## ACKNOWLEDGMENTS

WAPORA, Incorporated wishes to acknowledge the invaluable assistance, comments and criticisms received from many individuals during the course of this inspection manual's preparation and field testing. Those in the industrial sector providing the greatest amount of help include Messrs. W. Rakita and G. Schnabel of Rohm and Haas; F. Winterkamp and G. Lamb of DuPont; E. Fike and C. Reich of Fike Chemical; H. Kabernagel and W. King of FMC; H. Karawan, H. Coombs and R. Foster of Union Carbide; C. Strauss and L. Mattioli of Allied Chemical; G. Strickler and C. Dilmore of PPG; R. Weicker, H. Klotz and L. Mount of Nease Chemical; and C.E. Cooper of Borg-Warner. In addition, of those in the state and local environmental regulatory agencies offering assistance, the Maryland Bureau of Air Quality's Messrs. G. Ferreri and J. McQuade were most helpful in explaining the development of their toxic substances control program. Finally, WAPORA gratefully acknowledges the guidance and assistance rendered throughout this manual's development by the EPA Project Officer, Mr. Abraham Ferdas.

## CHAPTER 1

### INTRODUCTION

This Inspection Manual for Toxic Air Pollutant Emissions has been prepared in order to aid air pollution control agency surveillance personnel in their inspections of facilities that manufacture or process certain chemical substances that may be released into the atmosphere and subsequently threaten human health or other aspects of the environment. Since it is recognized that most air pollution inspectors are neither degreed chemical engineers nor experienced in the chemical process industries, this manual presupposes only a knowledge of air pollution fundamentals and elementary principles of chemistry on the part of the user. Nevertheless, it is hoped and intended that the information presented in this document will also prove to be useful to many of the more experienced control agency personnel who must deal with toxic substance problems.

In the absence of directly applicable source facility emission regulations (except in the cases of those few industries regulated by the National Emission Standards for Hazardous Air Pollutants, or by similarly-designed state standards - cases considered to be outside the scope of this manual), the inspector's job as related to toxic substances can be an extremely difficult one. Although the Clean Air Act and State Implementation Plan air pollution prohibitions apply to all air contaminants adversely affecting human health or welfare, demonstrating that observed effects are attributable to a specific emission source is a task that cannot ordinarily be accomplished by an inspector alone, and more often cannot be accomplished at all.

The Toxic Substances Control Act (Public Law 94-469) may provide some degree of relief from such difficulties through the provisions of Section 6, "Regulation of Hazardous Chemical Substances

and Mixtures," which allows the EPA to propose and adopt rules to prevent any "unreasonable risk of injury to health or the environment"; Section 7, "Imminent Hazards," which allows the EPA to immediately commence court action to prevent any "imminent and unreasonable risk of serious or widespread injury"; and other sections. It is conceivable that field inspectors may become involved in the implementation of this act, but this matter is beyond the scope of this manual.

Because of the great significance of the general lack of toxic substance emission standards to the field investigator, the first post-introductory chapter of this manual is devoted to a discussion of his authority to conduct toxic substance emission inspections, and of the limits that have been placed upon that authority.

While the purpose of preparing this document was not to develop a definition of toxicity, which could be a very complex task indeed, it was nevertheless necessary to describe what is meant by the term toxic substance as used in this manual. A chapter has also been devoted to this important point.

The subjects of the remaining chapters are emission sources; control techniques; start-ups, malfunctions and shut-downs; instrumentation, monitoring, record-keeping and reporting; and, most important, field investigations, including discussions of the inspection procedures to be employed and the forms to be completed.

## CHAPTER 2

### AUTHORITY TO INSPECT

The primary source of authority for conducting facility inspections is set forth in the Clean Air Act under Section 114, entitled "Inspection, Monitoring, and Entry." Although there are (with few exceptions) no specific toxic substance implementation plan provisions, standards of performance, or emission standards with which compliance may need to be determined, Section 114 also authorizes inspections for the purposes of "developing or assisting in the development of" such plans and standards, and carrying out Section 303, "Emergency Powers."

Since the effectiveness of an emission regulation is ordinarily highly dependent on its enforceability through a field surveillance program, the need for conducting inspections as regulations are developed is apparent; however, in order to insure that the field inspection experience gained is actually utilized in the development of regulations, those responsible for such activities should be kept informed of inspection plans and programs, requested to provide comments and suggestions, and provided with copies of inspection reports. In this way, the need to duplicate inspection visits will be avoided, and regulations will not need to be drafted, proposed or promulgated without the benefit of sufficient field experience to insure their enforceability simply because of the lack of time to initiate a trial inspection program, or the lack of knowledge that an inspection program has been on-going.

The justification for inspections needed to carry out the provisions of Section 303 of the Clean Air Act should require no elaboration here. Similarly, the penalties provided under Section 113, "Federal Enforcement," that are applicable to cases in which field investigators are refused

access (see paragraph 113(b)(4)) need not be dwelled upon. The sections of the Clean Air Act discussed above are presented as Exhibit 2-1.

## SELECTED SECTIONS OF THE CLEAN AIR ACT

## "FEDERAL ENFORCEMENT"

"SEC. 113. (a) (1) Whenever, on the basis of any information available to him, the Administrator finds that any person is in violation of any requirement of an applicable implementation plan, the Administrator shall notify the person in violation of the plan and the State in which the plan applies of such finding. If such violation extends beyond the 30th day after the date of the Administrator's notification, the Administrator may issue an order requiring such person to comply with the requirements of such plan or he may bring a civil action in accordance with subsection (b).

"(2) Whenever, on the basis of information available to him, the Administrator finds that violations of an applicable implementation plan are so widespread that such violations appear to result from a failure of the State in which the plan applies to enforce the plan effectively, he shall so notify the State. If the Administrator finds such failure extends beyond the thirtieth day after such notice, he shall give public notice of such finding. During the period beginning with such public notice and ending when such State satisfies the Administrator that it will enforce such plan (hereafter referred to in this section as 'period of Federally assumed enforcement'), the Administrator may enforce any requirement of such plan with respect to any person—

"(A) by issuing an order to comply with such requirement, or

"(B) by bringing a civil action under subsection (b).

"(3) Whenever, on the basis of any information available to him, the Administrator finds that any person is in violation of section 111(e) (relating to new source performance standards) or 112(c) (relating to standards for hazardous emissions), or is in violation of any requirement of section 114 (relating to inspections, etc.), he may issue an order requiring such person to comply with such section or requirement, or he may bring a civil action in accordance with subsection (b).

"(4) An order issued under this subsection (other than an order relating to a violation of section 112) shall not take effect until the person to whom it is issued has had an opportunity to confer with the Administrator concerning the alleged violation. A copy of any order issued under this subsection shall be sent to the State air pollution control agency of any State in which the violation occurs. Any order issued under this subsection shall state with reasonable specificity the nature of the violation, specify a time for compliance which the Administrator determines is reasonable, taking into account the seriousness of the violation and any good faith efforts to comply with applicable requirements. In

any case in which an order under this subsection (or notice to a violator under paragraph (1)) is issued to a corporation, a copy of such order (or notice) shall be issued to appropriate corporate officers.

"(b) The Administrator may commence a civil action for appropriate relief, including a permanent or temporary injunction, whenever any person—

"(1) violates or fails or refuses to comply with any order issued under subsection (a); or

"(2) violates any requirement of an applicable implementation plan during any period of Federally assumed enforcement more than 30 days after having been notified by the Administrator under subsection (a) (1) of a finding that such person is violating such requirement; or

"(3) violates section 111(e) or 112(c); or

"(4) fails or refuses to comply with any requirement of section 114.

Any action under this subsection may be brought in the district court of the United States for the district in which the defendant is located or resides or is doing business, and such court shall have jurisdiction to restrain such violation and to require compliance. Notice of the commencement of such action shall be given to the appropriate State air pollution control agency.

"(c) (1) Any person who knowingly—

"(A) violates any requirement of an applicable implementation plan during any period of Federally assumed enforcement more than 30 days after having been notified by the Administrator under subsection (a) (1) that such person is violating such requirement, or

"(B) violates or fails or refuses to comply with any order issued by the Administrator under subsection (a), or

"(C) violates section 111(e) or section 112(c)

shall be punished by a fine of not more than \$25,000 per day of violation, or by imprisonment for not more than one year, or by both. If the conviction is for a violation committed after the first conviction of such person under this paragraph, punishment shall be by a fine of not more than \$50,000 per day of violation, or by imprisonment for not more than two years, or by both.

"(2) Any person who knowingly makes any false statement, representation, or certification in any application, record, report, plan, or other document filed or required to be maintained under this Act or who falsifies, tampers with, or knowingly renders inaccurate any monitoring device or method required to be maintained under this Act, shall upon conviction, be punished by a fine of not more than \$10,000, or by imprisonment for not more than six months, or by both.

#### "INSPECTIONS, MONITORING, AND ENTRY

"SEC. 114. (a) For the purpose (i) of developing or assisting in the development of any implementation plan under section 110 or 111(d), any standard of performance under section 111, or any emission standard under section 112(ii) of determining whether any person is in violation of any such standard or any requirement of such a plan, or (iii) carrying out section 303—

"(1) the Administrator may require the owner or operator of any emission source to (A) establish and maintain such records, (B) make such reports, (C) install, use, and maintain such monitoring equipment or methods, (D) sample such emissions (in accordance with such methods, at such locations, at such intervals, and in such manner as the Administrator shall prescribe), and (E) provide such other information, as he may reasonably require; and

"(2) the Administrator of his authorized representative, upon presentation of his credentials—

"(A) shall have a right of entry to, upon, or through any premises in which an emission source is located or in which any records required to be maintained under paragraph (1) of this section are located, and

"(B) may at reasonable times have access to and copy any records, inspect any monitoring equipment or method required under paragraph (1), and sample any emissions which the owner or operator of such source is required to sample under paragraph (1).

"(b) (1) Each State may develop and submit to the Administrator a procedure for carrying out this section in such State. If the Administrator finds the State procedure is adequate, he may delegate to such State any authority he has to carry out this section (except with respect to new sources owned or operated by the United States).

"(2) Nothing in this subsection shall prohibit the Administrator from carrying out this section in a State.

"(c) Any records, reports or information obtained under subsection (a) shall be available to the public, except that upon a showing satisfactory to the Administrator by any person that records, reports, or information, or particular part thereof, (other than emission data) to which the Administrator has access under this section if made public, would divulge methods or processes entitled to protection as trade secrets of such person, the Administrator shall consider such record, report, or information or particular portion thereof confidential in accordance with the purposes of section 1905 of title 18 of the United States Code, except that such record, report, or information may be disclosed to other officers, employees, or authorized representatives of the United States concerned with carrying out this Act or when relevant in any proceeding under this Act.

#### "EMERGENCY POWERS

"SEC. 303. Notwithstanding any other provisions of this Act, the Administrator upon receipt of evidence that a pollution source or combination of sources (including moving sources) is presenting an imminent and substantial endangerment to the health of persons, and that appropriate State or local authorities have not acted to abate such sources, may bring suit on behalf of the United States in the appropriate United States district court to immediately restrain any person causing or contributing to the alleged pollution to stop the emission of air pollutants causing or contributing to such pollution or to take such other action as may be necessary.

## CHAPTER 3

### TOXICITY OF SUBSTANCES

As mentioned in the introductory chapter of this manual, it is not intended to give a general definition of toxicity here; rather, what is meant by the term as used throughout this document will be explained.

Although virtually any material may be considered to be toxic if it is sufficiently concentrated and pervasive, in common air pollution terminology only those gases that are potentially harmful when inhaled at concentration levels of below perhaps 10 parts per million (ppm) by volume in air, or 0.001 percent, are generally regarded as being of significant toxicity. Even so, the description of a material as toxic usually carries the connotation that harmful effects may result from concentrations well below those that are acceptable for the major air pollutants (which include gases such as carbon monoxide, nitrogen dioxide, and sulfur dioxide), for which the National Ambient Air Quality Standards range down to 0.05 ppm. Regarding particulate substances, which are not present in the air as separate molecules and are thus not reported on a parts-per-million basis, a material would not usually be described as toxic if it were not potentially harmful at concentrations well below the 75  $\mu\text{g}/\text{m}^3$  total suspended particulate matter ambient standard.

While Threshold Limit Values (TLV's) and other such standards have been adopted by the Occupational Safety and Health Administration (OSHA) (1) for a significant number of substances (see Exhibits 3-1 and 3-2), comparisons of these occupational exposure guidelines with ambient air quality standards may often prove misleading, and result in a serious underestimation of a material's toxicity. This may be explained by the fact that the

ambient standards are designed to protect a much larger and more varied population (including the very young, the old, and the unusually sensitive) than are the TLV's. As a result, the occupational standards are typically about two orders of magnitude less restrictive than the most stringent (long-term) ambient standards. Some of these relationships are presented in Exhibit 3-3. If one keeps this difference (and its variability) in mind, the TLV compilation can serve as a useful guide to material toxicity in many cases.

One particularly serious shortcoming of relying on TLV's as toxicity indicators is that for the great preponderance of chemicals in use, even those for which toxicity studies have been performed, TLV's have neither been adopted nor proposed. The results of these studies are summarized in the National Institute of Occupational Safety and Health (NIOSH) publication entitled "Toxic Substances List" (2). Unfortunately, the data presented in it (e.g., lethal doses in milligrams per kilogram of body weight for various species of animals) would probably not prove to be very useful to most toxic substance field investigators directly.

Another book, authored by N. Irving Sax and entitled "Dangerous Properties of Industrial Materials" (3), is about as extensive as the NIOSH publication but includes toxicity ratings on a scale of 3 units, with the maximum rating of 3 indicating severe toxicity. Ratings are assigned for both acute and chronic effects, and for different modes of exposure (e.g., inhalation).

For the purposes of a toxic substances air pollution field investigator, the chemical substance could be looked up in the Sax book's alphabetically-ordered listing (which includes cross-referencing in cases of multiple chemical names) and the toxicity rating listed for chronic inhalation exposures could be noted. The reason for the selection of a chronic exposure rating is that this would

almost invariably be the type of effect for which an inspector would be looking. The inhalation mode of exposure is obviously that type which is most closely related to possible air pollution effects. The material in question could be considered to be toxic (as described above) if the rating were a 3; lower ratings could be considered to indicate that the material is not particularly toxic. Such a functional definition of toxicity would of course be imperfect, but would typically be found to approximate the common conception of air pollutant toxicity reasonably well, and to more often be on the conservative side.

For chemical substances for which the letter "U" (for "unknown") is given instead of a numerical toxicity rating, or for which no space for a rating has even been provided, there is frequently a comment, reference to related chemical listings, or other information that may enable the toxicity of the material in question to be estimated. Occasionally, a chemical substance may be found to be unlisted. In such cases, the toxicity ratings of several other closely-related chemicals may be checked. (If the chemical structure or any other relevant property of the unlisted chemical is not known to the field investigator, he may first consult the Chemical Rubber Company (CRC) "Handbook of Chemistry and Physics" (4) listings of either organic or inorganic materials, as may be appropriate.) Both the NIOSH and Sax books mentioned above are also useful in that they catalog and cross-reference materials by their trade names as well as by their chemical names.

The development of a means to quantify potentially toxic levels is described in the document "Estimation of Permissible Concentrations of Pollutants for Continuous Exposure" (5). This document presents the intentionally conservative (on the average) relationships:

$$x_p = 1.65 \times 10^{-3} \text{ (TLV)}$$

and:

$$x_p = 4.77 \times 10^{-5} \text{ (LD}_{50}\text{)}$$

where:

$x_p$  = maximum permissible long-term  
(about monthly) average ambient  
air concentration (mg/m<sup>3</sup>)

TLV = threshold limit value (mg/m<sup>3</sup>)

LD<sub>50</sub> = lethal dose for 50% of rats (or  
else mice) when administered  
orally (orl), or else by intra-  
peritoneal (ipr), but not by intra-  
muscular (ims), injections (mg/kg  
of animal body weight)

The above formulae are based on the ambient air to working-place air exposure time ratio (168 hr/40 hr), the small child to adult respiratory volume per unit of body weight ratio (a factor of about 2), and the lower 95% confidence limit of a TLV-LD<sub>50</sub> correlation (see Exhibit 3-4). In addition, the above-mentioned document indicates that, for carcinogenic materials (which are believed to be characterized by an exposure-risk relationship having no threshold), an ambient concentration of 1 ng/m<sup>3</sup> is the lowest of concern and may thus be considered to be permissible. (See Exhibit 3-5 for carcinogens listed as part of Maryland Bureau of Air Quality's progressive toxic emission control program.) The results of either ambient monitoring or dispersion modeling can be compared to the calculated maximum permissible ambient air concentration in order to aid in the assessment of a potential toxic air pollution problem.

In keeping with the generally recommended practice for determining whether occupational exposures to mixtures of air contaminants are consistent with TLV's, the consistency of ambient exposures to mixtures with maximum permissible concentrations can be assumed if:

$$\sum^n (x_i/x_{pi}) \leq 1$$

where:

$\sum^n$  = summation of terms for all n mixture components

$x_i$  = actual concentration of mixture component i

$x_{pi}$  = maximum permissible concentration of mixture component i

This approach is equivalent to the statement that:

$$x_{pm} = 1/\sum^n (f_i/x_{pi})$$

where:

$x_{pm}$  = maximum permissible total mixture concentration

$\sum^n$  = summation of terms for all n mixture components

$f_i$  = fraction of component i in mixture (mass fraction if concentrations are expressed in mass/volume units, volume fraction if concentrations are expressed in volume/volume units)

$x_{pi}$  = maximum permissible concentration of mixture component i

When the toxicity of a material or mixture cannot be determined with a reasonable degree of certainty by methods such as those described above, it may be prudent for the field investigator to assume that the material or mixture in question is a toxic one.

It is worth noting at this point that, while

many materials are potentially toxic at concentrations so low as to be below the sensitivity of most commonly used measurement techniques, many materials are also odorous at extremely low concentrations (6,7,8). In cases where a field investigator can smell a material whose odor threshold is known to be above the permissible concentration, a toxicity problem may well exist. Conversely, if an inspector cannot smell a material whose odor threshold is below the permissible level (assuming he is at a suitable downwind location), a toxicity problem may well not exist, though the difficulty of detecting odors in the outdoor air at laboratory-test thresholds must be taken into account. Because of the value of odor in assessing potential atmospheric contaminant toxicity problems, an extensive list of odor descriptions and thresholds is included as Exhibit 3-6. These data should only be utilized with an understanding of the great uncertainties inherent in measuring odors (see the large ranges listed for some substances).

## EXHIBIT 3-1

### THRESHOLD LIMIT VALUES ADOPTED BY THE OCCUPATIONAL SAFETY AND HEALTH ADMINISTRATION

#### **Subpart Z--Toxic and Hazardous Substances**

**SOURCE:** 39 FR 23502, June 27, 1974, unless otherwise noted. Redesignated at 40 FR 27073, May 28, 1975.

#### **§ 1910.1000 Air contaminants.**

An employee's exposure to any material listed in table Z-1, Z-2, or Z-3 of this section shall be limited in accordance with the requirements of the following paragraphs of this section.

##### **(a) Table Z-1:**

(1) *Materials with names preceded by "C"—Ceiling Values.* An employee's exposure to any material in table Z-1, the name of which is preceded by a "C" (e.g., C Boron trifluoride), shall at no time exceed the ceiling value given for that material in the table.

(2) *Other materials—8-hour time weighted averages.* An employee's exposure to any material in table Z-1, the name of which is not preceded by "C", in any 8-hour work shift of a 40-hour work week, shall not exceed the 8-hour time weighted average given for that material in the table.

##### **(b) Table Z-2:**

(1) *8-hour time weighted averages.* An employee's exposure to any material listed in table Z-2, in any 8-hour work shift of a 40-hour work week, shall not exceed the 8-hour time weighted average limit given for that material in the table.

(2) *Acceptable ceiling concentrations.* An employee's exposure to a material listed in table Z-2 shall not exceed at any time during an 8-hour shift the acceptable ceiling concentration limit given for the material in the table, except for a time period, and up to a concentration not exceeding the maximum duration and concentration allowed in the column under "acceptable maximum peak above the acceptable ceiling concentration for an 8-hour shift".

(3) *Example.* During an 8-hour work shift, an employee may be exposed to a concentration of Benzene above 25 p.p.m. (but never above 50 p.p.m.) only for a maximum period of 10 minutes. Such exposure must be compensated by exposures to concentrations less than 10 p.p.m. so that the cumulative exposure for the entire 8-hour work shift does not exceed a weighted average of 10 p.p.m.

(c) **Table Z-3:** An employee's exposure to any material listed in table Z-3, in any 8-hour work shift of a 40-hour

work week, shall not exceed the 8-hour time weighted average limit given for that material in the table.

(d) Computation formulae:

(1) (i) The cumulative exposure for an 8-hour work shift shall be computed as follows:

$$E = \frac{C_1 T_1 + C_2 T_2 + \dots + C_n T_n}{8}$$

Where:

$E$  is the equivalent exposure for the working shift.

$C$  is the concentration during any period of time  $T$  where the concentration remains constant.

$T$  is the duration in hours of the exposure at the concentration  $C$ .

The value of  $E$  shall not exceed the 8-hour time weighted average limit in table Z-1, Z-2, or Z-3 for the material involved.

(ii) To illustrate the formula prescribed in subdivision (i) of this subparagraph, note that isoamyl acetate has an 8-hour time weighted average limit of 100 p.p.m. (table Z-1). Assume that an employee is subject to the following exposure:

Two hours exposure at 150 p.p.m.

Two hours exposure at 75 p.p.m.

Four hours exposure at 50 p.p.m.

Substituting this information in the formula, we have

$$\frac{2 \times 150 + 2 \times 75 + 4 \times 50}{8} = 81.25 \text{ p.p.m.}$$

Since 81.25 p.p.m. is less than 100 p.p.m., the 8-hour time weighted average limit, the exposure is acceptable.

(2) (i) In case of a mixture of air contaminants an employer shall compute the equivalent exposure as follows:

$$E_m = \frac{C_1}{L_1} + \frac{C_2}{L_2} + \dots + \frac{C_n}{L_n}$$

Where:

$E_m$  is the equivalent exposure for the mixture.

$C$  is the concentration of a particular contaminant.

$L$  is the exposure limit for that contaminant, from table Z-1, Z-2, or Z-3.

The value of  $E_m$  shall not exceed unity (1).

(ii) To illustrate the formula prescribed in subdivision (i) of this subparagraph, consider the following exposures:

Material	Actual concentration of 8-hour exposure	8-hour time weighted average exposure limit
Acetone (Table Z-1).....	500 p.p.m....	1,000 p.p.m.
2-Butanone (Table Z-1)....	45 p.p.m....	200 p.p.m.
Toluene (Table Z-2).....	40 p.p.m....	200 p.p.m.

Substituting in the formula, we have:

$$E_m = \frac{500}{1,000} + \frac{45}{200} + \frac{40}{200}$$

$$E_m = 0.500 + 0.225 + 0.200$$

$$E_m = 0.925$$

Since  $E_m$  is less than unity (1), the exposure combination is within acceptable limits.

(e) To achieve compliance with paragraph (a) through (d) of this section, administrative or engineering controls must first be determined and implemented whenever feasible. When such controls are not feasible to achieve full compliance, protective equipment or any other protective measures shall be used to keep the exposure of employees to air contaminants within the limits prescribed in this section. Any equipment and/or technical measures used for this purpose must be approved for each particular use by a competent industrial hygienist or other technically qualified person. Whenever respirators are used, their use shall comply with § 1910.134.

§ 1910.1001

TABLE Z-3—MINERAL DUSTS

Substance	Mppcf *	Mg/M <sup>3</sup>
<b>Silica:</b>		
Crystalline:		
Quartz (respirable).....	250 <sup>1</sup>	10mg/M <sup>3</sup> =
	%SiO <sub>2</sub> +8	%SiO <sub>2</sub> +2
Quartz (total dust).....		30mg/M <sup>3</sup>
		%SiO <sub>2</sub> +2
Cristobalite: Use 1/2 the value calculated from the count or mass formulae for quartz.		
Tridymite: Use 1/2 the value calculated from the formulae for quartz.		
Amorphous, including natural diatomaceous earth.....	20	80mg/M <sup>3</sup>
		%SiO <sub>2</sub>
<b>Silicates (less than 1% crystalline silica):</b>		
Mica.....	20	
Soapstone.....	20	
Talc (non-asbestos-form)...	20 <sup>2</sup>	
Talc (fibrous). Use asbestos limit.....		
Tremolite (see talc, fibrous)		
Portland cement.....	50	
Graphite (natural).....	15	
Coal dust (respirable fraction less than 5% SiO <sub>2</sub> ).....		2.4mg/M <sup>3</sup>
		or
For more than 5% SiO <sub>2</sub> .....		10mg/M <sup>3</sup>
		%SiO <sub>2</sub> +2
<b>Inert or Nuisance Dust:</b>		
Respirable fraction.....	15	5mg/M <sup>3</sup>
Total dust.....	50	15mg/M <sup>3</sup>

NOTE: Conversion factors—  
 mppcfX35.3=million particles per cubic meter  
 =particles per c.c.  
 \* Millions of particles per cubic foot of air, based on impinger samples counted by light-field technique.  
<sup>1</sup> The percentage of crystalline silica in the formula is the amount determined from air-borne samples, except in those instances in which other methods have been shown to be applicable.  
<sup>2</sup> As determined by the membrane filter method at 430X phase contrast magnification.  
 = Both concentration and percent quartz for the application of this limit are to be determined from the fraction passing a size-selector with the following characteristics:  
 = Containing < 1% quartz; if > 1% quartz, use quartz limit.

Aerodynamic diameter (unit density sphere)	Percent passing selector
2	90
2.5	75
3.5	50
5.0	25
10	0

The measurements under this note refer to the use of an AEC instrument. If the respirable fraction of coal dust is determined with a MRE the figure corresponding to that of 2.4 Mg/M<sup>3</sup> in the table for coal dust is 4.5 Mg/M<sup>3</sup>.

Vinyl acetate		0.55
p-Xylene	Sweet, moth balls	0.47
Xylene (isomer(s) unspecified)		0.27-20.

## CHAPTER 4

### EMISSION SOURCES

Since all air pollutants can be divided into two categories, gases and particulates, one must consider two types of potential atmospheric emissions. Gaseous emissions normally result from the evaporation of liquid materials or, less frequently encountered, the sublimation (change to the gaseous state without first passing through the liquid state) of solid materials. The rate of evolution of such emissions is almost always highly dependent on the volatility of the material under consideration.

The vapor pressures of a large number of organic materials are presented as a function of temperature in Exhibit 4-1, and similar data for inorganic materials are presented in Exhibit 4-2 (9). In order to use these exhibits to determine a material's vapor pressure (in millimeters of mercury), the temperature of the material (in degrees Centigrade) must be located on the line on which the material's name appears. At the top of the column in which the temperature is listed, the vapor pressure is indicated. Interpolation and extrapolation may be employed as needed; for accurate results, the listed data should be used to plot a smooth vapor pressure-versus-temperature curve, from which the vapor pressure at any temperature can be read. For cases in which the chemical of concern is not listed in the vapor pressure tables, the vapor pressures of chemicals having similar molecular weights and structures should be checked. (As noted previously, molecular weights and structures can be determined by using either the organic or inorganic tables of chemical properties that can be found in the CRC "Handbook of Chemistry and Physics.")

For example, consider the case of benzyl chloride, a toxic substance that has a Threshold Limit Value (TLV) of 1 part per million (ppm), to be present at a temperature of 70 degrees Fahrenheit, which is equivalent to  $(70-32)/1.8$ , or 21.1 degrees Centigrade ( $^{\circ}\text{C}$ ), and under normal atmospheric pressure (760 millimeters of mercury). The closest temperature to this on the line labeled benzyl chloride in Exhibit 4-1 is  $22.0^{\circ}\text{C}$ , which is located in the first vapor pressure column on the left, the column headed 1 millimeter of mercury (mm Hg). Since the actual temperature of  $21.1^{\circ}\text{C}$  is slightly below the listed temperature of  $22.0^{\circ}\text{C}$ , the actual vapor pressure is slightly less than 1 mm Hg. The equilibrium benzyl chloride concentration above the liquid phase would therefore be just under 1 mm Hg/760 mm Hg, 0.13 percent, or 1300 ppm.

Such a concentration would require efficient containment, emission control (for example, by activated carbon adsorption or thermal incineration - see the following chapter for details), or atmospheric dilution by a factor of well over three orders of magnitude before it could be safely inhaled for a significant period of time. Such degrees of dilution are in fact ordinarily obtained in cases of elevated release locations; however, it should also be recalled that ambient levels should typically be kept far below TLV concentrations. (The methods that can be used to evaluate a situation's potential for toxic air pollution problems are summarized in Exhibit 8-12).

Repeating the above calculation for a somewhat different case, in which the benzyl chloride is maintained under a pressure of 30 pounds per square inch gauge (psig), i.e., above the atmospheric pressure of about 14.7 psi, which is the same as  $30 + 14.7$  or 44.7 pounds per square inch absolute (psia), or 3.04 atmospheres (atm), or 2310 mm Hg, the equilibrium pollutant concentration would be reduced to 1 mm Hg/2310 mm Hg, 0.043 percent, or 430 ppm. On the other hand, if the benzyl chloride

were to be kept under a 10 psi vacuum (below the atmospheric pressure of 14.7 psi), which is the same as 4.7 psia, 0.32 atmospheres, or 243 mm Hg, the equilibrium pollutant concentration would be increased to 1 mm Hg/243 mm Hg, 0.41 percent, or 4100 ppm.

The above example calculations should serve to provide the toxic substance air pollution inspector with an indication of how to estimate emitted concentrations. (When mixtures of chemicals are involved, somewhat more complex calculations may be required, based on various approximate relationships, such as Raoult's Law, that are described in detail in physical chemistry textbooks.)

One additional example will be presented to show how mass emission rates, rather than just emitted concentrations, may be estimated. Suppose a 1500-gallon, or 200-cubic foot, vessel at atmospheric pressure that is almost empty but is saturated with benzyl chloride vapor is to be refilled with the chemical within a ten-minute period. At the 0.13 percent equilibrium concentration calculated above, the vessel's benzyl chloride vapor of  $200 \times 0.13\%$  or 0.26 cubic feet, or (from the ideal gas law) 0.085 pounds, will be displaced during the operation, at an average rate of  $0.085/10$  or 0.0085 pounds per minute. (If this seems to be a low emission rate, one might consider that the dilution air that would be required to reduce 0.0085 pounds per minute of benzyl chloride to its 1 ppm TLV amounts to 26,000 cubic feet per minute.)

A final general point that should be made regarding evaporative emission estimations is that, depending on the process situation, it may often be more appropriate to assume that considerably less than the equilibrium pollutant concentrations may be present, especially when the time element is small and the degree of mixing is low. A method for estimating storage tank

evaporative emissions based on vapor pressure data is presented as Exhibit 4-3, which has been reproduced from EPA Publication Number AP-42, "Compilation of Air Pollutant Emission Factors" (10). For fixed-roof petrochemical storage tanks, conservatively assuming the number of turnovers (the ratio of annual throughput to tank capacity) to be no greater than 36 per year, the evaporative emission formulae can be reduced to the expression:

$$E = MP (0.0104 D^{1.73} H^{0.51} \Delta T^{0.50} F_p C + 0.000024 G)$$

where:

E = evaporative emission rate (lb/yr)

M = molecular weight of petrochemical (lb/mole)

P = true vapor pressure of petrochemical at bulk liquid storage temperature (psia)

D = diameter of storage tank (ft)

H = average vapor space height (typically half of storage tank height, and including a correction for concave roof volume) (ft)

$\Delta T$  = average daily ambient temperature change, maximum minus minimum (typically about 20°F)

$F_p$  = paint factor, ranging from 1.00 for tanks whose roofs and shells are coated with white paint in good condition, to 1.58 for medium-gray painted tanks in poor condition (see Exhibit 4-3)

C = correction factor for tanks with diameters of less than 30 feet, approximately equal to  $D/20 - D^4/1,600,000$  (see Exhibit 4-3)

G = annual throughput of petrochemical (gal/yr)

The first term enclosed within the parentheses is needed to calculate the standing storage (breathing) loss, while the second term is needed to calculate the working (filling and emptying) loss.

Other potential sources of evaporative emissions of toxic substances include such chemical process equipment as reactor vessels, distillation columns, pumps, and compressors. Pollutant release points include stacks, vents, ejectors, and leaking ducts and pipes, and such occurrences as overflows and spills must also be considered. In addition, wastewater streams and solid waste accumulations should not be overlooked as possible sources of toxic evaporative emissions to the atmosphere, and treatment processes may actually result in increased releases of certain chemicals into the air. Such processes may often include the incineration of liquid or solid industrial waste materials.

Particulate emissions are ordinarily the result of the small particles present in a finely-divided (granular or powdered) solid material becoming airborne, or sometimes of very small droplets being entrained in an air stream flowing through a quantity of liquid, or over a liquid surface, or simply past a point where liquid splashing, spraying, or atomization (as at a high-pressure nozzle) occurs. (In cases where particulates are created by the condensation, reaction, or other transformation of gaseous pollutants, evaporative or other gaseous emission formation mechanisms are usually responsible.)

Just as gaseous emissions are most often attributable to the volatility of substances, particulate emissions are usually related to the degree to which materials are present in finely-divided form. This is due to the fact that coarser particles are much less likely to become and remain airborne. For example, 100-micrometer (or 0.1 mm) diameter particles settle to the ground so quickly that they are usually transported beyond

plant boundaries in significant quantities only in cases involving high initial release elevations and/or high wind speeds. Intermediate-sized particles, which have diameters of about 10 micrometers (or 0.01 mm) and are extremely difficult to distinguish as individual particles with the naked eye, are much more readily transported by the air over considerable distances. Very small particles, which have diameters of about 1 micrometer (0.001 mm) and are very difficult to see even with the aid of an optical microscope because their sizes approximate the wave-length of light, behave in many respects like gaseous molecules and have no significant tendency to undergo gravitational settling.

The percentage of small particles (those with diameters of less than a specified value) present in a finely-divided material which have the potential to become airborne may be determined based on a knowledge of the particle size distribution of the material. In air pollution work, the distribution most often encountered is the log-normal type, within which the logarithm of the particle diameter is distributed normally (according to the error function, or the standard bell curve) with respect to the mass of particles. For example, if one considers a granular material having a log-normal size distribution that is characterized by a mass median diameter of 100 micrometers and a geometric standard deviation of 2.5, it is known by definition that 68 percent of the mass of particles is between  $100/2.5$  and  $100 \times 2.5$ , or 40 micrometers and 250 micrometers, in diameter, while 16 percent of the mass is below 40 micrometers in diameter and the remaining 16 percent is above 250 micrometers in diameter. Through the utilization of graphical techniques or tabular data, the percentage of the mass of a finely-divided material below any size (chosen because of its likelihood of becoming airborne and being transported to the plant boundary or to a potentially sensitive or adversely affected receptor location) can be readily determined;

however, all of the particles below such a size may not actually be emitted, and in most cases only a small fraction of them will be released, depending on the degree to which the finely-divided material is exposed to the air, especially air in motion.

For some types of operations in which particulate emissions may be generated, emission rates may be estimated based on the data presented in EPA Publication Number AP-42, "Compilation of Air Pollutant Emission Factors." In cases where the source operation involved is not listed in AP-42, emission factors for similar operations may be considered for use, keeping in mind that the size distributions of the finely-divided process materials involved and their degrees of exposure to the air and its motion should be comparable. In the case of a solid material, its degree of dryness, dampness or stickiness may be highly significant. Since toxic substances may constitute only a fraction of the total emitted particulate matter, the composition of the finely-divided process material should be taken into account, including any systematic difference between the total and the toxic particle size distributions that may exist. Operations that may result in toxic substance particulate emissions include atomizing, blending, charging, conveying, crushing, cutting, drilling, mixing, packing, pulverizing, spraying, and others.

In the estimation of emission rates of potentially toxic materials, it may often be necessary to consider the differences in the weights of alternative chemical forms. For example, consider a process in which 4 pounds per day of vanadium (atomic symbol V, atomic weight 51) is converted to vanadium pentoxide fumes (molecular formula  $V_2O_5$ , molecular weight  $51 \times 2 + 16 \times 5$ , or 182) and subsequently released to the atmosphere. Since the  $V_2O_5$  has a mass of  $182/(51 \times 2)$ , or 1.75, times the mass of the vanadium it contains, the

emission rate of  $V_2O_5$  would be  $4 \times 1.75$ , or 7, pounds per day. Ambient concentrations calculated from this emission rate could then be compared directly to the  $V_2O_5$  fume TLV of  $50 \text{ ug/m}^3$ . It should be noted that in the cases of many toxic chemicals no such calculations would be required; for example, for the oxidation and emission of selenium, the increase in weight need not be calculated for the purpose of an ambient concentration evaluation, since the TLV for selenium compounds is  $200 \text{ ug/m}^3$  expressed as the weight of selenium only (not including the weight of oxygen or other atoms compounded with the selenium).

This concludes the chapter on the types of toxic substance emissions that can be expected from the various sources, and on how these emissions may be estimated.

### METHOD FOR ESTIMATING STORAGE TANK EMISSIONS

#### 4.3 STORAGE OF PETROLEUM PRODUCTS

*Revised by William M. Vataavuk  
and Richard K. Burr*

Fundamentally, the petroleum industry consists of three operations (1) crude oil production, (2) petroleum refining, and (3) transportation and marketing of finished products. Associated with these operations are evaporative emissions of various organic compounds, either in pure form or as mixtures.

From an air pollution standpoint, the petroleum industry is defined in terms of two kinds of evaporative losses: (1) storage and (2) marketing and transportation. (See Figure 4.4-1 for schematic of the industry and its points of emission.)

##### 4.3.1 Process Description<sup>1-5</sup>

Petroleum storage evaporation losses are associated with the containment of liquid organics in large vessels at oil fields, refineries, and product distribution terminals.

Six basic tank designs are used for petroleum storage vessels: (1) fixed-roof (cone roof), (2) floating roof (single deck pontoon and double deck), (3) covered floating roof, (4) internal floating cover, (5) variable vapor space, and (6) pressure (low and high).

The fixed roof tank (Figure 4.3-1) is the least expensive vessel for storing certain hydrocarbons and other organics. This tank generally consists of a steel, cylindrical container with a conical roof and is equipped with a pressure/vacuum vent, designed to operate at slight deviations ( $0.021 \text{ Mg/m}^2$  maximum) from atmospheric pressure.

Figure 4.3-1. Fixed roof storage tank.

A floating roof tank is a welded or riveted circular vessel with an external float-type pan or pontoon roof (single- or double-deck) equipped with single or double mechanical seals (Figure 4.3-2).

Figure 4.3-2. Double-deck floating roof storage tank (nonmetallic seal).

The floating roof prevents the formation of a volume of organic vapor above the liquid surface, which would otherwise be vented or displaced during filling and emptying. The seal, which is designed to close the annular space between the roof and vessel wall, consists of a relatively thin-gauge shoe ring supported against the tank shell around the roof.

The covered floating roof tank, simply a steel pan-type floating roof inside a fixed roof tank, is designed to reduce product losses and maintenance costs. Another type, the internal floating cover tank, contains a floating cover constructed of a material other than steel. Materials used include aluminum sheeting, glass-fiber-reinforced polyester sheeting, and rigid plastic foam panels.

The lifter and flexible diaphragm variable vapor space tanks are also used to reduce vapor losses (Figure 4.3-3). With the lifter tank, the roof is telescopic; i.e., it can move up or down as the vapor above the liquid surface expands or contracts. Flexible diaphragm tanks serve the same function through the expansion and contraction of a diaphragm.

Pressure tanks are especially designed for the storage of volatile organics under low (17 to 30 psia or 12 to 21  $\text{Mg/m}^2$ ) or high (up to 265 psia or 186  $\text{Mg/m}^2$ ) pressure and are constructed in many sizes and shapes, depending on the operating range. The most popular are the noded hemi-spheroid and the noded spheroid for low pressure and the spheroid for high pressure. Horizontal cylindrical forms are also commonly used for high pressure storage.

#### 4.3.2 Emissions and Controls<sup>1-3,5-7</sup>

There are six sources of emissions from petroleum in storage.

Figure 4.3-3. Variable vapor storage tank (wet-seal lifter type).

Breathing losses are associated with fixed roof tanks and consist of vapor expelled from the tank because of thermal expansion, barometric pressure changes, and added vaporization of the liquid.

Working losses consist of hydrocarbon vapor expelled from the vessel as a result of emptying or filling operations. Filling losses represent the amount of vapor (approximately equal to the volume of liquid input) that is vented to the atmosphere through displacement. After liquid is removed, emptying losses occur, because air drawn in during the operation results in growth of the vapor space. Both filling and emptying (together called "working") losses are associated primarily with fixed roof and variable vapor space tanks. Filling losses are also experienced from low pressure tankage, although to a lesser degree than from fixed roof tanks.

Primarily associated with floating roof tanks, standing storage losses result from the improper fit of the seal and shoe to the tank shell.

Wetting losses with floating roof vessels occur when a wetted tank wall is exposed to the atmosphere. These losses are negligible.

Finally, boiling loss is the vapor expelled when the temperature of the liquid in the tank reaches its boiling point and begins to vaporize.

The quantity of evaporation loss from storage tanks depends on several variables:

- (1) True vapor pressure of the liquid stored,
- (2) Diurnal temperature changes in the tank vapor space,

- (3) Height of the vapor space (tank outage),
- (4) Tank diameter,
- (5) Schedule of tank fillings and emptyings,
- (6) Mechanical condition of tank, and
- (7) Type of paint applied to outer surface.

The American Petroleum Institute has developed empirical formulae, based on extensive testing, that correlate breathing, working, and standing storage losses with the above parameters for fixed roof, floating roof, and variable vapor space vessels.

Fixed roof breathing losses can be estimated from:

$$B = \frac{2.74 WK}{V_c} \left( \frac{P}{14.7-P} \right)^{0.68} D^{1.73} H^{0.51} \Delta T^{0.50} F_p C \quad (1)$$

where: B = Breathing loss, lb/day-10<sup>3</sup> gal capacity  
P = True vapor pressure at bulk liquid temperature, psia  
D = Tank diameter, feet  
H = Average vapor space height, including correction for roof volume, feet  
ΔT = Average daily ambient temperature change, °F  
F<sub>p</sub> = Paint factor, determined from field tests (see Table 4.3-1)  
C = Adjustment factor for tanks smaller than 20 feet in diameter (see Figure 4.3-4)  
V<sub>c</sub> = Capacity of tank, barrels  
K = Factor dependent on liquid stored:  
= 0.014 for crude oil  
= 0.024 for gasoline  
= 0.023 for naphtha jet fuel (JP-4)  
= 0.020 for kerosene  
= 0.019 for distillate oil  
W = Density of liquid at storage conditions, lb/gal

Table 4.3-1. PAINT FACTORS FOR FIXED ROOF TANKS<sup>a</sup>

Tank Color		Paint factor (F <sub>p</sub> )	
		Paint condition	
Roof	Shell	Good	Poor
White	White	1.00	1.15
Aluminum (specular)	White	1.04	1.18
White	Aluminum (specular)	1.16	1.24
Aluminum (specular)	Aluminum (specular)	1.20	1.29
White	Aluminum (diffuse)	1.30	1.38
Aluminum (diffuse)	Aluminum (diffuse)	1.39	1.46
White	Gray	1.30	1.38
Light gray	Light gray	1.33	1.44 <sup>b</sup>
Medium gray	Medium gray	1.46	1.58 <sup>b</sup>

<sup>a</sup>Reference 2.

<sup>b</sup>Estimated from the ratios of the seven preceding paint factors.

Figure 4.3-4. Adjustment factor for small-diameter fixed roof tanks.<sup>2</sup>

Breathing losses of petrochemicals from fixed roof tanks can be estimated from the respective gasoline loss factor, calculated at their storage temperature:

$$B_p = 0.08 \left( \frac{M_p}{W_G} \right) \left( \frac{P_p}{P_G} \right) B_G \quad (2)$$

where:  $B_p, B_G$  = Breathing losses of petrochemical (p) and gasoline (G), lb/day- $10^3$  gal

$M_p$  = Molecular weight of petrochemical (p), lb/mole

$W$  = Liquid density of gasoline, lb/gal

$P_p, P_G$  = True vapor pressures of petrochemical (p) and gasoline (G) at their bulk storage temperature, psia

This same correlation can also be used to estimate petrochemical working loss, standing storage loss, or any other kind of loss from any storage tank.

A correlation for fixed roof tank working loss (combined emptying and filling) has also been developed:

$$F_f = 1000 W_m P \left( \frac{180 + N}{6N} \right) \quad (3)$$

where:  $F_f$  = Working loss, lb/ $10^3$  gal throughput

P = True vapor pressure at bulk liquid temperature, psia

N = Number of tank turnovers per year (ratio of annual throughput to tank capacity)

m = Factor dependent on liquid stored:

=  $3 \times 10^{-4}$  for gasoline

=  $2.25 \times 10^{-4}$  for crude oil

=  $3.24 \times 10^{-4}$  for naphtha jet fuel (JP-4)

=  $2.95 \times 10^{-4}$  for kerosene

=  $2.76 \times 10^{-4}$  for distillate oil

Standing storage losses from floating roof tanks can be calculated from:

$$S = \frac{2.74 WK_t}{V_c} D^{1.5} \left( \frac{P}{14.7 - P} \right)^{0.7} V_w^{0.7} K_s K_c K_p \quad (4)$$

where: S = Standing storage evaporation loss, lb/day- $10^3$  gal capacity

$K_t$  = Factor dependent on tank construction:

= 0.045 for welded tank, pan/pontoon roof, single/double seal

= 0.11 for riveted tank, pontoon roof, double seal

= 0.13 for riveted tank, pontoon roof, single seal

= 0.13 for riveted tank, pan roof, double seal

= 0.14 for riveted tank, pan roof, single seal

D = Tank diameter, feet; for  $D \geq 150$  feet (45.8 m) use " $D\sqrt{150}$ " instead of " $D^{1.5}$ ."

$V_w$  = Average wind velocity, mi/hr

$K_s$  = Seal factor:

= 1.00 for tight-fitting, modern seals

= 1.33 for loose-fitting, older seals (typical of pre-1942 installation)

$K_c$  = Factor dependent on liquid stored:

= 1.00 for gasoline

= 0.75 for crude oil

= 0.96 for naphtha jet fuel (JP-4)

= 0.83 for kerosene

= 0.79 for distillate oil

$K_p$  = Paint factor for color of shell and roof:

= 1.00 for light gray or aluminum

= 0.90 for white

Finally, filling losses from variable vapor space systems can be estimated by:

$$F_v = \frac{1000 W_m P}{V_t} (V_t - 0.25 V_e N) \quad (5)$$

where:  $m$  = Factor dependent on liquid stored (same as equation 3)

$F_v$  = Filling loss, lb/10<sup>3</sup> gal throughput

$V_t$  = Volume of liquid throughput, bbl/year

$V_e$  = Volume of expansion capacity, barrels

$N$  = Number of turnovers per year

$W$  = Density of liquid at storage conditions, lb/gal

Equations 1 through 5 can be used to calculate evaporative losses, provided the respective parameters are known. For those cases where such quantities are unknown or for quick loss estimates, however, Table 4.3-2 provides typical emission factors. Refinement of emission estimates by using these loss correlations may be desirable in areas where these sources contribute a substantial portion of the total evaporative emissions or are of major consequence in affecting the air quality.

The control methods most commonly used with fixed roof tanks are vapor recovery systems, which collect emissions from storage vessels and send them to gas recovery plants. The four recovery methods used are liquid absorption, vapor compression, vapor condensation, and adsorption in activated charcoal or silica gel.

Overall control efficiencies of vapor recovery systems vary from 90 to 95 percent, depending on the method used, the design of the unit, the organic compounds recovered, and the mechanical condition of the system.

In addition, water sprays, mechanical cooling, underground liquid storage, and optimum scheduling of tank turnovers are among the techniques used to minimize evaporative losses by reducing tank heat input.

Table 4.3-2. EVAPORATIVE EMISSION  
EMISSION FACTOR

Product	Vapor pressure ratio (P/P <sub>G</sub> )	Mole wt (M) (lb/mole)	Floating roof			
			Standing storage loss

## CHAPTER 5

### CONTROL TECHNIQUES

This chapter will include a description of the air pollution control techniques most applicable to the reduction or elimination of toxic substance emissions. For more details on the subject of the techniques mentioned here, and for descriptions of some of the less-generally applicable emission reduction measures, the reader is referred to such documents as EPA Publication Numbers AP-68, "Control Techniques for Hydrocarbons and Organic Solvent Emissions from Stationary Sources" (11), AP-51, "Control Techniques for Particulate Air Pollutants" (12), and AP-40, "Air Pollution Engineering Manual" (13).

One of the simplest and most highly efficient emission control techniques available is containment. The keeping of toxic materials in closed tanks, vessels, containers and other processing units that do not leak, are not allowed to overflow, and are not vented to the atmosphere any more often and in any greater quantity than is absolutely necessary will go a long way toward reducing atmospheric emissions. In the case of volatile materials, such containment may require equipment construction features that will enable considerable vapor pressures to be withstood.

Process modifications often prove to be a relatively easy method of effecting emission reductions. As discussed previously, the lowering of temperatures and raising of pressures tend to reduce the equilibrium vapor-phase concentrations of pollutants, and the minimization of exposures to air currents tends to reduce evaporation and aerosol generation rates. Reducing the amounts of toxic materials used or formed in processes, or substitution with a less-toxic or non-toxic material, is another simple type of emission control measure. Operating and maintenance

practices that can help to reduce emissions include the prevention of leaks, overflows, and spills, and the inspection of pressure relief valves to insure their proper closure and seating, and of gaskets, packing, seals and emergency rupture discs to insure their integrity.

Concerning types of add-on air pollution control equipment, the most widely applicable to organic gaseous toxic substance emissions are adsorbers and afterburners. Both are versatile enough to control the emissions of a very wide range of organic materials, and can be highly efficient over wide ranges of pollutant concentrations if properly designed, operated, and maintained.

The adsorption of the toxic substance onto activated carbon or another suitable medium is generally most economical when very low pollutant concentrations are involved, or when the recovered material would be of significant value and when the pollutant is not too volatile to be effectively adsorbed (such as is often the case for materials normally occurring only in the gaseous state). When the adsorptive capacity of the activated carbon or other medium is attained, the medium must be either replaced or regenerated (e.g., by steaming followed by cooling), in which latter case the pollutant can ordinarily be either re-used or incinerated.

The use of either direct-flame or catalytic afterburners to convert gaseous organic pollutants to harmless carbon dioxide and water (accompanied in some cases by some less harmless combustion products) is most economical at higher concentrations of pollutants that are not worth recovering, and for pollutants too volatile to be effectively adsorbed. An afterburner should be designed to have a sufficient gas stream residence time, or volume-of-combustion-chamber to volumetric-flow-rate-at-combustion-temperature ratio (normally at least about 0.3 to 0.5 seconds), a sufficient combustion chamber temperature (normally 1200°F to 2000°F

for direct-flame units, but as little as about 500°F to 800°F for catalytic units), and a sufficient entrance throat velocity (in direct-fired units) to result in good turbulence for thorough mixing (normally 25 to 50 feet per second).

Condensers (both those involving indirect heat transfer, such as shell-and-tube types, and those involving direct cooling medium-gas stream contact, such as the barometric types that cool through the latent heat effect as sprayed water evaporates into the gas stream) and absorbers (for example, packed columns with circulating liquids) are often employed in chemical processing plants, but typical process units would seldom be efficient enough to serve as final gaseous emission control devices.

In the case of inorganic gaseous emissions, a wide variety of wet scrubbing techniques could be considered for the achievement of emission control. The solubility of the gas of concern in the scrubbing liquid (which would often require adjustment to either an acidic or an alkaline condition) would be of primary concern; solubilities can be checked in such references as the CRC "Handbook of Chemistry and Physics," and R.H. Perry and C.H. Chilton's "Chemical Engineers' Handbook." Other important scrubber parameters include the liquid-to-gas flow rate ratio (L/G), the gas stream pressure drop ( $\Delta P$ ), and the contact time and conditions.

Particulate toxic substance emissions are most efficiently controlled by fabric filters (e.g., as contained in baghouses) or by panel filters. In the former case, the dust is generally removed in place by shaking or reverse-air techniques, while in the latter case the panels must be removed at intervals for replacement or reconditioning. Filtration is highly reliable if the media are correctly installed and maintained. The most important operational parameter is the

gas stream pressure drop, which will decrease if the gas stream is by-passing the media because of incorrect installation, excessive dust build-up, defective seals, a loss of media integrity, or other problems. For a toxic particulate pollutant whose physical nature renders filtration unsuitable, wet scrubbing is most likely to be employed. Cyclones, impingement separators and settling chambers would only infrequently provide adequate collection efficiencies for the final control of toxic particulate emissions. Electrostatic precipitators are much more complex control devices that can be very efficient but also sensitive and unreliable for most of the types of applications discussed here.

The reduction of both gaseous and particulate emissions depends not only upon the effective operation of add-on air pollution control equipment, but also upon the efficiency with which fugitive contaminants are captured and ducted to the control devices. In this regard, the importance of adequate hood design should not be overlooked. Hoods should be designed and operated so as to provide air velocities at locations of contaminant releases of at least the values indicated in Exhibit 5-1 (14).

A word on the utilization of tall stacks, or other such elevated release points, is appropriate at this point, since these are frequently employed for the purpose of reducing ground-level air pollutant concentrations. Many are of the opinion that a tall stack constitutes a simple and effective air pollution control device, resulting in the greatly increased atmospheric dilution of emissions; it is true that many of the principal pollutants are formed in nature at rates approaching or exceeding anthropogenic emission rates, but are harmless because of their distribution over wide areas of the globe. The same cannot usually be said of toxic substance emissions, many of which do not even exist in nature, and would tend to reach intolerable levels if emitted indefinitely,

even at low rates, because of the lack of natural means for their elimination from the environment. Thus, higher toxic substance release points may simply result in the substances being distributed over wider areas and adversely affecting more sensitive individuals and receptors, before the effects are noted, the causal substance detected, and the source of the emissions identified. For these reasons, tall stacks are not generally believed to be the proper means of effecting toxic substance air pollution control.

EXHIBIT 5-1

AIR VELOCITIES REQUIRED AT LOCATIONS  
OF CONTAMINANT RELEASES (14)

<u>Initial Dispersion</u> <u>of Contaminant</u>	<u>Examples of</u> <u>Contaminant Sources</u>	<u>Range of Required</u> <u>Capture Velocity (fpm)</u>
Released with practically no velocity into quiet air	Evaporation from tanks, degreasing, etc.	50-100
Released at low velocity into moderately still air	Spray booths, intermittent container filling, low-speed conveyor transfers, welding, plating, pickling	100-200
Active generation into zone of very rapid air motion	Spray painting in shallow booths, barrel filling, conveyor loading, crushers	200-500
Released at high initial velocity into zone of very rapid air motion	Grinding, abrasive blasting, tumbling	500-2000

Note: Greater capture velocities may be required because of the presence of externally-induced air motion such as room, thermal or mechanical currents.

## CHAPTER 6

### START-UPS, MALFUNCTIONS AND SHUT-DOWNS

This chapter deals with the excess emission situations that may be associated with process start-ups, malfunctions and shut-downs, in that these represent departures from normal operations during which ordinary emission control techniques may prove insufficient or ineffective.

Start-ups and shut-downs are relatively common occurrences that are often responsible for substantial portions of the total toxic substance emissions. One of the reasons for this fact is that many operations involving highly toxic materials are specialty processes conducted on a small scale, and in a batch rather than a continuous fashion, so that start-ups are frequent.

The cleaning and drying of reaction vessels, columns, piping and other appurtenances prior to start-ups or following shut-downs often necessitates the opening or exposure of this equipment to the air, during which evaporative emissions may occur. Such cleaning procedures may be especially common at specialty facilities where many different products are made in the same equipment.

When reaction vessels are charged with raw materials prior to start-up, and when these must be mixed, or when reaction vessels must be emptied following shut-down, and the products must be drummed, air that contains pollutants may be displaced more rapidly than at any time during the remainder of the operation, and spills and subsequent aerosol generation and/or evaporation may be the most likely to occur at these times. Often start-ups and shut-downs must be effected with some haste; often delays develop that prolong the time of exposure of toxic substances to the atmosphere; in either case, excess emissions may often be the result.

The multiplicity of tasks that need to be accomplished during start-ups and shut-downs, and the necessity that these be performed in a certain order, results in a higher likelihood of accidents and excessive emissions at these times. Air pollution control devices should be functioning before the processes whose emissions are to be controlled are started up, if possible, or else the devices should be on very soon after start-up is effected. Similarly, when shutting down, the pollution control devices should be turned off last, or as late as possible. In addition, the opening of any heated or pressured vessels containing toxic substances must be done with care if excess boil-over emissions are to be avoided.

Malfunctions that can result in excess toxic substance emissions may be either process-related or emission control device-related. When a process malfunction occurs that requires the shutting down of the operation, all of the types of excess emissions described above with respect to normal planned shut-downs may occur, but the abnormal and unplanned nature of the event results in an even greater likelihood of excess emissions. The emergency blow-down of an operation, during which materials may be removed from process equipment very rapidly in the interest of safety, can often be expected to result in exceeding the capacities of air pollution control devices to function effectively. If a process malfunction results in an excessive pressure build-up, an emergency relief valve may open or a rupture disc may burst, suddenly releasing a quantity of potentially toxic materials directly into the atmosphere.

Other, and often less dramatic, malfunctions involve only air pollution control equipment. This could involve such occurrences as the overheating and automatic by-passing of an adsorber or a baghouse (or, alternatively, the destruction of such equipment by heat or fire), or the loss of a wet scrubber's water supply. In such cases,

especially if there is no violation of applicable air pollution emission standards (as is often the case with toxic substance emissions) and if the resulting increased emissions are believed to be tolerable by the operator, the operation may simply be continued, perhaps indefinitely, without the benefit of air pollution emission controls.

## CHAPTER 7

### INSTRUMENTATION, MONITORING, RECORD-KEEPING AND REPORTING

The basic types of instrumentation related to toxic substance atmospheric emission evaluations provide the values of parameters associated with process conditions, air pollution control equipment operations, and gas stream properties. These instrumentation types are discussed in turn below.

Process instrumentation can enable determinations to be made of the concentrations and rates at which toxic pollutants may be evolved within process equipment. Conditions of temperature, pressure or vacuum, flow rate, weight or density, volume or level, and others in some cases are useful in uncontrolled emission estimation, being indicative (as discussed in greater detail previously) of such significant factors as toxic material vapor pressure and vapor-laden air displacement rates. Unusually high temperatures, vacuums, flow rates, levels, or rates of fluctuation of process conditions may be accompanied by abnormally high emissions.

Air pollution control equipment instrumentation is useful in estimating the removal efficiencies that may be obtained. In the case of an adsorption unit, the temperature of the bed is most important in determining the medium's capacity to adsorb a specified toxic substance, and unusual temperature increases may result in the bed actually becoming an emission source, as accumulations of potentially toxic materials may be desorbed. Such temperature increases may be attributable to the process emission source changing, a loss of cooling system effectiveness (where such a system is employed), or a latent heat of adsorption (which is related to the latent heat of condensation, or of evaporation, since the adsorption of a vapor is physically similar to its liquefaction from the gaseous state)

effect due to the adsorption of significant quantities of pollutants from the gas stream in a short period of time. The effectiveness of the adsorption medium's steam regeneration, where this step is employed, can be estimated by the temperature to which the bed is raised, and the temperature to which it is subsequently cooled before re-use, as well as by the amounts of condensed steam and organic materials accumulating during the regeneration stage. Finally, the gas stream pressure drop through the adsorption unit is related to the thickness of the bed, and the gas stream volumetric flow rate is related to the gas residence time in the bed, both of which are important parameters for estimating control efficiencies.

Afterburners may include combustion-zone temperature (which is about the same as exhaust temperature only if no heat recovery is employed) instrumentation, but the inlet gas stream volumetric flow rate, inlet temperature and pollutant heating value, and the rates of firing with natural gas (or other fuel, such as distillate oil if used) and of combustion air injection (if needed for the burner oxygen supply) can be used to calculate the combustion temperature by means of an enthalpy balance. The gas stream flow rate is also important because, if it is unusually low, the required degree of turbulence to effect complete pollutant combustion may not be achieved; while, if the flow rate is too high, in addition to the possibility of the combustion temperature dropping too low, the required residence time for complete combustion may not be obtained.

When scrubbers are utilized for emission control, the pollutant removal efficiencies obtained are ordinarily dependent upon the gas stream pressure drop and on the ratio of the liquid flow rate to the gas stream flow rate (L/G). In addition, the liquid stream pressure drop is of interest because an abnormally low reading may be indicative of insufficient atomization, and an unusually high

reading may be indicative of nozzle plugging (and reduced liquid flow). The acidity, alkalinity, density or other composition-indicator of the scrubbant may also be measured.

The functioning of a particulate matter filtration system is best indicated by the gas stream pressure drop, since an unusually low differential may result from gas stream by-passing (due to leaks, defective seals, incorrect valve settings, improper filter element installation or fit, tears in the filter cloth, etc.), and an unusually high pressure drop may indicate that emission control problems may be developing (such as the plugging of filter medium pores, or the malfunctioning of filter cleaning devices such as shakers or reverse-air equipment). Temperature recording instruments may indicate whether the filter material's upper temperature limit may be exceeded, or whether the dew point of the gas stream may be reached (which can result in filter material damage or simply difficulties due to an excessive pressure drop). The levels of collected particulate material in the hoppers of baghouses can also be checked to insure that the equipment is functioning.

Toxic substance atmospheric emission monitoring is not generally required by law and is often not practical because of the complexity and cost of the monitoring equipment that would be required. As a result, such monitoring would only infrequently be found at a continuous-type, large-scale operation and rarely found at a batch-type, small-scale operation. The results of in-plant monitoring undertaken to establish compliance with occupational safety and health standards, if available, may be useful in some cases but cannot be used directly since both the in-plant and ambient air concentrations, and the corresponding acceptable levels, will generally differ.

The record-keeping and reporting of toxic substance atmospheric emissions is also not

required; however, the authority to enter and inspect emission source premises discussed previously includes provisions for access to relevant records. The inspection of process emission source and air pollution control equipment parameter values, as are often recorded either in log books or on strip-type or circular chart recording machines, can reveal not only typical values, but also departures from normal that may be related to excessive emissions as discussed in detail previously; however, the possibilities of faulty instrument readings and non-functioning sensors should be kept in mind. Thus, process emission source and air pollution control equipment operational records may serve as a useful inspection and evaluation aid if the reliability of the records is properly taken into account.

## CHAPTER 8

### FIELD INVESTIGATIONS

This chapter is devoted to describing the performance of field investigations of potential toxic substance atmospheric emission facilities; however, a thorough understanding of the previous chapters included in this manual is required for the successful performance of the inspection procedures outlined here, which are intended to insure that atmospheric pollution attributable to the release of toxic substances is not allowed to occur.

Field investigations may be conducted either as a matter of routine or for various other purposes, such as in response to complaints, in checking on a visible or odorous emission noticed by chance, or in following up corrective measures required to alleviate a known problem. Routine facility visits may be made at a frequency to be determined based on regulatory agency policy, for example, on a quarterly schedule; however, the visits should not be made at regular intervals or on a pre-arranged basis if the most accurate picture of routine operating and maintenance conditions is to be gained by the inspector. On the other hand, the cooperative arrangement of an inspection visit can be beneficial in insuring that production is scheduled to be on-going and that time will not be wasted in gaining entry to the plant and in presenting an itinerary of the visit. Thus, the above factors must be weighed in deciding whether or not the inspection should be arranged with the facility owner or operator in advance.

Certain items of safety and inspection equipment should be taken on the visit by the field investigator (see Exhibit 8-1). The safety equipment includes a hard hat, safety eyeglasses or goggles, chemical-resistant safety shoes or boots, and a gas mask equipped with activated carbon canisters (or other suitable safety respirator).

In some cases, such additional safety items as ear protectors (for example, cotton plugs), protective gloves, and fireproof clothing may be required. The investigator may find it advisable to check on the existence of any unusual safety requirements in advance, since source facility owners and operators may refuse the investigator entry if the required safety equipment is not available.

Items of inspection equipment that the investigator may have need of include the appropriate credentials, an inspection manual and forms, a notebook and writing implements, a wristwatch, a camera with film, a tape measure, a flashlight, a compass (if directions in the plant area are not well known to the inspector), and sample bags (with ties) or containers, with a pocket knife or scraper and a sample brush. The inspector may know some of these items not to be required, depending on the characteristics of the facility to be visited.

Prior to attempting to conduct an emission source facility inspection, the field investigator should seek whatever relevant information may be available in the files of environmental regulatory agencies, and in some cases other governmental agencies. This information may prove valuable in helping the inspector to prepare an itinerary for the visit, to fill in some of the information required on the inspection forms in advance (so that the data may simply be checked rather than written out while at the plant, leaving more of the inspection time for actual observation), and to more readily detect variations from normal operating conditions. Before leaving to visit the facility in question, the investigator should, of course, be certain that he can locate it readily.

When the field investigator reaches the vicinity of the plant, he should circumnavigate it and complete a copy of the pre-entry chemical

emission source inspection form presented here as Exhibit 8-2. Many of the general items of information to be filled out on the pre-entry inspection form are of obvious relevance. These include the facility name, the facility address, the person to contact, his telephone number, the inspector's name, the inspection date and time, and the reason for the inspection. Meteorological conditions such as temperature, wind speed, wind direction, cloud cover and precipitation are relevant both as factors having some bearing on process conditions, atmospheric emissions, ambient concentrations, and the inspector's evaluations. It should be noted that the atmospheric stability condition, which may greatly influence the relationship between emission rates and ground-level concentrations, can be approximated based on the time of day, wind speed and cloud cover (see Turner's "Workbook of Atmospheric Dispersion Estimates," EPA Publication Number AP-26, for more details (15)).

While it is desirable for the inspector to view the facility from all directions, any visible emission evaluations should be accomplished with the wind direction being roughly perpendicular to an imaginary line drawn between the observation point and the source, with the sun being roughly at the observer's back (or, if the observation is being made at night, with the moon or other light source behind the plume as seen by the observer), and with a suitable background against which the plume can be viewed. Since toxic substance emissions may be of concern even in very low concentrations and quantities, even the faintest of visible emissions should be recorded as such. The information to be recorded includes the plume release location, its opacity and color, a description of the background against which the plume opacity is judged, the observer's location, the distance and direction from the observer to the plume, and the photograph number (if any is taken). Visible emission evaluations should be made in accordance with Method 9 of 40 CFR 60, Appendix A.

The odorous emission section of the pre-entry inspection form must of necessity be completed with largely subjective information. Odor strength, type and persistence should be judged carefully and recorded. The observer's location, the apparent release location, the distance and direction to the apparent source, and the number of any photograph taken should also be recorded. Any odorous emission evaluations must of course be made in the direction from the source toward which the wind is blowing at the time. As a guide for the estimation of toxic substance ambient concentrations, a list of odor descriptions and thresholds was presented as Exhibit 3-6. It may at times be advisable for a field investigator to familiarize himself with the odors characteristic of toxic substances that may be released from a plant that he is about to visit or has just visited.

The pre-entry inspection form also includes provisions for recording data regarding particulate deposition and ecological effects on any type of receptor. Observations of cumulative particulate matter deposition or ecological effects (which will probably only very seldom be evident, even to a trained observer familiar with the area's ecology) will most often be made in the direction of the prevailing wind at the time of the inspection visit, but may also be more frequent where the potentially sensitive ecological element is particularly close to the source. In the case of particulate matter deposition or a suspected ecological effect, photographs should be taken and samples should be obtained for subsequent analysis.

The field investigator may also wish to sketch the emission source facility location, for the purpose of showing relative source, receptor, and observation locations, before entering the plant. Such a sketch may help to clarify some of the information recorded above on the pre-entry inspection form.

When he has completed his pre-entry observations, the field investigator should proceed to the plant admission gate. As may be necessary to gain entry and to perform his duties, the inspector should present his credentials and state his intent; acquaint any plant official questioning the inspector's right to enter, examine records and copy information with the relevant provisions of Section 114 of the Clean Air Act (as discussed previously); and inform any plant official refusing to allow entry or inspection of the penalties prescribed under Section 113 of the Clean Air Act (as also discussed previously). Should the field investigator's right be persistently refused, he should make a written record of the name and position of the plant official involved and of any other relevant factors, depart from the plant, and report the incident to the environmental regulatory agency's attorney for further action.

If permitted to enter the premises of the facility, the field investigator should meet with the official in charge (who will often be the plant manager) or his designated representative (who may be the plant environmental engineer). The inspector should explain the purpose of his visit and propose an itinerary of what he would like to see and about how long he expects his visit to take. Ordinarily the inspector will want to review the plant's operating and maintenance records, logs and recording charts, making notes of any important emission-related information; inquire about the day's operating schedule and any unusual conditions, start-ups, malfunctions or shut-downs that may be occurring; and proceed with his observations of the on-going operations, the state of maintenance of process and control equipment, visible and odorous releases, and instrumentation readings related to atmospheric emissions.

A sample reactor inspection form is presented as Exhibit 8-3. The first few items to be entered on the form (facility name and address, inspector, date, and name of system), as well as on additional

forms to be described below, should not be omitted as they are necessary for the unambiguous identification of the inspection record, which may at some later time become inadvertently separated from other papers on which the identifying information has been recorded. The next information to be entered on the inspection form serves to identify the subject item of equipment, in this case the specific reactor, that may be a source of toxic air contaminant emissions to the atmosphere. The roll film numbers of any photographs taken of the reactor, whether from on or off the plant property, should also be recorded (as well as any pertinent notes regarding the on-going operation, the details of greatest interest, the view of the reactor being shown, etc.) on the inspection form; such photographs would generally not be intended for use as part of any subsequent litigation, but would rather serve to improve the field inspector's recollection of his visit as he writes his inspection report, to reveal details that he may have overlooked, and to confirm the identity of the subject reactor, should doubts arise for any reason, subsequent to the completion of the visit.

The remainder of the information to be entered on the reactor inspection form is that which would be required in order to arrive at an accurate judgment as to whether the reactor may constitute a significant source of potentially toxic atmospheric emissions. All other factors being equal, the magnitude of such emissions will often be approximately proportional to, or at least directly related to, the capacity of the reactor. Of the size-related items (capacity, diameter, and height or length), it would often be unnecessary to obtain the values of all three parameters; any two could be used to estimate the third (for a cylindrical vessel,  $V = \pi d^2 h / 4$  or  $V = \pi d^2 \ell / 4$ , where  $V$  is the volume in cubic feet,  $d$  is the diameter in feet,  $h$  is the height in feet, and  $\ell$  is the length in feet), and the capacity alone would usually be sufficient for the field inspector's needs. While viewing

the reactor for the purpose of size estimation, the inspector should also note the equipment's apparent physical condition, for example, the presence of leaks. Evidence of the leaking or spillage of potentially toxic liquid or solid materials (which may later become airborne) may be seen either on the reactor vessel itself, on the ground or floor below, or elsewhere in the area. Indications of gaseous leaks may be visible either directly, or through resulting particulate deposition or corrosion patterns on equipment surfaces, or may be noticeable due to the odorous nature of the leaking gas.

The type of reactor operation, usually either batch or continuous, should be check-marked on the inspection form. Batch operations often entail greater atmospheric emissions per unit of product, since they involve frequent start-ups and shut-downs, with the charging and removal of materials and related displacements of particulate- and/or vapor-laden air or other gas; continuous operations, while often larger in terms of total production, are generally steadier in nature and more fully enclosed, with little net volume change or displacement occurring. The reactor charging method should also be checked; dumping or pouring materials into an open reactor porthole is far more likely to result in atmospheric emissions than is charging through a tightly connected pipe. Certain additional items to be check-marked on the reactor inspection form apply to the use of agitation, which may raise dust, liquid droplets, or vapors that are subsequently released; heating, which may promote active boiling (similar to mechanical agitation in effect) as well as increase the vapor pressures and gas-phase concentrations of potentially toxic materials; cooling, which usually has the reverse effect and thus may decrease emissions; pressurization, which may decrease the vaporization of potentially toxic materials but may also increase losses through leakage; vacuum operation, whose effects may be the reverse of those due to pres-

surization; and certain types of auxiliary equipment (for example, fractionation columns, reflux condensers, steam or water ejectors, wet scrubbers, combustible-gas burners, etc.), which may serve to reduce emissions, whether primarily intended as either process or air pollution control equipment.

Further information to be recorded on the reactor inspection form provides additional details that may be needed by the field inspector for the determination of the significance of toxic substance emissions. The processing time, in combination with the reactor capacity noted previously, can be used for the estimation of process weight rate, to which the emission rate is ordinarily related. Alternatively, plant log books may be consulted for production rate data. The temperature cycle data (for example, 30 minutes heating, 60 minutes at 250°F, 30 minutes cooling) are useful in determining that portion of the operation time during which the critical reactor conditions and maximum emissions may actually occur, and may often be recorded automatically on circular charts; the pressure cycle data may serve a similar purpose. Abnormal values of recorded temperatures and/or pressures may be indicative of emission-related malfunctions. The discharging method and cleaning method employed during the operation and maintenance of the reactor, as they relate to its toxic substance emission potential, should also be entered on the inspection form.

One of the most important sections of the reactor inspection form is that in which the raw materials, intermediates, products and by-products are listed. Only the amounts of the raw materials and products need ordinarily be listed, and the amounts for either group alone may often be sufficient to determine the amounts for the other group. The emissions of a particular toxic material would most often be expected to be proportional to the amount of that material present. While reaction

intermediates and by-products are usually only present in small quantities, often not measured, and may be estimated if necessary based on considerations of chemical equilibria, kinetics, and stoichiometry, these materials can sometimes be of concern in terms of emission toxicity, particularly where the raw materials and products are not toxic and emission controls are thus inefficient or non-existent. In any case, a knowledge of the materials present in the reactor is a prerequisite to a determination of the equipment's potential for significant toxic substance emissions. The relevant biological, chemical and physical properties of the materials present can be investigated in detail subsequent to the inspection visit in order to permit as accurately as possible an assessment of each material's toxicity and emission rate.

The reactor inspection form, as well as additional forms described below, also includes provisions for the recording of exhaust gas information. As the field inspector makes a note of the location and height above grade of the exhaust release point, he should also record the plume opacity, the existence of any odor downwind, and the numbers of any photographs he may have the opportunity to obtain. Of the volumetric gas flow rate, vent top-inside diameter, and gas exit velocity, if any two are obtained, the third may be directly calculated (from  $G = \pi d^2 v / 4$ , where  $G$  is the volumetric gas flow rate in cubic feet per second,  $d$  is the vent top-inside diameter in feet, and  $v$  is the gas exit velocity in feet per second). Of the three parameters, the volumetric gas flow rate is by far the most important (as it represents flow conditions elsewhere in the system, as well as at the exit), and it alone may often be sufficient for the inspector's needs; however, if in addition to the estimation of emission rate (for example, by multiplying the volumetric gas flow rate times the exhaust-gas concentration of a toxic material) the resulting ambient air concentration or deposition rate is to be estimated through the utilization of diffusion modeling techniques, either

the vent diameter or the exit velocity, or both, may first be required in order to estimate the rise of the plume above the top of the stack or vent. The gas exit temperature would be needed by the field investigator in any case, for the conversion of the volumetric gas flow rate to that which would occur elsewhere in the system, where the temperature may differ. Exhaust gas monitoring equipment readings (for example, for the concentration of total hydrocarbons), if available, should also be noted by the inspector.

A few additional items that pertain to potential exhaust gas release from reactors in particular may also be entered on the inspection form. These include the valve pressure setting (which should prevent unnecessary releases), the rupture disc pressure rating (which should be adequate to prevent unnecessary blowouts), their conditions, and the use of any blowdown and spill controls (for example, diked areas, knockout drums or tanks for containment, flares or scrubbers for emission reduction, etc.). Finally, the reactor inspection form includes space for a sketch of the system. This should be included for all but the simplest operations. Flow rates and conditions of temperature and pressure that vary locally within the system may be indicated on the sketch. The reverse side of the inspection form should be used where more space is required, whether for the sketch or for other information for which the front side of the form contains insufficient space.

A sample dryer inspection form is presented as Exhibit 8-4. Since many of the items of information required for the completion of this form were discussed above in connection with the reactor inspection form, only the items unique to the dryer inspection form will be discussed here. The type of dryer (agitated, fluid bed, gravity, pneumatic conveying, rotary, screen, screw conveyor, spray, or tray) and type of heat trans-

fer (direct or indirect) should interest the inspector since the degree to which the material being dried is exposed to and mixed with the drying medium (air or other gas) is an important factor in determining not only how much drying occurs but also how much of any toxic material present may be transferred to the gas stream. The chemical composition of the drying gas stream, if other than that of air, may be important for the determination of the emission control efficiency obtainable when using certain devices or techniques. The composition of the material to be dried is of obvious relevance, since the toxic substance of concern would normally be contained in this material, and its physical form (for example, powdered, granular, pelletized, etc.), as well as mesh size, would be necessary in order to evaluate the possibility or degree of particle entrainment expected. Since interparticle cohesion is also of importance in this respect, the percentages of moisture (or organic liquid) in the material both before and after drying are also of interest.

A form intended for use during the inspection of grinding and milling operations is presented as Exhibit 8-5. Again, since many of the items required to complete the grinding or milling operation inspection form were discussed previously in connection with the reactor inspection form, their descriptions will not be repeated here. The type of the mill (for example, ball, hammer, jet, pebble, planetary, ring-roller, rod, roller, tube, vibratory, etc.) is directly related to the intensity of the grinding operation, the degree of size reduction achieved, and, thus, the likelihood, magnitude and nature of atmospheric emissions from the equipment. It should be noted that only dry grinding or milling operations would normally be expected to result in particulate emissions. In this regard, information concerning the chemical composition of the material being processed should be supplemented by the physical form and mesh size of the material both before and after the

grinding or milling operation.

A storage tank inspection form is included as Exhibit 8-6. This particular form is designed so that a single copy may be employed during the inspection of a considerable number of material storage tanks, such as may be encountered on a tank farm or elsewhere on the grounds of a large chemical production facility. The reasons for the inclusion of specific identifying information on the form were discussed previously in connection with the reactor inspection form. Many of the additional items to be completed (for example, material stored, storage temperature, rated capacity, annual throughput, tank diameter, tank height, roof color, shell color, condition of paint and general state of repair, etc.) are employed directly in the estimation of evaporative emissions according to such methods as those detailed in "Compilation of Air Pollutant Emission Factors," EPA Publication Number AP-42, Section 4.3, which was presented earlier in this inspection manual.

Additional items required to complete the storage tank inspection form may be employed in modifying the results of such an emission calculation. For example, the tank vent pressure setting may be sufficient to prevent some or even all atmospheric releases from the equipment. Since the storage tank evaporative emission calculation procedure applies to equipment outdoors and in the open, reductions in or the elimination of exposure to direct solar radiational heating (as well as to the clear nighttime conditions that promote radiational cooling) and to the effects of the wind may indicate that a downward adjustment should be made to the calculated emission rate. The storage tank level indicator reading is more than just an evaporative emission calculation input parameter (and suitable assumptions, such as that the average condition is one in which the tank is half-filled, could be made without checking the indicator); rather, the level indicator should be in a functioning and readable condition

so as to serve as an aid in the prevention of overfilling and spillage.

Finally, the storage tank inspection form includes provision for the recording of the use of atmospheric emission control equipment. In the case of storage tanks, a variety of control techniques beyond the more generally applicable gaseous emission reduction methods (which, for example, include absorption in a wet scrubber, adsorption on activated carbon, condensation in an indirect heat exchanger, incineration in a direct flame afterburner, etc.) are often employed. Such methods may include storage tank design measures such as floating- or expansion-roof or pressurized construction; return lines to stationary tanks, tank trucks, railroad tank cars, etc. for the vapor-laden air displaced during filling operations; other types of vapor balance and recovery systems, some of which may be rather complex in nature (for descriptions of these see such references as "Air Pollution Engineering Manual," EPA Publication Number AP-40, Chapter 10); and spill containment measures such as the construction of dikes around tanks that can allow spilled materials to be removed by pumping or other collection measures before evaporation occurs.

A pump and compressor inspection form is presented as Exhibit 8-7. In general, the emissions of any potentially toxic material that is being handled may be expected to be dependent on the flow rate through the equipment. The inlet and outlet fluid temperatures and pressures are important in determining the amount of material that may escape at the locations of seals between moving and stationary parts (for example, at rotating impeller shafts and reciprocating piston connecting rods) and, less often, at other points. Mechanical seals (ordinarily flat face-plate pairs, one rotating and one stationary, perpendicular to rotating shafts) are generally superior (to packed seals) for liquid containment purposes, espe-

cially the internal type utilizing hydrostatic pressure for a tighter seal. When double mechanical seals are employed, a pressurized purge liquid may be introduced between them to prevent leakage of the toxic liquid being pumped. Labyrinth seals, used in handling gases, include multiple knife-edges or touch-points to achieve a cumulative pressure drop through the series of orifices that minimizes gas leakage; in addition, a pressurized non-toxic purge gas may be introduced into the seal to counter such leakage. Except where a lubricant or purging fluid is continuously introduced under pressure, a small amount of leakage is to be expected even from seals in good condition. Add-on emission control equipment for pump and compressor leakage is seldom employed. It should be noted that a single pump and compressor form can be completed for a number of similar items of equipment by filling in ranges of data or typical values, rather than data representative of a single item of equipment only.

A hood and ductwork inspection form is presented as Exhibit 8-8. These items are important for the reduction of fugitive toxic substance emissions. In general, the greater the volumetric ventilation rate utilized in a potential fugitive emission area, the greater the percentage of air pollutants that may be captured for conveyance to the air pollution control equipment. (If no such equipment is employed, the hooding and ventilation only serve to alleviate in-plant toxicity problems.) The hood type (the design should enclose the source area as much as possible, and include flanges around entrance edges to keep the air flow on the source side of the hood), the hood dimensions and, most important, the distance to the source (whose inverse square is usually roughly proportional to the induced air velocity) are all factors that affect the hood's fugitive emission capture efficiency (14). The existence of a high air velocity near a central duct opening in the hood, but very low velocities

near the edges of the hood, can be remedied by such air flow distribution aids as multiple take-off duct openings, baffles, filter banks, etc. The velocity at the source that must be induced by the hood for efficient air pollutant capture is dependent on both the source release velocity (ranging from high for grinding operations to negligible for slow evaporation) and on the presence of interfering air currents (due to open doors and windows, nearby equipment operations, etc.). Lengths of ductwork operating under conditions of positive pressure may permit the escape of toxic air pollutants, and connection locations that are not tight-fitting should be checked for air leakage.

An industrial waste incinerator inspection form is included as Exhibit 8-9. Such incinerators should not be overlooked by the inspector, since they may constitute highly significant sources of toxic air pollutant emissions. The number of internal combustion chambers (usually two or three) physically separated by refractory walls is directly related to the incineration efficiency that may be obtained, since abrupt changes in the direction of gas flow that occur between chambers improve the mixing of potential pollutants, combustion air, heat and flame. The volume of each chamber can be used to calculate the corresponding residence time (volume divided by volumetric gas flow rate at combustion temperature), which would normally total about 0.3 to as much as 10 seconds. The waste preparation and charging method is an important factor in determining the controllability of combustion conditions, which should be maintained free of such effects as erratic burning or sudden flame quenching. Similarly, the draft should be well controlled, with the combustion air being preheated for the most effective incineration. The operating temperature of the unit should be maintained as high as possible, the normal range being 1600 to 2000°F. Temperature controls are ordinarily also necessary for the protection of the equipment itself.

In order to provide for the recording of sufficient information regarding air pollution emission control equipment, whether used in conjunction with a reactor, dryer, grinder, mill, storage tank, incinerator, or other potential source of atmospheric contaminants, an emission control equipment inspection form has been included as Exhibit 8-10. The information that is to be entered on this form would be adequate to permit a reasonable estimation of control effectiveness to be made. Although a great number of additional items could be employed for the most accurate determination of control efficiency, the specific data required and the computational methods involved have been detailed by others (for example, see "Air Pollution Engineering Manual," EPA Publication Number AP-40, Chapters 4 and 5), and their description is beyond the scope of this manual.

In addition to the usual identification information, the emission control equipment inspection form includes provisions for the entry of the name of the process emission source whose emissions are being controlled by the subject equipment. Certain items should be recorded regardless of the type or types of control equipment being employed. These include the gas volumetric flow rate (specified as the inlet or outlet value), the entrance temperature of the gas emanating from the source equipment, the exit temperature of the gas from the final control device, and the gas stream pressure drop through the control system. Space is also provided on the emission control equipment inspection form for entering the operating condition (satisfactory, or unsatisfactory due to the leaking of gas, plugging of lines, overloading of hoppers, etc.) of each device.

The following sections of the emission control equipment inspection form pertain to specific categories of devices; each category utilized for the control of the subject process emission source should be check-marked. For the vapor condenser category, a knowledge of the type (for example,

shell-and-tube, barometric, etc.) of device is essential to the understanding of its operation. A barometric condenser also functions as a wet scrubber, effecting a removal of particulate matter and additional control of soluble vapors contained in the exhaust gas stream. Information regarding the cooling fluid, the coolant flow rate, the coolant inlet temperature and the coolant outlet temperature is useful for calculating the total amount of heat transferred, the reduction in the exhaust gas stream temperature, and thus, the quantity of vapor that is removed from the exhaust gas stream and converted to liquid form. For an indirect condenser (such as one of the shell-and-tube variety), the heat transfer area may be either used as a check (the total amount of heat transferred should equal the product of the heat transfer area, the average temperature difference between the coolant and exhaust gas streams, and the overall heat transfer coefficient, which may be approximated in accordance with the data and methods presented in "Chemical Engineers' Handbook" by Perry and Chilton), or may be used in place of accurate coolant flow rate and temperature data to estimate the amount of heat transferred, the decrease in exhaust gas temperature, and the condenser's effectiveness. If the exhaust gas temperature is monitored and recorded, such calculations may not be necessary.

Scrubbers may vary considerably in design and in effectiveness for the removal of either particulate matter, vapors, or both. The type of scrubber (for example, spray, packed, venturi or ejector) being used is a good though highly approximate indicator of the control efficiency that may be obtained. A knowledge of the scrubbing liquid composition and pH is important in the case of gaseous contaminant emission control, since the solubility or reactivity of the contaminant in the liquid may be critical to the scrubber's effectiveness. The scrubbant circulating flow rate is also relevant to the device's ability to remove contaminants from the exhaust gas stream

for many types of scrubbers, and equipment removal efficiency as a function of flow rate may be either calculated or located in pertinent reference books. Because of the great variations in scrubber designs often encountered, and the often strong dependence of effectiveness on the scrubber's physical shape and size, space has been provided for the entry of information regarding the device's geometrical form and key internal dimensions (affecting gas and liquid flow inside the equipment). Alternatively, the monitoring or analysis of scrub-bant composition may be combined with blowdown and make-up rates to result in an estimation of contaminant removal efficiency and atmospheric emission rate.

Afterburners for the incineration of vapors or fine particulate matter in the exhaust gas stream may be of the direct flame or catalytic type, either of which may involve heat recovery (where the hot gases leaving the device preheat the gases entering, through indirect heat exchange). Time, temperature and turbulence are critical to the effectiveness of the device, the residence time of the gases being dependent upon the inside volume of the device, the temperature attained being dependent upon the fuel firing rate and utilization of heat recovery, and the turbulence being a function of such factors as the linear gas velocity as it passes through the device. The monitoring of the maximum gas temperature would be a useful indicator of the emission control efficiency that may be obtained.

An adsorber may contain either activated carbon or another suitable material having a characteristic capacity (in pounds of adsorbate per pound of adsorbant in the bed) for the removal and retention of any gas stream contaminant. Regeneration, usually with steam, causes the contaminant that has been concentrated in the adsorbant while the bed was on-line to be released, and a final emission control step (condensation, incineration, and/or other methods) must then be employed. The tempera-

ture of the adsorption medium, which may be monitored and recorded throughout the control-regeneration-cooling/drying (usually with clean air) cycle, may be used to gain important insight regarding the functioning of the regenerating type of adsorption system.

Filter types include fabric filters or "bag-houses" from which the accumulated particulate material is removed by such methods as shaking or blowing with reverse-direction air jets; and panel filters, which are either cleaned or replaced periodically. Both the filter material (because of its resistance to corrosive or hot gases, which may destroy the fabric) and the total filter surface (because of the considerations of particulate loading and gas stream pressure drop, which may lead to excessive wear and by-passing) are important in determining the success of filtration as a control measure. The field investigator should carefully note the disposition of the collected dust, since the very high efficiency obtainable through appropriate filtration procedures may be seriously overestimated should portions of the collected dust be lost because of careless handling. Filter pressure-drop monitoring is very useful.

Cyclone types include simple, multiple (parallel) or series arrangements - any may be operated wet so as to avoid the re-entrainment of particles from the inside walls of the devices. The cyclone's principle of operation involves the migration of particles suspended in the gas stream, under the influence of centrifugal force, across the diameter of the device and toward the wall for collection, as the gas stream simultaneously spirals downward. As a result, the collection efficiency obtained with a cyclone is dependent on its diameter and height. Since cyclones, when used as control equipment, only collect the larger particles and seldom attain extremely high efficiencies, the amount of particulate matter that is removed from the hopper is a good indicator of the amount that may be emitted to the atmosphere.

The emission control equipment inspection form also includes provisions for the description of any other type of control equipment that may be encountered by the field investigator. For such equipment, the inspector should record the type or name of the device involved, its mode of operation (for example, centrifugal, diffusive, electrostatic, gravitational, etc.), and its geometric form and dimensions relevant to the flow of the gas and the performance of the device.

A generally applicable emission source summary form (which can also be filled out by environmental regulatory personnel or by a source facility representative prior to or subsequent to the inspection visit) is presented as Exhibit 8-11. The form is chemical-substance emission oriented; each material of concern is to be listed in the first column, the equipment related to the substance is to be listed in the second column (along with any pertinent instrumentation readings, such as temperatures, pressures, volumes and flow rates, as discussed previously), and emission parameter information (where known, or when subsequently calculated) is to be listed in the remaining columns. A minimum of proprietary information need be sought in completing the form, since emission data are by law not entitled to confidential status.

A self-explanatory toxic emission preliminary assessment procedure that may be used by the inspector is outlined as Exhibit 8-12. Alternatively, after having completed his inspection visit and returned to his office, the field investigator can utilize the information he has gathered in estimating the uncontrolled emission rates and the efficiencies of air pollution control devices in reducing potentially toxic emissions (under both normal and abnormal operating conditions), approximating the ground-level ambient air concentrations of the toxic substances (in consultation with agency personnel responsible for atmospheric dispersion modeling, or employing appropriate references to obtain dilution factors (6) and/or

volumes (15)), and comparing the concentrations to permissible ambient levels determined as discussed previously in this manual, or by other means. The principal reference documents that are recommended for use by toxic air pollutant emission field investigators are listed in Exhibit 8-13. Finally, the field investigator should prepare a report for his supervisor including his observations and describing his findings. Since there are relatively few toxic substance emission standards, such inspection reports should be made available to those involved in the development of such regulations.

## NOTES:

- a. This refers to any substance other than air or water which at the conditions present has a vapor pressure of 1mm Hg or more, or is present to any extent as particles with dimensions of 1mm or less, may follow a direct or indirect path leading to the ambient air, and may then result in toxic effects.
- b. Items of equipment should be shown on a plant layout or plot plan, which should be attached to this sheet; equipment identification codes may be defined on this sheet and placed on the layout or plan.
- c. Maximum emission concentrations are rates that occur due to normal operating condition fluctuations, start-up and shut-down procedures, and malfunctions and breakdowns that can be reasonably expected to occur during the plant lifetime; all such maxima should be listed and their causes designated.
- d. Emission estimate basis may be test result, vapor pressure calculation, material balance, etc.

EXHIBIT 8-12  
TOXIC EMISSION PRELIMINARY ASSESSMENT PROCEDURE

1. What chemical substance is present that could be released?
  - a. Particulate less than 1 mm in size \_\_\_\_\_
  - b. Material with vapor pressure of at least 1 mm Hg \_\_\_\_\_
  
2. What are the source emissions prior to entering any control devices?
  - a. Concentration from vapor pressure or chemical equilibrium data, etc.:  
Average \_\_\_\_\_ mg/m<sup>3</sup> \_\_\_\_\_ mg/m<sup>3</sup>  
ppm Maximum \_\_\_\_\_ ppm
  
3. What is the expected emission control efficiency?  
Average emission conditions \_\_\_\_\_ %  
Maximum emission conditions \_\_\_\_\_ %
  
4. What are the emissions leaving the control devices?
  - a. Concentration: Average \_\_\_\_\_ mg/m<sup>3</sup> \_\_\_\_\_ mg/m<sup>3</sup>  
ppm Max. \_\_\_\_\_ ppm
  - b. Release rate: Average \_\_\_\_\_ lb/hr Max. \_\_\_\_\_ lb/hr
  
5. What is the expected peak ambient concentration?
  - a. From concentration dilution factor =  
3 (3.16 + Dist. to Boundary or Recep./10 Vent Diam.)<sup>2</sup>  
Average \_\_\_\_\_ mg/m<sup>3</sup> \_\_\_\_\_ mg/m<sup>3</sup>  
ppm Maximum \_\_\_\_\_ ppm
  - b. From release rate dilution volume =  
3.14 (Wind speed) (Release height)<sup>2</sup>  
Average \_\_\_\_\_ mg/m<sup>3</sup> \_\_\_\_\_ mg/m<sup>3</sup>  
ppm Maximum \_\_\_\_\_ ppm
  - c. From odor thresholds and perceptions  
Average \_\_\_\_\_ mg/m<sup>3</sup> \_\_\_\_\_ mg/m<sup>3</sup>  
ppm Maximum \_\_\_\_\_ ppm
  
6. What is the permissible ambient concentration?
  - a. Ambient standard, guideline or criterion  
Average \_\_\_\_\_ mg/m<sup>3</sup> \_\_\_\_\_ mg/m<sup>3</sup>  
ppm Maximum \_\_\_\_\_ ppm for \_\_\_\_\_ hr.
  - b. Calculated from  $1.65 \times 10^{-3}$  (TLV) \_\_\_\_\_ ppm
  - c. Calculated from  $4.77 \times 10^{-5}$  (LD<sub>50</sub> in mg/kg body wgt.) \_\_\_\_\_
  - d. Carcinogen recommended limit: 1 ng/m<sup>3</sup> or 0.000001 mg/m<sup>3</sup>
  
7. What is the potential for a toxic air pollution problem, based on a comparison of the answers to Questions 5 and 6?  
\_\_\_\_\_

16. ABSTRACT This inspection manual provides guidelines for federal, state and local environmental agency enforcement personnel who need to arrive at preliminary assessments of potential toxic air pollution problems associated with chemical processing facilities and other emission sources for cases in which standards and regulations have not been promulgated. Included in the manual are discussions of inspection authority, emission toxicity, emission sources, control techniques, unsteady operations, emission data, field investigations and a variety of inspection forms. These forms pertain to equipment as reactors, dryers, grinders, mills, storage tanks, pumps, compressors, hoods, ductwork, industrial waste incinerators and emission control devices. The manual also includes correlations for the estimation of emissions, dispersion, and toxicity (from lethal dosages - LD50's), and compilations of threshold limit values (TLV's), other Occupational Safety and Health Administration (OSHA) standards, known and potential carcinogens, odor descriptions and thresholds, vapor pressures, required air velocities for pollutant capture, safety and inspection equipment, toxic emission preliminary assessment procedures, and principal toxic emission references.
