#### **FOREWORD**

This report is the result of a cooperative effort between the Office of Research and Development's Hazardous Waste Engineering Research Laboratory (HWERL) and the Office of Air Quality Planning and Standard's Monitoring and Data Analysis Division (MDAD). The overall management of Tier 4 of the National Dioxin Study was the responsibility of MDAD. In addition, MDAD provided technical guidance for the source test covered by this report. HWERL was directly responsible for the management and technical direction of the source test.

#### 1.0 INTRODUCTION

This report summarizes the results of a dioxin/furan emissions test of a black liquor recovery boiler equipped with a wet-bottom electrostatic precipitator for particulate matter emissions control. Black liquor recovery boilers are used at Kraft pulp mills to produce process steam and to reclaim inorganic chemicals from spent wood pulping liquors. The test is the fourth in a series of several dioxin/furan emissions tests being conducted under Tier 4 of the National Dioxin Study. The primary objective of Tier 4 is to determine if various combustion sources are sources of dioxin and/or furan emissions. If any of the combustion sources are found to emit dioxin or furan, the secondary objective of Tier 4 is to quantify these emissions.

Black liquor recovery boilers are one of 16 combustion source categories being considered in the Tier 4 program. The tested black liquor boiler, hereafter referred to as boiler BLB-A, was selected for this test after an initial information screening and a one-day pretest survey visit. Boiler BLB-A is considered representative of new black liquor recovery boilers built in the last 5 to 10 years. The amount of chlorides present in the black liquor circuit at this site is typical of that found at other Kraft pulp mills.

This test report is organized as follows. A summary of test results and conclusions is provided in Section 2.0, followed by a detailed process description in Section 3.0. The source sampling and analysis plan is outlined in Section 4.0, and the dioxin test data are presented in Section 5.0. Sections 6.0 through 9.0 present various testing details. These include descriptions of the sampling locations and procedures (Section 6.0), descriptions of the analytical procedures (Section 7.0), and a summary of the quality assurance/quality control results (Section 8.0). The appendices contain data generated during the field sampling and analytical activities.

<sup>&</sup>lt;sup>a</sup>The term "dioxin/furan" and the acronyms PCDD and PCDF as used in this report refer to the polychlorinated dibenzo-p-dioxin and dibenzofuran homologues with four or more chlorine atoms.

#### 2.0 SUMMARY

#### 2.1 SOURCE SAMPLING AND ANALYSIS OVERVIEW

The host plant (Site 04) is a Kraft pulp mill that produces pulp and paper products. Black liquor recovery boiler BLB-A combusts concentrated spent liquor from the pulping process and recovers the inorganic chemicals used to produce pulp from wood chips. Particulate matter emissions from black liquor boiler BLB-A are controlled by a wet bottom electrostatic precipitator. A simplified process flow diagram of the system is shown in Figure 2-1.

The gaseous, liquid, and solid sampling performed during the test program is summarized in Table 2-1. Sampling for dioxin and furan was performed simultaneously at the electrostatic precipitator outlet exhaust stack and the electrostatic precipitator inlet location (i.e., black liquor boiler outlet) in each of a series of three test runs conducted on December 11 through 14, 1984. The dioxin/furan sampling was based on the October 1984 draft of the Modified Method 5 (MM5) procedure developed by the American Society of Mechanical Engineers (ASME) for measuring emissions of chlorinated organic compounds from municipal waste incinerators. Modifications to the ASME protocol are discussed in Section 6. MM5 train components and train rinses were analyzed for dioxins and furans by EMSL-TRP and ECL-BSL, two of three EPA laboratories collectively known as Troika. The dioxin/furan analysis quantified the 2378-TCDD\* isomer and the tetra- through octa- dioxin/furan homoloques present in the samples.

Dioxin/furan and dioxin/furan precursor analyses were performed on samples of the concentrated black liquor fed to the boiler. The black liquor dioxin/furan analyses were performed by EPA ECL-BSL and EMSL-RTP laboratories, and the dioxin precursor analyses were performed by Radian. The specific dioxin precursors analyzed for were chlorophenols, chlorobenzenes, polychlorinated biphenyls, and total chlorine. Samples of black liquor circuit intermediates (caustic, white liquor, and weak black liquor) and ClO<sub>2</sub>

<sup>\*</sup>The terms TCDD and TCDF as used in this report refer to tetrachloro dibenzo-p-dioxin and tetrachlorodibenzo furan.

TABLE 2-1. SOURCE SAMPLING AND ANALYSIS OVERVIEW

Item		Item Description		
1.	Number of test runs	-	Three identical test runs -(Runs -1, -2, 3).	
2.	Gaseous Sampling	<b>-</b>	MM5 sampling at black liquor boiler outlet and ESP outlet exhaust stack (Runs 1, 2, 3). Dioxin/furan analysis.	
		-	EPA Reference Methods 2 and 4 at black liquor boiler outlet and ESP outlet exhaust stack (Runs 1, 2, 3). Gas velocity and moisture.	
		-	Integrated bag sampling at black liquor boiler outlet and ESP outlet exhaust stack (Runs 1, 2, 3). CO <sub>2</sub> , O <sub>2</sub> , N <sub>2</sub> analysis for molecular weight determination.	
		-	HCl sampling at ESP Outlet exhaust stack (Runs 1, 2, 3). HCl analysis.	
		-	Continuous monitoring of CO, CO <sub>2</sub> , O <sub>2</sub> , SO <sub>2</sub> , and NO <sub>2</sub> , total hydrocarbons at black liquor boiler cutlet (Runs 1, 2, 3).	
3.	Liquid Sampling	-	Strong black liquor sampling (Runs 1, 2, 3,). Dioxin/furan analysis, dioxin/furan precursor analysis, and total chlorine analysis.	
		-	Caustic sampling (Runs 1, 2, 3). Total chlorine analysis.	
		-	White liquor sampling (Runs 1, 2, 3). Total chlorine analysis.	
		-	Weak black liquor sampling (Runs 1, 2, 3). Total chlorine analysis.	
		-	ClO, generation system by-product salt cake sampling (Runs 1, 2, 3). Total chlorine analysis.	
4.	Solids Sampling	-	Soil sampling <sup>a</sup> (one composite sample from 10 locations). Potential dioxin/furan analysis.	

<sup>&</sup>lt;sup>a</sup>Sample(s) to be analyzed pending evaluation of the dioxin/furan emissions data from the MM5 sampling train.

generation system by-product salt cake that is fed to the black liquor circuit were taken and analyzed by Radian for total chlorine. The total chlorine analyses of these streams were used to quantify the major chlorine inputs to the black liquor circuit. A single composite soil sample was also taken, but analysis of this sample was deferred pending evaluation of the dioxin/furan emissions data.

Continuous emissions monitoring (CEM) was performed at the electrostatic precipitator inlet location for CO,  ${\rm CO_2}$ ,  ${\rm NO_x}$ ,  ${\rm SO_2}$ , total hydrocarbons (THC), and  ${\rm O_2}$ . Total reduced sulfur (TRS) monitoring data taken regularly by the plant at the ESP outlet exhaust stack were also obtained. Plant personnel calibrated the TRS monitoring instrument daily during the test program. The continuous monitoring data were used in conjunction with process data to document the stability of combustion conditions during the test.

#### 2.2 SUMMARY OF RESULTS

The data obtained at Site BLB-A during the Tier 4 test program are summarized in Figure 2-2. Only the hepta- and octa-CDD species were consistently detected in the stack gas at the outlet from the ESP. For the furan species, the tetra-, hexa-, hepta- and octa-CDF homologues were consistently detected in the ESP outlet gas stream. As shown in Table 2-2, average as-measured stack gas concentrations of the total PCDD and total PCDF at the ESP outlet were 0.67 ng/dscm and 0.51 ng/dscm, respectively. The average hourly emission rates were 150 ug/hr for total PCDD and 114 ug/hr for total PCDF. Octa-CDD was the most prevalent of the tetra- through octa-chlorinated dioxin homologues, while the furans were fairly evenly distributed among the tetra- through octa-chlorinated furan homologues. The ESP appeared to have positive control for reducing dioxin/furan emissions although analytical uncertainties inherent in GC/MS analysis limited the ability to quantify the control efficiency accurately.

Analysis of the flue gas samples taken at the ESP inlet did not detect any 2378 TCDD or 2378 TCDF. Detectable quantities of PCDD and PCDF homologues were found in the inlet flue gas to the ESP. Average as-measured stack gas concentrations of total PCDD and total PCDF at the ESP inlet were 1.59 ng/dscm

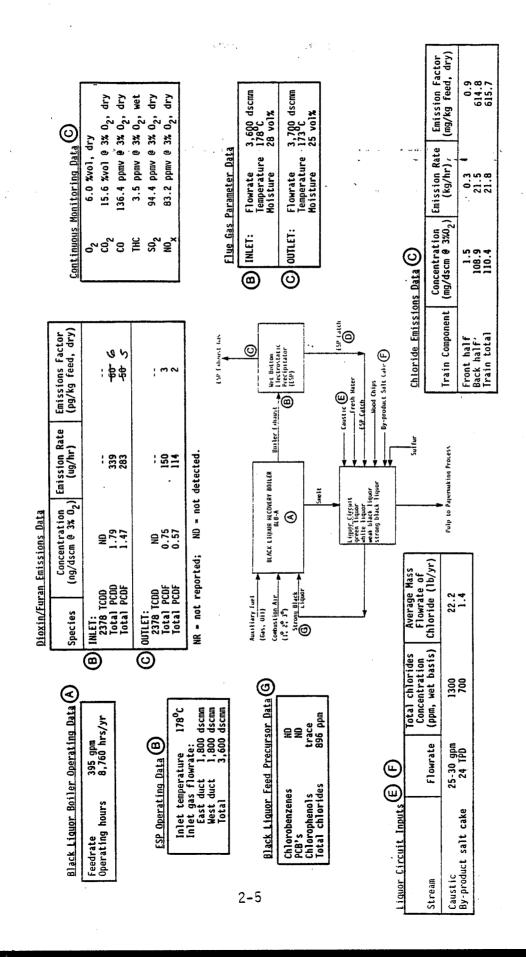

Figure 2-2. Data summary for Site BLB-A.

TABLE 2-2. SUMMARY OF MEAN DIOXIN AND FURAN EMISSIONS DATA FOR SITE BLB-A

Parameter	2378 TCDD <sup>a</sup>	Total PCDD	Total PCDF
INLET:		;	
Emissions Concentration (ng/dscm)			}
As-measured	ND	1.59	1.31
Corrected to 3% 0 <sub>2</sub>		1.79	1.47
Emissions Rate (ug/hr)	to van	339	283
OUTLET:			!
Emissions Concentration (ng/dscm)			
As-measured	ND	0.67	0.51
Corrected to 3% 02	49 - 40	0.75	0.57
Emissions Rate (ug/hr)	in mp	150	114

<sup>&</sup>lt;sup>a</sup>Values in parenthesis are detection limits expressed in the corresponding units.

ND - Not detected.

and 1.31 ng/dscm respectively. The hourly emission rates were 339 ug/hr for total PCDD and 283 ug/hr for total PCDF. The octa-chlorinated dioxin homologue was the predominant dioxin species while the furan species were distributed fairly evenly among the tetra- through hepta-CDF homologues.

Chloride emissions at the ESP outlet were measured at  $98.1 \, \text{mg/dscm}^2$  which corresponds to  $110.4 \, \text{ng/dscm}$  @  $3\% \, 0_2$ . The average chlorides emission factor was calculated to be  $615.7 \, \text{mg}$  chloride emitted per kilogram of black liquor fired on a dry basis.

The black liquor feed rate to Boiler BLB-A was 395 gpm during the test period. Precursor analysis of the black liquor did not detect chlorobenzenes or polychlorinated biphenyls. A trace amount of chlorophenols were detected, and the black liquor contained 896 ppm of total chlorides.

The ESP treated an average of 3,600 dscmm at a temperature of  $178^{\circ}$ C. At the ESP outlet, the measured flowrate was 3,700 dscmm at a temperature of  $173^{\circ}$ C. Average flue gas concentrations measured at the ESP outlet by the Radian continuous emissions monitoring system were:  $0_2$ , 6.0 vol%;  $0_2$ ,  $0_2$

#### 3.0 PROCESS DESCRIPTION

This section describes the host site and the black liquor recovery boiler/electrostatic precipitator system tested. Data summarizing the operation of the boiler and the precipitator during the test periods are presented in Section 5.0.

#### 3.1 FACILITY DESCRIPTION

The host plant (Site 04) is a typical Kraft pulp and paper mill with a rated capacity of 855 Mg/day (940 TPD) of air-dried pulp. The plant maintains three black liquor recovery boilers with rated capacities of 365 Mg/day (400 TPD), 590 Mg/day (650 TPD), and 815 Mg/day (900 TPD) of air-dried, unbleached pulp. Two of the three black liquor boilers were operating during the dioxin/furan tests, while the third was being modified for future use. These boilers are typically base-loaded. Two combination boilers firing bark, wood refuse, and non-condensible gases from the black liquor evaporators are swing-loaded to cover variations in process steam demand.

Pine logs and pine wood chips are transported to Site BLB-A by truck. To the best knowledge of plant personnel, none of the wood processed in the pulping circuit has been stored in salt water or treated with pentachlorophenol (PCP). Approximately 80 digester batches per day are processed in the 10 digesters at the pulping plant. Each batch consists of 55 Mg (60 tons) of wood chips, 42 cubic meters (1500 ft<sup>3</sup>) of white liquor, and a small amount of weak black liquor.

The contents of the finished digester batches are sent to a "blow tank" for intermittent storage and then to a countercurrent "brown stock washer" system. Pulp is separated from the rest of the finished digestor batch in the brown stock washers. Dirty water from the brown stock washers (i.e., weak black liquor) is sent to an evaporator system for solids concentration prior to being fired in the black liquor boiler. Typical process flow rates of various streams in the pulp mill circuit are shown in Table 3-1.

TABLE 3-1. TYPICAL PROCESS FLOW RATES OF VARIOUS PULP MILL MATERIALS AT SITE BLB-A

Material	Process Flow Rate	Other Information
-By-próduct salt cake	24 tons/day	Predominantly sodium sulfate
-White liquor	620 gpm	Sodium sulfide/ sodium hydroxide
-Weak black liquor	1800-2000 gpm	18 wt % solids density 8.7 lb/gal
-Strong black liquor	395 gpm <sup>a</sup>	65 wt % solids density 11.8 lb/gal
-Caustic	15-30 gpm <sup>b</sup>	20% Sodium Hydroxide

a. No. 3 recovery boiler (BLB-A), 260 gpm; No. 1 recovery boiler, 135 gpm.

b. Caustic flow rate during tests was 25-30 gpm.

Cleaned pulp from the brown stock washer is bleached, pressed, and rolled into a variety of paper products. Bleaching is performed using chlorine dioxide (ClO<sub>2</sub>), which is produced on-site using the the R3 process. Approximately 22 Mg/day (24 tons/day) of by-product salt cake (predominantly sodium sulfate, Na<sub>2</sub>SO<sub>4</sub>) from this process is fed to the black liquor circuit as a make-up material for sodium and sulfur losses. According to plant personnel, the atomic chlorine content of the by-product salt cake ranges from approximately 0.2 to 1.5 weight percent. Most of this chlorine is present in the form of chloride ion.

#### 3.2 BLACK LIQUOR RECOVERY BOILER DESCRIPTION

Black liquor recovery boiler BLB-A is a low odor Babcock and Wilcox recovery boiler with a rated capacity of 815 Mg/day (900-TPD) unbleached pulp. A schematic diagram of the pulping process is shown in Figure 3-1. The boiler is typically baseloaded and operates at a steady black liquor firing rate. Particulate matter emissions from the boiler are controlled by a wet bottom electrostatic precipitator.

The solids content of the concentrated black liquor fired in Boiler BLB-A is approximately 65 percent by weight. Concentration of the weak black liquor produced by the brown stock washers is accomplished using a three-stage multiple effect evaporator system and a "concentrator," which is essentially a large single stage evaporator. Noncondensible gases collected by the evaporator system are fired in one of the two combination power boilers at the plant. Strong black liquor from the concentrator flows through the bottom of the electrostatic precipitator that controls particulate matter emissions from boiler BLB-A. The precipitator catch is mixed with the strong black liquor before the liquor is fired in the boiler.

According to plant personnel, the chloride content of the concentrated black liquor fed to boiler BLB-A is typically 0.5 weight percent chlorine (wt % Cl), with a range of approximately 0.1 to 0.7 wt % Cl. Chlorine enters the black liquor circuit as inorganic chloride ions primarily through the  ${\rm ClO}_2$  generation system byproduct salt cake that is added to the weak black liquor

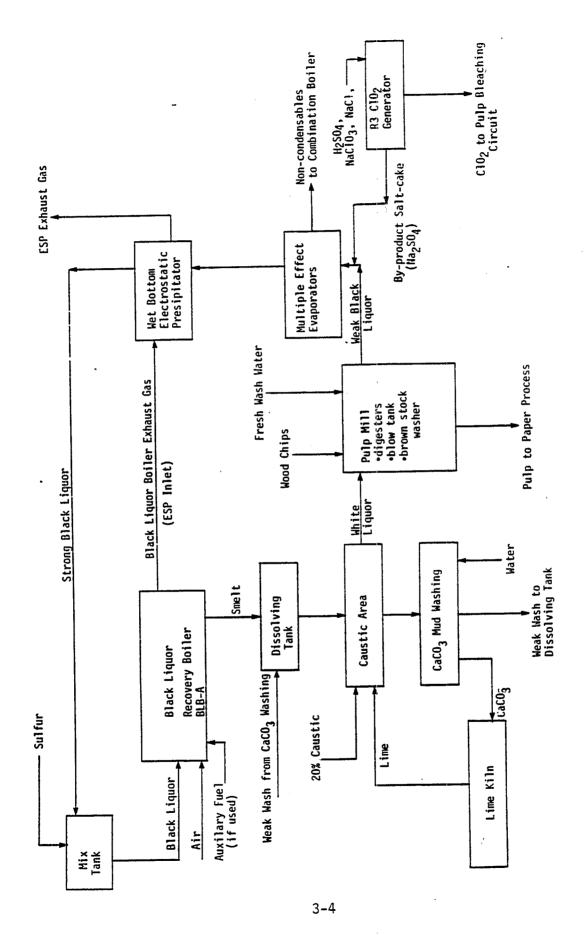

Figure 3-1. Process Flow Diagram for Site BLB-A

prior to the evaporators. The by-product salt cake contributes makeup sodium and sulfur to the black liquor circuit. The chlorine content of the by-product salt cake ranges from about 0.2 to 1.5 wt % Cl. Other potential sources of chlorine in the black liquor circuit are sodium hydroxide used in the conversion of green liquor to white liquor, wood chips fed to the pulping process, and fresh water used for CaCO<sub>3</sub> mud washing and pulp washing. Data on the relative amounts of chlorine added to the black liquor circuit through each of these sources have been developed from total chlorine analyses performed on process samples taken during the dioxin/furan tests.

Concentrated black liquor is sprayed into the combustion zone of boiler BLB-A at a temperature of approximately  $105^{\circ}C(250^{\circ}F)$  using four oscillating "guns". Primary, secondary, and tertiary combustion air is supplied to the boiler by forced draft fans. The primary:secondary:tertiary air ratio is approximately 1.4:1.8:1.0. The combustion air supply is computer controlled using flue gas oxygen monitoring and black liquor feed rate monitoring. Oxygen is continuously monitored at the economizer section of the boiler and at the electrostatic precipitator outlet stack, while carbon monoxide, opacity, and total reduced sulfur(TRS) are continuously monitored only at the electrostatic precipitator outlet stack. The target flue gas oxygen at the economizer section is 3.0 to 3.5 percent  $0_2$ . Opacity at the outlet stack is typically 15 percent. The Federal New Source Performance Standards (NSPS) TRS emissions limit for black liquor recovery boiler stacks is 5 ppm corrected to 8 percent oxygen. Plant personnel reported that boiler BLB-A is in compliance with the NSPS.

#### 3.3 ELECTROSTATIC PRECIPITATOR DESCRIPTION

Exhaust gases from black liquor recovery boiler BLB-A pass through a two-chamber Wheelabrator-Frye wet bottom electrostatic precipitator (ESP) for particulate removal. Each chamber of the precipitator handles approximately half of the total boiler exhaust gas flowrate. The ESP was designed for a total gas flowrate of 110,000 acmm (387,000 acfm) at an operating temperature of  $175^{\circ}$ C ( $350^{\circ}$ F). Total plate collection area is  $17,150 \text{ m}^2$  ( $184,570 \text{ ft}^2$ ), corresponding to a design specific collection area of approximately 0.16

 $\rm m^2/acmm~(0.5~ft^2/acfm)$ . An energy management system trims the power supply to the ESP to maintain a stack opacity of approximately 15 percent. The design particulate matter removal efficiency of the ESP is 99.6 percent when operated at full electrical power. Under typical power supply conditions, the particulate matter removal efficiency of the ESP is estimated by plant personnel to be 98.6 to 99.0 percent. The most recent particulate matter emissions data generated by the host plant showed a particulate grain loading of 0.005 gr/dscf in the precipitator exhaust gas.

#### 4.0 TEST DESCRIPTION

This section describes the field sampling, process monitoring, and analytical activities that were performed for test Site 04. The purpose of this section is to provide sufficient descriptive information about the test so that the test data presented in Section 5.0 can be easily understood. Specific testing details (specific sampling locations and procedures) are presented in Section 6.0.

This section is divided into three parts. Section 4.1 summarizes field sampling activities, Section 4.2 summarizes process monitoring activities, and Section 4.3 summarizes analytical activities performed during the test program.

#### 4.1 FIELD SAMPLING

Table 4-1 shows the source sampling and analysis matrix for test Site BLB-A. Three dioxin/furan emissions tests (Runs 01, 02, 03) were performed. Samples were taken simultaneously at the electrostatic precipitator (ESP) inlet location and the ESP outlet exhaust stack. These locations are shown as Points B and C on Figure 4-1. Dioxin/furan sampling followed the Modified Method 5 (MM5) sampling protocol developed by the American Society of Mechanical Engineers (ASME) for measuring emissions of chlorinated organic compounds. Testing was performed at the ESP outlet exhaust stack for a period corresponding to 240 minutes of on-line sampling. Testing was performed during the same time period at the ESP inlet location, but due to a number of filter changes and sample port changes the on-line sampling period for the inlet train was typically about 140 minutes.

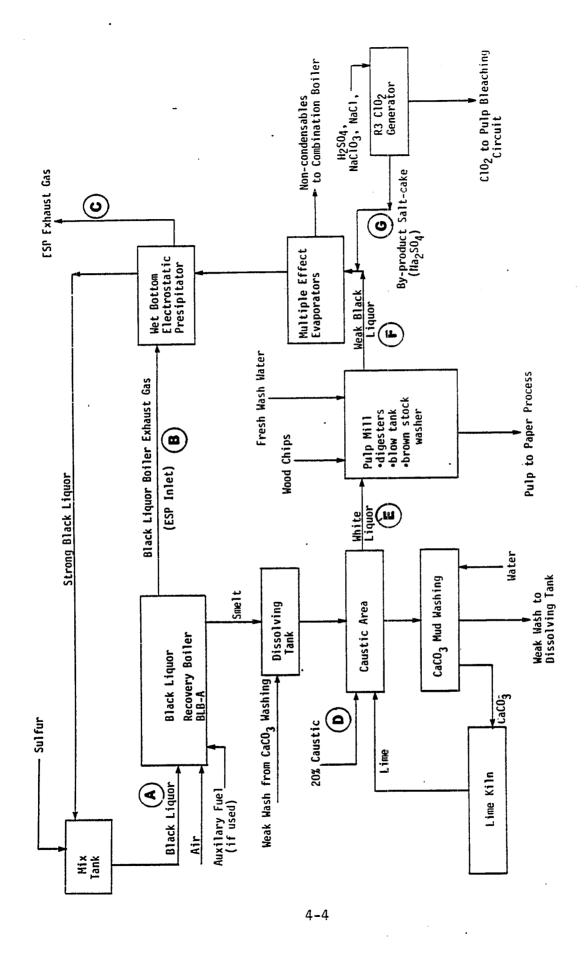

Concentrations of HCl in the flue gas were determined for each test day at the ESP outlet exhaust stack using another modification of EPA Method 5. The sampling train was identical to that of Method 5 except that water in the impingers was replaced with 0.1 M NaOH or 0.1 M KOH. Sodium hydroxide (NaOH) was used in the impinger during Run Ol according to typical HCl sampling procedures. The impinger solution was changed to potassium hydroxide for

subsequent runs at the suggestion of the National Council for Air and Stream Improvement (NCASI). The substitution of KOH in the impinger was performed in an effort to eliminate sodium chloride (NaCl) interferences in the HCl measurement.

Continuous emissions monitoring (CEM) of  $0_2$ , CO, CO $_2$ , SO $_2$ , NO $_X$ , and total hydrocarbons (THC) was performed during the three MM5 test runs. These data were obtained to assess variations in combustion during the sampling periods. Instantaneous concentration values for each species monitored were determined every five minutes by the CEM system.

Five types of process samples were taken during the MM5 test periods: strong black liquor, caustic (sodium hydroxide), white liquor, weak black liquor, and ClO<sub>2</sub> generation system by-product salt cake. The strong black liquor samples were taken to characterize dioxin/furan and dioxin/furan precursor contents of the material fed to the boiler. Three identical composites of hourly strong black liquor samples were prepared: one for dioxin/furan analysis by Troika, one for dioxin/furan precursor analysis by Radian/RTP, and one for total chloride analysis by Radian/Austin. The caustic, white liquor, weak black liquor, and ClO<sub>2</sub> generation system by-product salt cake samples were taken to indicate the major contributors of chloride to the mill liquor circuit. These samples were taken twice during each test day, and a single sample composite for each test run was sent to Radian/Austin for total chloride analysis.

Soil samples were collected from ten locations at the plant site. The ten samples were combined into a single composite, which was held for potential dioxin/furan analysis pending evaluation of the MM5 dioxin/furan emissions data.

#### 4.2 PROCESS DATA COLLECTION

Process data were collected to characterize the operation of the black liquor boiler and electrostatic precipitator (ESP) during the MM5 test periods. A computer system in the black liquor boiler control room was used to print out a graphic display of boiler load, boiler exhaust gas oxygen content, black liquor solids content, and stack CO concentration during the

test runs. In addition, hourly average steam flow, boiler  $\mathbf{0}_2$ , combustion air flow and temperature, black liquor characteristics, ESP gas flow and temperature, and ESP exhaust gas composition data were printed out by the computer in hourly log reports. Electrostatic precipitator voltage and current data were recorded manually at intermittent times throughout the test period. The process data are used in Section 5.1 with the CEM data to evaluate and compare combustion conditions during the three MM5 test periods.

#### 4.3 LABORATORY ANALYSES

Laboratory analyses performed on samples from test Site BLB-A included dioxin/furan analyses, dioxin/furan precursor analyses and chloride, sulfate, and sodium analyses. Samples analyzed for dioxin/furan are discussed in Section 4.3.1 and samples analyzed for dioxin precursors are discussed in Section 4.3.2. Samples analyzed for chloride (Cl<sup>-</sup>) are discussed in Section 4.3.3.

#### 4.3.1 Dioxin/Furan Analyses

All dioxin/furan analyses for Site 04 samples were performed by the EPA ECL-BSL and EMSL-RTP laboratories, two of the three laboratories collectively known as the Troika. Field samples requiring dioxin/furan analysis were prioritized by Tier 4 based on their relative importance to the Tier 4 program objectives. The priority levels, in order of decreasing importance, were designated Priority 1 through Priority 3.

Priority 1 samples were sent to Troika with instructions to perform immediate extraction and analysis. These included the MM5 train components for the electrostatic precipitator inlet and outlet sampling locations, and an MM5 train field blank.

Priority 2 samples sent to Troika were to be analyzed for dioxin/furan pending the results of the Priority 1 analyses. Priority 2 samples included only the strong black liquor samples.

Priority 3 samples included only the composite soil sample. The soil sample is being held by Radian's Research Triangle Park (RTP), N.C. laboratory pending evaluation of the Priority 1 and 2 analyses.

#### 4.3.2 Dioxin/Furan Precursor Analysis

Dioxin/furan precursor analyses of strong black liquor samples were performed by Radian/RTP. The specific dioxin/furan analyzed for included chlorophenols, chlorobenzenes, PCB's and total chlorine.

#### 4.3.3 Total Chloride Analysis

Chloride analysis was performed on the combined probe rinse/filter sample and on the back-half rinse/impinger solution sample for each HCL train (i.e., front-half and back-half analysis). Chloride analysis was also performed on the strong black liquor, caustic, white liquor, weak black liquor, and by-product salt cake.

#### 5.0 TEST RESULTS

The results of the Tier 4 dioxin/furan emissions test of black liquor boiler BLB-A are presented in this section. The individual test runs are designated as Runs 1-3.

Process data obtained during the test runs are presented in Section 5.1, and flue gas parameter data are contained in Section 5.2. Continuous monitoring results for  $0_2$ , C0,  $C0_2$ ,  $N0_x$ ,  $S0_2$ , and THC are presented in Section 5.3. The dioxin/furan emissions data are contained in Section 5.4. Strong black liquor and dioxin/furan precursor analyses are presented in Section 5.5. Results of HCl train sampling at the electrostatic precipitator (ESP) outlet and chlorine analysis data of various process samples are presented in Sections 5.6 and 5.7.

#### 5.1 PROCESS DATA

Process data were obtained to document black liquor boiler and electrostatic precipitator operation during the test runs. The boiler operating data are summarized in Section 5.1.1, and the electrostatic precipitator operating data are summarized in Section 5.1.2. In general, the data show that process operations were very stable during the three test runs.

#### 5.1.1 Black Liquor Boiler Operating Data

Plant-maintained data summarizing the mean operating conditions of black liquor boiler BLB-A during the three MM5 test runs are shown in Table 5-1. Continuous data on boiler load, flue gas oxygen content in the economizer section of the boiler, strong black liquor solids content, and flue gas carbon monoxide content at the ESP outlet exhaust stack are shown for each run in Figures 5-1, 5-2, and 5-3. These data plots were generated for the dioxin/furan test program by a computer system in the black liquor boiler control room. The data show that the incinerator was operated similarly during the individual test runs. There were no process upsets during any of the runs that resulted in sampling interruptions. The one hour data gap in Figure 5-3 is due to a brief malfunction in the data acquisition system. The process was stable during this time period.

TABLE 5-1. MEAN VALUES<sup>a</sup> OF VARIOUS BOILER OPERATING PARAMETERS MONITORED BY HOST PLANT AT SITE BLB-A

Run	Boiler Load <sup>b</sup> (10³1b/hr)	Boiler Oxygen <sup>c</sup> (%)	Black Liq. Flow (gpm)	Black L1q. % Solids (wt%)	Stack Oxygen (%)	Stack CO <sup>e</sup> (ppmv)	Stack TRSf (ppmv $0.8\%$ 0 <sub>2</sub> )	Stack Opacity (%)

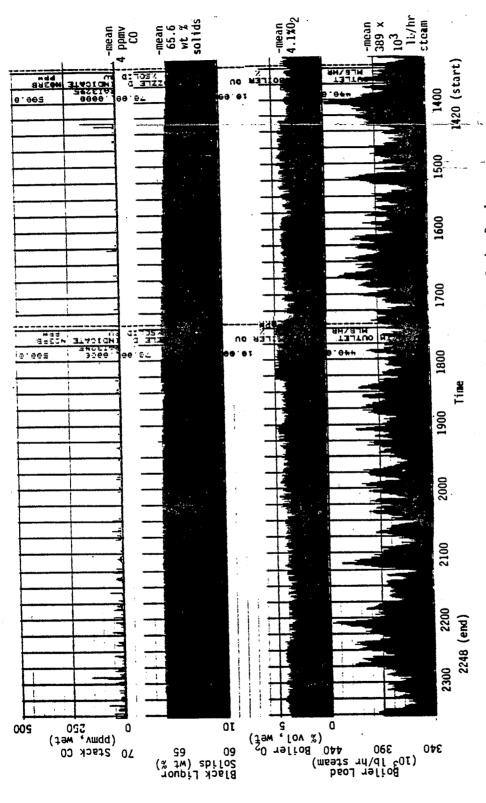

Figure 5-1. Continuously Monitored Boiler Operating Parameters During Run 1

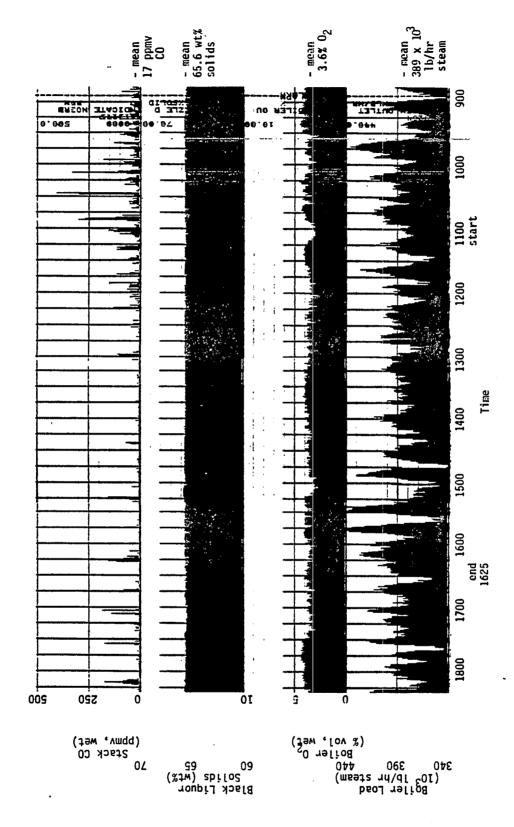

Figure 5-2 Continuously Monitored Boiler Operating Parameters During Run 2

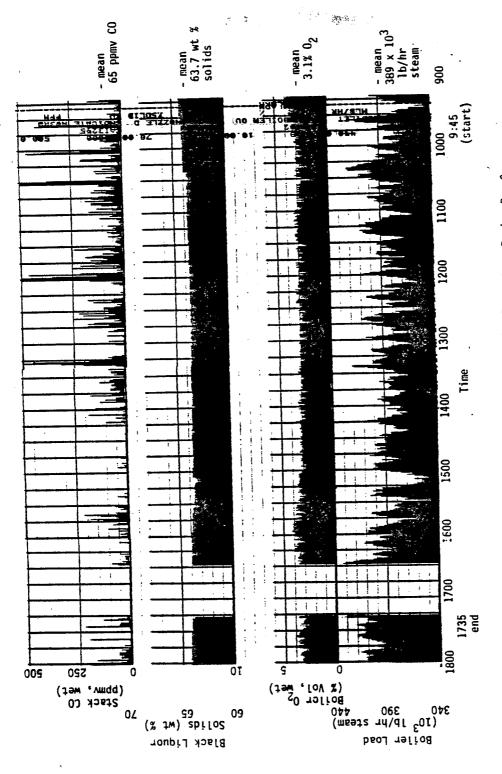

Figure 5-3. Continuously Monitored Boiler Operating Parameters During Run 3

The mean boiler load was identical for the three test runs: 176,000 kg/hr (389,000 lb/hr) steam corrected to 6305 kPa and  $755^{\circ}$ K (915 psi and  $1360^{\circ}$ R). The enthalpy of steam at these temperatures and pressure conditions is approximately 2210 kJ/kg (950 Btu/lb) relative to liquid water at the saturation temperature of the steam ( $552^{\circ}$ K, or  $994^{\circ}$ F). Thus, the steam output of the boiler on an energy basis averaged 110 MW (370 MMBtu/hr) for each of the three test runs. The maximum within-run deviation of the instantaneous boiler load values shown in Figures 5-1 through 5-3 is approximately  $\pm 13$  percent of the mean value for each run.

The mean flue gas oxygen values in the economizer section of boiler BLB-A were 4.1, 3.6, and 3.1 percent  $O_2$  (wet basis) for Runs 1-3 respectively. This corresponds to mean excess air values of approximately 30, 25, and 21 percent respectively. The maximum deviation of the instantaneous flue gas oxygen values shown in Figures 5-1 through 5-3 is approximately  $\pm 1$  percent  $O_2$ , which corresponds to a within-run excess air variability of approximately  $\pm 10$  percent excess air. Carbon monoxide data generated by the host plant are consistent with the oxygen monitoring data and show typical inverse  $CO/O_2$  behavior. Run 1, which showed the highest boiler flue gas oxygen value  $(4.1\%\ O_2)$ , also showed the lowest flue gas carbon monoxide value  $(4.6\ \text{ppmv}\ @\ 3\%\ O_2)$ . Run 3, which showed the lowest boiler flue gas oxygen value  $(3.1\%\ O_2$ , wet), showed the highest flue gas carbon monoxide value  $(76\ \text{ppmv}\ @\ 3\%\ O_2)$ . The plant continuous monitoring data are compared with the Radian continuous monitoring data in Section 5.2.

The solids content of the strong black liquor combusted in boiler BLB-A showed little variability during the test runs, although the mean value for Run 3 (63.7 wt % solids) was slightly lower than the mean values for Runs 1 and 2 (65.6 wt % solids). The black liquor flow rate also showed little variability. The flow rate was approximately 3.5 percent higher for Run 3 than for Runs 1 and 2. The low black liquor solids content and the high black liquor flow rate for Run 3 are probably related. In order to produce a constant amount of steam, the feed forward boiler control system responded to the lower solids content of the black liquor (i.e., lower heating value) by increasing the black liquor flow to the burners.

The TRS monitoring data showed an average of 4.0 ppmv TRS @ 8%  $0_2$ , which is in compliance with the Federal New Source Performance Standard (NSPS) for black liquor boilers. TRS values did not seem to track other combustion-related parameters such as  $0_2$  or CO. Stack opacity averaged 15.0 percent for each of the three test runs. The opacity values depend on electrostatic precipitator operation as well as combustion conditions in the boiler.

## 5.1.2 Electrostatic Precipitator Operating Data

Electrostatic precipitator (ESP) operating data maintained by the host plant are summarized in Table 5-2 for test runs 01, 02, and 03. The data show that the ESP was operated similarly during the three runs.

The ESP was set in the opacity control mode during each run, which is typical of normal operation at Site 04. Under the opacity control mode, the power supplied to the ESP is adjusted to maintain a stack outlet opacity of 15 percent. The total power consumption rate of the precipitation during the test runs was approximately 50 kw, split equally between the east and west halves of the unit. The mean outlet gas temperature ranged from  $174^{\rm O}$  to  $175^{\rm O}$ C (345° to 347° F), and the gas flow rates to the two halves of the unit were nearly identical. Opacity monitors stationed at the outlet from each half of the ESP varied considerably from east to west, but the east half and west half values were nearly constant between runs. Plant personnel were not certain whether the higher opacity values measured in the east half outlet were due to a difference in particulate matter removal efficiencies between the east and west halves, or whether the east half opacity monitor was not working correctly. In any event, the total stack opacity of the combined streams at the outlet exhaust stack was nearly constant at 15.0 percent. The low stack opacity values were consistent with visual observation.

The gas flow rate measured by Radian at the inlet to the ESP ranged from 7930 acmm to 8160 acmm (280,000 acfm to 288,000 acfm). Using a plate area of 17,150  $\rm m^2$  (184,570  $\rm ft^2$ ), this corresponds to a specific collection area of approximately 0.20  $\rm m^2/acmm$  (0.65  $\rm ft^2/acfm$ ) which is higher than the design value of 0.16  $\rm m^2/acmm$  (0.5  $\rm ft^2/acfm$ ).

TABLE 5-2. SUMMARY OF PLANT-MAINTAINED ELECTROSTATIC PRECIPITATOR OPERATING DATA FOR SITE BLB-A

Power consumption numbers are based on limited data (7 voltage-current pairs during the 3 tests)

#### 5.2 FLUE GAS PARAMETER DATA

Table 5-3 summarizes flue gas temperature, moisture, volumetric flowrate, and oxygen concentration data obtained at Site BLB-A. These parameters were fairly consistent among test runs. The average flue gas temperature and moisture content measured at the ESP inlet and outlet were 178°C, 27.8%, and 173°C, 24.8%, respectively. The average gas flowrates for the ESP inlet and outlet under actual stack temperature and moisture conditions were 8100 acmm (285,900 acfm) and 7,600 acmm (268,300 acfm), respectively. The average dry standard flowrate was 3,600 dscmm (127,100 dscfm) for the inlet and 3,700 dscmm (130,600 dscfm) for the outlet. Standard EPA conditions are 20°C (68°F) and 1 atm.

Flue gas oxygen concentration data were obtained from the plant  $0_2$  analyzer, the Radian CEM system, and integrated bag samples (EPA Method 3). The average ESP inlet  $0_2$  concentration of the flue gas measured by EPA Method 3, the Radian CEM, and the plant  $0_2$  analyzer was 5.2, 6.0, and 4.8 vol%, respectively. The ESP outlet  $0_2$  concentration was 5.0 vol%, as measured by EPA Method 3.

#### 5.3 CONTINUOUS EMISSIONS MONITORING DATA

Mean values and standard deviations of the continuously monitored combustion gases at the ESP inlet location  $(0_2,\ CO,\ CO_2,\ SO_2,\ NO_X$  and THC) are shown for each MM5 test run in Table 5-4. The data show that most of the runs have similar mean concentration values for the individual gases. The overall mean values for the three test runs are as follows: oxygen, 6.0 percent by volume (dry); carbon monoxide, 136 ppmv (dry @ 3%  $O_2$ ); carbon dioxide, 15.6 percent by volume (dry @ 3%  $O_2$ ); sulfur dioxide, 94 ppmv (dry @ 3%  $O_2$ ); nitrogen oxides, 83 ppmv (dry @ 3%  $O_2$ ); and total hydrocarbons, 4 ppmv (wet @ 3%  $O_2$ , as propane).

The mean oxygen concentration measured by the Radian CEM system at the ESP inlet was fairly consistent between runs, but was slightly higher for Run 03 (6.5%) than for Runs 01 and 02 (5.9 and 5.7%, respectively). This was not consistent with the trend of the measured oxygen content data obtained by the plant at the economizer section of the boiler and at the stack. Table 5-5

TABLE 5-3. FLUE GAS PARAMETERS AT SITE BLB-Aa

<sup>&</sup>lt;sup>a</sup>All concentrations expressed on a dry volume basis except for total hydrocarbon concentrations, which are expressed on a wet volume basis.

 $<sup>^{\</sup>mathrm{b}}$ Total hydrocarbon data are expressed in units of ppmv (wet) as propane.

summarizes the Radian CEM data at the ESP inlet location, the Radian Method 3 data at the ESP inlet and stack outlet locations, the plant CEM data at the economizer section of the boiler and the plant CEM data at the outlet stack location. While the data are not conclusive, it appears that a minor leakage may have developed in the Radian CEM sampling system during the tests.

Instantaneous concentration values obtained at 5-minute intervals for each of the continuously monitored combustion gases are tabulated in Appendix A-2 and are shown graphically as functions of time in Figures 5-4 through 5-9. These graphs show that in general the measured  $\mathbf{0}_2$  and  $\mathbf{N0}_{\mathbf{X}}$  values were fairly constant within runs. The CO and  $\mathbf{C0}_2$  data show considerable random scatter, much of which is attributable to instrument noise. However, the CO data do verify the trend toward higher CO levels for Runs 02 and 03 than for Run 01, as was also indicated by the plant CO monitor at the stack. The THC data do not seem to track either  $\mathbf{0}_2$  or CO data. THC peaks in the 20 ppm range were observed for each test run, but these peaks could not be correlated with variations in process conditions in the boiler.

The  $SO_2$  data show a distinctive cyclical behavior which is believed to be associated with the make-up sulfur addition rate in the black liquor mix tank. Peaks as high as 400 ppmv  $SO_2$  @ 3%  $O_2$  were observed during Runs 01 and 03, with lower peaks observed during Run 02.

### 5.4 MM5 DIOXIN/ FURAN EMISSIONS DATA

#### 5.4.1 Electrostatic Precipitator Inlet

Emission concentrations and emissions rate data measured at the electrostatic precipitator (ESP) inlet are shown in Table 5-6 and 5-7 for the 2378 TCDD, total PCDD, and total PCDF species. The data include dioxin and furan collection in the entire MM5 train, including filter, XAD sorbent trap, impingers, and sample train clean-up rinses.

Average as-measured ESP inlet concentrations of total PCDD, and PCDF species were 1.58 ng/dscm total PCDD and 1.31 ng/dscm total PCDF. When corrected to 3%  $0_2$  using the Radian CEM oxygen concentration data, these values correspond to 1.79 ng/dscm @ 3%  $0_2$  and 1.47 ng/dscm @ 3%  $0_2$ , respectively. Average emission rates were 340 ug/hr total PCDD, and 280 ug/hr

was not detectable .

total PCDF. Emissions of 2378 TCDD/were consistently below the detection limit: The total PCDD and PCDF emissions were fairly consistent between runs. The maximum deviation of any individual run from the overall average was approximately 56 percent for total PCDD emissions and 19 percent for total PCDF emissions.

Isomer and homologue-specific emission concentration data are summarized in Table 5-8 and 5-9 for the three test runs. Run-specific data tables showing homologue emission concentrations in both ng/dscm and parts-pertrillion units and homologue emission rates in ug/hr units are included in Appendix D. Detectable quantities were found for roughly two-thirds of the isomers and homologues analyzed for at the ESP inlet of Site BLB-A. Figure 5-10 is a histogram that shows the relative distributions of the 2378 TCDD/TCDF isomers and the tetra- through octa-PCDD/PCDF homologues in the inlet ESP emissions (mole basis). The distribution of dioxin species was extremely non-uniform among the various homologues. Only the hepta- and octa-CDD homologues were consistently detectable in the ESP inlet emissions. The octa-CDD homologue accounted for roughly 80 percent of the total dioxins detected. The hepta-CDD homologues accounted for the remaining 20 percent of the total dioxins in the ESP inlet emissions. The furan species were more uniformly distributed than the dioxin species, with the hepta-CDF homologue being the largest single contributor to the total PCDF emissions. contributions of the tetra- through octa-chlorinated furan homologues to the total PCDF were: tetra, 19-26%; penta, 0-24%; hexa, 33-50%; hepta, 12-24%; and octa, 0-8%.

Emission factors for the ESP inlet at site BLB-A are shown in Table 5-10. Average emission factors for total PCDD and total PCDF were 0.006 ug total PCDD emitted per Kg feed and 0.005 ug total PCDF emitted per Kg feed (dry solids feed basis). Emission factors for the various dioxin and furan homologues varied considerably between runs.

## 5.4.2 Electrostatic Precipitator Outlet

Emission concentrations and emissions rate data measured at the electrostatic precipitator (ESP) outlet are shown in Tables 5-11 and 5-12 for the 2378 TCDD, total PCDD, and total PCDF species. The data include dioxin and furan collected in the entire MM5 train, including filter, primary XAD resorbent trap, impingers, and sample train clean-up rinses.

Average as-measured outlet emission concentrations of total PCDD and PCDF were 0.67 ng/dscm total PCDD and 0.51 ng/dscm total PCDF. When corrected to 3%  $O_2$  using the EPA Method 3 oxygen concentration data, these values correspond to 0.75 ng/dscm 0 3%  $O_2$  and 0.57 ng/dscm 0 3%  $O_2$ , respectively. Average emission rates were 150 ug/hr total PCDD, and 110 ug/hr total PCDF. Emissions of 2378 TCDD were non-detectable for all three runs. The total PCDD and PCDF outlet emissions showed considerable variability between runs. The maximum deviation of any individual run from the overall average was approximately 80 percent for total PCDD and PCDF emissions.

Isomer and homologue specific outlet emission concentration data are summarized in Tables 5-13 and 5-14 for the three test runs. Run-specific data tables showing homologue emission concentrations in ng/dscm and parts-pertrillion units and homologue emission rates in ug/hr units are included in Appendix D. Detectable quantities were found for roughly half of the isomers and homologues analyzed for at the ESP outlet of Site BLB-A. Figure 5-11 is a histogram that shows the relative distributions of the 2378 TCDD/TCDF isomers and the tetra- through octa- PCDD/PCDF homologues in the ESP outlet emissions (mole basis). The distribution of dioxin species was non-uniform among the various homologues. Only the hepta and octa-CDD homologues were consistently detectable in the ESP outlet emissions. The octa-CDD homologue accounted for roughly 70 percent of the total dioxins found while the hexa-CDD isomer accounted for most of the remaining PCDD. The total PCDF emissions were more evenly distributed than the dioxin species with the contributions of the tetra- through octa-chlorinated furan homologues to the total PCDF being as follows: tetra, 10-33%; penta, 0-11%; hexa, 0-15%; hepta, 22-50%; and octa, 9-50%.

Emission factors for the ESP outlet at site BLB-A are shown in Table 5-15. Average outlet emission factors for total PCDF

NOTE: Emission factors were calculated using the black liquor dry solids feed rate.

were 0.003 ug total PCDD emitted per Kg feed and 0.002 ug total PCDF emitted per Kg feed (dry solids feed basis). The outlet emission factors for the individual dioxin and furan homologues varied considerably between test runs. 5.4.3 Reduction of Dioxin/Furan Concentrations Due to the ESP.

The dioxin/furans which condense on particulate in the stack gas are removed from the stack gas along with the particulate matter by the pollution control device. The dioxin/furan removal efficiency of the control device is calculated from the difference of the inlet and outlet concentration of each dioxin/furan homologue divided by the inlet concentration of each homologue. Each concentration value may have an analytical uncertainty of ±50%. An analysis of the uncertainty of the control device efficiency (contained in Appendix F) indicates that with a measured efficiency of greater than 67%, the true removal efficiency is most likely positive. With measured efficiencies between 67% and -200%, a definite conclusion cannot be drawn concerning the true removal efficiency, and below -200%, the true removal efficiency is most likely negative.

The measured ESP removal efficiences for each dioxin/furan homologue at Site BLB-A are summarized in Table 5-16. The PCDD/PCDF removal efficiencies across the ESP were widely scattered for the respective homologues and between runs. Run 03 indicates positive removal efficiency across the ESP while no conclusions can be made from the efficiencies calculated for Runs 01 and 02. The overall data is inconclusive concerning the true removal efficiency for the ESP.

#### 5.4.4 Economizer Ash Results

During the pre-survey site visit a single economizer ash sample was collected. This sample was analyzed for dioxin/furan to determine if it was necessary to sample the economizer ash during the actual site testing. Hexa-CDF and octa-CDD were the only homologues detected in concentrations of 0.01 ng/g (ppb) for each respective homologue. The detection limits for the homologues which were not detected were between 0.01 ng/g (ppb) and 0.02 ng/g (ppb). Due to the minimal concentrations of the dioxin/furan homologues found in this sample, the economizer ash was not sampled during the site testing.

TABLE 5-16. MEASURED ESP REMOVAL EFFICIENCIES AT SITE BLB-Aa

NOTE: dash (-) indicates that the species was not detected at the ESP inlet location.

 $<sup>^{\</sup>rm a}{\rm ESP}$  removal efficiency values were calculated using concentration data corrected to 3%  $\rm O_2$  (Table 5-9 and 5-14).

### 5.5 BLACK LIQUOR PRECURSOR DATA

As discussed in Section 4.3.2, the strong black liquor was sampled at Site BLB-A. These samples were analyzed for chlorinated benzenes, chlorinated biphenyls, and chlorinated phenols.

Table 5-17 summarizes the results of the precursor analyses. Trace levels of pentachlorophenols were detected for Run 02, but overall the specific precursors analyzed for (i.e., chlorobenzenes, chlorophenols, and chlorinated biphenyls) were not detected. This suggests that either (i) the specific precursors analyzed for were not present in the samples, or (ii) the precursors were not easily detected using the GC/MS procedure.

Table 5-18 presents the results of the strong black liquor and weak black liquor total chloride analyses. The chloride concentration was consistent among the three test runs. The greatest deviation of any run from the overall average was 36 percent for the strong black liquor and 27 percent for the weak black liquor. As seen from Table 5-18, the strong black liquor was roughly 2.5 times as concentrated as the weak black liquor with respect to total chloride content. This increase in chloride content follows from the process since the dirty water from the brown stock washers (i.e., weak black liquor) is sent to an evaporation system for solids concentration prior to being fired in the boiler.

#### 5.6 AUXILIARY PROCESS SAMPLE ANALYSES

In addition to the chloride analysis performed on the black liquor samples, chloride analysis was also performed on white liquor, by-product saltcake, and caustic samples collected at Site BLB-A. The results of the strong and weak black liquor chloride analyses are presented above in Section 5.5. Table 5-19 summarizes the data obtained from the total chloride analyses of the other process samples mentioned above. The majority of the chlorine entering the black liquor circuit comes from the caustic and the by-product salt cake with each contributing 122 and 7.7 ug chlorine/Mg of solids burned, respectively.

During the pre-survey plant visit a grab sample of the economizer ash was taken for dioxin/furan analysis. All of the homologues were below the detection limit for the method except for the octa-CDD and hexa-CDF

TABLE 5-17. SUMMARY OF DIOXIN PRECURSOR DATA FOR SITE BLB-A FEED SAMPLES

Average	1300	700	1500	

NS = Not sampled. By-product salt cake was not being produced during Run 03.

homologues. Ten parts per trillion of each of these homologues were detected in the economizer ash sample. The detection limits for the ash analysis ranged from 5 to 20 parts per trillion. The doixin/furan contamination in the economizer ash was obviously minimal.

#### 5.7 HC1 TRAIN CHLORIDE EMISSIONS DATA

Table 5-20 summarizes HCl train chloride emissions data measured at the electrostatic precipitator outlet sampling location. The data are reported as "front-half," "back-half," and "train-total" chloride emissions. The front-half emissions represent chlorides captured in the probe rinse/filter fraction of the HCl train, which may include metal chlorides contained in the particulate matter. The back-half emissions represent chlorides captured in the HCl sample train impingers, which would include HCl and any metal chlorides that pass through the sample train filter. The train-total emissions represent the sum of the front-half and back-half emissions.

As shown in Table 5-20, the average as-measured train-total chloride emissions concentration was approximately 98 mg/dscm (1.5 grains/dscf). Corrected to 3%  $0_2$  using the Radian CEM data, this corresponds to approximately 110 mg/dscm @ 3%  $0_2$  (1.7 gr/dscf @ 3%  $0_2$ ). The average train total chloride mass emission rate from the ESP outlet exhaust stack was about 22 Kg/hr (0.97 lb/hr). Chloride emissions were predominantly captured in the back half of the HCl sample train.

TABLE 5-20. HC1 TRAIN CHLORIDE EMISSIONS DATA FOR SITE BLB-A AT THE ELECTROSTATIC PRECIPITATOR OUTLET

Parameter	Run Ola	Run 01b	Run 02	Run 03	Average

#### 6.0 SAMPLING LOCATIONS AND PROCEDURES

Samples were collected from eight different locations at the test site. Two of the locations were for gaseous sampling, four were for liquid sampling, and two were for solid sampling. The source sampling and analysis matrix in Table 4-1 lists the sample locations, measured parameters, sampling methods, and analytical methods that were used.

Details on the sampling locations and methods are discussed in Section 6.1 through 6.3. Analytical procedures for continuous monitoring of CO,  ${\rm CO_2}$ ,  ${\rm NO_X}$ ,  ${\rm SO_2}$ , and THC are included in Section 6.1. All other analytical procedures are discussed in Section 7.

#### 6.1 GASEOUS SAMPLING

Four types of gaseous samples were taken during this test program:
Modified Method 5 (MM5), HCl, EPA Method 3, and continuous monitoring (CEM).
The sampling locations and methods are further discussed in this section.

## 6.1.1. Gaseous Sampling Locations

# 6.1.1.1 <u>Electrostatic Precipitator Outlet Exhaust Stack.</u>

The electrostatic precipitator (ESP) outlet exhaust stack sampling location is shown as point C in Figure 4-1. This location was used for dioxin sampling and HCl sampling using MM5 procedures described in Section 6.1.2.1 and 6.1.2.2. Gas velocity, molecular weight, and moisture were determined using EPA Methods 1 through 4. In addition, total reduced sulfur (TRS), CO,  $O_2$ , and opacity monitoring were performed by the plant at this location during the test periods.

Dimensions of the ESP outlet exhaust stack sampling location are shown in Figure 6-1. The diameter of the circular stack is 10.5 feet. Sampling ports were located approximately 4 duct diameters downstream of the connection between the ESP outlet ducting and the stack, and approximately 7.2 duct diameters upstream of the top of the stack. Based on EPA Method 1, a total of 24 traverse points were required for velocity determination at this location.

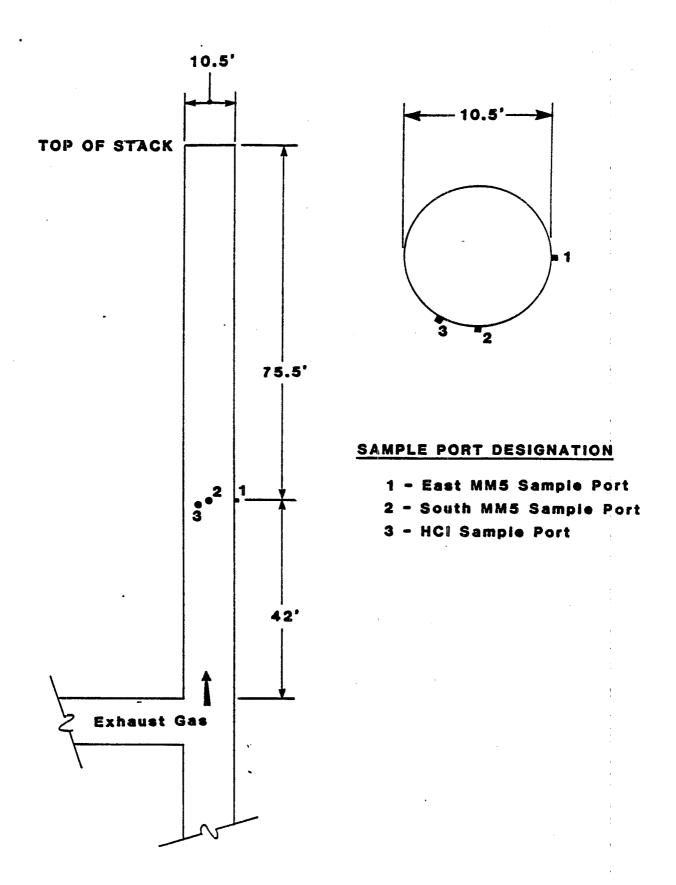

Figure 6-1 Dimensions of Electrostatic Precipitator Outlet Exhaust Stack

### 6.1.1.2 Black Liquor Boiler Outlet.

The black liquor boiler outlet sampling location (electrostatic precipitator inlet) is shown as point B in Figure 4-1. It consists of two identical rectangular ductwork sections that direct approximately equal volumetric flowrates of boiler exhaust gases to the East and West chambers of the ESP. Each of the two rectangular ductwork sections has four sampling ports. A schematic diagram of the ductwork is shown in Figure 6-2. This location was used for dioxin/furan sampling using MM5 procedures and for continuous monitoring of CO,  $CO_2$ ,  $O_2$ , total hydrocarbons (THC),  $NO_2$ , and  $SO_2$ . Gas velocity, molecular weight, and moisture were determined using EPA Methods 1 through 4. The dimensions of the black liquor boiler outlet sampling locations relative to the nearest flow disturbances are shown in Figure 6-3. The sampling ports were located less than 1 duct diameter downstream of a  $45^{\circ}$  bend and less than 1 duct diameter upstream of the inlet to the ESP. Seven of the ports were used for MM5 sampling, and the eighth port was dedicated to the continuous monitoring probe. Based on EPA Method 1, a total of 49 traverse points were used for velocity determination at this location.

## 6.1.2 <u>Gaseous Sampling Procedures</u>

Gaseous sampling procedures used during the testing are listed in Table 6-1. These procedures are discussed in detail in the Tier 4 Quality Assurance Project Plan (QAPP). A brief description of each method and any necessary deviations from the procedures outlined in the QAPP are provided in the following section.

# 6.1.2.1 Modified Method 5 (MM5).

Gas sampling for dioxins and furans was conducted according to the October 1984 draft of the ASME chlorinated organic compound sampling protocol. Minor deviations from the ASME protocol are discussed later in this section. This sampling method is a modified version of EPA Method 5 that includes a solid sorbent module for trapping vapor phase organics. The only differences in the sampling protocol which were not discussed in the Tier 4 QAPP are:

	CO, CO <sub>2</sub> , O <sub>2</sub> , SO <sub>2</sub> NO <sub>2</sub> and THC monitoring	Continuous monitors				

- (1) Benzene was substituted for hexane or toluene as both the cleanup and extractant solvent for both the MM5 filters and the XAD-2 resin. This was caused by a discrepancy between the draft ASME sampling protocol and the draft ASME analytical protocol. (November 16, 1985)
- (2) Methylene chloride was substituted for hexane as the final field rinse solvent for the MM5 train. Methylene chloride was also substituted for hexane in the glassware cleaning procedure. This was caused by a high field blank train. (February 27, 1985)

The MM5 sampling train was used to collect samples at the ESP outlet exhaust stack and at the black liquor boiler outlet sampling location. Following sample recovery, the various parts of the sample (filter, solvent rinses, sorbent trap, etc.) were sent to the EPA's Troika laboratories to quantify 2378-TCDD, tetra- through octa-dioxin homologues, and tetra- through octa-furan homologues. A total of three MM5 test runs were conducted simultaneously at each of the two sampling locations, with one test run being conducted at each location per test day. The MM5 samples were collected isokinetically over a 240-minute on line sampling period at the ESP outlet with a sample flow rate of approximately 0.75 scfm. Sampling was performed during the same time period at the ESP inlet location, but the actual on line sampling period was approximately 140 minutes. Multiple filter changes were required at this location because of the high particulate loading and the "sticky" nature of the particulate. The sample flow rate at the ESP inlet was approximately 0.6 scfm.

A schematic diagram of the MM5 sampling train is shown in Figure 6-4. Flue gas is pulled from the stack through a nozzle and a heated glass probe. Particulate matter is removed from the gas stream by means of a glass fiber filter housed in a teflon-sealed glass filter holder maintained at 248  $\pm$  25°F. The gas passes through a sorbent trap similar to that illustrated in Figure 6-5 for removal of organic constituents. The trap consists of separate sections for (1) cooling the gas stream, and (2) adsorbing the organic compounds on Amberlite XAD-2<sup>R</sup> resin (XAD). A chilled impinger train following the sorbent trap is used to remove water from the flue gas, and a dry gas meter is used to measure the sample gas flow.

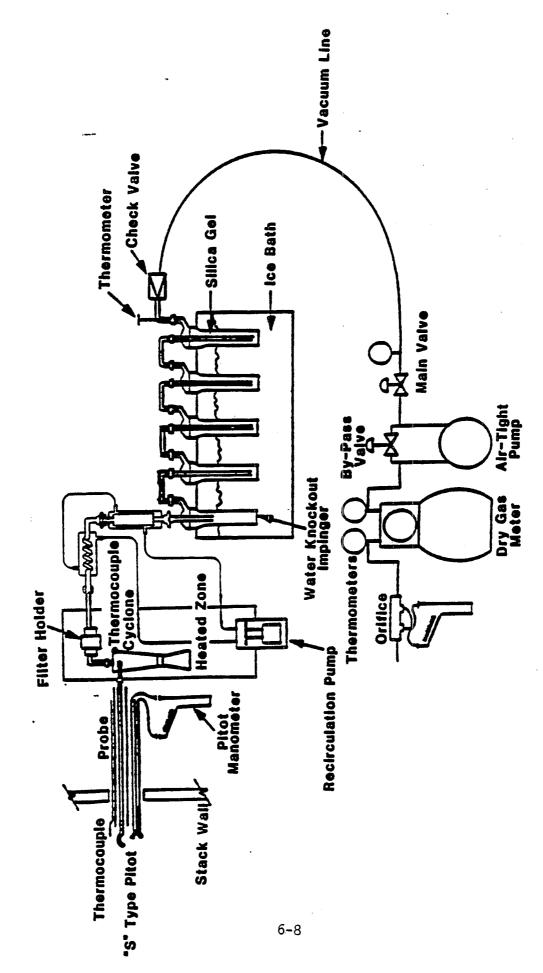

Figure 6-4 Modified Method 5 Train.

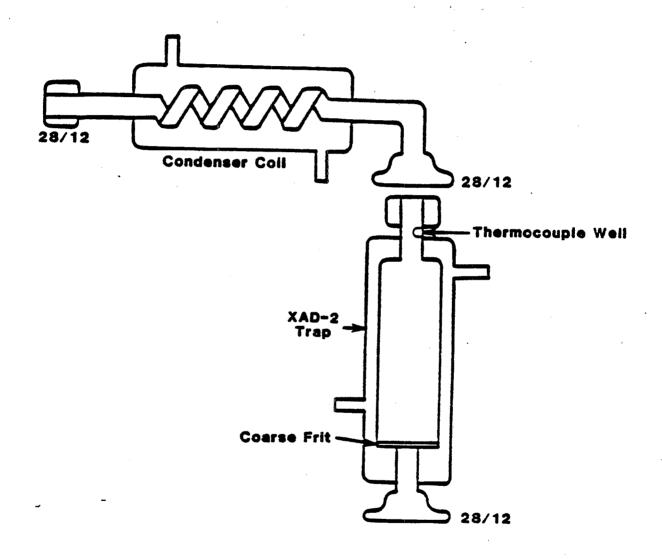

Figure 6-5 Adsorbent Sampling System.

Modifications to the ASME protocol that were instituted for this test site include the following:

- 1. Sample recovery was modified to include water in the sample train rinsing scheme. Water, acetone, and hexane were used in series to recover the probe, back-half/coil, and first impinger samples. Previous black liquor sampling experience has shown that water is necessary because the black liquor boiler particulate is soluble in water but insoluble in acetone.
- 2. The probe brush is specified in the ASME protocol as being inert material with a stainless steel handle. To ensure cleanliness, a separate nylon bristle brush attachable to a stainless steel handle was used for each probe cleaning.

#### 6.1.2.2 HCl Determination.

HCl concentrations in the ESP outlet exhaust stack were determined using another modification of EPA Method 5. The sample train components and operation were identical to those of Method 5 with the following exceptions:

- 1. No knockout impinger was used.
- During the first HC1 train run, water in the first two impingers 2. was replaced with 0.1 m NaOH. During the remaining HCl train (HCl runs 2 through 4), water in the first two impingers was replaced with 0.1M KOH. As discussed in Section 4.1, the substitution of KOH for NaOH in the impingers was performed at the suggestion of NCASI. The intent of the substitution was to eliminate NaCl interferences in the determination of HCl emissions by utilizing sodium, sulfate, and chloride material balances on the impinger solutions. Upon further study of this issue, it was determined that several additional chemical analysis would be needed to remove the potential NaCl interference. The uncertainty of the final result would be increased according to the uncertainty of each additional analysis. As a result, the plan to remove NaCl interferences was dropped and only the chloride analysis results were reported.
- Sampling was single point isokinetic with the nozzle placed at points in the stack with approximate average velocity.
- 4. The moisture/NaOH or KOH in the impingers was saved for laboratory analysis by ion chromatography for total chlorides. The impinger catch was analyzed by Radian's Austin, Texas laboratory.

Recovery of the HCl train provided a sample consisting of three components: probe rinse, filter, and back-half rinse/impinger catch.

A total of four HCl train runs were performed at the ESP outlet stack sampling location. HCl train runs 1 and 2 were performed on sample days 1 and 2, while HCl train runs 3 and 4 were performed on sample day 3. The fourth HCl run was performed because a broken impinger may have invalidated data from the first HCl run. The HCl samples were collected over on-line sample times of 100 to 175 minutes at a sample flow rate of approximately 0.8 scfm.

## 6.1.2.3 <u>Volumetric Gas Flow Rate Determination</u>.

The volumetric gas flow rate was determined at the ESP inlet and outlet sampling locations using EPA Method 2. Based on this method, the volumetric gas flow rate was determined by measuring the average velocity of the flue gas and the cross-sectional area of the duct. The average flue gas velocity was calculated from the average gas velocity pressure (P) across a S-type pitot tube, the average flue gas temperature, the wet molecular weight, and the absolute static pressure.

## 6.1.2.4 <u>Flue Gas Moisture Determination</u>.

The moisture content of the flue gas was determined at the ESP inlet and outlet sampling locations using EPA Method 4. Based on this method, a measured volume of particulate-free gas was pulled through a chilled impinger train. The quantity of condensed water was determined gravimetrically and then related to the volume of gas sampled to determine the moisture content.

# 6.1.2.5 <u>Flue Gas Molecular Weight Determination</u>.

The integrated sampling technique described in EPA Method 3 was used at the ESP inlet and outlet sampling locations to obtain a composite flue gas sample for fixed gas  $(O_2, CO_2, N_2)$  analysis. The fixed gas analysis was used to determine the molecular weight of the gas stream. A small diaphram pump and a stainless steel probe were used to extract single point flue gas samples. The samples were collected in a Tedlar bag. Moisture was removed from the gas sample by a water-cooled condenser so that the fixed gas analysis is on a dry basis.

The composition of the gas sample was determined using a Shimadzu Model 3BT analyzer instead of the Fyrite or Orsat analyzer prescribed in EPA Method 3. The Shimadzu instrument employs a gas chromatograph and a thermal conductivity detector to determine the fixed gas composition of the sample.

### 6.1.2.6 <u>Continuous Monitors</u>.

Continuous monitoring was performed at the boiler outlet sampling location for  $0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_3$ ,  $C0_2$ , and THC throughout the 4 to 6-hour period that MM5 dioxin sampling was being conducted each test day. The primary objectives of the continuous monitoring effort were to observe fluctuations in flue gas parameters and to provide an indication of combustion conditions. Sample acquisition was accomplished using an in-stack filter probe and a 150 ft length of heat-traced Teflon sample line connected to a mobile laboratory. The heat-traced sample line was maintained at a temperature of at least  $120^{\circ}$ C to prevent condensation in the sample line. The stack gas sample was drawn through the in-stack filter and sample line using pumps located in the mobile laboratory. Sample gas to be analyzed for C0,  $C0_2$ ,  $C0_2$ ,  $C0_2$ , and  $C0_2$ ,  $C0_2$ ,  $C0_2$ , and  $C0_2$ ,  $C0_2$ ,  $C0_2$ , and  $C0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_2$ , and  $C0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_2$ , and  $C0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_2$ , and  $C0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_2$ , and  $C0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_2$ , and  $C0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_2$ , and  $C0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_2$ , and  $C0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_2$ , and  $C0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_2$ , and  $C0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_2$ , and  $C0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_2$ , and  $C0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_2$ , and  $C0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_2$ , and  $C0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_2$ ,  $C0_2$ , and  $C0_2$ ,  $C0_2$ , and  $C0_2$ ,  $C0_$ 

An Anarad Model 412 nondispersive infrared (NDIR) analyzer was use to measure CO and  ${\rm CO_2}$ ; a Beckman Model 755 paramagnetic analyzer was used to measure  ${\rm O_2}$ ; a Teco Model 10 chemiluminescent analyzer was used to measure  ${\rm NO_x}$ ; a Teco Model 40 pulsed fluorescence analyzer was used to measure  ${\rm SO_2}$ ; and a Beckman Model 402 flame ionization analyzer was used to measure THC.

## 6.2 LIQUID SAMPLING

Four types of liquid samples were obtained during this test program: strong black liquor, caustic (sodium hydroxide), white liquor, and weak black liquor. The corresponding sampling locations are shown on Figure 4-1 as A, D, E, F, and G, respectively.

# 6.2.1 Strong Black Liquor Sampling

Strong black liquor samples were taken from the mix tank where liquid sulfur is added to the concentrated black liquor from the evaporators. Black liquor from the mix tank is fed directly to the feed guns in the boiler. The host site performs daily strong black liquor sampling at this location using a dipper-type sampler.

Three identical composite strong black liquor samples were obtained during each of the three tests: a 1-liter composite was shipped to Troika for dioxin analysis, another 1-liter composite was returned to Radian/RTP for dioxin precursor analysis, and a 125 ml composite was sent to Radian/Austin for total chlorine analysis. The composite strong black liquor samples for each run were comprised of hourly grab samples from the mix tank. It was necessary to heat the running hourly sample composite to prevent the sample from solidifying prior to taking the final sample aliquots. This was accomplished by wrapping the sample composite bottle with rubber-coated heat tape.

## 6.2.2 Auxiliary Black Liquor Circuit Sampling

Samples of caustic, white liquor, and weak black liquor were obtained to indicate the relative amounts of chlorine entering the black liquor circuit through various input sources. One 125 ml composite sample of each stream was obtained during each test. Individual samples were taken twice during each test run, and the composite sample were prepared accordingly. The samples were analyzed for total chlorine content only. The chlorine-content data was used in conjunction with mass flow data to determine the relative amounts of chlorine associated with each potential source of chlorine input to the black liquor circuit. The chlorine analysis was performed by the Radian Analytical Services laboratory in Austin, Texas using ion chromatography.

Caustic samples were taken from a sample tap in the transfer line leading from caustic storage to the causticizing area in the pulping circuit. White liquor samples were taken from a sample tap on the white liquor storage tank because there was no sampling location available on the transfer line leading from the storage tank to the digesters. Weak black liquor samples were taken from a sample tap in the transfer line leading to the concentrators.

#### 6.3 SOLID SAMPLING

Two types of solid samples were obtained at Site BLB-A: by-product salt cake from the  ${\rm ClO}_2$  generation process and soils from plant property. The sampling locations and methods are discussed below.

### 6.3.1 By-product Salt Cake Sampling

Samples of by-product salt cake from the  ${\rm C1O}_2$  generation system were obtained during Runs 01 and 02 at Site 04. This material was not being produced or fed to the black liquor circuit during Run 03, so no samples could be taken then. During Runs 01 and 02, approximately 300 grams of wet salt cake were obtained twice during the test run from a rotary filter used to separate precipitated salt cake from an aqueous by-product stream of the  ${\rm C1O}_2$  generation system. At the end of the test run a 125 g sample of the run composite was placed in a 125 ml bottle and sent to Radian's Austin Texas laboratory for total chloride analysis.

### 6.3.2 Soil Sampling

A single composite soil sample comprised of 10 individual soil samples was obtained at Site BLB-A. Soil sampling protocol for Tiers 3, 5, 6, and 7 of the National Dioxin Study are specified in the document, "Sampling Guidance Manual for the National Dioxin Study." A similar protocol was used for soil sampling at this test site. A total of 10 soil sampling locations were selected on plant property surrounding the black liquor boiler/power complex. The 10 individual soil sampling locations are shown in Figure 6-6 and are listed in Table 6-2. Soil samples were collected by forcing a bulb planter into the soil to a depth of 3 inches. The soil samples were then composited in a clean stainless steel bucket. Five hundred grams of the composite was placed in a 950 ml glass amber bottle and returned to Radian/RTP for archiving.

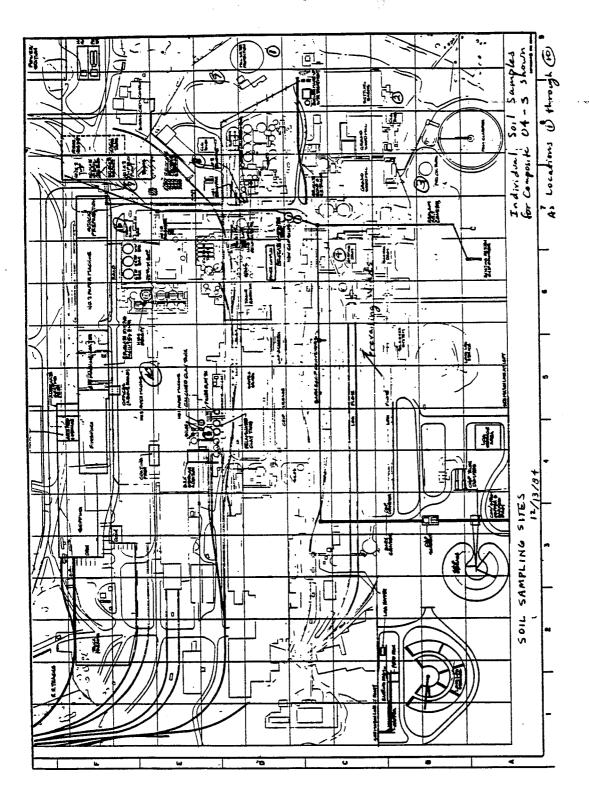

Figure 6-6 Soil Sampling Locations at Site BLB-A

TABLE 6-2. DESCRIPTION OF SOIL SAMPLING LOCATIONS AT SITE BLB-A

Individual Sample	Sampling Location Description <sup>a</sup>	:
1.	Near "mill water protection" area (D9)	1
2	Near settling basins (B8)	4 2
3	Near fuel oil tanks (B7)	
4	Near barking drum (C6)	
5	Near clay tanks (E4)	1

8	Near "CLG Tower" (E7)	
9	Near "Mill water protection" area (D8)	
10	Near No. 3 paper machine (E5)	

<sup>&</sup>lt;sup>a</sup>Sampling location coordinates for Figure 6-5 are listed in parenthesis.

#### 7.0 ANALYTICAL PROCEDURES

Laboratory procedures used to quantify dioxins/furans and dioxin/furan precursors in the Tier 4 samples are described in this section. Analyses for dioxins/furans were performed by EPA's ECL-BSL and EMSL-RTP laboratories. The procedures used for these analyses are described in detail in the Analytical Procedures and QA Plan for the Analysis of Tetra through Octa CDD's and CDF's in Samples from Tier 4 Combustion and Incineration Processes (addendum to EPA/600/3-85-/019, April, 1985).

Black liquor boiler feed samples from Site BLB-A were analyzed to determine concentrations of chlorinated phenols (CP), chlorobenzenes (CB), polychlorinated biphenyls (PCB's), total organic halogen (TOX), and total chlorine. Procedures used for these analyses are detailed in Section 7.2.

### 7.1 DIOXINS/FURANS

The analytical procedures described in this section were used for the determination of PCDD and PCDF in stack effluent samples (MM5). Samples consisting of organic solvents, aqueous solutions and solids were prepared for analysis using slightly different procedures. The organic solvent samples consisted of rinses from the MM5 probe, nozzle, filter housing and condenser coil. The impinger catch was an aqueous solution and the solid samples included the filter and XAD<sup>R</sup> resin. All aqueous and solid samples were extracted within 14 days of collection and then stored in this form until analysis. Isotopically-labeled surrogate compounds were added to all samples prior to extraction to allow determination of method efficiency and for quantification purposes.

Organic liquid samples (acetone and hexane or methylene chloride) were concentrated using a nitrogen blowdown apparatus. The residue, which contained particulates from the train probe and nozzle, was combined with the filter and handled as a solid sample. Solid samples were extracted with benzene in a Soxhlet apparatus for a period of at least 16 hours. The sample was then concentrated by nitrogen blowdown and subjected to chromatographic cleanup procedures.

Aqueous solutions were extracted with hexane by vigorous shaking for a three hour period. This extraction procedure was repeated three times, with the organic fractions ultimately being combined and concentrated for chromatographic cleanup.

The cleanup procedure involved using liquid chromatographic columns to separate the compounds of interest from other compounds present in the samples. Four different types of columns were used: a combination acid and base modified silica gel column, a basic alumina column, a PX-21 carbon/celite 545 column and a silica/diol micro column. These were used in successive steps, with the last two being used only if necessary.

The cleaned samples were analyzed using high resolution gas chromatography/high resolution mass spectrometry (GC/MS). The conditions for the analyses were as follows:

<u>Gas Chromatograph</u> - Injector configured for capillary column, splitless injection, injector temperature 280°C, helium carrier gas at 1.2 ml/min, initial column temperature 100°C: final column temperature 240°C, interface temperature 270°C.

Mass Spectrometer - Varian/MAT Model 311A, electron energy 70ev, filament emission 1MA, mass resolution 8,000 to 10,000, ion source temperature 270°C.

### 7.2 DIOXIN/FURAN PRECURSORS

Feed samples for Site BLB-A were analyzed by Radian/RTP for chlorophenols (CP), chlorobenzenes (CB) and polychlorinated biphenyls (PCB's) by GC/MS, total organic halides (TOX) by GC/Hall detector, and total chlorine by Parr Bomb combustion followed by ion chromatography. Analytical procedures are discussed in the following sections.

# 7.2.1 GC/MS Analyses

The analytical procedures used for determining CP, CB, and PCB concentrations in feed samples are modified versions of procedures typically used for the analysis of MM5 train components.

# 7.2.1.1 <u>Sample Preparation</u>

A flow chart for the sample preparation procedure used for Site BLB-B feed samples is shown in Figure 7-1. The first step involved adding 200 mL of

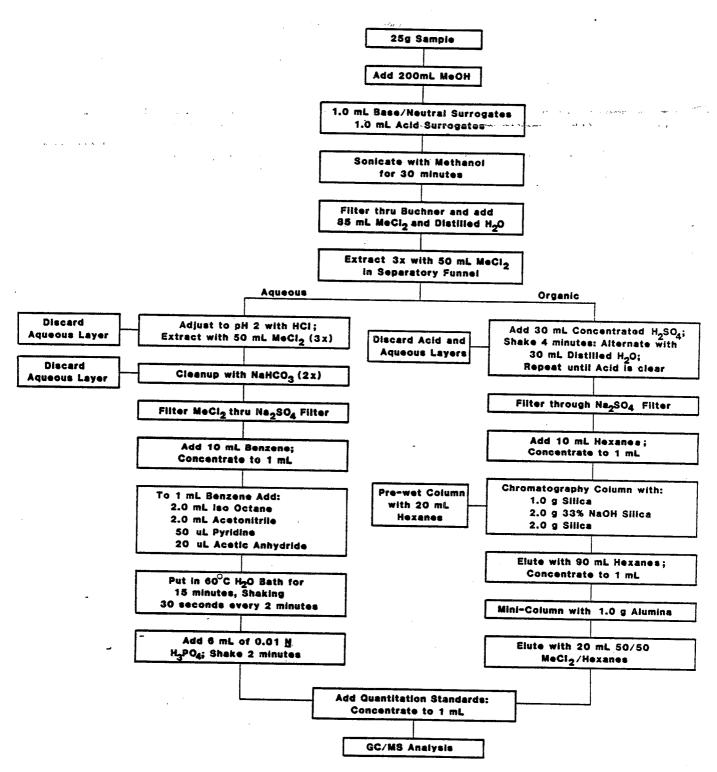

Figure 7-1. Sample preparation flow diagram for Site BLB-A precursor analyses.

methanol to the sample. The next step in the procedure involved adding labeled surrogate compounds to provide a measure of extraction method efficiency. The next step involved sonicating the sample for 30 minutes. The sonicated sample was filtered and rinsed with 85 mL methylene chloride (MeCl $_2$ ) and distilled  $\rm H_2O$ . The filtrate was extracted three times with 50 mL MeCl $_2$  in a separatory funnel and the resulting aqueous and organic fractions saved for derivatization and/or further cleanup. These procedures involve initial extraction of the sample with an appropriate solvent, preliminary separation of the compounds of interest by solvent partitioning and liquid chromatography, and analysis of the processed fractions. Solutions containing CP are derivatized prior to injection. Details on the procedures used for Site 05 samples are provided in the sections below.

The aqueous fraction (or acids portion) was acidified to pH 2 with HCl and then extracted three times with  $\mathrm{MeCl}_2$ , followed by two extractions with  $\mathrm{NaHCO}_3$ . The  $\mathrm{MeCl}_2$  from this extraction was dried with anhydrous  $\mathrm{Na}_2\mathrm{SO}_4$ , exchanged to benzene, and concentrated using a nitrogen blowdown apparatus. Acetylation of any CP present in the sample involved the following steps:

- 1. Add 2.0 mL isooctane, 2.0 mL acetonitrile, 50 uL pyridine, and 20 uL acetic anhydride to the extract. Put the test tube containing the extract in a 60°C water bath for 15 minutes, shaking 30 seconds every 2 minutes.
- 2. Add 6 mL of 0.01  $\underline{N}$  H<sub>3</sub>PO<sub>4</sub> to the test tube and agitate the sample for 2 minutes on a wrist action shaker.
- Remove the organic layer and add the quantitation standard.
   Concentrate the sample in a Reacti-Vial at room temperature (using prepurified N<sub>2</sub>) to 1 mL prior to GC/MS analysis.

Cleanup of the organic (or base/neutrals) layer from the initial  ${\rm MeCl}_2$  extraction involved successively washing the extract with concentrated  ${\rm H}_2{\rm SO}_4$  and deionized water. The acid or water was added in a 30 mL portion and the sample was shaken for two minutes. After the aqueous and organic layers were completely separated, the aqueous or acid layer was discarded. The acid

washing procedure was repeated until the acid layer was colorless. The sample was then dried with anhydrous  $Na_2SO_4$ , exchanged into hexanes and concentrated. Final cleanup of the sample by column chromatography involved the following procedure.

A glass macro-column, 20 mm o.d. x 230 mm in length, taper to 6 mm o.d. on one end was prepared. The column was packed with a plug of silanized glass wool, followed successively by 1.0 g silica, 2.0 g silica containing 33% (w/w) 1 M NaOH, and 2.0 g silica. The concentrate was quantitatively transferred to the column and eluted with 90 mL hexanes. The entire eluate was collected and concentrated to a volume of 1 mL in a centrifuge tube, as above.

A disposable liquid chromatography mini-column was constructed by cutting off a 5-mL Pyrex disposable pipette at the 2.0 mL mark and packing the lower portion of the tube with a small plug of siliconized glass wool, followed by 1 g of Woehlm basic alumina, which has been previously activated for at least 16 hours at 600°C in a muffle furnace and cooled in a desiccator for 30 minutes just before use. The concentrated eluate from above was quantitatively transferred onto the liquid chromatography column, and the centrifuge tube was rinsed consecutively with two 0.3-mL portions of a 3 percent MeCl<sub>2</sub>:hexanes solution, and the rinses were transferred to the chromatography column.

The column was eluted with 20 mL of a 50 percent (v/v)  $MeCl_2$ :hexanes, and the elute was retained. The retained fraction was concentrated to a volume of approximately 1.0 mL by heating the tubes in a water bath while passing a stream of prepurified  $N_2$  over the solutions. The quantitation standard was added and the final volume was adjusted to 1.0 mL prior to GC/MS analysis.

#### 7.2.1.2 Analysis

Analyses for CP, CB and PCBs present in the feed sample extracts were performed using a Finnigan Model 5100 mass spectrometer using selected ion monitoring. A fused silica capillary column was used for chromatographic separation of the compounds of interest. Analytical conditions for the GC/MS analysis are shown in Table 7-1.

Tuning of the GC/MS was performed daily as specified in the Tier 4 QA Project Plan. An internal standard calibration procedure was used for sample quantitation. Compounds of interest were calibrated against a fixed concentration of either  $d_{12}$ -chrysene (CB, PCB) or  $d_8$ -naphthalene (CP).

TABLE 7-1. INSTRUMENT CONDITIONS FOR GC/MS PRECURSOR ANALYSES

Parameter	Chlorobenzenes/ Polychlorinated Biphenyls	Chlorophenols		
Column	30 m WB DB-5 (1.0 u film thickness) fused silica capillary			
Injector Temperature	290 <sup>0</sup> C	290 <sup>0</sup> C		
Separator Oven Temperature	290°C	290°C		
Column Head Pressure	9 psi	9 psi		
He flow rate	1 mL/min	1 mL/min		
GC program	40(4)-290°C, 10°/min & hold	40(1)-290 <sup>0</sup> C, 12 <sup>0</sup> /min & hold		
Emission Current	0.50 ma	0.50 ma		
Electron Energy	70 ev	70 ev		
Injection Mode	Splitless 0.6 min, then 10:1 split			
Mode -	Electron ionization, Selected Monitoring	Ion		

Compounds of the calibration solution are shown in Table 7-2. For multi-point calibrations, this solution was injected at levels of 10, 50, 100, and 150 ng/mL.

Compound identification was confirmed by comparison of chromatographic retention times and mass spectra of unknowns with retention-times and mass spectra for reference compounds. Since the selected ion monitoring technique was necessary for the types of samples analyzed, care was taken to monitor a sufficiently wide mass region to avoid the potential for reporting false positives.

The instrument detection limit was estimated to be approximately 500 picograms on column. For a 50 g sample and 100 percent recovery of the analyte, this corresponds to a feed sample detection limit of 10 ppb.

#### 7.3 TOTAL CHLORINE ANALYSIS

Total chlorine concentrations in feed samples were determined by Parr Bomb combustion followed by ion chromatography (IC). A 0.5g sample was placed in the Parr Bomb with 10 mL of a 50 g/L Na<sub>2</sub>CO<sub>3</sub> solution. After combustion of the samples according to standard procedures (ASTM 2015), the contents of the bomb were rinsed into a 100 mL flask and diluted to 100 mL. The resulting solution was analyzed for chloride concentration (Cl<sup>-</sup>) by IC using standard anion conditions. For samples difficult to combust (such as sludges), 25 drops of paraffin oils were added to the bomb prior to combustion.

## 8.0 QUALITY ASSURANCE/ QUALITY CONTROL (QA/QC)

This section summarizes the results of quality assurance and quality control (QA/QC) activities for Site BLB-A. The flue gas and ash dioxin/furan data for this site were generally within the QC specifications presented in the Tier 4 QAPP. All of the surrogate recoveries for labeled TCDDs were within the specified limits of 50 to 120 percent. The surrogate recoveries for the ESP outlet, Run 02 sample was the only run not within the QC limits of 40 to 120 percent for hepta- and octa-CDDs. The results of the analysis of the fortified laboratory QC sample were all within 33 percent of the true value which is well within the Tier 4 objective of  $\pm$  50 percent. These data indicate that the dioxin/furan results are within accuracy criteria specified for Tier 4.

The dioxin/furan precursor analysis of the feed samples was not as accurate as the dioxin/furan homologue analysis. Surrogate recoveries of the base neutrals fraction were generally within the specified QC limits of  $\pm$  50 percent; however, the surrogate acid fractions were generally below the specified limits. In spite of the low recoveries of the acid fractions, the dioxin/furan precursor results are considered a reasonable approximation of the true precursor concentration in the feed samples.

The following sections summarize the results of all Site BLB-A QA/QC activities. Manual gas sampling methods are considered in Section 8.1 and continuous emission monitoring and molecular weight determinations are considered in Section 8.2. The laboratory analysis QA/QC activities are summarized in Section 8.3.

#### 8.1 MANUAL GAS SAMPLING

Manual gas sampling methods used at Site 04 included Modified Method 5 (MM5), the HCl acid train and EPA Methods 1 through 4. These methods are discussed in Section 6.0. Quality assurance and quality control (QA/QC) activities for the manual methods centered around 1) equipment calibration, 2) glassware precleaning, 3) procedural QC checks and 4) sample custody procedures. Key activities and QC results in each of these areas are

discussed in this section. Also discussed are problems encountered that may have affected data quality.

Pretest calibrations or inspections were conducted on pitot tubes, sampling nozzles, temperature sensors and analytical balances. Both preand post-test calibrations were also performed on dry gas meters. All of this equipment met the calibration criteria specified in the QAPP. Differences in pre- and post-test dry gas meter calibrations were less than 3.4 percent.

An extensive precleaning procedure was implemented for all sample train glassware and sample containers. This cleaning procedure, which is outlined in Table 8-1, was implemented to minimize the potential for sample contamination with substances that could potentially interfere with the analysis for dioxins and furans. To minimize the potential for contamination in the field, all sample train glassware was kept capped until use and a controlled environment was maintained in the recovery trailer during sample train assembly and recovery.

Procedural QC activities during manual gas sampling focused on:

- inspecting equipment visually
- collecting sampling train blanks
- ensuring the proper location and number of traverse points
- conducting pre-test, port change, and post-test sample train leak checks
- maintaining proper temperatures at the filter housing, sorbent trap and impinger train
- . maintaining isokinetic sampling rates, and
- . recording all data on preformatted data sheets.

Results of isokinetic calculations for the MM5 test runs are shown in Table 8-2. As shown in Table 8-2, the average isokinetic sampling rate for the MM5 and sampling trains achieved the QA objective of  $\pm$  10 percent for all test runs.

Sample custody procedures used during this program emphasized careful documentation of the samples collected and the use of chain-of-custody records for samples to be transported. Steps taken to identify and document samples collected included labeling each sample with a unique alphanumeric

#### TABLE 8-1. GLASSWARE PRECLEANING PROCEDURE

# NOTE: USE DISPOSABLE GLOVES AND ADEQUATE VENTILATION

- Soak all glassware in hot soapy water (Alconox ) 50° C or higher.
- 2. Distilled/ deionized  $H_20$  rinse  $(X3)^a$
- 3. Chromerge rinse if glass, otherwise skip to 6.
- 4. High purity liquid chromatography grade  $H_2^0$  rinse (X3).
- 5. Acetone rinse (X3), (pesticide grade).
- 6. Hexane rinse (X3), (pesticide grade).
- 7. Cap glassware with clean glass plugs or hexane rinsed aluminum foil.

a (X3) = three times.

Run	ESP Outlets Isokinetics			Meets QC Objective?
01	91.7	Yes	92.5	Yes
02	106.5	Yes	98.7	Yes
03	108.8	Yes	104.7	Yes

NOTE: The quality assurance objective for MM5 sampling was isokinetics of 100  $\pm$  10 percent.

code and logging the sample in a master sample logbook. All samples shipped to Troika or returned to Radian were also logged on chain-of-custody records that were signed by the sampler at shipment and then by the receiving laboratory when the samples arrived. Each sample container was also sealed with chain-of-custody seal so that the container could not be opened without tearing the seal.

# 8.2 CONTINUOUS MONITORING/ MOLECULAR WEIGHT DETERMINATION

Flue gas parameters monitored continuously during the MM5 test runs included CO,  $\rm CO_2$ ,  $\rm O_2$ , total hydrocarbons (THC),  $\rm SO_2$  and  $\rm NO_x$ . Concentrations of  $\rm CO_2$ ,  $\rm O_2$ , and  $\rm N_2$  were also determined for integrated bag samples of stack gas. Quality control results for these analyses are discussed in this section.

Drift check and quality control standard analysis results for the continuously monitored flue gas parameters are summarized in Table 8-3. The acceptance criterion for drift checks was an instrument drift within  $\pm 10$  percent. All data reduction was performed by assuming a linear drift of instrument response over the test day. The largest calibration drifts were observed for CO and CO<sub>2</sub>, both of which exceeded acceptance criterion for two of the three test runs. The instrument showing the smallest drift was the  $0_2$  monitor.

The quality control standards for this program consisted of mid-range standards that were not used for instrument calibration but were analyzed immediately after calibration to provide data on day-to-day instrument variability. The acceptance criterion for each control standard was agreement within ±10 percent of the running mean value. All of the instruments met this criterion on each test day except for the CO monitor. However, failure of the CO monitor to meet the acceptance criterion during test runs 2 and 3 is not entirely unexpected. The QC standard (2060 ppmv) was above the calibration range selected for the CO instrument during these test runs (0 to 520 ppmv) and, the CO instrument shows some non-linearity at low concentrations. The instrument was calibrated at a low range to maximize instrument accuracy near the CO levels present in the flue gas.

<sup>&</sup>lt;sup>a</sup> Instrument drift is defined as the percent difference between the instrument response to the input concentration at the beginning and end of the test run.

 $<sup>^{</sup>b}$  QC criteria was instrument drift within  $^{\pm}$  10 percent.

 $<sup>^{</sup> extsf{c}}$   $0^{ extsf{C}}$  criteria was output concentration within  $\pm$  10 percent of the running mean concentration for this test site.

 $<sup>^{</sup>m d}$  Output concentration within  $\pm$  10 percent of known value.

ND<sup>e</sup> Not determined due to calibration gas leakage prior to completion of post test calibration procedure,

Molecular weight was determined by analyzing integrated bag samples of stack gas for  ${\rm CO_2}$ ,  ${\rm O_2}$ , and  ${\rm N_2}$ . Quality control for this analysis involved duplicate analyses of calibration gases immediately before and after sample analysis. Analysis of the calibration was to be repeated until two consecutive analyses within  $\pm 5$  percent were obtained. This same criterion of  $\pm 5$  percent applied to duplicate analyses required for each sample quantitation. These criteria were met for all molecular weight determinations where valid integrated bag samples were obtained.

#### 8.3 LABORATORY ANALYSIS

QA/QC activities were carried out for dioxin/furan, precursor, and total chloride analyses performed on Site BLB-A samples. The dioxin/furan analyses of MM5 train samples performed by Troika are considered in Section 8.3.1; the precursor analyses of black liquor boiler feed samples performed by Radian/RTP are considered in Section 8.3.2; and the total chloride analyses of HCl train samples and process samples performed by Radian/Austin are considered in Section 8.3.3.

### 8.3.1 <u>Dioxin/Furan Analyses</u>

Two individual topics related to the dioxin/furan analyses at Site BLB-A are discussed in this section. Analytical recoveries of labeled surrogate compounds spiked onto MM5 train samples are reported in Section 8.3.1.1. Sample blank data are reported in Section 8.3.1.2.

# 8.3.1.1 <u>Surrogate Recoveries of the Test Samples</u>

Table 8-4 presents the analytical recovery data reported by Troika for four isotopically labeled surrogate compounds spiked onto the MM5 train samples. Samples were spiked with all four of the surrogates. The surrogate recovery results generally met the Tier 4 QA criteria of 50 to 120 percent recovery for the tetrachlorinated surrogates and 40 to 120 percent recovery for the hepta- and octa-chlorinated surrogates.

#### 8.3.1.2 Sample Blanks

Table 8-5 summarizes the analytical results reported by Troika for internal laboratory blanks, laboratory fortified quality control (QC) samples, proof blank MM5 train samples, and field recovery blank MM5 train samples. In general, the data showed good surrogate recoveries, with values

<sup>a</sup>True values represent the amounts of each homologue spiked into the laboratory fortified QC samples. Value shown in parenthesis is the percentage difference between the measured and the true value:

% = Measured Value = True Value × 100

True Value

ND = Not Detected NA = Not Applicable TCDD = Tetra-chlorinated dibenzo-p-dioxin

ranging from 42 to 106 percent. Comparison of the measured and spiked values for the laboratory fortified QC samples showed agreement well within the Tier 4 target of + 50 percent. Dioxin and furan species were non-detectable in the proof blank MM5 train sample except the octa-CDD isomer for which 0.5 ng was detected. Small but detectable quantities of hepta-CDD, octa-CDD and tetra-CDF were found in the field blank MM5 trains. The octa-CDD isomer was detected in the inlet and outlet field blanks in quantities of 0.8 and 1.0 ng, respectively. The tetra-CDF isomer was detected at the inlet but was non-detectable in the outlet field blank. Finally, 0.5 ng of the hepta-CDD isomer was detected at the outlet. Table 8-6 gives a comparison of the dioxin/furan analytical results for the field blank and test run MM5 trains. For the inlet values, only the octa-CDD homologue had a detectable field blank value, equal to 50 percent of the minimum test run value. However, for the outlet data, the hepta-CDD, octa-CDD, and tetra-CDF isomers had reported field blank values equal to 100, 77, and 40 percent of the minimum test run value, respectively. This indicates that there might have been some blanking problems at Site BLB-A. Emissions data reported in Section 5.4 are not blank-corrected.

### 8.3.2 Precursor Analyses

Table 8-7 presents analytical recovery efficiencies for seven isotopically labeled compounds used as surrogates for the target precursor analytes in the Site BLB-A feed samples. The surrogate recovery values in Table 8-7 vary considerably by specific surrogate species but are fairly uniform between runs for the same species. Several of the recoveries are below the 50 percent objective stated in the Tier 4 QA Project Plan and are below those generally considered achievable when analyzing for similar compounds in water or from MM5 train components. In spite of the relatively low surrogate recovery values for some of the feed samples, the resulting analytical sensitivity for the target analytes was considered acceptable for the purpose of this study.

## 8.3.3 <u>Total Chloride Analysis</u>

Total chloride analyses were performed by Radian/Austin on the HCl train samples. QA/QC activities include total chloride analysis of field recovery blank HCl train samples and total chloride analysis of an aliquot of NaOH

solution used in the sample train impinger rinses. Less than 1 mg/l chloride was detected in the aliquot of NaOH solution analyzed, while chloride concentrations of 2 and 1 mg/l were detected in the front and back halves of the field recovery blank train samples, respectively. These values were well below the typical test run values for this site.

a. Values shown in units used by host plant to convert from: multiply by:

1b/hr kg/hr 0.454

gpm cumeter/min 0.00379
b. Value shown for time "t" is the average value for

b. Value shown for time "t" is the average value for the one hour period preceding time "t"

c. Boiler load in 1031b/hr steam @ 914.7 psi, 1360°R (1452 Btu/1b)

d. Boiler oxygen measured in superheater section

e. Stack oxygen measured at ESP outlet stack (wet basis)

f. Stack CO measured at ESP outlet stack (wet basis, 0, as measured)

g. Stack TRS measured at ESP Outlet stack (dry basis,  $\acute{ ext{c}}$  orrected to 8% 0 $_2$ )

Hourly Average Values a of Various Boiler Parameters, Run #2

December 15, 1984

U. S. EPA ECC Toxicant Analysis Center Building 1105 Bay St. Louis, MO 39529

Attention: Danny McDaniel

Subject: Tier 4 - Analysis Instructions

Dear Sir:

The objective of this letter is to clarify instructions and priorities for individual samples from specific Tier 4 combustion sites. This instruction letter is No. 4 and pertains to EPA Site No. 04 at

The Episode No. is 2549, and SCC numbers assigned to this site were numbers DQ000401 through DQ000499.

SCC numbers  $\underline{00000401}$  through  $\underline{00000406}$  have been assigned to Troika for internal  $\underline{0A/0C}$  purposes. SCC numbers  $\underline{0000407}$  through  $\underline{0000418}$  have been assigned to samples included in this shipment and numbers  $\underline{00000419}$  have been assigned to samples being archived at Radian. All remaining SCC numbers are unused.

The sample shipment for <u>EPA Site No. 04</u> consists of 4 boxes containing 57 samples in 67 containers. (Note-The Modified Method 5 samples are comprised of 6 components as listed below. Some MM5 sample runs have more than one container per component as indicated by asterisk.) The sample shipment was shipped air freight on December 15, 1984 by Federal Express under Airbill(s) No.770332533 and No.544549655

Instructions for extraction and analysis follow.

 The following samples require immediate extraction and analysis (Priority #1 samples).

Radian Run <u>#04-MM5-B-01</u> (Total of 6 train components)

#### APPENDIX G

#### ERROR ANALYSIS OF CONTROL DEVICE EFFICIENCY CALCULATIONS

Objective: Given the analytical uncertainty of the dioxin/furan analyses ( $\pm$  50% accuracy), estimate the uncertainty of the control device efficiency calculations.

Let: Cout, meas = the measured concentration of a given dioxin/furan homologue at the outlet location.

Cin,meas = the measured concentration of a given dioxin/furan
homologue at the inlet location.

Cout, max = the maximum possible concentration of the dioxin/ furan homologue given the measured value Cout, meas.

Cout, min the minimum possible concentration of the dioxin/ furan homologue given the measured value Cout, meas.

in, max = the maximum possible concentration of the dioxin/ furan homologue, given the measured value Cin, meas.

Cin,min = the minimum possible concentration of the dioxin/ furan homologue, given the measured value Cin,meas.

E = the removal efficiency of the control device

Assuming  $\pm$  50 percent analytical accuracy:

$$C_{min} = C_{meas} - 0.5 C_{meas} = 0.5 C_{meas}$$

$$C_{\text{max}} = C_{\text{meas}} + 0.5 C_{\text{meas}} = 1.5 C_{\text{meas}}$$

Note that: 
$$E_{\text{max}} = \frac{C_{\text{in,max}} - C_{\text{out,min}}}{C_{\text{in,max}}} = \frac{1 - C_{\text{out,min}}}{C_{\text{in,max}}}$$

$$E_{\text{max}} = 1 - \frac{0.5 \text{ C}_{\text{out,meas}}}{1.5 \text{ C}_{\text{in,meas}}} = 1 - \frac{1}{3} (1 - E_{\text{meas}})$$

$$= \frac{2}{3} + \frac{1}{3} E_{\text{meas}}$$

$$E_{min} = \frac{C_{in,min} - C_{out,max}}{C_{in,min}} = \frac{1 - C_{out,max}}{C_{in,min}}$$

$$= 1 - \frac{1.5 C_{out,meas}}{0.5 C_{in,meas}}$$

$$= 1 - 3 (1 - E_{meas})$$

$$E_{min} = 3 E_{meas} - 2$$
Now,
$$E_{min} > 0 \longrightarrow Positive control (i.e., emissions reduction across the control device)$$

$$(3E_{meas} - 2) > 0$$

$$E_{meas} > \frac{2}{3}$$

Therefore, if  $E_{\text{meas}}$  is larger than 66.7 percent, the true removal efficiency can safely be assumed to be greater than zero.

And, 
$$E_{max} < 0$$
 negative control (i.e., emissions increase across the control device)  $\frac{2}{3} + \frac{1}{3} E_{meas} < 0$   $E_{meas} < -2$ 

Therefore, if  $E_{\text{meas}}$  is less than -200 percent, the true efficiency can safely be assumed to be less than zero.

#### To summarize:

$$E_{meas} > 66.7 \; percent$$
 positive control positive control positive conclusions can be drawn positive conclusions can be drawn positive conclusions can be drawn positive control positive co

#### 16. ABSTRACT

This report summarizes the results of a dioxin/furan emissions test of a black liquor recovery boiler equipped with a wet-bottom electrostatic precipitator for particulate matter emissions control. Black liquor recovery boilers are used at kraft pulp mills to produce process steam and to reclaim inorganic chemicals from spent wood pulping liquors. The test is the forth in a series of several dioxin/furan emissions tests being conducted under Tier 4 of the National Dioxin Study. The primary objective of Tier 4 is to determine if various combustion sources are sources of dioxin and/or furan emissions. If any of the combustion sources are found to emit dioxin or furan, the secondary objective of Tier 4 is to quantify these emissions.

Black liquor recovery boilers are one of 8 combustion source categories tested in the Tier 4 program. The test black liquor boiler, hereafter referred to as boiler BLB-A, was selected for this test after an initial information screening and a one-day pretest survey visit.

Data presented in the report include dioxin (tetra through octa homologue + 2378 TCDD) and furan (tetra through octa homologue + 2378 TCDF) results for stack samples. In addition, process data collected during sampling are also presented.
