

NATIONAL RADON MEASUREMENT PROFICIENCY (RMP) PROGRAM
CUMULATIVE PROFICIENCY REPORT

EPA Test Round 5

Prepared for the

Radon Division (ANR-464)
Office of Radiation Programs
U.S. Environmental Protection Agency
Washington, DC 20460

Under the Direction of
U.S. EPA Task Manager
Joseph R. Gearo, Jr.
National Coordinator
National RMP Program

September 1988

TABLE OF CONTENTS

Introduction.....	1
Selection of Measurement Method.....	2
Program Requirements.....	5
Explanation of Abbreviations.....	7
Table 1: Areas Serviced by Measurement Companies.....	9
Table 2: Performance Results of Companies.....	51

FOREWORD

This Cumulative Proficiency Report (CPR) is intended for use by Federal, State, and local officials, radon measurement companies, radon mitigation contractors, concerned homeowners, and other persons as an aid in selecting reliable sources of radon measurement services.

The CPR is a complete listing of participants who met EPA's National Radon Measurement Proficiency (RMP) Program requirements during Test Round 5 conducted between March through September 1988. It lists each participant's performance record, service area, address, and telephone number. It also indicates whether participants are laboratories or distributors and whether or not they have an EPA-approved quality assurance plan.

In addition, EPA publishes Proficiency Reports (PRs), which are simplified versions of the CPR but specific to each State. The PRs are available and distributed only through individual State Radiation Health Offices. Laboratories, companies, or individuals wishing to participate in the National (RMP) Program may obtain complete application information by calling or writing EPA's Radon Technical Information Service (RTIS) at:

RTIS
Research Triangle Institute
PO Box 12194
Research Triangle Park, nc 27709
(919) 541-7131

INTRODUCTION

Recent public concern about the health effects from exposure to radon has greatly increased the demand for companies qualified to measure radon and radon decay products in indoor air. In response to states' requests for assistance, the U.S. Environmental Protection Agency's Office of Radiation Programs has developed the National Radon Measurement Proficiency (RMP) Program within its Radon Division. Under this program, any company offering measurement services is invited to demonstrate its proficiency in measuring indoor radon gas and radon decay product concentrations.

The program's immediate objective is to assist States and the public in selecting companies that have demonstrated competence in measuring indoor radon and radon decay products. This is achieved by evaluating, on an EPA scheduled basis, the proficiency of companies' measurements and the quality of their data management. The companies that demonstrate their proficiency in each of the areas are listed in this Cumulative Proficiency Report. The program's long-term objectives are to promote standard measurement procedures among measurement companies and to establish quality assurance procedures for all measurement companies.

The National RMP Program is not designed for accrediting measurement companies. Nor does it certify, recommend, or endorse participating companies. The inclusion of a company in this report should not be interpreted as a certification or accreditation of that company. This report is only a source

of measurement companies that have demonstrated capabilities for measuring radon and radon decay products.

The testing periods are referred to as test "rounds". A company enrolls its measurement method(s) (e.g., activated charcoal adsorption) for evaluation. A primary company either owns analysis capabilities or makes all measurements and analyses with its own instrumentation and operators. This type of company may or may not offer measurement services directly to the public. A secondary company offers services ranging from detector distribution to home inspection and consultation. It must use one of the primary companies for its detector analyses.

The EPA instructs the primary companies to submit a specific number and type of detectors (e.g., five charcoal canisters) for exposure to known levels of radon and radon decay products. After exposure in a federal radon chamber, EPA returns the detectors to the company without revealing the radon gas or radon decay product concentration. The company analyzes the detector(s) and reports its measurements to EPA. The EPA compares these measurements with the known levels of exposure. If the company's results are within the established screening-measurement criterion, it passes the performance test with that method.

Companies meeting all the program requirements for a given method are listed in this Cumulative Proficiency Report. A company's method that fails after having been listed in a previous round's report is omitted entirely from this report and will not be reinstated until its next successful

performance in a round.

Table 1 lists all the proficient companies for the methods shown serving each State. Numerous companies distribute mail-in detectors and make measurements nationwide. The companies offering nationwide service are under the "Nationwide" heading, and precede the individual State headings.

Table 2 lists the companies' performance indicators for each round up to four performance rounds. In a case where a company offers primary services for one method but not another, the performance indicators in Table 2 are underscored to mark the method(s) for which it is a primary company. In addition, it indicates if they are "primary" or "secondary" companies, and shows whether they have submitted acceptable quality assurance (QA) plans. The EPA has requested, but has not required, that participating companies submit for review a copy of their QA plans. A "Q1" indicator instead of an "L1" in Table 2 indicates that the company has submitted a plan that complies with the QA criteria recommended by this program.

SELECTION OF MEASUREMENT METHOD

Several different measurement methods may be used to determine the radon or radon decay product concentrations in houses. In practice, the choice of a method is often dictated simply by availability -- if an adequate method is available, you use it. If alternative methods are available, then the cost or the duration of the measurement may become the deciding factor.

The EPA has developed measurement protocols for eight different methods and

believes that any of them, when used in accordance with EPA protocols, can produce valid results. This does not mean that all measurements made according to the suggested protocols will produce results with identical certainties. However, it does mean that the listed methods are capable of producing adequate results for screening or followup purposes.

Each method has its own advantages and disadvantages. Users must decide which method is best suited to their situations. The following sections detail the characteristics of the eight methods, pointing out some of the advantages and disadvantages of each one. This summary is not exhaustive, but is intended to guide the user in making an informed selection of a measurement method.

Continuous Radon Monitoring (CR) and Continuous Working-Level Monitoring (CW)

These measurement methods are similar because they both use an electronic detector to accumulate and store information related to the periodic (usually hourly) average concentrations of radon gas or radon decay products (working level). They are deployed in houses according to guidelines in the EPA protocol, and then turned on, or programmed for, the desired operating time -- a minimum of six hours for screening and twenty-four hours for followup measurements. At the end of the test, the monitor must be retrieved, and the results must be analyzed by a skilled instrument operator.

Advantages

- Relatively short measurement duration.

- Hourly results can track the variation of concentrations in the house.
- Very precise (most models).
- Results are available on-site (for CW).

Disadvantages

- Relatively expensive, cost may range from \$100 to \$300, depending on the type of services provided.
- Requires a skilled instrument operator.
- This, as does any short-term measurement, requires careful control of closed-house conditions twelve hours before and during the test.
- Because of the highly reactive nature of radon decay products, the continuous working-level measurements are much more susceptible to sampling error than radon gas measurements.

Alpha-Track Detection (AT)

The alpha-track method measures radon. The detector is a small sheet of special plastic material enclosed in a container with a filter-covered opening. The radon gas that enters the container decays, emitting alpha particles. The particles strike the plastic sheet, leaving tracks that can be chemically enhanced and counted using a microscope or an automated counting system.

The detectors are deployed in the home according to guidelines in the EPA protocol. They are left for periods of up to three months for screening and twelve months for followup measurements. At the end of the desired testing period, they must be returned to the distributor or analytical laboratory for processing and evaluation.

Advantages

- Relatively low-cost services; cost may range from \$20 to \$60.
- No special skills required for making the measurement.
- Can be distributed by mail.
- Completely passive, needs no external power.
- Can measure the long-term average concentrations over a twelve-month period, which is the optimal measurement of long-term concentrations.

Disadvantages

- Relatively long measurement period necessary; three months is the recommended minimum for currently available detectors.

Activated Charcoal Adsorption (CC)

The charcoal adsorption method measures radon gas. The detectors for this method consist of variously configured containers filled with a measured amount of activated charcoal. The container is usually perforated or screened to keep the charcoal from falling out, and some have a filter to keep out radon decay products. All charcoal adsorbers are stored in airtight containers when not being used for sampling.

Charcoal adsorbers can be received through the mail from a distributor. They are deployed in the home for up to seven days according to guidelines in the EPA protocols. At the end of testing, an adsorber is resealed and returned to the distributor or analytical laboratory for processing and evaluation.

Advantages

- Low cost for services; costs may range from \$10 to \$25.

- Can be distributed by mail.
- No special skills needed for making the measurement.
- Completely passive, needs no external power.
- With proper analysis, can yield precise results.

Disadvantages

- Some charcoal adsorbers are more sensitive than others to temperature and humidity.
- Limited to short-term testing.
- Requires, as does any short-term measurement, careful control of closed-house conditions twelve hours before and during the test.

RPISU - Radon Progeny Integrating Sampling Unit (RP)

The RPISU method measures radon decay products. RPISU detectors have a flow-rate air pump that pulls air continuously through a detector assembly. Depending on the model, the unit can be installed and operated by homeowners or skilled operators for three days or longer, according to guidelines in the EPA protocol. At the end of that time, the homeowner sends it to the distributor, or an operator removes the unit and returns it to the analysis laboratory for processing and evaluation.

Advantages

- Directly measures concentrations of radon decay products.
- Relatively short measurement period.
- The detector assembly and some entire units can be sent by mail.
- There is extensive experience in the use of RPISU's; therefore, measurement errors are well established.

Disadvantages

- Relatively expensive; cost may range from \$40 to \$150, depending on type of service provided.
- Some models may be both heavy and awkward to move.
- May be limited to locations with AC power.
- Some units must be installed and picked up by a skilled instrument operator.
- Because of the highly reactive nature of radon decay products, measurements are much more susceptible to sampling error than radon gas measurements.

Grab Radon (GR) and Grab Working-Level (GW)

The grab sampling methods measure concentrations of radon gas or radon decay product concentrations (working-level). The radon grab sample is collected in a special flask holding 100 to 2,000 cubic centimeters of air. The radon decay product grab sample is collected by drawing air through a filter upon which radon decay products, if present in the air, are collected. Both samples can be acquired simultaneously with some detector systems. All sampling should be done in accordance with guidelines in the EPA protocols.

For results of the grab radon test, operators must return to their offices to analyze the exposed detectors, and must delay the analysis for at least four hours after the testing. For most grab working-level (radon decay products) tests, operators can perform the analysis on location in an hour or less.

Advantages

- Results are quickly obtained.
- Equipment can be portable.

- Some detector systems can sample both radon gas and radon decay products simultaneously.
- Can acquire and evaluate several samples per day.
- Conditions during the measurement are known to the operator.

Disadvantages

- Relatively expensive; costs may range from \$80 to \$300, depending on the type of services offered.
- Very short measurement periods may not be representative of the long-term average concentrations.
- Requires a skilled operator.
- Requires, as does any short-term measurement, careful control of closed-house conditions twelve hours before and during the test.
- Because of the highly reactive nature of radon decay products, grab radon decay product measurements are much more susceptible to sampling error than radon gas measurements.

E-PERM (EP)

E-PERM (Electret Passive Environmental Radon Monitor) is an integrating detector used to measure radon gas. It is a canister containing a charged electret which reacts to the radiation emitted from radon and radon decay products.

E-PERMs can be received through the mail and installed in a home according to guidelines in the EPA protocol for two to seven days or three to twelve months, respectively, for short or long-term E-PERMs. At the end of the testing period, it is resealed and returned to the analytical laboratory for processing and evaluation.

Advantages

- The E-PERM is a relatively inexpensive (cost may range from \$8 - \$25) small detector that produces a result that is a true integrated average radon concentration.
- Two types of E-PERMs are available, allowing the method to be used for both short-term and long-term measurements.
- The laboratory analysis of E-PERMs is nondestructive, allowing results to be verified if necessary.

Disadvantages

- E-PERMs are sensitive to background gamma radiation, necessitating a background check and subtraction of an increment of voltage.
- EPA does not have extensive experience with this method.

PROGRAM REQUIREMENTS

For each method, participants must send with their applications a copy of the operating instructions they provide homeowners and/or those used by an instrument operator. These instructions must reflect the measurement procedures found in the EPA documents, "Interim Indoor Radon and Radon Decay Product Measurement Protocols" and "Interim Protocols for Screening and Followup Radon and Radon Decay Product Measurements". They must be accepted by, and on file with, EPA by the deadline specified on that round's schedule.

Once enrolled, a company must meet EPA's minimum screening-measurement requirements for each method. A company must meet all detector and analysis result deadlines as listed on the program schedule. Applications, detectors, and

analyses reporting forms received after scheduled deadlines will not be considered in the performance evaluation process. A company's detector(s) must be successfully tested every round to maintain its proficiency listing.

EXPLANATION OF ABBREVIATIONS

<u>Methods</u>	<u>Units</u>
AT - Alpha-track Detection	(pCi/L)
CC - Activated Charcoal Adsorption	(pCi/L)
CR - Continuous Radon Monitoring	(pCi/L)
CW - Continuous Working-Level Monitoring	(WL)
GR - Grab Radon Sampling	(pCi/L)
GW - Grab Working-Level Sampling	(WL)
RP - Radon Progeny Integrated Sampling Unit/RPISU	(WL)
EP - Electret-PERM	(pCi/L)

Measurement Units

- pCi/L - Picocuries per liter air, radon gas measurement units.
- WL - Working-level, radon decay products measurement units.

Definition of Performance Indicator

- L1 - Signifies a company's ability to meet all program requirements with the given measurement method in the performance test.
- Q1 - Same as L1, but in addition, the company has an approved QA plan on file with EPA.
- NL - Signifies a method's omission from the CPR because of unsuccessful participation. This indicator is only used when a method has passed a round, then failed, resulting in its performance record being omitted from a previous report, and has now passed again. "NL" is used in the method's reinstated performance record.

Others

- QA - Quality Assurance.
- DT - Detector(s) damaged or lost through no fault of the participant.
