United States Environmental Protection Agency AIR Office of Air Quality Planning and Standards Research Triangle Park, NC 27711 EPA-454/R-00-002 March 2000

### SEPA NATIONAL AIR POLLUTANT EMISSION TRENDS, 1900 - 1998

# U. S. EPA and the States -Working Together for Cleaner Air!

### Disclaimer

THIS REPORT HAS BEEN REVIEWED BY THE OFFICE OF AIR QUALITY PLANNING AND STANDARDS. MENTION OF TRADE NAMES OR COMMERCIAL PRODUCTS DOES NOT CONSTITUTE ENDORSEMENT OR RECOMMENDATION FOR USE.

### Foreword

This document presents the most recent estimates of national emissions of the criteria air pollutants. The emissions of each pollutant are estimated for many different source categories, which collectively account for all anthropogenic emissions. The report presents the total emissions from all 50 States and from each EPA region in the country. These estimates are updated annually.

This report tracks changes in national emissions since passage of the Clean Air Act Amendments of 1990. The emission trends are the net effect of many factors, including changes in the nation's economy and in industrial activity, technology, consumption of fuels, traffic, and other activities that cause air pollution. The trends also reflect changes in emissions as a result of air pollution regulations and emission controls. These reports will serve as a measure of our nation's progress in reducing air pollution emissions as a result of mandatory and voluntary controls and of continuous changes in national activity.

In addition to the extensive coverage of criteria air pollutant emissions from anthropogenic sources in the United States, this year's report continues to provide limited coverage of State-derived biogenic, greenhouse gas, and air toxic emissions, and emissions for Canada and Europe. Preliminary estimates are presented for the years 1990 through 1998. Final estimates (including refinements to the data used to estimate emissions) will be presented in future reports.

| 2-11. | Density Map of 1998 VOLATILE ORGANIC COMPOUND Emissions by County  |        |
| 2-12. | Density Map of 1998 SULFUR DIOXIDE Emissions by County   |        |
| 2-13. | Density Map of 1998 PARTICULATE MATTER (PM <sub>10</sub> ) Emissions by County                                     |        |
| 2-14. | Density Map of 1998 PARTICULATE MATTER (PM <sub>2.5</sub> ) Emissions by County                                    |        |
| 2-15. | Density Map of 1998 AMMONIA Emissions by County  |        |
| 3-1.  | Trend in Gross Domestic Product, Population, Vehicle Miles Traveled, Total Fuel Consumption, Combined              |        |
|       | VOLATILE ORGANIC COMPOUND and NITROGEN OXIDES Emissions, and SULFUR DIOXIDE Emissi                                 | ons,   |
|       | 1970 to 1998   | ,      |
| 3-2.  | Trend in CARBON MONOXIDE Emissions, 1940 to 1998   | 3-22   |
| 3-3.  | Trend in NITROGEN OXIDE Emissions, 1940 to 1998  |        |
| 3-4.  | Trend in VOLATILE ORGANIC COMPOUND Emissions, 1940 to 1998   |        |
| 3-5.  | Trend in SULFUR DIOXIDE Emissions, 1940 to 1998  |        |
| 3-6.  | Trend in Directly Emitted PARTICULATE MATTER (PM <sub>10</sub> ) Emissions Excluding Fugitive Dust Sources, 194    |        |
|       | 1998   |        |
| 3-7.  | Trend in Directly Emitted PARTICULATE MATTER (PM25) Emissions Excluding Fugitive Dust Sources, 199                 |        |
|       | 1998   |        |
| 3-8.  | Trend in LEAD Emissions, 1970 to 1998  |        |
| 3-9.  | Trend in AMMONIA Emissions, 1990 to 1998   |        |
| 4-1.  | SO <sub>2</sub> Emissions by Major Industrial Source Category, 1996  |        |
| 4-2.  | Industrial SO <sub>2</sub> Emissions (1900 to 2020)  |        |
| 4-3.  | SO <sub>2</sub> Emissions by Major Industrial Source Category, 2020  |        |
| 4-4.  | On-Road Emissions With and Without Desulfurization, 1993-1998  |        |
| 5-1.  | States Submitting Point and/or Area Source Data for the 1996 PEI   |        |
| 6-1.  | Density Map of NITROGEN OXIDES 1997 Biogenic Emissions by County   |        |
| 6-2.  | Density Map of VOLATILE ORGANIC COMPOUND 1997 Biogenic Emissions by County   |        |
| 7-1.  | 1996 NTI State Data Summary  |        |
| 7-2.  | U.S. Counties by Urban and Rural Designation   | 7-43   |
| 7-3.  | Baseline NTI (1990 to 1993) National Emissions by Urban vs. Rural  |        |
|       |  |        |

| 7-4.  | Baseline NTI (1990 to 1993) National Emissions of 188 HAPs by Urban vs. Rural                 | 7-45 |
|-------|---|------|
| 7-5.  | Baseline NTI (1990 to 1993) National Emissions of 33 HAPs by Urban vs. Rural                  | 7-46 |
| 7-6.  | Baseline NTI (1990 to 1993) 188 HAP Emissions by State and Source Sector                      | 7-47 |
| 7-7.  | Baseline NTI (1990 to 1993) 33 HAP Emissions by State and Source Sector                       | 7-48 |
| 7-8.  | Summed Baseline NTI (1990 to 1993) Emissions of 188 HAPs per Square Mile for U.S. Counties    | 7-49 |
| 7-9.  | Summed Baseline NTI (1990 to 1993) Emissions of 33 HAPs per Square Mile for U.S. Counties     | 7-50 |
| 7-10. | Summary Baseline NTI (1990 to 1993) of 33 HAPs National Emissions Percentage by Source Sector | 7-51 |
| 8-1.  | U.S. Carbon Dioxide Emissions by Sector (1994)  | 8-8  |
| 8-2.  | U.S. Carbon Dioxide Emissions from Industry (1994)  | 8-9  |
| 8-3.  | U.S. Carbon Dioxide Emissions by End-Use Sector (1994)  | 8-10 |

### Acknowledgement

This report was prepared with the help of many people. The EPA wishes to acknowledge the assistance of the Emission Inventory Trends Team of the Emission Factor and Inventory Group, the National Toxics Inventory Team of the Emission Factor and Inventory Group, the Utilities Emissions Representatives of the Clean Air Markets Division; the Nonroad Team of the Office of Transportation and Air Quality; and the Annual Reporting of Green House Gases Report Team of the Climate Policy and Programs Division; The agency also wishes to acknowledge the data and information that was provided by numerous people fromGovernment agencies and private institutions and organizations. This final document was prepared under Contract Number 68D-70067.

#### ES.1 WHAT INFORMATION IS PRESENTED IN THIS REPORT?

This report presents the United States (U.S.) Environmental Protection Agency's (EPA) latest estimates of national emissions for criteria air pollutants: carbon monoxide (CO), nitrogen oxides (NO<sub>x</sub>), volatile organic compounds (VOC), sulfur dioxide (SO<sub>2</sub>), particulate matter (PM) less than 10 microns in aerodynamic diameter ( $PM_{10}$ ), particulate matter less than 2.5 microns in aerodynamic diameter (PM<sub>2.5</sub>), and lead (Pb). In addition, estimates of ammonia (NH<sub>3</sub>), an important precursor for secondarily formed particles, are also presented. Estimates are presented for the years 1900 to 1998. Estimates for three criteria pollutants, NO<sub>x</sub>, SO<sub>2</sub>, and VOC, have been extrapolated back to 1900. Criteria pollutants are those for which ambient air standards have been set, based on established criteria for risk to human health and/or environmental degradation.

Data on emissions of hazardous air pollutants (HAPs), or air toxics, greenhouse gases (carbon dioxide  $[CO_2]$ , methane  $[CH_4]$ , nitrous oxide  $[N_2O]$ , hydrofluorocarbons {HFCs], perfluorocarbons (PFCs), and sulfur hexafluoride  $[SF_6]$ ), and biogenic sources are also included in this report for the United States. As a point of comparison, data for Canada for 1995 and for Europe for 1996 are presented for the criteria air pollutants.

Figures ES-1 and ES-2 present the long-term trends in the criteria air pollutant emissions from 1900 through 1998. Most of the criteria air pollutant emission levels peaked around 1970.  $PM_{10}$  emissions peaked earlier (around 1950) since smoke and particulates were the first pollutants to be regulated. Between 1970 and 1998 emissions for all criteria pollutants have generally declined (except for NO<sub>x</sub>), even though vehicle miles traveled (VMT) and gross domestic product (GDP) increased. For the last 2 years, SO<sub>2</sub> has shown a small increase in emissions. These air pollution decreases are attributable to the Clean Air Act (CAA) regulations beginning in 1970 and continuing into the 1990s. (Intermittent economic recession and improved manufacturing practices have also played a role.) Although not shown in these figures, the trend in PM<sub>25</sub> mirrors that of  $PM_{10}$  over the period that estimates have been made for  $PM_{2.5}$ (1990-1998). NH<sub>3</sub> has shown a modest increase over this same time period.

#### ES.2 WHAT ARE THE CURRENT EMISSION LEVELS?

Tables ES-1 and ES-2 present the most current emission estimates for the criteria and other air pollutants in the United States. U.S. criteria pollutant emissions decreased for CO, VOC, and NO<sub>x</sub>, and increased for Pb, SO<sub>2</sub>, and PM<sub>10</sub> from the previous year. The increase in  $SO_2$  emission estimates is a result of a modest increase in emissions in the electric utility and industrial process sectors, probably fueled by the strong economy. The reduction in CO and VOC emissions results from a sharp decrease in emissions from forest wildfires, as well as a decrease in mobile source emissions as a result of the use of new fuels (reformulated gasoline, oxygenated fuels, and lower Reid vapor pressures [RVP]). Particulate fugitive dust emissions from construction sources, paved roads, and unpaved roads increased due to the increases in construction and VMT. The most recent available Canadian data for 1995 and Europe for 1996 are summarized in Table ES-3.

A description of those source categories whose methods used for estimating CO,  $NO_x$ , VOC,  $SO_2$ ,  $PM_{10}$ ,  $PM_{2.5}$ ,  $NH_3$ , and Pb changed during the last year can be found in Chapter 5 of this report, while information on methods that did not change can be found in the National Air Pollutant Emission *Trends* Procedures Document.<sup>1</sup>

### ES.3 WHAT ARE THE TRENDS IN POLLUTANT EMISSIONS?

The level and composition of economic activity in the nation, demographic influences, meteorological conditions, and regulatory efforts to control emissions affect the trends in criteria air pollutant emissions. The emissions resulting from these economic, demographic, and regulatory influences are presented in Figures ES-1 and ES-2. The changes in emissions are presented in Table ES-4 for several time periods. Up until the 1950s, the greatest influence on emissions were economic and demographic. Emissions grew as the economy and population increased; emissions declined in periods of economic recession. Dramatic declines in emissions in the 1930s were due to the Great Depression. More recent recession in the mid/late-1970s (largely a result from disruptions in the world oil markets) and early 1990s also led to decreases in emissions.

Emissions also increase as a result of a shift in the demand for various products. For example, the tremendous increase in demand for refined petroleum products, especially motor gasoline after World War II, increased emissions associated with petroleum refining and on-road vehicles. Increased economic production as a result of World War II raised emissions to levels higher than those of the pre-Depression Era. The declines in the 1940s through 1970s in residential wood combustion resulted from the abundant supply, low relative prices, and convenience of fossil fuel-generated electricity.

In the 1950s the States issued air pollution statutes generally targeted toward smoke and particulate emissions. It was not until passage of the CAA as amended in 1970 (Congress passed the original CAA in 1963) that major strides were made in reducing air pollution. The 1970 Amendments created the EPA and charged it with three major tasks: 1) set National Ambient Air Quality Standards (NAAQS); 2) develop motor vehicle emission standards; and 3) set new source performance standards (NSPS). As a result of these standards, CO, VOC, SO<sub>2</sub>, and Pb emissions were reduced in the mid-1970s.

The Clean Air Act Amendments of 1990 (CAAA) are beginning to effect emission levels. For some source categories (such as non-road engines), standards began in 1996, but some significant emission reductions are not expected until after the year 2000. The robust U.S. economy in the late 1990s has provided a slight increase in emissions in some source sectors, although the influence of these increases has been largely offset by regulatory programs.

Some emission sources such as wildfires and fugitive dust have been influenced more by meteorological conditions than economic forces. Controls to reduce fugitive dust emissions resulting from the CAAA are beginning to take effect, but are only applied in the PM nonattainment areas (NAAs). The amount of land burned in wildfires varies greatly from year-to-year. Overall emission reductions from wildfires are a result of the U.S. Department of Agriculture's (USDA) Forest Service support of state efforts in fire prevention and early control. For example, in the year 1910, 5,201 fires burned approximately 5 million acres of land, whereas in the year 1990, 11,950 fires burned only one-third of a million acres of land.

More details on the effects of economic, demographic, and regulatory forces on emission levels are explained in Chapter 3.

#### Table ES-4. Percentage Change in National Emissions

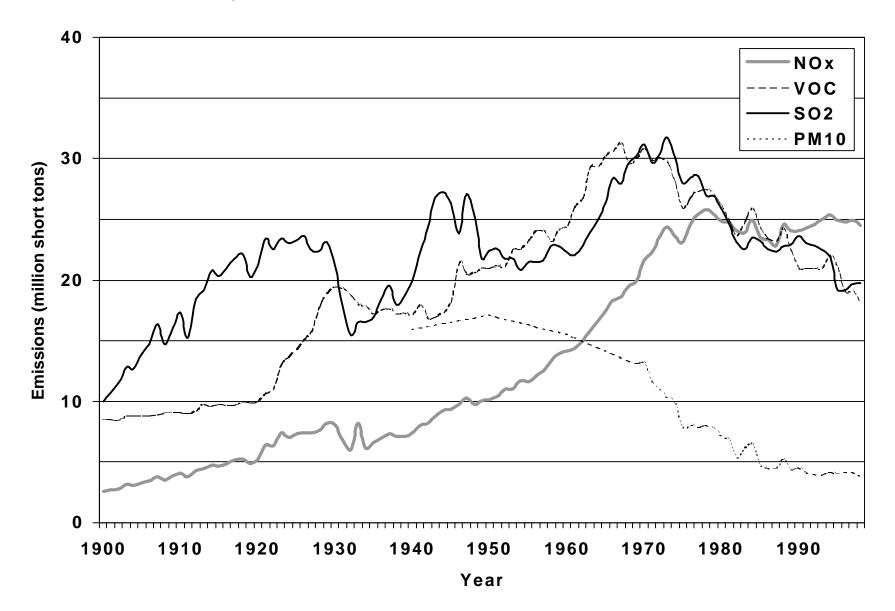

Note(s): \*  $PM_{10}$  emissions excluding miscellaneous and fugitive dust sources.

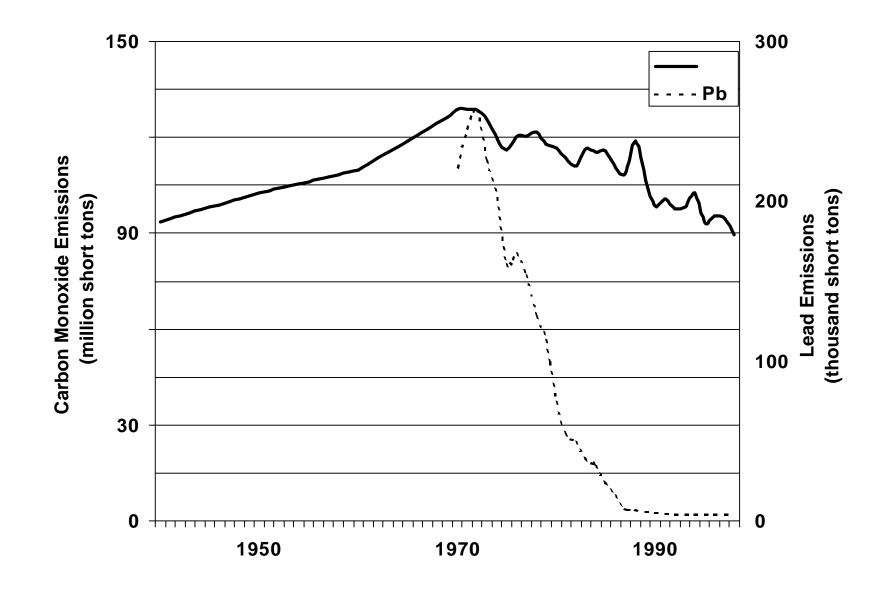

\*\* Miscellaneous sources include agriculture and forestry, fugitive dust includes roads and construction, and natural sources include primarily geogenic wind erosion.

\*\*\* NA denotes not available. Negative percent change indicates an increase in emissions.

\*\*\*\* There are significant changes in fugitive dust emission methodology between the years 1989 and 1990.

Figure ES-1. Trend in National Emissions, NITROGEN OXIDES, VOLATILE ORGANIC COMPOUNDS, SULFUR DIOXIDE (1900 to 1998), and Directly Emitted PARTICULATE MATTER (PM<sub>10</sub> [nonfugitive dust sources]; 1940 to 1998)

### Figure ES-2. Trend in National Emissions, CARBON MONOXIDE

Chapter 1.0

#### 1.1 WHAT INFORMATION IS PRESENTED IN THIS REPORT?

This report presents the United States (U.S.) Environmental Protection Agency's (EPA) latest estimates of national emissions for criteria air pollutants: carbon monoxide (CO), nitrogen oxides (NO<sub>x</sub>), volatile organic compounds (VOCs [excludes certain nonreactive organic compounds]), sulfur dioxide (SO<sub>2</sub>), particulate matter less than 10 microns (PM<sub>10</sub>), particulate matter less than 2.5 microns (PM<sub>2.5</sub>), and lead (Pb). Although not a criteria pollutant, emission estimates for ammonia (NH<sub>3</sub>), a compound that plays an important role in the secondary formation of particles, are also presented. The Clean Air Act (CAA) requires that the EPA Administrator publish a list of pollutants that have adverse effects on public health or welfare, and are emitted from numerous and diverse stationary or mobile sources. For each pollutant, the Administrator must compile and publish a "criteria" document. The criteria documents are scientific compendia of the studies documenting adverse effects of specific pollutants at various concentrations in the ambient air. For each pollutant, National Ambient Air Quality Standards (NAAQS) are set at levels that, based on the criteria, protect the public health and the public welfare from any known or anticipated adverse effects. These regulated pollutants are therefore called "criteria pollutants." We describe some of the health effects in section 1.2.

Summaries of ambient air quality measurements collected by federal, State, and local agencies, and the status of compliance with the NAAQS, can be found in the series of annual air quality trends reports, the most recent of which is the *National Air Quality and Emissions Trends Report, 1998* (EPA-454/R-00-003).

Graphs of national emission estimates, beginning in 1900 for  $NO_x$ , VOC, and  $SO_2$ , aggregated by major source category, are presented in Chapter 3. We provide more detail for these pollutants, and CO and  $PM_{10}$  beginning with 1940. Information related to  $PM_{2.5}$  and  $NH_3$  starts with 1990, the first year EPA developed estimates for these pollutants. We include additional detail for the current year. This report also contains information on estimation methods that we have updated during the past year. Revised international emissions from Europe and Canada, air toxic emissions, greenhouse gas emissions, and biogenic emissions are also presented.

#### 1.2 WHAT ARE THE HEALTH AND ENVIRONMENTAL EFFECTS OF CRITERIA POLLUTANTS?

CO enters the bloodstream and reduces the delivery of oxygen to the body's organs and tissues. The health threat from CO is most serious for those who suffer from cardiovascular disease, particularly those with angina or peripheral vascular disease. It affects healthy individuals also but only at higher concentration levels. Exposure to elevated CO levels is associated with impairment of visual perception, work capacity, manual dexterity, learning ability and performance of complex tasks.<sup>1</sup> Prolonged exposure to high levels can lead to death.

Nitric oxide (NO) is the principal oxide of nitrogen produced in combustion processes; it is readily oxidized in the atmosphere to nitrogen dioxide (NO<sub>2</sub>). Collectively, NO and NO2 are referred to as NOx. NO2 can irritate the lungs and lower resistance to respiratory infection (such as influenza). Nitrogen oxides are an important precursor both to ozone (O<sub>3</sub>) and to acidic deposition and may affect both terrestrial and aquatic ecosystems. Atmospheric deposition of nitrogen (nitrate,  $NO_x$ , other compounds derived from  $NO_x$ ) leads to excess nutrient enrichment problems (eutrophication); prominent examples are: Chesapeake Bay and several other nationally important estuaries along the East and Gulf Coasts.<sup>2</sup> Eutrophication can produce multiple adverse effects on water quality and the aquatic environment, including increased nuisance and toxic algal blooms, excessive phytoplankton growth, low or no dissolved oxygen in bottom waters, and reduced sunlight causing losses in submerged aquatic vegetation critical for healthy estuarine ecosystems. Nitrogen oxides are a precursor to the formation of nitrate particulate matter (PM) in the atmosphere; this effect is most important in western areas.<sup>3</sup> NO<sub>2</sub> and airborne nitrate also contribute to pollutant haze, which impairs visibility and can reduce residential property values and revenues from tourism.

VOCs are a principal component in the chemical and physical atmospheric reactions that form  $O_3$  and other photochemical oxidants. The reactivity of  $O_3$  causes health problems because it damages biological tissues and cells.  $O_3$ is also responsible each year for agricultural crop yield loss in the United States of several billion dollars and causes noticeable foliar damage in many crops and species of trees. Forest and ecosystem studies show that damage is resulting from current ambient  $O_3$  levels plus excess nutrient enrichment and, in certain high-elevation areas, acidification.<sup>3</sup>

 $SO_2$  is a precursor to the formation of sulfate PM, including acid and nonacid aerosols, in the atmosphere. Sulfate aerosols make up the largest single component of fine particulate matter in most locations in the eastern United States.<sup>4</sup> The major health effects of concern associated with exposures to high concentrations of SO<sub>2</sub>, sulfate aerosols, and PM, include effects on breathing, respiratory illness and symptoms, alterations in the lung's defenses, aggravation of existing respiratory and cardiovascular disease, and mortality. Children and the elderly may be particularly sensitive. Also,  $SO_2$  can produce foliar damage on trees and agricultural crops.

Together  $NO_x$  and  $SO_2$  are the major precursors to acidic deposition (acid rain), which is associated with several environmental and human health effects. These effects include acidification of lakes and streams, impacts on forest soils, accelerated corrosion of buildings and monuments, and visibility impairment plus respiratory effects on humans associated with fine sulfate and nitrate particles.

Based on studies of human populations exposed to ambient particle pollution (sometimes in the presence of  $SO_2$ ), and laboratory studies of animals and humans, the major effects of concern for human health include effects on breathing and respiratory symptoms, aggravation of existing respiratory and cardiovascular disease, alterations in the body's defense systems against foreign materials, damage to lung tissue, carcinogenesis, and premature mortality. Particulate matter causes damage to materials and soiling; it is a major cause of substantial visibility impairment in many parts of the United States.<sup>4</sup>

Fine particles  $(PM_{2.5})$  are of health concern because they easily reach the deepest recesses of the lungs. Batteries of scientific studies have linked fine particles (alone or in combination with other air pollutants), with a series of significant health problems, including:

- Premature death
- Respiratory related hospital admissions and emergency room visits
- Aggravated asthma
- Acute respiratory symptoms, including aggravated coughing and difficult or painful breathing
- Chronic bronchitis
- Decreased lung function that can be experienced as shortness of breath
- Work and school absences<sup>5</sup>

Exposure to Pb can occur through multiple pathways, including inhalation of air, diet and ingestion of Pb in food, water, soil, or dust. Pb accumulates in the body in blood, bone, and soft tissue. Because it is not readily excreted, Pb also affects the kidneys, liver, nervous system, and bloodforming organs. Excessive exposure to Pb may cause neurological impairments such as seizures, mental retardation and/or behavioral disorders. Even at low doses, Pb exposure is associated with changes in fundamental enzymatic, energy transfer and homeostatic mechanisms in the body. Fetuses, infants, and children are especially susceptible to low doses of Pb, often suffering central nervous system damage. Recent studies have also shown that Pb may be a factor in high blood pressure and subsequent heart disease in middle-aged Caucasian males.<sup>6</sup>

 $NH_3$ , in the presence of water in the atmosphere reacts with sulfates and nitrates to create ammonium sulfate and ammonium nitrate, both of which are particles. Particles formed via chemical reactions in the atmosphere are known as secondarily formed particles and play an important role in the overall  $PM_{2.5}$  particle budget.

#### **1.3 WHAT ENHANCEMENTS HAVE BEEN MADE TO THE REPORT?**

Since 1973, EPA has prepared estimates of annual national emissions in order to assess historic trends in criteria pollutant emissions. While these estimates were prepared using consistent methodologies and were useful for evaluating emission changes from year to year, they did not provide an absolute indication of emissions for any given year. Beginning with the 1993 Emission Trends Report (containing data through 1992), EPA established a goal of preparing emission trends that would also incorporate the best available annual estimates of emissions.<sup>a</sup>

The EPA's Emission Factor and Inventory Group (EFIG) has developed procedures and criteria for replacing *Trends* data with emissions data submitted by States as part of a variety of ongoing programs (such as  $O_3$  State Implementation Plan [SIP] submitted data). This report contains data obtained from several States through the 1996 periodic emission inventory (PEI) data submittals. Information related to how these data were incorporated into the National Emission Trends (NET) data base is given in Chapter 5.

The EFIG is also developing a data management and reporting system for emissions data. When the system is complete, the EFIG can extract the most current State inventories of emissions and supplement the gaps with EPAgenerated attainment area emission inventories. The EFIG has already made several changes to the *Trends* methodology to make the transition smoother.

In this report, there are five distinct time periods: 1900 to 1939, 1940 to 1984, 1985 to 1989, 1990 to 1996, and 1996 forward. Since the accuracy and availability of historical data is limited, we have not generally made revisions to estimates before 1984 (with some exceptions, discussed in Chapter 5).

However, many changes in current year totals have been incorporated into the reported estimates using State data.

Please note that methodologies within a given time period (especially more recent periods) will also vary, as we include more accurate data in the **Trends** data base.

Although there are many changes to the Trends methodology, some aspects have remained constant. For example, the 1900 through 1939 NO<sub>x</sub>, VOC, and SO<sub>2</sub> estimates are extracted from the National Acid Precipitation Assessment Program (NAPAP) historical emissions report.<sup>7,8</sup> In addition, Pb estimates (1970 to present), and all CO, NO<sub>x</sub>, VOC, SO<sub>2</sub>, and PM<sub>10</sub> estimates from 1940 to 1984 reported in Trends are based upon the previous national "top-down" methodology. Continuous emission monitoring (CEM) data reported by electric utilities to the Acid Rain Program's Emission Tracking System (ETS) were used, whenever available and complete, for NO<sub>x</sub>, SO<sub>2</sub>, and heat input values for the years 1996 and 1997. (These data apply to steam generated fossil-fuel units with nameplate capacity of at least 25 megawatts [MW].) These are some of the most accurate data collected by EPA because they represent actual monitored, instead of estimated, emissions.<sup>5</sup>

As has been stated in the past several Emission Trends Reports, EPA plans to incorporate as much State-derived data as possible into the Trends estimates. This report reflects the use of State data, specifically those data submitted by various States as part of the 1996 PEI reporting effort.

When data were not available, were deemed inappropriate for use in presenting emission Trends, or when EPA felt that we had a more robust mechanism for estimating emissions from a particular source sector, EPA relied on nationally derived estimates. We describe changes made to estimation techniques for this year in Chapter 5 of this report. Methods used for other source categories that we did not change for this year's report are detailed in the National Air Pollutant Emission Trends, Procedures Document, 1900-1996.9 In general we updated the 1996 inventory with State data and then projected estimates for 1997 and 1998 based on economic or other types of growth indicators (such as the State Energy Data System (SEDS) fuel consumption estimates) to develop estimates for 1997 and 1998. We also applied reductions resulting from the Clean Air Act Amendments of 1990 (CAAA) to the 1997 and 1998 estimates. Throughout the report we have indicated when the changes in emissions are due mainly to methodological changes.

We have made two other significant enhancements to the report. First, the discussions of emission estimates and emission trends are oriented around types of sources rather than around pollutants. EPA has found that in questions related to emissions and emission trends, most requesters want information related to how much of a pollutant is emitted by a particular source, rather than the total emissions of a pollutant no matter the source. While there are still sections that discuss overall emissions by pollutant, there are larger sections of the report that we have oriented around the following five categories:

- combustion;
- industrial;
- on-road;
- non-road; and
- miscellaneous.

In particular, these five broader categories are used to provide additional clarity for information presented graphically. When these broader categories are used, they represent emissions from the following Tier categories (see section 1.4 and Table 1-1 for Tier category descriptions):

| Category      | Tier 1 Categories Included |
|---------------|----------------------------|
| Combustion    | 1, 2 and 3                 |
| Industrial    | 4, 5, 6, 7, 8, 9, and 10   |
| On-road       | 11                         |
| Non-road      | 12                         |
| Miscellaneous | 13 and 14                  |

Some figures also show an "all other" category. The all other category represents the sum of all other Tier category emissions that are not specifically shown in the figure.

The second major change in the document is the usage of "plain language." In June 1998, President Clinton issued a memorandum instructing all government agencies to use plain language in new documents developed after October 1, 1998. Plain language is designed to produce documents that have logical organization, easy-to-read design features, and use common, everyday words (except necessary technical terms), "you" and other pronouns, the active voice (where possible), and short sentences (where possible). More information about the plain language initiative can be found at:

http://www.plainlanguage.gov/

#### 1.4 HOW IS THE REPORT STRUCTURED?

Changes made in the format of the October 1995<sup>10</sup> report, intended to make the report more comprehensible and informative, within the framework of the plain language initiative, are maintained for this report. The executive

summary presents a brief overview of each chapter of the report. In this introduction, Chapter 1, we inform the reader of changes to the report, the health effects of criteria air pollutants, and the structure of the report. A detailed account of the current year emissions by pollutant, source category, State, nonattainment area (NAA), county, and season and by a listing of top-emitting facilities is given in Chapter 2. National trends in emissions from 1900 (where available) to the current year and demographic, economic, and regulatory influences on emission trends are discussed in Chapter 3. Information on SO<sub>2</sub> emissions from industrial sources is presented in Chapter 4. An explanation of new methods of estimating pollutant emissions started during the past year is found in Chapter 5. Biogenic NO<sub>x</sub> and VOC emissions are presented in Chapter 6. Emissions from sources, noncriteria pollutants, or countries not traditionally part of the Trends report are displayed in Chapters 7, 8, and 9. The EPA and other governmental agencies developed these emissions. In each chapter, numeric superscripts represent references and alphabetic superscripts represent endnotes.

As in last year's report, all emissions reported in tables and figures in the body of the report are in units of thousand short tons, except Pb.<sup>b</sup> The pollutants are presented in the order of CO, NO<sub>x</sub>, VOC, SO<sub>2</sub>, PM<sub>10</sub>, PM<sub>2.5</sub>, Pb, and NH<sub>3</sub> throughout this report. We developed emissions at the county and Source Classification Code (SCC) level for the years 1985 to 1998 for most source categories. We then summed these emissions to the national Tier level. There are four levels in the tier categorization. The first and second level, respectively called Tier 1 and Tier 2, are the same for each of the six criteria pollutants. [NOTE: Tier 2 in this context should not be confused with the recently announced Tier II motor vehicle control standards] The third level, Tier 3, is unique for each pollutant. The fourth level, Tier 4, is the SCC level. The match-up between SCC and all three tier levels can be obtained by contacting EFIG (see Note at the bottom of Table 1-1). Table 1-1 lists the Tier 1 and Tier 2 categories used in Chapters 1 through 5 to present the criteria air pollutant emission estimates. Tables and figures appear at the end of each chapter in the order in which we have discussed them within the chapter. Appendix A contains tables listing emissions for each of the criteria pollutants by Tier 3 source categories. If emissions are reported as zero, the emissions are

less than 0.5 thousand tons (or 0.5 tons for Pb). "NA" indicates that the apportionment of the historic emissions to these subcategories is not possible. If a tier category does not appear, then emissions are not currently estimated for that category (either EPA estimates the emissions as zero or does not currently estimate the emissions due to time or resource limitations).

Throughout this report, emission estimates of  $PM_{10}$  and  $PM_{2.5}$  are presented by source category as total from all sources, including fugitive dust sources, and nonfugitive dust sources. Fugitive dust sources are included in the following tier categories.

| Tier 1 | Tier 1 Name        | Tier 2 | Tier 2 Name   |
|--------|--------------------|--------|---|
| 13     | Natural<br>Sources | 02     | Geogenic (wind erosion)   |
| 14     | Miscellaneous      | 01     | Agriculture and Forestry (agricultural crops or tilling and feedlots)   |
|        |                    | 07     | Fugitive Dust (paved and unpaved<br>roads; unpaved airstrips; construction;<br>mining and quarrying; wind erosion -<br>industrial; point source - haul roads) |

Emissions of  $NO_x$  are expressed as weight-equivalent  $NO_2$ . Thus, we have inflated the actual tons of NO emitted to report them as if they were  $NO_2$ . You should therefore assume that the molecular weight was that of  $NO_2$  when using numbers in this report.<sup>c</sup>

We report the VOC emissions as the actual weight of many different compounds. The relative amounts of the individual compounds emitted will determine the average molecular weight of a given source category's emissions. Therefore, no equivalent molecular weight standard exists for VOC. The VOC emissions referred to in this report exclude those organic compounds considered negligibly photochemically reactive, according to the EPA definition of VOC in the Code of Federal Regulations (40CFR51.100).<sup>11</sup> Thus, we have not included methane, ethane, and certain other organic compounds in the VOC totals.

a. The great majority of all emission data necessarily are estimates. Exhaustive, on-site quantification, source by source, is a practical, and an economic, impossibility.

b. Lead emissions are measured in short tons. Short tons can be converted to metric tons by dividing the emissions by a factor of 1.1023.

c. The term nitrogen oxides (NO<sub>x</sub>) encompasses emissions of both nitrogen dioxide (NO<sub>2</sub>) and nitric oxide (NO).

#### Table 1-1. Major Source Categories

The Source Classification Code (SCC) definitions and assignment to Tier category are available on the Technology Transfer Network's (919-541-1000) Emission Inventories/Emission Factors Information (CHIEF) Technical Information Area, or on the Internet (www.epa.gov/ttn/chief).

Chapter 2.0 1998 Emissions

#### 2.1 WHAT EMISSIONS DATA ARE PRESENTED IN THIS CHAPTER?

This chapter describes the carbon monoxide (CO), nitrogen oxides (NO<sub>x</sub>), volatile organic compound (VOC), sulfur dioxide (SO<sub>2</sub>), particulate matter less than 10 microns (PM<sub>10</sub>), particulate matter less than 2.5 microns (PM<sub>2.5</sub>), lead (Pb), and ammonia (NH<sub>3</sub>) emission estimates for 1998. Any notable trends from 1996 levels are discussed.

#### 2.2 HOW HAVE EMISSION ESTIMATES CHANGED FROM 1996 TO 1998 AND WHY?

Tables A-1 through A-7 provide detailed emission summaries for all pollutants at 5-year intervals from 1970 through 1985 and yearly for the period 1988 through 1998. Exact percentage changes from year to year for specific source categories can be calculated from those tables. In particular the tables show that between 1996 and 1998, overall emissions levels for CO and VOC decreased, NO<sub>x</sub> remained essentially level, while emissions for SO<sub>2</sub>, PM<sub>10</sub>, and PM<sub>2.5</sub>, and Pb increased. Specifically,

#### ... for utilities

• SO<sub>2</sub> emissions from point sources increased primarily due to coal-fired and oil-fired electric utilities. Increased burning of bituminous and anthracite coal by utilities created an increase of approximately 0.5 million tons/year of SO<sub>2</sub>.<sup>1</sup>

... for on-road vehicles

- Reductions due to fleet turnover (implementation of Tier I standards),<sup>2</sup> reformulated gasoline requirements, oxygenated fuel, and fuels with lower Reid vapor pressure resulted in the decrease in on-road CO, NO<sub>x</sub>, VOC, PM<sub>10</sub>, and PM<sub>2.5</sub> emissions despite the higher vehicle miles traveled (VMT) in 1998.
- Higher VMT caused an increase in SO<sub>2</sub> and NH<sub>3</sub> on-road emissions.

• Changes to 1990-1998 NO<sub>x</sub> emissions from heavyduty diesel vehicles (HDDV) due to adjustments in emissions due to the diesel defeat device (see section 5.7.4).

... for non-road vehicles

 1998 emissions decreased slightly for CO, NO<sub>x</sub>, and VOC, remained steady for Pb, and increased slightly for NO<sub>x</sub>, SO<sub>2</sub>, PM<sub>10</sub>, and PM<sub>2.5</sub> due to variations in fuel consumption by non-road engines<sup>3</sup> (gasoline and diesel) and vehicles (airplanes, locomotives, and marine vessels).

...for miscellaneous sources

• 1998 miscellaneous emissions decreased from 1996 levels for all pollutants except PM<sub>10</sub>, PM<sub>2.5</sub>, and NH<sub>3</sub>. Increases in particulate emissions were primarily the result of increased VMT on paved and unpaved roads, as well as growth in the construction sector due to the strong economy. Increases in NH<sub>3</sub> were primarily an inventory artifact resulting from improved activity data related to agricultural livestock operations.<sup>4</sup>

#### 2.2.1 What Sources Are the Main Contributors to 1998 CO Emissions?

Figure 2-1 is a pie chart showing 1998 CO emissions by source category. As the figure shows:

- On-road vehicles are major contributors to CO emissions, representing 57 percent of total national CO emissions. Of this 57 percent, just over half comes from light-duty gasoline vehicles (LDGVs [primarily cars]) and motorcycles.
- Non-road vehicles and engines contribute slightly more than 20 percent of total CO emissions. These emissions come primarily from gasoline consumption by lawn and garden, industrial, and recreational marine engines.

• Solvent utilization, storage and transport, and electric utility fuel combustion (three Tier 1 source categories) contribute slightly more than 0.5 percent to total national CO emissions. These source categories are combined with petroleum and related industries, industrial fuel combustion, other industrial processes, waste disposal and recycling, and chemical and allied product manufacturing, to create the "all other" grouping in Figure 2-1.

Table 2-1 presents the point and area split of the Tier 1 source categories. Area source emissions, including transportation sources and some minor point sources, comprise over 95 percent of total 1998 CO emissions.

#### 2.2.2 What Sources Are the Main Contributors to 1998 NO<sub>x</sub> Emissions?

Figure 2-2 is a pie chart showing 1998  $NO_x$  emissions by source category. As the figure shows:

- On-road vehicles account for 31 percent of total national NO<sub>x</sub> emissions. LDGVs are a major contributor (approximately 37 percent) to the 1998 on-road vehicle NO<sub>x</sub> emissions.
- Electric utilities represent 25 percent of total national NO<sub>x</sub> emissions in 1998. Coal combustion represents almost 90 percent of these emissions, with two-thirds of the coal combustion emissions coming from bituminous coal combustion.
- Solvent utilization, storage and transport, waste disposal and recycling, and metals processing (four Tier 1 source categories) constitute less that 1 percent of total national NO<sub>x</sub> emissions. The United States (U.S.) Environmental Protection Agency (EPA) includes these sources in the "all other" grouping in Figure 2-2, along with chemical and allied product manufacturing, other industrial processes, miscellaneous, and petroleum and related industries.

Table 2-1 presents the point and area split of the Tier 1 source categories. Area source emissions, including transportation sources, comprise 62 percent of total 1998 NO<sub>x</sub> emissions. On-road and non-road sources contribute 53 percent of the total  $NO_x$ .

#### 2.2.3 What Sources Are the Main Contributors to 1998 VOC Emissions?

Figure 2-3 shows 1998 VOC emissions by source category. As the figure indicates:

- Solvent utilization represents 30 percent of the total 1998 VOC emissions. Surface coating constitutes just over 40 percent of the solvent utilization emissions. The 26 specific subcategories of surface coating estimated by EPA are presented in Table A-3. Table A-3 also shows the effects of control programs on these sources. For example, co-control of VOCs related to maximum achievable control technology (MACT) controls can be seen for 1998 emissions from industrial adhesive surface coating operations. A MACT standard for that source category went into effect in 1998, reducing emissions by over 50 percent relative to 1996 and 1997 values.<sup>5</sup>
- On-road vehicles represented 29 percent of total national VOC emissions. LDGVs account for just over half of total national on-road vehicle VOC emissions.
- Electric utility fuel combustion and metals processing (two Tier 1 source categories) contribute slightly less than 3 percent of total national VOC emissions. EPA combines electric utility fuel combustion, metals processing, chemical and allied product manufacturing, petroleum and related industries, miscellaneous, other industrial processes and fuel combustion (industrial, other) into an "all other" grouping of Figure 2-3. This "all other" grouping contributed 21 percent to the total 1998 VOC emissions.

Table 2-1 presents the point and area source split of the Tier 1 source categories. Area source emissions, including transportation sources, make up 86 percent of total 1998 VOC emissions.

#### 2.2.4 What Sources Are the Main Contributors to 1998 SO<sub>2</sub> Emissions?

Figure 2-4 is a pie chart showing 1998  $SO_2$  emissions by source category. As the figure shows:

- Electric utilities contribute the majority of SO<sub>2</sub> emissions, representing over two-thirds (68 percent) of total national SO<sub>2</sub> emissions in 1998. Well over 90 percent of these emissions come from coal combustion. Bituminous coal combustion accounts three-fourths of the electric utility coal combustion emissions.
- Industrial coal combustion produced 15 percent of the 1998 SO<sub>2</sub> emissions.

• Solvent utilization, storage and transport, waste disposal and recycling, on-road sources, and miscellaneous (five Tier 1 source categories) account for 2 percent of total national SO<sub>2</sub> emissions. These sources, along with non-road sources, petroleum and related industries, and other industrial processes, comprise EPA's "all other" grouping.

Table 2-1 presents the point and area split of the Tier 1 source categories. Area source emissions, including transportation sources, make up 14 percent of total 1998  $SO_2$  emissions, while point sources make up the remainder.

#### 2.2.5 What Sources Are the Main Contributors to 1998 Particulate Matter (PM<sub>10</sub> and PM<sub>2.5</sub>) Emissions?

Figures 2-5 and 2-6 are pie charts showing 1998  $PM_{10}$  and  $PM_{2.5}$  emissions by source category. They depict the nonfugitive dust sources of  $PM_{10}$  and  $PM_{2.5}$ . As the figures show:

- Fuel combustion processes (utilities, industrial, commercial, and institutional boilers, and area source combustion) contribute the most to the nonfugitive dust portions of PM. Mobile sources, both on-road and non-road, are the next largest category of emitters. Industrial processes collectively comprise only about 10 percent of the nonfugitive dust sources, but they could have a significant effect on air quality in their vicinity.
- Wildfire  $PM_{10}$  and  $PM_{2.5}$  emissions for 1998 decreased significantly relative to 1996 and 1997 levels due to a dramatic reduction in the number of acres burned. Managed burning and wildfires comprise most of the area source combustion contributions in Figures 2-5 and 2-6.

Although the NET inventory shows that fugitive dust contributes a large percentage to the total PM emissions, a report by the Desert Research Institute found that about 75% of these emissions are within 2 m of the ground at the point they are measured. Thus, most of them are likely to be removed or deposited within a few km of their release, depending on atmospheric turbulence, temperature, soil moisture, availability of horizontal and vertical surfaces for impaction and initial suspension energy. This is consistent with the generally small amount of crustal materials found on speciated ambient samples.<sup>6</sup>

For a complete understanding of  $PM_{2.5}$  emissions, one should also consider the emissions of  $SO_2$ ,  $NO_x$ , and  $NH_3$ . These gases react in the atmosphere to form ammonium sulfate and ammonium nitrate fine particles; also, some

organic particles are formed from VOCs. These "secondary" fine particles (in contrast to the directly emitted particles from combustion and fugitive dust) can comprise as much as half the PM<sub>2.5</sub> measured in the U.S.<sup>7</sup> Source apportionment studies exist to help elucidate the role of primary PM (reflected in the NET) and secondary PM.

Table 2-1 presents the point and area split of the Tier 1 source categories. Area source emissions, including transportation sources, make up 96 percent of total 1998  $PM_{10}$  emissions. Methods and related data sources for several area source categories are currently being reviewed. These include unpaved roads, open burning, and construction.

Note that some emission estimates have not been updated. For example, wind erosion particulate emissions have been maintained at a constant value since 1996. Also, annual estimates of wind erosion emissions are difficult to interpret, owing to the extremely short duration of most wind events.

#### 2.2.6 What Sources Are the Main Contributors to 1998 Pb Emissions?

Figure 2-7 is a pie chart showing 1998 Pb emissions by source category. As the figure shows:

- Metals processing contributes 53 percent to total national Pb emissions. Nonferrous metal processing represents 65 percent of the 1998 metals processing emissions. Primary and secondary Pb products represent 46 and 37 percent, respectively, of the nonferrous metals in 1998.
- On-road emissions account for less than 0.5 percent of total national Pb emissions.
- EPA does not estimate Pb emissions for the following 5 Tier 1 source categories because Pb emissions from these sources are thought to be negligible: solvent utilization, storage and transport, petroleum and related industries, natural sources, and miscellaneous. Figure 2-7 shows the percentage contribution from the remaining 9 Tier 1 categories. The "all other" grouping includes chemical and allied product manufacturing, other industrial processes, and fuel combustion (electric utility and industrial).

#### 2.2.7 What Sources Are the Main Contributors to 1998 NH<sub>3</sub> Emissions?

Figure 2-8 is a pie chart showing  $1998 \text{ NH}_3$  emissions by source category. As the figure shows, livestock agriculture contributes the largest amount of NH<sub>3</sub> emissions. Livestock agriculture and fertilizer application combined comprise 86

percent of total national  $NH_3$  emissions in 1998. Currently, the USDA and EPA are working to refine the  $NH_3$  inventory for all source categories, including some natural and biogenic categories that are not in the current inventory. As mentioned above (section 2.2.5),  $NH_3$  is involved in the formation of ammonium sulfate and ammonium nitrate particles. The  $NH_3$  inventory is important to perform modeling simulations to understand the formation of these particles in the atmosphere using transport and transformation models.

#### 2.3 HOW DOES EPA ESTIMATE AND REPORT SPATIAL EMISSIONS?

EPA estimates emissions at the county level and then sums them to the state level for all criteria pollutants except Pb and for all source categories except fugitive dust sources and wildfires (whose emissions are estimated at the State level and are allocated to the county level using spatial surrogates). Figures 2-9 through 2-15 present the broad geographic distributions of 1998 emissions based on each county's tonnage per square mile. Specifically,

- Figure 2-9 shows that (on an emission density basis) the eastern third of the United States and the west coast emit more CO than the western two-thirds of the continental United States.
- Figures 2-10 through 2-12 show that the eastern half of the United States and the west coast emit more NO<sub>x</sub>, VOC, and SO<sub>2</sub> than the western half of the continental United States.
- Fugitive dust emissions, which predominate in rural and agricultural areas, comprise the major component of PM<sub>10</sub> and PM<sub>2.5</sub> emissions. NH<sub>3</sub> emissions follow a similar pattern, although they are primarily associated with agricultural and fertilizer sources rather than fugitive dust.

### 2.3.1 How Does My State Compare in Rank to Other States?

To understand how a particular State ranks relative to magnitude of emissions, refer to Table 2-2, which presents the total state-level emissions and state rankings for all pollutants.

- EPA summed the county-level emissions to produce the state-level emissions.
- The estimates for Alaska and Hawaii include only on-road vehicle, point source, residential wood combustion, and wildfire emissions. PM<sub>10</sub> and PM<sub>2.5</sub> estimates also include some fugitive dust estimates for Alaska and Hawaii. (A base year inventory similar to National Acid Precipitation Assessment Program (NAPAP) was not available for these states.)

### 2.4 WHAT ARE THE LARGEST POINT SOURCES IN THE INVENTORY?

Refer to Table 2-1 to understand which categories contain the largest amount of point sources. Historically, steel mills, smelters, utility plants, and petroleum refining produce the largest point source emissions. We usually provide point source top 50 lists in this report; however, this year new periodic emission inventory (PEI) point source data was received and was still being quality assured at press time. Once the State data is deemed accurate, EPA intends to post top 50 lists by pollutant on EPA's Emission Factor and Inventory Group's (EFIG) web site (expected later in 2000). The internet address for the EFIG is: http://www.epa.gov/ttn/chief/

Note(s): The sums of States may not equal National totals due to rounding.

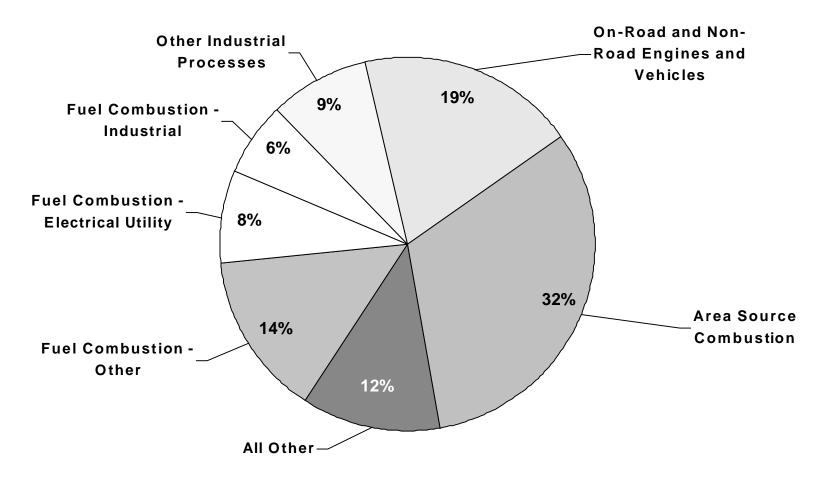

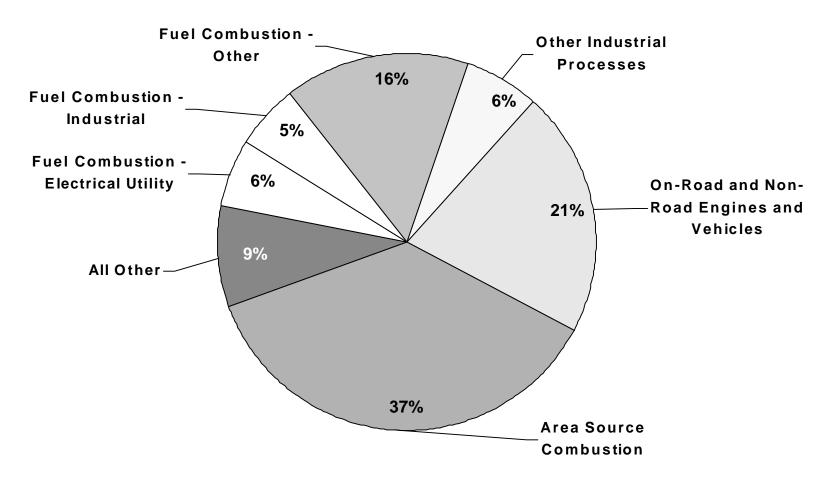

### Figure 2-5. 1998 Directly Emitted National PARTICULATE MATTER (PM<sub>10</sub>) Emissions by Principal Source Categories for Nonfugitive Dust Sources

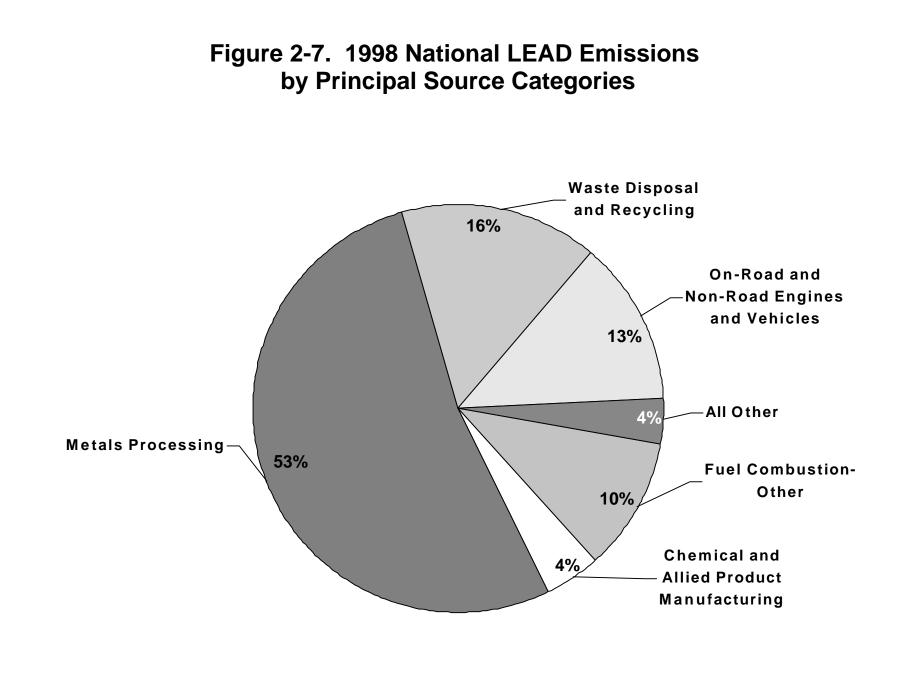

For a complete understanding of PM<sub>2.5</sub> emissions, one should also consider the emissions of SO<sub>2</sub>, NO<sub>x</sub>, and NH<sub>3</sub>. These gases react in the atmosphere to form ammonium sulfate and ammonium nitrate fine particles; also, some organic particles are formed from VOCs. These "secondary" fine particles (in contrast to the directly emitted particles from combustion and fugitive dust) can comprise as much as half the PM<sub>2.5</sub> measured in the United States.<sup>7</sup> Source apportionment studies exist to help elucidate the role of primary PM (reflected in the NET) and secondary PM. Note that emissions from fugitive dust sources are not included in the figure.

## National Emissions Trends, 1900 to 1998

#### 3.1 WHAT DATA ARE PRESENTED IN THIS CHAPTER?

This chapter presents historical trends in air pollutant emissions [carbon monoxide (CO), nitrogen oxides (NO<sub>x</sub>), volatile organic compounds (VOCs), sulfur dioxide (SO<sub>2</sub>), particulate matter less than 10 microns (PM<sub>10</sub>), particulate matter less than 2.5 microns (PM<sub>2.5</sub>), and lead (Pb). Although not a criteria pollutant, emission estimates for ammonia (NH<sub>3</sub>)] for the period 1900 through 1998 (where available). The source categories discussed in this chapter include: fuel combustion, industrial processes (chemical and allied products, metals processing, petroleum and related industries, other industrial processes, solvent utilization, storage and transport, and waste disposal and recycling), on-road vehicles, non-road engines and vehicles, and miscellaneous. This chapter also describes the effects that national economic activity and regulatory efforts have had on air pollutant emissions trends.

In this chapter, values representing changing emissions or the percentage change in emissions over various time periods are presented. It is important for the reader to realize that all values are estimates only and possess a large degree of uncertainty. Uncertainty analyses are ongoing at the United States (U.S.) Environmental Protection Agency (EPA) and will be reported in the FY2001 report.

#### 3.2 WHEN DID AIR POLLUTION CONTROL EFFORTS BEGIN AND HOW HAVE THEY EVOLVED?

In 1881, the cities of Chicago and Cincinnati, in an effort to control smoke and soot primarily from furnaces and locomotives, passed the first air pollution statutes in the United States. By the early 1900s, county governments began to pass their own pollution control laws. In 1952, Oregon became the first state to legislatively control air pollution, and other states soon followed, enacting air pollution statutes generally aimed at controlling smoke and particulates.

The Federal Government became involved in air pollution control in 1955 with the passage of the Air Pollution Control Act. This law limited Federal involvement in air pollution control to providing funding assistance for the States' air pollution research and training efforts. The shift by the Federal Government toward greater involvement in air pollution control began with the passage of the original Clean Air Act (CAA) in 1963. This act provided permanent Federal support for air pollution research, continued and increased Federal assistance to states for developing their air pollution control agencies, and a mechanism through which the Federal Government could assist states with cross-boundary air pollution problems. In 1965, Congress amended the CAA for the first time, directing the Secretary of Health, Education, and Welfare to set the first Federal emissions standards for motor vehicles.

In 1967, Congress passed the Air Quality Act, which required that states establish air quality control regions and that Health, Education, and Welfare, through the National Air Pollution Control Administration, conduct research on the effects of air pollution, operate a monitoring network, and promulgate criteria to serve as the basis for setting emission standards. States would then use the HEW information to set air quality standards. In addition, the Air Quality Act directed HEW to identify control technologies for states to use to attain the air quality standards that each state was to have established.

Several problems undermined this early period of federal air pollution control. The HEW belatedly issued guidance documents detailing the adverse health effects associated with common air pollutants; where guidance documents had been prepared, states either failed to set air quality standards or failed to develop implementation plans in a timely manner. In addition, the initial exhaust emission standards set by HEW in 1968 resulted only in relatively small reductions in automobile pollutants.

1970 marked the beginning of several major changes to federal air pollution control efforts. First, the Federal Government created a new federal agency, the EPA, on December 2, 1970, and charged it with the responsibility of setting National Ambient Air Quality Standards (NAAQS). Second, EPA was given the authority to develop national emissions standards for cars, trucks, and buses. Finally, Congress gave EPA the power to set emissions performance standards [known as new source performance standards (NSPS)] for all new sources of the common air pollutants. Under the CAA, the only major responsibility that states retained was that of determining how to control existing sources.

In response to its mandate, the EPA promulgated primary and secondary NAAQS in 1971 for photochemical oxidants, SO<sub>2</sub>, total suspended particulate (TSP), CO, and hydrocarbons. To comply with each of the NAAQS by a 1975 deadline, states had to develop and implement State Implementation Plans (SIPs) that would demonstrate how existing sources would be controlled. In 1977, Congress made additional modifications to the CAA, laying the groundwork for more significant changes to occur with the passage of the CAA Amendments (CAAA).

The photochemical oxidants standard formulated by EPA in 1971 set an hourly average level that was not to be exceeded more than once per year. In 1979, EPA changed the chemical designation of the NAAQS from photochemical oxidants to ozone ( $O_3$ ). In 1979, EPA revised the  $O_3$  standard from 0.08 parts per million (ppm) of  $O_3$  to 0.12 ppm of  $O_3$ measured over a 1-hour period, not to be exceeded more than three times in a 3-year period. In July 1997, EPA once again revised the  $O_3$  standard, returning it to 0.08 ppm of  $O_3$  but measured over an 8-hour period, where a formal exceedance was triggered by the fourth highest concentration over a 3-year period. The District of Columbia Circuit Court remanded this revision in May of 1999, placing the status of the new 8-hour  $O_3$  NAAQS in question.

The regulatory discussion in this report is not comprehensive; instead, it emphasizes some of the regulatory efforts that have targeted the major source categories for each air pollutant. An example is the national Acid Rain Program authorized by Title IV of the 1990 CAAA. The initial phase of its innovative market-based SO<sub>2</sub> reduction program began in 1995 and, during the first year of compliance, utilities cut SO<sub>2</sub> emissions from their Phase I (Table A) units by approximately 40 percent. Phase I of the Acid Rain NO<sub>x</sub> reduction program, a more conventional rate-based control program for coal-fired utility boilers, began in 1996 and contributed to the general decline in NO<sub>x</sub> emissions in the late 1990s.

However, the lack of detail available for all of the data precludes the possibility of analyzing some of the stationary source control measures [for example, state-specific regulations such as reasonably available control technology (RACT) provisions]. As a point of reference, Figure 3-1 presents the trends in gross domestic product (GDP), population, vehicle miles traveled (VMT), and total fuel consumption (that is, total fuel consumed by industrial, residential, commercial, and transportation sectors) from 1970 to 1998.

In the fall of 1998, EPA issued a new regulation requiring 22 states and the District of Columbia to submit SIPs to diminish the regional transport of ground-level  $O_3$  through reductions in NO<sub>x</sub>. This regulation is commonly known as the NO<sub>x</sub> SIP call. By reducing NO<sub>x</sub> emissions, this rule aims to reduce the transport of ground-level ozone across state

boundaries in the eastern half of the United States. The rule requires  $NO_x$  emission reduction measures to be in place by May 1, 2003. While EPA does not mandate which sources must reduce pollution, EPA expects utilities and large non-utility point sources to be the most likely sources of  $NO_x$  emissions reductions. The rule also establishes a  $NO_x$  Budget Trading Program which should enable states to achieve over 90 percent of the required emissions reductions in a highly cost-effective manner. EPA projects that full implementation of the  $NO_x$  SIP call would reduce  $NO_x$  emissions in the eastern United States by 25 percent, or approximately 1.142 million tons, beginning in the year 2003. Timing is uncertain due to litigation.

#### 3.3 WHAT ARE THE GENERAL HISTORICAL EMISSIONS TRENDS?

Tables 3-1 through 3-8 present emissions trends for the period 1940 through 1998 for CO, NO<sub>x</sub>, VOC, SO<sub>2</sub>, PM<sub>10</sub>, PM<sub>25</sub>, Pb, and NH<sub>3</sub>. Appendix Tables A-1 through A-7 present detailed emissions for the years 1970 through 1998, "where available." CO, VOC, SO<sub>2</sub>, and Pb emissions peaked in or around 1970, with a general downward trend during the 1970 to 1998 time frame. PM<sub>10</sub> emission levels peaked around 1950, steadily declined until the mid-1980s, and since then have remained relatively stable. NO<sub>x</sub> emissions steadily increased through the mid-1970s to 24.4 million tons in 1980, declined slightly during the early 1980s, and then climbed again, exceeding 25 million tons in 1994. Total NO<sub>x</sub> emissions have since declined slightly. From 1990 to 1998, NH<sub>3</sub> emissions rose by 14 percent, while PM<sub>2.5</sub> emissions remained relatively stable. Figures 3-2 through 3-9 depict emission estimates for each source category from 1940 to 1998 (where available).

#### 3.3.1 How Have CO Emissions Changed?

Table 3.1 shows historical trends in CO emissions by principal source categories. Total CO emissions peaked in 1970 and decreased rather steadily thereafter. A significant decrease in CO emissions occurred between 1973 and 1975 as a result of disruptions in world oil markets and a subsequent recession in the United States. (NO<sub>x</sub> and VOC emissions trends also showed similar short-term decreases from 1973 to 1975 for the same reasons.) The fluctuations of CO emissions in the late 1980s is due to the variation in wildfire activity from year-to-year.

## **3.3.2** How Have NO<sub>x</sub> and VOC Emissions Changed?

This report often considers  $NO_x$  and VOC together because they comprise the principal components in the chemical and physical atmospheric reactions that form  $O_3$  and other photochemical oxidants. Although an ambient air quality standard does not exist for VOC, VOC emissions are an important category from the standpoint of modeling  $O_3$ formation.

With regard to  $NO_x$ , total national emissions increased 233 percent between 1940 and 1998. Changes in emissions over this time period are shown in Table 3-2. From 1970 to 1997,  $NO_x$  emissions increased by approximately 19 percent, followed by a slight decline in 1998.

Table 3-3 presents the trend in VOC emissions from 1940 through 1998. Total national VOC emissions rose significantly from 1940 to 1970, but then declined almost as significantly from 1970 to 1998. In fact, 1998 levels exceed 1940 VOC emission levels by less than one million tons.

When calculating VOC emissions, EPA includes those emissions of VOC species that primarily contribute to the formation of  $O_3$  in total VOC emissions but excludes emissions of methane (CH<sub>4</sub>), a nonreactive compound. EPA makes no adjustments to include chlorofluorocarbons (CFCs) or to exclude ethane and other VOCs with negligible photochemical reactivity, and it estimates on-road vehicle emissions as nonmethane hydrocarbons. Chapter 6 discusses emissions of organic compounds from biogenic sources such as trees and other vegetation. According to recent research, natural sources emit almost the same level of VOC emissions as anthropogenic sources, but the extent to which biogenic VOC emissions contribute to oxidant formation has not been determined.

#### 3.3.3 How Have SO<sub>2</sub> Emissions Changed?

Table 3-4 presents the trend in  $SO_2$  emissions between 1940 and 1998. National  $SO_2$  emissions rose 56 percent from 1940 to 1970 and have since declined, primarily because of regulatory actions, especially those that targeted utility sources.

#### 3.3.4 How Have PM<sub>10</sub> Emissions Changed?

Table 3-5 presents the 1940 to 1998 trend in  $PM_{10}$  emissions. EPA divides  $PM_{10}$  sources into two categories: fugitive dust sources and nonfugitive dust sources.  $PM_{10}$  fugitive dust sources include natural sources (geogenic - wind erosion) and some miscellaneous sources. These miscellaneous sources include agriculture and forestry fugitive dust sources. The  $PM_{10}$  nonfugitive dust sources include all other  $PM_{10}$  sources. For 1998, EPA estimates that total national fugitive dust  $PM_{10}$  emissions are approximately 8

times greater than total emissions from nonfugitive dust sources. Since 1990, emissions from fugitive dust sources have increased slightly, primarily as the result of increases in unpaved road and construction emissions.

#### 3.3.5 How Have PM<sub>2.5</sub> Emissions Changed?

This most recent Trends report includes data on  $PM_{2.5}$ emission trends since 1990. EPA originally developed emissions estimates for  $PM_{2.5}$  under the National Particulate Inventory (NPI). This study consisted of a 1990 air emissions inventory for the United States (excluding Alaska and Hawaii), Canada, and Mexico. For the 1998 Trends report, EPA uses State particulate data where available to develop  $PM_{2.5}$  estimates. As can be seen in Table 3-6, overall  $PM_{2.5}$  emissions remain relatively constant from 1990 to 1998, while emissions from residential wood combustion decline significantly and emissions from natural sources fluctuate.

#### 3.3.6 How Have Pb Emissions Changed?

Table 3-7 provides data on Pb emissions from 1970 through 1998. The promulgation of a national ambient air quality standard for Pb in October 1978 has been the primary force behind the dramatic decrease in Pb emissions from 220,869 tons in 1970 to 3,973 tons in 1998.

#### 3.3.7 How Have NH<sub>3</sub> Emissions Changed?

This Trends report also includes data on  $NH_3$  emission trends since 1990. Table 3-8 presents the emissions data for  $NH_3$  since 1990. Fuel combustion-industrial, on-road vehicles, and miscellaneous sources saw the greatest growth in emissions during the 1990s, while chemical and allied product manufacturing and petroleum and related industries saw the greatest declines in emissions during that same period.

#### 3.4 HOW HAVE EMISSIONS IN THE MAJOR SOURCE CATEGORIES CHANGED?

This section discusses the trends in emissions from a source category perspective rather than a pollutant perspective. While each pollutant is discussed relative to the source category being considered, the main emphasis is on the changes that have occurred in that source category. In addition, this section occasionally discusses long term trends in emissions. As a point of reference, Table 3-13 presents total national (but not source category specific) emission estimates for each pollutant for each year available from 1900 to 1998.

#### 3.4.1 How Have Emissions in the Stationary Source Fuel Combustion Categories Changed?

The three stationary source fuel combustion categories are fuel combustion - electric utility, fuel combustion - industrial, and fuel combustion - other. Fuel combustion - other includes commercial/institutional coal, commercial/institutional oil, commercial/institutional gas, miscellaneous fuel combustion (except residential), residential wood and residential other. Figures 3-2 through 3-9, present trends in CO,  $NO_x$ , VOC, PM,  $PM_{2.5}$ , Pb, and  $NH_3$  emissions from fuel combustion sources from as early as 1940 in most cases, to 1998.

Emissions of SO<sub>2</sub> from fuel combustion sources peaked in 1973, declined sharply in the mid 1990s, but are rising again. NO<sub>x</sub> emissions from fuel combustion sources peaked a few years later, in 1977, and remained approximately constant at their peak level through the mid 1990s. Meanwhile, VOC and PM<sub>10</sub> emissions declined steadily from 1940 until the early 1970s. Emissions then rose, but declined again in the late 1980s. Pb emissions peaked in 1972 and have since declined significantly. Although overall CO emissions declined steadily from 1940 until 1970, they reversed trend after 1970, peaking at 8 million tons in 1985. PM<sub>2.5</sub> emissions have declined overall between 1990 and 1998. While NH<sub>3</sub> emissions from fuel combustion sources rose slightly since 1990, fuel combustion contributed less than 2 percent to national total NH<sub>3</sub> emissions throughout the 1990s.

Historically, residential wood contributes the largest quantity of fuel combustion CO and VOC emissions. Therefore, despite a gradual increase in CO and VOC emissions from electric utilities and industrial sources since 1940, the more substantial decline in emissions from residential wood consumption since 1985 accounts for the overall decline from the fuel combustion category since 1985. CO and VOC emissions from the fuel combustion category accounted for 16 and 12 percent of total national CO and VOC emissions in 1940 but only 6 and 5 percent in 1998.

In 1900, emissions from all fuel combustion sources represented 68 percent of total national VOC emissions, with residential wood combustion accounting for 90 percent of those emissions. From 1940 to 1970, residential wood consumption declined steadily as a result of the abundant supply, low relative prices, and convenience of fossil fuels relative to wood for home heating, cooking, and heating water. This decline halted in the early 1970s because disruptions in crude oil deliveries and related product markets caused prices for fossil fuel products to rise. These higher prices led to a resurgence in the use of wood for home heating and thus to a corresponding increase in emissions from residential wood combustion. By 1980, though, prices of fossil fuel products once again began to decline. As a result, residential wood consumption once again declined, as did the corresponding CO and VOC emissions.

With regard to  $NO_x$ , electric utilities contribute the largest percentage of  $NO_x$  emissions from the stationary source fuel combustion categories. In 1900, electric utilities accounted for 4 percent of total national 1998  $NO_x$  emissions, but by 1998 they accounted for 25 percent of total national  $NO_x$ emissions. Coal accounted for 88 percent of the electric utility  $NO_x$  emissions in 1998.

Fuel combustion-industrial contributes approximately 12 percent of total national 1998  $NO_x$  emissions. While emissions from this source have generally declined since 1970, they rose slightly from 1992 to 1996 (see Appendix Table A-2). Meanwhile,  $NO_x$  emissions from fuel combustion - other generally increased since 1940, although a small decline has occurred since 1992. Fuel combustion - other contributed less than 5 percent of total national  $NO_x$  emissions in 1998.

As with NO<sub>x</sub> emissions, electric utilities contributed 4 percent of total national  $SO_2$  emissions in 1900. These emissions increased by a factor of 5 over the period 1900 to 1925, but the onset of the Great Depression put a halt to the growth in these emissions during the 1930s. As the United States recovered from the Depression, emissions from electric utilities once again rose. By 1940, SO<sub>2</sub> emissions levels approximated pre-1930 levels. From 1940 to 1970, SO<sub>2</sub> emissions from electric utilities doubled every decade as a result of increased coal consumption. By 1970, emissions from coal combustion accounted for more than 90 percent of total  $SO_2$  emissions from electric utilities. With the help of regulatory controls, SO<sub>2</sub> emissions from electric utilities using all types of energy sources decreased approximately 38 percent from 1970 to 1996 (see Table A-4). Despite this decrease, electric utilities still accounted for 67 percent of the total national SO<sub>2</sub> emissions in 1998.

In 1940,  $PM_{10}$  emissions from fuel combustion represented approximately 31 percent of nonfugitive dust  $PM_{10}$  emissions. Electric utility  $PM_{10}$  emissions derive primarily from the combustion of coal. Emissions from this electric utilities increased by approximately 85 percent between 1940 and 1970, which corresponds to an increase in electric production using coal as an energy source during the same time period. Fuel combustion  $PM_{10}$  emissions have since declined from 1970 levels. In terms of  $PM_{2.5}$ , overall fuel combustion emissions remained fairly steady from 1990 through 1998. Fuel combustion sources contributed 9 percent of total national 1998  $PM_{2.5}$  emissions

Fuel combustion sources accounted for 5 percent of total national Pb emissions in 1970. Despite a 95 percent decline since 1970, fuel combustion sources still accounted for 13 percent of total national Pb emissions in 1998. Fuel combustion's contribution to total  $NH_3$  emissions remained less than 2 percent throughout the 1990 to 1998 time frame.

The overall decline in emissions from fuel combustion sources since the 1970s can be attributed to various regulatory actions. As mentioned previously,  $SO_2$  emissions from electric utilities using all types of energy sources decreased produced. Most new plants chose to meet this NSPS by shifting to lower-sulfur coals. An amendment to the CAA in 1977 effectively required any new coal-fired power plant not only to meet the original NSPS, but also to use some form of scrubbing equipment, even when using low-sulfur coal. Beginning in December 1976, a NSPS for new, modified, or reconstructed fossil-fuel-fired steam generators became effective, further promoting reductions in fuel combustion emissions. To help reduce PM emissions, EPA promulgated a TSP NAAQS in 1971. In 1987, EPA revised the TSP standard to include only PM<sub>10</sub>.

As a result of EPA's regulations,  $SO_2$  and  $PM_{10}$  emissions from coal-fired electric power facilities fell by 8 and 85 percent, respectively, between 1970 and 1993, despite the fact that consumption of coal to produce electricity increased 150 percent during that same period.<sup>2</sup>

Title IV (Acid Deposition Control) of the CAAA is an important factor in the decline in SO<sub>2</sub> emissions from fuel combustion sources and has contributed to the general decline of NO<sub>x</sub> emissions. Title IV specifies that annual SO<sub>2</sub> emissions must decrease by 10 million tons from 1980 emissions levels and suggests, as a guideline, that annual NO<sub>x</sub> emissions be reduced by 2 million tons from 1980 levels. Title IV defines two stages by which SO<sub>2</sub> reductions must occur. Phase I, which affects 263 mostly coal-fired units, began January 1, 1995. Phase II, which applies to the remaining affected Title IV units, began January 1, 2000. To achieve these reductions in a cost effective manner, utilities may choose from among a variety of possibilities, including participating in a market-based allowance trading system.<sup>3</sup>

Many utilities switched to low sulfur coal and some installed flue gas desulfurization equipment (also known as scrubbers) for their Phase I units, thereby achieving reductions in SO<sub>2</sub> emissions greater than those required under Title IV. These changes enabled utilities to reduce SO<sub>2</sub> emissions from their Phase I units from 7.4 million tons in 1994 to 4.5 million tons in 1995, the first year of compliance.

## **3.4.2** How Have Emissions in the Industrial Process Categories Changed?

Industrial processes include the following Tier 1 categories: chemical and allied products; metals processing; petroleum and related industries; other industrial processes; solvent utilization; storage and transport; and waste disposal and recycling.

 $\dot{CO}$ ,  $\dot{NO_x}$ , and VOC emissions from industrial processes peaked in 1950, 1960, and 1980, respectively. Industrial processes accounted for 12 percent of total national CO emissions in 1940 and 13 percent in 1970, but only 5 percent of total national CO emissions in 1998. With regard to  $NO_x$ emissions, industrial processes historically account for only a small percentage of the national total. Industrial processes accounted for an increasing share of national VOC emissions between 1900 and 1970. Although VOC emissions from industrial process sources declined by 41 percent from 1970 to 1998, they still account for 47 percent of total national VOC emissions. Emission control devices and process changes contributed to the decline in actual VOC emissions since 1970.

CO emissions from petroleum and related industries increased by a factor of 10 between 1940 and 1970 due to increases in refinery throughput and in demand for refined petroleum products. Since 1970, CO emissions from the petroleum refining industry have decreased by 83 percent due to the installation of emission control devices such as fluid catalytic cracking units and the retirement of obsolete high polluting processes such as the manufacture of carbon black by channel process. By 1998, petroleum refining accounted for less than 1 percent of total national CO emissions.

As mentioned previously, industrial processes account for only a small percentage of the national total NO<sub>x</sub> emissions. Within the industrial process category, though, waste disposal and recycling contributed the highest percentage of NO<sub>x</sub> emissions from 1940 to 1970. NO<sub>x</sub> emissions from the waste disposal and recycling category increased by 300 percent from 1940 to 1970, but then decreased by 78 percent from 1970 to 1998 to less than 1940 levels. After 1970, the other industrial processes category surpassed waste disposal and recycling as the biggest contributor of industrial process NO<sub>x</sub> emissions. The 34 percent increase in NO<sub>x</sub> emissions from industrial processes from 1980 to 1998 occurred partly because of a change in the methodology used to estimate emissions between 1984 and 1985.

Emissions of VOCs from petroleum and related industries and petroleum product storage and marketing operations increased during the mid-1970s as a result of increased demand for petroleum products, especially motor gasoline. After 1980, the emissions from these sources decreased as the result of product reformulation and the implementation of pollutant control measures.

Industrial process  $SO_2$  emissions peaked in 1970, when they contributed approximately 23 percent of the total national  $SO_2$  emissions. From 1970 to 1998, emissions decreased by 79 percent, and by 1998 industrial processes only contributed 8 percent of the national total  $SO_2$  emissions.

A major reason for the decline in industrial process  $SO_2$ emissions since 1970 comes from the decline in metals processing emissions. Although  $SO_2$  emissions from metals processing increased by 44 percent over the period 1940 to 1970, they decreased by almost 91 percent from 1970 through 1998 due to the increased use of emission control devices. By 1998, metals processing accounted for approximately 2 percent of total national  $SO_2$  emissions in 1998, down from 15 percent in 1970. In addition,  $SO_2$  emissions from nonferrous smelters have fallen significantly. By-product recovery of sulfuric acid at these smelters has increased since 1970, resulting in the recovered sulfuric acid not being emitted as  $SO_2$ .

Historically, copper processing contributed the largest percentage of metals processing  $SO_2$  emissions. To control copper processing  $SO_2$  emissions, EPA issued a NSPS to regulate  $SO_2$  emissions from copper smelters built, modified, or reconstructed after October 16, 1974. As a result,  $SO_2$  emissions from copper production facilities declined almost 97 percent between 1970 and 1998, even though copper production only declined by 15 percent during the time period (1970 to 1993).<sup>4</sup>

Emissions of  $SO_2$  from chemical and allied manufacturing, petroleum and related industries, and other industrial processes accounted for 4 percent of total  $SO_2$ emissions in 1940 and 7 percent in 1970. Since 1970,  $SO_2$ emissions from these sources have declined by 56 percent. The NSPS issued for sulfuric acid manufacturing plants built, modified, or reconstructed after 1972 is one major factor contributing to this decline.

 $PM_{10}$  emissions from industrial processes increased from 1940 to 1960, primarily as a result of increased industrial production. From 1960 to 1970, industrial output continued to grow, but  $PM_{10}$  emissions began to decline due to the installation of pollution control equipment mandated by state and local air pollution control programs. This decline was very slight, though, because the rise in emissions due to production increases more than offset the decline in emissions caused by the control devices.

In 1970, industrial processes contributed 66 percent of total national nonfugitive dust source  $PM_{10}$  emissions. By 1998, this contribution had decreased to 26 percent, reflecting the significant progress achieved in reducing emissions from industrial processes.

 $PM_{2.5}$  emissions from industrial processes have remained fairly steady throughout the 1990s, although emissions from all industrial process categories declined slightly between 1995 and 1998.

In 1970, the industrial process group's Pb emissions were 13 percent of almost 221 thousand tons, nationally. Seventyeight percent of this national total came from the on-road vehicles category which, by 1998 had been reduced to a mere 19 tons per year. Thus, while industrial process emissions of Pb have been reduced by 90 percent by 1998, they now represent 74 percent of the more dramatically reduced national total of less than 4 thousand tons per year.

Similar to  $PM_{2.5}$  emissions, emissions of  $NH_3$  from industrial process remained fairly steady throughout the 1990s. Emissions from all industrial process categories except other industrial processes declined slightly between 1995 and 1998.

## 3.4.3 How Have Emissions in the On-road Vehicle Categories Changed?

Historically, on-road vehicles have contributed significant amounts to national CO,  $NO_x$ , VOC, PM (if only nonfugitive dust emissions are considered), and Pb emissions levels but only small amounts to national SO<sub>2</sub> emission levels. The increasing popularity of motorized vehicles during the first half of the 20<sup>th</sup> century led to a corresponding increase in emissions from these vehicles.

Motorized vehicles became so popular that by 1970, onroad vehicles accounted for 35 percent of total NO<sub>x</sub> emissions, 68 percent of total CO emissions, 42 percent of total VOC emissions, and 78 percent of total Pb emissions.

In an effort to control rising emissions levels, in the early 1970s EPA developed CO, NO, and VOC emission limits for on-road vehicles. Table 3-9 lists the CO emission standards, expressed in grams per mile (gpm), for light-duty vehicles (LDV) and light-duty trucks (LDT). Table 3-10 and Table 3-11 list the NO<sub>x</sub> and VOC emissions limits for LDVs and LDTs, respectively. In addition to these limits, LDTs greater than 6,000 pounds and heavy-duty trucks must also meet NO<sub>x</sub> emissions standards. The Federal CO standards through 1975 applied only to gasoline-powered LDTs, whereas federal standards for 1976 and later applied to both gasoline and diesel-powered LDTs. In addition, EPA requires that 1984 and later model years meet a CO standard of 0.50 percent at idle (effective with the 1988 model year at higher altitudes). Similar to the NO<sub>x</sub> standards, other CO standards apply to LDTs more than 6,000 lbs, heavy-duty engines and vehicles, and non-road engines and vehicles.

With regard to additional CO emissions controls, the CAAA requires cars to meet a standard of 10 gpm at 20 degrees Fahrenheit, starting with the 1996 model year. This standard helps ensure that vehicular emission control devices work efficiently at low temperatures.

In general, the emission limits set by EPA resulted in significant decreases since 1970 in CO and VOC emitted by on-road vehicles. Since 1970, CO and VOC emissions from on-road vehicles have declined by almost 43 and 59 percent, respectively. NO<sub>x</sub> emissions from on-road vehicles peaked in the late 1970s but have declined slightly since then. Although NO<sub>x</sub> emissions levels from on-road vehicles are slightly higher than in 1970, VMT has more than doubled since 1970. The federal NO<sub>x</sub> emissions growth in check.

To achieve more significant  $NO_x$  emissions reductions, EPA issued new federal tailpipe emissions standards in December 1999 for passenger cars, light trucks, and larger passenger vehicles. These standards, known as Tier II standards, should help reduce air pollution. These standards will take effect beginning in 2004 and will apply to both cars and light-duty trucks, including sport utility vehicles (SUVs). Under the Tier II standards, affected vehicles must meet a 0.07 gpm standard for  $NO_x$ , which is a 77 percent reduction for cars and up to a 95 percent reduction for LDTs and SUVs. Vehicles weighing less than 6000 pounds will be phased-in to the new standard between 2004 and 2007. The heaviest LDTs will adopt a three-step approach, spanning from 2004 to 2009.

When it issued the Tier II standards, EPA also set new standards for sulfur levels in gasoline. Gasoline suppliers must meet an average sulfur level of 30 ppm by 2005, down from the current average of 300 ppm. The new sulfur levels will ensure the effectiveness of low emission-control technologies in vehicles. Auto makers and refiners will be allowed to meet these standards by averaging across the entire vehicle fleet and gasoline pool.

Pb emissions from on-road vehicles, which peaked in the early 1970s, have steadily decreased as the result of a series of regulatory actions that progressively reduced the Pb content of all gasoline. EPA mandates reduced the Pb content of gasoline dramatically, from an average of 1.0 gram per gallon (gpg) to 0.5 gpg on July 1, 1985, and still further to 0.1 gpg on January 1, 1986. In addition, as part of EPA's overall automotive emission control program, unleaded gasoline was introduced in 1975 for use in automobiles equipped with catalytic control devices, which help reduce CO, VOC, and NO<sub>x</sub> emissions. In 1975, unleaded gasoline's share of the total gasoline market totaled 13 percent. By 1982 this share had climbed to approximately 50 percent, and by 1996 (due to the CAAA prohibition on the use of leaded gasoline in highway vehicles after December 31, 1995) unleaded gasoline accounted for 100 percent of the total gasoline market.

Table A-6 (see Appendix A) shows that Pb emissions decreased dramatically between 1990 and 1991. This decrease is the result of large changes in the values for Pb in gasoline. Since the prohibition on Pb in gasoline did not officially begin until January 1, 1996, the reductions calculated for 1991 and later are primarily the result of limited data on trace Pb levels in gasoline for these years. Therefore, the full reduction that begins in 1991 may actually occur several years later.

Pb emissions from on-road vehicles have fallen significantly since the introduction of these regulations, and Pb emissions from on-road vehicles now account for less than 1 percent of national Pb emissions, down substantially from almost 82 percent of national emissions in 1980.

In an effort to reduce  $SO_2$  and PM (as sulfate particles) emissions from on-road vehicles, EPA published a regulation on August 21, 1990, that governs desulfurization of diesel motor fuel. This regulation states that as of October 1, 1993, all diesel fuel that contains a concentration of sulfur in excess of 0.05 percent by weight or that fails to meet a minimum cetane index of 40 cannot be used in motor vehicles.<sup>5</sup> Since implementation of these desulfurization regulations, EPA has found that  $SO_2$  emissions from diesel motor vehicles are reduced by approximately 75 percent.

In 1940, on-road vehicles accounted for just over 1 percent of nonfugitive dust  $PM_{10}$  emissions. Although the

1998 emissions from on-road vehicles represent 9 percent of the total national  $PM_{10}$  emissions from nonfugitive dust sources,  $PM_{10}$  emissions from on-road vehicles in1998 are approximately the same as those in 1940.

Absent regulation, it is reasonable to assume that a decrease in the price of gasoline will result in greater VMT, increased fuel use, and greater emissions, all other factors remaining unchanged. However, overall on-road vehicle emissions actually declined from 1970 to 1998, despite the fact that fuel use increased approximately 50 percent, VMT increased over 100 percent, and real gasoline prices decreased 17 percent during this same time period.<sup>1</sup> These trends indicate the success of regulations in reducing emissions from on-road vehicles.

#### 3.4.4 How Have Emissions in the Non-road Engines and Vehicle Categories Changed?

Unlike emissions trends for on-road vehicles, emissions of CO, NO<sub>x</sub>, and VOC from non-road engines and vehicles increased steadily from 1940 to 1996, with slight reductions in CO and VOC emissions over the past 2 years. SO<sub>2</sub> emissions declined by 97 percent from 1940 to 1970, but have since risen again, to about one third of 1940 levels. PM<sub>10</sub> emissions declined significantly from 1940 to 1960, rose slightly in the period from 1960 to 1990, and have declined slightly since 1990. PM<sub>2.5</sub> emissions have remained relatively level for the past 8 years. Pb emissions declined approximately 91 percent between 1970 and 1985, and they have continued to decline slightly since 1985. NH<sub>3</sub> emissions from non-road engines and vehicle over the past 9 years are quite negligible.

Non-road engines and vehicles contributed 9 percent of total national CO emissions in 1940, with emissions from railroad locomotives accounting for approximately 51 percent of this amount. CO emissions from non-road vehicles and engines have increased 90 percent from 1940 levels and now account for 22 percent of the national total, but now non-road gasoline equipment engines are the predominant sources of non-road CO emissions.

In 1900, non-road engines and vehicles accounted for 4 percent of total national VOC emissions, of which railroad emissions contributed 99 percent. Railroad VOC emissions peaked in 1920 at 20 percent of the national total and have decreased since then to less than 1 percent currently. Although railroad emissions decreased, emissions from non-road engines and vehicles increased 216 percent during the 1940 to 1998 period. As a result, emissions from non-road engines and vehicles as a percentage of the national total climbed from approximately 5 percent in 1940 to approximately 14 percent in 1998.

Similarly to on-road vehicle  $NO_x$  emissions trends, emissions from non-road engines and vehicles increased over the period from 1940 to 1998. To help slow this growth in emissions, EPA established emission control measures (Tier I standards) for new non-road diesel engines in certain horsepower categories. These standards began to take effect in 1996, with full phase-in for all horsepower categories scheduled for 2000. These controls should help reduce the amount of NO<sub>x</sub> emissions emitted by these sources.

In 1940, SO<sub>2</sub> and PM<sub>10</sub> emissions from non-road vehicles and engines both accounted for approximately 16 percent, respectively, of total national emissions for these two pollutants. Railroads contributed significantly to total 1940 SO<sub>2</sub> and PM<sub>10</sub> emissions. From 1940 to 1970, SO<sub>2</sub> and PM<sub>10</sub> emissions from railroads decreased by 99 percent as a result of the obsolescence of coal-fired locomotives. By 1998, nonroad engines and vehicles represented only 1 percent of the total 1998 national PM<sub>10</sub> emissions (16 percent of nonfugitive dust sources). While PM<sub>10</sub> emissions from non-road engines and vehicles declined, so did PM<sub>10</sub> emissions from most other nonfugitive dust sources.

#### 3.4.5 How Have Emissions in the Miscellaneous Categories Changed?

In 1940, CO emissions from "miscellaneous other combustion - forest wildfires" accounted for 27 percent of total national CO emissions. Although relatively erratic from year to year due to the uncontrolled nature of wildfires, wildfire CO emissions declined from 1940 levels to only 3 percent of total national CO emissions in 1998. Similarly, annual  $PM_{10}$  emissions from wildfires vary depending upon the incidence of wildfires and upon weather conditions in forested areas.

Miscellaneous source emissions accounted for 13 percent of the total 1940  $NO_x$  emissions. In 1998, the total emissions for the miscellaneous sources accounted for slightly more than 1 percent of national  $NO_x$  emissions.

In 1900, emissions from the miscellaneous sources category represented 24 percent of total VOC emissions. By 1998 they accounted for only 4 percent of national VOC emissions. With regard to  $SO_2$  emissions, miscellaneous sources accounted for less than 3 percent of total national  $SO_2$  emissions in 1940. By 1998, they contributed less than 0.1 percent of national  $SO_2$  emissions. Pb emissions from other/

miscellaneous sources account for a negligible amount of national Pb emissions. Meanwhile, miscellaneous emissions account for a substantial percentage of  $NH_3$  emissions. From 1990 to 1998, emissions from miscellaneous sources rose 13 percent, and they accounted for 86 percent of total national  $NH_3$  emissions in both 1990 and 1998.

#### 3.5 HOW HAVE EMISSIONS IN THE FUGITIVE DUST CATEGORIES CHANGED?

Fugitive dust source emission estimates were first presented in the *1991 Trends* report. At that time, EPA based its emission estimates upon old emission factors and limited data. The methods EPA used to produce the estimates relied on State-level default data for most source categories. In the 1997 Trends report, EPA revised the methods used to produce post-1989 estimates in order to reflect improved emission factors, improved activity data, or both.

For several source categories, the methodology for estimating fugitive dust emissions utilizes meteorological data such as the number of days with greater than 0.01 inches of precipitation and average monthly wind speed. These data can vary significantly from year-to-year, resulting in highly variable emissions.

 $PM_{10}$  and  $PM_{2.5}$  fugitive dust emissions can be determined from Tables 3-5 and 3-6 respectively. The categories that comprise the fugitive dust emission categories are identified in Chapter 1, section 1.4. As previously noted, estimates of  $PM_{10}$  fugitive dust prior to 1989 were based on crude methodologies and should be strongly discounted.  $PM_{10}$ emissions from fugitive dust sources decreased by 24 percent from 1985 to 1998 due primarily to the changes in emission methodologies for several of the fugitive dust sources, but also due to holding wind erosion constant from 1996 forward.

For 1998, EPA estimates total national fugitive dust  $PM_{10}$  and  $PM_{2.5}$  emissions to be approximately 8 and 2 times higher, respectively, than total national nonfugitive  $PM_{10}$  and  $PM_{2.5}$  emissions.

Note(s): NA = not available. For several source categories, emissions either prior to or beginning with 1985 are not available at the more detailed level but are contained in the more aggregate estimate. "Other" categories may contain emissions that could not be accurately allocated to specific source categories.

# Table 3-2. Total National Emissions of Nitrogen Oxides, 1940 through 1998(thousand short tons)

Note(s): NA = not available. For several source categories, emissions either prior to or beginning with 1985 are not available at the more detailed level but are contained in the more aggregate estimate. Zero values represent less than 500 short tons/year.

"Other" categories may contain emissions that could not be accurately allocated to specific source categories.

The 1985 fuel combustion, electric utility category is based on the National Allowance Data Base Version 2.11, Acid Rain Division, U.S. EPA, released March 23, 1993. Allocations at the Tier 3 levels are approximations only and are based on the methodology described in section 6.0, paragraph 6.2.1.1.

# Table 3-5. Total National Emissions of Directly Emitted Particulate Matter (PM10),1940 through 1998 (thousand short tons)

Note(s): NA = not available. For several source categories, emissions either prior to or beginning with 1985 are not available at the more detailed level but are contained in the more aggregate estimate. Zero values represent less than 500 short tons/year. Categories displayed below Tier 1 do not sum to Tier 1 totals because they are intended to show major contributors. In order to convert emissions to gigagrams (thousand metric tons), multiply the above values by 0.9072.

\* Although geogenic wind erosion emissions are included in this summary table, it is very difficult to interpret annual estimates of PM emissions from this source category in a meaningful way, owing to the highly episodic nature of the events that contribute to these emissions.

\*\* These are the main source categories of PM crustal material emissions. A report by the Desert Research Institute found that about 75% of these emissions are within 2 m of the ground at the point they are measured. Thus, most of them are likely to be removed or deposited within a few km of their release, depending on atmospheric turbulence, temperature, soil moisture, availability of horizontal and vertical surfaces for impaction and initial suspension energy. This is consistent with the generally small amount of crustal materials found on speciated ambient samples. (See reference 6 in Chapter 2.)

## Table 3-6. Total National Emissions of Directly Emitted Particulate Matter (PM2.5),1990 through 1998 (thousand short tons)

Note(s): NA = not available. Zero values represent less than 500 short tons/year.

Categories displayed below Tier 1 do not sum to Tier 1 totals because they are intended to show major contributors. In order to convert emissions to gigagrams (thousand metric tons), multiply the above values by 0.9072.

\* Although geogenic wind erosion emissions are included in this summary table, it is very difficult to interpret annual estimates of PM emissions from this source category in a meaningful way, owing to the highly episodic nature of the events that contribute to these emissions.

\* These are the main source categories of PM crustal material emissions. A report by the Desert Research Institute found that about 75% of these emissions are within 2 m of the ground at the point they are measured. Thus, most of them are likely to be removed or deposited within a few km of their release, depending on atmospheric turbulence, temperature, soil moisture, initial suspension energy and availability of horizontal and vertical surfaces for impaction. This is consistent with the generally small amount of crustal materials found on speciated ambient samples. (See reference 6 in Chapter 2.)

For a complete understanding of  $PM_{2.5}$  emissions, one should also consider the emissions of  $SO_2$ ,  $NO_x$ , and  $NH_3$ . These gases react in the atmosphere to form ammonium sulfate and ammonium nitrate fine particles; also, some organic particles are formed from VOCs. These "secondary" fine particles (in contrast to the directly emitted particles from combustion and fugitive dust) can comprise as much as half the  $PM_{2.5}$  measured in the United States.<sup>7</sup> Source apportionment studies exist to help elucidate the role of primary PM (reflected in the NET) and secondary PM.

Note(s): NA = not available. For several source categories, emissions either prior to or beginning with 1985 are not available at the more detailed level but are contained in the more aggregate estimate. Zero values represent less than 500 short tons/year. Categories displayed below Tier 1 do not sum to Tier 1 totals because they are intended to show major contributors. In order to convert emissions to gigagrams (thousand metric tons), multiply the above values by 0.9072.

#### Table 3-9. Carbon Monoxide Federal Emission Standards, 1970 to 1991

Note(s): <sup>1</sup> Standard applies for 1975-1978 model years.

<sup>2</sup> Certain vehicles were subject to a less stringent requirement of 7.0 grams per mile from model years 1980-1984.

<sup>3</sup> Standard applies for 1979-1983 model years.

<sup>4</sup> Standard applies for 1984-1991 model years.

The first vehicle standards were implemented by the Federal government in 1968 and were concentration based (ppm of exhaust for hydrocarbons and CO). The first mass based standards (g/mile) were in 1972.

## Table 3-10. Nitrogen Oxide and Volatile Organic Compound FederalEmission Limits for Light-Duty Vehicles, 1972 to 1991

| _                        | Emission Limit<br>(grams per mile)   |                  |  |  |  |
|--------------------------|--|------------------|--|--|--|
| Model Year               | NO <sub>x</sub>  | VOC <sup>1</sup> |  |  |  |
| 1972-1974                | 3.0 <sup>2</sup>   | 3.4              |  |  |  |
| 1975-1979                | 3.1 <sup>3</sup> , 2.0 <sup>4</sup>  | 1.5              |  |  |  |
| 1980-1991                | 1.0 <sup>5</sup>   | 0.41             |  |  |  |
| <sup>2</sup> Standard ap | chaust emission standards for Vo<br>blies for 1973-1974 model years.<br>blies for 1975-1976 model years. |                  |  |  |  |

Standard applies for 1975-1976 model years.
 Standard applies for 1977-1980 model years.

Standard applies for 1977-1980 model years.
 Standard applies for 1981-1991 model years.

The first vehicle standards were implemented by the Federal government in 1968 and were concentration based (ppm of exhaust for hydrocarbons and CO). The first mass based standards (g/mile) were in 1972.

# Table 3-11. Nitrogen Oxide and Volatile Organic Compound FederalEmission Limits for Light-Duty Trucks, 1972 to 1991

|            | Emission Limit<br>(grams per mile) |                  |  |  |  |
|------------|------------------------------------|------------------|--|--|--|
| Model Year | NO <sub>x</sub>                    | VOC <sup>1</sup> |  |  |  |
| 1972-1974  | 3.0 <sup>2</sup>                   | 3.4              |  |  |  |
| 1975-1978  | 3.1 <sup>3</sup>                   | 2.0              |  |  |  |
| 1979-1984  | 2.3 <sup>4</sup>                   | 1.7              |  |  |  |
| 1985-1991  | 1.2 <sup>5,6</sup>                 | 0.8              |  |  |  |

| Note(s): | 1 | These are exhaust emission standards for VOC.   |
|----------|---|---|
|          | 2 | Standard applies for 1973-1974 model years.   |
|          | 3 | Standard applies for 1975-1978 model years.   |
|          | 4 | Standard applies for 1979-1987 model years.   |
|          | 5 | Standard applies for 1988-1993 model years.   |
|          | 6 | Light-duty trucks with a loaded-vehicle weight more than 3,750 pounds are subject to a 1.7 grams per mile standard for these model years. |

The first vehicle standards were implemented by the Federal government in 1968 and were concentration based (ppm of exhaust for hydrocarbons and CO). The first mass based standards (g/mile) were in 1972.

Notes: <sup>1</sup> LDGT2: 11 years/120,000 miles

<sup>2</sup> Year Standard is 100 percent of vehicles affected

<sup>3</sup> Total hydrocarbons

<sup>4</sup> Nonmethane Hydrocarbon

<sup>5</sup> Any light light-duty truck up through 3,750 lbs loaded vehicle weight.

<sup>6</sup> Any light light-duty truck greater than 3,750 lbs loaded vehicle weight.

<sup>7</sup> Any heavy light-duty truck up through 5,750 lbs adjusted loaded vehicle weight.

<sup>8</sup> Any heavy light-duty truck greater than 5,750 lbs adjusted loaded vehicle weight.

The first vehicle standards were implemented by the Federal government in 1968 and were concentration based (ppm of exhaust for hydrocarbons and CO). The first mass based standards (g/mile) were in 1972.

### Chapter 4.0

### Section 406 of the Clean Air Act Amendments: Industrial SO<sub>2</sub> Emissions

This chapter discusses the impact of industrial sulfur dioxide  $(SO_2)$  emissions, the source categories comprising industrial emissions, base year emissions development, projected emissions methodology, long-term emission trends, and desulfurization of diesel fuel benefits.

#### 4.1 WHY A SEPARATE CHAPTER FOR INDUSTRIAL SO<sub>2</sub> EMISSIONS?

The major health effects associated with high exposures to  $SO_2$  in the ambient air include problems in breathing, respiratory illness, alterations in the lung's defenses, and aggravation of existing respiratory and cardiovascular disease. People most sensitive to  $SO_2$  include asthmatics and individuals with chronic lung disease (such as bronchitis or emphysema) or cardiovascular disease. Children and the elderly may also be sensitive.

 $SO_2$  also produces foliar damage on trees and agricultural crops.  $SO_2$  and nitrogen oxides ( $NO_x$ ) in the air cause acidic deposition, commonly known as acid rain. Acid rain is associated with a number of effects including acidification of lakes and streams, damage to high-elevation forests, and accelerated corrosion of buildings and monuments.  $SO_2$  and  $NO_x$  emissions also form sulfates and nitrates in the atmosphere that can significantly impair visibility.

This chapter provides information required under section 406 of the Clean Air Act Amendments (CAAA) of 1990 (42 U.S.C. 7651 note), which deals with  $SO_2$  emissions from industrial sources. Section 406(a) states that:

Not later than January 1, 1995 and every 5 years thereafter, the Administrator of the Environmental Protection Agency shall transmit to the Congress a report containing an inventory of national annual sulfur dioxide emissions from industrial sources (as defined in title IV of the Act), including units subject to section 405(g)(6) of the Clean Air Act, for all years for which data are available, as well as the likely trend in such emissions over the following 20year period. The reports shall also contain estimates of the actual emission reduction in each year resulting from promulgation of the diesel fuel desulfurization regulations under section 214.

As discussed below, the United States (U.S.) Environmental Protection Agency (EPA) intends this chapter to provide the information required in section 406(a).

### 4.1.1 What Source Categories Are Industrial Sources?

Several provisions of the CAA and the CAAA address what source categories are industrial sources. Section 402(24) of the CAA defines industrial sources. An industrial source is:

a unit that does not serve a generator that produces electricity, a "nonutility unit" as defined in this section, or a process source as defined in section 410(e).

Further, section 406(a) of the CAAA of 1990 states that "industrial sources" include units subject to section 405(g)(6) of the CAA. (EPA believes that the reference in section 406(b) to section 405(g)(5) is erroneous and reads if as referring to section 405(g)(6).) Section 405(g)(6) of the CAA excludes from the Acid Rain Program under Title IV of the CAA certain "qualifying small power production facilit[ies]," "qualifying cogeneration facilit[ies]," and "independent power production facilit[ies]."

In order to determine the scope of the term "industrial source," it is necessary to consider several other statutory and regulatory definitions and provisions. Section 402(15) of the CAA defines "unit" as a "fossil fuel-fired combustion device." Section 72.2 of the regulations implementing Title IV of the CAA defines "fossil-fuel fired" as combusting "fossil fuel or any derivative of fossil fuel alone or in combination with any other fuel, independent of the percentage of fossil fuel consumed in any calendar year." Section 402(17)(A) of the CAA provides that a "utility unit" is, with certain exceptions (e.g., for certain cogeneration units under section 402(17)(C)),

any unit that "serves a generator in any State that produces electricity for sale" or that, "during 1985, served a generator in any State that produced electricity for sale."

The categories of "industrial sources" referred to in section 406(a) of the CAAA of 1990 must be considered in light of these definitions and provisions. With regard to the category of "nonutility units," section 402(25) of the CAA defines a "nonutility unit" as "a unit other than a utility unit." This category comprises all stationary combustion devices that burn any fossil fuel and that are not affected units under the Acid Rain Program in Title IV of the CAA. Because the definition of this category excludes units that are utility units and, except for nonutility units that opt into the Acid Rain Program under section 410 of the CAA, only utility units are affected units, the category does not generally include any affected units.

For similar reasons, the next category of industrial sources, i.e., "units that do not serve a generator that produces electricity," excludes all utility units and thus generally excludes all affected units under the Acid Rain Program in Title IV of the CAA. However, there are some units that are not affected units under the Acid Rain Program (e.g., units in Alaska and Hawaii and certain cogeneration units under section 402(17)(C)) but that do serve a generator that produces electricity. Therefore, this category of industrial sources is smaller than the "nonutility unit" category and excludes some stationary fossil-fuel fired combustion devices that are not affected units.

Another category of industrial sources (i.e., "process sources") is not defined in Title IV of the CAA. Section 410(d) refers to "process sources" but does not define the term. For the purposes of this chapter, a process source is any source that emits  $SO_2$  as the result of a production or manufacturing process and not as the result of any type of fuel combustion.

The last category of industrial sources comprises units that are utility units but that are exempt from the Acid Rain Program under section 405(g)(6) of the CAA. This includes certain "qualifying small power production facilities" or "qualifying cogeneration facilities" under section 3(17)(C) or 3(18)(B) of the Federal Power Act and certain "independent power production facilities" under section 416(a)(2)(A), (B), and (D) of the CAA. These terms are defined in section 72.2 of the regulations implementing the Acid Rain Program.

Finally, for purposes of applying the 5.60 million ton annual cap for  $SO_2$  emissions from industrial sources, which is specified in section 406(b) of the CAAA of 1990, commercial/institutional/residential sources are excluded. This is because the 5.60 million ton cap was developed using emissions in the 1985 National Acid Precipitation Assessment Program NAPAP<sup>1</sup> inventory that cover sources involving industrial combustion and industrial/manufacturing processes and do not cover commercial/institutional/residential sources. Commercial/institutional/residential sources encompass combustion sources, such as those located at hospitals, universities, or residences, that are not related to the production of physical products.

In summary, industrial sources covered by the 5.60 million ton annual cap include: all stationary fossil-fuel fired combustion devices, except for affected utility units under the Acid Rain Program and except for commercial/institutional/ residential sources; and all process sources.

Table 4.1 presents the source categories defined as industrial sources.

#### 4.2 WHY USE 1996 AS THE BASE YEAR?

Section 406 of the CAAA of 1990 specifies a 5.60 million ton cap on SO<sub>2</sub> emissions from industrial sources. Congress derived the cap from industrial source emission estimates developed as part of the 1985 NAPAP inventory. The 1990 National Emission Trends inventory (now called the "NET inventory"), developed from the 1985 NAPAP inventory, served as the baseline for the previous industrial SO<sub>2</sub> emission projections presented in the report "National Annual Industrial Sulfur Dioxide Emission Trends, 1995-2015: Report to Congress."<sup>2</sup> Since that report, EPA, along with State and local agencies, revised the emission inventory for two separate time periods for different purposes. The most recent effort by EPA was the incorporation of 1996 Periodic Emission Inventories (PEI) into the NET inventory. (Refer to Section 5.6 for discussions on the PEI).

Since the 1996 NET inventory contains the most recent comprehensive emissions inventory, EPA chose it for the baseline for the industrial SO<sub>2</sub> emission estimates in this chapter. Table 4.2 presents the source of base year data for each of the 48 contiguous States. Thirty states provided 1996 point source emission inventories to the EPA, and 12 states provided acceptable 1996 area source emission inventories. The emissions for Oregon are from the Grand Canyon Visibility Transport Commission (GCVTC) 1990 inventory. The point source emissions for 7 other States and the area source emissions for 16 other States are estimated from the Ozone Transport Assessment Group (OTAG) 1990 inventory. The emission estimates for Alaska and Hawaii point sources are from multi-year Aerometric Information Retrieval System/ AIRS Facility Subsystem (AIRS/AFS) retrievals, and EPA has never sent these estimates to these States for review. EPA estimated the area source emissions for Alaska and Hawaii. The remaining emissions are from the 1985 NAPAP inventory.

For States that did not provide EPA with a 1996 complete inventory, EPA estimated their emissions for 1996 using Bureau of Economic Analysis (BEA) growth factors. EPA did not assume any new controls nor plant retirements for these sources. More details on the methodology to estimate 1985 to 1996 emissions can be found in the NET inventory procedures document.<sup>3</sup> Figure 4.1 presents the  $SO_2$  industrial source emissions by major source categories for the year 1996. Fuel combustion sources are the largest contributors to industrial  $SO_2$  emissions.

#### 4.3 HOW DID EPA PROJECT EMISSIONS?

In addition to a national inventory of  $SO_2$  emissions, section 406 of the CAAA of 1990 also calls for presentation of the likely trend in such emissions over the following 20-year period. Thus, Congress requires EPA to estimate future industrial source  $SO_2$  emissions under section 406. Although section 406 calls for development of the likely trend in emission for a 20-year period, EPA developed emission estimates from 1996 (the base year) to 2020 since 2020 represents 20 years from the completion date of this report.

EPA considered fuel switching, energy efficiency (the amount of energy saved from the use of more efficient processes through time), and economic growth in the development of these projections. In general, less fuel will be needed to provide the same amount of energy (in the form of steam) to an industrial process and the amount of energy needed per unit output will also decrease as processes become more efficient. Fuel switching and energy efficiency are reflected in energy correction factors based on information obtained from the U.S. Department of Energy (DOE) publication Annual Energy Outlook 1997. Economic growth factors were derived from the 1995 BEA Gross State Product (GSP) projections by 2-digit Standard Industrial Classification (SIC) code. These were applied to estimate changes in activity between 1996 and 2030.4 For the purposes of satisfying section 406 requirements, a value was needed on 3-year intervals through 2020. Therefore, projections were calculated by applying growth ratios among existing sources to their base year emissions (1996). Interpolated factors were then applied to these same categories to estimate the every 3-year trend.

Further analysis of the 20-year projection is currently underway at EPA and results will be reported in the next Trends Report (planned for January 2001 publication).

### 4.4 WHAT IS THE TREND IN INDUSTRIAL SO<sub>2</sub> EMISSIONS?

Figure 4.2 presents the estimated trends in industrial source  $SO_2$  emissions from 1900 to 2020. Table 4.3 presents the emissions by source category for every 3 years starting with 1996. The year 2007 is also displayed. The subcategories for solvent utilization and storage and transport are not displayed since these emissions are very small.

The emission estimates for the base year 1996 are 4.4 million short tons. The emission estimates show the industrial  $SO_2$  emissions increasing steadily with the 20-year rate at approximately 8 percent. Fuel combustion sources continue

to be the largest contributor to industrial  $SO_2$  emissions. The emission estimates show the fuel combustion emissions declining through the years, primarily from the result of energy efficiency factors. The largest increase in  $SO_2$  can be seen in chemical and allied manufacturing, which is projected to rise 30 percent in the 20-year period. Total industrial source  $SO_2$  emissions are currently projected to be approximately 4.7 million tons in 2020. Refer to Figure 4-3 for a graphical presentation of each category's 2020 contribution.

#### 4.4.1 Will the Cap Be Exceeded?

Section 406(b) of the CAAA of 1990 states:

Whenever the inventory required by this section indicates that sulfur dioxide emissions from industrial sources, including units subject to section 405(g)(6) of the [CAA], may reasonably be expected to reach levels greater than 5.60 million tons per year, the Administrator of the [EPA] shall take such actions under the [CAA] as may be appropriate to ensure that such emissions do not exceed 5.60 million tons per year. Such actions may include the promulgation of new and revised standards of performance for new sources, including units subject to section 405(g)(6) of the [CAA], under section 111(b) of the [CAA], as well as promulgation of standards of performance for existing sources, including units subject to section 405(g)(5) of the [CAA], under authority of this section.

(As noted above, the reference to section 405(g)(5) should be to section 405(g)(6).)

The current emission estimates indicate that emissions of  $SO_2$  from industrial sources will not exceed the 5.6 million tons per year cap through the year 2020. As stated earlier, more refinement of these estimates is ongoing and a revised projection will be released with the publication of the next Trends report.

### 4.5 WHAT ARE THE BENEFITS FROM DESULFURIZATION OF DIESEL FUELS?

Section 406(a) of the CAAA of 1990 also requires that EPA provide to Congress a report that contains estimates of the actual emission reduction in each year resulting from promulgation of the diesel fuel desulfurization regulations under section 214. As a result of the regulation, industry reduced the sulfur content of diesel fuel 0.25 to 0.05 percent as of October 1, 1993. Figure 4.4 displays the emissions for on-road sources with and without desulfurization. As shown, emission reductions in the year 1993 are smaller than the other years since industry lowered the sulfur content of the fuel in October of that year. For the years 1994 through 1998, Figure 4.4 shows a 51 percent decrease in total vehicle emissions and a 400 percent decrease in diesel vehicle emissions, relative to what emissions would be without the fuel desulfurization program.

### 4.5.1 Why Are Current 1993 Emissions Without Desulfurization Higher Than the Values Presented in the 1995 Report to Congress?

The 1993 emissions for on-road vehicles without desulfurization differs from similar values presented in the "National Annual Industrial Sulfur Dioxide Emission Trends, 1995-2015: Report to Congress." EPA generated the values in the previous report prior to the release of its PART5 emissions model, which EPA currently uses to generate  $SO_2$  emissions from on-road sources.

### **4.6 REFERENCES**

For all estimates prior to October 1, 1993, the previous calculation assumed a sulfur content of 0.20 instead of 0.25 percent, since the 0.20 value was the default value listed in EPA's AP-42 Emission Factor document.<sup>5</sup> When PART5 was released, the default value was changed to 0.25. However, past October 1, 1993, the default value was changed to 0.05, since 0.05 is the regulatory value:

| Sulfur Content     | Year reflected in data          |
|--------------------|---------------------------------|
| 0.20 (1995 Report) | Pre October 1, 1993             |
| 0.25 (This Report) | Pre October 1, 1993             |
| 0.05 (This Report) | All years after October 1, 1993 |

### National Criteria Pollutant Estimation Methodologies

### 5.1 WHAT INFORMATION IS PRESENTED IN THIS CHAPTER?

This chapter provides a list of the source categories in the National Emission Trends (NET) data base whose emission estimation methods have changed since the December 1997 *Trends* report and the years that were affected by the methodology changes. It also provides a brief description of the revised methods used to estimate emissions from these sources.

### 5.2 WHERE DO I GET INFORMATION ON THE METHODS USED TO ESTIMATE EMISSIONS FOR SOURCES WHOSE METHODS DID NOT CHANGE?

To obtain information on how emissions were estimated for sources not listed in this chapter, you should look in the *Trends* Procedures Document.<sup>1</sup> The *Trends* Procedures Document can be obtained on the Internet using the following website address:

#### http://www.epa.gov/ttn/chief/ei\_data.html#ETDP

In addition to the *Trends* Procedures Document, you should also look at the chapter entitled "Methodologies That Are New" and Appendix B of the *Trends* update document.<sup>2</sup> Methods used to estimate emissions for several source categories were changed last year, and descriptions of the changes are found in the "Methodologies That Are New" chapter of that report. The *Trends* update document can be found on the Internet using the following website address:

#### http://www.epa.gov/ttn/chief/trends98/emtrnd.html

Table 5-1 provides an overview of all sources whose emission estimation methodologies have changed since publication of the *Trends* Procedures Document.

### 5.3 WHAT OTHER THINGS SHOULD I KNOW ABOUT THE TRENDS ESTIMATION METHODS?

Each year, the United States (U.S.) Environmental Protection Agency (EPA) compiles emission estimates used in assessing trends in the amounts of criteria pollutants discharged into the air. Prior to 1993, the main purpose of the published trends was to portray relative progress in the control of air pollutant emissions nationally. Those estimates were based on standardized emission inventory procedures using aggregate national economic and demographic data. As interest in, and the need for emission figures for individual States and metropolitan areas increased, it was obvious those techniques lacked the precision needed to provide the detailed data, representative of diverse economic and geographic areas, that could realistically assess emission reduction efforts at these smaller scales.

In recent years, the preparation and presentation of national emission estimates has evolved toward meeting the need for more detailed and more accurate inventories. To achieve this goal, revised methodologies have been developed that support the incorporation of detailed State Implementation Plan (SIP) inventories and/or other regional inventories where available (e.g., Ozone Transport Assessment Group [OTAG], Grand Canyon Visibility Transport Commission [GCVTC], periodic emission inventories [PEI]). In addition to presenting national progress in reducing air emissions, local trends in emissions are now presented when possible.

Because of these changes in methodologies, <u>comparison of values with previous **Trends** reports</u> <u>is not a valid exercise</u>. You should use caution when comparing estimates for the years 1985 to 1997 from this report with values in any previous report.

Table 5-2 provides a general overview of where emission values were obtained for each State, for both point and area sources. Mobile source emissions are estimated by EPA for all States using the MOBILE model. EPA also prepares utility emission estimates. Table 5-3 indicates the source of

data for the two most important pollutants emitted by utilities (nitrogen oxides  $[NO_x]$  and sulfur dioxide  $[SO_2]$ ).

### 5.4 WHAT SOURCE CATEGORIES ARE ESTIMATED USING METHODS THAT DIFFER FROM THE PREVIOUS REPORT?

Table 5-1 provides a synopsis of the sources whose methods have changed since the publication of the last *Trends* report.<sup>1</sup> Some of the sources listed in Table 5-1 were updated during the preparation of emissions for the *Trends* update<sup>2</sup> and were described in the "Methodologies That Are New" chapter and Appendix B of that report. The shaded rows in Table 5-1 indicate source categories that were modified this year and are described in the sections of this chapter that follow.

#### 5.5 HOW WERE EMISSIONS FROM NON-ROAD SOURCES ESTIMATED?

One of the major changes in the methods used to estimate emissions this year was for non-road sources. EPA's Office of Transportation and Air Quality (OTAQ, formerly the Office of Mobile Sources [OMS]) has been working on a model that estimates the emissions from these sources for several years. The April 1999 draft version of the NONROAD model was available for use this year in estimating emissions from this source category (http://www.epa.gov/otaq/nonrdmdl.htm).

In large part, emission estimates for volatile organic compounds (VOC), NO<sub>x</sub>, carbon monoxide (CO), SO<sub>2</sub>, particulate matter (PM) less than 10 microns (PM<sub>10</sub>), and PM less than 2.5 microns (PM<sub>2.5</sub>) were calculated using the draft version of the NONROAD model, for all gasoline, diesel, compressed natural gas (CNG), and liquefied petroleum gas (LPG) nonroad equipment types at the 10-digit Source Classification Code (SCC) level. There were a few categories that were not calculated using the NONROAD model. The methods used to calculate emissions for those non-road sources are described in section 5.5.4 and 5.5.5. In addition, the NONROAD model does not contain emission factors to calculate ammonia (NH<sub>3</sub>) emissions. As a result, NH<sub>3</sub> emissions were calculated outside the model using fuel consumption estimates that were generated from the NONROAD model. The methods used to calculate other pollutants that are not included in the NONROAD model are described in section 5.5.6.

### 5.5.1 What Types of Sources are Included in the NONROAD Model?

The NONROAD model includes the following general categories:

- agricultural;
- airport support;
- light commercial;
- construction and mining;
- industrial;
- lawn and garden;
- logging;
- pleasure craft;
- railroad; and
- recreational equipment.

The model generates emissions at subcategory levels lower than the general categories listed above. The subcategories are equivalent to 10-digit SCC levels.

#### 5.5.2 What Years Were Estimated?

County-level criteria pollutant estimates for non-road sources were prepared for all years from 1985-1998 inclusive. National emission estimates were calculated for 1970, 1975, and 1980.

### 5.5.3 Were There Differences in the Methods Used to Calculate Non-road Emissions for Different Years?

Yes. EPA calculated county-level emissions differently for the periods 1985-1995, 1996, and 1997-1998. The methods used to calculate county-level emissions for 1985-1995 and 1997-1998 were identical. Two different methods were used due to time and budget constraints.

EPA calculated criteria pollutant emission estimates for 1996 using the draft NONROAD model adapted to run on a DEC Alpha UNIX workstation. A set of 385 input files was prepared in order to produce an annual county-level non-road emissions inventory for 1996. These input files included a default input file for each State that accounted for average statewide temperatures and seasonal (summer, fall, winter, and spring) Reid vapor pressures (RVP). Emissions for all counties in the United States were calculated using the default State input files. In some cases however, the estimates for particular counties were replaced with county-specific estimates, if those counties had significant differences in their RVP, fuel characteristics due to reformulated gasoline (RFG) and oxygenated fuel requirements, and Stage II controls.

For areas subject to Phase 1 of the Federal RFG program, separate RVP values were modeled in the 1996 NONROAD inputs for May through September. Oxygenated

fuel was modeled in the areas participating in this program in 1996. Four seasonal emissions files for each run were then added together, and the records for each State were combined to produce a database of annual and daily emissions.

Ozone season daily emissions were also estimated. Weekday or weekend day emissions must be specified separately when running the NONROAD model (i.e., annual and daily emissions cannot be generated during the same runs). Because of the time involved in preparing county-level estimates for the whole nation, daily emissions were estimated by using the summer season emissions generated by the NONROAD model, divided by 92 days rather than performing an additional set of calculations for weekday or weekend day emissions.

Emissions for 1985-1995 and 1997-1998 were calculated differently than 1996 emissions. The NONROAD model was run at the national level for all relevant inventory years. Each national run included three seasonal (i.e., summer, winter, fall/spring combined) NONROAD model runs per year to estimate annual criteria pollutant emissions. Seasonal runs were performed to account for differences in average seasonal temperature, as well as RVP. Fall and spring were combined since the average seasonal temperature for those seasons is generally equivalent.

Using the results of the national-level runs, we calculated a ratio by dividing national 10-digit SCC-level emission estimates for each year by their equivalent 1996 national values. County-level emissions were estimated for each year by multiplying each ratio times the 1996 county-level, SCClevel emissions. This approach ensures that the sum of all county-level emissions for any year are equivalent to the national-level estimates, but are distributed to the counties according to the 1996 distribution. This approach was utilized due to time and resource constraints.

Because the NONROAD model estimates growth in local equipment populations using one national average growth rate, the effects of growth should be reflected in the nationallevel runs for each alternate year aside from the base year 1996. The effects of federal non-road emission standards in future years (e.g., years beyond 1996) would also be accounted for. Because the model uses one average growth rate for the whole nation, the approach of using the 1996 county-level inventory as a basis for geographically allocating national inventories for other years was assumed to be reasonable. However, temperature and fuel inputs to reflect local conditions cannot be accounted for when doing a national-level run for a specified year.

As a quality assurance step, category-level emissions generated from the 1996 county-level NONROAD model UNIX runs and summed to the national level were compared with emissions resulting from 3 national, seasonal runs (summer, winter, fall/spring combined). Fall and spring seasonal runs were combined to save resources, since the temperatures for these two seasons are generally similar. This was also done to test the viability of the proposed approach for other years, which rely on national-level runs geographically allocated to the county-level using the 1996 county distribution. If a large disparity existed in the results obtained when running the model at the county-level versus the national level, it could also potentially result in a discontinuity in the emissions data from 1996 to 1997, or from 1995 to 1996. The results of these two separate runs are, in fact, reasonably comparable.

Revised emission estimates were also calculated for 1970, 1975, and 1980. Only national estimates are available for these years. We determined source category-specific ratios of the updated 1985 estimates to the previous Trends values. We then multiplied that ratio times the previous national Trends non-road value for each year to develop revised estimates.

### 5.5.4 Were There Non-road Emission Sources That Were Not Estimated Using the NONROAD Model?

Yes. Emissions for recreational gasoline powered equipment, aircraft, commercial marine vessels, and locomotives were estimated using other methods. EPA has determined that the draft version of the NONROAD model over estimates the equipment population for recreational gasoline powered equipment, so emissions for that category were estimated using the Trends methods used before introduction of the NONROAD model. For the other nonroad emission sources, the NONROAD model does not currently include estimation methods for these categories, so the current Trends method found in the *Trends* Procedures Document was used to develop the emission estimates.<sup>1</sup>

### 5.5.5 How Were Emissions Estimated for Categories Discussed in Section 5.5.4 Above?

As indicated above, the NONROAD model is still in draft form, and emission estimates for certain categories are still undergoing review. For example, large populations are reported for recreational gasoline equipment. This results in emission estimates that are significantly higher than prior year estimates. For this reason, EPA requested that emission estimates from the existing Trends data base be used in place of the NONROAD model estimates for this category.

Commercial aircraft and general aviation estimates for 1997 and 1998 were developed from 1996 values using updated landing-takeoff operations data from the Federal Aviation Administration (FAA) as growth factors. Military aircraft, unpaved airstrips, and aircraft refueling emissions were grown from 1996 using growth factors consistent with the current draft version of the Economic Growth Analysis System (EGAS).<sup>3</sup> Information on how the 1996 emission estimates for these sources were developed can be found in the *Trends* Procedures Document.<sup>1</sup>

EPA's OTAQ prepared 1995-1998 VOC, NO<sub>x</sub>, CO, and total PM national emission estimates for commercial marine diesel engines. PM<sub>10</sub> was assumed to be equivalent to PM, and PM<sub>2.5</sub> was estimated by multiplying PM<sub>10</sub> emissions by a factor of 0.92. These new national estimates were distributed to counties using the geographic distribution in the existing 1996 NET data base [i.e., the National Acid Precipitation Assessment Program (NAPAP) distribution, or the Statesupplied distribution, if a State had submitted data under OTAG for these categories]. Commercial marine emissions were not reported under the same SCC for all States in the data base. For example, some States reported commercial marine diesel emissions under the SCC 228000000, which could potentially include other fuel types (e.g., residual, gasoline). Therefore, a distribution was established based on emissions for all commercial marine SCCs. Because the OTAQ estimates included emissions from residual-fueled vessels, emissions corresponding to this SCC were removed, as well as emissions from the general SCC 228000000. Sulfur dioxide emissions reported for residual-fueled vessels were not removed, however, since OTAQ did not supply revised emissions for this pollutant.

In addition, records for several States had emissions for some pollutants, including  $SO_2$  and  $PM_{10}$ , but no VOC,  $NO_x$ , or CO emissions. We estimated the emissions for these pollutants, by using a national average ratio of VOC/PM<sub>10</sub>,  $NO_x/PM_{10}$ , and CO/PM<sub>10</sub> which were calculated from the available inventory data. These ratios were then applied to the PM<sub>10</sub> emissions to estimate the missing VOC,  $NO_x$ , and CO emissions.

For the years 1985-1994, we calculated the ratio of the 1995 revised OTAQ commercial marine emissions to the previous 1995 Trends emissions values for each pollutant. This ratio was then applied to emission estimates for the following SCCs: commercial marine diesel (2280002), commercial marine residual (2280003), and commercial marine unspecified fuel (2280000). This method was used to avoid a large disparity between existing Trends estimates and revised OTAQ estimates (which were only available back to 1995). We did not perform any additional data augmentation for these years.

1997 and 1998 emission estimates for commercial gasoline, commercial coal, and military marine vessels were grown from 1996 using growth factor values that were consistent with the current draft version of EGAS.

### 5.5.6 Were Any Pollutant Estimates Prepared Differently for Non-road Sources?

Yes, lead (Pb) and NH<sub>3</sub>. Pb was estimated using methods described in section 5.18 of the *Trends* Procedures Document.<sup>1</sup> For NONROAD model categories, NH<sub>3</sub>

emissions were calculated for the years 1990-1998, based on county-level fuel consumption estimates obtained from NONROAD model runs. Fuel consumption estimates were not available for LPG and CNG-fueled equipment. Emission factors provided by EPA's OTAQ were then applied to these activity data to estimate  $NH_3$  emissions for gasoline equipment (without catalysts) and diesel-fueled equipment. The emission factors were derived primarily from light-duty on-road vehicle emission measurements, and extrapolated to nonroad engines on a fuel consumption basis.

As indicated above, emission estimates for recreational gasoline equipment were maintained from the previous version of the NET. However, recreational gasoline NH<sub>3</sub> emissions were calculated differently. Recreational gasoline equipment NH<sub>3</sub> emissions were calculated based on the NONROAD model fuel consumption estimates. These estimates were then redistributed to existing NET records. This was done to avoid having records in the inventory that only contained NH<sub>3</sub> estimates, since many of the SCCs reported in the NONROAD model for this category were not present in the existing Trends inventory. In addition, many States had previously reported these emissions under the general SCCs 2260001000 (all 2-stroke gasoline recreational vehicles) and 2265001000 (all 4-stroke gasoline recreational vehicles), instead of the more specific recreational equipment types.

For aircraft, commercial marine, and locomotive categories, national fuel consumption estimates for 1996 were obtained from various sources. Jet fuel and aviation gasoline consumption for general aviation and commercial aircraft were obtained from the "FAA Aviation Forecasts Fiscal Years, 1998-2009."<sup>4</sup> For aircraft categories, NH<sub>3</sub> emission factors developed for diesel engines were applied to all fuel consumption estimates, since aviation gasoline consumption was determined to be relatively small compared to jet fuel, and the aircraft SCCs are not defined by fuel type. Diesel consumption estimates for locomotives were obtained from "Locomotive Emission Standards - Regulatory Support Document (RSD)."<sup>5</sup> For commercial marine, data for distillate and residual fuel oil were reported in "Fuel Oil and Kerosene Sales."<sup>6</sup>

To develop  $NH_3$  emissions for 1997 and 1998, 1996 base year  $NH_3$  emissions for these categories were projected for these categories using growth factors.  $SO_2$  emissions were not supplied by OTAQ for commercial marine and locomotives, and estimates for this pollutant were projected using growth factors as well.  $NH_3$  emissions were reported in the NET database for commercial marine and locomotive categories for historic years (i.e., 1990-1995); no changes were made to these historic estimates. Historic  $NH_3$ emissions were not available for aircraft, so there is a disparity between 1995 and 1996 for  $NH_3$  emissions for this category.

Once annual  $NH_3$  emissions were calculated, summer season daily emissions were estimated using seasonal profiles

available from the 1985 NAPAP study. SCC-specific summer seasonal fractions were applied to the annual emissions to generate summer season emissions, which were then divided by 92 days to estimate summer season daily emissions.

### 5.6 WHAT CHANGES WERE MADE IN THE METHOD USED TO ESTIMATE NONUTILITY POINT AND AREA SOURCE EMISSIONS?

EPA has tried over the last several years to ensure that the NET data base reflects State developed emission estimates whenever feasible. For example, 1990 NET emission estimates include State-developed data from OTAG and GCVTC inventories. Emissions for years following 1990 were supplemented with data from the Aerometric Information Retrieval System (AIRS). PEI and annual submission of emissions data for major point sources are required under the CAAA. As part of the PEI requirements, States containing nonattainment areas (NAAs) needed to submit a PEI for 1996. Consequently, one of EPA's goals was to include data developed by the States as part of the 1996 PEI effort in the NET. While the CAAA only requires submittal of ozone pollutant data for the PEI requirements, annual point source reporting is designed to cover all pollutants. Additionally, in the guidance provided to the States on the PEI submittal process, EPA encouraged States to submit emission estimates for all pollutants, since the NET contains estimates for all criteria pollutants and is to be the ultimate repository of the State data. To reduce the burden of preparing this inventory, EPA gave each State a copy of the 1996 NET inventory as a starting point in preparing their 1996 PEI.

In the past, EPA has estimated emissions for this group of sources by growing emissions using growth factors derived from the U.S. Department of Commerce, Bureau of Economic Analysis (BEA). As mentioned above, some data derived from AIRS was also used to supplement the emissions in certain years.

### 5.6.1 What Steps Were Required to Incorporate State PEI Data Into the NET?

The incorporation of the 1996 State/Local emission inventory data is a five step process:

- Data Collection;
- Quality Control (QC);
- Data Augmentation;
- Quality Assurance (QA); and
- Data Loading.

In the data collection step, EPA solicited PEI and annual point source data from the States. There were four acceptable formats States could use to submit their data: 1) the NET Input Format, 2) through AIRS/AIRS Facility Subsystem (AFS), 3) the Electronic Data Interchange X.12 format, and 4) the NET Overwrite Format.

In the QC step, EPA evaluated the data received to ensure that States had correctly characterized, on the 1996 Emission Inventory Submittal Form, the data they submitted (e.g., geographic coverage, pollutants, SCCs, annual and daily emissions), that the data were formatted correctly; that mandatory data elements were included, and the priority SCCs needed to incorporate the data were present (e.g., nonutility point and stationary area source SCCs). Any problems found were followed-up by a phone call to the State/local agency for review and resolution. If basic problems could not be resolved, the data were not included in this version of the NET. Data not included in this version of the NET will be incorporated in FY 2000.

In the data augmentation step, data elements required for the regional scale modeling or this report, that were not supplied in the State data set, were added to the NET. EPA needs a complete inventory containing VOC,  $NO_x$ , CO, SO<sub>2</sub>,  $PM_{10}$ ,  $PM_{2.5}$ , and  $NH_3$ . We added emission estimates to the NET for any of these pollutants if they were not included in the State submitted data. Each data element was characterized as "mandatory submission" or "data can be augmented." As part of the QC step, all data received was checked to ensure that data elements classified as mandatory submission were included in the data supplied by the States.

In the QA step, data were checked for reasonableness. QA reports highlighting questionable data were developed and sent to the States for review. Questionable data were either confirmed by the State as correct, corrected by the State, or in the case where the State did not respond, replaced using the data augmentation methods. The QA reports that were sent to States for review included:

- Tier 2 Summary;
- Top 20 Plants for Each Pollutant with Comparison to Current Data;
- NET Plants Not in the State Data;
- Geographic Coordinate Exceptions;
- Stack Parameter Exceptions; and
- Large Sources Without Emission Controls.

In the data loading step, EPA loaded State data that met the QA criteria, or was resolved during the QA step, into the NET data base. This resulted in a fully revised 1996 point and area source file.

### 5.6.2 How Many States Submitted Data for the 1996 PEI Effort?

Point source data for 34 States and area source data for 13 States was received as part of the PEI data incorporation effort. Figure 5-1 is a map of the United States that indicates which States provided 1) point source data that were utilized, 2) point source data that were not utilized at this time due to data quality problems, 3) point and area source data that were utilized, and 4) no data.

For the majority of States, the PEI point source submittals were made to the AFS. Some States submitted data in alternative formats, primarily using the NET Input Format.

### 5.6.3 Were Any State-Supplied Data Rejected in the QC Phase?

Yes. A few States' data were rejected either due to problems with data completeness, data format, or both. EPA is working to resolve these problems with the individual States and hopes to include data from these States in the next release of the NET. These States are indicated in Figure 5-1 as States whose data will be processed in 2000.

## 5.6.4 What Types of Data Were Augmented in the Data Augmentation Step?

As mentioned above, the NET contains emission estimates for all criteria pollutants (except Pb). Thus data elements and/or pollutant emissions that were missing in the State provided data needed to be augmented. The data augmentation procedure included augmenting information related to stack parameters (height, diameter, velocity, flow, temperature), location information (latitude and longitude), operating schedule (hours per day, days per week, hours per year, seasonal throughput), and emission estimates for pollutants not included in the State submittals. A detailed list of the items augmented in the data augmentation phase and the individual steps taken to augment the various data elements is provided in Barnard et. al.<sup>7</sup> and in the draft *Trends* Procedures Document currently being revised.<sup>8</sup>

### 5.6.5 What Quality Assurance Steps Were Taken to Ensure That the State Data Were Incorporated Correctly?

Quality assurance was an essential element of the data incorporation process. Extensive internal review of the data was performed to ensure that the data were retrieved and formatted correctly and that the data augmentation process was performed correctly. On-going reviews were made of the data to ensure that there were not duplicate records, that emissions values were not "out of range", and that the values for stack parameters were within normal operational values.

The most important part of the QA program was State review of the retrieved and augmented data. EPA prepared a review package for each State submitting data. The review package consisted of a number of reports and tables showing a variety of information about the preliminary data set.

In the past, QA of the NET inventory focused almost exclusively on the emission estimates. Due to the NET's change in focus to a modeling inventory, QA of the NET was expanded to cover additional data elements including stack parameters, geographic coordinates, emission control data, and operating schedule data.

To QA stack parameters, upper and lower limits were developed for each stack parameter carried in the NET. The Stack Exception Report in the QA package listed stacks in the NET where one or more of the parameters was above the upper bound or below the lower bound. High and low values not corrected by the States were replaced with the corresponding upper or lower bound value. The acceptable ranges for each stack parameter are listed below:

| Height      | 0 ft to 1,250 ft       |
|-------------|------------------------|
| Diameter    | 0 ft to 50 ft          |
| Temperature | 32°F to 2,250°F        |
| Velocity    | 0 ft/sec to 650 ft/sec |

To QA geographic coordinates, maps were generated for each State showing any facilities that were located outside of their State borders when plotted using the geographic coordinates supplied by the State. Coordinates not corrected by the States were replaced with the coordinates for the county centroid based on the State and county codes provided by the State.

## 5.6.6 What Did EPA Do With Comments Received by the States?

In the early review of the data, several States indicated that the emissions for their ozone precursor pollutants were not correct. The original downloads from AFS were designed to retrieve the default emissions value. However, several States indicated that they typically stored emissions data in one of the alternative emission fields. As a consequence, EPA surveyed the States that submitted data to determine which States submitted emissions data in something other than the default emissions field. Data for those States was retrieved a second time and augmented as required. The emissions for those States were re-summarized and sent back to the States for a final review.

Once comments from all of the review packages were received, modifications to the emissions or process data were made based on the State comments. Modification to the AFS PEI data were made to reflect either new data from the additional downloads, modifications based on the review packages sent out to the States, or based on data that remained anomalous (e.g., stack flow rates).

One portion of the State review package was a list of plants not included in the PEI submittals that were in the version of the 1996 NET provided to the States as a starting point for PEI preparation. Several States provided comments on that table indicating that 1) some or all of these facilities should be maintained, and 2) indicating that while they should be maintained, the emissions should be modified to reflect more accurate State-supplied values. The data for these plants were extracted from the NET and maintained in a separate file. Since the review packages only provided plant totals, ratios of old to new plant emissions were used to adjust the values of each segment's emissions and then the data were updated in the file.

### 5.6.7 Was There Any Additional Data Augmentation?

Yes. In addition to criteria pollutants, the NET also houses estimates of  $NH_3$  emissions. None of the States submitting PEI data submitted  $NH_3$  emissions. As a consequence, the  $NH_3$  emissions from the 1996 NET needed to be added back into the revised data base. Two steps were taken to perform this augmentation. First, plant-level total  $NO_x$  emissions were calculated for the PEI data submitted by the States. Then plant-level summaries of  $NH_3$  from the NET were developed. Where a match could be made using the State Federal Information Processing Standards (FIPS) code, county FIPS code, and plant identification (ID) code, segment-level emissions for  $NH_3$  were calculated using the following equation:

 $NH_3seg = (NO_xseg/NO_xplant) * NH_3plant$ 

where:

| NH <sub>3</sub> seg   | = | segment-level NH <sub>3</sub> emissions     |
|-----------------------|---|---|
| NO <sub>x</sub> seg   | = | PEI segment-level NO <sub>x</sub> emissions |
| NO <sub>x</sub> plant | = | PEI plant-level NO <sub>x</sub> emissions   |
| NH <sub>3</sub> plant | = | NET plant-level NH <sub>3</sub> emissions   |

In order to maintain the NH<sub>3</sub> totals currently in the NET, NH<sub>3</sub>-only plant/segment-level records were added for those facilities that did not match plants in the PEI submitted data.

### 5.6.8 Were There Emissions From Any Sources Submitted by the States That Were Not Incorporated into the NET?

A few source categories were not updated using Statesupplied PEI data. These source categories were not updated because EPA feels that the consistent methodology and the quality of the data involved in the calculation of emissions from these categories is at or above that provided by the States. For point sources, State-supplied utility emissions data for segments with SCCs beginning with 101 were not retained. For area sources, the categories not included from State data were on-road mobile and non-road. This approach will be revised in 2000, as data issues are resolved between the States and EPA for the utility and mobile categories.

### 5.6.9 How Were Nonutility Point and Area Sources for 1997 and 1998 Developed?

The PEI data incorporation effort was only for 1996 emissions. Thus, EPA had to develop 1997 and 1998 emissions internally. Emissions for nonutility point sources and many area sources were developed using growth factors.

To develop 1997 and 1998 emission estimates, EPA compiled a set of emission growth factors to apply to the 1996 NET inventory. For the most part, these growth factors were developed using procedures that are similar to those used by EGAS.<sup>3</sup> The current, publically available version of EGAS is version 3.0. Because EGAS version 3.0 was released in 1995, EPA has recently been working to develop an EGAS Version 4.0. The growth factors used for developing 1997 and 1998 estimates were developed using the draft version of EGAS 4.0. As part of the EGAS version 4.0 development effort, EPA has obtained more recent data/models and updated some of the underlying EGAS files. Two of the major changes that EPA has been performing are: (1) incorporating new economic models from Regional Economic Models, Inc. (REMI); and (2) revising the EGAS 3.0 crosswalk that is used to assign REMI model-derived growth factors to SCCs. The REMI models, which included 72 modeling regions in EGAS 3.0, cover the continental United States. While many modeling regions cover an entire State, some States have separate models for ozone NAAs and rest-of-state areas. For this effort, updated REMI models were available that provide historical (through 1996) and forecast (through 2035) socioeconomic data for each of 75 modeling regions in the United States (three new modeling regions were added in North Carolina).<sup>9</sup> As part of the revisions to the EGAS 3.0 crosswalk, EPA reviewed each of the previous SCC assignments and incorporated new assignments for over 2,600 additional SCCs.

The EPA applied REMI model-derived growth factors to point sources at the Standard Industrial Classification (SIC) code-level whenever SIC code information was available in the inventory. Because REMI's models provide output for 172 economic sectors, which are roughly equivalent to 3-digit SIC codes, REMI output was first directly matched to the SIC code information available from the point source component of the NET inventory. For some point source records, SIC code information was missing, available at less than a 3-digit SIC code level, or invalid (did not represent a valid SIC code). For these point source records, EPA assigned REMI model-derived growth factors to SCCs using the revised EGAS crosswalk. Because the REMI models do not include Alaska and Hawaii, it was necessary to utilize a different source of projections data for these States. The BEA released a set of gross State product (GSP) projections in 1995.<sup>10</sup> These projections, which are generally available at a 2-digit SIC code level, were used to develop growth factors for Alaska and Hawaii. The BEA-derived growth factors were first matched with point sources in the inventory at the 2-digit SIC code level. For point sources with missing/invalid SIC code information, and for all area sources, EPA matched BEA data with emission sources using an updated EGAS 3.0 crosswalk matching BEA sectors with SCCs.

EGAS 3.0 includes a number of models that project energy consumption by sector and fuel type (e.g., residential natural gas consumption). The revisions to the energy consumption modules in EGAS 3.0 have not yet been completed. Because these updates are expected to include the use of Department of Energy (DOE) energy projections data, EPA compiled the DOE's forecast data for use in adjusting the REMI/BEA data for projected changes in energy intensity.<sup>11</sup> Specifically, the EPA calculated the following national energy intensity factors for 1996, 1997, and 1998:

- Residential fuel combustion projected delivered energy by fuel type divided by projected residential floor space;
- Commercial/institutional fuel combustion projected delivered energy by fuel type divided by projected commercial floor space; and
- Industrial fuel combustion projected delivered energy by fuel type for both specific industries (e.g., refining industry) and for total industrial fuel use divided by projected constant dollar industrial output (specific industry or total industrial output).

Next, EPA calculated the ratios of national 1996 energy intensity to both the national 1997 and 1998 energy intensity for each sector/fuel type. For residential natural gas consumption, for example, EPA developed 1996:1997 and 1996:1998 ratios of residential natural gas consumption per square foot of residential floor space. These ratios were then used to adjust the EGAS modeling region-specific REMI/BEA population-based residential fuel consumption growth factors.

Finally, for VOC emissions, controls were implemented for several maximum achievable control technology (MACT) sources. If a source category was subject to MACT in either 1997 or 1998, the 1996 control efficiency for that source was compared with the control efficiency that the MACT control would have on VOC. If the 1996 control efficiency was greater than or equal to the MACT control efficiency then the data was maintained at the 1996 level. If the 1996 control efficiency was lower than the MACT standard, then uncontrolled emissions were back-calculated using the 1996 control efficiency and then controlled emissions were calculated from the uncontrolled levels using the MACT control efficiency. The MACT control efficiency value was also inserted into the data base field for control efficiency. It was assumed that the MACT controls operated for the entire year, even if they were not scheduled to come on-line until the middle to latter part of the year.

### 5.7 WHAT OTHER METHODOLOGY CHANGES WERE THERE?

Methodology changes or changes in the underlying data used to calculate emissions were made for agricultural livestock, structural fire, and prescribed burning emissions. In addition, corrections were made in how on-road mobile  $NO_x$  emissions were calculated to account for the heavy-duty  $NO_x$  defeat device on heavy-duty diesel engines. (See Section 5.7.4.)

### 5.7.1 What Changes Were Made in How Agricultural Livestock Emissions Were Calculated?

EPA had calculated PM and NH<sub>3</sub> emissions from agricultural livestock sources using U.S. Department of Agriculture (USDA) Census of Agriculture data on animal populations. The Census of Agriculture is conducted every 5 years. Thus, we had been required to develop a methodology that could be used to estimate emissions in years between the publication of the Census of Agriculture data. EPA used BEA State-level farm sector growth factors to estimate emissions for the years between Census of Agriculture publications. For the time period that EPA had estimated emissions from this source category (1990-1997) only one Census of Agriculture publication had been prepared (1992). The 1997 Census of Agriculture was released in the spring of 1999. An evaluation of the actual statistics on livestock populations following release of the 1997 Census of Agriculture indicated that the livestock population data for 1997 was very similar to the 1992 data. However, the NET inventory had shown approximately a 25 percent drop in total NH<sub>3</sub> emissions from 1992 to 1997 which was due almost entirely to an approximately 40 percent drop in emissions in the livestock category. Apparently agricultural commodity prices dropped between 1992 and 1997, but livestock populations stayed more or less stable. Since the BEA statistics use commodity prices rather than animal population data, the post-1992 inventories would be underestimated.

Thus EPA decided that the emission estimates for this source category should be revised using more appropriate data

on animal populations. The 1987 Census of Agriculture data were obtained and in conjunction with the 1992 and 1997 data a linear estimation method was developed to predict animal populations for intermediate years and to project to 1998. The linear estimates developed were State and animal specific. In some cases, development of the linear regression used to estimate animal populations resulted in negative values. In those cases, the animal population was set to zero.

Using the revised animal population data with the current emission factors<sup>1</sup>, revised estimates were developed. The changes only affected  $NH_3$  and PM emission estimates.

### 5.7.2 What Changes Were Made in How Structural Fire Emissions Were Calculated?

EPA has an on-going program to improve the quality of emission estimates. That program, the Emission Inventory Improvement Program (EIIP) routinely evaluates the methods used to estimate emissions from various sources. Recent work by the EIIP had identified a revision to the loading factor used to estimate emissions from structural fires. The revised value for the loading factor was obtained from the California Air Resources Board.<sup>12</sup>

Using the revised loading factor, emission estimates were revised starting with 1990. Since several States submitted data for this source during the OTAG data collection process, revised and updated 1990 emission estimates for this source were developed by EPA only for non-OTAG States. Once the 1990 estimates were revised, 1991-1995 estimates were calculated by using a growth factor developed for the ongoing revision to EGAS. The growth factor for the revised version of EGAS was developed using a regression equation that relates national population to the amount of material burned in structural fires. State-level population is then used as an input to predict the amount of material burned in each State, using the regression equation. Both OTAG and non-OTAG estimates were grown.

Estimates for 1996 were developed using updated activity data and the California Air Resources Board's loading factor for non-OTAG states. OTAG States were grown using the EGAS growth factors. Then, as part of the 1996 PEI data incorporation effort, 1996 emissions were replaced by Statesupplied data obtained during the PEI effort.

Estimates for 1997 and 1998 were developed identically to how the base 1996 data were developed, except that there was no replacement with State-supplied data, since there was no equivalent to the PEI data for those years.

### 5.7.3 What Changes Were Made in How Prescribed Burning Emissions Were Calculated?

EPA updated prescribed burning emissions estimates to better reflect data now available with which to calculate growth in this sector. In earlier versions of the NET, emissions for prescribed burning were grown using population as a surrogate. EPA felt that population was not an appropriate growth surrogate for prescribed burning. A method developed for the Section 812 Prospective<sup>13</sup> study which held private land acreage constant, but develops a growth index for public lands based on national statistics for acres burned, was initiated this year. The technique uses 1990 estimates as a base year, since values for 1990 include actual data for a number of States, especially those in the GCVTC inventory.

EPA used information on the fraction of public including State-owned and private land from the Section 812 Prospective study to allocate a portion of the emissions to each of these components. Then, a national ratio of acres burned on public lands was developed using U.S. Forest Service data.<sup>14</sup> Growth factors were then developed by calculating a ratio for the year of interest relative to 1990 (the base year). The growth factor was then multiplied by the fraction of emissions attributable to public lands. This value was then added back to the remaining emissions (i.e., those attributable to private lands) to obtain the emissions for each year. This is a rough estimate. The actual number of acress burned each year varies greatly and is a function of fuel moisture, fuel density, meteorology, and other factors.

### 5.7.4 How Did EPA Account for Emissions from Heavy-Duty Diesel Engines that Used the NO<sub>x</sub> Defeat Device?

On October 22, 1998, EPA reached a settlement agreement with seven manufacturers of diesel truck engines. EPA had found that the engines in as many as 1.3 million trucks built over the last 10 years had devices that defeated pollution controls. Those allegations were related to excessive  $NO_x$  emissions during highway driving that were not occurring during engine certification testing. The engine electronic control module would switch to those fuel-efficient, but high  $NO_x$ , operation modes during highway driving. Federal officials considered such engine control software "defeat devices", which are illegal under the federal laws.

For purposes of this report, a defeat device is a vehicle component or software which allows excess emissions to be produced during operating modes which are not explicitly covered by a certification test while still controlling emissions during the certification test. In the case of the heavy-duty  $NO_x$  defeat device, the device was active (shut off emission control

systems) during steady-state operating modes such as cruising down the freeway, but was mostly inactive during transient operation. It was built into heavy-duty diesel vehicles (HDDVs) beginning in the 1988 model year, and completely removed by the 2000 model year. In the late 1980's and early 1990's the defeat device was being phased into the fleet and was mostly confined to the heavy end of the heavy-duty diesels (8a and 8b vehicles). However, by the mid to late 1990's it was widespread on virtually all of the heavy end engines and most of the medium and light end heavy-duty diesels.

EPA's MOBILE model used to calculate emissions from on-road vehicles is designed based on engine certification testing. Thus, the use of the defeat devices by HDDVs caused the emission factors calculated by those models to underestimate emissions from these vehicles. In order to determine that actual emissions arising from the use of these devices, EPA developed a series of spreadsheet models to provide corrected emission factors for heavy-duty vehicles that would account for the underestimated emissions.<sup>15</sup> EPA's OTAQ spreadsheets contain multiplicative factors representing the ratio of HDDV NO<sub>x</sub> emissions with the defeat devices to the HDDV NO<sub>x</sub> emissions without the defeat devices. These factors differ by calendar year, roadway type, and vehicle speed. The HDDV NO<sub>x</sub> emissions, calculated using the MOBILE5b HDDV NO<sub>x</sub> emission factors, were revised by multiplying the appropriate factor at the State/ county/roadway type level of detail for the years 1990 through 1998. Additional details on the spreadsheet models can be found at the following website address:

### Table 5-1. Emission Estimation Methods That Have Changed Since the Last Report

| Year of Inventory | Pollutant  | Category   | Methodology Change*   |
|-------------------|--|--|---|
| 1990              | CO, VOC, NO <sub>x</sub>                               | Primarily nonutility point<br>sources and 17 states<br>worth of area sources | A combination of Ozone Transport Assessment Group (OTAG), Grand<br>Canyon Visibility Transport Commission Inventory (GCVTC), and Aerometric<br>Information Retrieval System (AIRS) data was added to inventory, replacing<br>some units but primarily just adding more units. (Ozone season daily data<br>received was developed into annual data). |
| 1990              | PM <sub>10</sub> , PM <sub>2.5</sub> , SO <sub>2</sub> | As above   | State data received as above was augmented with PM and $SO_2$ data through an $SO_2$ and PM to $NO_x$ uncontrolled emission factor ratio.   |
| 1991-1995         | All but Pb   | Primarily nonutility point<br>sources and 17 states<br>worth of area sources | NAPAP, AIRS data, GCVTC and Grand Canyon projections from the 1990 inventory using Bureau of Economic Analysis (BEA) growth indicators.   |
| 1990              | All but Pb   | on-road mobile   | 1990, 1995, 1996 use state-supplied MOBILE model inputs where applicable. See Reference 1 for a list of States supplying model inputs.  |
| 1990              | All but Pb   | on-road mobile   | Used state supplied vehicle miles traveled (VMT) where applicable. See Reference 1 for a list of States providing VMT.  |
| 1985-1989         | All but Pb   | chemical and allied  | Removed rule effectiveness from pre-1990 chemical and allied product emissions.   |
| 1985-1994         | NO <sub>x</sub>  | utilities  | Used $NO_x$ emission rates from Acid Rain Division (ARD) instead of AP-42 emission factors.   |
| 1994-1998         | NO <sub>x</sub> , SO <sub>2</sub>                      | utilities  | Based Phase I units on CEM data from ARD, remaining units are from DOE767 survey data (small amount of units).  |
| 1996              | All but Pb   | nonutility point (35 states)<br>and area sources (14<br>states)              | Added state-supplied data directly received from states or retrieved from<br>AIRS as part of the PEI inventory effort, as directed by the states.<br>5 State submittals were select cities only.  |
| 1997-1998         | All but Pb   | nonutility point and area sources  | Projected through 1998 based on the 1996 PEI enhanced database using EGAS derived growth factors and BEA growth factors where applicable.   |
| 1970, 1975, 1980  | All but Pb   | non-road sources   | Generated national-level nonroad emission estimates based on category-<br>specific ratios of 1996 NONROAD model outputs to previous year national<br>estimates.   |
| 1985-1998         | All but Pb   | non-road sources   | Ran the beta version of the NONROAD model for all counties in U.S. for 1996. Used the NONROAD model to calculate national emissions for the other years and then used SCC-specific ratios for the other years relative to 1996 (year in question/1996) to determine county-level estimates.   |
| 1985-1998         | All but Pb   | non-road sources   | For commercial marine diesel, EPA's OTAQ provided revised national VOC, $NO_{x1}$ CO, and PM emission estimates for commercial marine diesel engines. National estimates were distributed to counties using the geographic distribution in the existing NET.  |
| 1990-1998         | All but Pb   | Miscellaneous-agric.<br>forestry   | Revised allocation of Census of Agriculture activity data between the 1990<br>and 1997 census: used agricultural surrogates instead of economic<br>surrogates.  |
| 1990-1998         | РМ   | Miscellaneous -agric.<br>crops   | Began using tillage activity data using the Conservation Technology<br>Information Center, Purdue University, data, and also changed silt value<br>methodology from 1990 onward.  |
| 1989-1998         | РМ   | Miscellaneous-managed<br>burning   | Based on USDA Forest Service inventory of PM from prescribed burning.<br>Public percentage of acres burned projected from 1990 using national-level<br>growth factor developed from total U.S. acres burned, while private portion<br>held constant.  |
| 1990-1998         | РМ   | Miscellaneous<br>-construction   | Changed the emission factor in 1990: changed from using a former AP-42 value to using latest AP-42 findings report: "Improvement of Specific Emission Factors" - change occurred in Trends year 1997.   |
| 1990-1998         | РМ   | paved roads  | The rain correction factor in the paved road equation was reduced by 50 percent for the years 1990 onward due to uncertainty associated with the actual reduction in emissions due to precipitation on paved road surfaces.   |
| 1990-1998         | All but Pb   | structural fires   | For non-OTAG States, revised 1990 and 1996 emissions based on new loading factor value. Projected all States using EGAS regression equations, which relate State-level population to the amount of material burned in structure fires.  |

\* For a list of specific data sources used for each State, please see Section 4.1 of reference 8.

Chapter 6.0

#### 6.1 WHAT EMISSIONS DATA DOES EPA PRESENT IN THIS CHAPTER?

This chapter presents preliminary biogenic volatile organic compound (VOC) and nitric oxide (NO) emissions for 1988, 1990, 1991, 1995, 1996, and 1997. Estimates for 1998 are not available because the United States (U.S.) Environmental Protection Agency (EPA) did not have the resources to develop biogenic estimates for that year. The 1998 estimates will be included in the 1999 Trends report. Tables 6-1 and 6-2 show VOC and NO emissions, respectively. Tables 2-1, A-2, and A-3 do not contain the biogenic emission estimates because EPA only tracks anthropogenic emissions for regulatory purposes.

### 6.2 HOW WERE THESE EMISSIONS GENERATED?

EPA calculated the biogenic emissions for 1988, 1991, 1995, 1996, and 1997 using the Biogenic Emissions Inventory System - Version 2 (BEIS2).<sup>1,2,3</sup> EPA used a slightly different version of BEIS2 to generate the 1990 estimates.

### 6.3 WHY DO THESE EMISSIONS VARY?

Differences in climatology (i.e., temperature and cloud cover) and land use strongly affect biogenic emissions.

### 6.4 HOW DOES TEMPERATURE AFFECT EMISSIONS?

Annual emissions correlate very strongly with changes in annual temperature patterns. The highest emissions levels occur in the summer when temperatures rise the highest. An increase of 10°C can cause over a two-fold increase in VOC and NO emissions. Tables 6-3 and 6-4 show the seasonal allocation of VOC and NO emissions, respectively.

### 6.5 HOW DOES LAND USE AFFECT EMISSIONS?

Variations in land use can greatly affect spatial variation in biogenic emissions densities. In the southern United States and Missouri, large areas of oak trees show high VOC densities, while in the midwestern United States, areas of fertilized crop lands show relatively high densities of NO. Figures 6-1 and 6-2 show the spatial variation in biogenic emission densities across the United States.

### 6.6 WHAT IS THE UNCERTAINTY ASSOCIATED WITH THESE ESTIMATES?

These estimates have an uncertainty factor of a maximum of two. However, biogenic emissions research continues to be quite active, and EPA expects improvements in these emission estimates in the next few years.

Chapter 7.0

#### 7.1 WHAT INFORMATION IS PRESENTED IN THIS CHAPTER?

This chapter discusses hazardous air pollutants (HAPs). HAPs are commonly referred to as "air toxics" or "toxic air pollutants." They are pollutants known to cause or suspected of causing cancer or other serious human health effects or ecosystem damage. Section 112 of the Clean Air Act (CAA) now lists 188 pollutants or chemical groups as HAPs and targets stationary sources of these pollutants for regulation.<sup>1</sup> Examples of air toxics include heavy metals like mercury and chromium; organic chemicals like benzene, 1,3-butadiene, perchloroethylene, dioxins, and polycyclic organic matter.

HAPs are emitted from literally thousands of sources including: point sources (such as electric power utilities or industrial manufacturers), smaller area sources (such as neighborhood dry cleaners or service stations), and mobile sources (such as automobiles or airplanes). Adverse effects to human health and the environment due to HAPs can result from exposure to air toxics from individual facilities, exposure to mixtures of pollutants found in urban settings, or exposure to pollutants emitted from distant sources that are transported through the atmosphere over regional, national or In addition to breathing air even global airsheds. contaminated with air toxics, people can also be exposed to some HAPs through other pathways such as through the ingestion of contaminated food from waters polluted from the deposition of HAPs from the air to water bodies (e.g. fish contaminated with mercury).

## 7.2 WHAT ARE THE HEALTH AND ENVIRONMENTAL EFFECTS OF HAPs?

Most of the information on potential health effects of HAPs is derived from experimental animal data and studies of exposed workers. The different health effects which may be caused by HAPs include cancer, neurological, cardiovascular, and respiratory effects, effects on the liver, kidney, immune system, and reproductive system, and effects on fetal and child development. More than half of the 188 HAPs have been classified by the United States (U.S.) (EPA) as "known," "probable," or "possible" human carcinogens. Known human carcinogens are those that have been demonstrated to cause cancer in humans. Probable and possible human carcinogens include chemicals that we are less certain cause cancer in people, yet for which laboratory animal testing or limited human data indicates carcinogenic effects.

Some HAPs pose particular hazards to people of a certain age or stage in life (e.g., young children, adolescents, adults, or elderly people). Available data suggest that about a third of HAPs (e.g., mercury) may be developmental or reproductive toxicants in humans. This means that exposure during the development of a fetus or young child may prevent normal development into a healthy adult. Other such critical exposures may affect the ability to conceive or give birth to a healthy child. Toxic air pollutants can have a variety of environmental impacts in addition to the threats they pose to human health. Animals, like humans, may experience health problems if they breathe sufficient concentrations of HAPs over time, or ingest HAPs through contaminated food (e.g. fish).

## 7.3 WHY ARE AIR TOXICS INVENTORIES NEEDED?

Section 112 of the CAA added a new approach to the regulation of HAPs, consisting of two phases. The first requires the development of technology-based emissions standards for sources emitting the 188 HAPs. The second phase requires the evaluation of any remaining problems or risks, and development of additional regulations to address sources of those problems, as needed. In implementing the Section 112 provisions, EPA has collected information that helps characterize air toxics emissions. Emission inventories are a key component of this characterization process and also provide important information with which to monitor progress towards meeting the emission reduction goals.

# 7.3.1 Which EPA Regulatory Activities Use HAP Emission Inventories?

Phase One:

Under Section 112 of the CAA, the first phase of requirements is comprised of the technology-based standards, known as maximum achievable control technology (MACT) and generally achievable control technology (GACT)

regulations. All large stationary sources, or "major" sources, of the 188 HAPs must be addressed by such regulations, as well as the smaller, "area" stationary sources found to produce significant risk or emit priority pollutants such as those identified under Section 112(c)(6) or the Integrated Urban Air Toxics Strategy described below. Some combustion sources, such as municipal waste combustors, and medical waste incinerators are regulated under equivalent requirements in Section 129. The purpose of this technology-based approach is to use available control technologies, changes in work practices, or pollution prevention methods to get emission reductions for as many of the HAPs as possible. It is expected that the MACT and GACT standards will reduce a majority of the HAP emissions and, in turn, reduce risks from regulated sources. This initial phase has generated emissions data for several industries as they are studied in the MACT and GACT regulatory development process as well as other CAA provisions that require EPA to evaluate emissions of utility industry HAP emissions, mercury, and other specific air toxics. These requirements are summarized below.

**Utility Study, Section 112(n)(1)(A)** requires a report to Congress on the "hazards to public health reasonably anticipated to occur as a result of the emissions of electric utility steam generating units."

**Mercury Study, Section 112(n)(1)(B)** requires a report to Congress regarding emissions of mercury that "shall consider the rate and mass of such emissions, the health and environmental effects of such emissions..."

**Specific Pollutants, Section 112(c)(6)** requires a "list of categories and subcategories of sources assuring that sources accounting for not less that 90 percent of the aggregate emissions of each pollutant are subject to standards." This provision applies to seven specific HAPs: alkylated lead (Pb) compounds, mercury, dioxins, polycyclic organic matter (POM), hexachlorobenzene, polychlorinated biphenyls (PCBs) and furans.

Area Source Program, Section 112(c)(3) requires that the "emissions of the 30 hazardous air pollutants that present the greatest threat to public health in the largest number of urban areas are subject to regulation."

**Implementation of Section 112 through Title V of the CAA** requires the Administrator to perform an oversight role with respect to State issued permits, including permits issued to major sources of HAP emissions. In order to determine whether that program is being appropriately and lawfully administrated by the States with respect to major HAP sources, a HAP emission inventory is necessary. States are developing programs to regulate HAPs and their Title V programs must include permits for all HAP sources emitting major quantities of HAPs (10 tons of one HAP or 25 tons of multiple HAPs per year). Thus the Administrator believes maintaining an inventory of such sources is necessary and appropriate.

### Phase Two:

After application of these technology-based standards and studies, in the second phase, the CAA requires strategies and programs for evaluating remaining risks and effects and ensuring that the overall program has achieved sufficient improvement. This phase will be implemented through programs that evaluate these remaining risk and effects. Such programs are described below.

**Integrated Urban Air Toxics Strategy** responds to the requirements of Sections 112(k) and 112(c)(3) of the CAA, and also reflects activities to control mobile source emissions required under section 202(l). The goals of the Integrated Urban Air Toxics Strategy consist of the following: 1) attain a 75-percent reduction in incidence of cancer attributable to exposure to HAPs emitted by stationary sources; 2) attain a substantial reduction in public health risks posed by HAP emissions from area sources; and 3) address disproportionate impacts of air toxics Strategy was finalized in July 19, 1999 *Federal Register.*<sup>2</sup>

**Residual Risk, Section 112(f)** requires an assessment of the residual risk after certain Section 112 standards are implemented. Residual risk standards are to be developed as determined necessary eight years after promulgation of these standards.

The Great Waters Program, Section 112(m) requires EPA to identify "the extent of atmospheric deposition of hazardous air pollutants" to specified water bodies, "evaluate any adverse effects to pubic health or the environment caused by such deposition," and determine whether additional regulations are warranted.

Inventories play a crucial role in each of these programs as the inventory information is used to evaluate current emissions, emissions reductions achieved, and identify the numerous source categories which emit specific pollutants. Inventories are an important tool in evaluating the risk reductions goals for the Integrated Urban Air Toxics Strategy. In addition, EPA is also using information from inventories to plan what future work might need to be done. For more information on Section 112 programs refer to the EPA's website at http://www.epa.gov/ttn/uatw.html.

## 7.4 WHAT IS EPA'S PLAN TO GATHER THE NECESSARY TOXICS DATA?

As the EPA began working to meet the air toxics requirements of the CAA, it became clear that there was a strong need for a central source of air toxics emissions and inventory data from which to conduct the analyses required by the CAA, and to have a place to centrally store and share the data being generated through various programs. The increased availability of air toxics emissions data will assist EPA program offices and other agencies that use emissions data to evaluate state, local, or tribal air pollution related issues. Air toxics data needs vary from national estimates of emissions to regional estimates, county-level estimates, and facility-specific estimates, and even down to process-specific estimates. Thus, in 1993, EPA began development of a national air toxics inventory data base now referred to as the National Toxics Inventory (NTI).

## 7.5 WHAT IS THE NTI?

The NTI is a central repository of estimated emissions for the 188 HAPs for all anthropogenic (manmade) sources.

### 7.5.1 How was the NTI Developed?

The national estimates of the HAPs included in the NTI to date were calculated using existing information; no source testing or industry surveys were conducted specifically for the purposes of generating the NTI. Existing emission inventory data were obtained from a variety of state and local data bases and EPA programs (such as the Toxics Release Inventory (TRI), standards development programs, and other studies required by the CAA such as the Utility Study). Sometimes emissions information is available from direct measurement of emissions at a given source. However, for logistical and financial reasons direct measurement, or stack testing, cannot be performed at every source and instead, most inventory data are developed via various estimation techniques.

Many of the national emissions estimates in the NTI (primarily for area and mobile sources) were developed by applying an emission factor, which is an emissions estimate based on test data and correlated to some other process activity. For example an emissions factor could be expressed in terms of grams emitted per ton of coal burned or per vehicle mile traveled. To estimate emissions, these factors were combined with information about the activity levels of a source, such as the production levels at the facility, the number of hours of operation, or the amount of fuel consumed.

Because there are multiple programs investigating HAP emissions in the United States, emissions data and source activity data are continually changing and improving. Since estimating emissions requires making various assumptions, the estimates are applicable for a specific time period and may not necessarily agree with other published estimates due to differences in base years, emission factors and activity data, and calculation assumptions. It should be recognized that some of the data presented in the NTI for a given base year is likely to change as more information and improved estimation approaches are developed.

EPA established a hierarchy of emissions estimation methods in order to prepare the inventory. The hierarchy is used to sort through overlapping data sources of varying quality or reliability. EPA prefers to use existing inventories that are final, and whose estimates are judged to be acceptable.

The hierarchy is (with data sources listed by preference):

- 1. Data developed by State and local air agencies;
- 2. Data from EPA's Emissions Standards Division, collected and developed for standards development;
- Data from existing EPA inventories, such as those developed to support requirements of CAA Sections 112(k)<sup>4</sup> and 112(c)(6);<sup>5</sup> and
- 4. Emissions reported in the TRI data base,<sup>6</sup> and emissions that EPA generated using emission factors and activity factors.

If emissions data were not available for certain source categories through these references (1 - 4 above), emissions factors and activity data were used to estimate emissions. Emission factors used were evaluated for their currency, completeness, representativeness, and overall quality. The emission factors generally came from EPA's AP-42 document,<sup>7</sup> EPA's Locating and Estimating Document Series,<sup>8</sup> or the Factor Information Retrieval (FIRE) system.<sup>9</sup> Most of the activity data were obtained from sources such as the Energy Information Administration (fuel consumption reports), the Forest Service (fires and burned acreage), and other EPA offices (waste disposal reports). Industry trade publications, commercially published business directories, and journals were also sources of activity data.

The EPA's Office of Transportation and Air Quality (OTAQ) assisted in the development of the mobile source emissions estimates. Mobile sources include "on-road" vehicles, such as cars, trucks, and motorcycles, as well as "nonroad" vehicles and equipment, such as airplanes, boats, or lawnmowers. For many of the HAPs emitted from mobile sources, details on the emission estimation procedures are provided in the Section 112(k) inventory report.<sup>3</sup>

#### 7.5.2 What are the NTI Base Years?

#### The Baseline NTI (1990 - 1993)

The first iteration of the NTI, referred to as the Baseline NTI, provides a composite of emissions estimates intended to represent the 1990 to 1993 time frame. Much of the baseline NTI data are for 1990, because a large portion of the national emissions data in the NTI was developed under the Section 112(c)(6) and Section 112(k) programs which targeted a 1990 base year. The TRI data and state and local data included for California, Houston, and Phoenix are for a 1993 base year. Emissions for the MACT source category portion of the NTI are annual emissions ranging from 1990 to 1993, and represent emissions from these sources before MACT standards were implemented. The estimates in the Baseline inventory are aggregated to the county level and cover the 50 United States. The emissions summaries and graphics provided in this report are based exclusively on the Baseline NTI.

#### The 1996 NTI

EPA has recently completed the 1996 NTI. The 1996 version differs significantly from the Baseline NTI. Unlike the Baseline NTI which has emissions estimates from all counties by source category and pollutant, the 1996 NTI contains facility- and location-specific information making it suitable for input to computer air quality models (computer models used to for dispersion calculations which predict resultant ambient air concentrations). Methods for mobile source emissions estimates were significantly improved in the 1996 NTI also. The 1996 NTI data set contains estimates for all 50 United States and for Puerto Rico and the Virgin Islands. It has been compiled in cooperation with State and local agencies which have submitted data they have gathered during facility permitting and other regulatory activities. The 1996 NTI contains data and/or comments supplied by 46 States, Puerto Rico, and the Virgin Islands. Figure 7-1 highlights the state and local agencies that contributed data to the 1996 NTI. Subsequent base year NTIs will contain this same level of model-ready detail and will be compiled every 3 years (1999, 2002, etc.).

The 1996 NTI was completed in January 2000, but the results could not be summarized for comparison to Baseline NTI emissions in time to be printed in this document. Thus, because only one data set is summarized here, this report does not show an emissions trend over time. Instead, it provides the baseline from which trends can be measured in future reports.

## 7.5.3 How are Emissions Allocated to Source Types and Counties?

For purposes of the Baseline NTI, the emission estimates were further refined in two ways. First, the emissions were allocated by source type including major sources, area sources and mobile sources. Then the emissions were spatially allocated. The sections below describe these analyses.

#### Major/Area Source Allocation

The national emission estimates for stationary source categories were allocated according to whether the emitting source category was classified as "major," "area," or could be classified partially as both. According to Title I, Section 112(a) of the CAA, a "major source" is any stationary source (including all emission points and units located within a contiguous area and under common control) of air pollution that has the potential to emit, considering controls, 10 tons or more per year of any HAP or 25 tons or more per year of any combination of HAPs. An "area source" is any stationary source of HAPs that does not qualify as a major source. Major sources may include co-located sources which can have components that emit less that 10 tons per year of an individual HAP or 25 tons or more per year of any combination of HAP.

#### Spatial Allocation

Emissions were assigned to counties by a number of methods. In some cases, where actual locations were not known, emissions were assigned to individual counties using surrogate approaches. Some examples of surrogate approaches include proportioning national emissions to counties based on population, proportioning emissions from some industrial sectors to counties based on 1990 Standard Industrial Classification (SIC) code employment estimates, and assigning emissions from forest fires to counties based on forested acres.

#### 7.5.4 What are Urban/Rural Allocations?

The emission estimates were also spatially allocated on an urban and rural basis in order to meet some of the requirements of the Integrated Urban Air Toxics Strategy. To do this, U.S. Census Bureau statistical data were used.<sup>9</sup> The Census Bureau has designated the portion of every county in the United States that is considered urban. The criteria used include population density and total population. Using population data and urban designations, every county in the United States was classified as one of the following categories:

- Urban-1 (U1) counties are included in a metropolitan statistical area with a population greater than 250,000;
- Urban-2 (U2) counties in which the Census Bureau designates more than 50 percent of the county population as urban; and
- Rural (R) counties in which the Census Bureau designates less than 50 percent of the county population as urban.

In the summary of 1993 NTI emissions and graphics that follow, "urban" has been designated to be the sum of U1 plus U2 counties. Figure 7-2 identifies the urban/rural counties in the 50 United States using the Integrated Urban Air Toxics Strategy definition described above. Note that these urban/ rural designations have been derived exclusively for inventory purposes and do not indicate regulatory applicability.

# 7.5.5 What Changes Have Been Made Since the Last Trends Report?

Emission inventories are dynamic, with enhancements being made on an ongoing basis. Many revisions were made in the Baseline NTI since what was reported in the last Trends document. Public review of the compilation of the Section 112(k) Urban Air Toxics inventory and new information that became available through the MACT/GACT program led to most of these changes. Some errors in the earlier data base were also corrected. These changes led to a significant decrease in the estimates of emissions from stationary sources.

# 7.6 HOW ARE THE EMISSIONS SUMMARIZED?

The emissions summarized in the following pages represents the most recent version of the Baseline NTI. (This version is the "9901" version of the inventory and, as stated previously, represents a composite of emissions estimates from the 1990 to 1993 time period.) Because of the volume of data, much of the emissions information shown here involves the summary of emissions across pollutants. This cross-pollutant summary is done primarily for the sake of comparison to show the mass of all HAP emissions across source sectors (major, area, mobile), tier groups (industry sectors), populations centers (urban and rural), and geographic regions (national and state).

Any evaluation of exposure or resultant risk posed by these emissions would depend on the presence, exposure, and toxicity of individual pollutants, and cannot be surmised from the data provided here.

The sum of Baseline NTI emissions from all sources and from the 50 United States is 5.9 million tons. This version

(9901) of the NTI includes emission estimates for 169 of the 188 individual and group (e.g., metal compound groups) HAPs. A list of the HAPs included is presented in Table 7-1. Approximately 580,000 tons of HAP emissions that could not be speciated into individual chemical species. These "unspeciated HAP" emissions come primarily from the synthetic organic chemicals industry MACT data. These emissions are primarily volatile organic compounds. A small subset (approximately 64 tons) of these emissions are metals and other particulate matter. It should be noted that this will Pb to the undercounting of individual HAP species from these sources, for example, benzene emissions. The Baseline NTI includes estimates for approximately 960 source categories.

# 7.6.1 What Individual Pollutant Detail is Given?

As part of the Integrated Urban Air Toxics Strategy, EPA identified a list of the 33 air toxics that present the greatest threat to public health in the largest number of urban areas (see Table 7-2 for list of urban air toxics). In identifying the list of "urban air toxics" pollutants EPA looked at pollutants regardless of the source sector (major, area, or mobile), from which they were emitted. Thus, EPA looked at pollutants that pose a health threat in urban areas in the aggregate, from stationary area, stationary major and mobile sources. However, the CAA requires that EPA identify at least 30 HAPs that "result from area sources." Thus, of these 33 urban air toxics, EPA identified the 30 with the greatest contribution from smaller commercial and industrial operations or so-called "area" sources. These 30 are important for establishing a list of area source categories for regulation as required by section 112(k). However, in addition to the requirement to list area source categories, the Integrated Urban Air Toxics Strategy contains the three risk reduction goals discussed earlier. It is important to remember that in looking at the risk reduction goals the Integrated Urban Air Toxics Strategy states EPA will look at the risk from all 188 HAPs, not just that associated with the 33 urban air toxics. The 33 urban air toxics represent those pollutants that are a priority on a national scale. However, on the local scale other HAPs may be play a more important role in local health risks. The emissions data that follows highlights the emissions of these 33 priority HAPs in comparison to all of the 188 HAPs. For additional background information on the Integrated Urban Air Toxics Strategy, visit EPA's website at http://www.epa.gov/ttn/uatw/urban/urbanpg.html.

As explained previously, because the Integrated Urban Air Toxics Strategy is designed to focus on emissions from urban areas, all emissions in the NTI are flagged accordingly to indicate whether the county from which the emissions come meets the urban definition. Figures 7-3 through Figure 7-5 indicate the percentages of national emissions totals that are from rural and urban counties and attributable to the major, area, on-road, and nonroad source sectors. Figures 7-6 and 7-7 show the summed emissions of the 188 HAPs and 33 HAPs, respectively, by state and source sector. Figures 7-8 and 7-9 present a map graphic portraying the percentiles of the summed emissions densities in tons per square mile. Figure 7-10 shows national emissions percentage of each of the 33 HAPs divided among source sectors (major, area, onroad, nonroad).

The Baseline NTI emissions are further summarized in several ways. Table 7-3 includes all 188 HAPs summed by total, urban, and rural allocations and by point, area, and mobile (on-road and nonroad) contributions. Table 7-4 repeats this information with more detail about how the point, area, and mobile sectors exist in urban and rural counties. Tables 7-5 and 7-6 indicate the summed 188 and 33 HAPs, respectively, by State and point, area, on-road, and nonroad emissions. Tables 7-7 and 7-8 summarize the 33 HAPs by source tier groups. Tiering is a method of broadly categorizing industry sectors. Tier 1 provides the most general classification (e.g., fuel combustion) with Tier 2 supplying more detail (e.g., fuel combustion by coal, oil, gas, and other fuel types). Although currently criteria pollutant and HAP emission inventories are compiled separately, and therefore the Tier groups could not be matched exactly, every effort has been made to match Tier groups as much as possible. Table 7-7 indicates Tier 1 groups and Table 7-8, Tier 1 along with Tier 2.

Within the Tier 2 groupings, emissions in the NTI are flagged according to whether they come from source categories being reviewed for MACT/GACT regulations. The MACT source emissions that are flagged in the Baseline NTI data set reflect source categories for which EPA has developed emissions estimates as part of ongoing regulatory develop-ment. Although utility emissions have a "MACT flag," no determination has been made as yet regarding whether these sources will be subject to MACT standards. Combustion sources being reviewed under section 129 are also flagged. The source categories and pollutants that are MACT flagged indicate those considered in the Integrated Urban Strategy analyses (used to determine the list of priority HAPs) prior to publication of the Strategy. That analysis resulted in an additional listing of source categories, published in the July 19, 1999 Federal Register.<sup>2</sup> These newly listed source categories do not yet have MACT flags in the NTI; once standards have been initiated to the point that emissions covered by new standards can be identified, the inventory will reflect them.

### 7.7 REFERENCES

- This list originally included 189 chemicals. The CAA allows EPA to modify this list if new scientific information becomes available that indicates a change should be made. Using this authority, the Agency modified the list to remove caprolactam in 1996, reducing the list to 188 pollutants (Hazardous Air Pollutant List; Modification, 61 FR 30816, June 18, 1996).

Table 7-4 (continued)

0.29578 Note(s): EPA uses a data base to store these emissions. Since the data base stores very large and very small amounts, the number of decimal places displayed are an artifact of that storage and are not intended to suggest true precision of large values.

Note(s): EPA uses a data base to store these emissions. Since the data base stores very large and very small amounts, the number of decimal places displayed are an artifact of that storage and are not intended to suggest true precision of large values.

The estimates included in these tables have uncertainties and will improve/change as better data and estimation techniques become available over time.

## Table 7-7 (continued)

Note(s): EPA uses a data base to store these emissions. Since the data base stores very large and very small amounts, the number of decimal places displayed are an artifact of that storage and are not intended to suggest true precision of large values.

The estimates included in these tables have uncertainties and will improve/change as better data and estimation techniques become available over time.

# Table 7-8. Baseline NTI (1990 to 1993) 33 HAPs by Tier 1 and Tier 2

|                         |   | Emissions (tpy) for 33 Urban HAPs |           |               |                      |              |                        |               |  |  |

Note(s): EPA uses a data base to store these emissions. Since the data base stores very large and very small amounts, the number of decimal places displayed are an artifact of that storage and are not intended to suggest true precision of large values.

The estimates included in these tables have uncertainties and will improve/change as better data and estimation techniques become available over time.

Note(s): EPA uses a data base to store these emissions. Since the data base stores very large and very small amounts, the number of decimal places displayed are an artifact of that storage and are not intended to suggest true precision of large values.

The estimates included in these tables have uncertainties and will improve/change as better data and estimation techniques become available over time.

Note(s): EPA uses a data base to store these emissions. Since the data base stores very large and very small amounts, the number of decimal places displayed are an artifact of that storage and are not intended to suggest true precision of large values.

The estimates included in these tables have uncertainties and will improve/change as better data and estimation techniques become available over time.

Note(s): EPA uses a data base to store these emissions. Since the data base stores very large and very small amounts, the number of decimal places displayed are an artifact of that storage and are not intended to suggest true precision of large values.

The estimates included in these tables have uncertainties and will improve/change as better data and estimation techniques become available over time.

Note(s): EPA uses a data base to store these emissions. Since the data base stores very large and very small amounts, the number of decimal places displayed are an artifact of that storage and are not intended to suggest true precision of large values.

The estimates included in these tables have uncertainties and will improve/change as better data and estimation techniques become available over time.

### National Greenhouse Gas Emissions

### 8.1 WHAT INFORMATION IS PRESENTED IN THIS CHAPTER?

This chapter summarizes the latest information on anthropogenic greenhouse gas emissions in the United States from 1990 through 1997. For a more detailed discussion, the reader is referred to the Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-1997, April 1999, United States (U.S.) Environmental Protection Agency (EPA), EPA 236-R-99-003. This report is produced annually and submitted by the U.S. Government to the United Nations as part of our commitments under the Framework Convention on Climate Change (UNFCCC). Readers interested in the international efforts to address the problem of climate change through negotiation are referred to the home page of the UNFCCC at http://www.unfccc.de. Readers interested in more background on the science of climate change, global warming or greenhouse gases are referred to the Intergovernmental Panel on Climate Change (IPCC) via their website at http://www.ipcc.ch.

To ensure that the U.S. greenhouse gas emissions inventory meets the reporting requirements of the UNFCCC, the estimates were calculated using methodologies consistent with those recommended in the *Revised 1996 IPCC Guidelines for National Greenhouse Gas Inventories*<sup>1</sup>. For most source categories the IPCC default methodologies were expanded in order to incorporate emission factors and data specific to the United States, resulting in a more comprehensive and detailed estimate of U.S. emissions. (See Section 8.3.3.)

### 8.2 WHAT ARE THE RECENT TRENDS IN U.S. GREENHOUSE GAS EMISSIONS?

Naturally occurring greenhouse gases include water vapor, carbon dioxide (CO<sub>2</sub>), methane (CH<sub>4</sub>), nitrous oxide (N<sub>2</sub>O), and ozone (O<sub>3</sub>). Several classes of halogenated substances that contain fluorine, chlorine, or bromine are also greenhouse gases, but they are, for the most part, solely a product of industrial activities. Chlorofluorocarbons (CFCs)

and hydrochlorofluorocarbons (HCFCs) are halocarbons that contain chlorine, while halocarbons that contain bromine are referred to as halons. Other fluorine containing halogenated substances include hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride ( $SF_6$ ).

Total U.S. greenhouse gas emissions rose in 1997 to 1,813.6 million metric tons of carbon equivalents (MMTCE). The single year increase in emissions from 1996 to 1997 was 1.3 percent (23.1 MMTCE), down from the previous year's increase of 3.3 percent. Overall, emissions of greenhouse gases have increased 11 percent above 1990 levels. Table 8-1 provides a detailed summary of U.S. greenhouse gas emissions and sinks for 1990 through 1997.

In 1997, the primary greenhouse gas emitted by human activities was  $CO_2$ . The largest source of  $CO_2$  and of overall greenhouse gas emissions in the United States was fossil fuel combustion.  $CH_4$  emissions resulted primarily from decomposition of wastes in landfills, manure and enteric fermentation associated with domestic livestock, natural gas systems, and coal mining. Emissions of N<sub>2</sub>0 were dominated by agricultural soil management and mobile source fossil fuel combustion. The substitution of O<sub>3</sub> depleting substances and emissions of HFC-23 during the production of HCFC-22 were the primary contributors to aggregate HFC emissions. PFC emissions came mainly from primary aluminum production, while electrical transmission and distribution systems emitted the majority of SF<sub>6</sub>.

As the largest source of U.S. greenhouse gas emissions,  $CO_2$  from fossil fuel combustion accounted for 81 percent of emissions in 1997 when each gas is weighted by its Global Warming Potential (see Figure 8-1 in the *Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1900-1997* for a discussion of global warming potentials). Emissions from fossil fuel combustion grew by 11 percent (138.8 MMTCE) over the 8-year period and were responsible for over three-quarters of the increase in national emissions. The annual increase in CO<sub>2</sub> emissions from this source was 1.3 percent in 1997, down from the previous year when emissions increased by 3.6 percent.

The dramatic increase in fossil fuel combustion related  $CO_2$  emissions in 1996 was primarily a function of two factors: 1) fuel switching by electric utilities from natural gas to more carbon intensive coal as gas prices rose sharply due

to weather conditions, which drove up residential consumption of natural gas for heating; and 2) higher petroleum consumption for transportation. In 1997, by comparison, electric utility natural gas consumption rose to regain much of the previous year's decline as the supply available rose due to lower residential consumption. Despite this increase in natural gas consumption by utilities and relatively stagnant U.S. electricity consumption, coal consumption rose in 1997 to offset the temporary shut-down of several nuclear power plants. Petroleum consumption for transportation activities in 1997 also grew by less than a percent, compared to almost 4 percent the previous year (see Table 8-2).

Overall, from 1990 to 1997, total emissions of  $CO_2$ ,  $CH_4$ , and  $N_2O$  increased by 143.5 (11 percent), 9.7 (6 percent), and 13.4 MMTCE (14 percent), respectively. During the same period, weighted emissions of HFCs, PFCs, and SF<sub>6</sub> rose by 14.9 MMTCE (67 percent). Despite being emitted in smaller quantities, emissions of HFCs, PFCs, and SF<sub>6</sub> are significant because of their extremely high global warming potentials and, in the cases of PFCs and SF<sub>6</sub>, long atmospheric lifetimes. Conversely, U.S. greenhouse gas emissions were partly offset by carbon sequestration in forests, which was estimated to be 11 percent of total emissions.

Other significant trends in emissions from other source categories over the 8-year period of 1990 through 1997 included:

- Aggregate HFC and PFC emissions resulting from the substitution of ozone depleting substances (e.g., CFCs) increased dramatically (by 14.4 MMTCE). This increase was partly offset, however, by reductions in PFC emissions from aluminum production (41 percent) and HFC emissions from HCFC-22 production (14 percent), both as a result of voluntary industry emission reduction efforts and, in the former case, from falling domestic aluminum production.
- Combined N<sub>2</sub>O and CH<sub>4</sub> emissions from mobile source fossil fuel combustion rose 3.9 MMTCE (26 percent), primarily due to increased rates of N<sub>2</sub>O generation in highway vehicles.
- CH<sub>4</sub> emissions from the decomposition of waste in municipal and industrial landfills rose by 10.5 MMTCE (19 percent) as the amount of organic matter in landfills steadily accumulated.
- Emissions from coal mining dropped by 5.2 MMTCE (21 percent) as the use of CH<sub>4</sub> from degasification systems increased significantly.
- N<sub>2</sub>O emissions from agricultural soil management increased by 8.8 MMTCE (13 percent) as fertilizer

consumption and cultivation of nitrogen fixing crops rose.

• An additional domestic adipic acid plant installed emission control systems in 1997, which was estimated to have resulted in a 1.4 MMTCE (27 percent) decline in emissions from 1996 to 1997 despite an increase in production.

### 8.3 WAS A MORE DETAILED ANALYSIS OF INDUSTRIAL EMISSIONS CONDUCTED?

Yes. An analysis of the industrial sector was conducted to provide greater resolution on the greenhouse gas emissions and energy consumption trends in the industrial end-use sector.

Figures 8-1 through 8-3 present  $CO_2$  emissions data by industry end-use sector for the entire United States in the year 1994.

#### 8.3.1 What Data Were Used in this Analysis?

This analysis was based on data contained in several EPA and Energy Information Administration (EIA) reports: the Manufacturing Consumption of Energy 1994, DOE/EIA-0512(94);<sup>2</sup> The Annual Energy Review 1997, DOE/EIA-0384(97);<sup>3</sup> Emissions of Greenhouse Gases in the United States 1997, DOE/EIA-0573(97);<sup>4</sup> and the Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-1996, EPA 236-R-98-006.<sup>5</sup>

The Annual Energy Review, EIA and the Emissions of Greenhouse Gases, EPA were used to develop national estimates of  $CO_2$  for the year 1994. Both of these inventories report data on  $CO_2$  emissions caused by both fuel combustion and industrial processes, and both were included in this analysis. Typically, fossil fuel combustion represents 81 percent of total U.S. greenhouse gas emissions and 99 percent of total U.S.  $CO_2$  emissions, although there is some year-to-year variance. Cement manufacture is the largest remaining source of industrial  $CO_2$  emissions, and has been estimated to contribute about 10 MMTCE to annual U.S. emissions. For more information on industrial sources of  $CO_2$  or other greenhouse gas emission data, the reader is referred to the EPA inventory document or web site at www.epa.gov/globalwarming/inventory.

The Manufacturing Consumption of Energy (MECS) data were used to develop the detailed estimates for the industry sector. The MECS data are prepared once every 4 years, thus 1994 is presented as the most recent year for which the MECS data are available. The MECS data contain rich detail on manufacturing industries, but no information on the non-manufacturing industries, such as agricultural activity, mining, and construction. The MECS data were

#### 8.3.2 What are the Results?

The results of this analysis show that the majority of  $CO_2$  emissions can be attributed to a few major end-use sectors.

The utility sector, which represents 36 percent of total  $CO_2$  emissions in 1994, supplies energy to industry. Emissions resulting from electricity production can thus be prorated to industry on the basis of electricity consumption. Ideally, this would be done on a regional basis in order to best capture the complexity of our nation's energy supply system and to account for variations in carbon emissions per kilowatt hour. However, this analysis uses national averages to develop the carbon emissions embedded in electricity consumption and attributes these emissions to the industries on the basis of their electricity demand.

Figure 8.1 shows total U.S.  $CO_2$  emissions in 1994. Utilities contribute 36 percent of that total, with transportation the second largest sector at 30 percent of total  $CO_2$  emissions. Emissions from utilities were estimated at 492 MMTCE in 1994, with 87 percent of that total resulting from coal consumption, 9 percent from natural gas, and 4 percent from petroleum fuel consumption.

Figure 8.2 presents all industrial emissions of  $CO_2$  - both manufacturing and non-manufacturing - and the graph was developed to account for both "on-site" and "off-site" emissions. In this case, on-site emissions are process-related emissions such as  $CO_2$  flux from lime calcination, and off-site emissions refer to the emissions that result from fossil fuel consumption at power plants supplying electricity to industry.

Figure 8.3 presents  $CO_2$  emissions for the entire United States, and differs from Figure 8.1 in that utility sector has been "mapped" into the various end-use sectors that consume the electricity generated at utilities. Table 8.4 presents the  $CO_2$  emissions data in tabular form.

#### 8.3.3 What Methodologies were Utilized?

Emissions of greenhouse gases from various sources have been estimated using methodologies that are consistent with the *Revised 1996 IPCC Guidelines for National Greenhouse Gas Inventories.*<sup>1</sup> To the extent possible, the present U.S. inventory relies on published activity and emission factor data. Depending on the emission source category, activity data can include fuel consumption or deliveries, vehicle-miles traveled, raw material processed, etc.; emission factors are factors that relate quantities of emissions to an activity. For some sources, IPCC default methodologies and emission factors have been employed. However, for emission sources considered to be significant sources in the United States, the IPCC default methodologies were expanded and more comprehensive methods were applied. The Annexes of the *Inventory of U.S. Greenhouse Gas Emissions and Sinks:* 1990-1997 contain additional detail and documentation on the calculations and assumptions used to obtain these estimates. This report can be found online at www.epa.gov/ globalwarming/inventory.

Inventory emission estimates from energy consumption and production activities are based primarily on the latest official fuel consumption data from the EIA/DOE.  $CO_2$ emissions from fuel combusted in ships or aircraft engaged in the international transport of passengers or cargo are not included in U.S. totals, but are reported separately as international bunkers in accordance with IPCC reporting guidelines.<sup>1</sup> CO<sub>2</sub> emissions from fuel combusted within U.S. territories, however, are included in U.S. totals.

Data on fuel consumption for the United States and its territories, carbon content of fuels, and percent of carbon sequestered in non-energy uses were obtained directly from the EIA/DOE. Fuel consumption data were obtained primarily from the *Monthly Energy Review*<sup>6</sup> and various EIA databases. U.S. marine bunker fuel consumption data for distillate and residual fuel oil was taken from Fuel Oil and *Kerosene Sales*.<sup>7</sup> Marine bunker fuel consumption in U.S. territories was collected from internal EIA databases<sup>8</sup> used to prepare the International Energy Annual.9 Jet fuel consumption for aviation international bunkers was taken from Fuel Cost and Consumption,<sup>10</sup> which are monthly data releases by the Department of Transportation's Bureau of Transportation Statistics (DOT/BTS), and unpublished data from the Bureau of Economic Analysis (BEA).<sup>11</sup> The data collected by DOT/BTS includes fuel consumed for international commercial flights both originating and terminating in the United States. One-half of this value was assumed to have been purchased in the United States.<sup>a</sup>

IPCC<sup>1</sup> provided combustion efficiency rates for petroleum and natural gas. Bechtel<sup>11</sup> provided the combustion efficiency rates for coal. Vehicle type fuel consumption data for the allocation of transportation sector emissions were primarily taken from the *Transportation Energy Databook*<sup>12</sup> prepared by the Center for Transportation Analysis at Oak Ridge National Laboratory (DOE 1993, 1994, 1995, 1996, 1997, 1998). All jet fuel and aviation gasoline were assumed to have been consumed in aircraft.

#### Table 8-1. Recent Trends in U.S. Greenhouse Gas Emissions and Sinks (MMTCE)

+ Does not exceed 0.05 MMTCE

<sup>a</sup> Sinks are only included in net emissions total. Estimates of net carbon sequestration due to land-use change and forestry activities exclude nonforest soils, and are based partially upon projections of forest carbon stocks.

<sup>b</sup> Emissions from International Bunker Fuels are not included in totals.

Note: Totals may not sum due to independent rounding.

### Table 8-2. Annual Percent Change in CO2 Emissions from Fossil FuelCombustion for Selected Sectors and Fuels

| Sector           | Fuel Type   | 1995 to 1996 | 1996 to 1997 |
|------------------|-------------|--------------|--------------|
| Electric Utility | Coal        | 5.7%         | 2.9%         |
| Electric Utility | Natural Gas | -14.6%       | 8.7%         |
| Residential      | Natural Gas | 8.1%         | -4.4%        |
| Transportation*  | Petroleum   | 3.4%         | 0.3%         |

\* Excludes emissions from International Bunker Fuels

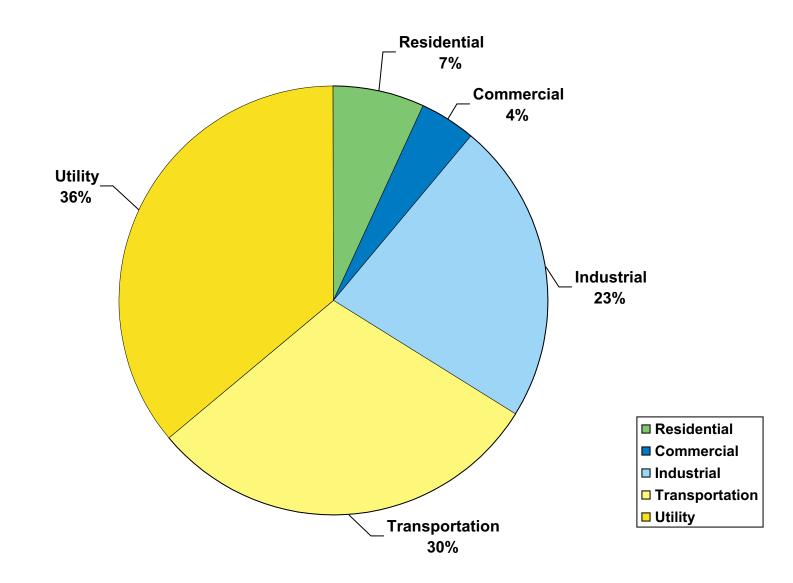

### Table 8-3. Carbon Coefficients, MMTCE/QBtu (Q=E15)

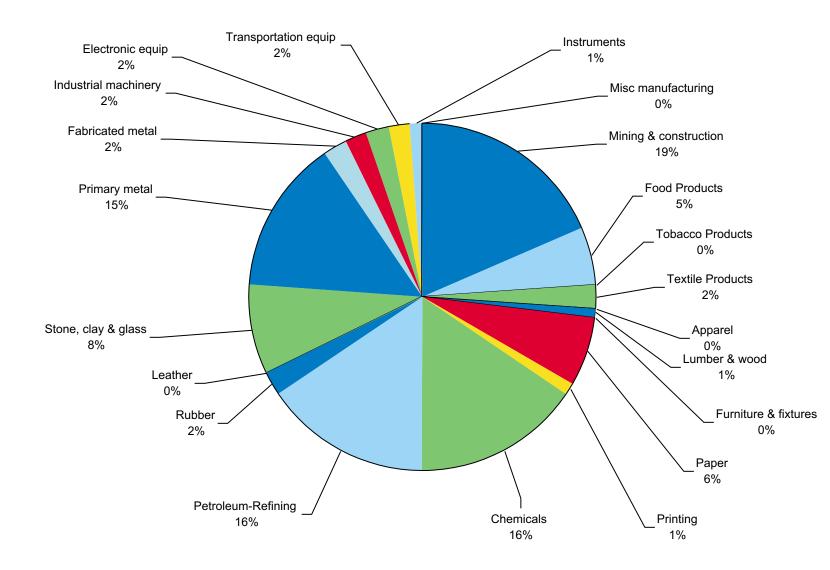

| Year | Electricity | <b>Residual Oil</b> | Distillate Oil | NG | LPG   | Coal | Coke | Still Gas |
|------|-------------|---------------------|----------------|----|-------|------|------|-----------|
| 1994 | 50          | 21.49               | 19.95          | 14 | 17.01 | 25   | 25   | 20.19     |
| 1995 | 50          | 21.49               | 19.95          | 14 | 16.99 | 25   | 25   | 20.23     |

### Figure 8-3. U.S. Carbon Dioxide Emissions by End-Use Sector in 1994

### 9.1 WHAT DATA ARE PRESENTED IN THIS CHAPTER?

This chapter presents the 1996 European emission estimates for the pollutants carbon monoxide (CO), nitrogen oxides (NO<sub>x</sub>), sulfur dioxide (SO<sub>2</sub>), nonmethane volatile organic compounds (NMVOCs), methane (CH<sub>4</sub>), carbon dioxide (CO<sub>2</sub>), nitrous oxide (N<sub>2</sub>O), and ammonia (NH<sub>3</sub>), and the 1995 Canadian emission estimates for the pollutants CO, NO<sub>x</sub>, volatile organic compounds (VOC), SO<sub>2</sub>, total particulate (TP), particulate matter (PM) less than 10 microns in diameter (PM<sub>10</sub>), and PM less than 2.5 microns in diameter (PM<sub>2.5</sub>).

### 9.2 WHAT EUROPEAN EMISSIONS ARE PRESENTED?

In 1993, the European Union launched the European Environment Agency (EEA) with a mandate to orchestrate, cross-check, and put to strategic use information relevant to protecting and improving Europe's environment.<sup>1</sup> CORINAIR (Coordination of Environmental Air) is the air emission inventory for Europe The CORINAIR project is part of the work program of the EEA. The EEA designated the European Topic Center on Air Emissions (ETC/AEM) to perform the CORINAIR project by assisting participating countries to report their national inventories as required under international obligations. Based on these reports the ETC/AEM prepares the European air emission inventory and database.<sup>2</sup>

The countries that submitted 1996 data on emissions of ozone precursors and acidifying pollutants to CORINAIR include Austria, the Czech Republic, Denmark, Finland, France, Germany, Greece, Ireland, Luxembourg, the Netherlands, Norway, Slovenia, and the United Kingdom. In addition, the following countries submitted 1996 data on emissions of greenhouse gases to the United Nations Framework Convention on Climate Change (UNFCCC): Austria, Belgium, the Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Ireland, Luxembourg, the Netherlands, Norway, Slovenia, Spain, Sweden, and the United Kingdom. Table 9-1 shows European national total emissions for 1996 for the following pollutants:  $SO_2$ ,  $NO_x$ , NMVOC,  $CH_4$ , CO,  $CO_2$ , and  $NH_3$ . Tables 9-2 through 9-8 present 1996 country-level summary data by CORINAIR/EMEP (Cooperative Programme for Monitoring and Evaluation of the Long Range Transmission of Air Pollutants in Europe) source category for  $SO_2$ ,  $NO_x$ , NMVOC, CO, and  $NH_3$ . The CORINAIR/EMEP source categories include:

- Combustion in energy and transformation industries
- Nonindustrial combustion plants
- Combustion in manufacturing industry
- Production processes
- Extraction and distribution of fossil fuels/geothermal energy
- Solvent and other product use
- Road transport
- Other mobile sources and machinery
- Waste treatment and disposal
- Agriculture and forestry, land use and woodstock change
- Nature

Because some countries included estimates of NMVOC and  $CO_2$  emissions in the Nature and the Agriculture categories, these tables include a "Comparable Total" line, omitting these two categories for each country.

Tables 9-9 to 9-13 present 1996 country-level summary data by EEA source category for  $CH_4$ ,  $CO_2$ , and  $N_2O$ . The EEA source categories include Energy, Industry, Transport, Agriculture, Waste, and Other.

### 9.3 WHAT CANADIAN EMISSIONS ARE PRESENTED?

The criteria air pollutant annual emissions data for Canada were provided by Environment Canada<sup>3</sup> for 1995. Emissions were provided for CO,  $NO_x$ , VOC,  $SO_2$ , TP,  $PM_{10}$ , and  $PM_{2.5}$ . Table 9-14 presents the emission estimates for Canada by major source category. Table 9-15 presents the emissions for Canada by Province.

#### Table 9-2. 1996 Emission Estimates for Austria and the Czech Republic by CORINAIR/EMEP Source Category and Pollutant (thousand short tons)

Note(s): NA = not available. Totals presented in this table may not equal the sum of the individual source categories due to rounding. Negative emissions represent a sink for greenhouse gas.

### Table 9-3. 1996 Emission Estimates for Denmark and Finland by CORINAIR/EMEP Source Category and Pollutant (thousand short tons)

| Denmark  | SO <sub>2</sub>   | NOx   | NMVOC  | CO  | NH <sub>3</sub>                         |
|--|---|---|--|---|---|

Note(s): NA = not available. For several source categories, emissions either prior to or beginning with 1985 are not available at the more detailed level but are contained in the ore aggregate estimate. "Other" categories may contain emissions that could not be accurately allocated to specific source categories. Zero values represent less than 500 short tons/year. In order to convert emissions to gigagrams (thousand metric tons), multiply the above values by 0.9072.

Note(s): NA = not available. For several source categories, emissions either prior to or beginning with 1985 are not available at the more detailed level but are contained in the more aggregate estimate.

"Other" categories may contain emissions that could not be accurately allocated to specific source categories.

Zero values represent less than 500 short tons/year. In order to convert emissions to gigagrams (thousand metric tons), multiply the above values by 0.9072.

Note(s): NA = not available. For several source categories, emissions either prior to or beginning with 1985 are not available at the more detailed level but are contained in the more aggregate estimate. "Other" categories may contain emissions that could not be accurately allocated to specific source categories. Zero values represent less than 500 short tons/year. No data was available after 1984 to weigh the emissions from residential wood burning devices. In order to convert emissions to gigagrams (thousand metric tons), multiply the above values by 0.9072.

# Table A-4. Sulfur Dioxide Emissions (thousand short tons)

| Source Category                       | 1970   | 1975   | 1980   | 1985   | 1988   | 1989   | 1990   | 1991   | 1992   | 1993   | 1994   | 1995   | 1996   | 1997   | 1998   |

Note(s): NA = not available. For several source categories, emissions either prior to or beginning with 1985 are not available at the more detailed level but are contained in the more aggregate estimate.

"Other" categories may contain emissions that could not be accurately allocated to specific source categories.

Zero values represent less than 500 short tons/year. The 1985 fuel combustion, electric utility category is based on the National Allowance Data Base Version 2.11, Acid Rain Division, U.S. EPA, released March 23, 1993. Allocations at the Tier 3 levels are approximations only and are based on the methodology described in section 6.0, paragraph 6.2.1.1. In order to convert emissions to gigagrams (thousand metric tons), multiply the above values by 0.9072.

Note(s): NA = not available. For several source categories, emissions either prior to or beginning with 1985 are not available at the more detailed level but are contained in the more aggregate estimate. "Other" categories may contain emissions that could not be accurately allocated to specific source categories.

Zero values represent less than 500 short tons/year.

No data was available after 1984 to weigh the emissions from residential wood burning devices.

In order to convert emissions to gigagrams (thousand metric tons), multiply the above values by 0.9072.

\* Although geogenic wind erosion emissions are included in this summary table, it is very difficult to interpret annual estimates of PM emissions from this source category in a meaningful way, owing to the highly episodic nature of the events that contribute to these emissions.

\*\* These are the main source categories of PM crustal material emissions. A report by the Desert Research Institute found that about 75% of these emissions are within 2 m of the ground at the point they are measured. Thus, most of them are likely to be removed or deposited within a few km of their release, depending on atmospheric turbulence. temperature, soil moisture, availability of horizontal and vertical surfaces for impaction and initial suspension energy. This is consistent with the generally small amount of crustal materials found on speciated ambient samples. (See reference 6 in Chapter 2.)

### Table A-6. Directly Emitted Particulate Matter (PM<sub>2.5</sub>) Emissions (continued)

Note(s): NA = not available.

"Other" categories may contain emissions that could not be accurately allocated to specific source categories.

Zero values represent less than 500 short tons/year.

In order to convert emissions to gigagrams (thousand metric tons), multiply the above values by 0.9072.

\* Although geogenic wind erosion emissions are included in this summary table, it is very difficult to interpret annual estimates of PM emissions from this source category in a meaningful way, owing to the highly episodic nature of the events that contribute to these emissions.

\*\* These are the main source categories of PM crustal material emissions. A report by the Desert Research Institute found that about 75% of these emissions are within 2 m of the ground at the point they are measured. Thus, most of them are likely to be removed or deposited within a few km of their release, depending on atmospheric turbulence, temperature, soil moisture, initial suspension energy and availability of horizontal and vertical surfaces for impaction. This is consistent with the generally small amount of crustal materials found on speciated ambient samples. (See reference 6 in Chapter 2.)

#### Table A-8. Ammonia (NH<sub>3</sub>) Emissions (continued)

Note(s): NA = not available.

"Other" categories may contain emissions that could not be accurately allocated to specific source categories. Zero values represent less than 500 short tons/year.

In order to convert emissions to gigagrams (thousand metric tons), multiply the above values by 0.9072.

| <ul> <li>15. SUPPLEMENTARY NOTES</li> <li>16. ABSTRACT         The Emission Factor and Inventory Group (EFIG) annually produces a publication on the trends in emissions of criteria pollutants. The emission estimates developed and included in the Emission Trends database have been utilized to support development of the National Particulates inventory, in support of recent evaluations of the particulate matter and ozone NAAQS, in support of the National Air Toxics Assessment, and to satisfy requirements under CAAA406(g). Included in this report are criteria, toxics, biogenics, greenhouse gases, and international criteria emission estimates.     </li> <li>KEY WORDS/DESCRIPTORS: CRITERIA AIR POLLUTANT, EMISSIONS TRENDS, GREENHOUSE GASES, BIOGENICS, AIR TOXICS, INTERNATIONAL EMISSIONS.</li> </ul> |   |  |  |  |  |
