## **SECTION ONE**

### **INTRODUCTION**

The EPA proposed effluent limitations guidelines and standards for the offshore segment of the oil and gas industry on August 26, 1985. The proposed regulations covered produced water, drilling fluids, drill cuttings, produced sand, deck drainage, and well treatment fluids, as well as sanitary and domestic wastes discharges. A Notice of Data Availability and Request for Comments relating to the discharge of drilling fluids and drill cuttings was published on October 21, 1988. On November 26, 1990, and March 13, 1991, the Agency reproposed effluent limitations guidelines and standards for both drilling and production wastes.

This cost-effectiveness analysis (ce) is in support of the promulgation of final effluent limitations guidelines and standards for the offshore oil and gas industry. Incremental pollution control options are considered for several waste streams:

- Drilling fluids and drill cuttings. Drilling fluids are liquids used to lubricate the drill bit and carry away cut rock to the surface in a well drilling operation. Drill cuttings are fragments of the host rock removed by the drilling operation.
- Produced water. The production of oil and gas results in the generation, separation, and discharge of waters and sand associated with hydrocarbons in the subsea reservoirs (i.e., produced waters and produced sand, respectively).
- Produced sand.<sup>1</sup>

These options include effluent limitations guidelines and standards based on BAT (Best Available control Technology economically achievable) and NSPS (New Source Performance Standards), that are being considered under authority of the Federal Water Pollution Control Act, as amended (the Clean Water Act). EPA has identified several pollution control options,

---

<sup>1</sup>Other effluents are included in the rulemaking, e.g., domestic wastes, sanitary wastes, deck drainage, and treatment, workover and completion fluids. No toxic pollutant removals were quantified for incremental pollution controls on these waste streams; therefore they do not appear in the cost-effectiveness analysis.

each with different levels of pollution abatement and compliance cost. The ce analysis is a useful tool for comparing the costs of the regulatory options with their relative ability to remove toxic pollutants. EPA's cost-effectiveness methodology is not intended to analyze the removal of conventional pollutants (oil and grease, BOD, TSS, fecal coliform, and pH). The removal of conventional pollutants is not addressed in this report.

This report is primarily concerned with the total annualized cost incurred by the offshore oil and gas industry in complying with the regulations. The effectiveness measure used is pounds of pollutant removed weighted by an estimate of their relative toxicity. The rationale for this measure, referred to as "pound equivalents (pe) removed," is described later in this report.

Section Two discusses the background of the cost-effectiveness methodology employed in this report. Section Three describes the alternative options under consideration, explains how the ce was calculated, and lists the pollutants included in the analysis. Section Four presents the findings. Appendices A through C contain tables of pollutants removed (in pounds and pound-equivalents) for drilling fluids and drill cuttings, BAT produced water, and NSPS produced water options, respectively.

## **SECTION TWO**

### **BACKGROUND METHODOLOGY**

Cost-effectiveness (ce) is defined as the incremental annualized cost of a pollution control option in an industry or industry subcategory per incremental pound equivalent of pollutant removed annually by that control option.

Cost-effectiveness analyses account for differences in toxicity among the pollutants with toxic weighting factors. These factors are necessary because different pollutants have different potential effects on human and aquatic life. For example, a pound of zinc in an effluent stream has a significantly different potential effect than a pound of PCBs. Toxic weighting factors for pollutants are derived using ambient water quality criteria and toxicity values. For most industries, toxic weighting factors are derived from chronic freshwater aquatic criteria. In cases where a human health criterion has also been established for the consumption of fish, then the sum of both the human and aquatic criteria are used in deriving toxic weighting factors. However, in this study of an industry that discharges into the ocean, chronic saltwater aquatic criteria are used wherever available. Chronic saltwater aquatic criteria are available for most of the pollutants considered in the analysis (see Tables 2-1 and 2-2). These toxic weighting factors are then standardized by relating them to a particular pollutant.

Copper was selected as the standard pollutant for developing weighting factors since it is a toxic metal pollutant and is commonly detected and removed from industrial effluents.<sup>1</sup> Some examples of the effect of different aquatic and human health criteria on weighting factors are shown in Table 2-3.

As indicated in Table 2-3, 1 pound of copper poses the same relative hazard as 2.9 pounds of nickel in the marine environment, since copper has a salt water toxic weight

---

<sup>1</sup>EPA uses the old freshwater quality criterion for copper (5.6 ug/l) as the standardization factor to retain comparability of the new ce results with values derived for previously regulated industries. The toxic weighing factor for copper itself reflects the newer water quality criterion for this pollutant.

TABLE 2-3

WEIGHTING FACTORS BASED ON COPPER FRESHWATER CHRONIC CRITERIA  
10-5 RISK LEVEL

Pollutant	Human Health Criteria (ug/l)	Aquatic Chronic Saltwater Criteria (ug/l)	Aquatic Chronic Freshwater Criteria (ug/l)	Weighting Calculation	Final Weight
Copper	--	2.9	12	5.6/2.9	1.9310
Zinc	--	86	110	5.6/86	0.0651
Nickel	4600	8.3	160	(5.6/4,600)+(5.6/8.3)	0.6759
Cadmium	170	9.3	1.1	(5.6/170)+(5.6/9.3)	0.6351
Benzene	710	255	265	(5.6/710)+(5.6/255)	0.0298
Titanium	--	--	191	5.6/191	0.0293

Note: Based on ingestion of 6.5 grams of fish products per day.

-- Not available.

approximately 2.9 times as large as the toxic weight of nickel (i.e.,  $1.931 \div .6759$ ). As shown in Tables 2-1 and 2-2, mercury, arsenic, beryllium, silver, benzo(a)pyrene, p-chloro-m-cresol, and radium have toxic weighting factors larger than that of copper.

The final weights are used to calculate the "pound equivalent" unit -- a standard measure of toxicity. Pound equivalents are calculated as the number of pounds of pollutant multiplied by the weighting factor. Thus, in ce analysis, the amount of pollutant removed by a control option is weighted by its relative toxicity. Cost-effectiveness is calculated as the ratio of incremental annual cost of an option to the incremental pound equivalents removed by that option.

The pollutants included in ce analysis are the regulated pollutants and selected non-regulated ones. Non-regulated pollutants are included because they can be removed incidentally as a result of a particular treatment technology, even though they are not specifically limited. (For example, when drilling fluids and drill cuttings are barged and disposed in an onshore landfill, some toxic metals such as arsenic are removed from the marine environment, even though there is no specific limitation on arsenic; the cost-effectiveness reflects the removal of arsenic.) Some of the factors considered in selecting non-regulated pollutants include toxicity, frequency of occurrence, and amount of pollutant in the waste stream.

The data set for an industry-specific ce analysis contains the following information:

- Wastewater pollutants;
- The pollution control approaches identified by the Office of Science and Technology, Engineering and Analysis Division;
- Annual volume of loadings by pollutant -- currently, and at each BAT/NSPS control level;
- Toxic weighting factor for each pollutant;
- Annualized costs for each control option (where results are adjusted to 1981 dollars to enable comparison among all industries).

Criteria or toxicity values have been developed for the priority pollutants and were taken from data in the 1980 Ambient Water Quality Criteria Document (EPA 440/5-80 Series), and

updated criteria documents in the EPA 440/5-85 and EPA 440/5-87 series. Criteria for a few of the nonconventional pollutants were taken from the 1976 Quality Criteria for Water, EPA-440/9-76-023.

## **SECTION THREE**

### **COST-EFFECTIVENESS ANALYSIS METHODOLOGY FOR THE OFFSHORE OIL AND GAS INDUSTRY**

#### **3.1 REGULATORY OPTIONS**

The cost-effectiveness report for the March 1991 reproposal of effluent guidelines and standards of performance for the offshore oil and gas industry investigated three oil price scenarios and two development scenarios for NSPS projections. In order to focus on the new information for estimating the costs and associated pollutant removals, only one development scenario is analyzed in this report. This is the \$21/bbl restricted, or constrained, development scenario presented in the proposal. Given the long time frame for the projections (15 years), recent oil prices, and the volatility of oil prices, the \$21/bbl oil price assumption was the most reasonable of the three possibilities. Given current Presidential and State restrictions on offshore activity, the restricted, or constrained, development scenario was chosen.

##### **3.1.1 Drilling Fluids and Drill Cuttings**

Four options for BAT and NSPS were developed for the control of drilling fluids and drill cuttings. The following requirements are included in some combination in the various options:

- No discharge of diesel oil.
- No discharge of "free oil" as measured by the static sheen test.
- Toxicity limitation as measured by a 96-hour LC50 test.
- Limitations on cadmium and mercury in the stock barite.
- Zero discharge of drilling fluids and drill cuttings based on distance from shore. The technology basis for the zero discharge requirement is onshore treatment and/or disposal.

These requirements have been combined into four options:

- **3 Mile Gulf/California** — For all regions except Alaska, drilling wastes from wells located within three miles of shore must meet zero discharge requirements. In these regions, the disposal of drilling wastes from wells located beyond three miles of shore must meet limitations on toxicity, no discharge of diesel oil, no discharge of free oil as determined by the static sheen test, and limitations on mercury (1 mg/kg) and cadmium (3 mg/kg) content in the stock barite. Alaska is excluded from the zero discharge requirement, but all discharges must meet the requirements for toxicity, free oil, diesel oil, cadmium, and mercury.
- **8 Mile Gulf/ 3 Mile California** — Zero discharge for all wells in the Gulf of Mexico located within eight miles from shore and zero discharge for all wells offshore California located within three miles of shore. All wells located beyond eight miles of shore in the Gulf of Mexico, beyond three miles of shore off California, and all wells drilled offshore Alaska permitted to discharge drilling fluids and drill cuttings that are in compliance with the requirements for toxicity, free oil, diesel oil, cadmium, and mercury.
- **Zero Discharge Gulf/California** — Zero discharge for all wells located in the Gulf of Mexico and offshore California. All wells being drilled offshore Alaska permitted to discharge drilling fluids and drill cuttings that are in compliance with the requirements for toxicity, free oil, diesel oil, cadmium, and mercury.
- **4 Mile Gulf/California** — The requirements are the same as in the 3 Mile Gulf/California option, except that the boundary determining the zero discharge requirement is set at 4 miles from shore. This option is comparable to the preferred option in the March 1991 proposal.

### 3.1.2 Produced Water

Three disposal technologies are considered for produced water:

- Zero discharge of produced water (technologically based on reinjection).
- Filtration of produced water prior to discharge. The costs and removals for this alternative are based on updated information for granular filtration.
- Improved performance of gas flotation.

Five disposal options are considered in the economic impact for BAT and NSPS produced water regulations. The options for BAT are summarized in Table 3-1, while those for NSPS are listed in Table 3-2. BAT options are distinguished by the exclusion of existing Gulf of Mexico single-well structures with their own production equipment from zero discharge requirements; these structures must meet flotation limitations. No exclusion from zero discharge requirements is made under NSPS for these structures. The BAT Flotation All option includes costs for two years of monitoring for radium in produced water, however, no monitoring requirement is included in the BAT limitation; the NSPS Flotation All option includes no costs for radium monitoring. BAT and NSPS options for Alaska are distinguished in the costing efforts because existing offshore Alaskan structures (BAT) are already required to meet zero discharge requirements by State permit conditions (so they will incur no BAT costs), but costs for projected structures in Alaskan waters are included in the calculation of NSPS costs. The limitations for Alaska, however, are the same under BAT and NSPS. All existing structures off California (BAT) are excluded from meeting zero discharge requirements and instead must comply with improved gas flotation limitations.

### **3.1.3 Produced Sand**

Produced sand consists of the slurried particles used in hydraulic fracturing and the accumulated formation sands and other particles (including scale) generated during production. This waste stream also includes sludges generated in the produced water system, such as tank bottoms from oil/water separators and solids removed in filtration. The option considered in this analysis is zero discharge of all produced sand.

## **3.2 ANALYTICAL APPROACH**

For each of the options considered here, the pound equivalents of pollutants removed were obtained by multiplying the pounds of each pollutant removed annually by that pollutant's toxic weighting factor and summing the pound equivalents for each approach. Regional totals were then summed to obtain the national totals. Removals were calculated relative to the

**TABLE 3-1**  
**PRODUCED WATER

---

baseline defined by current practices, i.e. they represent the incremental quantities of pollutants which would be removed as a result of this rule.

Table 3-3 shows the removals for the zero discharge option for drilling fluids and drill cuttings from the Gulf of Mexico. Appendix A contains the tables showing pounds and pound-equivalents removed for drilling fluids and drill cuttings; Appendix B contains the tables for the BAT produced water options; and tables for NSPS produced water options are given in Appendix C. To enable comparisons between industries, these costs were converted to 1981 dollars by dividing by a factor of 1.21 (based on the change in the Construction Cost Index from 1981 to 1986; see Engineering News Record, March 17, 1988).

Following standard procedures for the Agency's cost-effectiveness analyses, the options were ranked in order of increasing stringency (i.e., increasing pound equivalents removed). The incremental cost-effectiveness of each option was calculated by the following equation:

$$ce_k = \frac{ATC_k - ATC_{k-1}}{pe_k - pe_{k-1}}$$

where:

- |         |   |  |
|---------|---|--|
| $ce_k$  | = | cost-effectiveness of Option K;        |
| $ATC_k$ | = | annualized treatment cost of Option K; |
| $pe_k$  | = | pound equivalent removed at Option K.  |

## **SECTION FOUR**

### **COST-EFFECTIVENESS RESULTS**

Cost-effectiveness (ce) analysis was performed for each of the incremental pollution control options for each waste stream. Section 4.1 discusses ce for drilling fluids and drill cuttings. Section 4.2 discusses ce for BAT produced water while Section 4.3 considers ce for NSPS produced water. The cost-effectiveness of the regulatory option for produced sand is discussed in Section 4.4.

#### **4.1 COST-EFFECTIVENESS FOR DRILLING FLUIDS AND DRILL CUTTINGS**

Table 4-1 and Figure 4-1 show the cost-effectiveness analysis for drilling fluids and drill cuttings. The costs and removals are based on the \$21/bbl oil price, restricted development scenario. The ce report for the March 1991 proposal investigates the sensitivity of the ce analysis for this waste stream to changes in oil price and development assumptions.

Cost-effectiveness for the 3 Mile Gulf/California option is \$44 per pound equivalent (pe) removed. The incremental ce for the other options is approximately \$72-\$73 per pound equivalent. Appendix A contains the tables for the pounds and pound equivalents removed for the drilling waste options.

#### **4.2 COST-EFFECTIVENESS FOR BAT PRODUCED WATER**

Cost-effectiveness analysis was performed for each of the five options for BAT produced water. Table 4-2 and Figure 4-2 summarize the results of this analysis. The BPT All option is the same as current practices; there are no costs or removals associated with this option. Incremental cost-effectiveness ranges from \$33/pe for the Flotation All option to \$653/pe for the Filter 4 Miles option. The incremental cost-effectiveness for the two options where the Gulf 1b projects are excluded from the Zero Discharge requirement ranges from \$244/pe to \$573/pe.

TABLE 4-1

COST-EFFECTIVENESS FOR OFFSHORE OIL AND GAS  
DRILLING FLUIDS AND DRILL CUTTINGS

Option	Total Annual			Incremental			Incremental Cost- Effectiveness \$/PE (1981 \$)
	PE Removed	Cost (1986 \$) (\$000)	Cost (1981 \$) (\$000)	PE Removed	Cost (1981 \$) (\$000)		
Current	0	\$0	\$0	--	--	--	--
3 Mile Gulf/ California	357,955	\$18,954	\$15,664	357,955	\$15,664		\$43.76
4 Mile Gulf/ California	383,702	\$21,217	\$17,535	25,747	\$1,870		\$72.64
8 Mile Gulf/ 3 Mile California	521,490	\$33,291	\$27,513	137,789	\$9,979		\$72.42
Zero Discharge Gulf/ California	1,822,906	\$148,421	\$122,662	1,301,415	\$95,149		\$73.11

Note: Factor for converting 1986 dollars to 1981 dollar 1.21.  
The cost-effectiveness is standardized in 1981 dollars to facilitate comparison among  
numerous regulated industries.

Projects in Alaska are excluded from the zero discharge limitation.

**FIGURE 4-2**  
**COST-EFFECTIVENESS**  
**BAT PRODUCED WATER**

#### **4.3 COST-EFFECTIVENESS FOR NSPS PRODUCED WATER**

The cost-effectiveness information for NSPS produced water is summarized in Table 4-3 and Figure 4-3. As with BAT produced water, the BPT All option under NSPS has no costs or removals associated with it. The Filter 4 Miles option does not appear because it has lower removals and higher costs than the Flotation All option. Under these circumstances, the Filter 4 Miles option is considered dominated by the Flotation All option, and is removed from the analysis. The cost-effectiveness of the remaining options range from \$17/pe for the Flotation All option to \$295/pe for the Zero Discharge Gulf and Alaska option.

#### **4.4 PRODUCED SAND**

Zero discharge of produced sand is estimated to remove 3.8 million microcuries (3.8 grams) of Radium-226 and Radium-228 (see Development Document for details). Given a conversion factor of 453.6 grams to a pound, and a toxic weighting factor of 1,300,000 for radium, an estimated 10,842 pound-equivalents of radium are removed by the zero discharge requirement. Toxic removals associated with other pollutants, such as organics, were not quantified for this waste stream.

The cost associated with the zero discharge requirement for produced sand is \$3.814 million dollars (1986 dollars; \$3.152 million in 1981 dollars). Hence, the cost-effectiveness for the zero discharge requirement for produced sand is \$291/pe.

#### **4.5 SUMMARY**

Table 4-4 summarizes the range in cost-effectiveness for the offshore oil and gas industry effluent controls to the cost-effectiveness of BAT regulations for other industries. Table 4-5 summarizes the same information for NSPS regulations. All costs are shown in 1981 dollars. The effect of combined costs on the regulated industry has been examined in the economic impact analysis.
