U.S. Environmental Protection Agency

Foreword

The many benefits of our modern, developing, industrial society are accompanied by certain hazards. Careful assessment of the relative risk of existing and new man-made environmental hazards is necessary for the establishment of sound regulatory policy. These regulations serve to enhance the quality of our environment in order to promote the public health and welfare and the productive capacity of our Nation's population.

The complexities of environmental problems originate in the deep interdependent relationships between the various physical and biological segments of man's natural and social world. Solutions to these environmental problems require an integrated program of research and development using input from a number of disciplines. The Health Effects Research Laboratory, Research Triangle Park, NC and Cincinnati, OH conducts a coordinated environmental health research program in toxicology, epidemiology and clinical studies using human volunteer subjects. Wide ranges of pollutants known or suspected to cause health problems are studied. The research focuses on air pollutants, water pollutants, toxic substances, hazardous wastes, pesticides and non-ionizing radiation. The laboratory participates in the development and revision of air and water quality criteria and health assessment documents on pollutants for which regulatory actions are being considered. Direct support to the regulatory function of the Agency is provided in the form of expert testimony and preparation of affidavits as well as expert advice to the Administrator to assure the adequacy of environmental regulatory decisions involving the protection of the health and welfare of all U.S. inhabitants

This report contains cancer mortality rates and changes in rates for counties of the United States for the time periods of 1950-1959, 1960-1969, 1970-1979. Included are mortality data for each of 35 site-specific cancers for each sex and for white and non-white races. Further, this report ranks counties nationally by percentile (for each cancer site, race, and sex) for their percent change from 1950-1959 to 1970-1979 and for their 1970-1979 age-adjusted death rate Knowledge of these geographic and temporal differences in cancer mortality is useful for generating hypotheses of environmental determinants of human cancer

F Gordon Hueter

Health Effects Research Laboratory

Abstract

With the reduction in deaths from contagious disease during the past century and the reduction in deaths due to cardiovascular diseases during the past decade, the relative importance of cancer mortality has increased. Cancer is the second leading cause of death in the United States, accounting for approximately 400,000 deaths in 1979.

This report contains cancer mortality rates and changes in rates for counties of the United States for 1950-1959, 1960-1969, and 1970-1979. This report includes the number of deaths and cancer mortality rates age-adjusted to the 1970 U.S. population for each of 35 site-specific cancers for four race-sex groups. Further, counties are ranked nationally by percentile for 1970-1979 age-adjusted death rates and for percent change from 1950-1959 to 1970-1979.

Over the three periods covered by this report, there have been marked fluctuations in mortality for several site-specific cancers. Total cancer mortality rates increased 16% for white males and 39% for non-white males. Among the ten major cancer sites, lung cancer mortality increased most noticeably. White male lung cancer mortality increased 116% from 1950-1959 to 1970-1979 and white female lung cancer mortality increased 199%. Non-white lung cancer rates rose even more sharply. Non-white male and female lung cancer mortality increased 185% and 188%.

Cancer mortality data as arranged in this report have many uses. For example the geographic and temporal differences are useful in developing and examining hypotheses concerning the influence of various environmental factors. The degree of consistency of such differences across the four race-sex groups and among the age groups can furnish additional insights into possible causative factors. Elevated rates in even one race-sex group may suggest hypotheses for further investigation.

Acknowledgment

We wish to acknowledge the support and help of the National Center for Health Statistics (NCHS), especially to thank Joyce Scott, June S. Pearce, and Katheryn G. Lyndon, who checked our comparability between the seventh, eighth, and ninth revision of the International Classification of Diseases (ICD) and verified that our classifications and tables matched the format used to code cause of death from the certificates.

We wish to acknowledge the support and help of Ms. Constance Percy, Demographic Analysis Section, Biometry Branch, National Cancer Institute in facilitating the updating of our data base to include 1979 mortality, and to check our comparability between the eighth and ninth revision of the International Classification of Diseases (ICD).

We wish to acknowledge the support and help of members of the USEPA Health Effects Research Laboratory, especially Drs. Carl Hayes, Robert Chapman, and William Nelson for their encouragement, critical reviews, and suggestions, and Drs. Victor Hasselblad and John Creason for their review of the statistical procedures and suggestions.

We wish to acknowledge other scientists for their technical reviews and helpful suggestions, especially Dr. Donald F. Austin, Resource for Cancer Epidemiology Section, California Department of Health Services; Dr. John F. Finklea, Department of Public Health, University of Alabama in Birmingham; Drs. Clark Heath, Jean French, Roy Ing, Brian Plikaytis, and Mathew Zack, Centers for Disease Control; and Drs. Kenneth G. Manton and Max A. Woodbury, Center for Demographic Studies and Medical Center, Duke University.

Section 1

Introduction and Summary

Introduction

With the reduction in deaths from contagious diseases during the past century and the reduction in deaths due to cardiovascular diseases during the past decade, the relative importance of cancer mortality has increased. Cancer is the second leading cause of death in the United States, accounting for approximately 400,000 deaths in 1979 (1,2). The increase in cancer deaths over the past three decades has been accompanied by increased cigarette consumption, industrial expansion, increased use of private automobiles and other modes of transportation, and growth in chemical production, as well as changes in life style, occupation, and many advances in the knowledge, detection, and treatment of cancer (1,3,4,5). However, the lag time between exposure and clinical diagnosis suggests that the relevant exposure for current cancer deaths may have occurred 10, 15, 20 or more years in the past.

The geographic distribution of cancer has been used for various epidemiologic purposes. "U.S. Cancer Mortality by County: 1950-1969" by Mason and McKay provided 20-year average cancer mortality rates by county (6). In this publication, and also in the two companion atlases by Mason *et al.*, the importance of analyses of county mortality data is discussed (7,8). The three publications have been most useful in identifying high-risk areas, allowing correlational analyses to suggest potential risk factors, and selecting areas for further cancer studies.

We provide a similar approach for screening county mortality data; but in place of 20-year average rates, we present cancer mortality rates for counties in the United States for three decades: 1950-1959, 1960-1969, and 1970-1979. These additional data include: cancer mortality rates for each of the three decades; percent change in rates between each of the decades; percentile rank of counties for percent change between 1950-1959 and 1970-1979; percentile rank of counties by average annual cancer death rates for 1970-1979. We use an asterisk to identify counties with observed number of deaths significantly larger than the expected.

Major Results

The present report collates virtually all reported cancer deaths in the United States from 1950 through 1979, a 30-year period. More than 8 million cancer deaths occurred during this period. These results may be subject to various interpretations, yet certain features of the data are unmistakable.

Over the three decades covered by this report, there have been marked fluctuations in mortality for several site-specific cancers. Some of these changes have involved all four race/sex groups, while others have been race and/or sex specific. Total cancer mortality rates increased 16% for white males and 39% for non-white males. Female cancer mortality rates declined slightly for whites and remained virtually unchanged for non-whites.

Among the ten major cancer sites, lung cancer mortality increased most noticeabaly. White male lung cancer mortality increased 116% from 1950-1959 to 1970-1979 and white female lung cancer mortality increased 199%. Non-white lung cancer rates rose even more sharply. Non-white male and female lung cancer mortality increased 185% and 188%. Interestingly, the largest part of this increase occurred between the first two periods for white and non-white males, while this increase occurred between the second and third periods for female lung cancer mortality. We observed consistent increments in pancreatic cancer mortality for all race/sex groups. Increments were 17% and 14% for white males and females, while non-whites experienced greater increases of 37% and 47%. Mortality from cancer of the large intestine increased among white males (17%), non-white males (61%), and non-white females (24%). Only white females experienced a decline (9%) for this site. Stomach cancer mortality continued to decline. All four race/sex groups experienced a decrement of greater than 40% from 1950-59 to 1970-79. Rectal cancer also declined for all race/sex groups. For this site, the decrements for white males, white females, non-white males, and non-white females were 36%, 44%, 19%, 38%, respectively.

Marked changes over time also occurred for several less common cancer sites. Most striking among these changes was the large increment in multiple myeloma. Mortality from this cause of death increased sharply for white males (85%) and females (78%), and even more sharply for non-white males (141%) and females (140%). Melanoma mortality continued to rise in the four race-sex categories, white males (88%), white females (51%), non-white males (49%), and non-white females (15%). Laryngeal cancer mortality rose only slightly for white males (5%), but white females (53%) and especially non-white males (68%) and females (54%) exhibited larger increases. Esophageal cancer showed little change for whites, but non-whites experienced increments of 53% and 65% for males and females, respectively. Less common cancer sites characterized by decreasing mortality included cancer of the bone and, for females, cancer of the uterine corpus. Bone cancer mortality declined 41%, 43%, 32%, and 46% among the four race/sex groups. Mortality from cancer of the chorion and uterus declined 46% for whites and 57% for non-whites.

Uses of These Tables

The mortality rates and percent change in mortality rates in this report may be used for various epidemiologic studies and purposes. These data may be used to identify counties and groups of counties with high cancer mortality rates, with large increments in cancer mortality, or both. A second use of these data would be to locate counties with unique demographic, environmental, and industrial characteristics and determine if they had remarkable mortality rates and mortality trends. High mortality rates and high percent change in mortality rates occurring in both sexes suggests a possible connection with an environmental exposure or other risk factors unrelated to sex, while high mortality rates among men only suggest the existence of occupational or other sex-related risk factors. An indicated use of this report, then, along with other secondary data on ambient environmental pollution levels or emission data, demographic characteristics, etc., follows the step-wise cancer research approach as described by Blot *et al.* (9).

Researchers may use this report to identify counties and groups of counties for developing and implementing a detailed monitoring program of ambient environmental pollutants, or for performing in depth field studies, e.g., cancer case control studies. Whether the study is an environmental monitoring or an epidemiologic field study, this report provides a method of screening cancer mortality data to select areas most suitable for study.

Another important use of this report will be as a ready reference for EPA and other governmental agencies, state and local health departments, universities, and citizens' groups. When local communities are concerned about a specific cancer situation, this report provides an historic data base with which to compare the current local conditions. Thus, this data base is an important resource for responding to community questions and concerns.

Considerations in Application

The many uses and strengths of these cancer mortality data have just been discussed. There are also several characteristics that users should bear in mind in using these data. The major characteristics are related to the accuracy and completeness of the death certificate information, the effects of changes over time in classification, coding and population characteristics and the effects of migration and latent period of disease.

Several studies have compared the diagnostic classification information on the death certificate to diagnostic information from other sources such as hospital records or autopsy results (10,11,12).These studies have generally shown the overall agreement between diagnosis and underlying cause of death to be very high for the most frequent causes of mortality. Studies of completeness and consistency of the demographic information on the death certificate have also shown high agreement (11). Although these results are very encouraging, the user should be aware of potential limitations in interpretation.

Studies of temporal trends in cancer mortality require recognition of possible effects of the decennial revisions of the International Classification of Diseases (ICD) during the 30 year span of our study. We discuss our treatment of the comparability issue in Section 3,C. We generated equivalent codes for the sixth, seventh, eighth and ninth edition of the ICD.

In Section 3,A. we discuss our method to establish fixed equivalent county boundaries over the 30 years.

The rapid scientific development in medical diagnostic practice over the 30 years have increased the precision of identifying site specific cancers. At the level of aggregation used in this report, this characteristic should have little effect on the results for most cancer sites; however, users should be aware of this characteristic in using these data.

Population distribution by age, sex, and race affects cancer mortality. In Section 3,B. we discuss our use of the total U.S. population for 1970 as the standard for 1950-1979. Population proportions of the above demographic characteristics not only vary across counties but vary over time within counties due to migration, births, deaths and possibly changes in competing risks of death (13-14). The effect of relative changes in these factors is complicated by the relatively long latent period between exposure and appearance for most types of cancer. Therefore, hypotheses concerning cause and effect relationships deserve careful, and cautious, consideration.

A final reminder is that these cancer mortality data are presented in terms of geographic risk. Our major purpose is to examine the spatial and temporal differences in order to generate hypotheses about possible environmental factors. In this respect, this report differs from those studies which have been concerned with the temporal trend in cancer rates per se, such as Pollack and Horm (2).

Many of these characteristics have been discussed in more detail elsewhere in the literature (10-14). These data are the prime source in documenting geographic patterns of cancer rates and trends over the 30 year period. With these characteristics in mind, we believe these new mortality data can provide a fresh perspective to the assessment of cancer mortality differences.

Section 2

Materials and Methods

A. Source and Description of Data

This report uses data from both the National Center for Health Statistics (NCHS) and the Bureau of Census.

1. Death Records - General Characteristics:
   - Years available: We have virtually all cancer death records for 1950-1979.
   - International Classification of Diseases: We used ICD codes from the ninth revision for 1979 mortality and in our tables, and the table of contents. NCHS used the International Classification of Diseases adapted for use in the United States (ICDA) instead of the unmodified ICD codes from the eighth revision to classify and code the underlying cause of death for years 1968-1978 (15). The comparability tables follow NCHS practice in use of ICD for edition 6, 7, 9, and ICDA for edition 8. We have used ICD in place of ICDA when referring to editions other than 8, when referring to two or more editions, and in general discussion.
   - Each death record contains the county of residence, year and month of death, age in years, race (white or non-white), sex, and ICD rubric. For more detail on death records see Technical Appendix from Vital Statistics of the United States 1977 and other years (16).
2. Death Records - Special Characteristics:
   - Mortality data as coded for 1952 combined five boroughs of New York City. We used the average ratio for years 1950, 1951, 1953, and 1954 of each borough in New York City to estimate 1952 deaths in each borough.
   - New Jersey did not code race in 1962 and 1963. F. W. McKay, National Cancer Institute, gave us the estimates he used in their publications (6,7,8).
   - We include all cancer deaths during 1972 even though Vital Statistics of the United States 1972 used only a 50 percent sample in their publication (16).
   - Over the 30 years covered in this report, the International Classification of Diseases (ICD) has undergone four revisions: sixth, seventh, eighth, and ninth. We have included a table of comparative ICD codes from each revision. Also in the table, codes from the sixth and seventh editions are grouped together because for our purposes they are essentially identical. For comparability over the 30 years, we did not include Polycythemia Vera or Myelofibrosis (ICDA 208, 209) since only the eighth edition classified these as cancer.
3. Population records:
   - Census years 1950, 1960, 1970, 1980.
   - Detail: By county, race, and sex, 5 year age groups through 84, and 85+.
   - Population 1950 census: Available 1950 Bureau of Census population for each county, race, and sex were for 5 year age groups through 74, 75-85, and 85+. In order to make the 1950 county counts consistent with 1960, 1970, and 1980 data, we used the U.S. race and sex specific counts for age 75-79, and 80-84 from the U.S. Bureau of Census 20% enumeration sample to estimate the percent of age 75-84 age group who were in the 75-79 age group. Using this percentage, we estimated the county counts in the 75-79 age group and assigned the residual to the 80-84 age group.
   - Interpolation between census years: We used a simple linear interpolation to generate mid-year population estimates between census years.
4. Geographic detail:
   - "County" as used in this report refers to a county, parish in Louisiana, independent city, or a combination of counties as shown in technical notes.
   - Through the years, political area changes have taken place. In many cases, the only way to keep a consistent geographical area was to combine counties. This is especially evident in Virginia where independent cities have annexed parts of counties. Details of these changes are given in the technical notes on changes and combination of counties.

B. Calculations

1 Average annual age-adjusted mortality rate:

- We calculated annual age-adjusted mortality rates (per 100,000) for counties listed on the death certificate as the county of usual residence by cancer site, race, and sex with the total U.S. age, specific population for 1970 used as the standard for the total study period 1950-1979. The table in Section 3B presents the standard million population used in this study. This report contains rates for each of the contiguous states for 1950-1979. We added Alaska and Hawaii rates for 1960-1979. The District of Columbia has been included as a

separate entity which is listed both as a state and a county.

- Formula for average annual age-adjusted death rate per 100,000:

$$S(i,y) = D(i,y)/R(i,y)$$

$$A(y) = \sum_{i=1}^{n} S(i,y)\,P(i)(100{,}000) / \sum_{i=1}^{n} P(i)$$

$$A(d) = \sum_{y=1}^{m} A(y)/m$$

S(i,y) = Age-specific death rates in age group i, year y.
D(i,y) = Number of deaths in age group i, in year y.
R(i,y) = Mid-year population in age group i, in year y.
A(y) = Age-adjusted death rate per 100,000 in year y.
P(i) = Number of age group i in the standard population (1970 U.S. population).
A(d) = Average annual age-adjusted death rate per decade.
y = Year index.
i = Age index.
n = Number of age groups (18 age groups: 0-4, 5-9, 10-14, 15-19, 20-24, 25-29, 29-34, 35-39, 40-44, 45-49, 50-54, 55-59, 60-64, 65-69, 70-74, 75-79, 80-84, 85+).
m = (10), number of years in period.
d = Decade (i.e., 1950-1959, 1960-1969, or 1970-1979).

2. Expected number of deaths:

- Expected number of deaths for each race, sex group by year are calculated by multiplying the U.S. age-specific death ratio for each age interval by the county population of the specific age group, adding over all age groups, and then adding over all years in each time period (1950-1959, 1960-1969, 1970-1979).
- Formula for the expected number of deaths for each race, sex, cancer site, county, and the year:

$$E(k,j,y) = \sum_{i=1}^{18} D(i,j,y)\,P(i,k,y)/P(i,y)$$

y = year index (i.e., 1950, 1951, ..., 1979)
i = age index (i.e., 0-4, 5-9, 10-14, ..., 80-84, 85+)
k = county index
j = cancer site index

E(k,j,y) = Expected number of deaths in the kth county from the jth cancer site in the yth year.
D(i,j,y) = Number of deaths in the U.S. from the jth cancer site, in the ith age group, in the yth year.
P(i,y) = The U.S. population in the ith age group in the yth year.
P(i,k,y) = The population in the ith age group, kth county, and the yth year.

$$E(k,j) = \sum_{y=1}^{m} E(k,j,y) = \lambda$$

λ = Expected number of deaths in the kth county from the jth cancer site for the decade.
m = Number of years in the decade.

- Given the expected number of deaths λ, use the function below to calculate the probability that the number of deaths is less than the observed number n.

$$\text{Prob}(X \leq n) = \sum_{X=0}^{n} (\lambda^{x} e^{-\lambda})/X!$$

n = number of observed deaths

- If the Prob($X \leq n$)$>$.975, flag the county as being statistically significant. This deviation is the upper limit of a 95% confidence interval.
- For counties with 36 or more deaths for a cancer site in a decade (1950-1959, 1960-1969, 1970-1979), we used the normal approximation for the interval of the expected value of a poisson variable (17). Formula for calculating the upper confidence limit:

$$U = \lambda + 1/2 + 3/8\,z^2 + z(\lambda + 1/2 + 1/8\,z^2)^{0.5}$$

U = Upper confidence limit
λ = expected number of deaths
z = 1.96 for the 95% confidence interval.

- Counties with an observed number of deaths larger than the upper confidence limit are identified by an asterisk in the table.

3. Percent change in mortality rates:

- In the process of generating percent change in death rates, we generated total deaths and rates for each decade, percent change from 1950-1959 to 1960-1969, from 1960-1969 to 1970-1979 and from 1950-1959 to 1970-1979. For each race and sex, counties are percentile ranked for percent change from 1950-1959 to 1970-1979 and percentile ranked for average rate per 100,000 for 1970-1979. There may be up to 31 counties in a percentile. This report is presented in three separate volumes. These volumes have cancer sites arranged by ICD number in sequential order as found in the ICD ninth edition.

4. Special cases (which were rare) are dealt with as follows:

   - If any age group the population is less than the number of deaths, the population is increased to the number of deaths. This occurs in small populations if deaths occur before census count or due to anomolies of population estimates.
   - Percent change must have a non-zero age-adjusted death rate for both numerator and denominator to be printed. This restriction also holds for ranking of percent change between 1950-1959 and 1970-1979.
   - Death records with unknown age or other missing information were omitted from the calculations.

5. Methods for ranking counties.

   - Calculation of percentile rank of rate per 100,000 population for 1970-1979 includes all counties with a rate of zero or greater listed in the tables.
   - Calculation of percentile rank for percent change in rates from 1950-1959 to 1970-1979 includes all counties with percent changes listed in the table Both of the rankings include all counties less those left blank or not printed. The formula is:

$$PC = 100\,(R)/(NCR + 1)$$

where PC = percentile
R = rank given
NCR = number of counties ranked (i.e., 3065 counties for the 1970-1979 rate or less for percent change)

   - The United States and individual states are not included in the ranking.

C. Report Page Layout

1. Clarification of table headings:

- The first row of the heading contains, from left to right, the race and sex, the name of site-specific cancer, and the ICD code from the ninth revision;
- Columns headed "Deaths" and "Rate" under 1950-1959, 1960-1969, and 1970-1979 contain the total number of deaths and age-adjusted average annual death rate per 100,000 occurring during each period;
- An asterisk indicates that the observed number of deaths in a specific county is significantly larger than the expected number of deaths;
- The center column lists the United States, each state, and county in alphabetical order under the state with independent cities within the state at the end of all counties;
- Columns headed 60S/50S, 70S/60S, and 70S/50S under percent change indicate the percent change in mortality rate between 1950-1959 and 1960-1969, 1960-1969 and 1970-1979, and 1950-1959 and 1970-1979; and
- Columns headed 70S/50S and 1970S under percentile contain the percentile rank of counties for the percent change between 1950-1959 and 1970-1979 and the percentile rank of counties for the average annual rate for 1970-1979. Percentiles range from 99 for the highest to 00 for the lowest.

2. Explanation of blank entries in the table:

   - In case of no deaths in a decade, the period is left blank.
   - In case of no deaths from a site specific cancer in the 30 year period, the line is not printed.

Section 3

Technical Notes

A. Area Recodes and Combination of Counties

Changes in boundaries during the 30 year period made it necessary to combine counties and cities to have a defined area which would not change over the period. When changes in boundaries involve negligible percentage of the population in the areas, we did not combine areas. Virginia, with independent cities located outside and frequently between counties, has required the most adjustment. The following areas are combined:

1. Alaska—entire state
2. Colorado
   Denver includes Arapahoe County.
3. Georgia
   Muscogee County includes Chattahoochee County
4. Hawaii
   Maui County includes Kalawao County.
5. Montana
   Park County includes the Montana portion of Yellowstone National Park.
6. South Dakota
   a. Dewey County includes the former Armstrong County.
   b. Jackson County includes the former Washabaugh County.
7. Virginia-Counties
   a. Albemarle County includes Charlottesville.
   b. Alleghany County includes Clifton Forge, and Covington.
   c. Arlington County includes the city of Falls Church.
   d. Augusta County includes the cities of Staunton and Waynesboro.
   e. Bedford County includes Campbell County and the cities of Lynchburg and Bedford.
   f. Carroll County includes Galax City and Grayson County.
   g. Chesterfield County includes the cities of Richmond and Colonial Heights.
   h. Dinwiddie County includes Prince George County and the cities of Petersburg and Hopewell.
   i. Fairfax County includes the cities of Alexandria and Fairfax.
   j. Frederick County includes Winchester City.
   k. Greensville County includes the city of Emporia.
   l. Halifax County includes the city of South Boston.
   m. Henry County includes Martinsville City.
   n. James City County includes York and New Kent Counties, and the cities of Williamsburg, and Poquoson.
   o. Montgomery County includes Radford City.
   p. Pittsylvania County includes Danville City.
   q. Prince William County includes Manassas and Manassas Park.
   r. Roanoke County includes Roanoke and Salem cities.
   s. Rockbridge County includes the cities of Buena Vista and Lexington.
   t. Rockingham County includes Harrisonburg City.
   u. Southampton County includes Franklin City.
   v. Spottsylvania County includes Fredericksburg City.
   w. Washington County includes Bristol City.
   x. Wise County includes Norton City.
8. Virginia-cities
   a. Chesapeake includes the counties of Norfolk and Princess Anne, and the cities of Norfolk, Portsmouth, South Norfolk, and Virginia Beach.
   b. Hampton City includes Elizabeth City County.
   c. Newport News City includes Warwick.
   d. Suffolk City includes Nansemond County.
9. Wisconsin
   Menominee County includes Oconto and Shawano Counties
10. Wyoming
    Park County includes Teton County and the Wyoming portion of Yellowstone National Park.

B. Standard Million Population

The standard population used is the total 1970 U.S. population as shown below.

United States
Standard Million Populations by Age for 1970

Age	Population
All ages	1,000,000
<5	84,416
5-9	98,204
10-14	102,304
15-19	93,845
20-24	80,561
25-29	66,320
30-34	56,249
35-39	54,656
40-44	58,958
45-49	59,622
50-54	54,643
55-59	49,077
60-64	42,403
65-69	34,406
70-74	26,789
75-79	18,871
80-84	11,241
85+	7,435

C. Constructing Equivalent Cause of Death Categories Across Years

The rates and trends generated in the present work cover 30 years spanning four editions of the ICD. This long time span required achieving comparability between time periods covered when different rules of classification of underlying cause of death were in effect. We did not want to create artifically increased rates by attributing deaths to a site specific cancer solely because of a change in classification rules. To avoid this potential artifact, we developed comparability codes for translation between the 6th, 7th, 8th, and 9th edition (revision) of the International Classification of Diseases (see table below).

Several authors have attempted to create equivalencies between editions of the ICD (18,19,20). The National Center for Health Statistics conducted the most intensive studies to test comparability by generating comparability ratios. However, for some cancer sites no absolute equivalence can ever be achieved. At the level of aggregation we are using, this should present few problems since whatever effects remain should apply equally to all counties. However, users of these data should keep in mind potential problems relating to coding in equivalencies.

Cancer Site Comparability Table

Cancer Site	ICD 9	ICDA 8	ICD 6* & 7
Lip	140	140	140
Oral cavity including tongue	141,143-146,148,149	141,143-146,148,149	141,143-145,147,148
Salivary gland	142	142	142
Nasopharynx	147	147	146
Esophagus	150	150	150
Stomach	151	151	151
Large intestine	153,159.0	153	153
Rectum	154 except 154.3	154	154
Liver and gallbladder including bile ducts	155,156	155,156,197.8	155*
Pancreas	157	157	157
Nose, nasal cavities, middle ear and accessory sinuses	160	160	160
Larynx	161	161	161
Trachea, bronchus and lung including pleura and other respiratory sites	162,163,165	162,163.0, 163.9	162,163
Bone including jaw	170	170	196
Connective and soft tissue	164.1,171	171,192.4,192.5	197,193.3,193.4**
Malignant melanoma of skin	172	172	190
Nonmelanoma skin cancer	173,154.3	173 except 173.5	191
Breast	174,175	174	170
Cervix uteri	180	180	171

Cancer Site Comparability Table

Cancer Site	ICD 9	ICDA 8	ICD 6* & 7
Chorion, corpus uterus and uterus not otherwise specified	179,181,182	181,182	172,173,174
Ovary, fallopian tube and broad ligament	183	183	175
Prostate	185	185	177
Testis	186	186	178
Bladder and other urinary organs	188,189.3	188,189.9	181
Kidney and ureter	189 except 189.3	189.0,189.1,189.2	180
Eye	190	190	192
Brain and other parts of the nervous system	191,192	191,192 except 192.4 & 192.5	193 except 193.3 & 193.4*
Thyroid gland	193	193	194
Thymus and other endocrine glands	194,164.0	194	195
Lymphosarcoma and reticulum cell sarcoma including other lymphoma	159.1,200,202 except 202.2-.6	200,202	200,202,205
Hodgkin's disease	201	201	201
Multiple myeloma	203 except 203.1	203	203
Leukemias	204-208,202.4,203 1	204-207	204
Secondary, site unspecified and not previously listed cancers	152,158,159.2-.9,164 2-.9, 184,187,195-199, 202.2,.3,.5,.6	152,158,159,163.1,173.5 184,187,195,196,197 0-.7, 197.9,198,199	152,156,158,159,164 165,176,179,198,199
All cancers	140-208	140-207	140-205

*Code 156 ICD 6 and 7 secondary and unspecified cannot be separated. For this reason, death rates for 1950-1959 and 1970-1979 are not comparable and the comparison should not be used

**Code 193 ICD 6 cannot be subdivided. For this reason deaths from malignant neoplasm of brain and other parts of the nervous system for years 1950-1957 contain deaths from malignant neoplasm of peripheral nerves and sympathetic nervous system.
