INTRODUCTION

In the spring of 1988, nine municipalities in the Greater New York Metropolitan Area applied to the U.S. Environmental Protection Agency (EPA) Region II for permits to dump municipal sludge at the 106-Mile Deepwater Municipal Sludge Site (106-Mile Site). As part of the application review, data from the applicants were included in a data management system entitled "Data Management and Reporting for Ocean Dumping of Municipal Sludge." This report, which accompanies the database, summarizes the procedures used to process the data and presents summary statistics on several parameters.

The sludge data incorporated into the database were accumulated as permittee reports on sludges dumped at the 12-Mile Sewage Sludge Site and the 106-Mile Site. Since regulation of the dumping of sludge began in 1976, EPA has required periodic reports on the physical and chemical characteristics of dumped municipal sludges. Ocean dumpers, initially granted permits by EPA to dump at the 12-Mile Sewage Sludge Site and then allowed to continue to dump under court order, are required to submit data periodically on sludge toxicity, metal concentrations, and several other physical and chemical parameters.

Anticipating applications, EPA Region II issued guidance ("Information and Data Requirements under Section 102 of the Marine Protection, Research, and Sanctuaries Act for Municipalities Applying for Special Ocean Dumping Permits to Dump Municipal Sewage Treatment Sludge into Ocean Waters Governed by EPA Region II") indicating what data were required in the applications. In addition to the toxicity results and metal concentrations required under the original dumping permits, additional information was sought on the concentrations of organic compounds and indicators of pathogenic organisms that might be present. The database can accept most of these parameters, however, no historical data are available.

METHODS

Data reports for each permit applicant were obtained from EPA Region II. The reports were of several types: monthly reports, quarterly reports, semi-annual reports, and summaries of periodic reports. Reports contained data for one or more sample dates. See Table 1 for the distribution of sample dates among plants and years. In general, the reports consisted of a summary page (which differed in format among applicants) that presented analytical results as single values without quality control information. However, laboratory records and calculation sheets were included for toxicity tests. One applicant (Middlesex County Utilities Authority, see below) also routinely submitted reports to the EPA that were prepared for the New Jersey Department of Environmental Protection.

The reports were separated into groups, one for each permit applicant. Within each applicant, reports were further grouped by laboratory (for most applicants, two or three laboratories had analyzed sludge samples over the 5-year period). The separation by laboratory made data entry easier by having several data sheets of the same reporting

TABLE 1. NUMBER OF SAMPLES INCLUDED IN THE DATABASE BY PERMITTEE AND PLANT BY YEAR.

format together. The reports were copied, and the parameters and values to be entered into the database were highlighted with a marking pen to further assist in data entry.

All highlighted data were entered into a free-format database twice by two different operators. The resulting computer files were compared electronically, and entry errors were corrected by comparing file values with the original data and changing incorrect values in the file. Thus the data are an accurate representation of the data that were provided.

Once an error-free database was achieved, summary listings and summary statistics were obtained using SAS (v 6.03). The summary listing (by applicant, plant, and parameter) indicated that there were differences in reporting units for several parameters (particularly metals) and that the sample dates for many reports were not sample dates but dates that samples were received by the laboratory or dates they were analyzed.

Known differences in units were resolved by converting all concentration data to mg/L. However, for some reports, the reporting units for many parameters were not listed. In these cases, if reports from the same laboratory were available, the units on those other reports were used. These units were assumed to be correct if the data with unknown units fell within the range of data for the reports with known units. If the units could not be resolved, the data were not included in the database.

Missing sample dates were resolved by reexamining the entire set of original data reports. If no sample date was listed anywhere in those reports, the earliest date appearing on the laboratory report was used (usually the date of receipt of the sample by the laboratory). This date appeared to be within 2 or 3 days of the date that the sample was taken for those cases where it was possible to determine both dates.

Once sample dates were resolved, duplicate entries were removed. Duplicate entries were determined by comparing the time sequence of results for each applicant. If the same values appeared in sequence, the sample dates were rechecked, and obvious duplicates were removed.

Summary statistics were then calculated for all parameters for each applicant. The summary statistics for each plant were based on the lognormal distribution, using the following formulas:

$$\mu = \sum \ln [x_i] / n \quad (1)$$

$$\sigma^2 = \sum (\ln [x_i] - \mu)^2 / (n - 1) \quad (2)$$

$$\text{mean} = e^{[\mu + \sigma^2/2]} \quad (3)$$

$$\text{standard deviation} = \sqrt{e^{[2\mu + \sigma^2]} (e^{\sigma^2} - 1)} \quad (4)$$

$$\text{coefficient of variation} = \mu / \sigma \quad (5)$$

$$95\text{th percentile} = e^{[\mu + 1.645\sigma]} \quad (6)$$

$$5\text{th percentile} = e^{[\mu - 1.645\sigma]} \quad (7)$$

where μ is the mean of the natural logarithm of individual observations, x_i is the value of each observation, n is the number of observations, σ^2 is the variance of the logged individual observations, and e is the base of the natural logarithm.

Once the means, standard deviations, coefficients of variation, and percentiles had been calculated for each parameter for each applicant and plant, the data were summarized in a series of tables, one for each parameter. These tables were then inspected for consistency to determine whether the variability of any parameters for a plant exceeded the expected range of variability for all plants. It was assumed that if the variability of a parameter for any given plant was much greater than the variability of other plants, the reported value for that parameter was probably in error. Values that were based on single observations were also eliminated.

To determine whether the variability of a parameter for a plant was within the expected range, the data for each plant and parameter whose coefficient of variation was greater than 1.0 were inspected. When high CVs were associated with five or more data points, this usually meant that there was one outlying data point. Such data points were removed, and the CV was recalculated. If the resulting CV was less than 1.0, no further action was taken. Otherwise, other apparent outliers were also removed. If a high CV was associated with two data points, both data points were removed. With three data points, if one point was substantially different from the other two and that of other plants for the same parameter, it was removed. Otherwise, all three data points were removed. Data that were eliminated in this way are presented in Table 2. Eliminated data are not included in statistical summaries.

Finally, lognormal means, standard deviations, and coefficients of variation across all plants were calculated in a spreadsheet implemented by Microsoft Works (Macintosh v 1.1). For this analysis, the means, standard deviations, and coefficients of variation were calculated on all data for all plants. The results were used as a guide to setting input range limits for the database.

RESULTS

For the nine applicants, there were a total of 22 individual sewage treatment plants. All except one applicant dump sewage sludge from only one plant. The other applicant (the City of New York) dumps sludges from 14 plants.

For organizational purposes, data are reported in three categories: toxicity tests (for *Meridita meridita* and *Mystidopsis bahia*), metals (concentrations of arsenic, cadmium, chromium, copper, lead, mercury, nickel, and zinc), and general parameters (specific gravity, pH, COD, oil and grease, petroleum hydrocarbons, total nonfilterable residue, and total residue).

Data Quality

The data that are summarized in this report are of unknown quality. Given the lack of quality control information and the fact that some samples were known to be analyzed

several months after collection, it is suspected that data quality is poor. Specific problems that prevent a good assessment of data quality are presented in the following paragraphs.

Values for all parameters were seldom reported consistently either over time or among plants. Each of the four laboratories preparing reports had a different format. Applicants often forwarded the laboratory report with only a cover letter, so data were not consistently presented. In many cases, it was not clear what analytical methods were used (except for toxicity tests). Quality control data (such as detection limits, blanks, spiked samples) were not presented for any parameter except toxicity. Thus, it is not clear that the data are accurate or comparable among applicants or plants.

The identity of the waste sampled was also not obvious. In some cases, data sheets were marked as "composite." According to one of the applicants, composite samples (at least for Passaic Valley Sewerage Commission) were taken over a period of 4 days prior to barge loading. Other data sheets were marked as a "barge sample." However, the barge being sampled and other sludges that were present in the sample were not identified. The discrepancies in the data indicate that more than one plant's sludge was probably being sampled. However, many of the data were not labeled. It was thus not possible to determine, on a routine basis, whether a report was for a "barge sample," "composite," or other sample type.

Finally, as mentioned in the Methods section, results were often reported without units. Many of the data were eliminated because the appropriate units could not be determined. For one plant, data for the same parameter were reported in mg/kg, mg/kg-dry, mg/L, μ g/L, and with no units on different data sheets. Although it is expected that concentrations of pollutants would be much higher in dried sludge, the ranges of concentrations reported as mg/L and mg/kg overlapped. On a few data sheets where results were reported as mg/kg and mg/L, it was not possible to determine the conversion factor used (even though there were several parameters that would allow converting one to the other). Thus, even though there were many data that might have been used in this analysis, they were ignored because they could not be converted to appropriate units with any certainty.

Statistical Summaries Among Plants

Table 3 presents the lognormal mean, standard deviation, coefficient of variation, and 95th and 5th percentiles for the 20 parameters that were reported consistently by each plant. All of the parameters were reported for the majority of plants (at least 14 of the 22). Some of the data were not included in this table because of excessive variability as described in the previous section. Other parameters that are available in the database were not reported because data exist for only one or two plants. The following paragraphs summarize the data appearing in this table.

Menidia and *Mysidopsis* are similar in their responses (as well as in their variability of response across plants) to the sludges.

TABLE 3. MEANS, STANDARD DEVIATIONS, COEFFICIENTS OF VARIATION, AND 5TH AND 95TH PERCENTILES FOR COMMONLY MEASURED PARAMETERS

Parameter	ND	N	Mean	Standard deviation	Coefficient of variation	5th percentile	95th percentile
Arsenic	7	59	323	529	1.64	26	1,101
Cadmium	4	67	1,877	3,913	2.09	96	6,829
Chromium	0	69	16,925	30,493	1.80	1,136	59,376
Copper	0	70	66,124	65,159	0.99	12,148	182,602
Lead	0	71	22,939	41,355	1.80	1,538	80,490
Mercury	4	60	104.4	93.1	0.89	22.1	274.2
Nickel	0	65	6,795	9,926	1.46	662	22,268
Zinc	0	70	77,676	86,843	1.12	11,772	227,791
<i>♂</i>							
<i>Menidia menidia</i>	18	144	22,282	23,720	1.06	3,644	63,867
<i>Mysidopsis bahia</i>	3	159	18,761	24,173	1.29	2,260	58,541
COD	0	66	36,630	19,479	0.53	14,231	73,499
Oil and grease	0	69	3,659	3,397	0.93	733	9,810
Petroleum hydrocarbons	0	69	1,689	1,856	1.10	263	4,913
pH	0	51	6.72	0.90	0.13	5.36	8.29
Specific gravity	0	67	1.009	0.025	0.02	0.969	1.050
Total residue	0	72	31,711	17,009	0.54	12,220	63,906
Total filterable residue	0	66	23,868	15,266	0.64	7,673	52,688

Units for metals: $\mu\text{g/L}$

Units for toxicity, COD, oil and grease, petroleum hydrocarbons, total residue, and total filterable residue: mg/L

Units for specific gravity: g/cc

Of the metals measured, zinc has the highest average concentration across plants, followed by copper, lead, and chromium. Lead and chromium are the most variable across plants, suggesting industrial sources for these metals.

Of the general parameters, pH and specific gravity are most similar among plants. COD is most variable, and the other parameters (oil and grease, petroleum hydrocarbons, and two forms of residues) are in between.

According to these data, the sewage sludges average about 3.3 percent solids. Total filterable residue was only 2.5 percent of the sludges, on average.

Statistical Summaries Within Plants

Tables 4 - 20 present statistical summaries for each parameter for each plant, including the number of values recorded as nondetectable, less than, or greater than (ND); the number of samples included; the lognormal mean and standard deviation, the coefficient of variation, and the 5th and 95th percentiles for each parameter. Arithmetic means and coefficients of variation for data across all plants are also presented.

There are no data for 13 percent of the cases, and 10 percent of the cases are single values. In total, about 30 percent of the cases are not usable.

DISCUSSION

In general, these data are of acceptable quality to determine trial permit limits for the municipal sludges proposed to be dumped at the 106-Mile Municipal Sludge Dumpsite. The outlier detection routine used for these data was designed to represent the same kind of scheme that would be used once the data management system for these data is available. It is therefore reasonable to assume that it was not biased. With this elimination routine, some of the large variability within plants was reduced, but some was not reduced substantially. Since lognormal means and percentiles are a function of the standard deviation, high variability in a parameter for a plant increases the mean and both increases and decreases the 95th and 5th percentiles, respectively, for that plant. Such variability may substantially decrease the allowable sludge dumping rate for that plant.

Because the Ocean Dumping Regulations require data on all chemicals for which there are marine water quality criteria (see 40 CFR 227), the data in this report are only sufficient for calculating permit limits for most metals and toxicity for most plants. No data are available (in appropriate units) for calculation of permit limits based on the marine water quality criteria for pesticides. Until these data are available, and until sufficient metals data are available for all plants, final permit limits cannot be determined.
