1. INTRODUCTION

The effects of lead toxicity on human health has been extensively researched and recognized for decades. The insidious effects that lead causes on the health of children has received increased attention in recent years. Due to mouthing behavior, increased uptake of lead compared to adults, nutrition and other factors, children under seven years of age present a sub-population at increased risk to the adverse effects of lead exposure.

This study considers the known environmental sources of lead in 83 cities, estimates the probability distribution of lead in children under seven years of age in each of the cities, and compares the numbers at risk. The ultimate objective of the study is to estimate the probability distribution of blood-lead in childhood populations, and then to compare geographic areas to ascertain severity of the problem. This appendix describes the support that the Geographic Information Management Systems Office (GISMO) provided to Project LEAP (Lead Education and Abatement Program). This appendix also presents maps for the communities in the ten cities with the highest number of children with expected high blood-lead concentrations, and the ten cities expected to have the highest percentages of children with high blood concentrations. For all cities, tables are provided to relate community areas - derived for the study - to U.S. Bureau of Census tract areas.

This project required multiple steps of computer analysis in varying computer architecture environments. One of the objectives of the study was to demonstrate that many of the processes could be automated and the varying computer architectures could loosely interact. Section 2 describes the steps necessary to move a library of data from one PC to another and produce a second library of summary files for input to a dispersion model. It also describes the process of using a Geographic Information System (GIS) to compare the modeled results with monitored data.

Sections 3 and 4 describe transferring data from a GIS to a PC environment, using the data for input to a Uptake Biokinetic Model and joining the results of the modelling to the GIS.

Section 5 describes mapping the results of the UBK model.

2. INDUSTRIAL SOURCE LONG TERM MODEL SUPPORT

Every significant point source of lead did not have an associated ambient air monitoring station, consequently, the ISCLT model was used to estimate ground level concentrations from stack emissions and meteorological data.

Geographic Information System Management Office (GISMO) support to Project LEAP consisted of obtaining a library of meteorological data for input to the model, producing GIS ARC/Info coverages of the results, and utilizing GIS to compare modelled surrogate concentrations with ambient air concentrations.

2.1. Meteorological Data Support (Obtaining Data)

The Region 5 GISMO office developed a procedure to interface the National Weather Service (NWS) data to the EPA ISCLT model. The ISCLT model requires as input surface and upper air meteorological data. For each of the seventeen facilities modeled, the meteorological data from the closest surface and upper air station were obtained. The data were available through the Technology Transfer Network (TTN) of The Office of Air Quality Planning and Standards (OAQPS). OAQPS obtained the data from the NWS National Climatic Data Center (NCDC).

A library of raw observations were obtained from Region 5 NWS monitoring stations by transferring the archived files from the TNN. The IBM-PC environment was subsequently used to process the data to the format required by the ISCLT model. A second library was produced of all the processed meteorological data.

2.2. Meteorological Data Support (Processing data)

Three arrays of meteorological data are necessary to execute the ISCLT model. They are:

1. Joint frequency of occurrence of wind-speed and wind-direction categories classified according to the Pasquill stability categories. The arrays were created using the STAR

(stability array) program provided by TNN.

2. Array of average ambient air temperatures was classified according to season and stability category. The array was generated using a procedure written using the Statistical Analysis System (SAS). SAS Proc Means procedure was used to output the averages to a second SAS file, which a SAS procedure was used to generate a formatted file required by the ISCLT model.
3. The same procedure was used to generate an array of median mixing heights classified according to wind speed, stability and season, except using Proc Univariate instead of means.

2.3. Create GIS Coverages from ISCLT Modelling Results

The output from the ISCLT model consists of cartesian coordinates and ground level concentrations of lead. For convenience, we chose Universe Transverse Mercator (UTM) coordinates as output from the model and input to the Geographic Information System (GIS) software. UTM coordinates were the most convenient to use because the facilities are located using UTM coordinates, the ISCLT model uses meters, and the GIS accepts UTM projection data.

The Statistical Analysis System (SAS) was used to pre-process the output from the ISCLT model prior to input to GIS. SAS also produced contour plots for reviewing the model results.

The GISMO office utilized Dbase III Plus to automate many of the steps necessary to produce a GIS coverage. From the SAS output, Dbase III files were generated for each of the seventeen modelled facilities. A Dbase procedure was written to group the data into the three UTM zones in Region 5, and to produce formatted files for input to ARC/INFO. The Dbase procedure also wrote Arc Macro Language programs (AMLS) that produced the GIS coverages.

2.4. Comparing Modelled and Monitored Data

Ambient air quality data were obtained from the Aerometric Information Retrieval System Air Quality Subsystem (AIRS) and produced into GIS point coverages. The procedure consisted of generating formatted files from AIRS, transferring the data to the PC environment, creating Dbase files, and executing a Dbase procedure that wrote an AML that would produce a GIS ARC/INFO point coverage. The Dbase procedure standardizes the format of latitude and longitude, and verifies the cartesian coordinates are within Region 5.

The monitored and modelled data were compared by finding the closest modelled location to the air monitoring locations. An ARC/INFO file was produced that included the AIRS identification number, the distance to the nearest modelled point, the name of the facility, the monitored yearly mean and the modelled yearly mean for 1988. The contours of the modelled results as well as the location of the monitored site is shown as figure 1.

3. DEMOGRAPHIC DATA SUPPORT

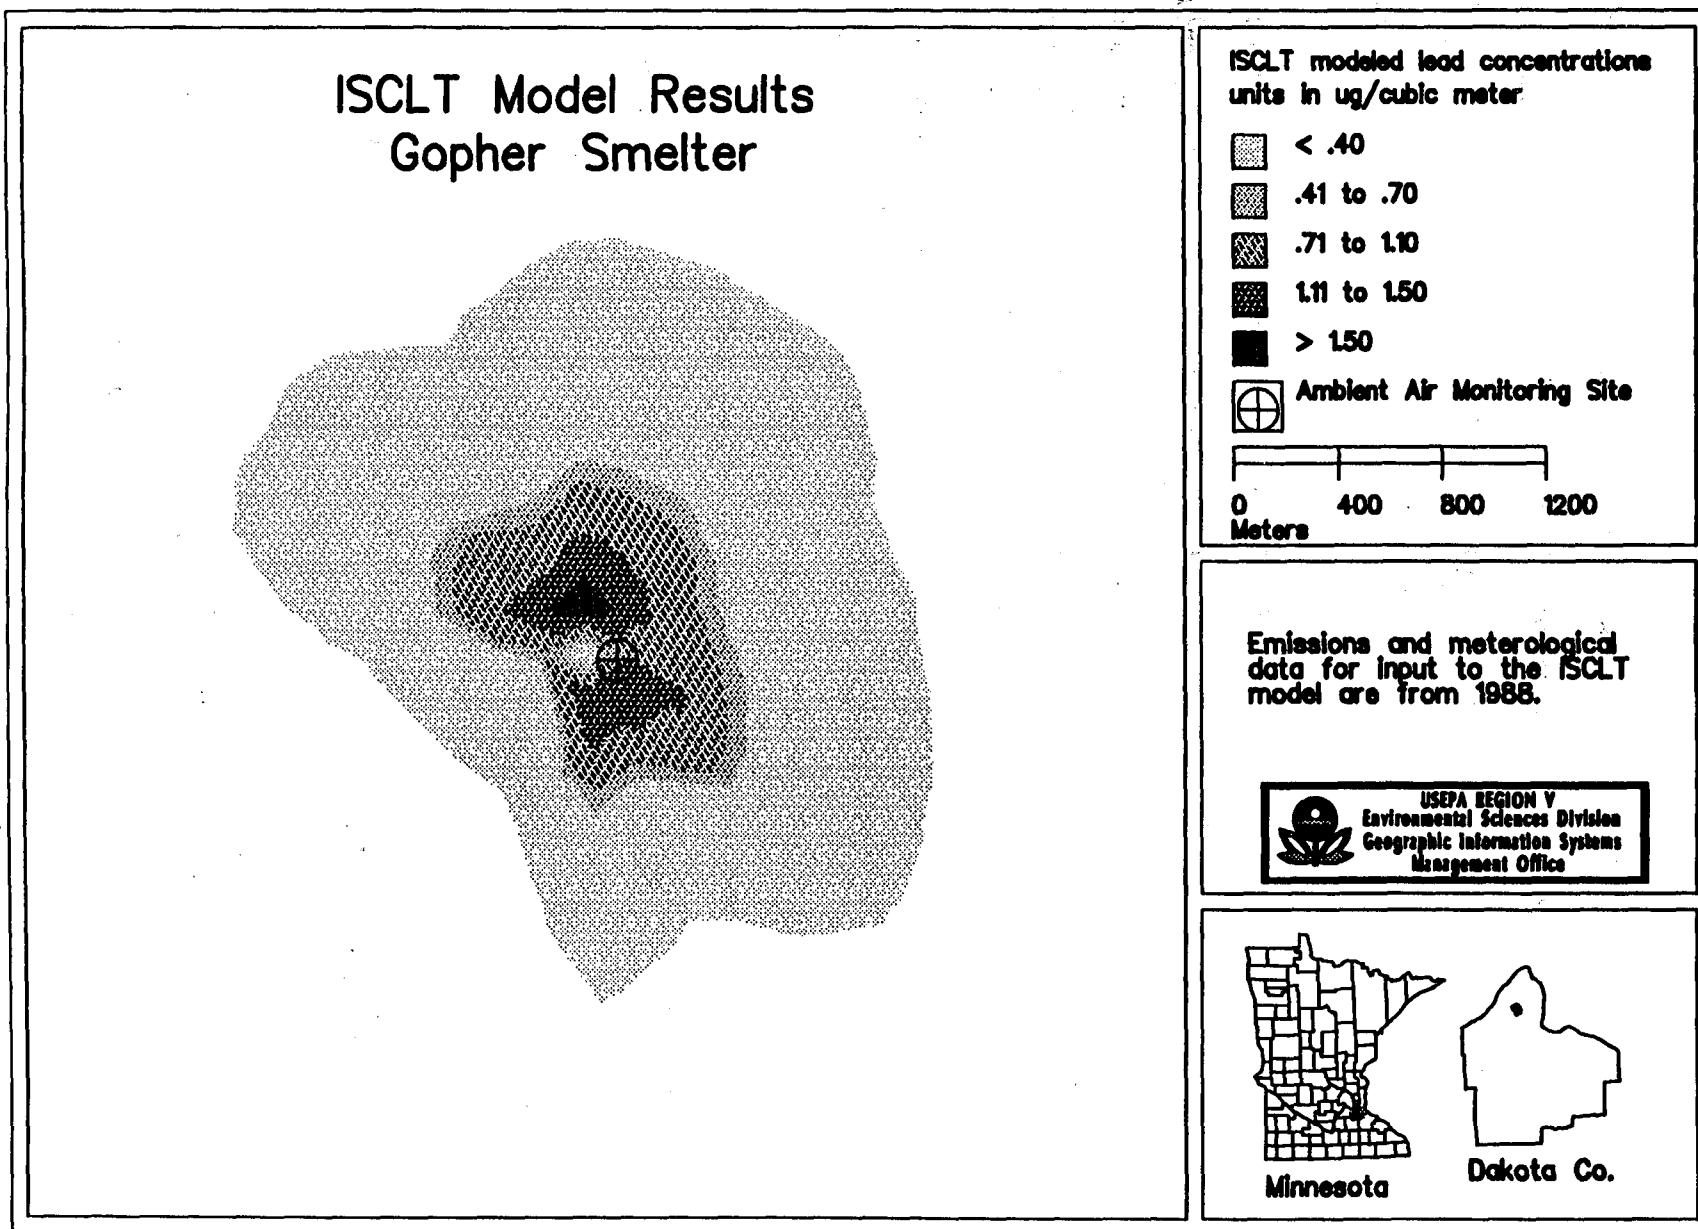

Because children are at elevated risk, project LEAP used a targeted population of children under seven years of age, and [women of child bearing age as a surrogate for] the fetus. Within this population group, African-American and Hispanic children were particularly targeted in recognition of increased body burden susceptibility and thus vulnerability to the uptake and effects of lead exposure. Project LEAP required demographic data that could provide information concerning ethnicity, age, income, housing age and location.

3.1. Choices in Demographic Data

EPA has acquired demographic data to support the program offices across the Agency in their risk-based decision making processes. Most of EPA's demographic data was obtained from the U.S. Census Bureau; however, some data was obtained from private vendors.

The Census Bureau collects demographic information during a decennial census derived either

FIGURE 1

from the Short-Form or Long-Form questionnaire. Short-Form data is referred to as 100 percent data, because it is asked of the entire population. Long-Form is referred to as sampled data because it is collected from approximately 1 out of 6 households.

Private vendors provide data not available from the Census Bureau, such as projections of population counts beyond the current available census. This is estimated data derived from Census Bureau data and growth indicators.

The National Census structure for urban areas consists of blocks, block groups, tracts, counties, states, census divisions, census regions and the total United States.

Access to EPA demographic related data products is provided through the Geographic Resources Information and Data System (GRIDS). During the initial analysis phase of Project LEAP, the demographic data available through GRIDS consisted of 1980 Bureau of Census data and Donnelley Marketing Population Data (1970, 1980, 1990 estimated, 1995 estimated).

3.2. Choosing Donnelley Data

Because Project LEAP used 1988 environmental data, it was necessary to use Donnelley Marketing Population Data estimated for 1990 as the demographic data most representative of the exposure period.

Donnelley Marketing Population data contains information on sex, age, race, housing and income. The geographic data available for the Donnelley data consists of the centroid of the block group.

3.3. Creating Polygon Coverages from Point Data

From the centroid of the block group it was necessary for Project LEAP to produce polygons at the community level. The first step was to create a point coverage from the centroid of the block groups. From the block group point coverages thiessen polygons were produced. Thiessen polygons are created by joining every point to its neighbors, bisecting the resulting lines, drawing perpendicular lines at the

bisected points and creating polygons from the intersected lines. Figure 2 is an example of the generation of thiessen polygons from block group point data.

3.4. Creating LEAP Communities

The Bureau of Census defines areas by block, block group, tract and place. In general a census tract has a population of about 4,000 people and a place would be an entire city population. Because Project LEAP analysis is at the community level, it was necessary to subdivide cities in larger areas than census tracts. Groups or aggregates of tracts were created to form the LEAP communities.

The procedure developed to define LEAP communities was performed in the PC architecture environment using DBase III plus. The first step in developing communities was to create Dbase files of the Donnelley data at the block group level. ARC/INFO files of the Donnelley data were used to generate formatted files that were subsequently transferred to a PC and appended to a Dbase structure. The block group data were sorted by county and tract and a simple procedure written to count the tracts and replace the integer to a new field. Groups of ten census tracts became LEAP communities.

Figure 2 illustrates the entire process of creating the census tract point coverage, the thiessen polygons of block groups and the dissolving to LEAP communities.

4. UPTAKE BIOKINETIC MODEL RESULTS

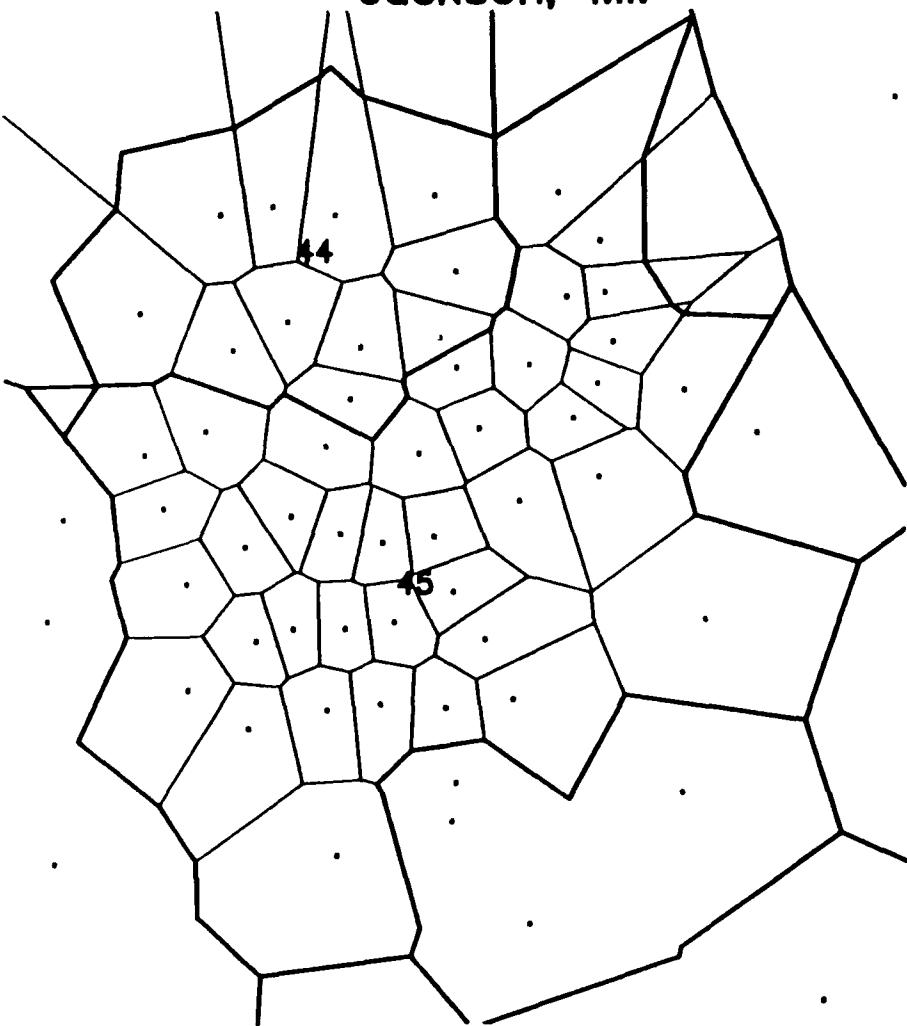

The UBK model used environmental concentrations and demographic information to determine the percentage of exceedance of expected blood-lead for each community. The percentage, applied against the population data for the community, provided an estimate of children at risk.

4.1. Summarizing the Demographic Data for the UBK Analysis

Dbase III was used to total the demographic data from the block group level to the community level and write the results to a second Dbase file. Subsequently the Dbase demographic file was imported into Lotus and used in obtaining input parameters for the UBK model and in determining the number of children at risk.

FIGURE 2

**Thiessen Polygon Results
Jackson, Mi.**

Thiessen polygons are generated by connecting each point to its neighboring points. The resulting lines are bisected and perpendicular lines drawn at the bisected points. The boundaries of the polygons are determined where the bisecting lines meet.

-  Thiessen Polygons
-  LEAP Communities

4.2. Creating ARC/INFO GIS Coverages from the UBK Model Results

The analysis to determine the percentage and number of children at risk was calculated using Lotus and the results exported to a Dbase III file. Based on the expected percentages of children to have blood-lead levels greater than 10 µg/dL Pb-B, the LEAP communities were assigned one of five group numbers. The group numbers were associated with a shade symbol used to create the maps of the cities. A Dbase III procedure was used to write an AML that created an INFO file of the UBK results. Using the LEAP community identification number as a relational field, the INFO polygon attribute file was joined to the file of results of the UBK model.

5. Producing Maps of the UBK Model Results

Maps were produced for the 10 top ranked cities by percentile of children exceeding 10µg/dL Pb-B and for the 10 top ranked cities for number of expected children exceeding 10 µg/dL PB-B.

5.1. Choosing UBK Map Features

The features in the map displays included the LEAP community borders, county borders, state borders and shading the communities based on the percentage of children with modeled blood-lead concentrations exceeding 10µg/dL Pb-B.

5.2. Choosing the UBK Categories

The range and distribution of UBK results were used to determine the number of categories and the break points for the categories. It was decided to have five categories. The highest category was defined at greater than 21, since few communities had percentages greater than 21. There are two categories less than the 10µg/dL Pb-B and three categories greater than the 10µg/dL Pb-B.

5.3 Designing the Color Shades for the Communities

The color shades for the communities with greater than 10µg/dL Pb-B were done using three progressively darker shades of red. The two shades less than 10µg/dL Pb-B were done in green and yellow.

6. Maps of LEAP Communities

Figures 3 through 16 consist of maps of Region 5 cities with the highest modelled blood lead concentrations. The integer within each community indicates its assigned identification number. A table follows each map listing the census tracts within every community. Following the maps are tables for the remaining central cities for which the UBK model was run.
