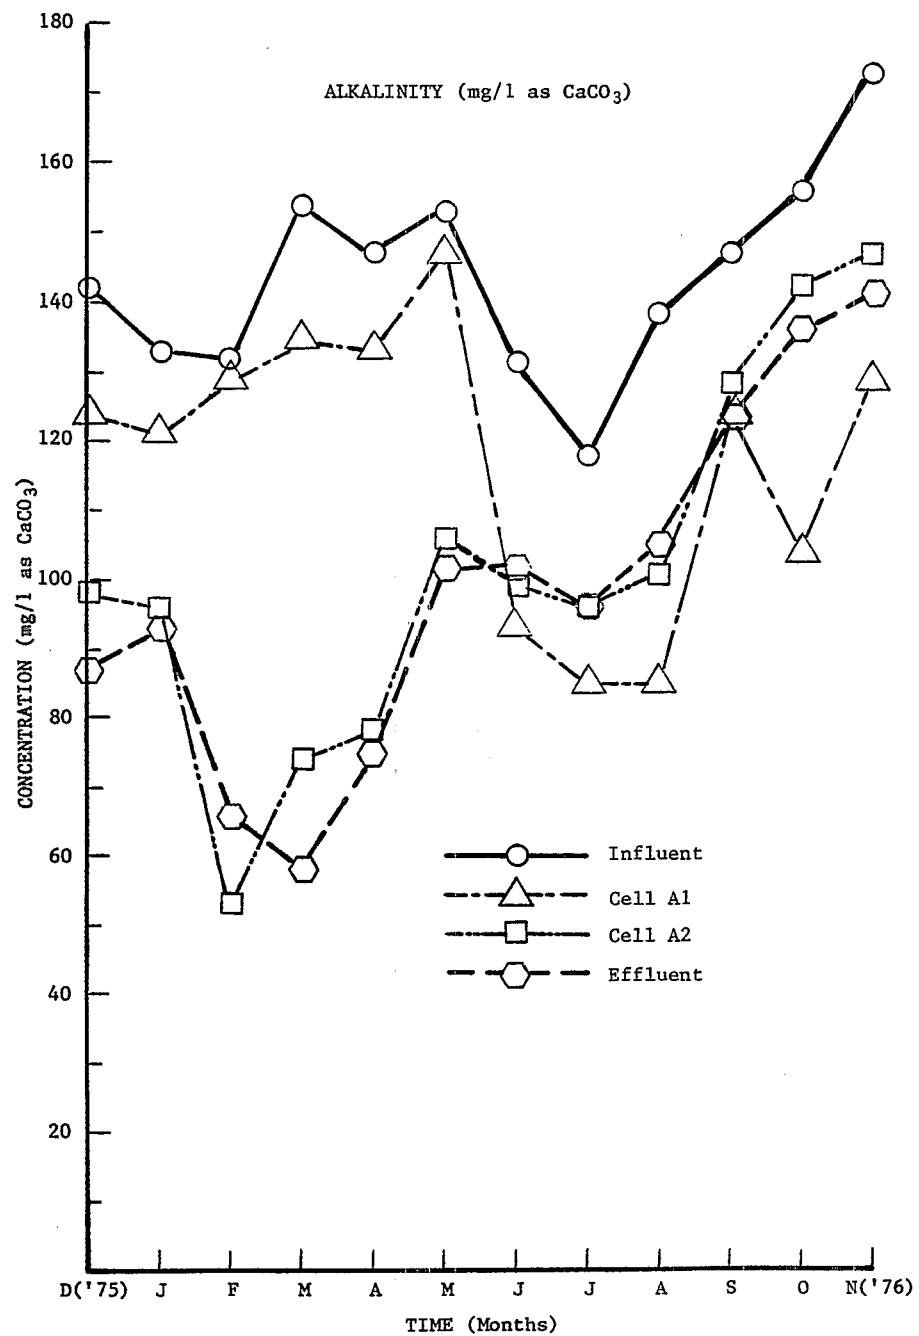

Figure 17. Monthly average alkalinity concentrations for the Orange Grove Lagoon System.

chemical composition of the sample. Mean concentrations observed for the Orange Grove Lagoon System were 140 mg/l, 117 mg/l, 101 mg/l and 98 mg/l as CaCO₃ for raw influent, A1 effluent, A2 effluent, and S2 effluent respectively. An overall average system alkalinity reduction of 30.1% was calculated from the collected data. Lowest values were observed during July through August for the first aeration cell where bacterial activity (and hence CO₂ production) was greatest. Alkalinity content was significantly reduced during the winter months in Cells A2 and S2. Commencing in July, an increasing trend in alkalinity content was noted for all cells which corresponded with raw influent observations.

TEMPERATURE, pH, AND DISSOLVED OXYGEN (DO)

Due to significant diurnal variations measurements of temperature, pH, and dissolved oxygen were made in situ. Values, therefore, reflect the time at which sampling was performed.

Temperature

The average monthly and yearly temperatures observed at each sampling location in the Orange Grove Lagoon System are reported in Table 30.

TABLE 30. MONTHLY AVERAGE TEMPERATURE OF THE RAW WASTEWATER INFLUENT AND THE EFFLUENT FROM EACH CELL IN THE ORANGE GROVE AERATED LAGOON SYSTEM

MONTH	Temperature °C - monthly averages			
	INFLUENT	CELL A1	CELL A2	EFFLUENT
December '75	19.7	12.3	10.7	10.9
January	18.6	13.7	12.0	12.0
February	19.4	19.2	19.2	18.8
March	16.6	15.6	15.6	15.3
April	21.9	21.8	21.8	21.4
May	23.7	23.0	23.0	22.4
June	26.1	27.7	28.0	26.9
July	27.0	29.0	29.0	28.0
August	28.3	29.4	28.9	28.1
September	28.0	27.0	26.0	25.0
October	26.4	24.3	24.0	23.6
November '76	17.7	18.0	19.0	18.0
YEARLY MEAN	23.4	22.3	21.8	21.2

As expected the highest temperatures were observed during the summer months of July - September with the lowest being recorded during December and January. These winter months also experienced the greatest temperature drop through the treatment system (an 8.8°C loss). Average yearly temperature values were 23.4, 22.3, 21.8, and 21.2°C for the wastewater influent and effluents from Cell A1, A2, and S2, respectively. These results do not indicate a significant change through the system.

pH

Monthly medians and ranges of pH for the raw wastewater and cell effluents are given in Table 31. As indicated, little pH variation was observed between sampling locations. Seasonal trends were also negligible. The influent pH ranged from 6.8-7.5; whereas, the effluent ranged from 6.8-7.5. Thus, the system was in compliance with secondary standards of 6.5 to 9.0 and state limits of 6.0 to 7.8.

Dissolved Oxygen (DO)

The average monthly and yearly average DO concentration for the wastewater influent and lagoon contents are given in Table 32. Respective DO levels for influent and Cells A1, A2, and S2 were 0.6, 2.8, 3.8 and 2.8 mg/l. Influent DO was generally less than 1 mg/l as expected. Highest pond DO values occurred in December and January when temperatures and biological activity were lowest. The operation period of July - November was characterized by low lagoon DO contents (<2.5 mg/l) which resulted in inhibition to nitrification. This phenomena was particularly evident in the final aeration cell A2 and settling basin S2.

4. TITLE AND SUBTITLE PERFORMANCE EVALUATION OF THE AERATED LAGOON SYSTEM AT NORTH GULFPORT, MISSISSIPPI		5. REPORT DATE March 1980 (Issuing Date)
7. AUTHOR(S) Andrew J. Englande, Jr.		6. PERFORMING ORGANIZATION CODE
9. PERFORMING ORGANIZATION NAME AND ADDRESS Department of Environmental Health Sciences Tulane University School of Public Health and Tropical Medicine New Orleans, Louisiana 70112		8. PERFORMING ORGANIZATION REPORT NO.
12. SPONSORING AGENCY NAME AND ADDRESS Municipal Environmental Research Laboratory--Cin., OH Office of Research and Development U.S. Environmental Protection Agency Cincinnati, Ohio 45268		10. PROGRAM ELEMENT NO. 1BC822, SOS #3, Task D-1/26
		11. CONTRACT/GRANT NO. R-803899
15. SUPPLEMENTARY NOTES Project Officer: Ronald F. Lewis (513) 684-7644		13. TYPE OF REPORT AND PERIOD COVERED Final - 8/1/75 to 7/31/77
16. ABSTRACT This report from the Department of Environmental Health Sciences of Tulane University presents the data collected over a one-year monitoring period at the Orange Grove Lagoon System located in Gulfport, Mississippi.		14. SPONSORING AGENCY CODE EPA/600/14
Results indicate that during the study period the treatment system did not exceed the federal biochemical oxygen demand average monthly requirement of 30 mg/l nor the seven consecutive day limit of 45 mg/l. The stringent permit level of 15 mg/l set by the Mississippi Air and Water Pollution Control Commission, however, was exceeded in all cases. A yearly average of 30.7 mg/l of Total Suspended Solids was recorded. The system never exceeded federal or state pH criteria. Fecal coliform standards of 200 colonies/100 ml were met only during the months of January and February. Non-compliance was due to low residual chlorine levels resulting from poor design and operational control. Other parameters were monitored, summarized, and discussed.		
From the results, well designed and operated multi-celled aerated lagoons in similar climates should be capable of meeting the Federal Secondary Treatment Standards. Additional polishing may be required if there are more stringent limitations imposed for discharge into water quality limited receiving waters.
