# **PHASE I INVESTIGATION OF DIOXIN/FURAN SOIL LEVELS IN COLUMBUS, OHIO**

**February 22, 1996**

## **SUMMARY**

This report presents results from the analysis of polychlorinated dibenzo-p-dioxins and polychlorinated dibenzofurans (PCDD/PCDF) in 34 soil samples from the area around a municipal Waste-to-Energy (WTE) facility located in Columbus, OH. These samples were analyzed according to U.S. Environmental Protection Agency (EPA) Method 8290 and the Quality Assurance Project Plan (QAPP) established for this project.

## **BACKGROUND INFORMATION**

The U.S. EPA Office of Pollution Prevention and Toxics conducted an initial soil sampling study to characterize site contamination at the Columbus WTE facility. This report provides a perspective on PCDD/PCDF contamination in the soil samples collected for Phase I of this program. Phase II sampling will be directed according to the results from the Phase I samples. These results, and information from previous and concurrent investigations may indicate that more comprehensive sampling efforts are required for future site contamination studies.

## **EXPERIMENTAL PROCEDURES**

The 34 samples were processed in two sets of 17 with a method blank, a matrix spike, matrix spike duplicate, and sample duplicate processed with each set. In addition to these four laboratory quality control (QC) samples, one of the background soils was spiked with PCDD/PCDF at 5 times the method detection limits (MDL) to verify that detection limits were achieved. Method detection limits are 1, 5, and 10 pg/g for the respective tetra, penta/hexa/hepta, and octa congeners. This detection limit (DL) sample was included in the

first sample set. The soil samples and associated QC samples processed in each set, in order of analysis, are as follows:

<u>Set #1:</u>	<u>Set #2:</u>

Approximately 10 g of each soil sample was used to determine percent solids (percent dry weight). Another approximately 10 g of each sample was combined with sodium sulfate for extraction. All samples were spiked with isotopically labeled analogs of fifteen of the seventeen 2,3,7,8-substituted PCDD/PCDF prior to extraction. The samples were extracted for approximately 18 hours with toluene in a Soxhlet apparatus. Extracts were spiked with  $^{37}\text{Cl}_4\text{-}2,3,7,8\text{-TCDD}$  cleanup standard, partitioned against base and acid solutions, and processed through acid/base silica, basic alumina, and carbon AX-21/Celite cleanup columns. Extracts were spiked with 1,2,3,4-TCDD- $^{13}\text{C}_{12}$ /1,2,3,7,8,9-HxCDD- $^{13}\text{C}_{12}$  recovery standard and concentrated to a final volume of 20  $\mu\text{L}$ .

During the final sample preparation steps for the second set of samples, a stop work order was received from EPA. Sample extracts were processed through the carbon column cleanup procedure and were ready for final sample concentration. The extracts, in 100-mL round bottom flasks, were sealed with teflon tape and stored in a refrigerator for 3 weeks until authorization to proceed was received. During this storage period, four sample extracts, S19, S20, S21, and S22, went dry in the round bottom flasks. After reconstituting these four samples with 1 mL of hexane, all of the Set #2 samples were concentrated to a final volume of 20  $\mu$ L as with Set #1.

Sample extracts were analyzed on a VG AutoSpec high resolution gas chromatography/high resolution mass spectrometer (HRGC/HRMS) (Serial #X088, System #6744) in the selected ion monitoring mode on a J&W DB-5 capillary column (Serial #4499117) at an instrument resolution of approximately 10,000 (10 percent valley). A Hewlett Packard 5890 Series II Gas Chromatograph (C128/83) served as the inlet. Data reduction was performed on a VAX station 3100, M38, Model WS42A-BC (Serial #AB11300V6D) using OpusQuan software. The criteria used to identify chromatographic peaks were: (1)  $\geq 2.5$  signal-to-noise ratio; (2) ion abundance ratios within 15% of theoretical values; (3) retention times of native analytes within  $\pm 2$  seconds of  $^{13}\text{C}_{12}$ -labelled internal standards; and (4) no diphenyl ether interferences. Some samples were diluted to reduce chromatographic interference problems. The dilution factor is noted on individual analysis data sheets. Because 2,3,7,8-TCDF is not completely resolved from all other tetra-chlorinated isomers on the DB-5 column, second column confirmation of 2,3,7,8-TCDF levels above 1 pg/g dry weight in the initial analysis was performed on a J&W DB-Dioxin column (Serial #2743516) for 14 samples.

Per the QAPP for this project, the following deviations to Method 8290, which are part of routine sample preparation/analysis in Battelle's Dioxin Laboratory, were employed:

### Sample Preparation

1. The following additional internal standards were added to the samples prior to extraction to improve analytical accuracy:

$^{13}\text{C}_{12}$ -2,3,4,7,8-PeCDF  
 $^{13}\text{C}_{12}$ -1,2,3,6,7,8-HxCDF  
 $^{13}\text{C}_{12}$ -2,3,4,6,7,8-HxCDF

$^{13}\text{C}_{12}$ -1,2,3,4,7,8-HxCDD  
 $^{13}\text{C}_{12}$ -1,2,3,7,8,9-HxCDF  
 $^{13}\text{C}_{12}$ -1,2,3,4,7,8,9-HpCDF

2. A cleanup standard,  $^{37}\text{Cl}_4$ -2,3,7,8-TCDD, was added to the samples prior to processing through cleanup columns to evaluate analyte recovery through cleanup.
3. A 30-mL volume of acid was used for the first acid wash of the sample extract, rather than 40-mL; 20 mL of acid was used for each successive acid wash instead of 40 mL; 15 mL of base was used for the base wash; and 20 mL of distilled water was used instead of the 40 mL of 5% sodium chloride washes.
4. In the acid/base silica column cleanup, a 1-g plug of silica gel was placed between the basic silica and the acid silica layers. In addition, sodium sulfate was added to the top of the column. The column is rinsed with 30 mL of hexane instead of 10 mL. The sample was usually applied in 5 mL of hexane instead of the 2 mL of hexane specified in Method 8290. The column was eluted with 75 mL of hexane instead of 90 mL.
5. In the alumina column cleanup, Sigma basic alumina, WB-2, activity grade I, was used instead of acidic or neutral alumina. For the first elution, the alumina column was rinsed with 15 mL of 3% methylene chloride/hexane instead of 20 mL of hexane. The second elution, containing the PCDD/PCDF, consisted of 40 mL of 50% methylene chloride/hexane instead of 15 mL of 60% methylene chloride/hexane specified in Method 8290.
6. For the carbon column cleanup, the columns did not include plugs of celite at the top and bottom of the carbon/celite packed bed. The carbon column was eluted with 30 mL of toluene instead of 20 mL as specified in Method 8290.

### **Sample Analysis**

1. Commercially-prepared calibration standards at concentrations specified in Method 1613 were used instead of calibration concentrations specified in Method 8290. The Method 1613 calibration concentrations cover a wider range and lower limits for some compounds than the Method 8290 calibration concentrations.
2. Typical injection volume was 0.5  $\mu\text{L}$  or 1  $\mu\text{L}$  instead of 2  $\mu\text{L}$  specified in Method 8290. Acceptable sensitivity (i.e., 1 pg/g detection limit for soil samples) has been demonstrated by Battelle using the smaller injection volume.

## **SAMPLE RESULTS**

Appendix A includes data sheets with analytical results from the initial analysis and associated quality control results. Abbreviated analysis data sheets presenting only sample results are provided in Appendix B. Data sheets in Appendix C present 2,3,7,8-TCDF concentrations from second column confirmation analysis of 14 samples. Where applicable,

results from the 2,3,7,8-TCDF second column confirmation analysis have been inserted into the initial analysis data sheets in Appendices A and B. Please note the following when reviewing these results:

- (1) The "\*" on the data sheets indicates that the analyte was not detected at a concentration above the sample limit of detection.
- (2) The HRGC/HRMS instrumentation was calibrated in the ranges corresponding to analyte levels in the samples of 1.3 to 520 pg/g dry weight for tetra compounds, 6.4 to 2560 pg/g dry weight for penta through hepta compounds, and 13 to 5120 pg/g dry weight for octa compounds. These calibration ranges are based on an average sample dry weight of 7.8 g and a 1- $\mu$ L injection volume. Concentrations below these calibration ranges have been reported; however, accuracy of concentrations outside the calibration range cannot be guaranteed.
- (3) Of the 34 samples, 29 had 2,3,7,8-TCDF concentrations above 1 pg/g dry weight and required second column confirmation analysis. Only 14 of these 29 samples received a second column confirmation analysis due to budget constraints. For those samples which received a second column confirmation run, the 2,3,7,8-TCDF value from the second run has been inserted into the initial data sheet. The 2,3,7,8-TCDF values for the 14 extracts which were processed through the second column confirmation run showed a 25% - 50% decrease from 2,3,7,8-TCDF values obtained in the initial analysis.
- (4) Some samples had polychlorinated diphenyl ether (PCDPE) responses at the same retention time as 1,2,3,4,7,8-HxCDF and 1,2,3,6,7,8-HxCDF. Per Method 8290, Section 7.8.4.4, 1,2,3,4,7,8-HxCDF and 1,2,3,6,7,8-HxCDF peaks could not be identified definitively as PCDF and were therefore not quantified as PCDF.
- (5) The matrix spike recoveries for S34 MS and S34 MSD were calculated using the equation:

$$\% \text{ REC} = 100 (\text{MS conc. found}) / (\text{Spike conc.} + \text{Background conc.})$$

(L. P. Provost and R. S. Elder, "Interpretation of Percent Recovery Data," *Amer. Lab.*, 15(12), pg. 57, 1983). The above equation was employed since the background level of analytes was much higher than the spike level. In this method of calculating percent recovery, the small spike levels are not "lost in the noise" of large background levels.

- (6) Sample S27 had very poor chromatography in the 2,3,7,8-TCDD window which may have affected its detection.

- (7) In some instances an analyte concentration which is slightly below the instrument limit of quantitation (LOQ) has been reported. In these cases, the analyst judged the analyte met Method 8290 identification criteria and so the concentration determined has been reported along with the sample limit of detection (LOD) and the instrument limit of quantitation (LOQ).
- (8) The sample limits of detection shown on the data sheets were calculated according to Method 8290, Section 7.9.5.1.1. For all but two analyses, the LODs achieved were well below the method detection limits outlined in Method 8290 of 1, 5, and 10 pg/g for tetra, penta/hexa/hepta, and octa congeners. The S03 and S03 DL spike samples had to be diluted 1:2 due to chromatographic interferences. As a result, the LODs shown on the data sheets in Appendix A are above the method detection limits for these two samples. The LOD achieved for OCDD in two samples was higher than the method detection limit of 10 pg/g, however, since OCDD was found at much higher levels in background soil samples, this high LOD does not adversely impact the sample results.

## QUALITY CONTROL RESULTS

Appendix C contains summary tables of quality control results for matrix spike, matrix spike duplicate, sample duplicate, standard reference material, and detection limit (DL) samples. In addition, prior method detection limit study results and prior soil SRM results have been provided.

Method Blanks: A method blank was processed with each of the two sample sets to demonstrate freedom from contamination in the laboratory processing and analysis procedures. A 10-g aliquot of sodium sulfate was processed through all extraction, cleanup, and analysis procedures as if it were an actual sample. PCDD/PCDF were not detected or were detected at levels below the sample limits of detection achieved for the background soil samples S03 and S04.

Field Blanks: In order to verify that the reference matrix (playsand) used for field blanks was PCDD/PCDF-free prior to use, a 10-g aliquot of the playsand was spiked with internal standards, extracted, and processed through all cleanup procedures as described for field samples. In addition, an aliquot of methylene chloride was used to rinse the jars in which the

field blanks would be shipped. Both playsand extract and the jar rinsate samples were analyzed and found to be free of PCDD/PCDF. Field blank samples were thus prepared by rinsing new 500-mL jars with methylene chloride, filling about 1/2 full with playsand, and sealing jars with lids and teflon tape.

The field blanks for Phase I sampling effort were samples S01, S17, and S32. In each case, PCDD/PCDF were not detected or were detected at levels well below both the LOQ and below the sample limit of detection achieved for the background soil samples S03 and S04.

Surrogate Internal Standards: Each sample was spiked with  $^{13}\text{C}_{12}$ -labeled analogs of fifteen of the seventeen 2,3,7,8-PCDD/PCDF prior to extraction. Recovery of these internal standards gives an indication of method performance. All internal standard recoveries were within the 40-135 percent limit stated in Method 8290 except for OCDD- $^{13}\text{C}_{12}$  in sample S18 and several internal standards in samples S20 and S23. For sample S23, chromatographic interferences may have caused the low internal standard recoveries. The low recoveries for sample S20 may have resulted from the sample going dry during the storage period required by the stop work order.

Matrix Spike/Matrix Spike Duplicate: A matrix spike (MS) and matrix spike duplicate (MSD) were processed with each sample batch by spiking both samples with a low level of the seventeen 2,3,7,8-PCDD/PCDF and processing through all extraction, cleanup, and analysis procedures.

Spike recoveries for these four quality control samples were 81 to 139 percent with one exception. Recovery of the 1,2,3,7,8,9-HxCDD in the S34 matrix spike and S34 matrix spike duplicate was high and is attributed to polychlorinated diphenyl ether interference. Recoveries of all of the analytes in the S34 MS and S34 MSD were calculated using the equation listed on the data table in Appendix D. The equation was employed since the background level of analytes was much higher than the spike level. In this method of calculating percent recovery, the small spike levels are not "lost in the noise" of large background levels.

Required control limits for matrix spike/matrix spike duplicate agreement were  $\pm 20\%$  relative percent difference (RPD). This control limit was met for both sets of matrix spike/matrix spike duplicates.

Sample Duplicates: One sediment sample was processed in duplicate for both extraction sets. Required control limits for duplicates were less than 25% RPD for analytes at levels greater than ten times the method detection limit. The control limit was met for all analytes in both samples. In S09, RPD greater than 25 percent were obtained for some analytes but in these cases analyte concentrations were less than ten times the method detection limit and in most cases below the instrument limit of quantitation.

Standard Reference Material: One soil standard reference material (Cambridge Isotope Laboratories #EDF-2513) was received with the soil samples, designated S02. This soil SRM was extracted with the first set of samples. Recoveries of the analytes ranged from 86.4% for 1,2,3,6,7,8-HxCDD to 123.5% for OCDD. A table of previous results obtained for this soil SRM can be found in Appendix D.

Detection Limit (DL) Sample: One of the background soils (S03) was used to verify that method detection limits were achieved. Two aliquots of S03, one spiked with PCDD/PCDF at about 5 times the method detection limit (MDL) and one unspiked to serve as its background, were extracted with the first set of samples. The recoveries of the analytes ranged from 75.0% to 117.0%. Recoveries were calculated using the same equation as for the S34 MS/S34 MSD:

$$\% \text{ REC} = 100 (\text{Conc. found}) / (\text{Spike conc.} + \text{Background conc.})$$

(L. P. Provost and R. S. Elder, "Interpretation of Percent Recovery Data," *Amer. Lab.*, 15(12), pg. 57, 1983). The above equation was employed due to the high OCDD background concentration measured in unspiked sample S03. In this method of calculating percent recovery, the small spike levels are not "lost in the noise" of large background levels.

The acceptable recoveries obtained for the DL sample demonstrate that PCDD/PCDF concentrations near the method detection limit can be accurately quantified.
