DISCLAIMER

This report has been reviewed by the Environmental Research Laboratory, U.S. Environmental Protection Agency, Athens, Georgia, and approved for publication. Approval does not signify that the contents necessarily reflect the views and policies of the U.S. Environmental Protection Agency, nor does mention of trade names or commercial products constitute endorsement or recommendation for use.

FOREWARD

ABSTRACT

Samples of 63 effluent and 22 intake waters were collected from a wide range of chemical manufacturers in areas across the United States. The samples were analyzed for organic compounds in an effort to identify previously unknown and potentially hazardous organic pollutants. Each water sample was preconcentrated for analysis of organic compounds in four fractions: volatile organics by helium-gas stripping and semivolatile organics by extraction with methylene chloride resulting in separate neutral, acidic and basic fractions. All sample analyses involved a GC/MS/COMP system that used high-resolution glass capillary GC columns. Organic constituents were identified using the computerized Biemann mass spectral matching system together with some manual interpretation and quantified using GC-FID peak area determinations.

Over 570 compounds were tentatively identified of which 33 are priority pollutants. Generally, industrial effluents contained few priority pollutants. Most of the components found in the effluents were specific for a particular industrial site and did not appear in reoccurring patterns. The data suggest that many possible environmentally important compounds would be overlooked if frequency of occurrence is the major criterion for determining environmentally significant compounds.

We recommend that future studies concentrate on basic compound analyses and that the biological activity of a compound(s) be established first before exhaustive screening programs are initiated for environmental pollutants. Mass spectral data bases containing all the organic compounds produced by industry should be developed.

This report was submitted in fulfillment of Contract No. 68-01-4350 by Battelle, Columbus Laboratories, under the sponsorship of the U.S. Environmental Protection Agency. This report covers the period September 30, 1976, to November 30, 1978, and work was completed as of September 30, 1978.

ACKNOWLEDGMENT

Battelle's Columbus Laboratories and the project team members express their appreciation to Ann Alford and Dr. Wayne Garrison of the Environmental Research Laboratory, USEPA, Athens, Georgia, and to Dr. Vincent DeCarlo of EPA's Office of Toxic Substances for helpful recommendations concerning site selection and analytical protocols. Gratitude is also expressed to the regional USEPA offices whose cooperation facilitated the process of locating sampling sites.

INTRODUCTION

There has been an increasing concern in recent years that man and his environment are being exposed to unknown industrial pollutants which may represent significant hazards. One approach to assessing the potential hazards involves a detailed chemical characterization of waste effluents. The objective of this program was the identification and quantification of organic compounds present in representative industrial final aqueous effluents. The information obtained will help the U.S. Environmental Protection Agency in its efforts in determining the health and environmental effects of industrial effluents, determining transport and degradation mechanisms, developing and assessing monitoring and control technology, and assessing wastewater disposal permits.

Priority was given to major industrial activities that were most apt to have significant amounts of organic compounds in their final aqueous effluents. Four different fractions from each effluent sample were analyzed by gas chromatography (GC) and gas chromatography-mass spectrometry (GC-MS) procedures. The fractions were acidic and neutral volatiles, neutral semi-volatiles, acidic semivolatiles, and basic semivolatiles.

The program was designed as a cursory survey of wastewater effluent samples. A computerized mass spectral search system was used as the basis for compound identifications. High-resolution glass capillary GC columns were used to obtain the best possible mass spectra from the GC/MS/COMP systems. Because of the large number of samples, this program provided for only limited manual mass spectral interpretation.

CONCLUSIONS AND RECOMMENDATIONS

The conclusions and recommendations concerning this project are divided into three categories: (1) those which deal with the analytical protocol used in this program; (2) those which deal with the analytical results obtained; and (3) those concerned with the design of future studies for detecting environmentally significant pollutants.

ANALYTICAL PROTOCOL

- Stringent quality assurance protocols, such as those established for this program, must be followed during the performance of each analysis. Particularly important are instrument calibration (GC/MS/COMP), process and field blanks, uniformity of capillary GC system performance and recovery of representative standard compounds from spiked samples.
- Capillary column GC/MS for volatile analysis was demonstrated in this program to be a sensitive and specific method suitable for routine work. The improved resolution of the capillary column (compared to packed columns) provides well resolved peaks which result in cleaner mass spectra and thus more certain identification of the various volatile compounds. However, capillary columns are not the answer for every analytical problem.
- Basic priority pollutants were not found in the industrial effluents using SE-30 glass capillary columns. Benzidine and 3,3'-dichlorobenzidine could only be detected reliably at levels of greater than 50 µg/l with our method. Consequently, if lower detection limits are necessary for benzidine analysis, more suitable methods should be used. One such method is the electrochemical detection of benzidines following HPLC separation.
- Mass spectral and relative retention time data bases containing most, if not all, of the organic compounds produced by industry should be developed. Present data bases contain mass spectra of less than 20% of the presently manufactured industrial compounds. Consequently, identification of "unknown" pollutants was difficult due to the incomplete data bases of the mass spectral matching systems. Manual

interpretation procedures are not feasible for a screening project of this scale.

- The majority of pollutants present at levels greater than 10 µg/l were tentatively identified. However, there is considerable uncertainty associated with some of the interpretations. In general the most common and most frequently studied compounds (i.e., hydrocarbons, halocarbons, fatty acids, and phenols) are identified with a high degree of certainty. Pollutants which have not been previously identified are of particular interest in this type of study but they are less likely to be included in data bases and less likely to be correctly identified.
- The Biemann computer mass spectral matching system does provide a useful "first guess" in the identification of an unknown compound, but it is unreliable in determining the degree of certainty of a particular compound identification. Thus, the computer generated GC/MS data alone are not sufficient evidence for the positive identification of "unknown" compounds. Retention time data and manual interpretation must be used.
- Many samples contained only a few components as determined by preliminary GC analysis, whereas others contained many compounds in high concentrations. Consequently, the GC screening procedure used (i.e., priority rating system) saved time and money by determining which samples contained a sufficient number of components above a specified concentration level (10 µg/l) to warrant subsequent GC/MS/COMP analysis. However, the relatively few contaminants present in those samples not analyzed by GC/MS may have been potentially toxic components that should be of concern.

ANALYTICAL RESULTS

- Caution should be used when interpreting the analytical data, especially the frequency of occurrence tables, because this was only a limited study.
- Generally, industrial effluents contain few priority pollutants. In the semivolatile fractions only 17 priority pollutants were identified and these occurred collectively 78 times--only 10% of the 816 occurrences of semivolatile compounds. This percentage of occurrence of priority pollutants is the upper limit since the unidentified compounds would not be priority pollutants.
- Priority pollutants are most prevalent in the purgeable fractions of industrial effluents. This was expected since most of these compounds are common industrial solvents. Twenty-two priority

pollutants were identified and occurred collectively 359 times--51% of the 710 occurrences of purgeable compounds.

- Most of the components found in the effluents were specific for a particular industrial site and did not appear in reoccurring patterns. Specifically, 176 out of 261 neutral compounds, 56 out of 104 acidic compounds, 39 out of 49 basic compounds, and 85 out of 159 volatile compounds occurred only once. These data suggest that many possible environmentally important compounds (mutagenic, toxic, carcinogenic) would be overlooked if frequency of occurrence is the major criterion for determining environmentally significant compounds.
- Few polycyclic aromatic hydrocarbons (PAH's) were identified in industrial effluents. This fact supports the combustion airborne hypothesis that PAH's enter the surface waters primarily as a result of the combustion of fossil fuels.
- Many different types of heterocyclic compounds appeared in the basic fraction. Such compounds are very likely toxic or mutagenic and may prove to be environmentally significant.

FUTURE STUDIES

- We recommend that future studies concentrate on basic compounds using suitable methods of identification and that appropriate tests for compound activity (toxicity, mutagenicity, carcinogenicity) be conducted.
- We recommend that future studies concerning the environmental impact of various compounds first identify which compounds are biologically active (toxicity, mutagenicity, carcinogenicity) and then apply suitable methods for their detection in the environment. This could be accomplished by fractionating extracts using liquid chromatography and screening the fractions by bioassay techniques (e.g., Ames mutagenicity assay, mammalian cell toxicity assay). Active fractions would be subfractionated and studied in detail to identify the biologically active components.
- The current study was concerned only with volatile and semi-volatile components. The many nonvolatile organic components that were undoubtedly present and which may be biologically active were ignored. We recommend that future studies include efforts to identify biologically active nonvolatile components. This could be accomplished most efficiently by combining liquid chromatographic fractionation and bioassay techniques with HPLC-MS and HPLC/IR studies.

SAMPLING

SITE SELECTION

The objective of sampling site selection was to develop a sampling design system which allowed the collection of representative, usable and statistically reliable data concerning the possible source of organic pollutants entering receiving waters. A preliminary list of 478 organic chemical manufacturing facilities was compiled and classified according to type of chemical industry. Sampling sites were chosen from this list using the following criteria:

- (1) Type of industry
- (2) Potential toxicity of anticipated pollutants
- (3) Production capacity of company
- (4) Willingness of company to permit sampling

In retrospect, the main factor for site selection was the willingness of the company to permit sampling. The other major criterion was the type of industry to be considered. These industries included all types of organic chemical manufacturers and even steel manufacturers because of their coal tar production. Table 1 summarizes the various types of chemicals produced by these companies.

Letters were sent to 250 corporations requesting permission to sample at some 450 sites. Each company was informed that data obtained from their water samples would not be identified with their respective company. In this way each company's identity will remain confidential. Approximately 10% of the corporations contacted refused to participate. Many corporations (94 out of 250) had sampling sites (100) which discharged into municipal treatment plants. These sites were not applicable for this project since only those effluents which were discharged directly into surface waters were of interest. Eighteen corporations requested that intake water be analyzed as well as effluent water. In this way, chemicals identified as being introduced via the intake water would not be erroneously attributed to the manufacturing operations.

SAMPLE COLLECTION AND PRESERVATION

Samples were collected from sites in Ohio, West Virginia, Pennsylvania, New Jersey, New York, Louisiana, Kentucky, Delaware, and Texas. In total, samples of 63 outfalls and 22 intakes (plant water supply) were collected.

TABLE 1. CHEMICALS PRODUCED BY COMPANIES SAMPLED

rubber processing chemicals	surfactants
plastics and resins	elastomers
dyes, color agents and pigments	catalysts and catalyst supports
aromatic hydrocarbons	polymers
surface-active agents	organic intermediates

organic sufrace coatings	printing inks
flavor and fragrance chemicals	peroxides
pesticides	chlorine compounds
epoxys	edible fats, oils, etc.
miscellaneous organic chemicals	synthetic rubbers

Samples were collected in such a way as to provide as representative a sample as possible from each sampling site. This required close coordination with facilities personnel to ensure that sampling was performed during a representative stage of the production cycle. In many cases effluents from the various operations of a particular plant were pooled and may have been subjected to purification treatment prior to discharge. These pooled samples averaged many of the periodic fluctuations in the composition of the effluents and permitted a grab sample to be taken which was reasonably representative of several hours of operation. For this reason and because grab sampling is by far the least costly method, grab samples were collected at all the sites. Other advantages of grab sampling are that contamination is minimized and the sample can be immediately capped and cooled to prevent loss of volatile compounds.

Grab samples for analysis of semivolatile compounds were collected in pre-washed one-half gallon glass bottles containing 5 grams of potassium bisulfate (KHSO₄) and 75 grams of sodium chloride. Two bottles of sample were collected at each intake (or process water source) and process water outfall. Each bottle was filled approximately half full with sample water. Next, 150 ml of high purity distilled-in-glass methylene chloride was added followed by the remaining half portion of sample water. The methylene chloride prevents microbiological degradation and retards hydrolytic degradation of many organic components by removing them from the aqueous phase. A field blank was collected at each site in the same manner as a sample using distilled water (taken to each site from the laboratory) instead of waste or inlet water. All bottles were appropriately labelled and stored on ice.

Grab samples to be analyzed for volatile compounds were collected in 40 ml glass vials. Four samples were collected at both the inlet and outfall by filling each vial until it overflowed. This sampling method ensured that no air remained in the samples. The completely filled vials were sealed with screw-caps containing Teflon-lined silicon rubber septa and stored cap-side down on ice. A field blank consisting of distilled water was prepared at each site using the preceding overflow method. All water samples were stored at 4°C until they were extracted and/or analyzed by GC/MS.

SAMPLE ANALYSES

All sample analyses involved a GC/MS/COMP system that used high-resolution glass capillary GC columns. Volatile compounds were purged from water by helium, trapped on Tenax and subsequently desorbed. Semivolatile compounds were extracted from water with methylene chloride using an extraction scheme that gave the neutrals, acids, and bases as three separate fractions. These three fractions were analyzed by GC as well as by GC/MS/COMP.

INSTRUMENTATION

A Tekmar Liquid Sample Concentrator, Model LSC-1, was used for purging the volatile compounds. The device was equipped with a 25-ml sample container and the adsorbent tube was packed with 6 inches of 60/80 mesh Tenax GC. A 25-ml gas tight syringe with a 3-way valve and 12-inch needle was used to transfer the water samples to the LSC-1.

The GC/MS system for both the volatile and semivolatile analyses consisted of a Finnigan Model 9500 gas chromatograph coupled with a Finnigan Model 3200 quadrupole mass spectrometer. The mass spectrometer was interfaced to a Systems Industries Model 150 data system.

The GC column for volatile analyses was a 50 m x 0.25 mm i.d. glass capillary column (Perkin-Elmer) coated with SF-96 (a low molecular weight methyl silicone fluid). Figure 1 illustrates the instrumentation used in our purge and trap method.

The GC analyses of semivolatile compounds were performed using a Varian Model 1840 or Hewlett-Packard Model 5730 gas chromatograph equipped with a Hewlett-Packard automatic sampler. Each GC was fitted with a 30 m x 0.22 mm i.d. SE-30 glass capillary column (J. & W. Scientific). The calculation of retention index and concentration relative to the internal standard (pentadecylbenzene) was performed by a Spectra-Physics Model 4000 chromatography data system.

VOLATILE ANALYSIS PROCEDURES

During the course of this project it was mutually decided with the sponsor that all 85 samples would be analyzed for volatile compounds by using capillary column GC/MS instead of the usual packed column GC/MS system. The employment of capillary column GC/MS for routine volatile analyses proved to be a significant technical improvement in this project by providing well resolved GC peaks which result in clean mass spectra of volatile compounds.

6

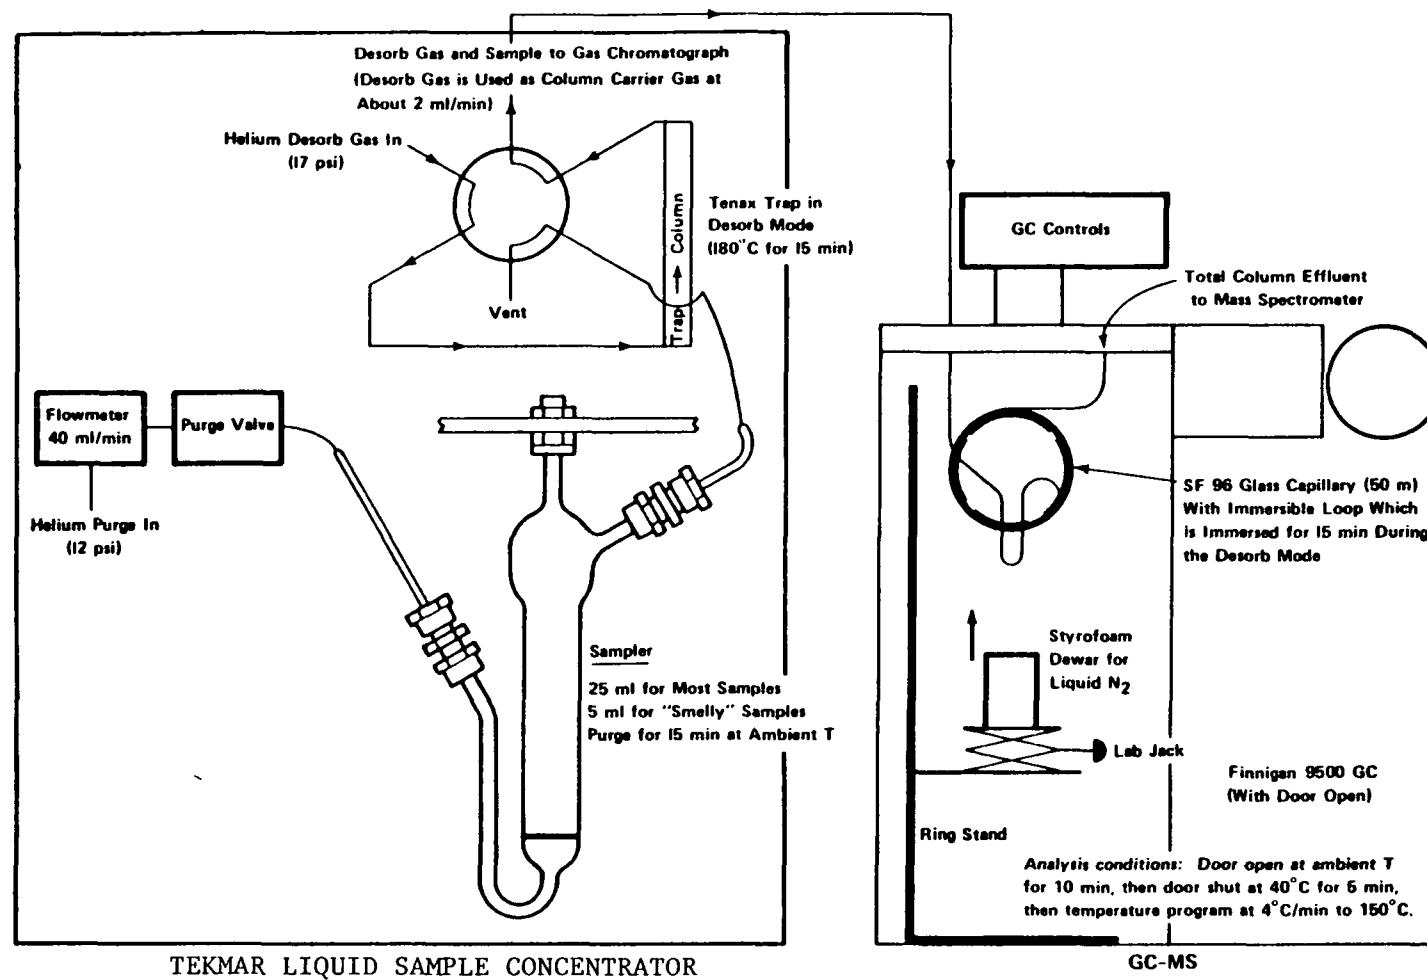

FIGURE 1. INSTRUMENTATION FOR PURGE AND TRAP ANALYSIS

Experimental Method

Since the glass capillary column was attached directly to the mass spectrometer, cryogenic trapping was used to concentrate the entire volatile sample as a plug on the head of the column. Thus no compounds were pumped away with the helium by passing through a separator. However, this method did require some modification of the procedure described in "Sampling and Analysis Procedures for Screening of Industrial Effluents for Priority Pollutants".(1) One modification was the use of only Tenax in the adsorbent tube. If silica gel was added at the front of the adsorbent tube, large amounts of water vapor were eluted during the desorption step. This water sometimes formed a plug in the glass capillary column. In a second modification, the LSC-1 Desorb Mode outlet was used as the capillary column carrier gas. The helium entered a "T" at the back of the LSC-1 and a small pressure regulator was installed between the Desorb and Purge inlets. The pressure was set at 15 psi for the Desorb inlet (i.e., 15 psi was the pressure at the head of the capillary column) and the purge regulator was set at 12 psi. The flow rate through the capillary column was about 3 ml/min. The first coil of the glass capillary column was fashioned into a U-tube about 4 cm deep which was immersed in liquid nitrogen during the desorption step.

To analyze a sample, 25.0 ml of water sample was poured into the gas-tight syringe followed by the addition of 200 μ l of a solution containing 200 ng of the internal standard (the internal standard was prepared by diluting 74 μ l (100 mg) of 1,2,3-trichloropropane to 10.0 ml with methanol and then diluting 10 μ l of this solution containing 100 μ g of internal standard to 100 ml with sparged water); this gives an internal standard concentration of 8 μ g/l. The sample was added to the purging device through a septum and sparged for 15 min with helium at a flow rate of 40 ml per min. The Texax trap was then desorbed for 15 min at 180° with the capillary U-tube immersed in liquid nitrogen. The LSC-1 was then switched to the Purge mode, the liquid nitrogen was removed from the capillary column, and data acquisition started. A plug of air reached the source in the mass spectrometer in about three minutes followed by the separated organic components.

The GC/MS conditions were as follows: 1) the initial column temperature was 25°C and held at this temperature for 10 min after the solvent front (air) passed through the column; 2) the column was quickly heated to 40°C and held at this temperature for 5 min; 3) the column was then temperature programmed at 4°C/min to 130°C and held at the final temperature until all the volatile components eluted (usually 10-15 min); 4) the MS was scanned from m/e 40-350 with the sensitivity at 10^{-7} and the electron multiplier voltage at about -2.00 KV. Between each run the purging device was rinsed several times with sparged distilled water and the Tenax trap was baked out at 210°C for 15 minutes.

2-Bromo-1-chloropropane was initially used as the internal standard. However, experiments revealed that the 2-bromo-1-chloropropane was not completely resolved from toluene and also exhibited two isomer peaks on the

SF-96 capillary column. Consequently, 1,2,3-trichloropropane was used as the internal standard. The internal standard (200 ng) was added to each sample including the blanks and reference solutions. Retention times relative to 1,2,3-trichloropropane were calculated for each compound found in the samples. Figure 2 shows a typical RGC of the volatile components in an industrial wastewater samples.

Quantitation

The quantitation of each volatile compound using extracted ion currents of major ions of each compound would be time consuming (computer time) and costly. Therefore, it was mutually agreed with the sponsor that a semi-quantitative estimation of the amount of each volatile component found would be adequate for this program. Relative peak heights of reference compounds (i.e., response factors) in the normalized total ion chromatogram (T.I.C.) were used to estimate the concentrations of each compound in the samples. The relative responses of acetone, diethyl ether, benzene, chlorobenzene, and o-xylene (compounds which appear in many of the industrial samples) were determined to be in a 20-fold range and depended upon the stripping efficiency of the procedure (related to compound solubility and volatility) and the ionization and chromatographic characteristics (polarity, molecular weight, etc.) of the compounds. For compounds identified in the samples, estimated relative response factors were used to estimate the approximate quantity of each compound. Initially, relative responses for a few samples could not be obtained because the sample components were so concentrated that the internal standard peak was not observed in the normalized TIC plot. Consequently, three additional internal standards (bromochloromethane, 2-bromo-1-chloropropane and 1,4-dichlorobutane) were added to all samples. This modification permitted reliable semi-quantification of the volatile compounds in the industrial water samples. Table 2 lists the relative responses of internal and external standards used in our semi-quantification of volatile compounds.

SEMOVOLATILE ANALYSIS PROCEDURES

Each of the 85 water samples was extracted to give three fractions containing the neutral, acidic, and basic semivolatile compounds, respectively. These fractions were gas chromatographed (methylated acid fraction) to obtain semiquantitative data and to prioritize the respective fractions for subsequent GC/MS/COMP analysis. Only the top priority fractions (total of 89) were analyzed by GC/MS/COMP.

Experimental Method

Semivolatile organic compounds were extracted from each water sample using the procedure illustrated in Figure 3.

Each 1500 ml sample, previously treated with 5 g of KHSO₄ and 75 g of NaCl, was spiked with three internal standards--hexaethylbenzene, 2,4-dimethylaniline and palmitic acid. The pH was adjusted to pH≈1 using H₂SO₄ and the sample extracted three times with nanograde distilled in glass

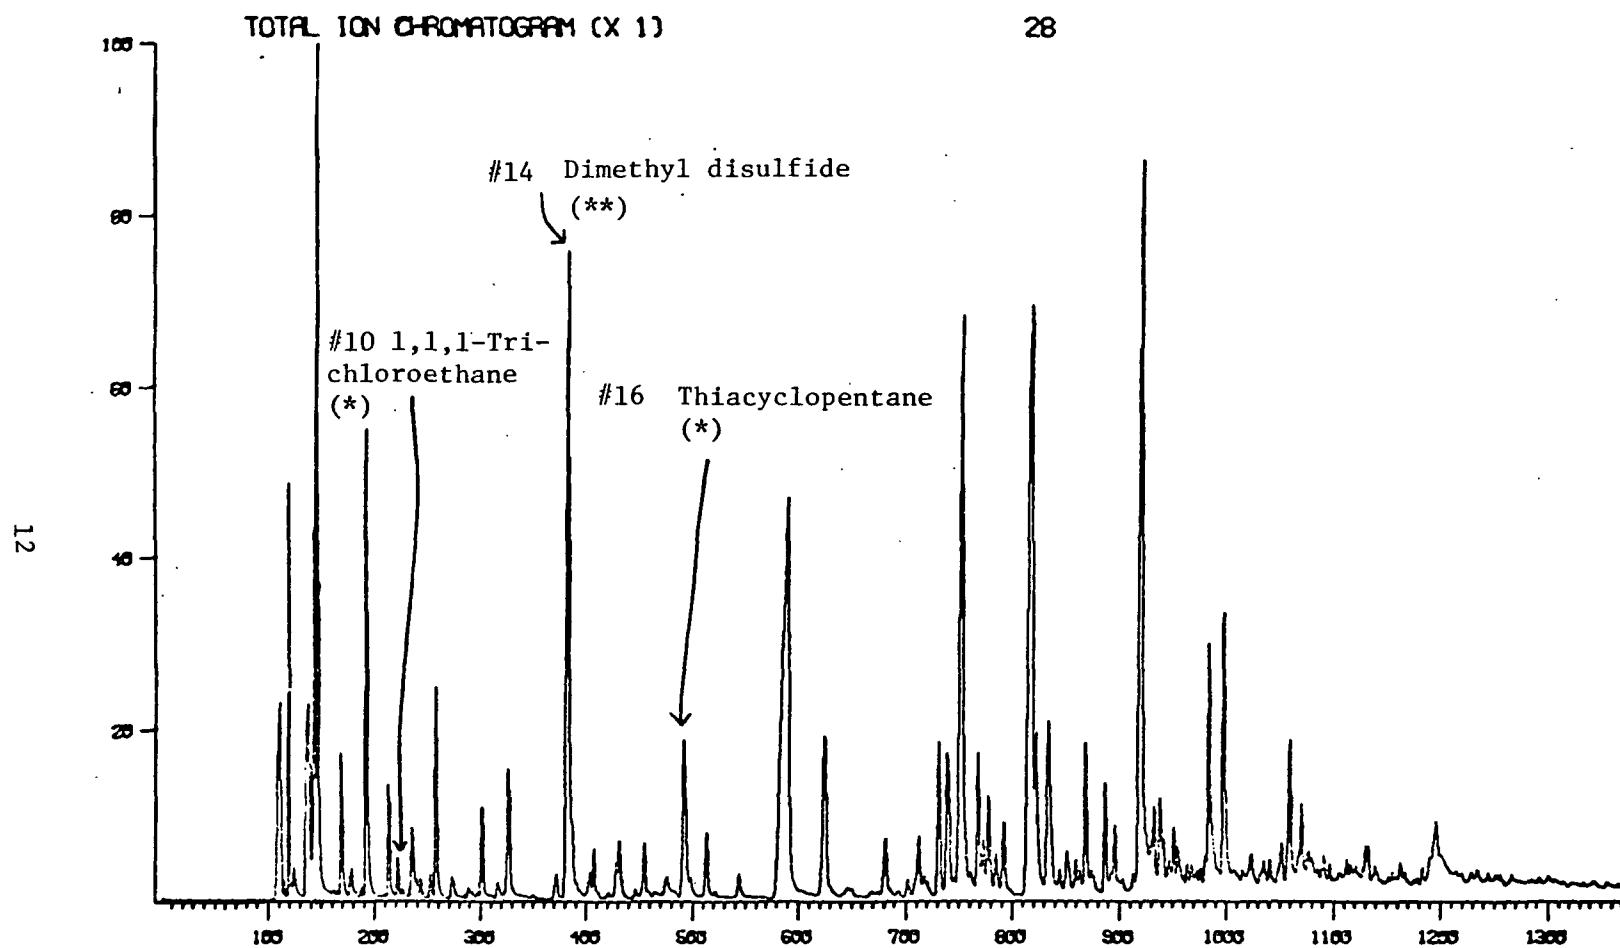

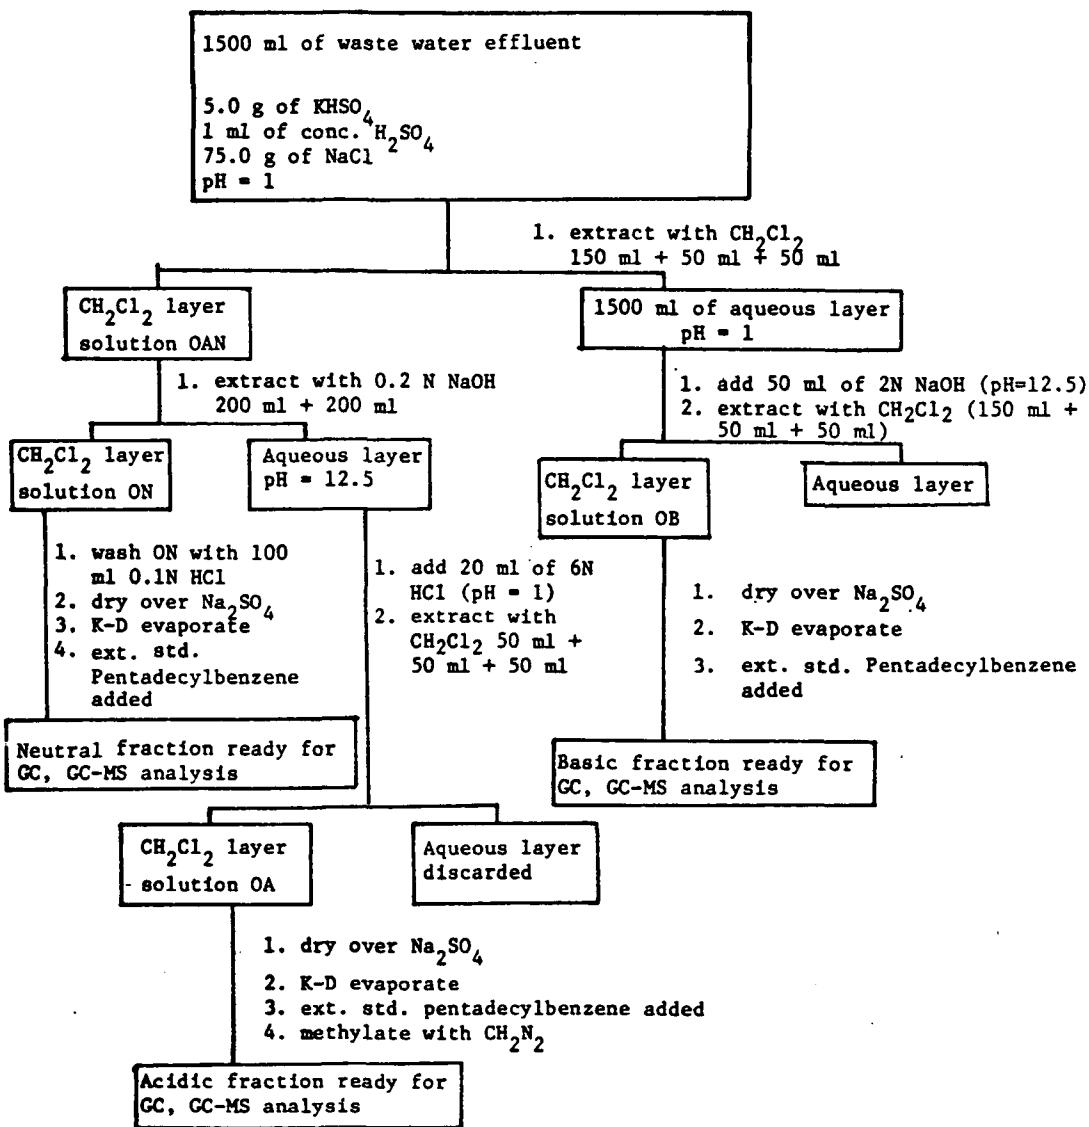

Figure 2. Total ion chromatogram of volatile fraction of industrial effluent.

TABLE 2. INTERNAL STANDARDS AND EXTERNAL STANDARDS

Compound	Amount in 25-ml water sample, ng	Concentration, μg/l	Relative Response ^a

FIGURE 3. EXTRACTION PROCEDURE

methylene chloride. The combined methylene chloride extracts (neutral and acidic fractions) were extracted twice with 0.2N NaOH resulting in organic (neutral fraction) and aqueous (acidic fraction) layers. The organic layer was washed with 0.1N HCl, dried over anhydrous sodium sulfate, filtered, and concentrated to 400 μ l using a Kuderna-Danish evaporator.

The aqueous layer (acidic fraction) was made acidic ($pH \approx 1$) with 6N HCl and extracted three times with methylene chloride. The resulting organic layer was dried, filtered and concentrated to 400 μ l. The solution was split in half. Half was methylated using a diazomethane generator and the other half was stored for possible reanalysis.

The original acidic aqueous layer (basic fraction) was made alkaline, ($pH \approx 12.5$) using 2N NaOH, extracted three times with methylene chloride, dried, filtered, and concentrated to 400 μ l.

An internal standard, 20 μ g of pentadecylbenzene was added to each of the respective fractions together with 400 μ l of benzene. Each fraction was concentrated to 400 μ l, split in half and stored at 4°C until GC or GC/MS analysis. By replacing methylene chloride with the higher boiling solvent benzene, samples had longer storage life. More importantly, the "solvent effect" produced by benzene improved column resolution and peak shape in subsequent splitless injections of GC/MS analyses.

All 255 fractions were analyzed by GC using the conditions listed in Table 3.

TABLE 3. GAS CHROMATOGRAPHIC CONDITIONS*

Injection procedure	2 μ l 10:1 split
Initial temperature	60°C

*30 m x 0.22 mm i.d. SE-30 glass capillary column.

Figures 4, 5 and 6 illustrate typical gas chromatograms of the respective neutral, acidic, and basic fractions from industrial waste-water effluents. The GC/MS conditions for semivolatile compound analysis were similar except that a 2 μ l splitless injection was used.

Quantitation

The emphasis of this program was on the identification and not quantification of organic compounds. Consequently, semiquantitative methods based solely on gas chromatography were sufficient. The Spectra-Physics 4000 data

16

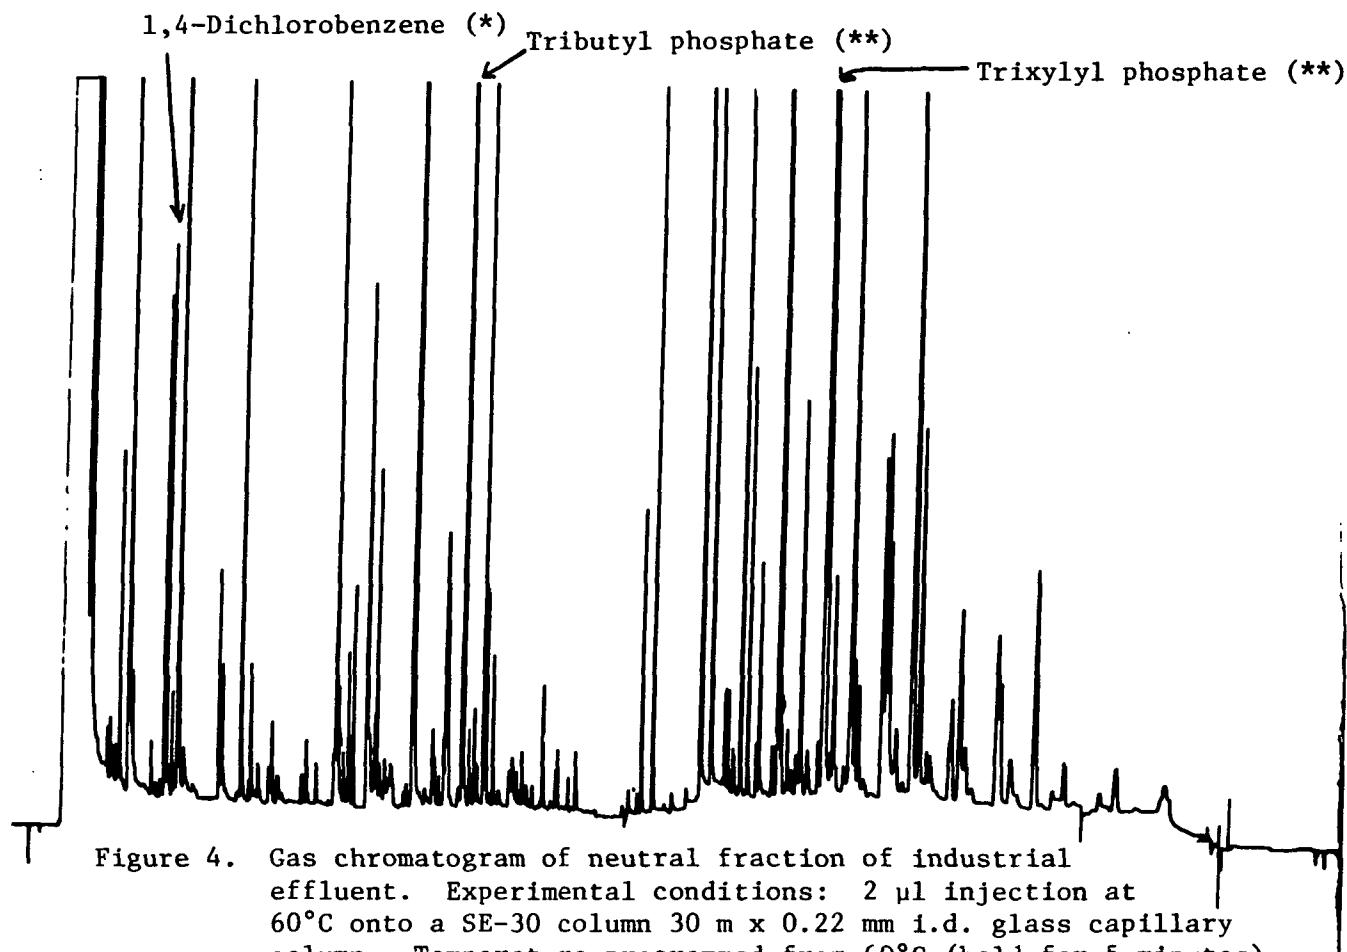

Figure 4. Gas chromatogram of neutral fraction of industrial effluent. Experimental conditions: 2 μ l injection at 60°C onto a SE-30 column 30 m x 0.22 mm i.d. glass capillary column. Temperature programmed from 60°C (held for 5 minutes) at 4°/min to 260°C (held for 35 minutes).

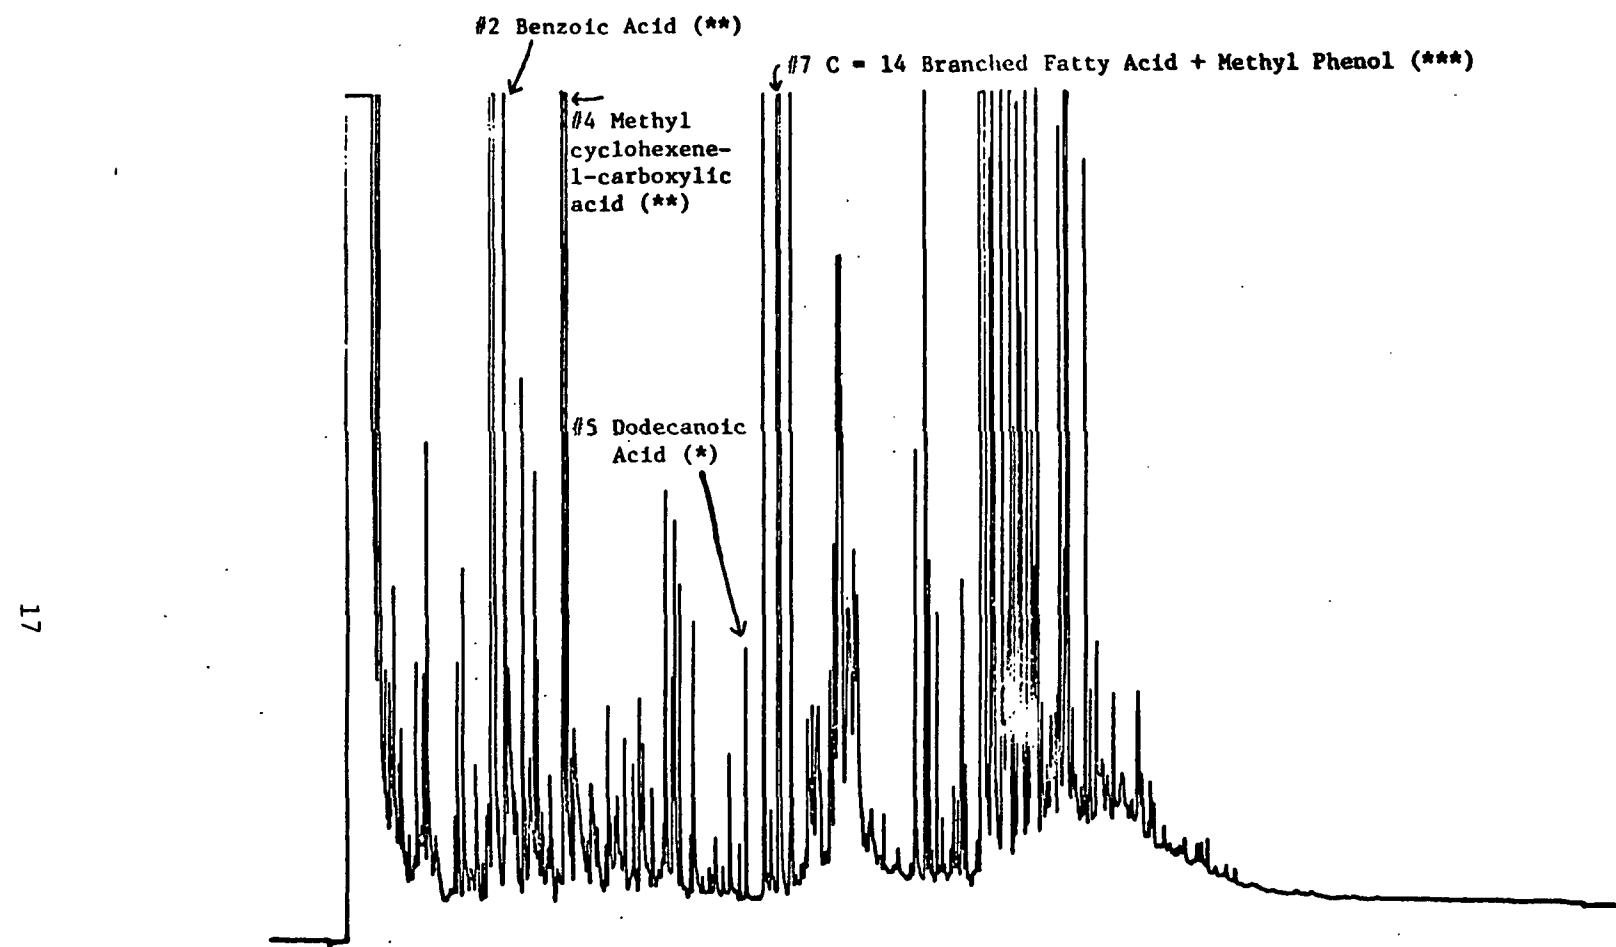

Figure 5. Gas chromatogram of acidic fraction of industrial effluent. Experimental conditions: 2 μ l injection at 60°C onto a SE-30 column 30 m x 0.22 mm i.d. glass capillary column. Temperature programmed from 60°C (held for 5 minutes) at 4°/min to 260°C (held for 35 minutes).

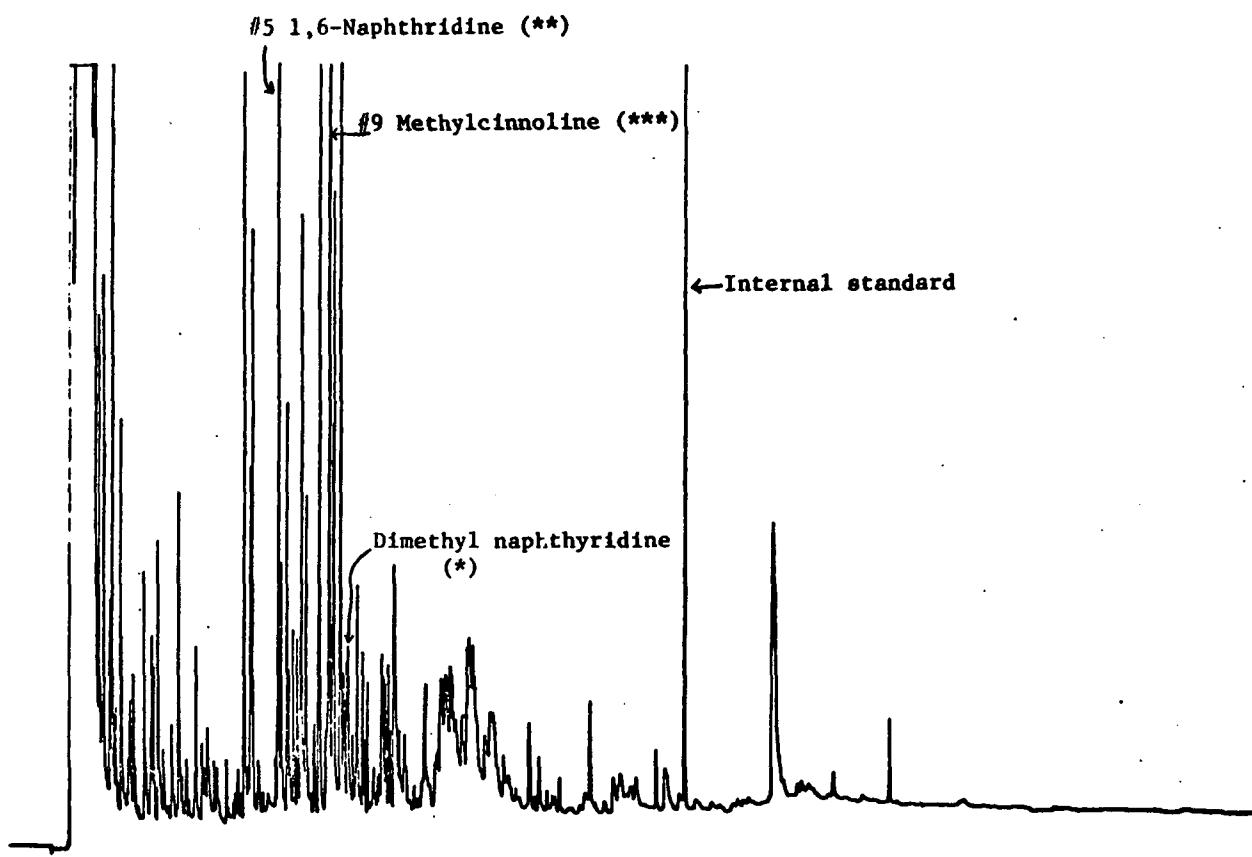

Figure 6. Gas chromatogram of basic fraction of industrial effluent. Experimental conditions: 2 μ l injection at 60°C onto a SE-30 column 30 m x 0.22 mm i.d. glass capillary column. Temperature programmed from 60°C (held for 5 minutes) at 4°/min to 260°C (held for 35 minutes).

system calculated concentrations using pentadecylbenzene as an internal standard. The sample component concentrations were calculated using "estimated response factors" which were obtained by correlating the following:

- (1) The relative response of a similar compound found in the BCL Standard Mixtures (Table 4);
- (2) The recovery of the respective fractions (determined by comparison of internal with external standard);
- (3) The shape of the respective GC peak and baseline (which indicated how accurately each peak area was integrated).

The reliability of our quantitative data depended ultimately upon the computer integration of the respective GC peak areas. Because of actual problems associated with this procedure (co-eluting compounds, poor GC peak shape and/or irregular baseline), the following ranges were established for reporting compound concentrations:

- (1) * = less than 10 $\mu\text{g}/\text{l}$
- (2) ** = 10-100 $\mu\text{g}/\text{l}$
- (3) *** = greater than 100 $\mu\text{g}/\text{l}$.

QUALITY ASSURANCE STUDIES

An essential and enlightening aspect of this project was the continued use of various quality assurance measures. Because of the variety of chemical and physical properties of compounds expected to be found and the $\mu\text{g}/\text{l}$ detection limit, stringent standards were necessary to validate our procedures for the extraction, detection, and identification of compounds from industrial wastewater effluents. These quality assurance standards included instrumental calibration, recovery studies, and process and field blank studies.

Gas Chromatograph Calibration

A standard solution containing 2,6-dimethylphenol (DMP), 2,4-dimethylaniline (DMA), decylaldehyde, decanol, *n*-tridecane, and *n*-tetradecane was injected into the GC to determine the polarity, separation number (SN), and number of effective plates (N_{eff}) of the glass capillary column. This evaluation was made each time a column was connected in the GC and each time column degradation was suspected. In order for a GC column to have been acceptable for sample analysis the following conditions had to be met.

- (1) $N_{eff} \geq 50,000$
- (2) $SN \leq 25$
- (3) Area of DMP/Area of DMA = 0.5 to 2.0

Table 4. Recovery of Compounds in BCL Standard Mixture

Compound	No. of Runs	Recovery, %	Relative Standard Deviation, %
1. Chlorobenzene	4	94.3 \pm 8.7	9.2

- (4) Width of half height for decanol \leq 4 x width at half height for tridecane.

In addition, a mixture containing C₉ to C₃₂ n-paraffins was analyzed periodically to calibrate the retention time in terms of retention index (R.I.). This retention index calibration was made each time a column was connected in the GC and each time the retention index of the internal standard changed by 4 units relative to the previously calibrated value. A typical gas chromatogram obtained by the injection of this calibration standard mixture is shown in Figure 7.

GC-MS-COMP Calibration and Evaluation

The GC-MS-COMP system is checked daily by injecting a tune-up standard mixture and employing the following procedures and criteria.

Mass Spectrometer Tune Up

- (1) Adjust zero level of the mass spectrometer using a preamplifier setting 10⁻⁸ amp/volt, and the filament (800 μ A) and electron multiplier (\sim 2kV, gain \sim 5 x 10⁴) on.
- (2) Admit FC-43 into the ion source and tune the MS as follows:
 - (a) Using the potentiometers on the "Ion Source Controller", optimize the electronics to give highest intensity with best peak shape for m/e 219 as described by the manufacturer (see service manual).
 - (b) Set the controls to scan the range 400-600, and further adjust the ion source controller to give a 219 ion peak intensity of \sim 50-70% of that of the repeller to \sim 10 V, then decreasing the ion energy slightly. Again focus on m/e 219 and adjust the lens voltage for good peak shape. Tuning in this manner will favor the high mass end of the spectrum (i.e. >200). Decafluorotriphenyl-phosphine (DFTPP) is admitted via the solids probe into the mass spectrometer. Its spectrum should be comparable to that of Eichelberger, et al. [(Anal. Chem., 46 (7), 995 (1975)]. A spectrum of DFTPP taken in this manner is shown in Figure 8.
 - (c) Check peak shape and resolution at 18, 69, 219, 264, 414, and 502.
 - (d) Check calibration using CONT mode using 10 samples/amu.

22

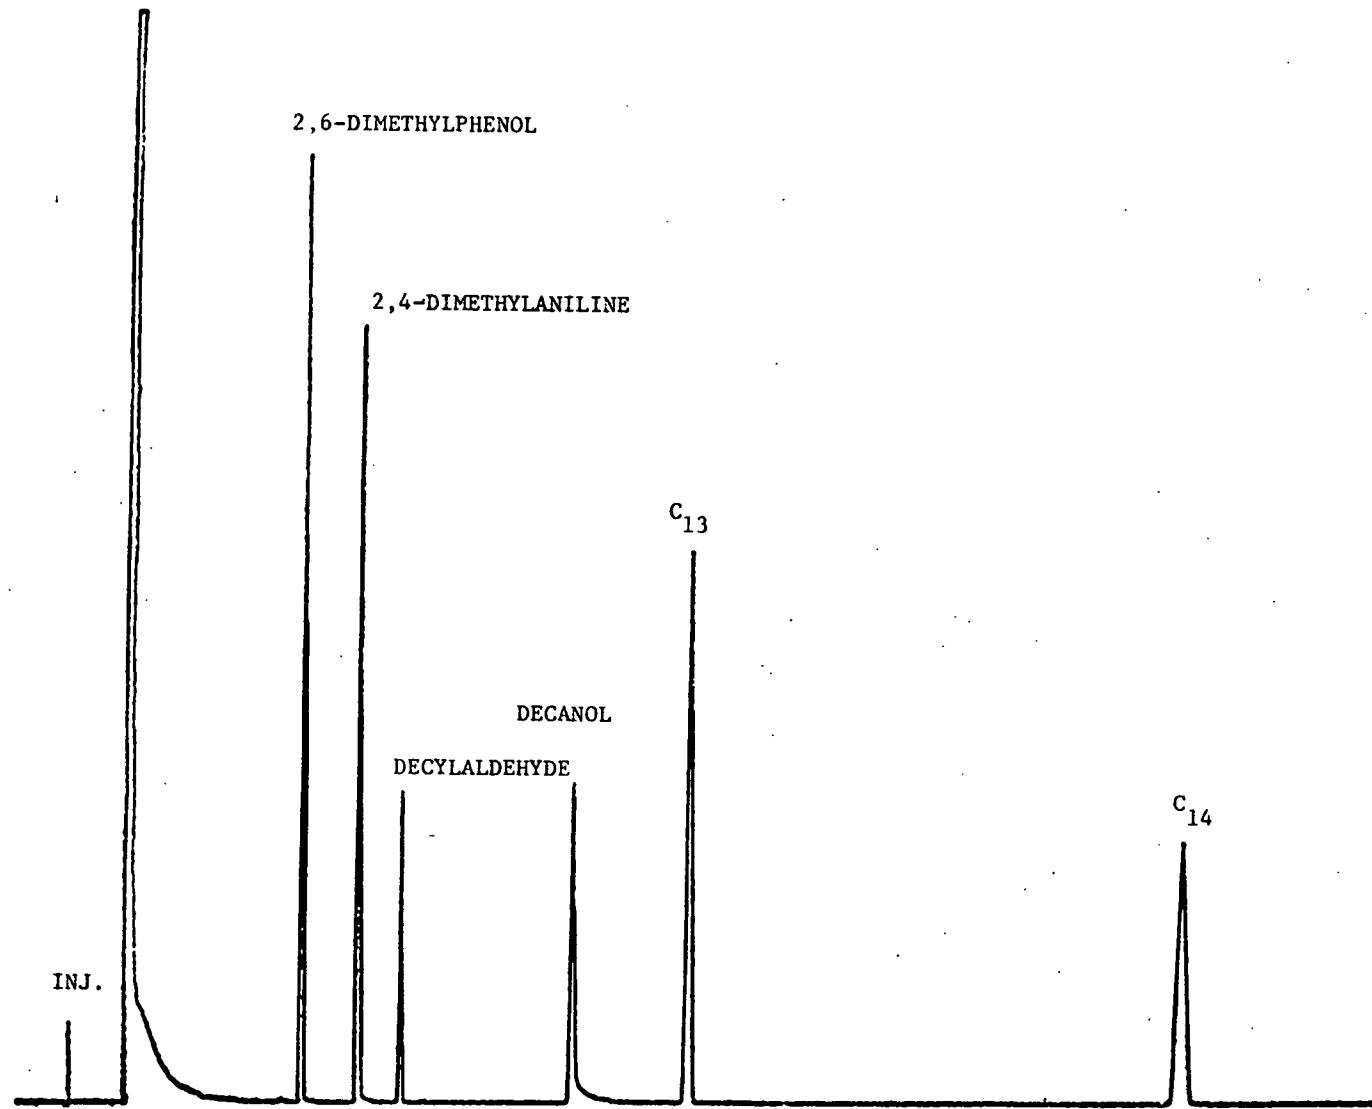

Figure 7. Glass capillary gas chromatogram of the calibration standard used for non-polar columns.

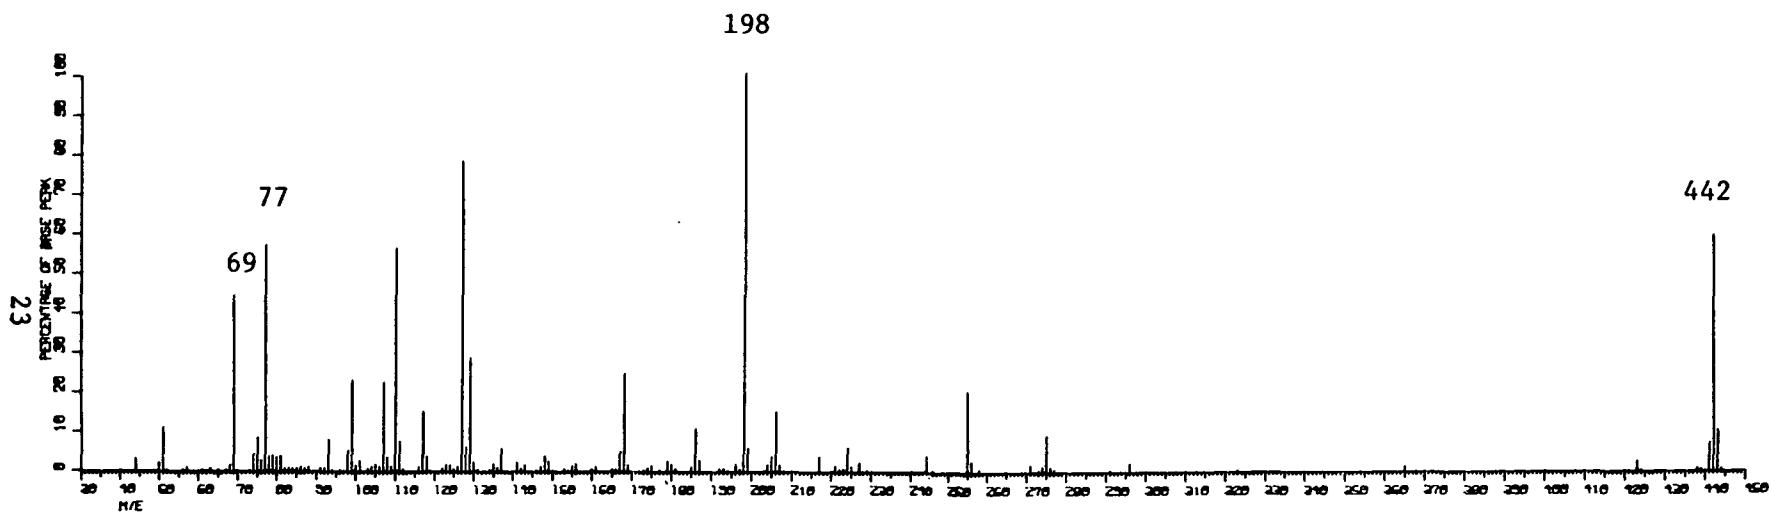

Figure 8. Electron impact mass spectrum of DFTPP

GC-MS Tune Up Mixture

Inject 1.0 μ l of the "Tune Up Mixture" using a syringe with a 4" needle and splitless techniques. This mixture contains 30 ng each of 2,4-dimethylaniline and 2,6-dimethylphenol, and 10 ng each of 1-octadecene, octadecane, phytane, DFTPP, and methyl stearate. The conditions of the GC and computer are as follows:

- (1) GC
 - (a) Cool column to room temperature
 - (b) Set initial temperature to 20°C and final temperature to 200°C
 - (c) Set the program rate to 20°C/min
 - (d) Inject 1.0 μ l of the mixture using splitless techniques
 - (e) When the solvent elutes into the mass spectrometer, begin the temperature program
 - (f) Data collection can begin after solvent has passed
- (2) Data System
 - (a) Mode: IFSS
 - (b) Max repeat count: 5
 - (c) Integration time: 2
 - (d) Check lower threshold: 2
 - (e) Lower threshold: 3
 - (f) Upper threshold: 1
 - (g) Clock: Y
 - (h) Fast scan opt: Y
 - (i) Delay between scans: CR
 - (j) Start clock 10 seconds after GC injection

GC-MS-Comp Evaluation

The resulting data were evaluated using the Selected Ion Summation Program (SIS) and plotting the Reconstructed Gas Chromatogram (RGC). A typical SIS reconstructed chromatogram is shown in Figure 9. The following parameters were evaluated:

- (1) Capillary column pH - Peak heights of aniline (DMA) and phenol (DMP) were equal if the column was neutral; a decrease in aniline indicated an acidic column and a decrease in phenol indicated a basic column. Area of DMP/Area of DMA should be within the range of 0.5 to 2.0.
- (2) Capillary column resolution - The hydrocarbon GC peaks were used to evaluate resolution. The GC peaks should be resolved with no more than a 50% valley.

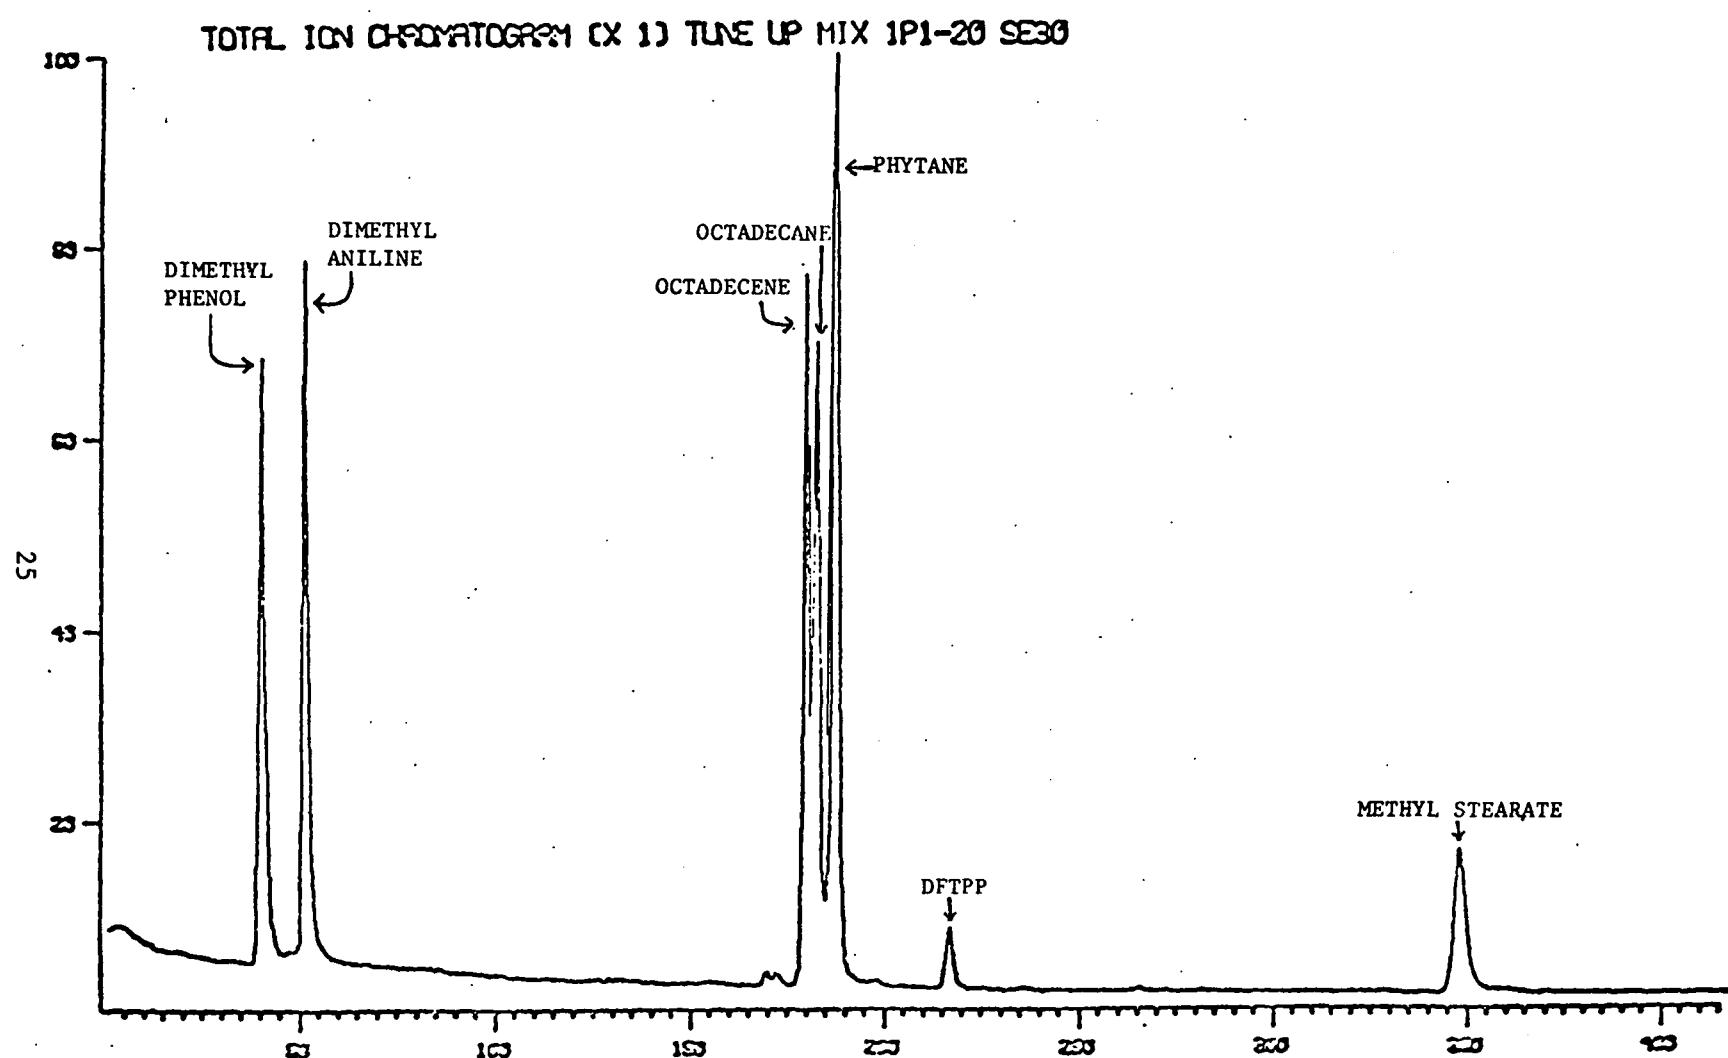

Figure 9. GC-MS-COMP tune up mixture chromatogram on a 30M SE30 capillary column

Table 5. Decafluorotriphenylphosphine (DFTPP)

Mass	Ion Abundance Criteria
51	30-60% of Mass 198
68	Less than 2% of Mass 69
70	Less than 2% of Mass 69
127	40-60% of Mass 198
197	Less than 1% of Mass 198
198	Base peak, 100% relative abundance
199	5-9% of Mass 198
275	10-30% of Mass 198
365	1% of Mass 198
441	Less than Mass 443
442	Greater than 40% of Mass 198
443	17-23% of Mass 442

Eichelberger, et al., Analytical Chemistry, 47 (7)
995 (1975).

- (3) MS Tuning - DFTPP was used to evaluate the MS tuning under dynamic conditions. A spectrum on the front side of the DFTPP GC peak (before peak maximum if possible) was observed using CRTPLT. Eichelberger's criteria were used to evaluate this spectrum. A summary of these criteria are given in Table 5.
- (4) GC/MS transfer line - Methyl stearate was included in the mixture to evaluate the transfer line system of the GC/MS. When the transfer line was inadequately heated, the methyl stearate peak tailed. Obtaining a symmetrical peak for methyl stearate verified that large, involatile molecules can elute from the capillary column into the mass spectrometer.

Recovery Studies

For the semivolatile compound recovery studies, 13 neutral compounds, 5 basic compounds and 5 acid compounds (BCL Standard Mixture, see Table 4) were selected to ensure a wide range of GC retention times and different functional groups. Recovery studies were performed by analysis of process blanks spiked with the BCL Standard Mixture at a level of 13.3 $\mu\text{g}/\text{l}$. Two process blanks were analyzed in one set of runs and three process blanks were analyzed in another set of runs one week later. Recovery data are given in Table 4. Representative gas chromatograms of neutral, basic and acidic process blanks are shown in Figures 10, 11 and 12, respectively.

For most compounds, recovery was greater than 80%. Coeluting contaminants accounted for excessively high recoveries for pentadecanol and carbazole. Two compounds, *p*-nitrophenol and *m*-nitrobenzoic acid gave low recoveries, 27% and 45%, respectively. This was expected since these two acid compounds are very polar and fairly soluble in water. The reproducibility of the recoveries achievable is indicated by relative standard deviations of less than 15% in most cases.

As is true for all analytical programs, a continuing quality assurance program is necessary to ensure continued reliability of data. Consequently, weekly recovery checks carried out over a period of 4 months were made for this program. Table 6 lists these results.

The periodic recoveries of each compound in the BCL standard mixture generally averaged over 70%. The reproducibility of the respective recoveries was indicated by relative standard deviations of approximately 20% in most cases. Only the polar compounds *p*-nitrophenol, *m*-nitrobenzoic acid and *m*-nitroaniline had low recoveries and/or high relative standard deviations.

Process and Field Blank Studies

Blank studies were performed on each of the following reagents used in the sample collection and extraction procedures: CH_2Cl_2 , NaCl , KHSO_4 , Na_2SO_4 , 2*N* NaOH , 6*N* HCl , H_2O (millipore water). Methylene chloride was studied by 1000-fold concentration followed by GC analysis. All other reagents were extracted with CH_2Cl_2 which was then concentrated for GC analysis. Similar studies were carried out on the diazomethane generator, sample vials, filter paper, and Teflon liners (for vial caps). The GC results indicated that

no contaminants from these sources were present at levels equivalent to <1 µg/l of water analyzed. Figures 13, 14, and 15 show typical examples of neutral, basic, and acidic process blanks, respectively.

Volatile sample blanks were generally run at the beginning of each day's analyses. The water used was previously sparged overnight with 50 ml/min of nitrogen at 50°C. The sparged water blanks generally yielded several small peaks (<1 µg/l) which probably are contaminants in the commercial distilled water. Figures 16, 17, and 18 show volatile sample process blanks and water spiked with internal and external standards.

Field blanks were obtained for each site sampled. Analysis of various field blanks for volatile and semivolatile compounds indicated no significant contamination occurred during any of our sampling procedures. Methylene chloride and chloroform were found in many of the volatile field blanks but at levels below the concentrations found in the respective effluent samples.

PRIORITY CRITERIA FOR GC/MS ANALYSES

In an effort to obtain as much useful information as possible within a limited budget it was mutually agreed with the sponsor that GC/MS analysis of semivolatiles would be performed only on selected fractions. Priority was given to those fractions which were shown by GC analysis to contain several components at levels higher than 10 µg/liter that could not be tentatively identified on the basis of their GC patterns and retention indices. Table 7 lists the three priority ratings and their respective criteria. In most cases, only the "++" rated fractions were analyzed by GC/MS. In total, 89 fractions (39 neutrals, 29 acidics and 21 basics) were analyzed by GC/MS.

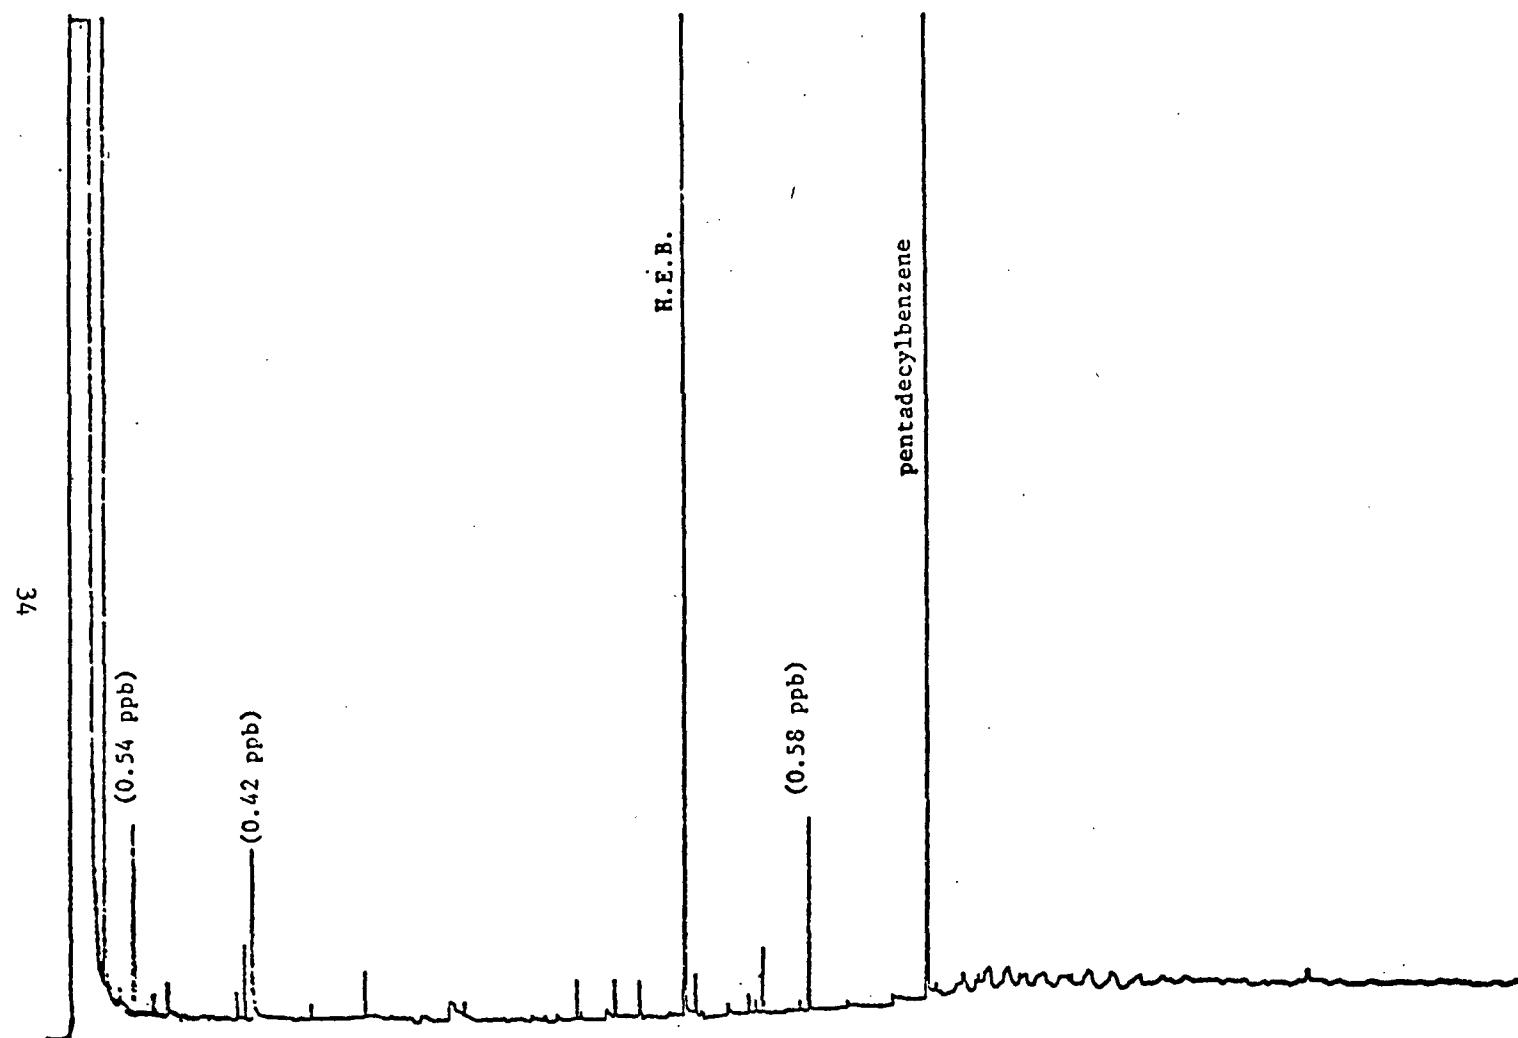

Figure 13. Neutral fraction process blank

Experimental conditions: 2 μ l injection at 60°C onto a SE-30 column 30m x 0.22 mm i.d. glass capillary column. Temperature programmed from 60°C (held for 5 minutes) at 4°/min to 260°C (held for 35 minutes).

TABLE 7. PRIORITY CRITERIA FOR GC-MS ANALYSIS

Priority	Criteria
0	A zero priority rating is given to any fraction which contains no compounds above a concentration of 4 µg/l or contains compounds > 4 µg/l that have been tentatively identified by retention index or GC patterns in context with historical data.
+	A "+" priority rating is given to fractions on the basis of the following criteria. Compounds greater than 4 µg/l but not sufficient for ++ priority.
++	<p>A "++" priority rating is given to fractions on the basis of the following criteria.</p> <ul style="list-style-type: none"> • 10 or more neutral compounds with conc > 10 µg/l not previously identified • 4 or more acidic compounds with conc > 10 µg/l not previously identified • 2 or more basic compounds with conc > 10 µg/l not previously identified • Conc. of any given compounds <u>>100 µg/l.</u>

RESULTS AND DISCUSSION

The procedures used to tentatively identify each organic compound, while specific for individual compounds, employed these general operations. First, the GC/MS/COMP analysis of each sample generated many individual mass spectra and total ion chromatograms (TIC). Inspection of each TIC resulted in the selection of a mass spectrum number and a background subtract spectrum number for each "peak" likely to produce a good mass spectrum. Second, a computerized Biemann mass spectral matching system (NIH-EPA data base, $\approx 25,000$ spectra) generated a Similarly Index (S.I.=1.000=perfect match) for the spectrum of each semivolatile compound with a concentration greater than $10 \mu\text{g/l}$ and selected volatile compounds. The S.I. provided a good first guess as to a compound's identity, but it was unreliable in determining the degree of certainty of a compound's identity. Consequently, many of the mass spectra were manually interpreted and compared to reference spectra in published data bases (2,3) before a tentative identification was made.

Samples containing many and/or concentrated components produced "mixed" mass spectra (two or more compounds eluting simultaneously) in the GC/MS analysis. In many instances of coeluting peaks only general compound names could be assigned (alkyl alcohol, subst. benzoic acid, subst. benzene). Individual isomers and/or members of a class of compounds (C₅-alkylbenzenes, fatty acid methyl esters) were rarely identified because time and funds did not permit the required analyses with authentic compounds. In general, the two limiting factors concerning the tentative identification of organic compounds were the "purity" of each sample component mass spectrum and whether or not each compound's spectrum was in accessible data bases.

TENTATIVE IDENTIFICATION OF VOLATILE COMPOUNDS

The analysis of 63 industrial effluents for purgeable organic compounds resulted in tentative identifications of 159 compounds. In general, the compounds were cleanly separated from each other resulting in clean, easily interpretable spectra. A few samples were selected for Biemann spectral matching on the computer, but most of the compounds were tentatively identified using manual interpretation procedures and the aid of published data bases.(2,3)

Table 8 is a comprehensive list of the volatile compounds tentatively identified in the 63 industrial waste-water effluents and their frequency of occurrence. The purgeable organic compounds tentatively identified in each of the 85 samples (63 effluents, 22 intakes) are listed in tables found in Appendix A.

Sulfur Compounds				
Miscellaneous Compounds	19	30	0	0
Miscellaneous Compounds	4	4	0	0
TOTAL	159	710	22	359

The effluent samples analyzed for purgeable components ranged in complexity from those as clean as drinking water to some that were quite smelly and containing compounds with concentrations in the mg/l range. The most polluted samples (number and amount of compounds) were from paint companies. Generally, most volatile compounds were found in the 10-100 µg/l range. The 159 compounds are classified in Table 9.

These compounds range in volatility from chloroethane (b.p. = 12.3°C) to trichlorobenzene (b.p. = 213.5°C), which was also identified in the semi-volatile fractions. In some cases, such as C₃-alkylbenzenes, many isomers of the same generic compounds were identified but were classified as one compound in Tables 8 and 9.

Twenty-two purgeable priority pollutants were identified and they occurred 359 times, 51% of the total number of occurrences of volatile compounds. Thirteen priority pollutants occurred in more than 10% of the total samples while only methylene chloride, chloroform, toluene and 1,1,1-trichloroethane occurred in more than half the samples.

TENTATIVE IDENTIFICATION OF NEUTRAL COMPOUNDS

The GC/MS analysis of 33 industrial effluents for neutral semivolatile compounds resulted in the tentative identification of 261 compounds listed in Table 10. Generally, the neutral fractions contained more compounds than either the acidic or basic fractions. Concentration levels were usually in the 10-100 µg/l range but numerous compounds were found in greater than 100 µg/l concentrations. In many cases, the large number and/or high concentration of compounds resulted in coeluting peaks. Consequently, the mass spectra were mixtures of two or more compounds. In many of these cases, only general identifications could be made, if at all. Tables found in Appendix A list the neutral semivolatile compounds tentatively identified in each of the 39 priority rated neutral fractions (33 effluents, 6 intakes). The 261 neutral compounds are classified in Table 11.

Hydrocarbons and halocarbons accounted for about 51% of the compounds while 30% were aromatic compounds. Alkylbenzenes, particularly C₂-alkylbenzenes, occurred the most frequently. Eleven priority pollutants were identified and occurred collectively 46 times, 10% of the 474 total occurrences of neutral compounds.

General patterns concerning the type of industry versus compounds in effluents could not be distinguished in this project due to the limited number of samples. However, some interesting compounds were found, such as: N-methyl-N-nitrosomethanaminobenzene, iodochlorocyclohexane, and substituted benzofuranones.

TENTATIVE IDENTIFICATION OF ACIDIC COMPOUNDS

The GC/MS analysis of 26 industrial effluents for acidic semivolatile compounds resulted in the tentative identification of 104 compounds. The compounds listed in Table 12 are names as the parent compound, although methylation with diazomethane meant that certain acidic compounds were actually identified as methyl esters and/or methyl ethers.

Table 10. Neutral compounds tentatively identified
in 33 industrial effluents

Halophenols	8	26	4	16
Benzenesulfonic acid derivatives	4	9	0	0
Heterocyclic compounds	4	4	0	0
Miscellaneous compounds	11	12	0	0
TOTAL	104	272	6	32

Because mass spectra of many of these methylated compounds were not included in accessible data bases the number of tentative identifications in the acidic fractions was limited. Tables in Appendix A list the acidic semivolatile compounds tentatively identified in each of the 29 priority rated acidic fractions (26 effluents, 3 intakes).

The acidic fractions of the 26 effluent samples analyzed were generally less complex than the neutral fractions but contained more components than the basic fractions. Most acidic compounds were found with concentrations of 10-100 µg/l. No particular type of company had effluents which could be distinguished from one another on the basis of their acidic compound content (concentration and number of compounds). The 104 acidic compounds are classified in Table 13.

Not surprisingly, aliphatic acids were the most numerous compounds followed by alkylphenols and aromatic acids. Six priority pollutants were identified - phenol (12 times), chlorophenol (7 times), dichlorophenol (3 times), trichlorophenol (3 times), dimethylphenol (4 times) and chloromethylphenol (3 times). Fifty-six compounds occurred only once, while phenol and benzoic acid occurred 12 and 11 times respectively. The acidic compounds occurred a total of 272 times while priority pollutants accounted for only 32 occurrences, about 12% of the total number of occurrences.

TENTATIVE IDENTIFICATION OF BASIC COMPOUNDS

The analysis of 21 industrial effluents for basic semivolatile compounds resulted in the tentative identification of 49 compounds listed in Table 14. Tables found in Appendix A list the basic compounds tentatively identified in each of the 21 effluent samples.

Generally, the basic compounds found in the effluent samples were present in smaller numbers and lower concentration (<10 µg/l) compared to the neutral and acidic compounds. Steel companies, as a group, had effluents with the highest number of basic compounds, and in some cases, the basic compounds were the most concentrated components in the sample. It should be noted that all the basic compounds present in the effluent extracts probably did not elute from the SE-30 capillary column. This result was expected-- future analyses should use a more suitable column for basic components. The 49 basic compounds are classified in Table 15.

The basic compounds occurred a total of 70 times while no priority pollutants were identified. Methyl pyridine occurred most frequently (8 times) while 39 of the 49 compounds occurred only once. The heterocyclic compounds would appear to be the most interesting group of compounds both in biological activity and environmental significance.

SUMMARY OF IDENTIFIED COMPOUNDS IN INDUSTRIAL EFFLUENT SURVEY

During the course of this industrial effluent survey many different types of data have been generated. Correlation of these different data types can be done in a number of ways depending upon one's perspective and interests. Table 16 correlates the number of identified compounds with various other parameters. This representation may be useful in determinating the environmental significance of compounds found in industrial effluents.

TABLE 16. SUMMARY OF IDENTIFIED COMPOUNDS IN INDUSTRIAL EFFLUENT SURVEY

Sample Type	No. of Effluents Analyzed	No. of Compounds Identified	Total No. of Occurrences	No. Found in Only One Effluent	Priority Pollutants	
					No. Identified	Total No. of Occurrences
Purged Effluent	63	159	710	85	22	359
Extract-neutral fraction	33	261	474	176	11	46
Extract-acid fraction	26	104	272	56	6	32
Extract-basic fraction	21	49	70	39	0	0
TOTAL		573 ^(a)	1526	356	39 ^(b)	437

(a) Because some purged compounds were also present in extracts, less than 573 different compounds were identified.

(b) Toluene, ethylbenzene, chlorobenzene, dichlorobenzene trichlorobenzene, and naphthalene were found in both purgeable and neutral fractions. A total of 33 different priority pollutants were identified in this survey.

15. SUPPLEMENTARY NOTES		
16. ABSTRACT <p>Samples of 63 effluent and 22 intake waters were collected from a wide range of chemical manufacturers in areas across the United States. The samples were analyzed for organic compounds in an effort to identify previously unknown and potentially hazardous organic pollutants. Each water sample was preconcentrated for analysis of organic compounds in four fractions: volatile organics by helium-gas stripping and semivolatile organics by extraction with methylene chloride resulting in separate neutral, acidic and basic fractions. All sample analyses involved a GC/MS/COMP system that used high-resolution glass capillary GC columns. Organic constituents were identified using the computerized Biemann mass spectral matching system together with some manual interpretation and quantified using GC-FID peak area determinations.</p> <p>Over 570 compounds were tentatively identified of which 33 are priority pollutants. Generally, industrial effluents contained few priority pollutants. Most of the components found in the effluents were specific for a particular industrial site and did not appear in reoccurring patterns. The data suggest that many possible environmentally important compounds would be overlooked if frequency of occurrence is the major criterion for determining environmentally significant compounds.</p> <p>We recommend that future studies concentrate on basic compound analyses and that the biological activity of a compound(s) be established first before exhaustive screening programs are initiated for environmental pollutants. Mass spectral data bases containing all the organic compounds produced by industry should be developed.</p>
