DISCLAIMER

This report has been reviewed by the Office of Toxic Substances, U. S. Environmental Protection Agency, and approved for publication. Approval does not signify that the contents necessarily reflect the views and policies of the U. S. Environmental Protection Agency, nor does mention of trade names or commercial products constitute endorsement or recommendation for use.

ABSTRACT

Methods for the analysis of polybrominated biphenyls (PBBs) by gas chromatography/mass spectrometry/computer (GC/MS/COMP) were developed using a 45 cm x 0.2 cm i.d. glass column packed with 2% OV-101 coated on Gas-Chrom Q. The column was programmed from 150-300°C at 20°C/min for the chromatography of mono- through pentabromobiphenyl and from 220-300°C at 12°C/min for hexa- through decabromobiphenyl. Two separate analyses were required to adequately separate the lower isomers and to yield definitive peaks for the higher isomers. A total of 80 samples were analyzed by GC/MS in the Multiple Ion Detection (MID) mode. They contained from undetectable to 860 µg/ml of PBBs. The higher isomers accounted for the majority of the PBBs found. Mass spectra obtained during GC/MS analysis of some of the more highly concentrated samples not only confirmed the presence of PBBs, but also detected polybrominated biphenyl ethers and other brominated compounds.

Three commercial samples of decabromobiphenyl ether ($C_{12}Br_{10}^{\ \ 0}$) were analyzed for impurities by GC/MS using the same conditions as for the higher PBBs. All three samples contained $C_{12}Br_{9}^{\ \ }$ ClO in small amounts and one sample contained traces of $C_{12}H_{2}Br_{8}^{\ \ 0}$ and $C_{12}HBr_{9}^{\ \ 0}$.

1.0 INTRODUCTION

Polybrominated biphenyls (PBBs) are used extensively as flame retardants for polymers, textiles, and other materials. (1) The major component of the most common commercial mixture, Fire Master PB- $6^{\otimes(2)}$, is hexabromobiphenyl. (3-7) Concern about the environmental impact and health effects of wide spread use of PBBs has been aroused by a recent major environmental catastrophe in Michigan. (4-8) Their chemical similarity to polychlorinated biphenyls (PCB) and polychlorinated naphthalenes (PCN) has raised the question of bioconcentration and toxicity to the point to warrant a test of the carcinogenicity of hexabromobiphenyl by the National Cancer Institute Bioassay Program. (9)

Spurred by the Michigan disaster, analytical methodologies have been developed and applied to feeds (5), dairy products (4) and soils. (6,7) Although extensive analytical work is being carried out with respect to samples originating in Michigan, little attention has been directed at more generalized pollution resulting from normal manufacture and use of PBBs throughout the United States. This research was designed to study potential industrial sources of PBBs and to assess their environmental occurrence.

2.0 SUMMARY, CONCLUSIONS AND RECOMMENDATIONS

Methods for the analysis of polybrominated biphenyls (PBBs) by gas chromatography/mass spectrometry/computer (GC/MS/COMP) were developed. Mono- through pentabromobiphenyls were analyzed using a 45 cm x 0.2 cm i.d. glass column packed with 2% OV-101 coated on Gas-Chrom Q and a flow rate of 30 cc/min helium. The column temperature was 150° initially, raised at 25°/min to 300°, then held constant. Hexa- through decabromobiphenyls were analyzed using the same gas chromatographic (GC) conditions as for the lower isomers except the flow rate was 20 cc/min and the column temperature was 220° initially, programmed at 12°/min to 300°, then held constant. Samples were analyzed using the mass spectrometer in the Multiple Ion Detection (MID) mode to achieve greater sensitivity.

A total of 87 samples were received from Environmental Sciences and Engineering (ES&E), Gainesville, Florida who collected, extracted, and added an external standard to the samples (EPA Contract No. 69-01-3248). The samples received included not only extracts of environmental samples, but also blanks, spikes, duplicates, etc. for quality control purposes.

The samples were analyzed for PBBs (both high and low levels of bromination). The total amounts of PBBs found ranged from undetectable to 860 μ g/ml. The higher isomers accounted for the majority of the PBBs found.

Mass spectra obtained during GC/MS analysis of some of the more highly concentrated samples confirmed the presence of PBBs and polybrominated biphenyl ethers and other brominated aromatics were also identified.

Three commercial samples of decabromobiphenyl ether ($C_{12}Br_{10}^{}$ 0) were analyzed by GC/MS to determine if impurities were present. The gas chromatographic conditions were the same as those used for the higher PBBs. All three samples were found to contain $C_{12}Br_{9}^{}$ ClO in small amounts and one sample contained traces of $C_{12}H_{2}Br_{8}^{}$ 0 and $C_{12}HBr_{9}^{}$ 0. Further research in

this area should be directed at the unusual fragmentation of decabromobiphenyl ether observed in the mass spectra. The trace impurities present in decabromobiphenyl ether could best be further investigated by high performance liquid chromatographic fractionation of large amounts of the sample to concentrate these impurities for mass spectrometric identification.

3.0 OBJECTIVES

The major emphasis of this research was to analyze a series of environmental samples for PBBs by GC/MS. The specific objectives were to (1) develop gas chromatographic conditions which separated the PBB components and elutes the compounds of interest within a short time with definitive, easily quantifiable peaks; (2) develop a quantification procedure for the PBBs found in the samples; (3) analyze the samples; (4) interpret the data; (5) confirm the presence of PBBs in some of the more highly concentrated samples; and (6) analyze three samples of commercially available decabromobiphenyl ether to determine gas chromatographable impurities.

4.0 METHOD DEVELOPMENT

Methods were developed for the analysis of PBBs by GC/MS using a short GC column. Each sample was analyzed twice, once separating the lower isomers and once eluting the higher isomers quickly to provide sharp peaks for detection and quantitation. Preliminary investigation using direct probe mass spectrometry for analysis of samples was shown not to be feasible. The development of analytical conditions is discussed in detail below.

4.1 EXPERIMENTAL APPARATUS, INSTRUMENTS AND CHEMICALS

Toluene (Burdick and Jackson, Muskegon, Michigan) was redistilled prior to use. Polybrominated biphenyls (4-bromobiphenyl, 4,4'-dibromobiphenyl, 2,2',5-tribromobiphenyl, 2,2',5,5'-tetrabromobiphenyl, 2,2',4,5,6-pentabromobiphenyl, 2,2',4,4',5,5'-hexabromobiphenyl, 2,2',3,3',5,5',6,6'-octabromobiphenyl, and decabromobiphenyl) and octachloronaphthalene were purchased from RFR Corporation, Hope, Rhode Island.

Analysis of all samples was accomplished using a Finnigan 3300 quadrupole GC/MS equipped with a PDP/12 computer. Direct probe analysis of a decabromobiphenyl ether sample was accomplished using an AEI MS 902 high resolution mass spectrometer. Complete descriptions of the instruments are presented in Appendix A.

4.2 DIRECT PROBE MASS SPECTROMETRIC ANALYSIS OF PBBs

Initial experiments using direct probe mass spectrometry indicated that this technique potentially could be an easy, sensitive, and very quick method of analyzing samples for the higher order PBB isomers. This avenue was pursued because these isomers were found to chromatograph poorly when using instrumental conditions for the analysis of PCBs and PCNs. Although the sensitivity of the direct probe for standards was excellent (<0.5 ng) and the sample analysis was completed within about 2-3 minutes (Figure 1), the procedure was non-reproducible. Furthermore, it suffered from non-specificity for environmental samples.

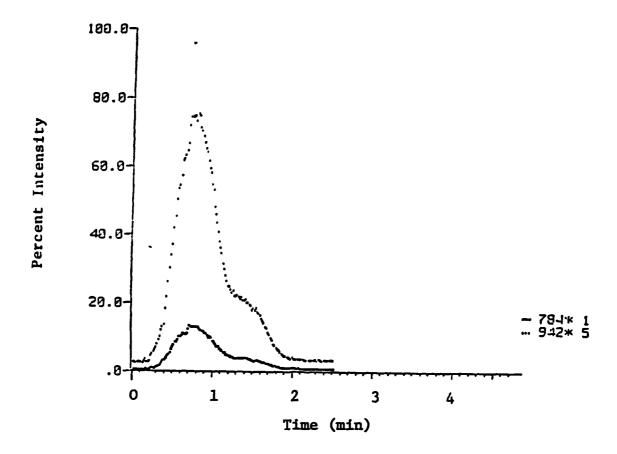

Figure 1. Plot of ion intensities vs. time during direct probe mass spectrometry analysis of "Soil Extract/Hexane Spiked" sample.

4.3 GC/MS/COMP ANALYSIS OF HIGHLY BROMINATED PBBs

Initial experiments indicated that, under the conditions necessary for resolution of the lower brominated PBBs, the highly brominated PBBs had long retention times and eluted as broad, diffuse peaks. Since such broad peaks were not conducive to quantification and reduced the sensitivity of the analysis, GC conditions were sought which eluted these compounds quickly as definitive peaks. These conditions, which were adopted for the analysis of samples, required a 45 cm x 0.2 cm i.d. glass column packed with 2% OV-101 coated on Gas-Chrom Q and a flow rate of 20 cc/min helium. temperature of the molecular separator was 280°, the injection port 270°, and the GC column 220° initially, and then programmed at 12°/min to 300°. Under these conditions, hexa-, hepta-, octa-, nona-, and decabromobiphenyls and the octachloronaphthalene standard were resolved as definitive peaks. Decabromobiphenyl eluted within 6 min (Figure 2, Table 1). Hepta- and nonabromobiphenyl were not commercially available, but were found to be impurities in the standards. As seen in Figure 2, both isomers of nonabromobiphenyl are present, with retention times of 4.6 and 5.2 min.

The mass spectrometer ionization volatage was 70 eV (nominal) and the electron multiplier voltage was between 1.8-2.2 kV. The spectrometer was either scanned from m/e 100-1000 or used in the MID mode as discussed below.

4.4 GC/MS/COMP ANALYSIS OF LOWER BROMINATED PBBs

Gas chromatographic conditions were developed for separating the lower (mono- through penta-) brominated PBBs which also eluted the higher isomers within a reasonable time in preparation for another injection. The GC/MS conditions were the same as described above, except the column temperature was 150° initially, raised at 20°/min to 300°, then held constant, and the flow rate was 30 cc/min. Figure 3 and Table 2 illustrate the separations and retention times obtained under these conditions.

4.5 SELECTION OF m/e IONS FOR MID ANALYSIS

Multiple ion detection (MID) is an operational mode for gas chromatograph/mass spectrometers where several m/e values are monitored through the chromatogram. To obtain each m/e value preset voltages are step-jumped at short time intervals. Since this technique also allows integration of ion

intensity for a longer time period for the desired ions than in the customary full-scan mode, the sensitivity of the instrument generally is increased by approximately two orders of magnitude. By judicious selection of m/e values for monitoring specific compounds, interference by unwanted compounds can usually be minimized.

Eight m/e ions were selected for monitoring the PBBs with the ninth channel devoted to detection of the octachloronaphthalene external standard (Table 4). Ions were chosen from the parent cluster even though they were not necessarily the most intense to reduce the probability of interference from fragments of other PBBs or compounds.

The m/e ions selected were generally those most intense in the parent cluster. The natural abundance of two major bromine isotopes (atomic weights of 79 and 81) yields a cluster of ions with the different isotopic permutations as shown in Table 3. This table illustrates clearly that the parent ion (M) was not nearly as intense as ions at or near the centroid of the cluster.

The m/e ions selected for MID analysis are shown in Table 4. Two m/e ions are listed for each isomer and to the extent possible, both ions were used to confirm the presence of brominated compounds. The relative intensity of the two m/e ions as calculated from the theoretical isotopic abundance was used for comparing and confirming the identity and purity of the PBBs monitored in environmental samples.

4.6 SELECTION OF EXTERNAL STANDARD

Octachloronaphthalene (OCN) was selected as an external standard based on its similar retention time to the middle isomers of the PBBs, its high molecular weight, unique parent ion, and low likelihood of occurrence in these environmental samples. The environmental occurrence of OCN has been shown to be relatively infrequent even in areas where high concentrations of other polychlorinated naphthalenes were observed. (11) The high molecular weight and unique parent ion of OCN reduced the chance of interference from background or sample components. In addition, the low volatility of OCN decreased the possibility of loss prior to analysis.

4.7 QUANTITATION

Quantitation was achieved by comparing the computer-calculated integrated area of the PBB isomers with the integrated response for a known amount of octachloronaphthalene. To compensate for differences in ionization cross-section, the relative molar response of available PBB standards was obtained.

The calculation of the relative molar response (RMR) factor allows the estimation of the levels of sample components without establishing a calibration curve. The RMR is calculated as the integrated peak area of a known amount of the compound, A_{unk}^o , with respect to the integrated peak area of a known amount of standard, A_{std}^o (in this case octachloronaphthalene), according to the equation

$$RMR = \frac{A_{unk}^{o}/moles_{unk}}{A_{std}^{o}/moles_{std}} = \frac{(A_{unk}^{o})(mw_{unk})(g_{std})}{(A_{std}^{o})(mw_{std})(g_{unk})}$$
 (Equation 1)

From this calculated value, the concentration of an identified compound in a sample is calculated by rearranging Equation 1 to give

$$g_{unk} = \frac{(A_{unk})(mw_{unk})(g_{std})}{(A_{std})(mw_{std})(RMR)}$$
 (Equation 2)

The use of RMR for quantitation by GC/MS has been successful in repeated applications to similar research problems. $^{(10-12)}$

The RMRs for the available PBB isomers were calculated from the numerical integrations of peaks observed in the appropriate MID channel. The RMRs listed in Table 5 are mean values of three injections of each of three replicate standard mixtures. The standard of 2,2',3,3',5,5',6,6'- octabromobiphenyl was found to be severely contaminated by hepta- and nonabromobiphenyl isomers, so they were not used in the RMR calculations. The RMR values listed for hepta-, octa-, and nonabromobiphenyl were calculated from a linear interpolation between the RMR values obtained for hexa- and decabromobiphenyl.

Several qualifications must be recognized regarding the RMR values presented in Table 5. The values obtained for these positional isomers were probably not highly precise for other isomers since differences in the

 $^{^{\}rm d}$ Value obtained by linear interpolation between values for 2,2',4,4',5,5'-hexabromobiphenyl and decabromobiphenyl

ionization cross-section may occur. The purity of the standards in some cases were questionable; a small quantity of nona- and hepta- were found in the decabromobiphenyl and hexabromobiphenyl samples, respectively. Both impurities were judged to be <5% and were ignored for the RMR determinations. The relative molar response depends not only on the ionization cross-section, but also on instrumental parameters, including the ion slit widths, exact mass setting, and electronic drift. These considerations were more pronounced over the wider mass ranges used in PBB analysis. Thus, the accuracy of PBB analysis is highly dependent upon the precise determinations of the RMR factor.

4.8 REPRODUCIBILITY

Two samples were analyzed by multiple injections to check the reproducibility of analysis for the various isomers and over the range of PBB levels found. Table 6 summarizes the results for the triplicate analysis of sample number 6077 for the lower isomers. The reproducibility is better than ±10%. Table 7 illustrates the replicate analyses of sample 6058 for the higher isomers. The lack of reproducibility observed for hexa- and heptabromobiphenyl was attributed to the low concentrations, which approached the detection limit. The reproducibility of the analyses for the higher PBB isomers was somewhat impaired by instrumental instabilities at higher m/e values. It is important to note the agreement between the first analysis and the subsequent analyses which were obtained at different time periods (days). This agreement supports the use of RMR values for quantitation.

5.0 SAMPLE RECEIPT

Samples were received from ES&E generally in 1.0 ml conical reaction vials with Teflon®-lined septum caps. Each sample had been spiked with 5 ng/µl octachloronaphthalene as an external standard for retention time correlation and quantification. Samples were shipped in ice and were stored at 5° following receipt. Each sample was logged for quality control purposes (a sample log book was used to record the status of each sample) as it was processed and the receipt and numerical coding confirmed via telephone with personnel at ES&E.

A total of 87 samples were received, as listed in Tables 8 and 9 in Section 6.

6.0 ANALYSIS OF ENVIRONMENTAL SAMPLES FOR PBBs

6.1 SAMPLE ANALYSIS

Using the GC/MS methods discussed in Section 4, the samples were analyzed first for the higher PBB isomers (hexa- through decabromobiphenyl) and then for the lower isomers (mono- through pentabromobiphenyl). On the advice of the Project Officer, some of the samples for which no higher isomers were detected were not analyzed for the lower isomers. In addition, the last batch of samples was received after the period of performance ended and were not analyzed.

The results of the analysis of blanks and spiked samples are presented in Table 8. Table 9 summarizes the results of the analysis of numbered samples and numbered spikes.

A sample of the OCN solution (5 ng/ μ l) used to spike the samples were obtained for ES&E and compared with the OCN solution (4.9 ng/ μ l) prepared in house. Replicate analyses of the two samples yielded integrated areas of 485.4 \pm 25.5 and 313.5 \pm 18.2, respectively. Taking into account the calculated concentrations, the OCN sample from ES&E was 1.52 times more concentrated that that prepared in house. Since the value directly affects the concentrations in the sample (see Equation 2), the values in Tables 8 and 9 reflect this correction.

6.2 CONFIRMATION FROM MASS SPECTRAL DATA

Several samples contained sufficient concentrations of PBBs for acquisition of full mass spectra. These analyses confirmed the presence of PBB isomers and several other related compounds were also detected.

Sample number 6077 contained a large number of bromobenzene, bromotoluene, and bromobiphenyl ether species as shown in Table 10. The total ion current (TIC) chromatogram and representative mass spectra are presented in Appendix B.

7.0 ANALYSIS OF COMMERCIAL DECABROMOBIPHENYL ETHER SAMPLES FOR IMPURITIES

Three commercial samples of decabromobiphenyl ether ("Decabrom", ${}^{\rm C}_{12}{}^{\rm Br}_{10}{}^{\rm O}$) were analyzed by GC/MS and direct probe mass spectrometry for characterization of any potentially toxic impurities.

One sample of decabromobiphenyl ether (DECABROM-PS) was purchased from Polyscience, Inc., Warrington, Pennsylvania, Lot No. 5-46-8.

Another sample was obtained through the courtesy of Great Lakes Chemical Co., West Lafayette, Indiana, "Decabromobiphenyl Oxide, Great Lakes DE-83, Ref. No. NY-8860, 6-2-77". This sample is hereafter referred to as DECABROM-GRL.

The third sample was obtained through the courtesy of Dow Chemical Co., Midland, Michigan, Decabromobiphenyl Oxide, FR 300 BA, Lot No. 06076-2, 2# sample. This sample is hereafter referred to as DECABROM-DW.

Solutions of each sample were prepared at 1 mg/ml in toluene. The samples were subjected to GC/MS/COMP analysis on a Finnigan 3300 system using the chromatographic conditions for the higher PBBs (45 cm x 0.2 cm i.d. glass column packed with 2% OV-101 on Gas-Chrom Q; 220° initial, programmed at 12°/min to 300°; 30 cc/min helium carrier gas).

The samples were found to contain primarily $C_{12}Br_{10}^{}0$ with small amounts of $C_{12}Br_{9}^{}$ ClO. DDECABROM-DW also contained traces of $C_{12}H_{2}Br_{8}^{}0$ and $C_{12}HBr_{9}^{}0$. These results are summarized in Figures C-1 through C-3. Two ion clusters were present in the mass spectrum of $C_{12}Br_{10}^{}0$ and $C_{12}Br_{9}^{}ClO$ (Figure C-1) which were not readily assignable as fragments of either molecule. These clusters, centered at m/e 692 and m/e 613, do not result from simple debromination or dechlorination of either of the two molecules, so the samples were examined further to determine if additional impurities were present. Close examination of the GC/MS data indicated that these clusters co-eluted

with the other ions attributed to $C_{12}Br_{10}O$ and its fragments. Exact mass measurements (to 4 decimal places) were made by direct probe mass spectral analysis using an AEI MS 902 (see Appenix A for a description of the system). Computerized peak matching found excellent correlation of $C_{11}Br_7$ with the ion cluster centered at m/e 692 and a mixture of $C_{11}Br_6$ and $C_{11}Br_6H$ with the ion cluster centered at m/e 613. Both the GC/MS and direct probe MS data indicated that $C_{11}Br_7$ and $C_{11}Br_6$ are fragments of $C_{12}Br_{10}O$, implying an unusual loss of CO from the diphenyl ether molecule. The origin of the $C_{11}Br_6H$ species remain unidentified.

In summary, the impurities found in three decabromobiphenyl ether samples were $C_{12}Br_9C10$ (three samples), $C_{12}H_2Br_80$ (one sample), and $C_{12}HBr_90$ (one sample).

APPENDIX A

DESCRIPTION OF MASS SPECTROMETERS USED IN THIS PROGRAM

FINNIGAN 3300 GC/MS WITH PDP/12 COMPUTER

The Finnigan 3300 mass spectrometer has a mass range of 1000, with unit resolution over the entire range. Calibration of the system is routinely performed with PC-43 for lower mass ranges and tris(perfluoroheptyl)-atriazine in the higher ranges.

The PDP/12 computer is on-line with the Finnigan system. Long term storage of data is on LINC tapes or removable disc packs. The computer can subsequently treat stored data in several different ways to facilitate interpretation: (a) a reconstructed gas chromatogram is routinely made to obtain retention times; scan number for a given gas chromatographic peak is obtained by operator interaction with a CRT display; (b) any given mass spectrum or an entire series of scans are corrected for background signal (column bleed, septum bleed, etc.); (c) plots of intensities of specific ions (mass fragmentography) are made from the scan data. This type of information is often useful, when correlated with retention time data, for simplifying the identification of particular compounds. Peak areas are also readily obtainable from these mass chromatograms and can be used to provide quantitative information; (d) normalized mass spectra are plotted, using different types of normalization or amplification factors in order to facilitate identification; (e) hard copy output of normalized data in digital form, with various forms of background correction, is also available.

The GC system in use on the Finnigan mass spectrometer is a Finnigan 9500.

The basic hardware of the PDP/12 consists of an 8K central processor fitted with a teletype, random access disc, CRT display and electrostatic printer/plotter. The interface to the mass spectrometer was custom-designed and built and consists of both analog to digital as well as digital to analog interfaces. The latter involves several unique concepts in interface design, since by using this system it is possible to put the entire mass spectral scanning operation under computer control. Since the data acquisition phase of the spectrometer operation is controlled entirely by the computer, a large number of different types of acquisition protocols have been implemented. For example, in the multiple ion detection mode, up

up to nine individual peaks can be selected within the entire mass spectral range, and acquired for varying time intervals as selected by the operator. In the repetitive scanning mode, scan intervals down to one scan per second are possible with entire scans recorded either on LINC tapes or disc.

All data processing operations are carried out interactively by means of programs stored on the small computer.

AEI MODEL 902 HIGH RESOLUTION MASS SPECTROMETER

The spectrometer is equipped with computerized data acquisition and direct-line access to the Triangle Universities Computation Center (TUCC). The PDP/8 computer on this mass spectrometer is fitted with a teletype, high speed paper tape reader and punch, and random access disc. The mass spectrometer interface is of conventional design, making use of a 15 kHz A/D converter, which is suitable for high resolution data acquisition.

Mass spectra are acquired at high resolution with on-line data reduction to the level of peak intensities and peak times. This information is stored on the disc. Under usual operating conditions, a number of spectra are accumulated on the disc and then are sent en masse to the Triangle Universities Computation Center (TUCC) IBM 370/165 for all further processing. The data are transmitted to TUCC by means of a program specially designed and executed at CLS. The technique employed involves having the PDP/8 simulate an IBM 2780 card reader which is interfaced by a synchronous 2000 Baud modem to the telephone line. The communication protocol employed is standard IBM bi-synchronous communication with the PDP/8 carrying out the entire protocol by suitable software. Once received at TUCC, the data are processed by means of programs developed at CLS, and reports either returned to the laboratory or sent out as required to any of the many terminals located in the TUCC facility.

15. SUPPLEMENTARY NOTES

16. ABSTRACT

Methods for the analysis of polybrominated biphenyls (PBBs) by gas chromatography/ mass spectrometry/computer (GC/MS/COMP) were developed using a 45 cm x 0.2 cm i.d. glass column packed with 2% OV-101 coated on Gas-Chrom Q. The column was programmed from 150-300°C at 20°C/min for the chromatography of mono- through pentabromobiphenyl and from 220-300°C at 12°C/min for hexa- through decabromobiphenyl. Two separate analyses were required to adequately separate the lower isomers and to yield definitive peaks for the higher isomers. A total of 80 samples were analyzed by GC/MS in the Multiple Ion Detection (MID) mode. They contained from undetectable to 860 $\mu g/ml$ of PBBs. The higher isomers accounted for the majority of the PBBs found. Mass spectra obtained during GC/MS analysis of some of the more highly concentrated samples not only confirmed the presence of PBBs, but also detected polybrominated biphenyl ethers and other brominated compounds.

Three commercial samples of decabromobiphenyl ether ($C_{12}Br_{10}O$) were analyzed for impurities by GC/MS using the same conditions as for the higher PBBs. All three samples contained $C_{12}Br_9ClO$ in small amounts and one sample contained traces of $C_{12}H_2Br_8O$ and $C_{12}HBr_9O$.

INSTRUCTIONS

1. REPORT NUMBER

Insert the EPA report number as it appears on the cover of the publication.

2. LEAVE BLANK

3. RECIPIENTS ACCESSION NUMBER

Reserved for use by each report recipient.

4. TITLE AND SUBTITLE

Title should indicate clearly and briefly the subject coverage of the report, and be displayed prominently. Set subtitle, if used, in smaller type or otherwise subordinate it to main title. When a report is prepared in more than one volume, repeat the primary title, add volume number and include subtitle for the specific title.

5. REPORT DATE

Each report shall carry a date indicating at least month and year. Indicate the basis on which it was selected (e.g., date of issue, date of approval, date of preparation, etc.).

6. PERFORMING ORGANIZATION CODE

Leave blank.

7. AUTHOR(S)

Give name(s) in conventional order (John R. Doe, J. Robert Doe, etc.). List author's affiliation if it differs from the performing organization.

8. PERFORMING ORGANIZATION REPORT NUMBER

Insert if performing organization wishes to assign this number.

9. PERFORMING ORGANIZATION NAME AND ADDRESS

Give name, street, city, state, and ZIP code. List no more than two levels of an organizational hirearchy.

10. PROGRAM ELEMENT NUMBER

Use the program element number under which the report was prepared. Subordinate numbers may be included in parentheses.

11. CONTRACT/GRANT NUMBER

Insert contract or grant number under which report was prepared.

12. SPONSORING AGENCY NAME AND ADDRESS

Include ZIP code.

13. TYPE OF REPORT AND PERIOD COVERED

Indicate interim final, etc., and if applicable, dates covered.

14. SPONSORING AGENCY CODE

Insert appropriate code.

15. SUPPLEMENTARY NOTES

Enter information not included elsewhere but useful, such as: Prepared in cooperation with, Translation of, Presented at conference of, To be published in, Supersedes, Supplements, etc.

16. ABSTRACT

Include a brief (200 words or less) factual summary of the most significant information contained in the report. If the report contains a significant bibliography or literature survey, mention it here.

17. KEY WORDS AND DOCUMENT ANALYSIS

(a) DESCRIPTORS - Select from the Thesaurus of Engineering and Scientific Terms the proper authorized terms that identify the major concept of the research and are sufficiently specific and precise to be used as index entries for cataloging.

(b) IDENTIFIERS AND OPEN-ENDED TERMS - Use identifiers for project names, code names, equipment designators, etc. Use open-ended terms written in descriptor form for those subjects for which no descriptor exists.

(c) COSATI FIELD GROUP - Field and group assignments are to be taken from the 1965 COSATI Subject Category List. Since the majority of documents are multidisciplinary in nature, the Primary Field/Group assignment(s) will be specific discipline, area of human endeavor, or type of physical object. The application(s) will be cross-referenced with secondary Field/Group assignments that will follow the primary posting(s).

18. DISTRIBUTION STATEMENT

Denote releasability to the public or limitation for reasons other than security for example "Release Unlimited." Cite any availability to the public, with address and price.

19. & 20. SECURITY CLASSIFICATION

DO NOT submit classified reports to the National Technical Information service.

21. NUMBER OF PAGES

Insert the total number of pages, including this one and unnumbered pages, but exclude distribution list, if any.

22. PRICE

Insert the price set by the National Technical Information Service or the Government Printing Office, if known.
