

Air Quality Impact of Proposed HDV  
Emission Standards - Summary of Results

December 1979

Office of Air, Noise, and Radiation  
U.S. Environmental Protection Agency

This report presents the results of the estimated air quality impact of the proposed 1984 heavy-duty vehicle (HDV) emission standards for HC and CO. The proposed standards are based on a 90% reduction from the average emissions of the 1969 baseline fleet. In addition to the proposed standards, a no control case and two alternative control strategies were investigated. The four scenarios that were examined are summarized below:

- Case 1: No HDV standards beyond 1979 (base case).
- Case 2: HDV standards reflecting 85% reduction.  
(1.9/23.3 g/BHP-hr for HC/CO)
- Case 3: HDV standards reflecting 90% reduction.  
(1.3/15.5 g/BHP-hr for HC/CO)
- Case 4: HDV standards reflecting 95% reduction.  
(0.64/7.7 g/BHP-hr for HC/CO)

The assessment of the CO air quality impact of these scenarios was made using the Modified Rollback Model. Both the Rollback Model and EKMA were used for projecting ozone ( $O_3$ ). The methodology used in these analyses is described in Reference 1. The data assumptions for the non-mobile emission sources also are outlined in that reference. This report focuses on the mobile source data assumptions that were used as input to the air quality assessment.

The mobile source composite emission factors for each of the control strategies were calculated using a modified version of MOBILE1. The majority of the MOBILE1 modifications dealt with revisions of the HDV emission factors. The HDV zero mileage emissions and deterioration rates were altered to be consistent with those given in Appendix A of HDV regulatory analysis package (Reference 2). MOBILE1 was further modified to reflect the proposed 1984 light-duty truck (LDT) regulations and the expected dieselization of LDTs. The explicit MOBILE1 modifications are documented in Reference 3.

For light-duty vehicles (LDVs), no MOBILE1 alterations were made in this analysis. The MOBILE1 inputs were set to the normal FTP conditions. I/M credits were applied to LDVs assuming a 30% stringency program with no mechanic training. The I/M program was applied to all model year LDVs and was assumed to start in 1982. The same I/M program benefits were applied to pre-1984 LDTs. For 1984 and later model year LDTs, I/M benefits were implicitly assumed in the equations presented in Appendix A of Reference 2.

The composite emission factors calculated by MOBILE1 are given in Tables 1-4 for each scenario. The tables give the composite non-methane HC (NMHC) and CO emission factors for the base year 1976 and each of the evaluation years 1980, 1985, 1990, 1995, 1999.

The 1976 calendar year composite emission factors from Tables 1-4 were used to develop the mobile source portion of the base year emission inventories. The emission factors for all other sources in the inventories were taken directly from the 1976 NEDS. The regions included in the emission inventories and air quality projections were selected by OAQPS. The selected areas represent most of the large urbanized regions that are located at low altitude (outside of California) and that have recorded violations of the ambient O<sub>3</sub> or CO standards. The base year regional inventories are given in Appendix A of this report.

The mobile source emission ratios that were used in projecting future year inventories and air quality are given in Tables 5 and 6 for NMHC and CO respectively. Each ratio represents the emission factor projected for a future calendar year divided by the 1976 base year emission factor for the comparable vehicle category and scenario.

For CO, the LDV and LDT vehicle miles traveled (VMT) growth rate used in the projections was assumed to be 1% compounded annually. This value was chosen to reflect the assumption that CO is generally a hot spot problem in areas where traffic density is near saturation and thus, growth is expected to be small. The NMHC inventory and O<sub>3</sub> air quality was projected using LDV and LDT growth rates of 2% compounded annually. A higher growth rate of 3% compounded annually was also included to give a range of VMT growth for the NMHC inventory and ozone analysis. These growth rates are consistent with the rates used in the analysis of the national air quality standard for O<sub>3</sub>.

Growth rates of -2% per year for heavy-duty gas vehicles (HDGs) and 5% per year for heavy-duty diesel vehicles (HDDs) were used for both the NMHC and CO projections. These rates reflect the expected shift in sales from gasoline to diesel powered trucks and the resultant change in VMT. The derivation of these VMT growth rates is detailed in Appendix A of the HDV regulation package.

The stationary source growth rates, control assumptions, and contribution factors for this analysis were provided by OAQPS and are described in Reference 1.

The average percent reduction in ambient air quality concentrations from the 1976 base year are presented in Table 7 for ozone, and Table 8 for CO. Of course, the greatest air quality reductions are associated with the most stringent set of standards, the 95% reduction case. For the proposed regulations, the average reductions in CO ambient concentrations is 74% for calendar year 1999. The 2% growth rate assumption for LDTs and LDVs results in ozone reductions of 31-54% (EKMA vs. Rollback) for the proposed regulations for 1999. A range of 19-40% ozone reduction results when the 3% LDT and LDV growth rate is assumed for the same scenario. For comparison, the ambient CO percent reduction for the no further control case is 67% for 1999. The percent reductions are 29-52% at 2% growth or 18-39% at 3% growth for ozone in the 1999 no further control case.

The supporting region by region air quality projections for each pollutant and strategy are presented in Appendix B of this report. The projected total inventories for all the regions combined are presented in Appendix C.
