## F O R E W O R D

The National Eutrophication Survey was initiated in 1972 in response to an Administration commitment to investigate the nationwide threat of accelerated eutrophication to freshwater lakes and reservoirs.

### OBJECTIVES

The Survey was designed to develop, in conjunction with state environmental agencies, information on nutrient sources, concentrations, and impact on selected freshwater lakes as a basis for formulating comprehensive and coordinated national, regional, and state management practices relating to point-source discharge reduction and non-point source pollution abatement in lake watersheds.

### ANALYTIC APPROACH

The mathematical and statistical procedures selected for the Survey's eutrophication analysis are based on related concepts that:

- a. A generalized representation or model relating sources, concentrations, and impacts can be constructed.
- b. By applying measurements of relevant parameters associated with lake degradation, the generalized model can be transformed into an operational representation of a lake, its drainage basin, and related nutrients.
- c. With such a transformation, an assessment of the potential for eutrophication control can be made.

### LAKE ANALYSIS

In this report, the first stage of evaluation of lake and watershed data collected from the study lake and its drainage basin is documented. The report is formatted to provide state environmental agencies with specific information for basin planning [§303(e)], water quality criteria/standards review [§303(c)], clean lakes [§314(a,b)], and water quality monitoring [§106 and §305(b)] activities mandated by the Federal Water Pollution Control Act Amendments of 1972.

Beyond the single lake analysis, broader based correlations between nutrient concentrations (and loading) and trophic condition are being made to advance the rationale and data base for refinement of nutrient water quality criteria for the Nation's fresh water lakes. Likewise, multivariate evaluations for the relationships between land use, nutrient export, and trophic condition, by lake class or use, are being developed to assist in the formulation of planning guidelines and policies by EPA and to augment plans implementation by the states.

#### ACKNOWLEDGEMENT

The staff of the National Eutrophication Survey (Office of Research & Development, U. S. Environmental Protection Agency) expresses sincere appreciation to the Texas Water Quality Board for professional involvement, to the Texas National Guard for conducting the tributary sampling phase of the Survey, and to those Texas wastewater treatment plant operators who voluntarily provided effluent samples.

Hugh C. Yantis, Jr., Executive Director of the Texas Water Quality Board, and John B. Latchford, Jr., Director, and the staff of the Field Operations Division provided invaluable lake documentation and counsel during the Survey, reviewed the preliminary reports, and provided critiques most useful in the preparation of this Working Paper series.

Major General Thomas Bishop, the Adjutant General of Texas, and Project Officer Colonel William L. Seals, who directed the volunteer efforts of the Texas National Guardsmen, are also gratefully acknowledged for their assistance to the Survey.

WRIGHT PATMAN (TEXARKANA) RESERVOIR

STORET NO. 4833

I. CONCLUSIONS

A. Trophic Condition:

Survey data indicate that Wright Patman Reservoir is eutrophic; i.e., well supplied with nutrients and quite productive. Whether nutrient enrichment is beneficial or deleterious depends on the actual or potential effect on the uses of the reservoir. In this regard, no nuisance conditions are known to personnel of the Texas Water Quality Board and there is little or no impairment of the designated beneficial uses of this water body.

Wright Patman Reservoir ranked thirty-third in overall trophic quality when the 39 Texas reservoirs sampled in 1974 were compared using a combination of six water quality parameters\*. Thirty-four reservoirs had less median total phosphorus, 33 had less median dissolved orthophosphorus, 18 had less and one had the same median inorganic nitrogen, 32 had less mean chlorophyll a, and 33 had greater mean Secchi disc transparency.

Survey limnologists noted heavy growths of submerged and emergent vegetation at station 4 during the March, May, and November sampling visits.

\* See Appendix A.

B. Rate-Limiting Nutrient:

The algal assay results indicate that Wright Patman Reservoir was limited by nitrogen at the time the samples were taken (03/22/74 and 11/08/74). The reservoir data indicate nitrogen limitation at all sampling times and stations.

C. Nutrient Controllability:

1. Point sources--During the sampling year, point sources contributed an estimated 13.8% of the total phosphorus load to Wright Patman Reservoir. The wastewater treatment plants at Sulphur Springs contributed 4.5%, the plant at Commerce contributed 3.9%, and seven other municipal facilities collectively contributed 5.4%. In addition, nine other domestic wastewater treatment plants discharge to tributaries in the drainage basin (Wyatt, 1976) beyond the 40-kilometer limit of the Survey\*. These sources may be significant as indicated by the phosphorus export rates of Sulphur River and Cuthand Creek (see discussion below).

The present phosphorus loading of  $2.05 \text{ g/m}^2/\text{year}$  is more than two times that proposed by Vollenweider (Vollenweider and Dillon, 1974) as a eutrophic loading (see page 18). However, even complete removal of phosphorus at the listed point sources would only reduce the loading to  $1.77 \text{ g/m}^2/\text{year}$ ; and, regardless of the applicability of Vollenweider's eutrophic level to Texas reservoirs, because of the persistent nitrogen-limited condition of the reservoir, it does

\* See Working Paper No. 175, "...Survey Methods 1973-1976".

not see likely that control of phosphorus at those sources would result in a shift to phosphorus limitation. Further investigation is needed to more accurately determine the controllability of phosphorus from all sources in the drainage basin, including land-use practices (see non-point discussion below).

There was an apparent phosphorus loss from the reservoir during the sampling year (see page 16). This probably is due in part to the great distances that the sampling sites were located upstream from the reservoir (see map, page vii); i.e., the entire phosphorus load from each drainage area would not have been measured. Also, it is possible that the loss may be the result of underestimation of point sources which discharge below tributary sampling sites; e.g., to Sulphur River below L-1 and Cuthand Creek below M-1.

2. Non-point sources--Non-point sources contributed an estimated 86.2% of the total phosphorus input to Wright Patman Reservoir during the sampling year. The Sulphur River contributed 44.4%, and seven other gaged tributaries collectively contributed 21.0% of the total. Ungaged minor tributaries and immediate drainage were estimated to have contributed 19.9%.

The phosphorus export rates of Sulphur River ( $32 \text{ g/km}^2/\text{year}$ ) and Cuthand Creek ( $29 \text{ kg/km}^2/\text{year}$ ) were appreciably higher than the rates of the other measured tributaries in the drainage basin (see page 17). This may be indicative of an underestimation of point sources impacting those streams, the impact of point sources

beyond the 40-kilometer Survey limit, or land-use practices. However, the export rates of the tributaries of this reservoir are similar to the rates of the tributaries of nearby Lake O'The Pines\* and may be typical of this part of the state because of greater precipitation.

### III. WATER QUALITY SUMMARY

Wright Patman Reservoir was sampled four times during 1974 by means of a pontoon-equipped Huey helicopter. Each time, samples for physical and chemical parameters were collected from one or more depths at four stations on the reservoir (see map, page vi). During each visit, a single depth-integrated (4.6 m or near bottom to surface) sample was composited from the stations for phytoplankton identification and enumeration; and during the first visit, a single 18.9-liter depth-integrated sample was composited for algal assays. Also each time, a depth-integrated sample was collected from each of the stations for chlorophyll a analysis. The maximum depths sampled were 4.6 meters at stations 1 and 2, 4.9 meters at station 3, and 1.5 meters at station 4.

The sampling results are presented in full in Appendix D and are summarized in the following table (August nutrient samples were not preserved properly and were not analyzed).

## b. November sample

<u>Spike (mg/l)</u>	<u>Ortho P Conc. (mg/l)</u>	<u>Inorganic N Conc. (mg/l)</u>	<u>Maximum yield (mg/l-dry wt.)</u>
Control	0.086	0.043	1.3
0.050 P	0.136	0.043	1.3
0.050 P + 1.0 N	0.136	1.043	27.5
1.0 N	0.086	1.043	28.2

## 2. Discussion -

The control yields of the assay alga, Selenastrum capricornutum, indicate that the potential primary productivity of Wright Patman Reservoir was moderately high at the times the samples were collected (03/22/74 and 11/8/74). Also, in both assays, the lack of increase in yield with the addition of phosphorus until nitrogen was also added, indicates that the reservoir was limited by nitrogen at those times. Note that the addition of nitrogen alone resulted in yields much greater than those of the controls.

The reservoir data indicate nitrogen limitation as well; i.e., the mean inorganic nitrogen to orthophosphorus ratios were 9 to 1 or less at all sampling stations and times, and nitrogen limitation would be expected.

IV. NUTRIENT LOADINGS  
(See Appendix E for data)

For the determination of nutrient loadings, the Texas National Guard collected monthly near-surface grab samples from each of the tributary sites indicated on the map (page vii), except for the months of April and May when two samples were collected. Sampling was begun in September, 1974, and was completed in August, 1975.

Through an interagency agreement, stream flow estimates for the year of sampling and a "normalized" or average year were provided by the Texas District Office of the U.S. Geological Survey for the tributary sites nearest the reservoir.

In this report, nutrient loads for sampled tributaries were calculated using mean annual concentrations and mean annual flows. Nutrient loads shown are those measured minus point-source loads, if any. Nutrient loads for the aqueduct were calculated using the mean concentrations measured in the Sulphur River outlet (station A-1) and multiplying by the mean aqueduct flow.

Nutrient loads for unsampled "minor tributaries and immediate drainage" ("ZZ" of U.S.G.S.) were estimated using the mean concentrations in Rock Creek at station C-1 and the mean ZZ flow.

The operators of the Maud and Redwater wastewater treatment plants provided monthly effluent samples and corresponding flow data. The nine other listed wastewater treatment plants did not participate; nutrient loads from these sources were estimated at 1.134 kg P and 3.401 kg N/capita/year, and flows were estimated at  $0.3785 \text{ m}^3/\text{capita/day}$ .

## A. Waste Sources:

## 1. Known municipal\* -

<u>Name</u>	<u>Pop. Served</u>	<u>Treatment</u>	<u>Mean Flow (m<sup>3</sup>/d)</u>	<u>Receiving Water</u>

Horse Creek	0.109	0.920

\* See Working Paper No. 175.

F. Yearly Loads:

In the following table, the existing phosphorus loadings are compared to those proposed by Vollenweider (Vollenweider and Dillon, 1974). Essentially, his "dangerous" loading is one at which the receiving water would become eutrophic or remain eutrophic; his "permissible" loading is that which would result in the receiving water remaining oligotrophic or becoming oligotrophic if morphometry permitted. A mesotrophic loading would be considered one between "dangerous" and "permissible".

Note that Vollenweider's model may not be applicable to water bodies with short hydraulic retention times.

	Total Phosphorus		Total Nitrogen	
	Total	Accumulated	Total	Accumulated
grams/m <sup>2</sup> /yr	2.05	Loss*	18.4	0.6

Vollenweider phosphorus loadings  
(g/m<sup>2</sup>/yr) based on mean depth and mean  
hydraulic retention time of Wright Patman Reservoir:

"Dangerous" (eutrophic loading)	0.84
"Permissible" (oligotrophic loading)	0.42

\* There was an apparent loss of phosphorus during the sampling year. This would not be expected to occur even in a reservoir with a mean hydraulic retention time of only 57 days. This may indicate unknown point sources which discharge directly to the reservoir, underestimation of phosphorus loads from the point sources discharging directly to the reservoir, resubilization of previously sedimented phosphorus, or tributary sampling sites located too far upstream (see map, page vii).
