1.0 INTRODUCTION

The purpose of this testing program was to obtain emissions data for uncontrolled and controlled hydrochloric acid (HCl), particulate matter (PM) and speciated hydrocarbon Hazardous Air Pollutants (HAPs) from a secondary aluminum processing plant to support a national emission standard for hazardous air pollutants (NESHAP).

The Culp Aluminum Alloys facility in Steele, Alabama, is a secondary aluminum reclamation facility. The Culp facility accepts many different forms of scrap aluminum feedstock, and operates a chip dryer to volatilize oils and lubricants from scrap aluminum chips prior to the remelting operation. The chip dryer emissions are captured by closed hoods and are ducted to a lime injected baghouse. There is a side-well reverberatory furnace that is used to remelt, flux, and alloy aluminum scrap that has been pre-processed in the chip dryer operation in addition to non-processed purchased aluminum scrap. The side-well reverberatory furnace emissions are captured by a canopy hood located above the charging and refluxing side-well and ducted to a lime injected baghouse. Emissions from the hearth stack are uncontrolled.

The existing total hydrocarbons (THC) emissions test data from secondary aluminum smelting plants had not been speciated to determine HAP content. Additional data were needed to identify HAPs emitted and their respective emission rates from melting furnace and chip drying operations at secondary aluminum smelting plants. Also, information on the HCl, PM, and dioxin/furan (D/F) removal efficiency of baghouses with dry lime injection was needed.

Source tests were required to quantify and characterize the HCl, PM, D/F, and HAP emissions and to assess control device performance from chip drying and side-well reverberatory furnace #1 operations, and to identify, quantify, and assess the performance of a lime injected baghouse at two lime injection rates for HCl from the side-well reverberatory furnace #1 operations. Application of the following stationary source test methods was required to adequately characterize these processes:

- Determination of D/F using EPA Method 23;
- Determination of HCl and PM using EPA Method 26A and EPA Method 320; and
- Screening for speciated hydrocarbon HAPs using EPA Method 320.

The objective of this work assignment was to perform all activities necessary to characterize specified point sources for the parameters listed above. The facility selected for testing, the Culp Aluminum Alloys Plant located in Steele, Alabama, has lime injected baghouses as control technology.

1.1 Objectives

The objective of the testing at the Culp Aluminum Alloys facility, in Steele, Alabama, was to perform all activities necessary to characterize the lime injected baghouses for the following emission components:

- Determination of D/F using EPA Method 23;
- Determination of HCl/PM using EPA Method 26A and EPA Method 320; and
- Screening for speciated hydrocarbon HAPs using EPA Method 320.

For the manual methods, testing was performed simultaneously at the inlet and outlet of the chip dryer lime injected baghouse and simultaneously at the reverberatory furnace #1 lime injected baghouse. FTIR testing was not simultaneous at inlet/outlet; the FTIR alternated between inlet/outlet (for example, ten minutes inlet/ten minutes outlet). In addition, a day of testing was performed using EPA Method 320 to identify, quantify, and assess the performance of the lime injected baghouse associated with the reverberatory furnace #1 for HCl removal at two injection rates of lime. Two additional days were required to perform a Method 301 validation of FTIR for HCl: one day each for the two baghouses.

1.2 Brief Site Discussion

The Culp Aluminum Alloys Plant is located in Steele, Alabama, approximately 4 miles south of Gadsden, Alabama. The plant is a secondary aluminum plant, primarily smelting recycled aluminum. Culp Aluminum Alloys primarily recycles aluminum parts to create a secondary aluminum alloy which is used in cast aluminum. The plant operates 24 hours per day, but the chip dryer process is down Monday from 7 AM to 4 PM, except for the furnaces.

The Culp Aluminum Alloys Plant has two baghouses associated with the furnaces as control devices: the first baghouse is the original one while the second is newer. The exhaust stacks on both are approximately the same size. Furnace #1 and Furnace #2 differ in that Furnace #2 has an additional exhaust from the sweat furnace. The sweat furnace is used to separate plastic parts and metals of higher melting points from the aluminum prior to placing the aluminum into the furnace.

1.3 Emissions Measurements Program

This section provides an overview of the emissions measurement program conducted at the Culp Aluminum Alloys Plant in Steele, Alabama. Included in this section are summaries of the test matrix, sampling locations, sampling methods, and laboratory analysis. Additional detail on these topics are provided in the sections that follow.

1.3.1 Test Matrix

The sampling and analytical matrix that was performed at Culp Aluminum Alloys is presented in Table 1-1, with the schedule that was followed in the field. Manual and Fourier Transform Infrared (FTIR) instrumental emissions tests were performed, with detailed descriptions of these sampling and analytical procedures provided in Section 5.0 of this document.

Table 1-1. Culp Aluminum Alloys Facility (Steele, Alabama) Test Matrix
Industry: Secondary Aluminum
Process: Aluminum Chip Drying and Smelting

Sampling Location	Runs/ Date	Sample Type	Reference Method	Sampling Duration	Analysis Method	Laboratory
E2 Chip Dryer Lime Injected Baghouse Outlet	1 day 12/03/97	HCl Validation	Method 320	4-8 hours	FTIR	ERG

E3/E4 Reverberatory Furnace #1 Lime Injected Baghouse	1 day 12/07/97	HCl Removal efficiency study	Method 320	4-8 hours	FTIR	ERG
E3/E4 Reverberatory Furnace #1 Lime Injected Baghouse	1 day 12/07/97	HCl Validation	Method 320	8-10 hours	FTIR	ERG
E3/E4 Reverberatory Furnace #1 Lime Injected Baghouse Inlet/Outlet	6[2] Run 1 12/08/97 Run 2 12/09/97 Run 3 12/10/97 Run 4 12/11/97	HCl/PM Dioxins/Furans All species detected by FTIR[1]	Method 26A Method 23 Method 320	4 hours	Method 26A Method 8290 Method 320	Triangle Labs Triangle Labs ERG

[1] All species detected by FTIR includes all gaseous HAPs (i.e., HCl), as well as criteria pollutants (i.e., NO_2, SO_2, CO).

[2] Work Assignment Manager elected to perform four test runs in the field.

1.3.2 Test Schedule

The daily test schedule is shown in Table 1-1. The test required one day of set-up at the chip dryer lime injected baghouse, two test days at the inlet/outlet of the chip dryer lime injected baghouse, one day of process operating parameter optimization using FTIR, and five test days at the inlet/outlet of the reverberatory furnace #1 lime injected baghouse. One day was allowed as contingency/tear-down. The facility did not operate on Mondays from 7 AM to 4 PM, except for the furnaces; allowance was made for the plant schedule in the test schedule. Each test day was 12 to 16 hours in length. Set-up and tear-down days were 8 to 10 hours in length.

1.4 Test Report

This final report, presenting all data collected and the results of the analyses, has been prepared in six sections and two volumes, as described below:

- Section 1 provides an introduction to the testing effort and includes a brief description of the test site and an overview of the emissions measurements program;
- Section 2 gives a summary of the test results for the PM, HCl, D/F tests, and the FTIR results for HCl and selected HAPs;
- Section 3 provides a description of the process and plant operation during the field test. These data are to be supplied by EPA through Research Triangle Institute to be included at a later date;
- Section 4 gives a discussion of the sampling locations;
- Section 5 presents detailed descriptions of the sampling and analysis procedures; and
- Section 6 provides details of the quality assurance/quality control procedures used on this program and the QC results.

The appendices containing copies of the actual field data sheets and the results of the laboratory analyses are contained in Volume 2.

2.0 SUMMARY OF RESULTS

This section provides the results of the emissions test program conducted at the Culp Aluminum Alloys plant from December 2 to December 11, 1997. Included in this section are the results for the manual tests conducted for PM, HCl, Cl_2, dioxin and furan and for the extractive FTIR test conducted for HCl and screening for selected HAPs. Testing was performed at the inlet and outlet of the baghouse associated with the chip dryer and at the inlet and outlet of the baghouse associated with the reverberatory furnace number 1.

2.1 Emissions Test Log

Twenty eight manual tests were performed over a nine day period (14 D/F and 14 HCl/PM). Table 2-1 presents the emissions test log which shows the test date, location, run number, test type and run times for each method. Concurrent with the manual testing at each location were extractive FTIR measurements for HCl.

Table 2-2 shows the volume of stack gas sampled for each run in dry standard cubic meters (dscm) and Table 2-3 shows the stack gas volumetric flow rate during each run in dry standard cubic meters per minute (dscmm). The percent relative standard deviation (%RSD) calculated for the stack flow rates (shown in Table 2-3) was less than 10 % indicating that each process flow was maintained at a fairly constant rate over the respective test days. All related field data sheets are given in Appendix A.

2.2 Dioxin/Furan Results

2.2.1 Overview

Three 4-hour D/F tests were performed at the inlet and outlet of the baghouse associated with the chip dryer operation (total of 6) and four 6-hour tests were performed at the inlet and outlet of the baghouse associated with the reverberatory furnace number 1 (total of 8). The sampling and analysis procedures followed EPA Method 23 protocol. All results except for the 2,3,7,8-tetrachlorodibenzofuran (2,3,7,8-TCDF) were determined by high resolution gas chromatography (HRGC)/high resolution mass spectrometry (HRMS) using a DB-5 capillary gas chromatographic column. The 2,3,7,8-TCDF was determined by HRGC/HRMS using a DB-225 column which gives improved chromatographic resolution for this compound over the DB-5 and thus a more accurate quantitation. Any compound that was not detected is reported as a "less than" value with this value being the instrument detection limit. A "less than" value rather than a "0" is used in all appropriate calculations. All D/F raw data can be found in Appendix B of this report.

2.2.2 Dioxin/Furan Emission Results

Chip Dryer

Tables 2-4 and 2-5 present the concentration, in nanograms per dry standard cubic meter (ng/dscm), of the selected D/F congeners by run number, the average concentration over the three runs and the %RSD for the chip dryer inlet and outlet, respectively. These values were calculated by dividing the reported analytical results, in ng, by the appropriate sample volume collected, in dscm, from Table 2-2. As indicated in Table 2-4 (dryer inlet), the concentration values of several congeners in Runs 1 and 2 are presented as "greater than" values and should be considered estimates. The amount of these analytes detected in the sample extracts exceeded the calibration curve. The observed concentrations for Run 3 are generally lower by a factor of two than those observed for Runs 1 and 2, causing the %RSDs for most analytes to be in the 40 to

Table 2-4. Chip Dryer, Inlet D/F Stack Gas Concentration, ng/dscm

50 range. The fact that different feed stocks or combinations of feed stocks were used for each of the runs is the most probable explanation for this. The feed stock for Run 1 was continuous during the run. The feed stock for Run 2 was the remainder of the feed stock used during Run 1 (depleted after approximately the first half of Run 2) plus a portion of a new feed stock of different material and different oily coating. The feed stock for Run 3 was a combination of the remainder of the second feed stock from Run 2 plus a third feed stock material with yet another different oily coating. Each lot of feed stock material used during the testing was added to the loading hopper as needed until it was depleted, followed by the next lot until it was depleted and so on. Each lot of material was processed as a discrete material type and oily coating with no mixing or blending of the three lots. Table 2-5 (dryer outlet) shows concentrations considerably lower than the inlet for Runs 1 and 2, whereas for Run 3 the inlet and outlet values are similar. The %RSDs generally in the 20 to 30 range still reflect the use of three different lots of feed stock.

Table 2-6 shows the D/F stack emission rate from the chip dryer outlet in micrograms of analyte per megagram (μg/Mg) of feed stock for each of the three runs, the average and the %RSD. These values were calculated using standard conversion factors (i.e., pounds to grams) and from the concentrations given in Table 2-5, the stack flow rates given in Table 2-3 and the number of pounds of each feed stock consumed during the test period as supplied by the facility. The latter data set (pounds of feed stock consumed) for each of the three runs was not a straightforward calculation. Mitigating factors included:

- Each lot of feed was processed at a different rate;
- Combinations of feed stock were used during two of the runs; and
- Two of the feed stocks were processed beginning on one day, finishing on the next day with the process shut down over night.

For run number one a single lot of feed stock was used, but it was processed over a two day period (32,000 pounds in 8 hours on the first day during Run 1 and 4,740 pounds in 3.5 hours on the next day during the first part of Run 2). The feed rate of feed stock consumed during Run 1

Table 2-6. Chip Dryer, Outlet D/F Emission Rate, µg/Mg Feed

Congener	Run 1	Outlet Run 2	Run 3	Average	%RSD
2,3,7,8-TCDD	4.50	5.41	3.79	4.57	17.7
1,2,3,7,8-PeCDD	18.3	25.5	19.2	21.0	18.5

2,3,4,7,8-PeCDF	122	170	129	140	18.3
1,2,3,4,7,8-HxCDF	77.2	112	89.3	92.8	19.0
1,2,3,6,7,8-HxCDF	35.4	49.4	41.5	42.1	16.7
2,3,4,6,7,8-HxCDF	22.1	32.0	24.0	26.1	20.2
1,2,3,7,8,9-HxCDF	1.22	1.43	1.16	1.27	10.9
1,2,3,4,6,7,8-HpCDF	21.0	27.8	20.7	23.2	17.2
1,2,3,4,7,8,9-HpCDF	2.52	3.01	1.92	2.48	22.0
OCDF	3.06	3.17	1.85	2.69	27.2

was therefore calculated by dividing 32,000 by 8. The same logic was followed for Runs 2 and 3, except that two different lots were used during each run and the average feed rate was therefore determined. The feed rate calculations are summarized below:

Run No.	Lot	Feed Time-Date	Pounds of Feed	Feed Rate	Avg. Feed Rate, lbs/hr
1	1	8 hrs-12/5/97	32,000	4,000 lbs/hr	4,000
2	1	3.5 hrs-12/6/97	4,740	1,354	1,959
2	2	8 hrs-12/6/97	20,500	2,563	
3	2	8 hrs-12/6/97	20,500	2,563	3,032
3	3	2 hrs-12/6/97	7,000	3,500	

Table 2-7 shows the D/F congener concentrations in ng/dscm converted to 2,3,7,8-TCDD toxicity equivalents as well as a summation of the values presented as total chlorinated dioxins and total chlorinated furans.

Reverberatory Furnace #1

A total of four tests was performed collecting samples simultaneously at the inlet and outlet of the baghouse associated with furnace number 1. Each test was performed over the duration of a batch cycle starting at the time of the first furnace charge and ending at the time of the last tap out, a period ranging from approximately five and one-half hours to six and one-half hours. The same product was produced during each of the four tests. Each batch followed a three stage process: charging, mixing and tap-out. Charging required approximately four hours to complete, mixing one hour and tap-out one hour. The highest emissions were observed during the charging process (as observed from the real time FTIR data for HCl). A "front-end loader" Caterpillar tractor was used to charge feed stock or flux to the furnace approximately every ten minutes during the charging stage. As each load was added emissions were visible in the form of clouds of black smoke/soot which were captured by an overhead hood and directed to the baghouse.

[1]Toxicity Equivalence Factor

Tables 2-8 and 2-9 present the concentration, in ng/dscm, of the selected D/F congeners by run number, the average concentration over the three runs and the %RSD for the reverberatory furnace No. 1 inlet and outlet, respectively. These values were calculated by dividing the reported analytical results, in ng, by the appropriate sample volume collected, in dscm, from Table 2-2. As indicated in Table 2-8 (furnace inlet) the concentration value of the octachlorofuran in Run 2 is presented as a "greater than" value and should be considered an estimate. The amount of this analyte detected in the sample extract exceeded the calibration curve.

*Values below calibration curve and/or less than 5 x MDL; should be considered estimates

The observed concentrations for the four runs at the inlet are generally of the same magnitude as indicated by the low %RSDs. Table 2-9 (furnace outlet) shows the concentrations to be considerably lower than those at the inlet by a factor of 10 to 100. Several of the analytes exhibited a concentration level below the calibration curve, less than 5 times the detection limit or not detected. These factors contribute to the high %RSD observed, not unusual in this situation.

Table 2-10 shows the D/F stack emission rate from the furnace number 2 outlet in micrograms of analyte per megagram (µg/Mg) of feed stock for each of the four runs, the average and the %RSD. These values were calculated using standard conversion factors (i.e., pounds to grams), the concentrations given in Table 2-9, the stack flow rates given in Table 2-3 and the number of pounds of feed stock consumed during the test period as supplied by the facility. Although the feed stock was added only during the first four hours of each batch, the feed rate was calculated using the total pounds consumed divided by the length of the total batch process. This calculation process was necessary to correspond with the emissions collected by the integrated sample over the duration of the entire batch process including charging, mixing and tap-out. The latter data set (pounds of feed stock consumed) for each of the four runs is given below:

Run No.	Lot	Batch Time-Date	Feed Consumed, lbs.	Feed Rate, lbs./hr
1	1	6 hrs-12/8/97	70,200	11,700
2	2	6.5 hrs-12/9/97	70,200	10,800
3	3	5.75 hrs-12/10/97	75,600	13,148
4	4	6.5 hrs-12/11/98	81,000	12,462

Table 2-11 shows the congener concentrations in ng/dscm converted to 2,3,7,8-TCDD toxicity equivalents as well as a summation of the values presented as total chlorinated dioxins and total chlorinated furans.

[1]Toxicity Equivalence Factor

2.3 HCl Results

2.3.1 Overview

Three 4-hour HCl/Cl_2 tests were performed at the inlet and outlet of the baghouse associated with the chip dryer operation (total of 6) and four 6-hour tests were performed at the inlet and outlet of the baghouse associated with the reverberatory furnace number 1 (total of 8). The sampling and analysis procedures followed EPA Method 26A protocol. Prior to testing, the plant personnel replaced all fabric filters in the baghouse with new ones and performed the appropriate leak checks. All analyses were performed by ion chromatography using the samples as received from the field. Any compound that was not detected is reported as a "less than"

value with this value being the instrument detection limit. A "less than" value rather than a "0" is used in all appropriate calculations. All HCl/Cl_2 raw data can be found in Appendix C of this report.

2.3.2 HCl Emission Results

Chip Dryer

The baghouse associated with the chip dryer is injected with lime (hydrated calcium hydroxide) for the purpose of reducing HCl emissions. The reaction between the two compounds forms calcium chloride and water. The lime injection to the baghouse was continuous at a feed rate of approximately 50 pounds per hour. Table 2-12 gives the concentration, in micrograms per dry standard cubic meters (µg/dscm), the average concentration over the three runs and the %RSD for the inlet and outlet, respectively. The results for Run 3 inlet are invalid as the sample was compromised during sample recovery in the field. Chlorine was not detected (at the instrument detection limit) in any samples at either the inlet or the outlet. The HCl results for Runs 1 and 2 inlet and Runs 1 and 2 outlet are very consistent among themselves with the outlet concentrations representing about 3% of the amount entering the baghouse. Table 2-13 gives the concentrations in parts per million (ppm) in order to provide an easy comparison to the FTIR results which are also presented in ppm and provided in Section 2.5 of this report.

The emission rate of HCl/Cl_2, in pounds/hour (lbs/hr), was calculated using the concentration results from Table 2-12 and the stack flow rate data from Table 2-3 and is presented in Table 2-14. Using the average emission rates calculated for the inlet and the outlet, a baghouse percent removal efficiency for HCl was determined to be 96.9%, as shown in Table 2-15. The emission rate of HCl/Cl_2 was also determined as pounds per ton of feed stock using the data given in Table 2-14 and the feed stock feed rates for the chip dryer given in Section 2.2.2 above. These results are given in Table 2-16.

[1]Run 3 compromised during sample collection, Runs 1 and 2 used to calculate average
[2]NA, Not Applicable

Reverberatory Furnace Number 1

The results for the reverberatory furnace #1 are given in Tables 2-12 through 2-16 following the same sequence as the chip dryer. During Test Runs 1 and 2, lime was fed continuously to the baghouse (Condition 1). During Test Runs 3 and 4, lime was added to the lime feed hopper at the rate of one 50 lb bag every two hours (Condition 2). Lime was consumed at the rate of approximately 50 pounds per 30 minutes during the test period. The concentration results presented in Tables 2-12 and 2-13 for HCl for Runs 1 and 2 are consistent among themselves for both the inlet and outlet. Run 4 inlet results were consistent with Runs 1 and 2. However, the outlet results were approximately a factor of 2 higher than for Runs 1 and 2. The fact that one of the four baghouse modules (module 4) had developed a leak and was off-line could be a possible explanation for this observation. The Run 3 inlet HCl concentration was observed to be approximately half that for the other runs, possibly because furnace Cl_2 flow supply was not turned on until at least an hour into the test.

The baghouse removal efficiency for HCl was determined for Condition 1 using the average of the emission rate results from Runs 1 and 2 and for Condition 2 using the average of Runs 3 and 4. The results are presented in Table 2-15. The removal efficiency for Condition 2 was slightly less than that for Condition 1, with both well above 95%. The emission rate of HCl/Cl_2 was also determined as pounds per ton of feed stock using the data given in Table 2-14 and the feed stock feed rates for the furnace given in Section 2.2.2, above. These results are given in Table 2-16.

2.4 Particulate Results

2.4.1 Overview

Particulate matter emissions were determined from the same sampling trains used for the determination of HCl emissions. PM collected on the filter and in the front half acetone rinse (nozzle, probe, front-half filter holder) was analyzed gravimetrically. PM stack concentrations in grains per dry standard cubic meter (gr/dscm), PM emission rate in pounds per ton of feed (lbs/Ton) and pounds per hour (lbs/Hr), and the PM removal efficiency of each baghouse as a percent (%) for the chip dryer and furnace number 1 operations are presented below. The results of the PM testing are presented in Tables 2-17 through 2-20. All raw data for the PM determinations can be found in Appendix D.

2.4.2 Particulate Emission Results

Chip Dryer

Table 2-17 gives the concentration, in gr/dscm, the average concentration over the three runs and the %RSD for the inlet and outlet. The average of the three runs was 20.3 and 0.778 for the inlet and outlet, respectively.

Table 2-17. Stack Gas Particulate Matter Concentration, gr/dscm

Baghouse Location	gr/dscm					%RSD
	Run 1	Run 2	Run 3	Run 4	Average	
Chip Dryer Inlet	27.8	19.3	13.9	NA	20.3	34.5
Chip Dryer Outlet	2.07	0.529	1.10	NA	1.23	63.2

Table 2-19. Baghouse Particulate Removal Efficiency,%

Location	lbs/hr		
	Avg. Inlet Rate	Avg. Outlet Rate	Removal Efficiency %
Chip Dryer Baghouse	25.9	1.66	93.6
Furnace 1 Baghouse	27.9	0.317	98.9

Table 2-20. Particulate Matter Emission Rate, lbs/Ton of Feed

Baghouse Location	lbs/ton of Feed					%RSD
	Run 1	Run 2	Run 3	Run 4	Average	
Chip Dryer Inlet	16.9	27.3	11.190	NA	18.5	44.3
Chip Dryer Outlet	1.35	0.791	0.982	NA	1.04	27.5
Furnace 1 Inlet	7.73	5.35	2.82	3.07	4.74	48.3
Furnace 1 Outlet	0.173	0.0289	0.00970	0.00555	0.0543	147

The emission rate of PM, in lbs/hr, was calculated using the concentration results from Table 2-17 and the stack flow rate data from Table 2-3 and is presented in Table 2-18. Using the average emission rates calculated for the inlet and the outlet, a baghouse percent removal efficiency for PM was determined to be 93.6%, as shown in Table 2-19. The emission rate of PM was also determined as pounds per ton of feed stock using the data given in Table 2-18 and the feed stock feed rates for the chip dryer given in Section 2.2.2 above. These results are given in Table 2-20.

Reverberatory Furnace Number 1

Table 2-17 gives the concentration, in gr/dscm, the average concentration over the four runs and the %RSD for the inlet and outlet. The average of the four runs was 4.68 and 0.0455 for the inlet and outlet respectively. The inlet PM concentrations for Runs 1 and 2 (condition 1) are noticeably higher than for Runs 3 and 4 (condition 2), possibly due to the lower lime injection rate that occurred during Runs 3 and 4. The high variability between the outlet results is due to the low mass of PM present on the filters. Values near the limit of detection have inherent increased variability.

The emission rate of PM, in lbs/hr, was calculated using the concentration results from Table 2-17 and the stack flow rate data from Table 2-3 and is presented in Table 2-18. Using the

average emission rates calculated for the inlet and the outlet, a baghouse percent removal efficiency for PM was determined to be 98.9%, as shown in Table 2-19. The emission rate of PM was also determined as pounds per ton of feed stock using the data given in Table 2-18 and the feed stock feed rates for furnace number 2 given in Section 2.2.2 above. These results are given in Table 2-20.

2.5 FTIR Results

2.5.1 Overview

FTIR data for HCl and other species were collected at the inlet and outlet of the baghouses associated with the chip dryer and reverberatory furnace 1. FTIR data collection was synchronized with manual HCl and dioxin/furan testing to allow semi-quantitative comparison of the FTIR and manual HCl results. Due to partitioning of FTIR analysis time between unconditioned and conditioned inlet/outlet samples, only 25% of FTIR data during a given run on the chip dryer and 38% on the furnace were collected simultaneously with the corresponding inlet or outlet manual train sampling.

FTIR data were collected at each location by alternating sample analysis between inlet and outlet every 10 minutes. Both inlet and outlet sampling systems continuously withdrew sample from their respective location. Each 10 minute measurement period contained ten 1 minute average data points. The first two data points from each period were discarded to eliminate data for samples containing both inlet and outlet sample gas. Two data points correspond to the measured response time of the complete FTIR sampling and analysis system (see below for details on measurement of system response time) A 1 minute average data point is generated by analysis of a composite spectrum consisting of an average of 43 FTIR spectra collected over the 1 minute time period.

Section 2.1 gives the schedule of the tests performed at the Culp facility. Both unconditioned samples and conditioned samples were analyzed. Conditioned samples were

generated by passing the raw sample gas through a water vapor/carbon dioxide scrubbing system (See Section 5.3 for details). Unconditioned and conditioned samples extracted from the chip dryer baghouse were measured during the first and last two-hour periods for each four hour run, respectively. At the reverberatory furnace #1, the sampling order went as follows: 2 hours unconditioned, 1 hour conditioned, and 2 hours unconditioned. Two unattended unconditioned overnight runs were also conducted to look continuously at reverberatory furnace #1 hood baghouse outlet emissions. Those results are reported in Section 2.5.2.2.

Baghouse removal efficiency for HCl was measured from the inlet/outlet data from each location and is reported in Section 2.5.2.2. Optimization of the reverberatory furnace 1 baghouse for HCl removal was also carried out. The removal efficiency was found to exceed 90% for all tests at all lime injection rates tested.

EPA Method 301 validation tests for HCl were carried out on the chip dryer baghouse outlet, and reverberatory furnace #1 baghouse inlet and outlet. In all three tests, the Method 301 statistical calculations showed that the FTIR method demonstrated acceptable precision and no statistically significant bias for HCl. Details of the validation results can be found in Section 2.5.2.1.

A comparison of the FTIR and Method 26A results for both the chip dryer and furnace tests are presented in Section 2.5.2.6

2.5.2 FTIR Emission Results

This section contains the FTIR EPA Method 301 HCl validation results, HCl test results, and screening results for the chip dryer and reverberatory furnace #1 hood baghouse inlet and outlet. Also included are results for the reverberatory furnace #1 hood baghouse HCl removal efficiency optimization tests.

2.5.2.1 EPA Method 301 FTIR Validation Results for HCl

EPA Method 301 validation testing for HCl was performed on the chip dryer outlet, and reverberatory furnace #1 hood inlet/outlet. The spiking procedure is given in Section 5.3.2. Five-minute measurement periods were used for the chip dryer outlet, while 1-minute measurement periods for both inlet and outlet of the reverberatory furnace #1 were used. The 1-minute periods were used because of the rapidly fluctuating nature of the furnace emissions. Table 2-21 summarizes the validation results.

Table 2-21. Summary of EPA Method 301 FTIR Validation Results for HCl

Location	Date	Spiked/Unspiked Precision Acceptable?	Statistically Significant Bias?
Chip Dryer Outlet	12/03/97	Yes/Yes	No
Furnace 1 Inlet	12/07/97	Yes/Yes	No
Furnace 1 Outlet	12/07/97	Yes/Yes	No

Note: Acceptable precision is equal to or less than 50% RSD.

Detailed results of the validation testing can be found in Appendix E.

2.5.2.2 FTIR HCl Test Results

The estimated FTIR HCl detection limit for this study is 0.05 ppmv.

While it is instructive to compare HCl results from both FTIR and manual methods, care must be taken in interpreting the two sets of results. The FTIR system measured HCl at a given inlet or outlet only 25 % of the time; the corresponding manual method was integrated over the entire sampling period. Half of the FTIR instrument analysis time was split equally between inlet and outlet as unconditioned and conditioned samples. Since HCl was measured only in

unconditioned samples, this sampling scheme results in a 25% duty cycle for the total run for HCl measurement at a given inlet or outlet. The potential difference between FTIR and manual results will increase with greater fluctuations in the HCl concentration during the run, since the FTIR captures 25% of the manual method sample for a given inlet or outlet run. Greatest fluctuation in HCl was observed during charging operations on the furnace #1 inlet to the baghouse.

Results given below are organized by location. HCl removal efficiency was also calculated for each run.

Chip Dryer Baghouse Outlet/Inlet HCl Results—Table 2-22 gives a summary of the chip dryer baghouse outlet/inlet FTIR HCl results. The average inlet concentrations were consistent between runs, but the outlet concentrations varied by a factor of 10.

During Run 1, a large slug of particulate matter filled the FTIR inlet heated filter assembly which prevented sampling of the inlet gas. The FTIR system was allowed to measure the outlet while the inlet filter system was cleaned; thirty more data points were therefore measured on the outlet versus the inlet. These extra 30 data points were reported in the preliminary data, but they are not included in the results presented in Table 2-22. The removal of the extra 30 data points does not cause any significant changes in the Run 1 results, however.

Reverberatory Furnace 1 Baghouse Outlet/Inlet HCl Results—Table 2-23 gives the FTIR HCl results for the reverberatory furnace baghouse inlet and outlet during charging of the furnace with scrap aluminum. Table 2-24 shows the FTIR HCl results for the reverberatory furnace #1 hood baghouse inlet and outlet during tapping operations. In all cases, HCl removal efficiency due to the lime-injected baghouse was greater than 90 percent.

Tables 2-23 and 2-24 clearly show that the respective inlet and outlet concentrations during charging are somewhat higher on average than during tapping. This result is expected, due to the nature of the loading process, where hydrocarbons from oils coated on the charge material provide the source of hydrogen for HCl production. Tapping operations do not involve the addition of any material to the furnace, so the HCl levels would be expected to be lower.

Further examination of the data shows that the standard deviation of HCl inlet and outlet levels during loading is significantly higher than during tapping. This variation stems from the greater variation in the HCl emissions during loading due to the periodic addition of hydrocarbon material to the furnace. During tapping operations, the furnace is not charged, and less variation is expected.

Tables 2-25 and 2-26 are the combined loading and tapping results and a grand average of all 4 runs, respectively. The combined results were generated by an average of the respective

data in Tables 2-23 and 2-24 weighted by the number of sample points. Computation of the grand average was a simple unweighted average of the 4 runs.

Table 2-27 gives the FTIR HCl results of the unconditional reverberatory furnace 1 baghouse outlet during two overnight periods. Five minute averages were collected for each data point, instead of the usual 1 minute average collected in all other tests.

2.5.2.3 FTIR Process Optimization

The reverberatory furnace #1 hood baghouse HCl destruction efficiencies were measured as a function of lime injection rate. Examination of Table 2-23 shows there is no apparent effect of lime injection rate on the measured removal efficiency. Runs 1 and 2 utilized a continuous lime injection at a rate of 50 lbs per half hour. Runs 3 and 4 examined the emissions during a lime

injection rate of 50 lbs per half hour period with 50 lb being added every 2 hours. In all cases, 90+ percent HCl removal efficiency was obtained.

2.5.2.4 FTIR Screening Results

Screening data for species other than HCl were collected concurrently with the HCl data. FTIR spectral data were examined for any other species present in the samples. Conditioned samples were measured to estimate concentrations of aromatic and some hydrocarbon species. Unconditioned samples were analyzed for other hydrocarbon and criteria species.

Tables 2-28 and 2-29 give summary statistics on the dominant species detected besides HCl for the chip dryer inlet and outlet, respectively. Tables 2-30 and 2-31 are the screening results for the furnace 1 inlet and outlet, respectively. In addition to HAP species, non-HAP species are also reported to aid in understanding of the process chemistry, if desired.

2.5.2.5 FTIR Sampling and Measurement System Response Time Measurement

FTIR system sampling and measurement system response time was determined by measurement of concentration versus time of a dynamic spike of the sample gas. HCl and SF_6 spike gas were introduced via a remote-controlled solenoid valve located upstream of the heated probe filter. The time required to obtain 90 percent response was measured three times. Figure 2-1 illustrates data gathered on-site which show the three measurements. It is clear from the figure that the 90 percent response time is approximately 2 minutes (i.e., two data points). The figure also shows that the SF_6 and HCl response times are approximately the same, with HCl slightly lagging relative to SF_6.

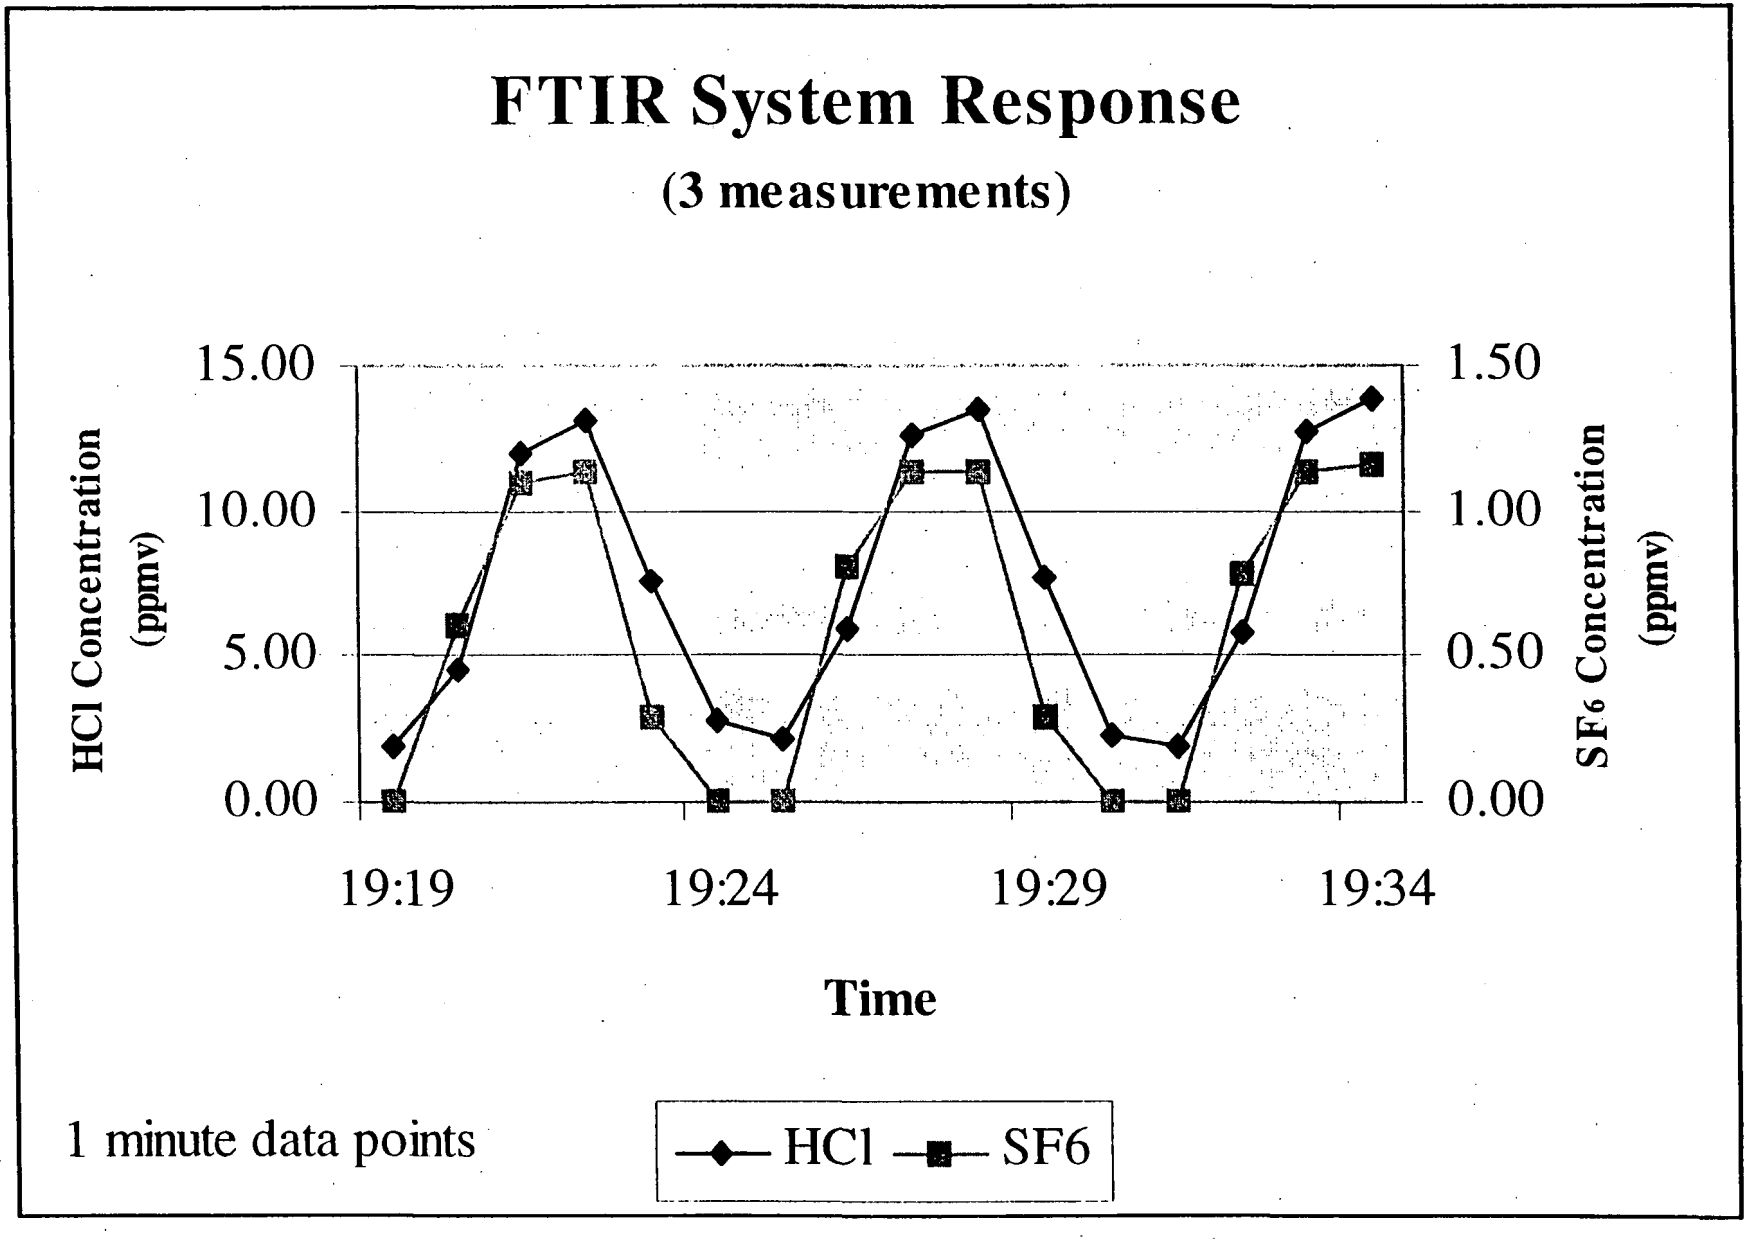

Figure 2-1. FTIR System Response Profile (Measured on 7 December 1997)

2.5.2.6 Comparison of FTIR and Method 26A Results for HCl

Table 2-32 shows the comparison between the two sets of results for both the chip dryer and furnace.

Table 2-32. Comparison of FTIR and Method 26A results for HCl, ppm[1]

Location	FTIR	Method 26A
Chip Dryer Inlet	8.12	27.45
Chip Dryer Outlet	2.48	1.10
Furnace 1 Inlet	70.15	70.37
Furnace 1 Outlet	2.83	0.862

[1]Average of test runs at each location

While it is instructive to compare HCl results from both FTIR and manual methods, care must be taken in interpreting the two sets of results. For the chip dryer, the FTIR system measured HCl at a given inlet or outlet only 25 % of the time compared to the corresponding manual method which was integrated over the entire sampling period, due to splitting half of the FTIR instrument analysis time equally between inlet and outlet as unconditioned and conditioned samples. Since HCl was measured only in unconditioned samples, this sampling scheme results in a 25% duty cycle for the total run for HCl measurement at either the chip dryer inlet or outlet. The corresponding FTIR data capture for either the furnace inlet #1 or outlet was approximately 38%.

Future testing which incorporates both FTIR and Method 26A should include full concurrent sampling to facilitate unbiased comparison between the two methods.

3.0 DESCRIPTION OF FACILITY

(To be supplied by Research Triangle Institute).

4.0 SAMPLING LOCATIONS

The sampling locations that were used during the emissions testing program at Culp Aluminum Alloys are described in this section. Flue gas samples were collected at the inlet and at the outlet of the lime-injected baghouses using manual methods and FTIR, with two 4" ID ports to allow for the operation of two manual sampling methods and one 3" ID port for the FTIR. The configurations of the sampling locations are shown in Figures 4-1 (E1, chip dryer baghouse inlet), 4-2 (E2, chip dryer baghouse outlet), 4-3 (E3, reverberatory furnace #1 baghouse inlet), and 4-4 (E4, reverberatory furnace #1 baghouse outlet).

The chip dryer operated at approximately 150° F, with a slightly negative pressure at the fan inlet and a slightly positive pressure at the outlet. At the inlet and outlet of the reverberatory furnace #1 baghouse, 4" ports were available. FTIR ports were installed horizontally and upstream from manual ports. The baghouse operated at approximately 175° F, with a slightly positive pressure.

The inlet of the lime-injected baghouse for the chip dryer was a circular duct 18" in diameter, and the outlet was a circular duct 25" in diameter. Two 4" ID ports were installed at 90 degrees to each other, one horizontally and one vertically on top of the duct, and a third 3" ID port was installed upstream of the other ports for the FTIR sampling probe.

The inlet to the reverberatory furnace #1 baghouse was a circular duct 42" in diameter. Two 4" ports and one 3" port were installed; the two 4" ports were 90 degrees to each other. The outlet was an exhaust stack 48" in diameter, approximately 30 feet above the ground. The outlet had two 4" ports; a third port (3" ID) was installed for the FTIR upstream of the other two ports. The position and number of traverse points for each location are shown in Figures 4-5 through 4-8. For stacks having diameters greater than 0.61 m (24 in.), no traverse points were located within 2.5 cm (1.00 in.) of the stack walls.

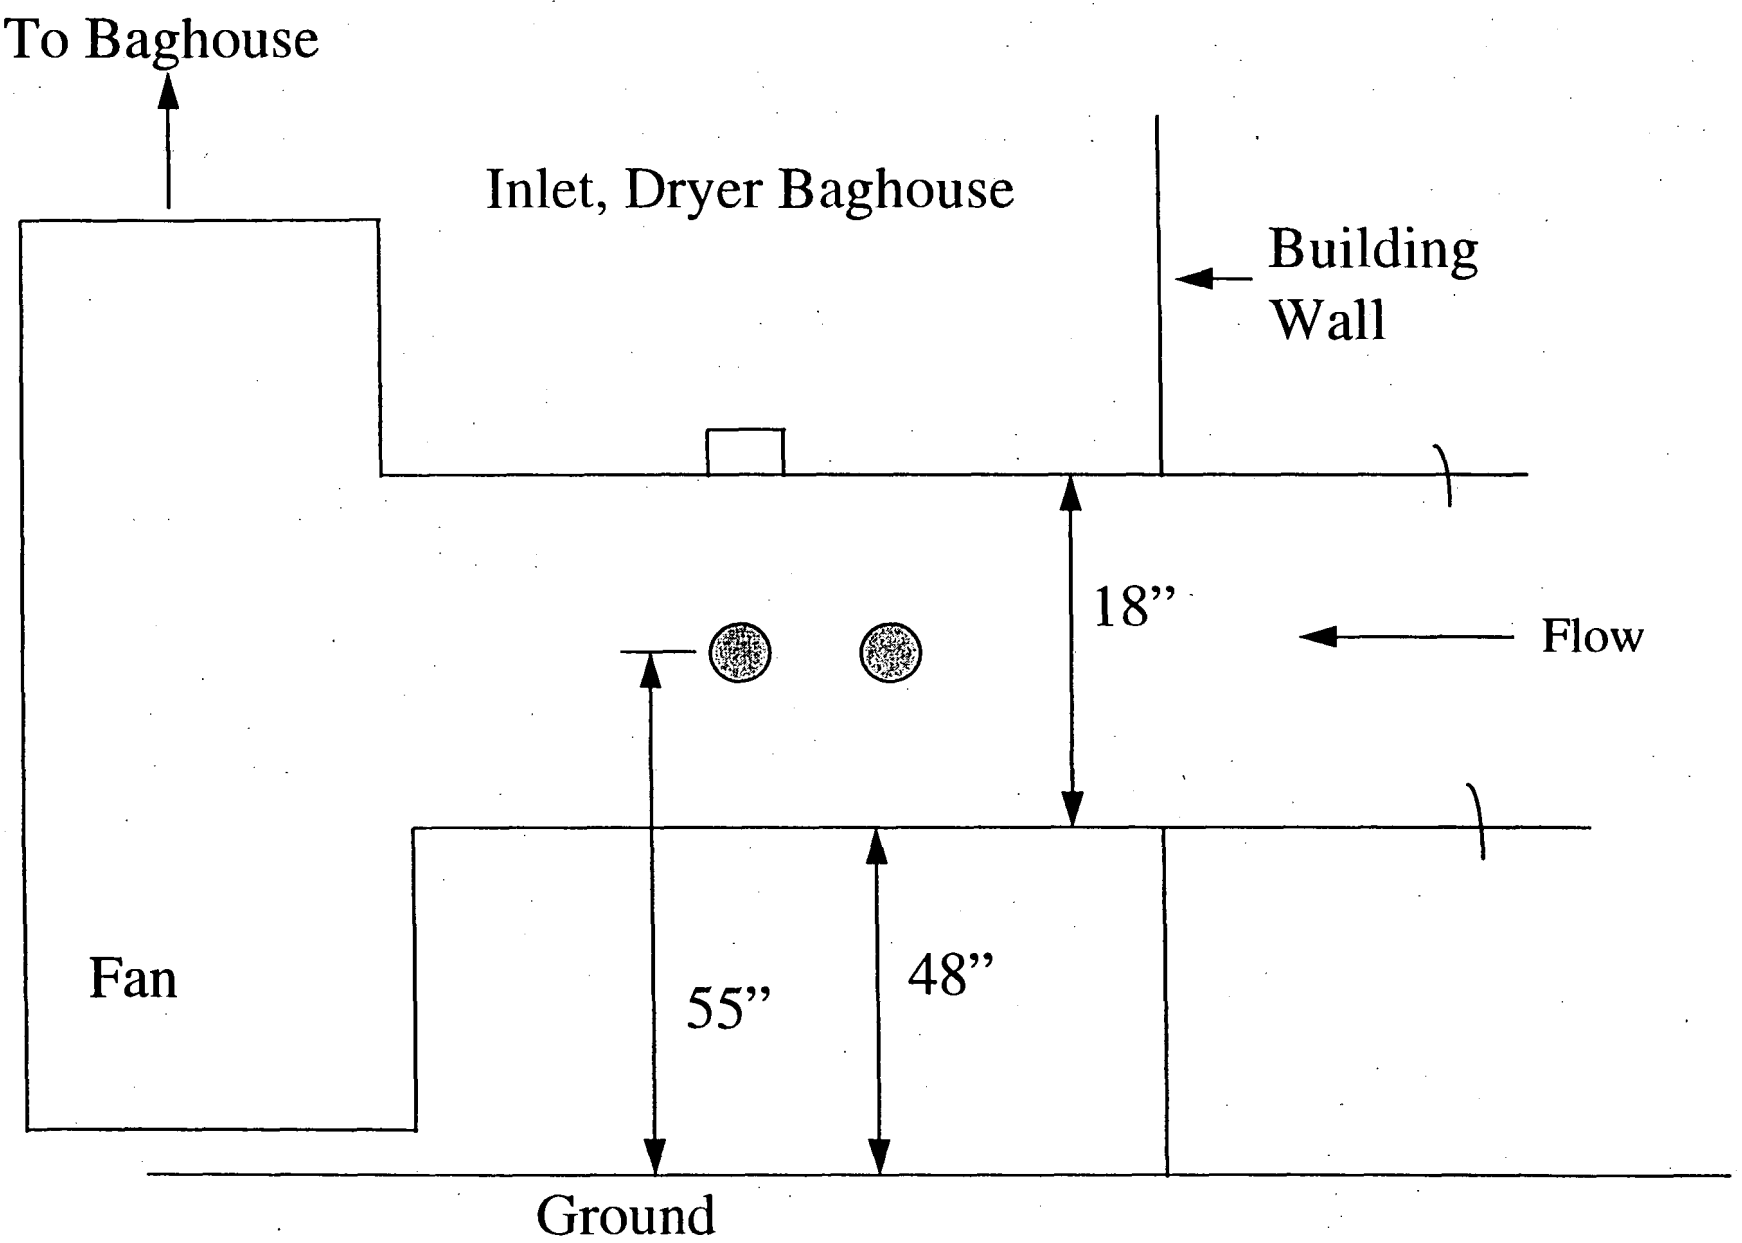

Figure 4-1. E1, Chip Dryer Baghouse Inlet

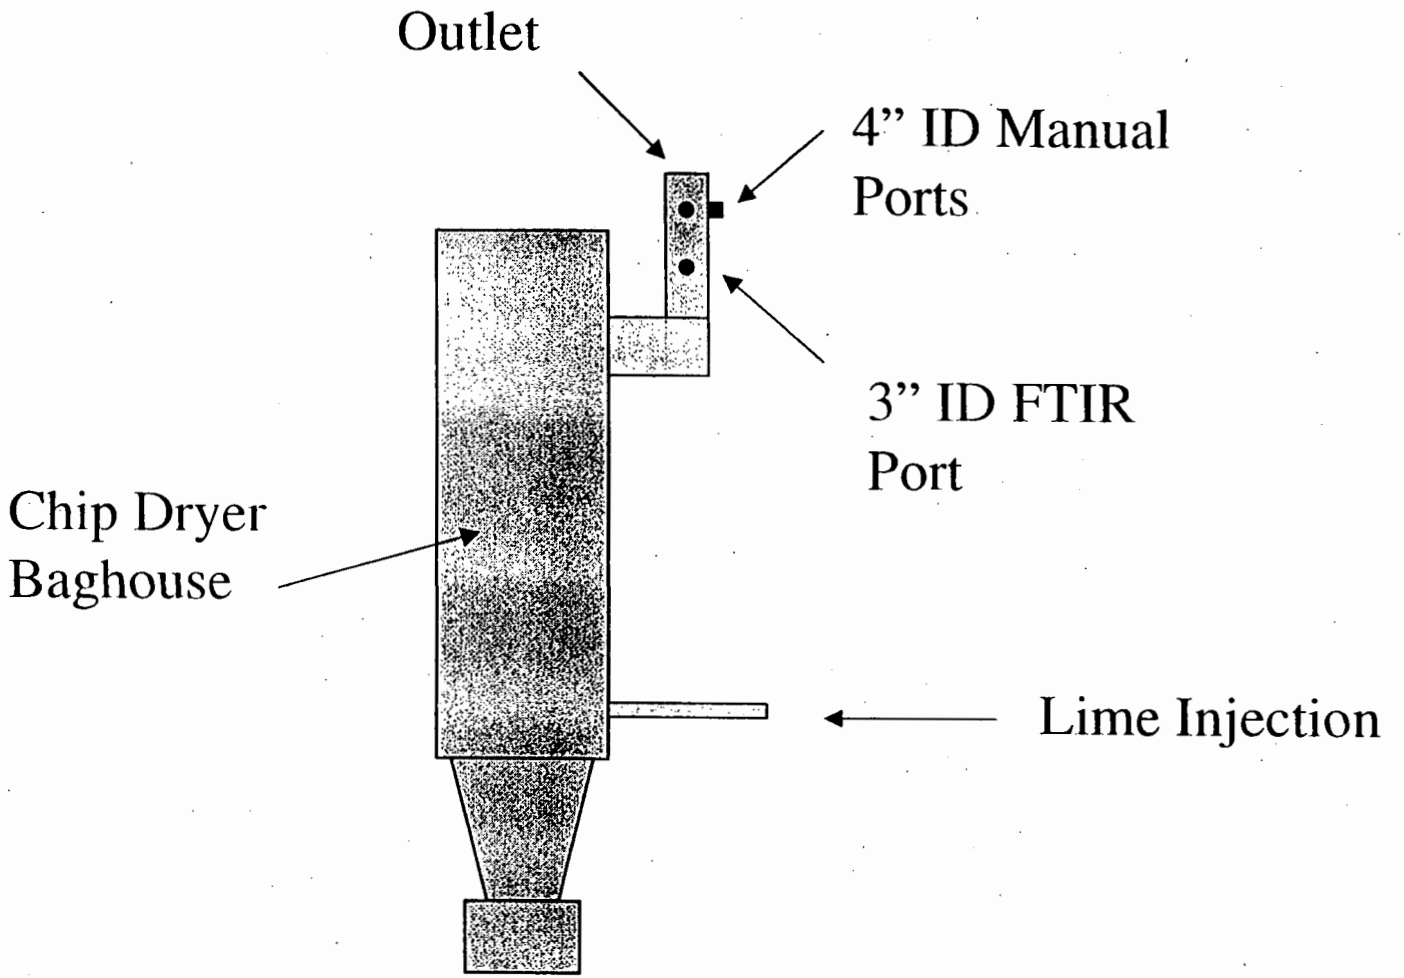

Figure 4-2. E2, Chip Dryer Baghouse Outlet

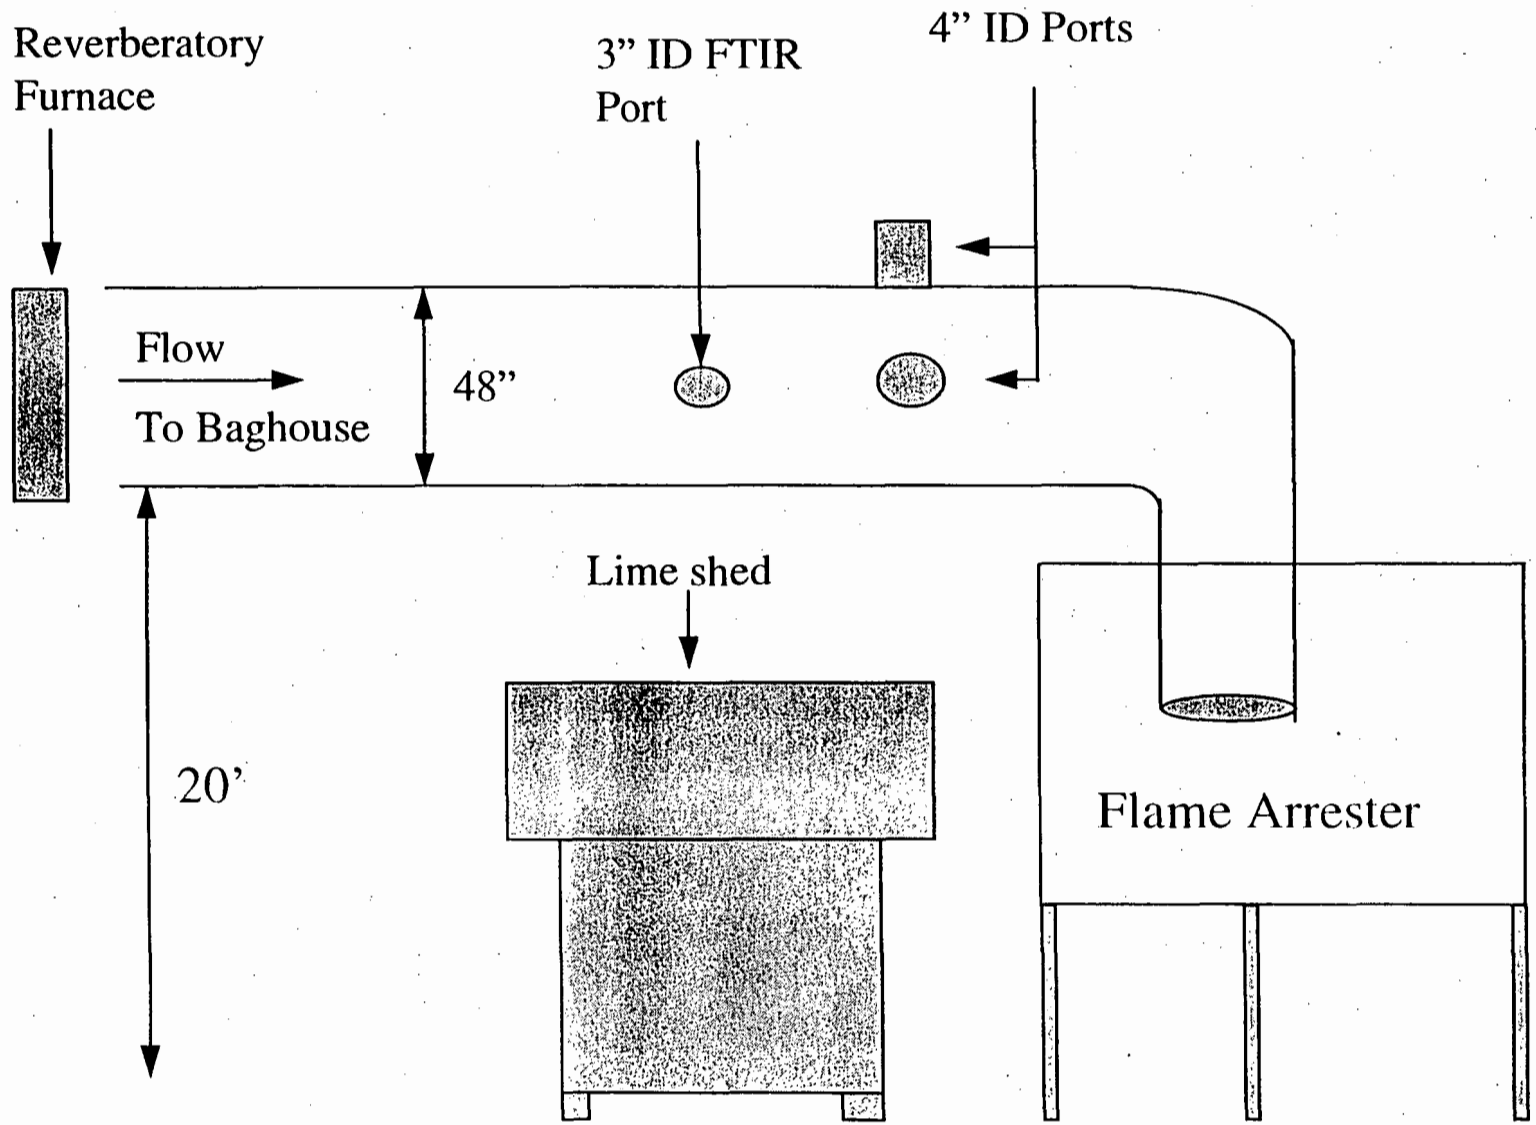

Figure 4-3. E3, Reverberatory Furnace Baghouse Inlet

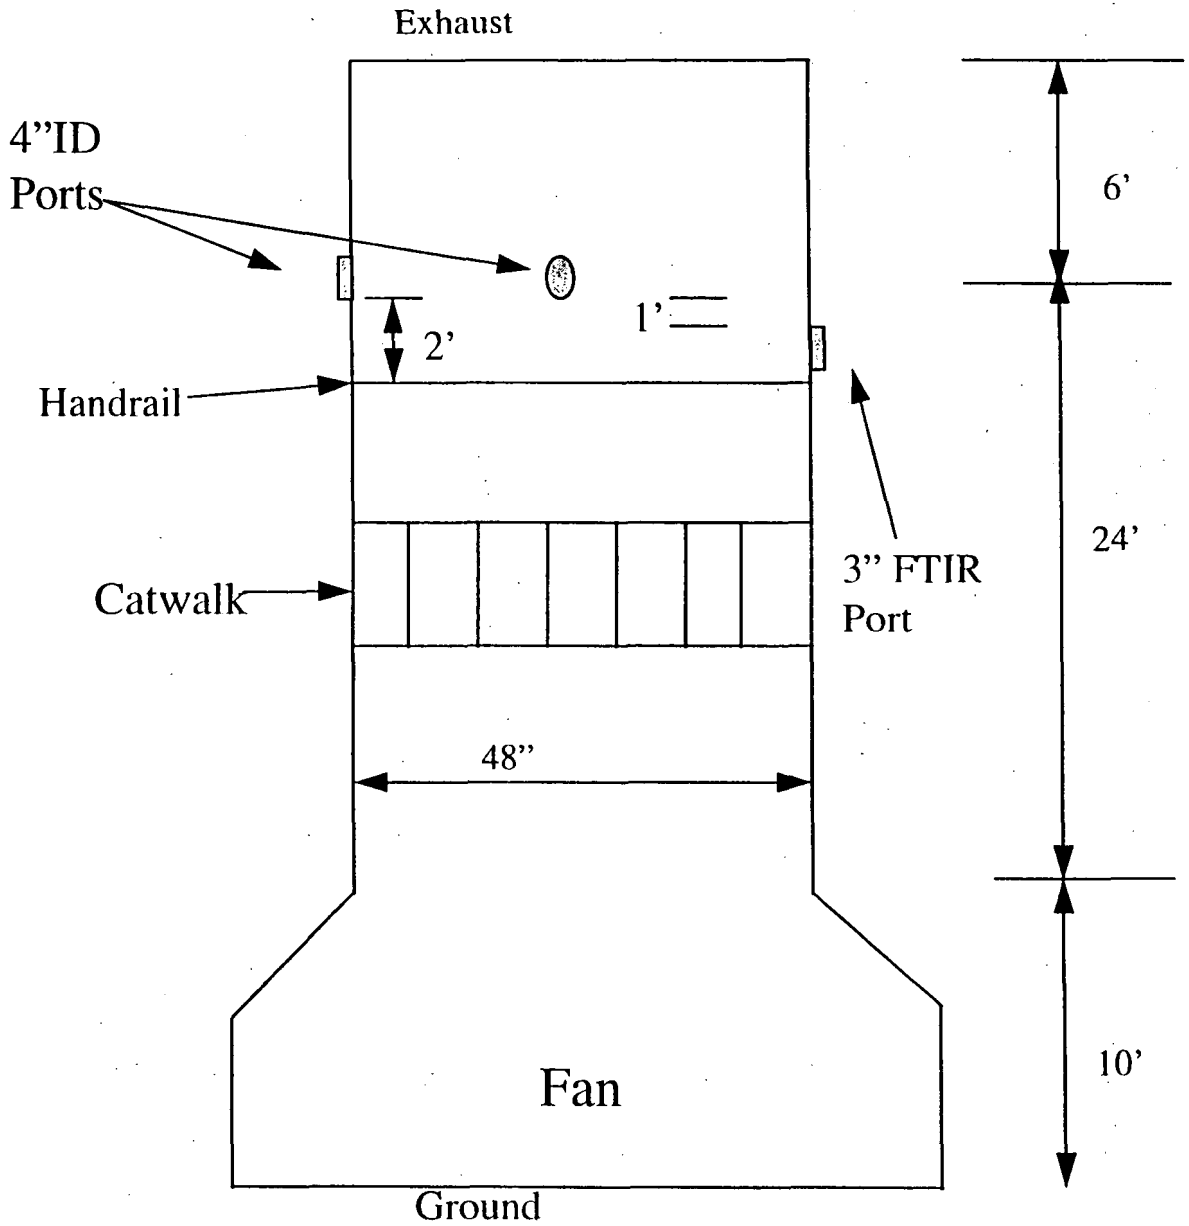

Figure 4-4. E4, Reverberatory Furnace Baghouse Outlet

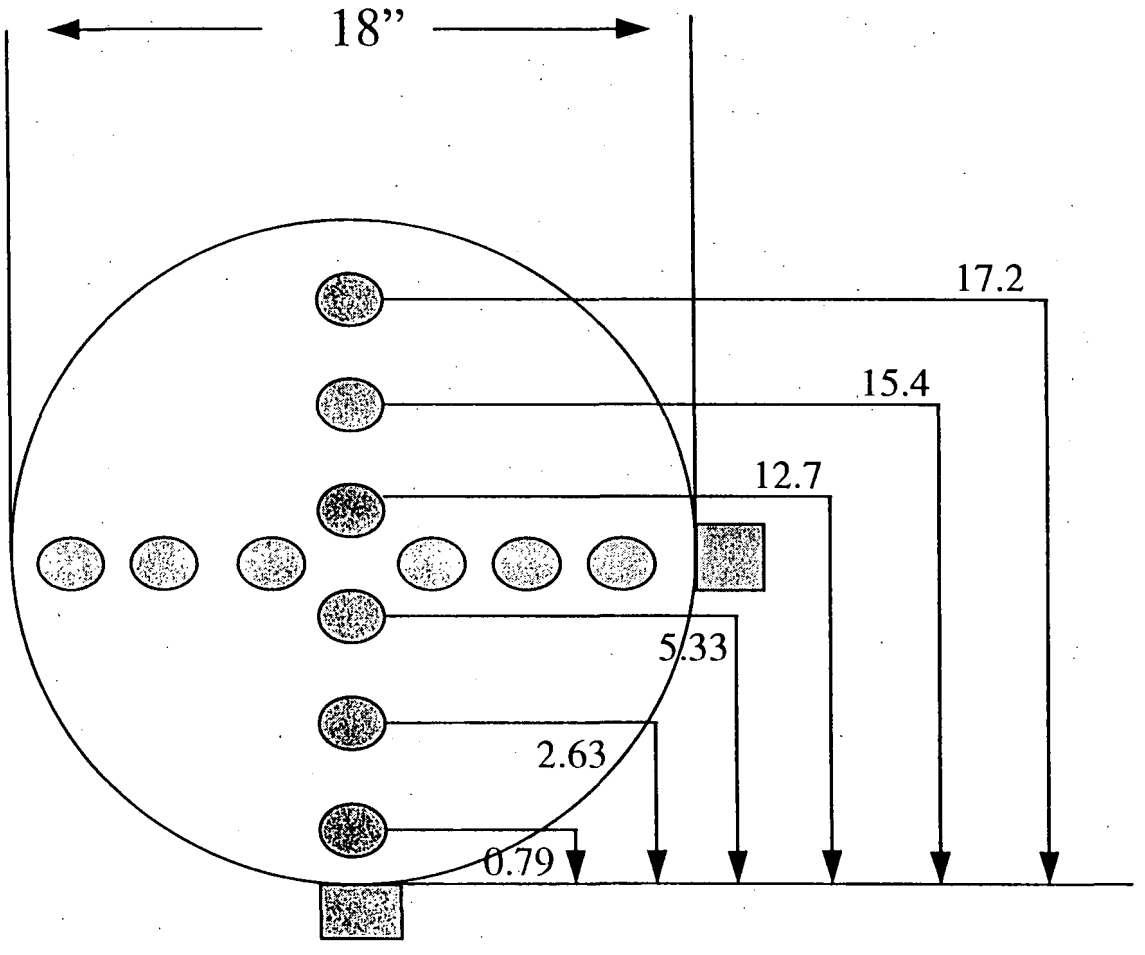

Figure 4-5. Chip Dryer Baghouse Inlet, Traverse Points

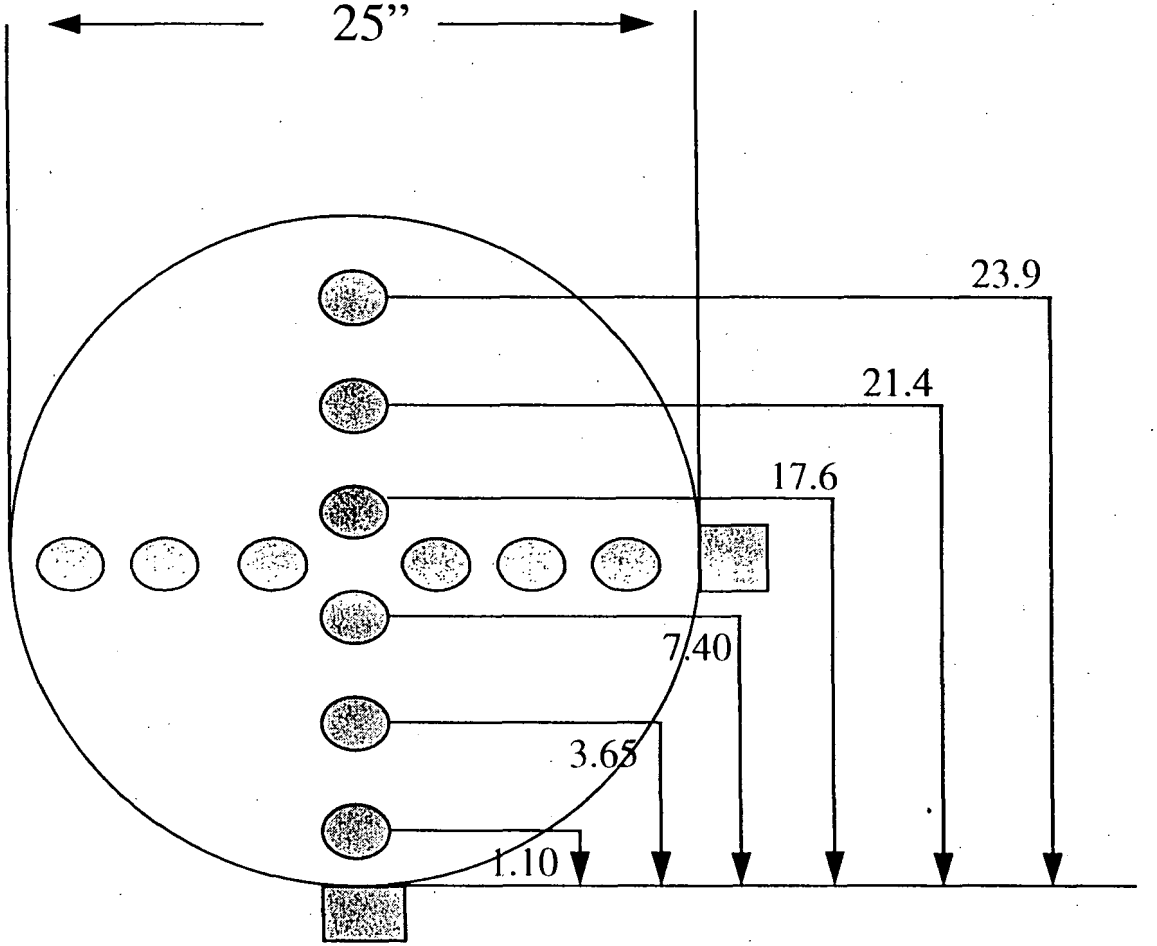

Figure 4-6. Chip Dryer Baghouse Outlet, Traverse Points

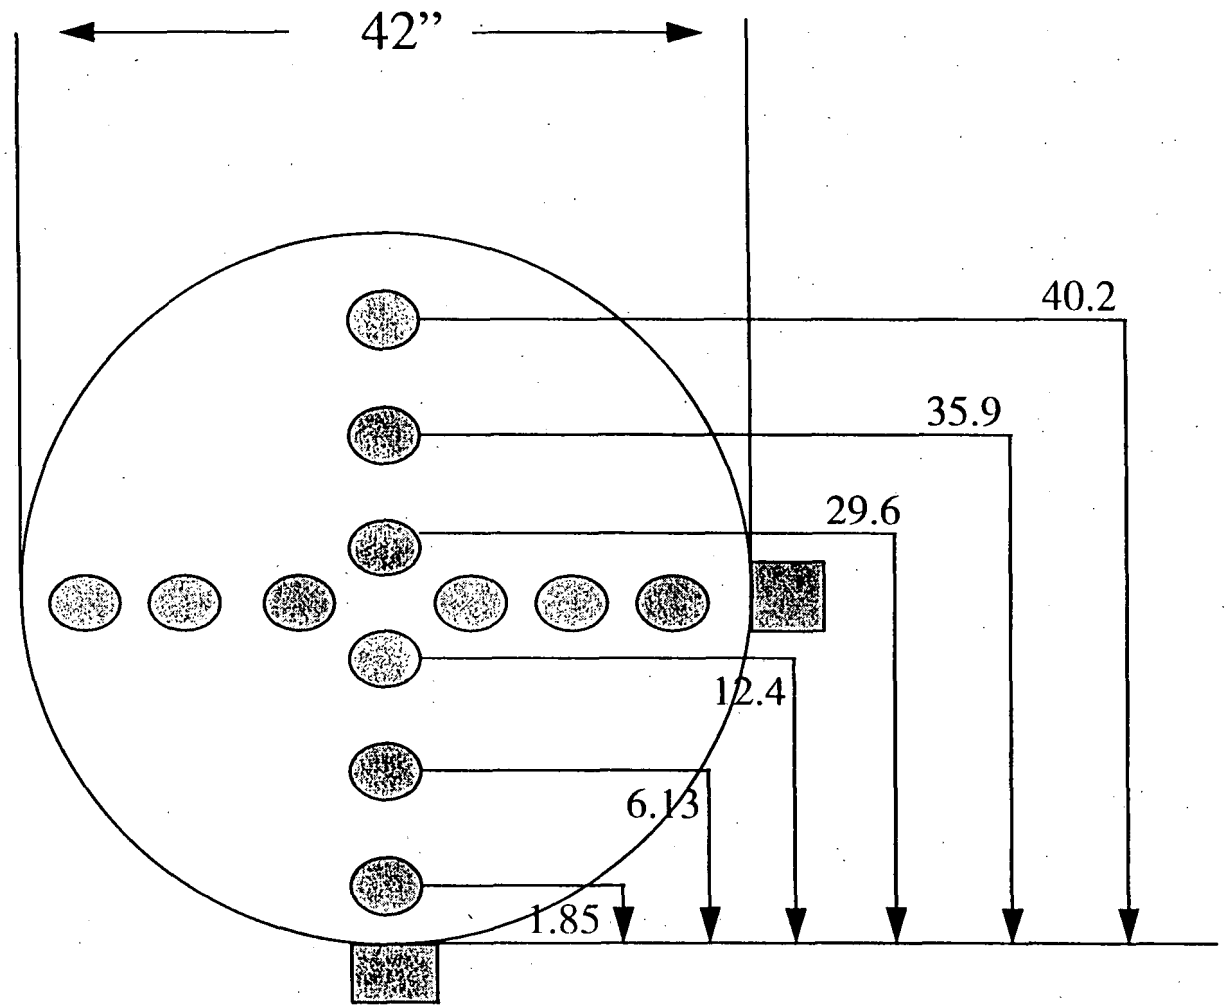

Figure 4-7. Reverberatory Furnace Baghouse Inlet Traverse Points

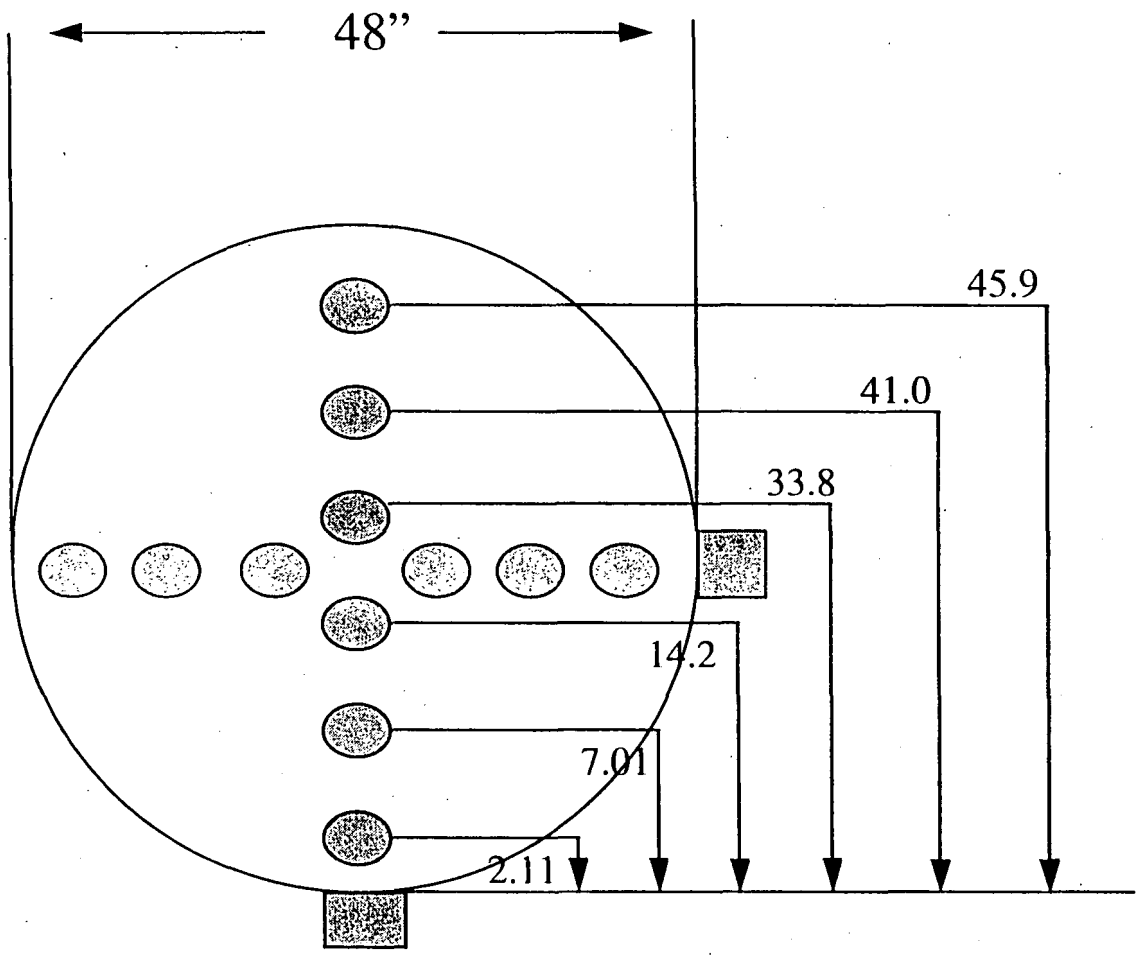

Figure 4-8. Reverberatory Furnace Baghouse Outlet Traverse Points

For stack diameters equal to or less than 0.61 m (24 in.), no traverse points was located within 1.3 cm (0.50 in.) of the stack walls. When any of the traverse points fell within 2.5 cm (1.00 in.) of the stack walls, they were relocated to a distance of 2.5 cm (1.00 in.) or a distance equal to the nozzle inside diameter, whichever was larger.

All test ports and their locations met the requirements of EPA Method 1.

5.0 SAMPLING AND ANALYTICAL PROCEDURES BY ANALYTE

The sampling and analytical procedures used for the Culp Aluminum Alloys plant test program are the most recent revisions of the published EPA methods. In this section, descriptions of each sampling and analytical method by analyte are provided.

5.1 Chlorinated Dibenzo-*p*-Dioxin and Chlorinated Dibenzofuran Emissions Testing Using EPA Method 23

The sampling and analytical method for determining flue gas emissions of Polychlorinated Dibenzo-*p*-Dioxins and Polychlorinated Dibenzofurans (CDD/CDF) is EPA Method 23.

5.1.1 Method 23 Sampling Equipment

The method uses the sampling train shown in Figure 5-1. The Method 23 sampling system is similar to a Method 5 train with the following exceptions:

- All components (glass probe/nozzle liner, all other glassware, filters) are pre-cleaned using solvent rinses and extraction techniques; and
- A condensing coil and XAD-2® resin absorption module are located between the filter and impinger train.

5.1.2 Method 23 Equipment Preparation

In addition to the standard EPA Method 5 requirements, Method 23 includes several unique preparation steps which ensure that the sampling train components are not contaminated with organics that may interfere with analysis. The glassware, glass fiber filters and absorbing resin are cleaned and the filters and resin are checked for 42 residuals before they are packed.

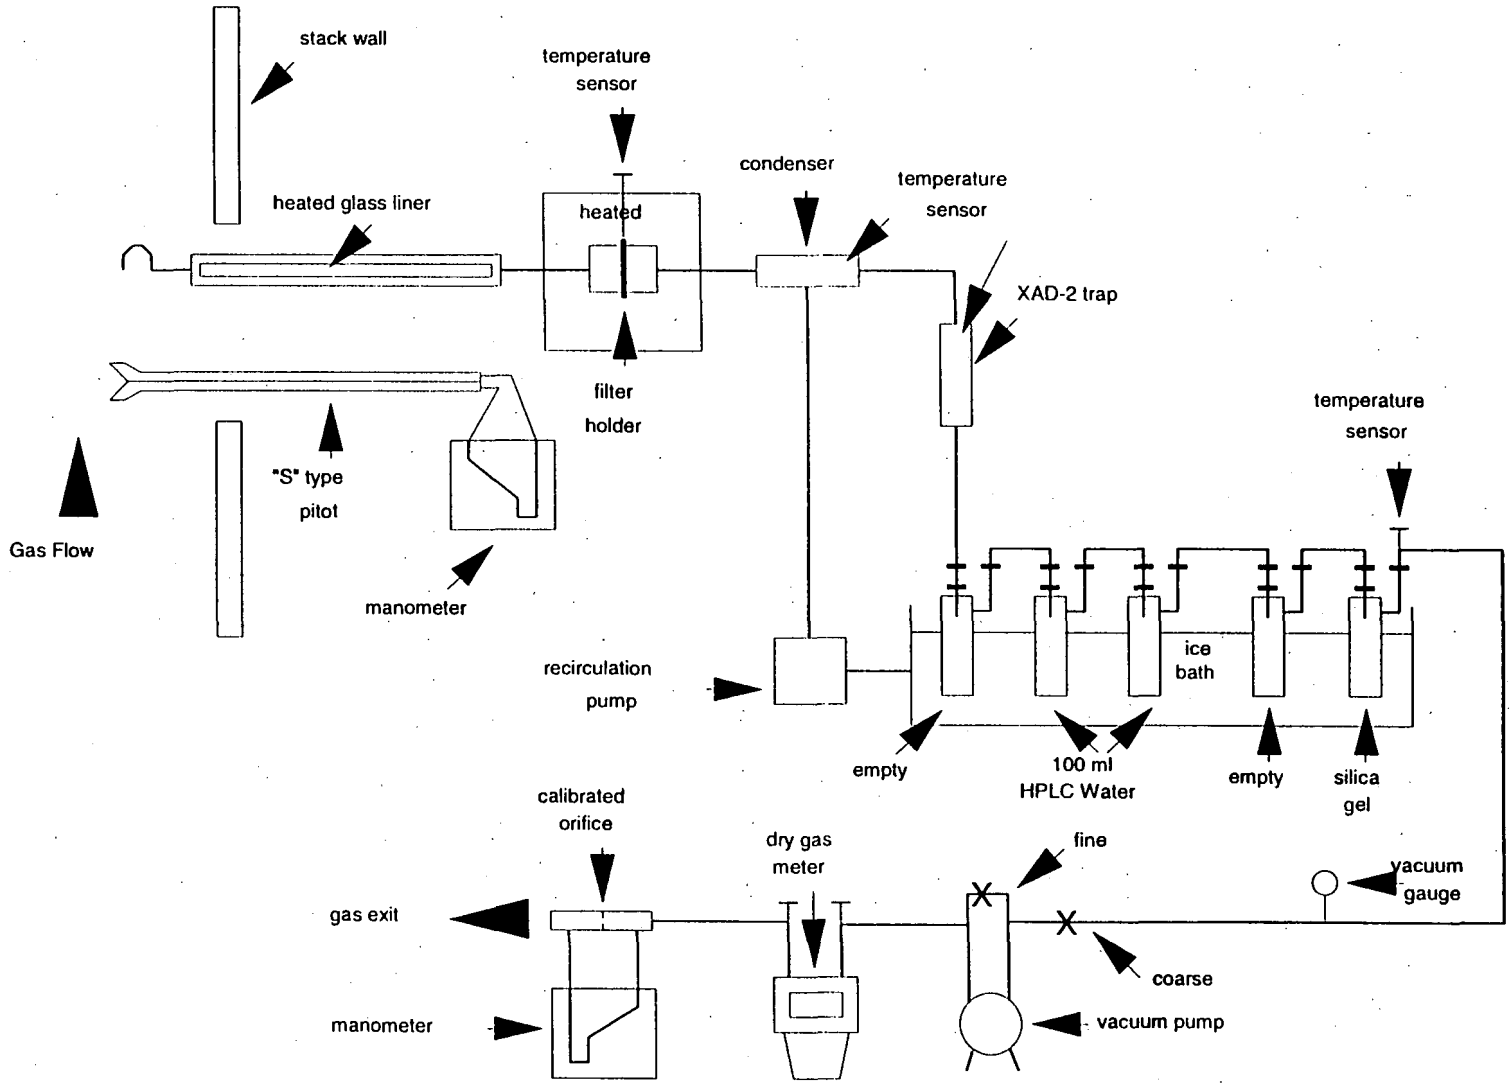

Figure 5-1. Method 23 Sampling Train Configuration

5.1.2.1 Glassware Preparation

The glassware preparation procedure is shown in Table 5-1. Glassware is washed in soapy water, rinsed with distilled water, baked and then rinsed with acetone followed by methylene chloride. Clean glassware is allowed to dry under a hood loosely covered with foil to prevent laboratory contamination. Once the glassware is dry, the air exposed ends are sealed with methylene chloride rinsed aluminum foil. All the glass components of the sampling train including the glass nozzles plus any flasks, petri dishes, graduated cylinders and pipets that are used during sampling and recovery will be cleaned according to this procedure. Non-glass components (such as the Teflon®-coated filter screens and seals, tweezers, Teflon® squeeze bottles, Nylon® probe brushes and Nylon® nozzle brushes) are cleaned following the same procedure except that no baking is performed.

5.1.2.2 XAD-2® Resin and Filter Preparation

XAD-2® absorbing resin and glass fiber filters are pre-cleaned by separate procedures according to the specified method. Only pesticide grade solvents and HPLC grade water are used to prepare for organic sampling, and to recover these samples. The lot number, manufacturer and grade of each reagent used are recorded in the laboratory notebook.

To prepare the filters, a batch of 50 is placed in a Soxhlet extractor pre-cleaned by extraction with toluene. The Soxhlet is charged with fresh toluene and refluxes for 16 hours. After the extraction, the toluene is analyzed as described in Sections 5.1 and 5.3 of the reference method (EPA Method 23) for the presence of tetrachlorodibenzo-*p*-dioxins (TCDD) and tetrachlorodibenzofurans (TCDF). If these analytes are found, the filters are re-extracted until the analyte is not detected. The filters are then dried completely under a clean nitrogen (N_2) stream. Each filter is individually checked for holes, tears, creases or discolorations, and if any are found, the filter is discarded. Acceptable filters are stored in a pre-cleaned petri dish, labeled by date of analysis and sealed with Teflon® tape.

Table 5-1. Method 23 Glassware Cleaning Procedure (Train Components, Sample Containers and Laboratory Glassware)

NOTE: USE VITON® GLOVES AND ADEQUATE VENTILATION WHEN RINSING WITH SOLVENTS
1. Soak all glassware in hot soapy water (laboratory detergent).
2. Rinse with tap water to remove soap.
3. Rinse with HPLC-grade H_2O, three times
4. Bake at 450° F for 2 hours.[a]
5. Rinse with acetone (pesticide grade), three times.
6. Rinse with methylene chloride (pesticide grade), three times.
7. Cap glassware with clean glass plugs or methylene chloride rinsed aluminum foil.
8. Mark cleaned glassware with color-coded identification sticker.
9. Rinse glassware immediately before using with acetone and methylene chloride (laboratory proof).

[a] Step (4) has been added to the cleanup procedure to replace the dichromate soak specified in the reference method. ERG has demonstrated in the past that baking glassware sufficiently removes organic artifacts. Step 4 is not used for probe liners and non-glass components of the train that cannot withstand 450° F (i.e., Teflon®-coated filter screen and seals, tweezers, Teflon® squeeze bottles, Nylon® probe and nozzle brushes).

To prepare the absorbing resin, the XAD-2® resin is cleaned in the following sequential order:

- Rinse with HPLC grade water, discard water;
- Soak in HPLC grade water overnight, discard water;
- Extract in Soxhlet with HPLC grade water for 8 hours, discard water;
- Extract with methanol for 22 hours, discard solvent;
- Extract with methylene chloride for 22 hours, discard solvent;
- Extract with methylene chloride for 22 hours, retain an aliquot of solvent for analysis of CDDs and CDFs by HRGC/HRMS; and
- Dry resin under a clean N_2 stream.

Once the resin is completely dry, it is checked for the presence of methylene chloride, CDDs and CDFs as described in Section 3.1.2.3.1 of the reference method. If any analytes are found, the resin is re-extracted. If methylene chloride is found, the resin is dried until the excess solvent is removed. The absorbent is to be used within four weeks of cleaning.

The cleaned XAD-2® resin is spiked before shipment to the field with five CDD/CDF internal standards. Due to the special handling considerations required for the internal standards, the spiking is performed by Triangle Laboratories. For convenience and to minimize contamination, Triangle Laboratories also performs the resin and filter cleanup procedures and loads the resin into the glass traps.

5.1.2.3 Method 23 Sampling Train Preparation

The remaining preparation includes calibration and leak checking of all sampling train equipment, including meter boxes, thermocouples, nozzles, pitot tubes, and umbilicals.

Referenced calibration procedures are followed when available. The results are properly documented in a laboratory notebook or project file and retained.

5.1.3 Method 23 Sampling Operations

5.1.3.1 Preliminary Measurements

Prior to sampling (data collected during presurvey), preliminary measurements are required to ensure isokinetic sampling. These measurements include determining the traverse point locations, performing a preliminary velocity traverse, cyclonic flow check and moisture determination. These measurements are used to calculate a "K factor." The K factor is used to determine an isokinetic sampling rate from stack gas flow readings taken during sampling.

Measurements are then made of the duct inside diameter, port nozzle length, and the distances to the nearest upstream and downstream flow disturbances. These measurements are then used to determine sampling point locations by following EPA Reference Method 1 guidelines. The distances are then marked on the sampling probe using an indelible marker.

5.1.3.2 Assembling the Train

Method 23 sampling train components are collected in the recovery trailer and final train assembly is performed at the stack location. First, the empty, clean impingers are assembled and laid out in the proper order in the recovery trailer. Each ground glass joint is carefully inspected for hairline cracks. The first impinger is a knockout impinger which has a short tip. The purpose of this impinger is to collect condensate which forms in the coil and XAD-2® resin trap. The next two impingers are modified tip impingers which each contain 100 mL of HPLC grade water. The fourth impinger is empty, and the fifth impinger contains 200 to 300 grams of blue indicating silica gel. After the impingers are loaded each impinger is weighed, the initial weight and contents of each impinger are recorded on a recovery data sheet. The heights of all the impingers are approximately the same to obtain a leak free seal. The open

ends of the train are sealed with methylene chloride-rinsed aluminum foil, or clean ground glass caps.

The second step is to load the filter into the filter holder in the recovery trailer. The filter holder is then capped off and placed with the resin trap and condenser coil (capped) into the impinger bucket. A supply of precleaned foil and socket joints is also placed in the bucket in a clean plastic bag for the convenience of the samplers. Sealing greases are not used to avoid contamination of the sample. The train components are transferred to the sampling location and assembled as previously shown in Figure 5-1. The heated probe and filter box will be a single unit mounted on a vertical monorail. The chilled impinger box with the condenser and XAD-2® trap will be placed on the floor of the scaffolding.

5.1.3.3 Sampling Procedures

After the train is assembled, the heaters for the probe liner and heated filter box are turned on and the sorbent module/condenser coil recirculating pump is turned on. When the system reaches the appropriate temperatures, the sampling train is ready for pre-test leak checking. The temperature of the sorbent module resin must not exceed 50° C (120° F) at any time and during testing it must not exceed 20° C (68° F). The filter temperature is maintained at 120 ±14° F (248 ±25° F). The probe temperature is maintained above 100° C (212° F).

The sampling trains are leak checked at the start and finish of sampling. (Method 5/23 protocol only requires post-test leak checks and recommends pre-test leak checks.) ERG protocol also incorporates leak checks before and after every port change. An acceptable pre-test leak rate is less than 0.02 acfm (ft^3/min) at approximately 15 inches of Hg. If during testing, a piece of glassware needs to be emptied or replaced, a leak check is performed before the glassware piece is removed, and after the train is re-assembled.

To leak check the assembled train, the nozzle end is capped off and a vacuum of 15 inches Hg is pulled in the system. When the system is evacuated, the volume of gas flowing

through the system is timed for 60 seconds. After the leak rate is determined, the cap is slowly removed from the nozzle end until the vacuum drops off, and then the pump is turned off. If the leak rate requirement is not met, the train is systematically checked by first capping the train at the filter, at the first impinger, etc., until the leak is located and corrected.

After a successful pre-test leak check has been conducted, all train components are at their specified temperatures and initial data are recorded (DGM reading), the test can be initiated. Sampling train data are recorded periodically on standard data forms. A checklist for CDD/CDF sampling is included in Table 5-2. A sampling operation that is unique to CDD/CDF sampling is that the gas temperature entering the resin trap must be below 20° C (68° F). The gas is cooled by a water jacket condenser through which ice water is circulated.

The leak rates and sampling start and stop times are recorded on the sampling task log. Also, any other events that occur during sampling are recorded on the task log such as sorbent module heat excursions, pitot cleaning, thermocouple malfunctions, heater malfunctions or any other unusual occurrences.

If the probe liner breaks while DGM is not running (i.e., during port changes or after the run is completed), the probe liner is replaced, the run is completed, and sample recovery done on both the broken sections of the glass liner and the replacement liner. If the break occurs while the DGM is running and the exact time of the break is noted, the test is stopped so that the probe liner can be replaced. The run is then completed and sample recovery done on all liner sections. If the recovered sample appears unusual, the sample is discarded and an additional run is performed later. If the recovered sample appears normal, the run is tentatively acceptable.

At the conclusion of the test run, the sample pump (or flow) is turned off, the probe is removed from the duct, a final DGM reading is taken, and a post-test leak check is completed. The procedure is identical to the pre-test procedure. However, the vacuum should be at least one inch Hg higher than the highest vacuum attained during sampling. An acceptable leak rate is less than 4% of the average sample rate or 0.02 acfm (whichever is lower).

Table 5-2. CDD/CDF Sampling Checklist

Before test starts:

1. Check impinger set to verify the correct order, orientation and number of impingers. Verify probe markings, and remark if necessary.

2. Check that you have all the correct pieces of glassware. Have a spare probe liner, probe sheath, meter box and filter ready to go at location.

3. Check for data sheets and barometric pressure.

4. Prepare bag sampling equipment for CO_2/O_2, except when using CEMs for CO_2/O_2 determinations.

5. Examine meter box - level it, zero the manometers and confirm that the pump is operational.

6. Verify the filter is loaded correctly and as tightly as possible; place filter in line with the train and leak check at 15 inches Hg.

7. Add probe to train.

8. Check thermocouples - make sure they are reading correctly.

9. Conduct pitot leak check, recheck manometer zero.

10. Do final leak check; record leak rate and vacuum on sampling log.

11. Turn on variacs and check to see that the heat is increasing.

12. Check that cooling water is on and flowing. Add ice to impinger buckets.

13. Check isokinetic K-factor - make sure it is correct. (Refer to previous results to confirm assumptions. Two people should calculate this independently to double check it.)

Table 5-2. CDD/CDF Sampling Checklist (continued)

During Test:

1. Notify field task leader of any sampling problems ASAP. Train operator should fill in sampling log and document any abnormalities.

2. Perform simultaneous/concurrent testing with other locations (if applicable). Maintain filter temperature between 248° F ±25° F. Keep temperature as steady as possible. Maintain the resin trap and impinger temperatures below 68° F. Maintain probe temperature above 212° F.

3. Leak check between ports and record on data sheet. Leak check if the test is stopped to change silica gel, to decant condensate, or to change filters.

4. Record sampling times, rate, and location for the fixed gas bag sampling (CO, CO_2, O_2), if applicable.

5. Blow back pitot tubes periodically if moisture entrapment is expected.

6. Change filter if vacuum suddenly increases or exceeds 15 inches Hg.

7. Check impinger solutions every ½ hour; if the knockout impinger is approaching full, stop test and empty it into a pre-weighed bottle and replace it in the train.

8. Check impinger silica gel every ½ hour; if indicator color begins to fade, request a prefilled, preweighed impinger from the recovery trailer.

9. Check the ice in the impinger bucket frequently. If the stack gas temperatures are high, the ice will melt at the bottom rapidly. Maintain condenser coil and silica gel impinger gas temperatures below 20° C (68° F).

After test is completed:

1. Record final meter reading.

2. Do final leak check of sampling train at maximum vacuum during test.

Table 5-2. CDD/CDF Sampling Checklist (continued)

3. Do final pitot leak check.

4. Check completeness of data sheet. Verify the impinger bucket identification is recorded on the data sheets. Note any abnormal conditions.

5. Leak check, check functions (level, zero, etc.) of pitot tubes and inspect for tip damage.

6. Disassemble train, cap sections, and take each section and all data sheets down to recovery trailer.

7. Probe recovery (use 950 mL bottles)
   a) Bring probes into recovery trailer (or other enclosed area).
   b) Wipe the exterior of the probe to remove any loose material that could contaminate the sample.
   c) Carefully remove the nozzle/probe liner and cap it off with prerinsed aluminum foil.
   d) For acetone rinses (all trains)
      - Attach precleaned cyclone flask to probe to catch rinses
      - Wet all sides of probe interior with acetone
      - While holding the probe in an inclined position, put precleaned probe brush down into probe and brush it in and out
      - Rinse the brush, while in the probe, with acetone
      - Do this at least 3 times until all the particulate has been recovered.
      - Recover acetone into a preweighed, prelabeled sample container
   e) Follow the procedure outlined in (d) using methylene chloride. Recover the solvent into the same acetone recovery bottle.
   f) Follow the procedure outlined in (d) using toluene. Recover this solvent into a separate preweighed prelabeled sample container.

8. Cap both ends of nozzle/probe liner for the next day, and store in dry safe place.

9. Make sure data sheets are completely filled out, legible, and give them to the field task leader.

5.1.4 CDD/CDF Sample Recovery

To facilitate transfer from the sampling location to the recovery trailer, the sampling train is disassembled into the following sections: the probe liner, filter holder, filter to condenser glassware, condenser and sorbent module, and the impingers in their bucket. Each of these sections is capped with methylene chloride rinsed aluminum foil or ground glass caps before removal to the recovery trailer. Once in the trailer, field recovery follows the scheme in Figure 5-2. The samples are recovered and stored in cleaned amber glass bottles to prevent light degradation.

The probe and nozzle are first rinsed with approximately 100 mL of acetone and brushed to remove any particulate. This first rinse is followed with a rinse of methylene chloride. Both of these rinses are collected in the same bottle. The same two solvents are used to rinse the cyclone, front/back half filter holder, filter support, connecting glassware and condenser. These rinses are added to the probe rinse bottle. All of the components listed above are again rinsed with toluene, but collected in a separate container. In addition, the Teflon® transfer line used with the vertical sampler will be filled with toluene and allowed to stand for 5 minutes before adding to the toluene rinses. The filter is carefully removed from the filter holder, placed in a pre-labeled petri dish and sealed with Teflon® tape for transport to the laboratory.

The contents of impingers 1-4 (H_2O) and impinger 5 (silica gel) are weighed to 0.5 mg and then discarded.

The solvents used for train recovery are all pesticide grade. The use of the highest grade reagents for train recovery is essential to prevent the introduction of chemical impurities which interfere with the quantitative analytical determinations.

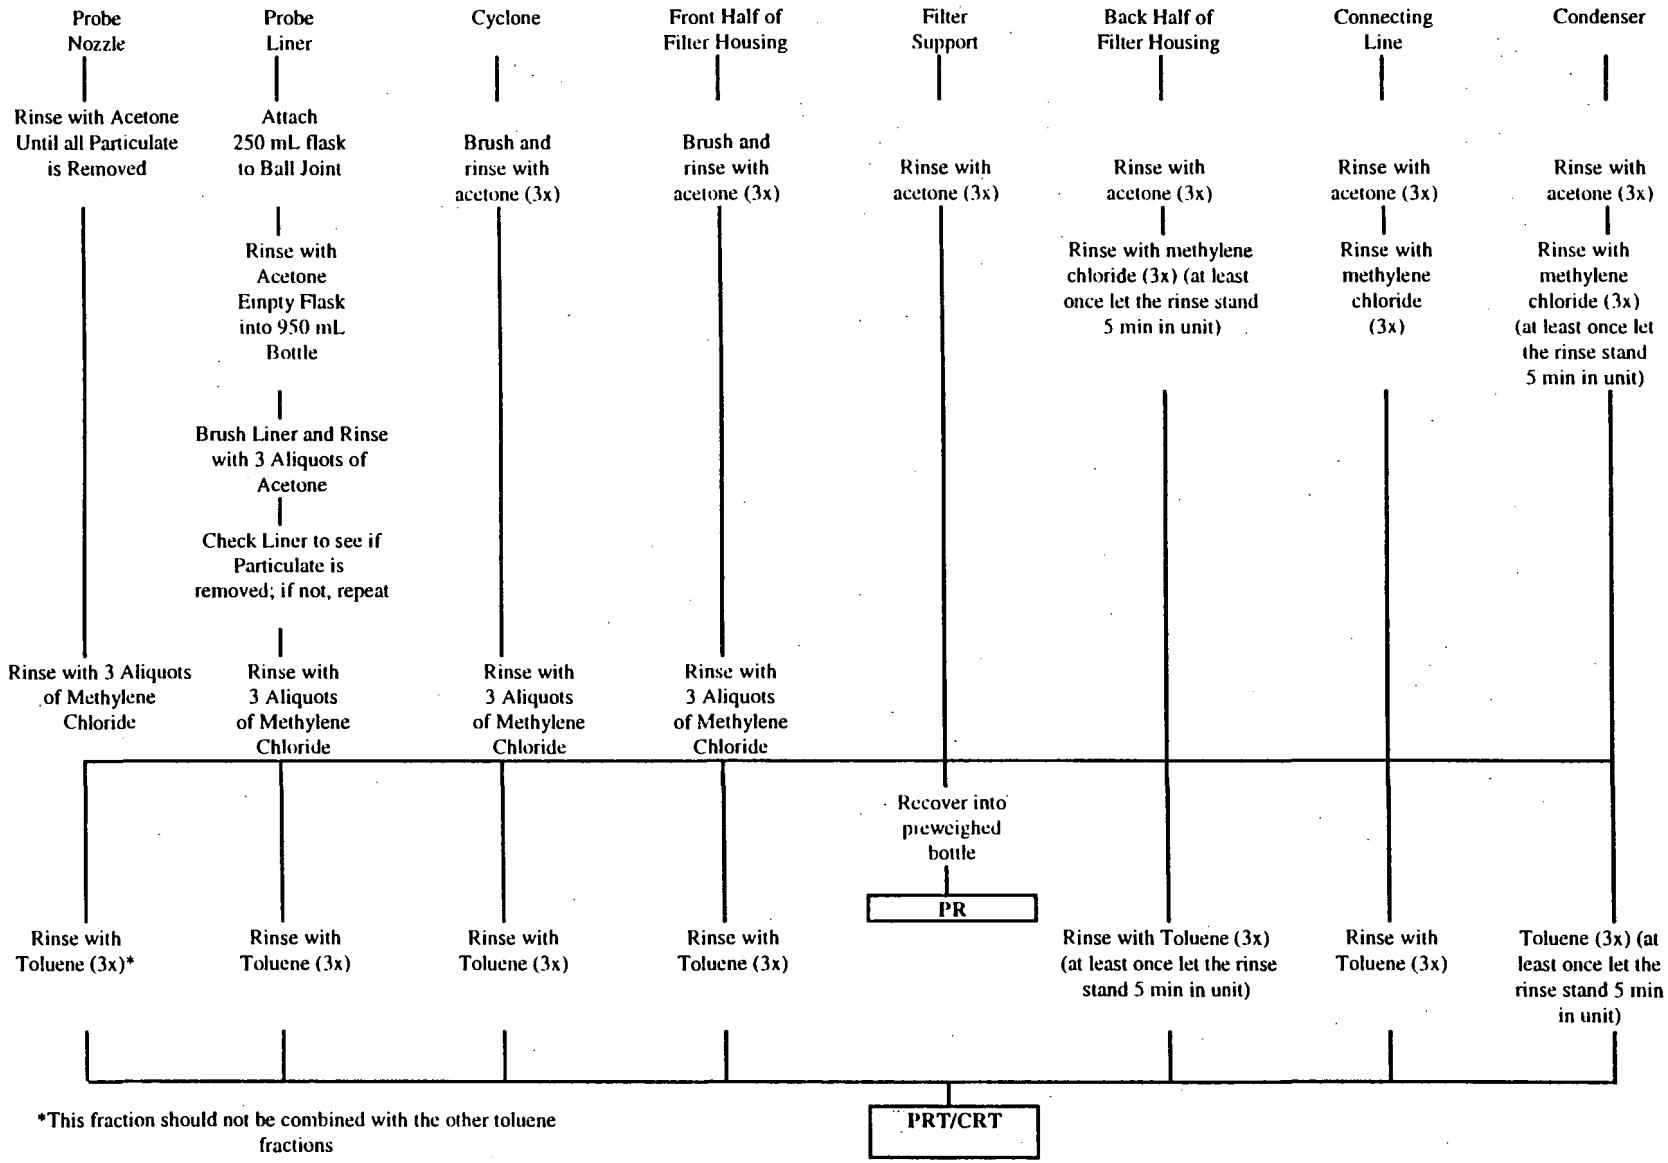

Figure 5-2. Method 23 Field Recovery Scheme

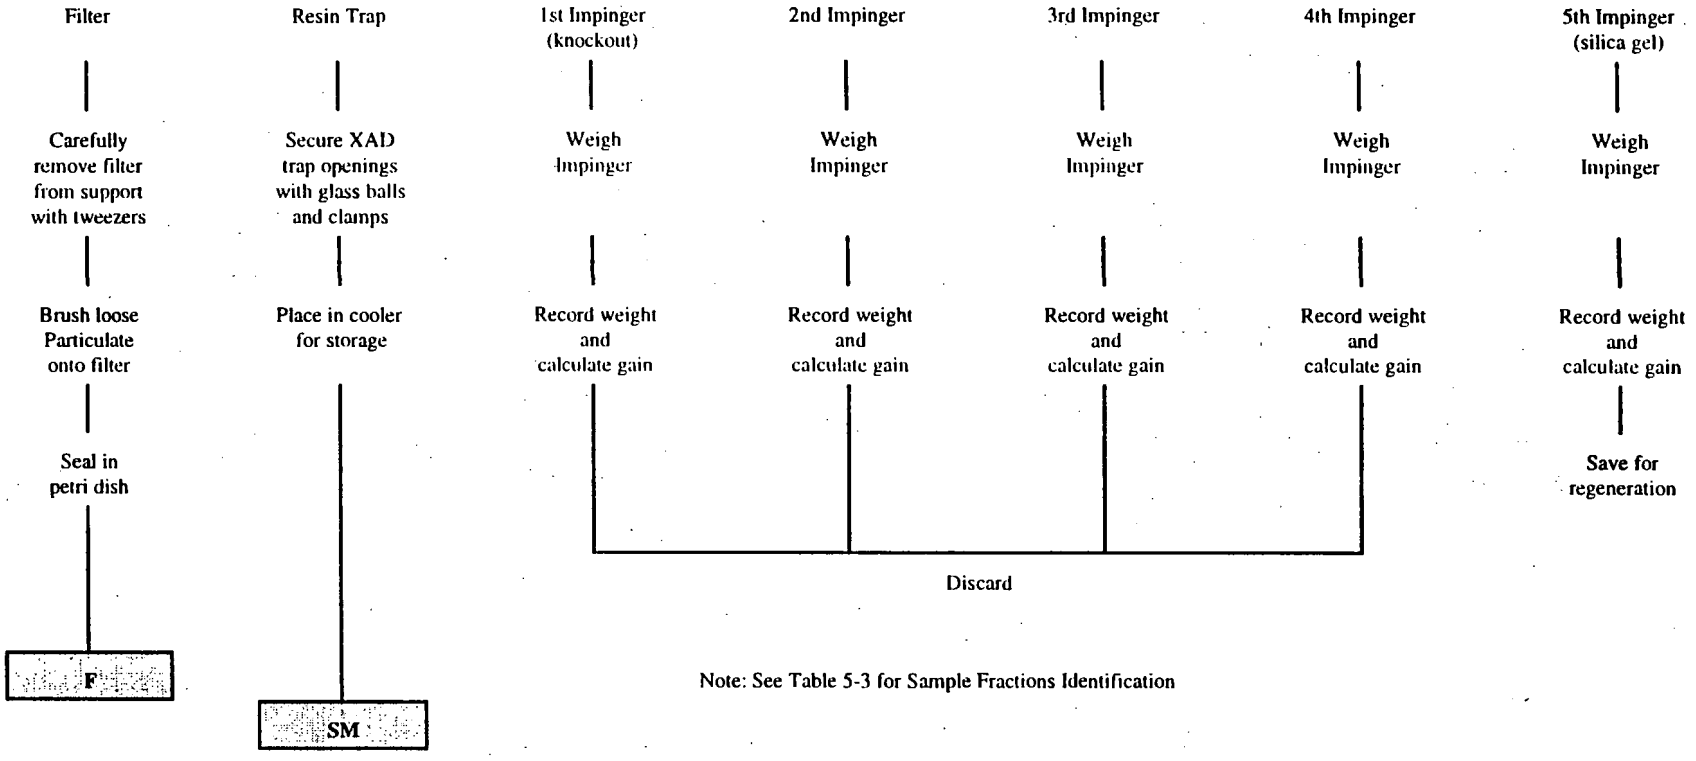

Figure 5-2. Method 23 Field Recovery Schedule (continued)

The train components recovered in the field are listed in Table 5-3. All recovered samples are stored in coolers on ice at all times. The samples will be delivered to the analytical laboratory upon return to ERG accompanied by written information designating target analytes.

Table 5-3. Method 23 Sample Fractions Shipped To Analytical Laboratory

Container/ Component	Code	Fraction
1	F	Filter(s)
2	PR[a]	Acetone and methylene chloride rinses of nozzle/probe, cyclone, front half/back filter holder, filter support, connecting glassware, condenser
3	PRT CRT	Toluene rinse of nozzle/probe, cyclone, front half/back half filter holder, filter support, connecting line and condenser
4	SM	XAD-2® resin trap (sorbent module)

[a]Rinses include acetone and methylene chloride recovered into the same sample bottle.

5.1.5 CDD/CDF Analytical Procedures

The analytical procedure used to obtain analyte concentrations from a single flue gas sample is high resolution gas chromatography (HRGC) and high resolution mass spectrometry (HRMS) (resolution from 8000-10000 m/z). The target CDD/CDF congeners are listed in Table 5-4. The analysis was performed by Triangle Laboratories, Inc., by Method 23/8290.

The Method 23 samples are prepared and analyzed according to the scheme in Figure 5-3. The XAD-2® and filter (along with the concentrated acetone/methylene chloride rinses) are placed in a Soxhlet extractor and extracted with toluene. This extract is added to the toluene train rinses and then concentrated by rotary evaporation. This concentrated sample extract is added to the toluene train rinses and then concentrated by rotary evaporation. This concentrated sample is subjected to a sample cleanup procedure before analysis. For the

Table 5-4. CDD/CDF Congeners To Be Analyzed

DIOXINS:

2,3,7,8-tetrachlorodibenzo-*p*-dioxin (2,3,7,8-TCDD)
Total tetrachlorinated dibenzo-*p*-dioxins (TCDD)
1,2,3,7,8-pentachlorodibenzo-*p*-dioxin (1,2,3,7,8-PeCDD)
Total pentachlorinated dibenzo-*p*-dioxins (PeCDD)
1,2,4,5,7,8-hexachlorodibenzo-*p*-dioxin (1,2,3,4,7,8-HxCDD)
1,2,3,6,7,8-hexachlorodibenzo-*p*-dioxin (1,2,4,5,7,8-HxCDD)
1,2,3,7,8,9-hexachlorodibenzo-*p*-dioxin (1,2,3,7,8,9-HxCDD)
Total hexachlorinated dibenzo-*p*-dioxins (HxCDD)
1,2,3,4,6,7,8-heptachlorodibenzo-*p*-dioxin (1,2,3,4,6,7,8-HpCDD)
Total heptachlorinated dibenzo-*p*-dioxins (HpCDD)
Total octachlorinated dibenzo-*p*-dioxin (OCDD)

FURANS:

2,3,7,8-tetrachlorodibenzofurans (2,3,7,8-TCDF)
Total tetrachlorinated dibenzofurans (TCDF)
1,2,3,7,8-pentachlorodibenzofuran (1,2,3,7,8-PeCDF)
2,3,4,7,8-pentachlorodibenzofuran (2,3,4,7,8-PeCDF)
Total pentachlorinated dibenzofurans (PeCDF)
1,2,3,4,7,8-hexachlorodibenzofuran (1,2,3,4,7,8-HxCDF)
1,2,3,6,7,8-hexachlorodibenzofuran (1,2,3,6,7,8-HxCDF)
2,3,4,6,7,8-hexachlorodibenzofuran (2,3,4,6,7,8-HxCDF)
1,2,3,7,8,9-hexachlorodibenzofuran (1,2,3,7,8,9-HxCDF)
Total hexachlorinated dibenzofuran (HxCDF)
1,2,3,4,6,7,8-heptachlorodibenzofuran (1,2,3,4,6,7,8-HpCDF)
1,2,3,4,7,8,9-heptachlorodibenzofuran (1,2,3,4,7,8,9-HpCDF)
Total heptachlorinated dibenzofurans (HpCDF)
Total octachlorinated dibenzofuran (OCDF)

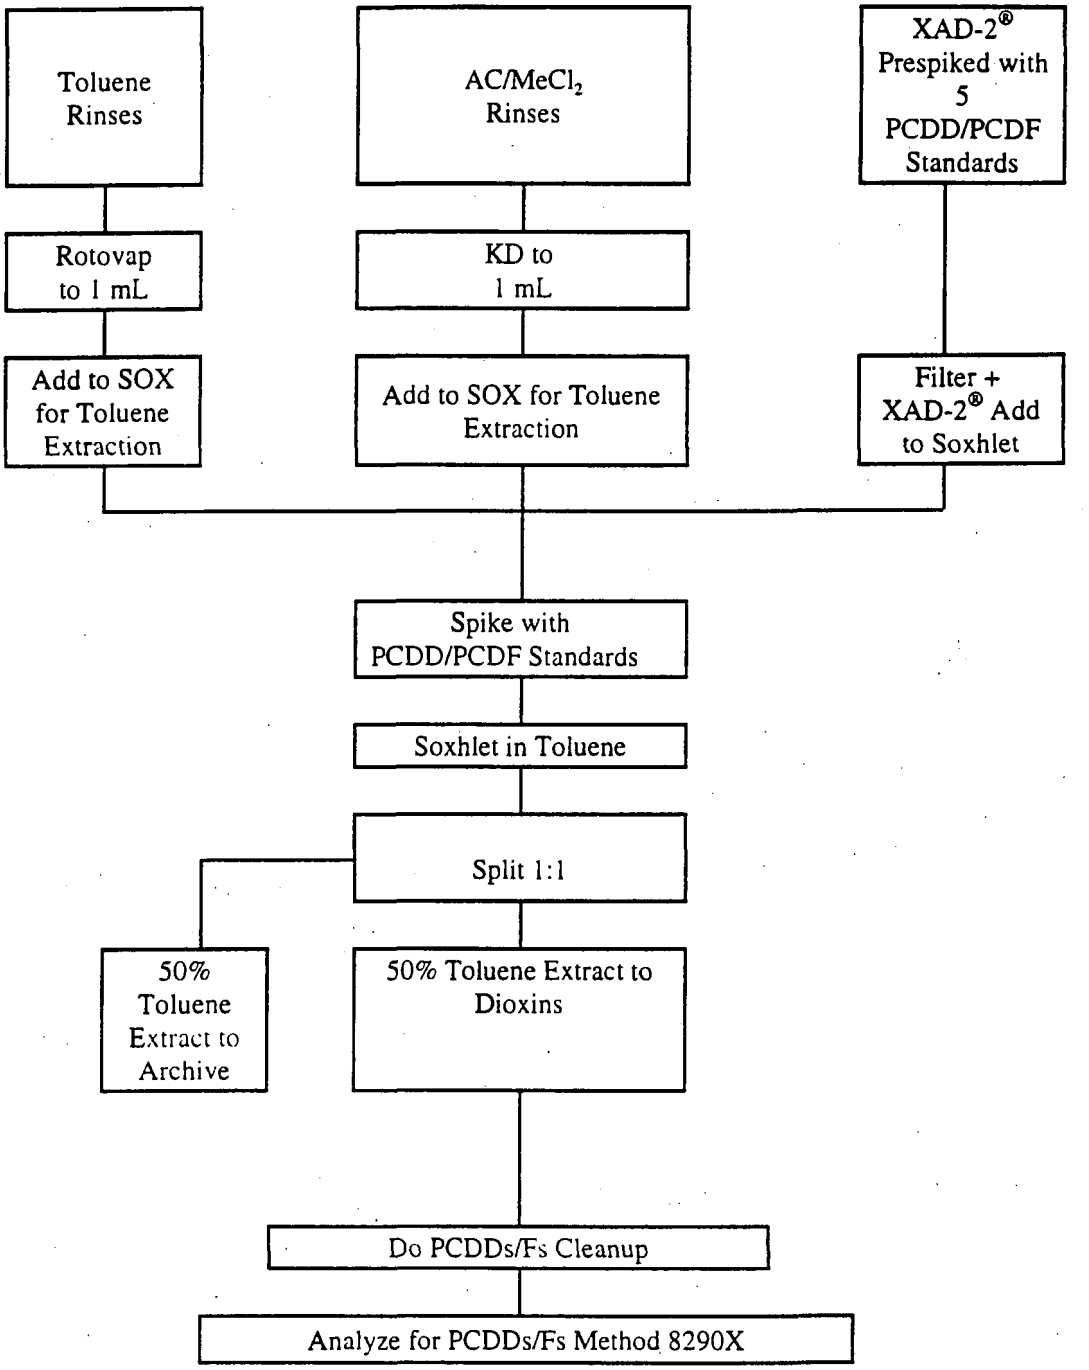

Figure 5-3. Extraction and Analysis Schematic for Method 23 Samples

CDD/CDF analysis, isotopically-labeled surrogate compounds and internal standards and surrogates that are used are described in detail in EPA Method 23.

Data from the mass spectrometer are recorded and stored on a computer file as well as printed on paper. Results such as amount detected, detection limit, retention time, and internal standard and surrogate standard recoveries are calculated by computer. The chromatograms are retained by the analytical laboratory and also included in the analytical report delivered to ERG.

5.1.5.1 Preparation of Samples for Extraction

Upon receiving the sample shipment, the samples are checked against the chain-of custody forms and then assigned an analytical laboratory sample number. Each sample component is reweighed to determine if leakage occurred during travel. Color, appearance, and other particulars of the samples are noted. Samples are extracted within 21 days of collection and processed through cleanup procedures before concentration and analysis.

5.1.5.2 Calibration of GC/MS System

A five-point calibration of the GC/MS system is performed to demonstrate instrument linearity over the concentration range of interest. Relative response factors are calculated for each dioxin/furan congener or compound of interest. The response factors are verified on a daily basis using a continuing calibration standard consisting of a mid-level standard. The instrument performance is acceptable only if the measured response factors for the labeled and unlabeled compounds and the ion-abundance ratios are within the allowable limits specified in the method.

5.1.6 CDD/CDF Analytical Quality Control

All quality control procedures specified in the test method are followed. Blanks are used to determine analytical contamination, calibration standards are used for instrument calibration and linearity checks, internal standards are used to determine isomer recoveries and

adjust response factors for matrix effects, surrogate standards are used to measure the collection efficiency of the sampling methodology and an alternate standard is used as a column efficiency check.

5.1.6.1 CDD/CDF Quality Control Blanks

Four different types of sample blanks are collected for CDD/CDF analysis. The types of blanks that are required are shown in Table 5-5.

Table 5-5. Method 23 Blanks Collected

Blank	Collection	Analysis
Field Blanks	One run collected for each sample location) and analyzed	Analyze with field samples
Glassware Proof Blank	Each train to be used (2) will be loaded and quantitatively recovered prior to sampling	Archive for potential analysis
Method Blank	At least one for each analytical batch (laboratory generated)	Analyze with each analytical batch of field samples
Reagent Blanks	One 500 mL sample for each reagent and lot	Archive for potential analysis

Reagent blanks of 500 mL of each reagent used at the test site are saved for potential analysis. Each reagent blank is of the same lot as was used during the sampling program. Each lot number and reagent grade is recorded on the field blank label and in the laboratory notebook (acetone, methylene chloride, toluene, filter, XAD-2®).

A glassware blank (proof blank) is recovered from each set of sample train glassware that is used to collect the organic samples. The precleaned glassware, which consists of a probe liner, filter holder, condenser coil, and impinger set, is loaded as if for sampling and then quantitatively recovered exactly as the samples will be. Analysis of the generated fractions will be used to check the effectiveness of the glassware cleaning procedure only if sample analysis indicates a potential contamination problem.

A field blank is collected from a set of CDD/CDF glassware that has been used to collect at least one sample and has been recovered. The train is re-loaded, leak checked and left at a sampling location during a test run. The train is then recovered. The purpose of the field blank is to measure the level of contamination that occurs from handling, loading, recovering, leak checking, and transporting the sampling train. The field blanks are analyzed with the flue gas samples. If they are unsatisfactory in terms of contamination, reagent blanks may be analyzed to determine the specific source of contamination.

In addition to the three types of blanks that are required for the sampling program, the analytical laboratory will analyze a method blank with each set of flue gas samples. This method blank will consist of preparing and analyzing an aliquot of toluene by the exact procedure used for the samples analysis. The purpose of this method blank is to verify that there is no laboratory contamination of the field samples.

5.1.6.2 Quality Control Standards and Duplicates

Recoveries of the internal standards must be between 40 to 130% for the tetra- through hexachlorinated compounds and in the range of 25 to 130% for the hepta- and octachlorinated homologs. If these requirements are not met, the data will be acceptable if the signal to noise ratio is greater than or equal to ten. If these requirements are met, the results for the native (sampled) species are adjusted according to the internal standard recoveries.

Surrogate standard recoveries must be between 70 to 130%. If the recoveries of all standards are less than 70%, the project director will be notified immediately to determine if the surrogate results will be used to adjust the results of the native species.

Duplicate analysis is performed for every ten samples. The purpose of this duplicate analysis is to evaluate the precision of the combined sample preparation and analytical methodology.

5.1.7 *Analytes and Detection Limits for Method 23*

The target analytes are the tetra- through octachlorinated dibenzodioxins and chlorinated dibenzofurans. The detection limit of the individual compounds is dependent on the detection limit of the analytical method, the volume of the final extract and the total volume of gaseous sample collected in the sampling trains. Following the protocol of Method 23, the fractions to be collected for analysis from each train are:

- Fraction 1—Filter;
- Fraction 2—XAD-2® sorbent module;
- Fraction 3—Acetone and methylene chloride rinses of all train components prior to sorbent module and;
- Fraction 4—Toluene rinses of all train components prior to the sorbent module.

Following the sample preparation protocol outlined in Method 23, a single combined sample is presented for analysis for D/F by high resolution gas chromatography/high resolution mass spectrometry. (The individual samples will no longer be available for analysis.) The final volume of this sample is 200 μL of which a 2 μL aliquot is injected into the instrument. Using an instrument detection limit of 50 pg for tetra-, 250 pg for penta- through hepta-, and 500 pg for octachlorinated D/F, the total minimum detectable amounts can be calculated and are given in Table 5-6.

Using a four hour sampling time at an assumed sampling rate of 0.65 to 0.75 cfm, the MDLs shown in Table 5-7 are possible. The sampling flow rate at the outlet location will be dictated by the flow rate of the stack gas since isokinetic sampling will be performed.

Table 5-6. Analytical Detection Limits For Dioxins/Furans

Analyte	Total Detectable Amount, ng
Tetra CDDs	5
Penta CDDs	25
Hexa CDDs	25
Hepta CDDs	25
Octa CDD	50
Tetra CDFs	5
Penta CDFs	25
Hexa CDFs	25
Hepta CDFs	25
Octa CDF	50

NOTE: D/F analysis by High Resolution Mass Spectrometry assumes a 2 μL injection of a 200 μL sample extract.

Table 5-7. CDD/CDF Method Detection Limits

Sampling Time, Hours	4
Sampling Rate, cfm	0.75
Sample Volume, m^3	5.1
	MDL, ng/m^3
Tetra CDDs	0.98
Penta CDDs	4.9
Hexa CDDs	4.9
Hepta CDDs	4.9
Octa CDD	9.8
Tetra CDFs	0.98
Penta CDFs	4.9
Hexa CDFs	4.9
Hepta CDFs	4.9
Octa CDF	9.8

5.2 Hydrochloric Acid/Particulate Matter Emissions Testing Using EPA Method 26A

Hydrogen chloride (HCl) sampling is accomplished using EPA Method 26A, Determination of Hydrogen Halide and Halogen Emissions from Stationary Sources - Isokinetic Method. Method 26A is particularly suited for sampling at sources emitting acid particulate matter (i.e., hydrogen chloride dissolved in water droplets). In this method, a gas sample is extracted isokinetically from the stationary source and passed through acidified water. In acidified water, HCl solubilizes and forms chloride (Cl^-) ions. Ion chromatography (IC) is used to detect the chloride ions present in the sample. In addition, sampling for Particulate Matter (PM) is also performed according to the EPA Method 26A protocol. This method is applicable to the determination of particulate mass emissions collected on a glass fiber filter and any material that condenses at or above the filter temperature of 120±14°C (248±25°F) from various types of process controls and combustion sources. The particulate mass, which includes any material that condenses at or above the filter temperature, is determined gravimetrically after removal of uncombined water.

Particulate concentrations are based on the weight gain of the filter and any condensible PM recovered from the acetone rinses of the probe, nozzle, and front half of the filter.

5.2.1 Method 26A Sampling Equipment

The EPA Method 26A methodology uses the sampling train shown in Figure 5-4. The 5-impinger train consists of a borosilicate glass nozzle/probe liner followed by a heated filter assembly with a Teflon® filter support, a series of impingers and a meter box and vacuum pump as specified in EPA Method 5. The sample is not exposed to any metal surfaces in this train.

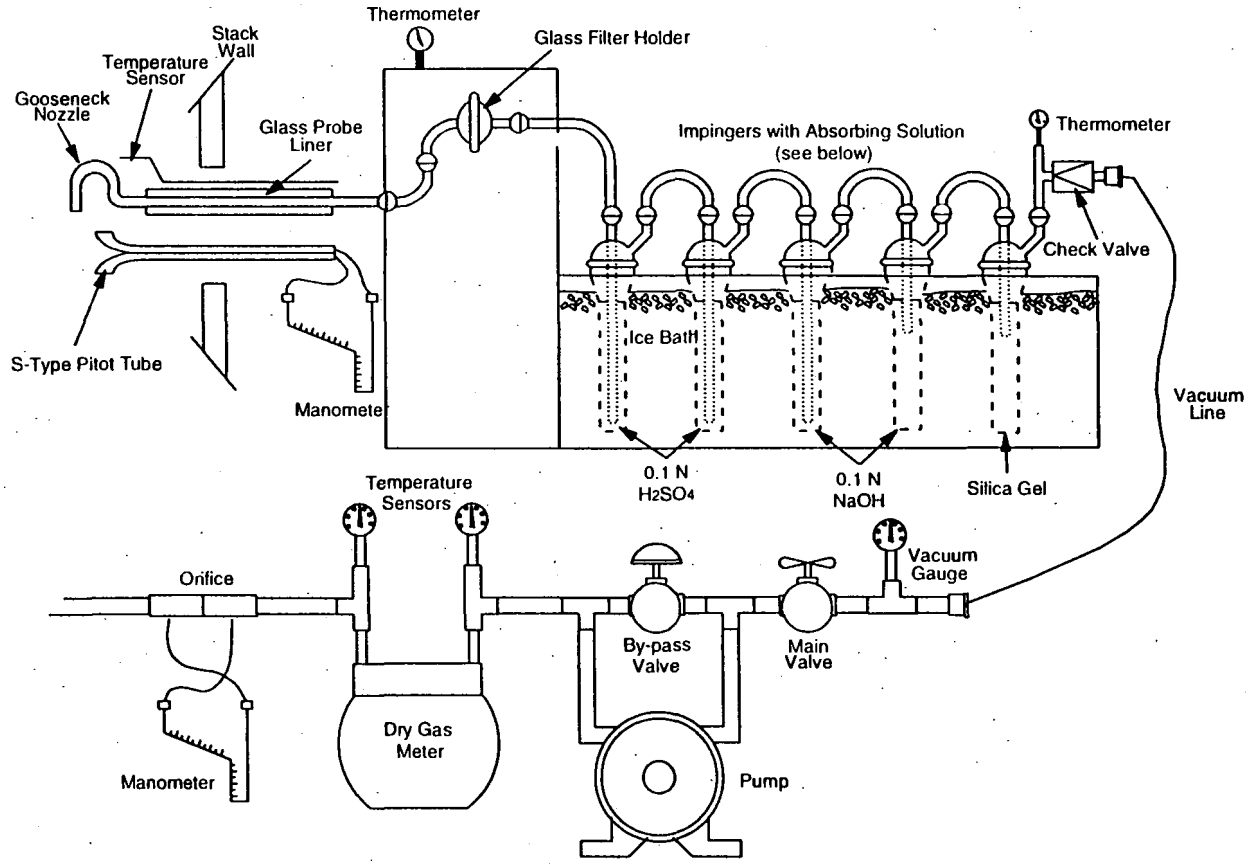

Figure 5-4. Schematic of Method 26A Sampling Train

The contents of the sequential impingers are:

- Impinger #1 (Greenburg-Smith) and Impinger #2 (Greenburg-Smith), known volumes of 0.1N H_2SO_4 (nominal 100 mL);
- Impinger #3 (modified Greenburg-Smith) and Impinger #4 (modified Greenburg-Smith), known volumes of 0.1 N NaOH;
- Impinger #5 (modified Greenburg-Smith), indicating silica gel.

5.2.2 Method 26A Sampling Equipment Preparation

5.2.2.1 Glassware Preparation

Glassware is washed in soapy water, rinsed with hot tap water, rinsed with Type II water, rinsed with acetone to remove the water, rinsed three times with acetone and then air dried. This procedure is used on all the glass components of the sampling train including the glass nozzles plus any sample bottles, Erlenmeyer flasks, petri dishes, and graduated cylinders. Non-glass components (such as the Teflon®-coated filter screens and seals, tweezers, Teflon® squeeze bottles, Teflon® probe brushes) are cleaned following the same procedure. The cleaning procedure is summarized in Table 5-8.

5.2.2.2 Reagent Preparation

The sample train filters are Pallflex® TX40HI45 Teflon® mat filters that meet the criteria specified in Section 3.1.1 of EPA Method 5. These filters are used as received from the vendor. The acetone is purchased as HPLC grade to ensure a low residue after evaporation. The reagent water is distilled/deionized grade that meets the requirements of ASTM Type 3 water or equivalent. The lot number, manufacturer and grade of each reagent that is used are recorded in the laboratory notebook.

Table 5-8. Glassware Cleaning Procedure (Method 26A Train Components)

NOTE: USE DISPOSABLE GLOVES AND ADEQUATE VENTILATION
1. Soak all glassware in hot soapy water (laboratory detergent).
2. Rinse with tap water to remove soap.
3. Rinse with HPLC grade water (three times).
4. Rinse with acetone (three times).
5. Air dry.
6. Cap glassware with clean glass plugs or Parafilm.®
7. Mark cleaned glassware with color-coded identification sticker.

The analyst wears both safety glasses and protective gloves when the reagents are mixed or handled. Each reagent has its own designated transferTeflon® squeeze bottle and is marked for identification and used only for the reagent for which it is designated.

5.2.2.3 Equipment Preparation

The remaining preparation includes calibration and leak checking of all of the train equipment, including meter boxes, thermocouples, nozzles, pitot tubes, and umbilicals. Referenced calibration procedures are followed when available, and the results are properly documented and retained. A discussion of the techniques used to calibrate this equipment is presented below.

Type-S Pitot Tube Calibration. The EPA has specified guidelines concerning the construction and geometry of an acceptable Type-S pitot tube. If the specified design and

construction guidelines are met, a pitot tube coefficient of 0.84 is used. Information pertaining to the design and construction of the Type-S pitot tube is presented in detail in Section 3.1.1 of EPA Document 600/4-77-027b. Only Type-S pitot tubes meeting the required EPA specifications are used. Pitot tubes are inspected and documented as meeting EPA specifications prior to field sampling.

Sampling Nozzle Calibration. Glass nozzles are used for isokinetic sampling. Calculation of the isokinetic sampling rate requires that the cross sectional area of the sampling nozzle be accurately and precisely known. All nozzles are thoroughly cleaned, visually inspected and calibrated according to the procedure outlined in Section 3.4.2 of EPA Document 600/4-77-027b.

Temperature Measuring Device Calibration. Accurate temperature measurements are required during source sampling. Bimetallic stem thermometers and thermocouple temperature sensors are calibrated using the procedure described in Section 3.4.2 of EPA Document 600/4-77-027b. Each temperature sensor is calibrated at a minimum of two points over the anticipated range of use against a NIST-traceable mercury-in-glass thermometer. All sensors are calibrated prior to field sampling.

Dry Gas Meter Device Calibration. Dry gas meters (DGMs) are used in the Method 5 sampling trains to monitor the sampling rate and to measure the sample volume. All DGMs are calibrated to document the volume correction factor just prior to shipping of the equipment to the field. Post-test calibration checks are performed as soon as possible after the equipment has been returned to the ERG Laboratory. Pre- and post-test calibration should agree to within 5%.

Prior to calibration, a positive pressure leak check of the system is performed using the procedure outlined in Section 3.3.2 of EPA Document 600/4-77-237b. The system is placed under approximately 10 inches of water pressure and a gauge oil manometer is used to determine if a pressure decrease can be detected over a one-minute period. If leaks are detected, they are eliminated before actual calibration are performed.

After the sampling console is assembled and leak checked, the pump is to run for 15 minutes, to allow the pump and DGM to warm up. The valve is then adjusted to obtain the desired flow rate. For the pre-test calibration, data are collected at orifice manometer settings (ΔH) of 0.5, 1.0, 1.5, 2.0, 3.0 and 4.0 in H_2O. Gas volumes of 5 ft^3 are used for the two lower orifice settings, and volumes of 10 ft^3 are used for the higher settings. The individual gas meter correction factors (Y_i) are calculated for each orifice setting and averaged. The method requires that each of the individual correction factors fall within ±2% of the average correction factor or the meter is cleaned, adjusted, and recalibrated. In addition, ERG requires that the average correction factor be within 1.00 ±1%. For the post-test calibration, the meter is calibrated three times at the average orifice setting and vacuum which were used during the actual test.

5.2.3 Method 26A Sampling Operations

5.2.3.1 Preliminary Measurements

Prior to sampling, preliminary measurements are required to ensure isokinetic sampling. These preliminary measurements include determining the traverse point locations, performing a preliminary velocity traverse and a cyclonic flow check. These measurements are used to calculate a "K factor." The K factor is used to determine an isokinetic sampling rate from stack gas flow readings taken during sampling.

Measurements are then made of the duct inside diameter, port nozzle length, and the distances to the nearest upstream and downstream flow disturbances. These measurements are then used to determine sampling point locations by following EPA Reference Method 1 guidelines. The distances are then marked on the sampling probe using an indelible marker.

5.2.3.2 Assembling the Train

Assembling the Method 26A sampling train components is begun in the recovery trailer and final train assembly is performed at the stack location. First, the empty, clean impingers are

assembled and laid out in the proper order in the recovery trailer. Each ground glass joint is carefully inspected for hairline cracks. After the impingers are loaded, each impinger is weighed, and the initial weight and contents of each impinger are recorded on a recovery data sheet. The impingers are connected together using clean glass U-tube connectors and arranged in the impinger bucket. The height of all the impingers is approximately the same to obtain a leak free seal. The open ends of the train are sealed with Parafilm® or clean ground glass caps.

The second step is to load the filter into the filter holder in the recovery trailer. The filter holder is then capped off and placed into the impinger bucket. To avoid contamination of the sample, sealing greases are not used. The train components are transferred to the sampling location and assembled as previously shown in Figure 5-4.

5.2.3.3 Sampling Procedures

After the train is assembled, the heaters are turned on for the probe liner and heated filter box. When the system reaches the appropriate temperatures, the sampling train is ready for pre-test leak checking. The gas stream exiting the heated filter is maintained at a temperature of 120 ±14°C (248 ±25°F). The filter temperature is initially set at 120 ±14°C (248 ±25°F) and the probe temperature at 100°C (212°F). The temperature of these two heated zones will be regulated as necessary to maintain the proper temperature of the gas exiting the filter.

The sampling trains are leak checked at the start and finish of sampling. (Method 26A protocol requires post-test leak checks and recommends pre-test leak checks.) ERG protocol also incorporates leak checks before and after every port change. An acceptable pre-test leak rate is less than 0.02 acfm (ft^3/min) at approximately 15 inches of mercury (in. Hg). If, during testing, a piece of glassware needs to be emptied or replaced, a leak check is performed before the glassware piece is removed, and after the train is re-assembled.

To leak check the assembled train, the nozzle end is capped off and a vacuum of 15 in. Hg is pulled in the system. When the system is evacuated, the volume of gas flowing

through the system is timed for 60 seconds. After the leak rate is determined, the cap is slowly removed from the nozzle end until the vacuum drops off, and then the pump is turned off. If the leak rate requirement is not met, the train is systematically checked by first capping the train at the filter, at the first impinger, etc., until the leak is located and corrected.

After a successful pre-test leak check has been conducted, all train components are at their specified temperatures and initial data are recorded (dry gas meter (DGM) reading), the test can be initiated. Sampling train data are recorded periodically (specific interval to be determined) on standard data forms. A checklist for sampling is included in Table 5-9.

The leak rates and sampling start and stop times are recorded on the sampling task log. Also, any other events that occur during sampling are recorded on the task log, such as pitot cleaning, thermocouple malfunctions, heater malfunctions, or any other unusual occurrences.

At the conclusion of the test run, the sample pump (or flow) is turned off, the probe is removed from the duct, a final DGM reading is taken, and a post-test leak check is completed. The procedure is identical to the pre-test procedure; however, the vacuum should be at least one inch Hg higher than the highest vacuum attained during sampling. An acceptable leak rate is less than 4% of the average sample rate or 0.02 acfm (whichever is lower). If a final leak rate on-site does not meet the acceptance criterion, the test run may still be accepted upon approval of the EPA test administrator. If so, the measured leak rate is reduced by subtracting the allowable leak rate from it and then multiplied for the period of time in which the leak occurred. This "leaked volume" is then subtracted from the measured gas volume in order to determine the final gas sample volume.

5.2.4 Method 26A Sample Recovery

Recovery procedures begin as soon as the probe is removed from the stack and the post-test leak check is completed.

Table 5-9. Sampling Checklist for EPA Method 26A

Before Test Starts:

1. Check impinger set (right order and number). Verify probe markings, and re-mark if necessary.
2. Check that you have all the correct pieces of glassware.
3. Check for data sheets and barometric pressure.
4. Sampling equipment needs to be ready for Method 3 analysis.
5. Leak check pitot tubes.
6. Examine meter box - level it and confirm that the pump is operational.
7. Assemble train to the filter and leak check at 15 in. Hg. Attach probe to train and do final leak check; record leak rate and pressure on sampling log.
8. Check out thermocouples - make sure they are reading correctly.
9. Turn on heaters and check to see that their temperatures are increasing.
10. Check that cooling water is on and flowing (if required). Add ice to impinger buckets.
11. Check isokinetic K-factor - make sure it is correct. (Refer to previous results to confirm assumptions). (Two people should calculate this independently to double check it).
12. Have a spare probe liner, probe sheath, meter box and filter ready to go at location.

Table 5-9. Sampling Checklist for EPA Method 26A (continued)

During Test:

1. Notify crew chief of any sampling problems ASAP. Train operator should fill in sampling log.

2. Perform simultaneous/concurrent testing with other locations (if applicable). Maintain filter temperature at 120 ±14° C (248 ±25° F). Keep temperature as steady as possible. Maintain impinger temperatures below 68° F. Maintain probe temperature above 100° C (212° F) or as required to maintain the proper filter temperature.

3. Leak check between ports and record on sampling log.

4. Record sampling rate times and location for the fixed gas (CO_2, O_2) sample (if applicable).

5. Blow back pitot tubes at inlet location every 15 minutes.

6. Change filter if pressure drop exceeds 20 in. Hg.

7. Check impinger silica gel every ½ hr; if indicator changes color request a pre-filled impinger from van lab and replace.

8. Check manometer fluid levels and zero every hour.

After Test is Completed:

1. Record final meter reading.

2. Check completeness of data sheet.

3. Do final leak check of sampling train at maximum vacuum during test.

4. Leak check each leg of pitot tubes.

5. Disassemble train. Cap sections. Take sections to recovery trailer.

Table 5-9. Sampling Checklist for EPA Method 26A (continued)

6. Probe/cyclone recovery (use 500 mL bottles)
   For acetone rinses (all trains)
   - Attach flask to end of probe (separate recovery containers will be used for each sampling location)
   - Add 50 mL of acetone
   - Put a brush down probe, and brush back and forth
   - Rinse back and forth in probe
   - Empty out acetone in sample jar
   - Do this 3 times so that the final combined acetone rinse volume is ≤ 150 mL.

7. Reattach nozzle and cap for next day, store in dry safe place.

8. Make sure data sheets are completely filled out and give to location leader.

To facilitate transfer from the sampling location to the recovery trailer, the sampling train is disassembled into three sections: the nozzle/probe liner, filter holder and impingers in their bucket. Each of these sections is capped with Teflon® tape or Parafilm® before removal to the recovery trailer. All train components are rinsed and the samples collected in separate, prelabeled, precleaned sample containers to avoid cross contamination of inlet and outlet samples. Trains of each type are recovered in separate areas of the mobile laboratory to avoid cross contamination or mistakes in recovery sequences.

Once in the trailers, the sampling train is recovered as separate front and back half fractions. A diagram illustrating front half and back half sample recovery procedures is shown in Figure 5-5. No equipment with exposed metal surfaces is used in the sample recovery procedures. The weight gain in each of the impingers is recorded to determine the moisture content in the flue gas. Following weighing of the impingers, the front half of the train is recovered, which includes the filter and all sample-exposed surfaces forward of the filter. The

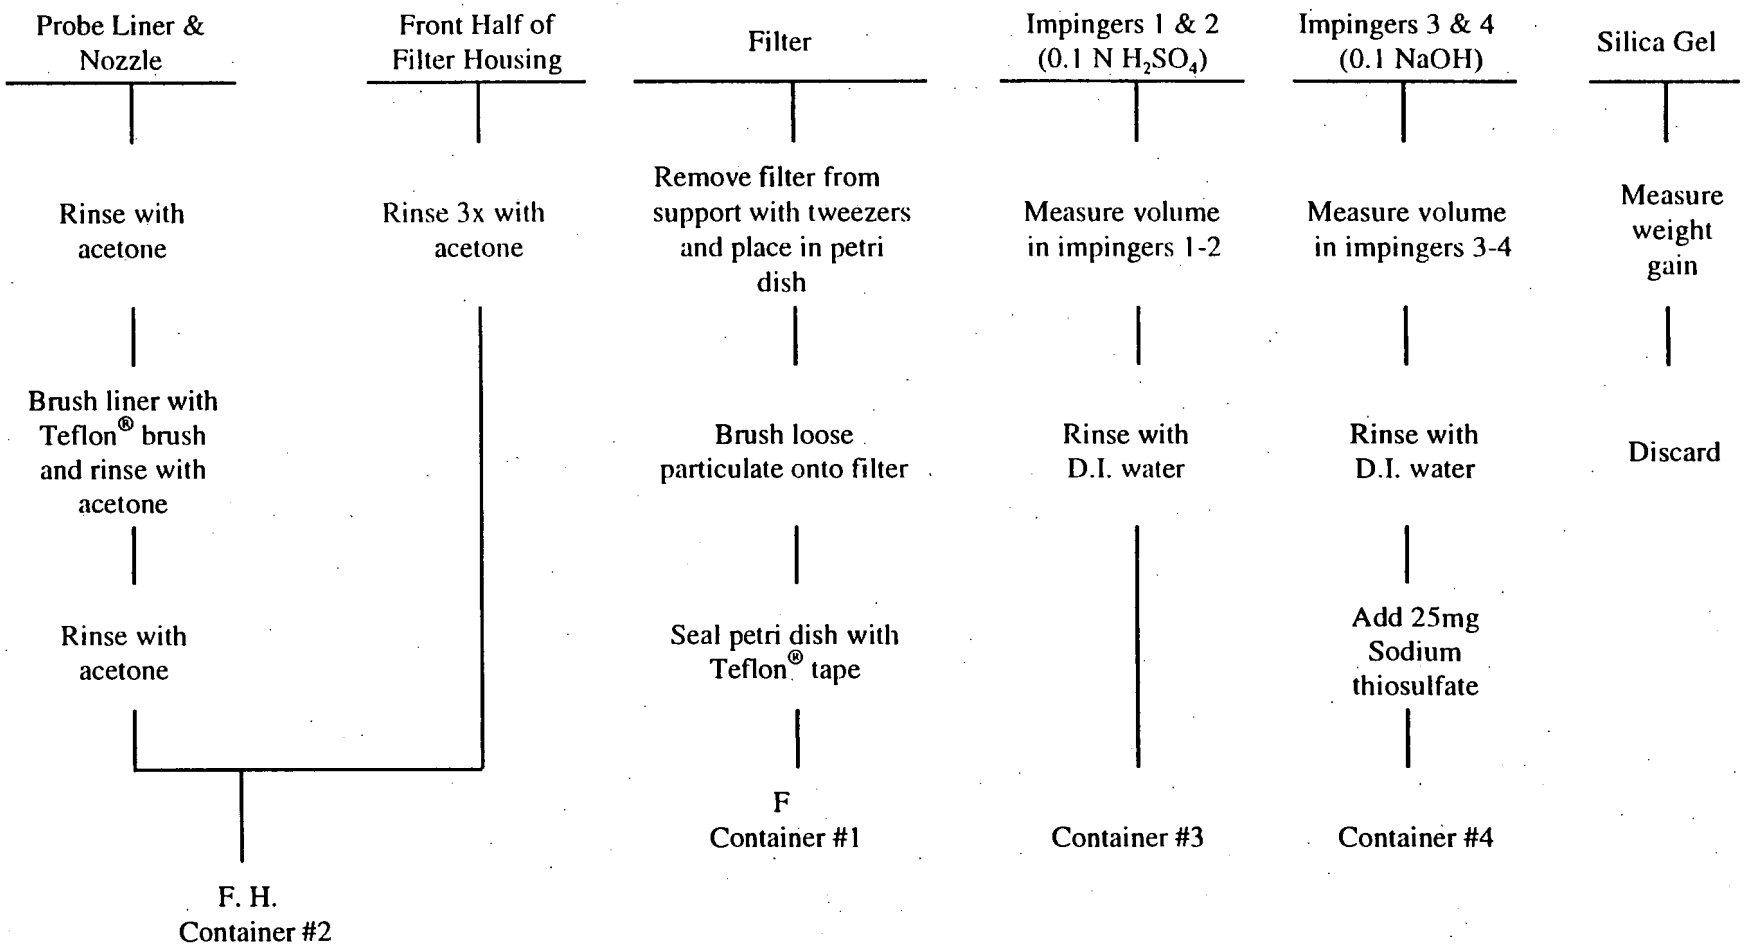

Figure 5-5. Method 26A Sample Recovery Scheme

probe liner is rinsed with acetone by tilting and rotating the probe while squirting acetone into its upper end so that all inside surfaces are wetted. The acetone will be quantitatively collected into the appropriate bottle. This rinse is followed by additional brush/rinse procedures using a non-metallic brush; the probe is held in an inclined position and acetone is squirted into the upper end as the brush is pushed through with a twisting action. All of the acetone and particulate will be caught in the sample container. This procedure is repeated until no visible particulate remains and finished with a final acetone rinse of the probe and brush. The front half of the glass filter holder is also rinsed with acetone until all visible particulate is removed. These rinses are added to the probe rinses. After all front half acetone washes are collected, the cap is tightened, the liquid level marked and the bottle weighed to determine the acetone rinse volume. This sample is Container #2. The method specifies that a nominal volume of 100 mL of acetone must be used for rinsing these components. For blank correction purposes, the exact weight or volume of acetone used is measured. An acetone reagent blank of approximately the same volume as the acetone rinses is analyzed with the samples.

The filter is carefully removed from the filter support and placed in a clean, well-marked glass petri dish (Container # 1) and sealed with Teflon® tape.

After measuring the volume of liquid in the first four impingers and determining the weight gain of the desiccant in the fifth impinger the contents of the first four impingers are recovered.

The contents of the first and second impingers (0.1 N H_2SO_4) and the water rinses of the impingers and connecting glassware are transferred to a separate container labeled "Container No. 3." The contents of the third and fourth impingers (0.1 N NaOH) and the water rinses of the impingers and connecting glassware are transferred to a separate container labeled "Container No. 4." Add 25 mg of sodium thiosulfate to Container No. 4 and mix well. Seal the sample bottles and package for transport to the laboratory for analysis.

A reagent blank is recovered in the field for each of the following reagents:

- Acetone—200 mL sample size;
- Filter blank—one each;
- 0.1 N H_2SO_4 - 200 mL sample size; and
- 0.1 N NaOH - 200 mL sample size, containing 50 mg of sodium thiosulfate.

Each reagent blank is of the same lot as was used during the sampling program. The volumes collected are greater than that required for sample preparation in order to provide sufficient amounts in case of sample loss during preparation or to compensate for larger volumes of train rinses. Each lot number and reagent grade is recorded on the reagent blank label.

One field blank was collected at each lime-injected baghouse inlet, and one at each lime-injected baghouse outlet. A field blank is generated by preparing a sampling train as if for actual sample collection, performing a leak check at the sampling location, then sealing the inlet and outlet of the train and leaving it at the sampling location during the length of an actual test run.

One glassware proof blank will be collected for each train prior to sampling. A proof blank is generated by rinsing the components of a train, prior to use, with the recovery solvent(s) specified in the method.

The liquid level of each sample container is marked on the bottle in order to determine if any sample loss occurred during shipment. If sample loss has occurred, the sample may be voided or a method may be used to incorporate a correction factor to scale the final results depending on the volume of the loss.

Following the protocol of Method 26A, the fractions to be collected for analysis from each train are:

- Fraction 1—Filter;
- Fraction 2—Probe/nozzle/cyclone and filter front half acetone rinses;
- Fraction 3 - Contents of Impingers 1 and 2 plus water rinses; and
- Fraction 4 - contents of Impingers 3 and 4 plus water rinses.

5.2.5 HCl Analytical Procedures

Before analysis, the samples are checked against the chain of custody forms, logged into the laboratory sample tracking system, and assigned a laboratory sample number. Each sample is then examined to determine if any leakage occurred and any color or other particulars of the samples are noted.

The samples are analyzed using ion chromatography (IC). Analytical conditions are determined by the type of analytical column used and whether suppressed or nonsuppressed IC is used. Prior to sample analysis, a stable baseline is established and water samples are injected until no chloride, bromide, or fluoride appears in the chromatogram. The IC is then calibrated using standards spanning the appropriate concentration range, starting with the standard at the lowest concentration. Next, a check sample is injected in duplicate, followed by a water blank and field samples. The calibration standards are re-injected at the end of the analyses to allow compensation for any drift in the instrument response during analysis of the field samples. The chloride sample concentrations are calculated from either the ion peak area or the peak height and the calibration curve.

5.2.6 HCl Analytical Quality Control

The IC is calibrated with a minimum of three concentrations, not including zero. A correlation coefficient of greater than or equal to 0.995 must be achieved to have an acceptable calibration. At least 10 percent of the total number of samples are analyzed in duplicate. Ion concentrations in the duplicates must agree to within ± 20 percent.

5.2.7 Particulate Analysis

The general gravimetric procedure described in Method 5, Section 4.3 is followed. Both filters and precleaned beakers are weighed to a constant weight before use. The same balance used for taring is used for weighing the samples. The balance room is maintained at a constant temperature and humidity. The preparation and analysis scheme for Method 5 is shown in Figure 5-6. The particulate was determined as part of the Method 26A Train samples.

The filter (Container #1) is desiccated to a constant weight for a minimum of 24 hours and then an initial weighing is performed. Weight gain is reported to the nearest 0.1 mg. A second weight determination is made after again desiccating for a minimum of 6 hours. "Constant weight" means a difference of no more than 0.5 mg or 1% of the total weight less tare weight, whichever is greater, between two consecutive weighings made 6 hours apart. Report the final weight as the average of these two values. The filter tare and final weights will be determined under the same conditions of temperature and humidity.

The acetone rinses (Container #2) are transfer to a tared beaker, along with three acetone rinses of Container #2, and evaporated to dryness at ambient temperature, placed in a desiccator for 24 hours and weighed to a constant weight. The total volume of acetone used in preparation of the sample is duplicated for the preparation of a reagent blank.

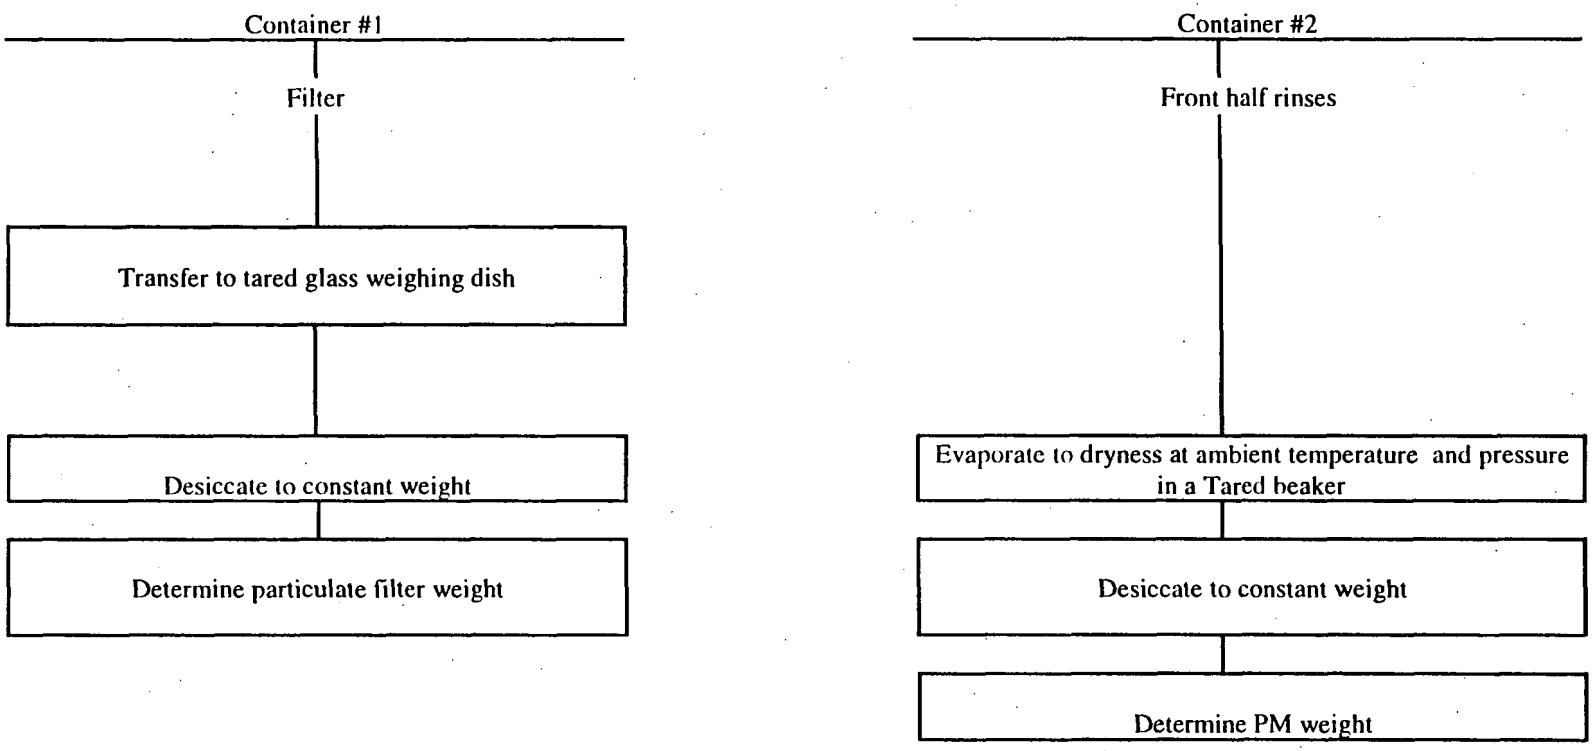

Figure 5-6. Method 5 Preparation and Analysis Scheme (Integral Part of Method 26A)

5.2.8 *Quality Control for Gravimetric Procedures*

All quality control procedures specified in the test method are followed. All field reagent blanks are processed and analyzed as specified in the test method. Prior to each gravimetric determination, the balance calibration is verified using a series of certified weights covering the range of weights encountered for the samples.

5.3 FTIR EPA Method 320

The extractive FTIR measurement method is based on continuous extraction of sample gas from the stack, transporting the sample to the FTIR spectrometer and performing real-time spectral measurement of the sample gas. The sample gas spectra are analyzed in real-time for target analytes, archived and possibly re-analyzed at a later date for other target analytes.

5.3.1 *FTIR Sampling Equipment*

The FTIR measurement system met the sampling and analysis requirements set forth in EPA Draft Method 320, "Measurement of Vapor Phase Organic and Inorganic Emissions By Extractive Fourier Transform Infrared Spectroscopy". This system has been used with complete success with many source categories, and can also be adapted to switch quickly between two sources (i.e., inlet and outlet) with a single FTIR spectrometer.

The sampling and measurement system consists of the following components:

- Heated probe;
- Heated filter;
- Heat-traced Teflon® sample line;
- Teflon® coated, heated-head sample pump;
- FTIR spectrometer;

- FTIR sample conditioning system; and
- QA/QC apparatus.

Figure 5-7 illustrates the FTIR sampling and measurement system. In operation at a stationary source, the sample is continuously extracted from the stack through the heated probe. Sample gas is then sent into a heated filter assembly which will remove any particulate matter from the sample stream to protect the remainder of the sampling and analysis system. The probe liner and filter body are made of glass, and the filter element is polytetrafluoroethylene (PTFE or Teflon®). In addition to providing an inert surface, the glass body filter allows the operator to observe the filter loading during sampling operations. The probe and filter are contained in a heated box which is mounted on the stack and maintained at a temperature of 121° C (250° F).

After passing through the filter assembly, the sample gas is transported to the FTIR spectrometer by a primary heat-traced PTFE sample line maintained at 149° C (300° F) driven by a heated- PTFE head sample pump maintained at 204° C (400° F). The sampling flow rate through the probe, filter, and sampling line is a nominal 20 liters per minute (Lpm). Sample gas then enters an atmospheric pressure heated PTFE distribution manifold where it is sent to the FTIR spectrometer via a slipstream flowing at 9 Lpm. Other slipstreams can be sent to other instruments, if necessary. Excess sample gas not used by instruments is vented to atmosphere.

FTIR spectrometer sample gas is taken from the distribution manifold by a secondary heated PTFE head sample pump maintained at 204° C (400° F) and directed into the FTIR sample cell maintained at 185° C (365° F) for real-time analysis. The cell is made of nickel-plated aluminum, with gold-plated glass substrate mirrors and potassium chloride windows. Exhaust gas from the cell is vented to the atmosphere.

Sample conditioning (when required) is achieved by passing raw sample gas through a PermaPure® drier and a series of impingers filled with sodium (or lithium) hydroxide pellets. The PermaPure® drier selectively removes water vapor and the sodium hydroxide pellets remove CO_2 and other acid gases. The sample conditioning apparatus is switched into the FTIR sample

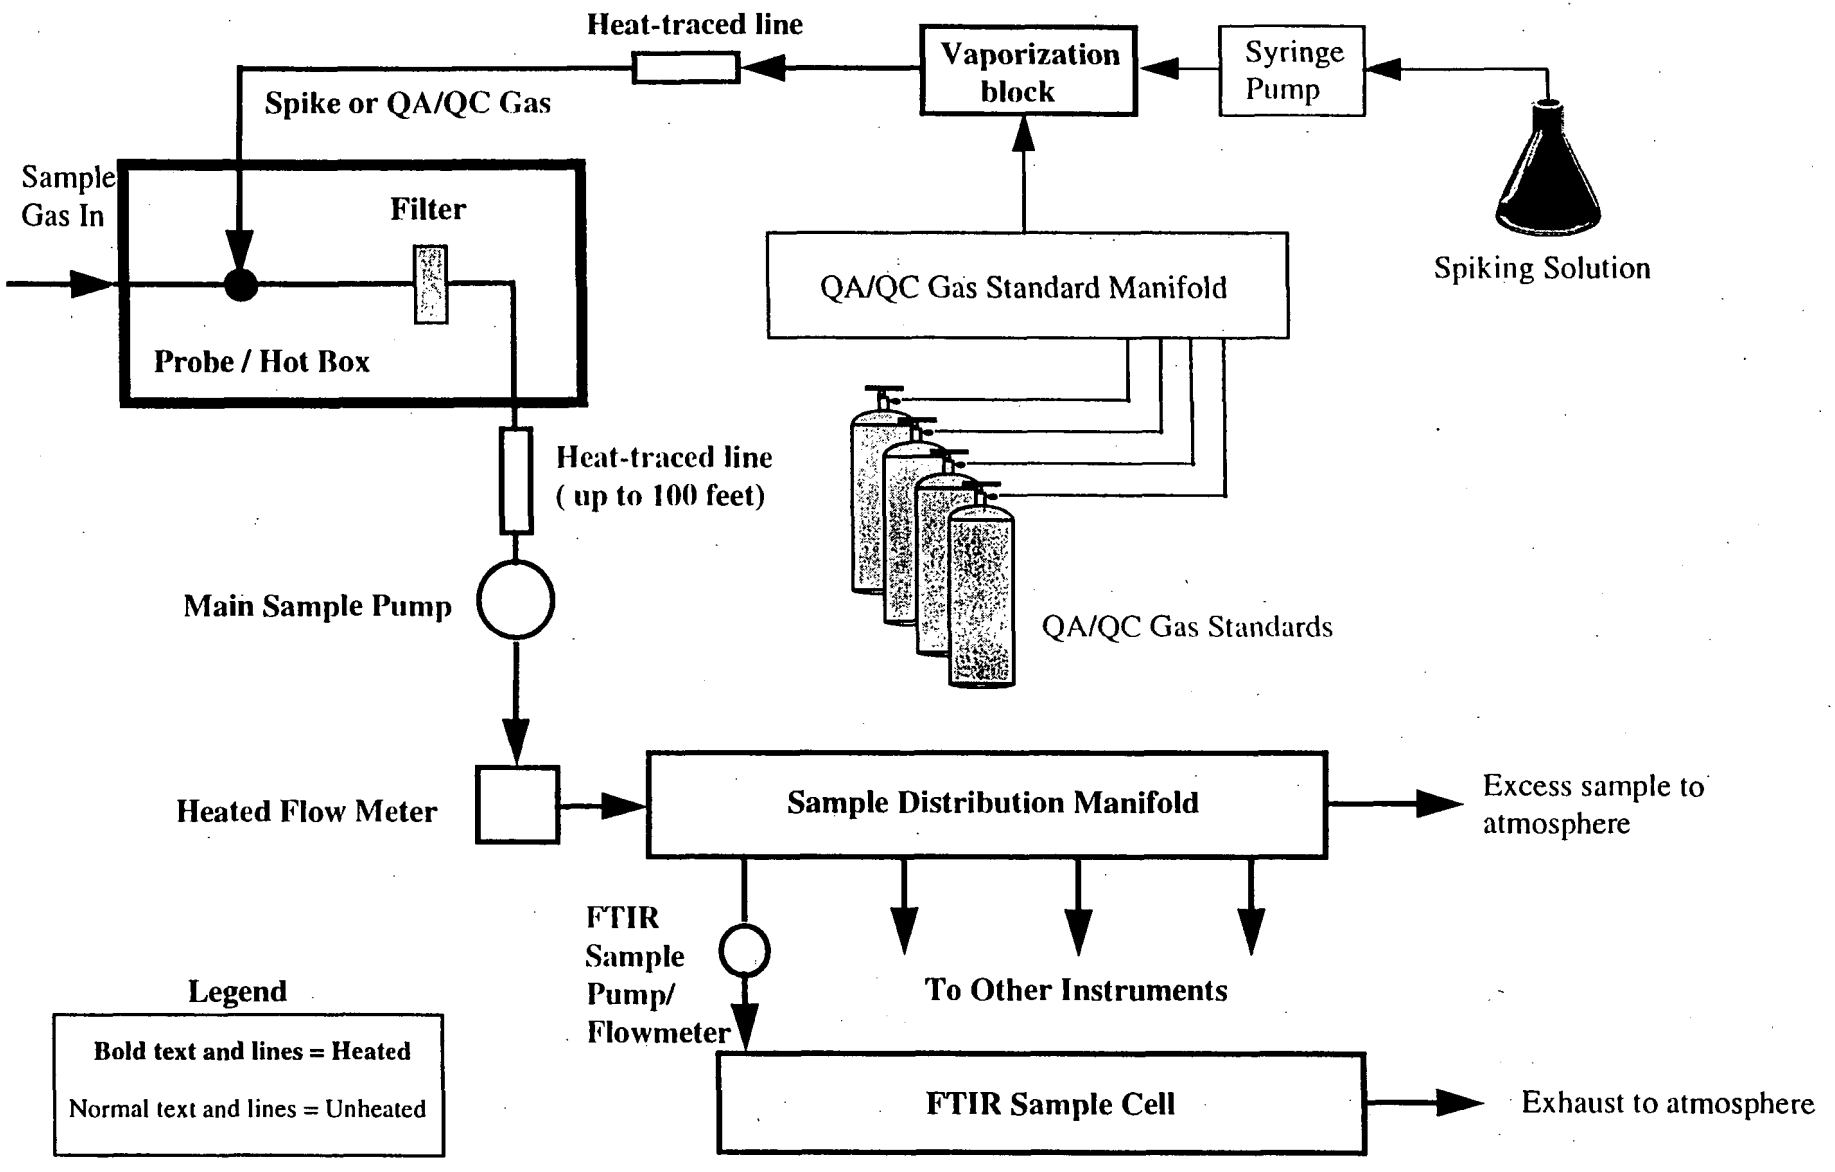

Figure 5-7. FTIR Sampling and Measurement System

path by a valving system. Lower detection limits for some compounds can be achieved with a conditioned sample.

5.3.2 Preparation for Sampling

The heated sampling lines, probes, and heated filter were positioned at the inlet and outlet locations. All heated components were brought to operating temperature, and a leak check of both inlet and outlet sampling systems was performed. The leak check was performed by plugging the end of the probe and watching the main sample rotameter to see that the value goes to zero.

A background spectrum was measured using zero air or zero nitrogen through the cell. Next the QC gases were measured by flushing the cell and they must agree to within ±10% of target value. The QC gases used for this program included:

- Halocarbon 22, used to calibrate the pathlength. Halocarbon 22 is used for its highly linear response due to the lack of sharp spectral features, and is an extremely stable compound.

- Carbon monoxide (CO); used for frequency calibration. Carbon monoxide is directly injected into the sample cell to measure photometric accuracy, validity of the non-linear correction algorithm and serve as a frequency (i.e., wavelength) calibration. Acceptable limits for CO standard analysis are ±5 percent of certified concentration;

- Methane/nitric oxide/carbon dioxide mixture, used for overall system performance check (calibration transfer standard) (acceptance limits are ±5% of the certified concentration); and

- Hydrogen chloride standard, analyzed to verify the instrumental response of HCl, a key target analyte (acceptance limits are ±10% of certified concentration).

The sampling and measurement system spike test was used to perform validation and directly challenge the complete system and provide information on system accuracy and bias. This test is conducted to satisfy the requirements set in EPA Draft Method 320 entitled

"Measurement of Vapor Phase Organic and Inorganic Emissions By Extractive Fourier Transform Infrared Spectroscopy". Section B.1.C of Method 320 gives a description of the dynamic spiking apparatus.

The FTIRS spiking procedure used was the following:

- Measure native stack gas for a 5 minute period;
- Start spike gas flow into sample stream, upstream of the heated filter;
- Let system equilibrate for 5 minutes;
- Measure spiked sample stream for 5 minutes;
- Turn off spike gas flow;
- Let system equilibrate with native stack gas for 5 minutes; and
- Repeat cycle, two more times.

The above procedure produces 3 spiked/unspiked sample pairs per hour. Spike recovery and three relative standard deviations for 3 spiked/unspiked sample pairs were computed from the procedure given in Section 8.6.2 of EPA Draft Method 320. The recovery must be 70-130% and the Percent Relative Standard Deviation must be less than or equal to 50% for the method to be valid for this source category.

The spiked/unspiked pairs are not simultaneously recorded, since only one FTIRS system will be available, but due to the expected steady nature of the source, this procedure produced acceptable results.

The FTIR sampling and analysis system was validated for HCI at the outlet of the chip dryer baghouse and the inlet and outlet of the reverberatory furnace #1 and was used as a screening tool for the other HAPs.

5.3.3 Sampling

FTIR sampling was performed simultaneously with the manual testing. The start and stop times, as well as port change times, were coordinated with the FTIR operator, so that FTIR data files could be coordinated with manual method start and stop times. FTIR inlet/outlet sampling was accomplished using two heated transfer lines, using a valving system to switch from one to the other.

Table 5-10 gives typical FTIR operating conditions. These parameters provide detection limits of 0.1-1 ppm for typical FTIR analytes, while providing adequate dynamic range (nominally 1-1000 ppm). Some of these parameters are sample matrix dependent.

Table 5-10. Typical FTIR Operating Parameters

Parameter	Value
Spectral Range (cm^{-1})	400 - 4000
Spectral Resolution (cm^{-1})	0.5 (or better)
Optical Cell Pathlength (m)	3.2 (variable -- 1-10)
Optical Cell Temperature (° C)	185
Sample Flow Rate (liters/minute)	9 (3.0 optical cell volumes/minute)
Integration Time (minutes)	1 (Average of 40 spectra)

Sample flow rate was determined by the data averaging interval and FTIR spectrometer sample cell volume. A minimum of 3 sample cell volumes of gas must flow through the system to provide a representative sample during a single integration period. Typically, a 1 minute averaging period with a 3 liter volume sample cell gives a minimum flow rate of 9 liters per minute (LPM). Typically a flow rate of 20 standard Lpm is used to accommodate the FTIR and other instrumentation on-site, and to minimize sample residence time in the sampling system.

The temperature of all sampling system components were nominally 221-204° F (250-400° C) to prevent condensation of water vapor or other analytes in the sampling system. The FTIR sample cell temperature was maintained at 365° F (185° C) to ensure that condensation of high-boiling point analytes on the cell optics is minimized.

FTIR sample cell pressure was monitored in real-time in order to calculate analyte concentration in parts-per-million. It is normally operated near atmospheric pressure with the cell pressure continuously monitored.

Stack gas temperature was also be monitored to provide information on potential sample analyte condensation in the sampling system. If the stack gas temperature is higher than the lowest sampling system component temperature, then an assessment by the spectroscopist or field team leader must be made whether any analytes of interest may condense within the sampling system, resulting in measurement bias.

Sampling probe location was determined by the requirements set in EPA Method 1 in terms of duct diameters upstream and downstream of disturbances. Concurrent EPA Method 2 velocity measurements were carried out at the same process stream location as the FTIR sampling point to provide mass emission rate determination. The stack gas velocity and flow rate were determined by the manual test methods.

Before testing, sample matrix effects were assessed on-site by the spectroscopist and adjustments to the optical pathlength and spectral analysis regions were made. Once the adjustments have been made, they rarely need to be further refined at a given source type.

Sampling and analysis procedures are straightforward for a single-source measurement. Once QA/QC procedures have been completed for a given test day, the sample is allowed to flow continuously through the FTIR spectrometer cell and the software is instructed to start spectral data collection. Usually, the spectrometer collects one interferogram per second and averages a number of interferograms to form a time-integrated interferogram. Typical averaging times

range from 1 to 5 minutes. The interferogram is converted into a spectrum and analyzed for the target analytes. After spectral analysis, the spectrum is stored on the computer and later permanently archived. Spectral data collection is stopped after a pre-determined time, corresponding to a "run". Typical runs were 4 hours long, giving 240 one-minute averaged points for each target analyte. At the end of the test day, the end-of-day QA/QC procedures were conducted.

Before any testing is started at a given site, an initial "snapshot" of the stack gas is taken with the FTIR measurement and analysis system to determine the true sample matrix. If any target analytes are present at significantly higher levels than expected, adjustments will be made to the cell pathlength and/or the spectral analysis regions used for quantitative analysis. These adjustments will minimize interferences due to unexpectedly high levels of detected analytes.

Since sample conditioning was required for certain analytes, the FTIR spectrometer divided its analysis time between conditioned and unconditioned samples. Usually, the analysis time is split into blocks to minimize dead time due to switching between sample types. For example, the first half of the run period is dedicated to conditioned samples, and the last half of the run is committed to unconditioned samples. The order used at Culp Aluminum Alloys is shown in the table below.

Sampling Conditions	**Sampling Time**	**Inlet**	**Outlet**
Chip Dryer Unconditioned	First half of Test	2 minute cell purge 8 minute sample collection	2 minute cell purge 8 minute sample collection
Chip Dryer Conditioned	Second half of Test	2 minute cell purge 8 minute sample collection	2 minute cell purge 8 minute sample collection
Furnace Unconditioned	First half of Charging	2 minute cell purge 8 minute sample collection	2 minute cell purge 8 minute sample collection
Furnace Conditioned	Second half of Charging	2 minute cell purge 8 minute sample collection	2 minute cell purge 8 minute sample collection
Furnace Unconditioned	Duration of Mixing Top Out	2 minute cell purge 8 minute sample collection	2 minute cell purge 8 minute sample collection

The sample being delivered to the FTIR cell alternated between the inlet and the outlet. The switching valve, located just upstream of the common manifold, was manually activated every 10 minutes to provide twelve ten-minute sample collections during each two-hour period.

FTIR method performance is gauged from the results of the QA/QC procedures given in Section B5 of Draft EPA Method 320. Acceptable spiking tests must meet acceptance criteria of 50 percent relative standard deviation (RSD) and accuracy of within ± 30 percent. The acceptable instrument diagnostic and system response check accuracy must be within ± 5 percent of target. Acceptable system response check precision was 5 percent RSD.

The ERG validated spectral database includes the compounds shown in Table 5-11. These spectra were validated in the laboratory at a cell temperature of 185° C against certified gaseous standards. Any compounds identified in the stack gas and not included in the ERG database can be quantified if necessary after subsequent laboratory spectral acquisition.

5.3.4 FTIR Method Data Review, Validation, and Verification Requirements

Quantitative analysis is performed by a mathematical method called multi-variate least squares (commonly known as Classical Least Squares or CLS). CLS constructs an optimized linear combination (or 'fit') of the reference spectra to duplicate the sample spectrum, utilizing the Beer-Lambert Law. The Beer-Lambert Law states that the absorbance of a particular spectral feature due to a single analyte is proportional to its concentration. This relationship is the basis of FTIR quantitative analysis. The coefficients of each compound in the linear fit yield the concentration of that compound. If it is found that the quantitative analysis of a given compound responds non-linearly to concentration, a calibration curve is developed by measuring a series of reference spectra with differing optical depths (concentration times pathlength) and using them in the linear fit. Low molecular weight species such as water vapor and carbon monoxide require non-linear correction, possibly even at levels as low as 100 ppm-meters (concentration times pathlength). Analytes greater than 50-60 amu molecular weight usually do not require non-

Table 5-11. Compounds for Which Reference FTIR Spectra Are Available in the ERG Spectral Library[a]

1,3-butadiene	cyclohexane
1-butene	ethylbenzene
2-methyl-2-propanol	formaldehyde
2-methylbutane	water vapor
2-methoxyethanol	hydrogen chloride
2-methylpropane	hydrogen fluoride
2-propanol	isobutylene
4-vinylcyclohexane	methylene chloride
acetic acid	methyl ethyl ketone
acetone	*m*-xylene
acrolein	*p*-xylene
benzene	*o*-xylene
acetylene	phenol

acetaldehyde	nitric oxide
methanol	nitrogen dioxide
methane	*n*-pentane
carbon monoxide	carbonyl sulfide
carbon dioxide	sulfur dioxide
cyclopropane	styrene
cyclopentane	toluene

[a] Spectra were collected at a cell temperature of 185° C.

linear corrections. An experienced spectroscopist can determine whether non-linear corrections are necessary for an analyte in a given source testing scenario.

The following procedures were conducted to review the FTIR data:

A. Post-test Data Review procedure (on-site)

1. Examine the concentration vs. time series plot for each compound of interest, and identify regions with the following characteristics:
   - sudden change in concentration;
   - unrealistic concentration values;
   - significant changes in 95 percent confidence intervals reported by software; and
   - sudden increase of noise in data.
2. Select representative spectra from the time periods indicated from Step 1.
3. Subtract from each representative spectrum chosen in Step 2 a spectrum which was taken immediately prior in time to the indicated time region.
4. Manually quantitate (including any non-linear corrections) for the species in question and compare the result to the difference in software-computed concentrations for respective spectra.
5. If concentration values in Step 4 do not agree to within 5 percent, determine whether the difference is due to a recoverable or non-recoverable error.

6 (i). If the error is non-recoverable, the spectra in the indicated time region are declared invalid.

6 (ii). If the error is recoverable, and time permits, determine possible source(s) of error and attempt to correct. If time is critical, proceed with measurement. If correction is achieved, conduct QA/QC checks before continuing.

7. Determine the peak-to-peak scatter or the root mean square (RMS) noise-equivalent-absorbance (NEA) for the representative spectra.
8. If the NEA exceeds 1×10^{-3} absorbance units, the spectra in the time region are declared invalid (due to non-recoverable error).
9. Data found invalid are subject to re-measurement.

B. Final Data Review (off-site)

The procedures for final data review included those given above; however, if a non-recoverable error was found during this phase, the data were considered invalid. In addition, the following procedures were carried out by the spectroscopist to perform a final data validation:

1. If any recoverable data errors are detected from the procedure, determine the cause and perform any necessary corrections.

2. For analytes which were not detected or detected at low levels:
   a) estimate detection limits from validated data;
   b) check for measurement bias.

5.3.5 QC for the FTIR

The FTIR QA/QC apparatus was used to perform two functions:

- Dynamic analyte spiking; and
- Instrumental performance checks.

Dynamic analyte spiking is used for quality control/quality assurance of the complete sampling and analysis system. Dynamic spiking is continuous spiking of the sample gas to provide information on system response, sample matrix effects, and potential sampling system biases. Spiking is accomplished by either:

- Direct introduction of a certified gas standard; or
- Volatilization of a spiking solution.

Certified gas standards are preferred due to simplicity of use, but many target analytes cannot be obtained as certified gas standards, and must be spiked using standards generated by volatilized solutions.

Gaseous spiking is carried out by metering the spike gas into the sample stream at a known rate. Spike levels are calculated from mass balance principles. When certified gas standards are used, a dilution tracer, such as sulfur hexafluoride, is used to directly measure the fraction of spike gas spiked into the sample. This technique can be used instead of mass balance calculations.

Before any testing is started at a given site, an initial "snapshot" of the stack gas is taken with the FTIRS measurement and analysis system to determine the true sample matrix. If any target analytes are present at significantly higher levels than expected, adjustments will be made to the cell pathlength and/or the spectral analysis regions used for quantitative analysis. These adjustments will minimize interferences due to unexpectedly high levels of detected analytes.

FTIRS method performance is gauged from the results of the QA/QC. Acceptable spiking tests will meet Method 301 criteria (i.e., 50 percent relative standard deviation (RSD) and accuracy of within ± 30 percent) or a statistical equivalent when less than 12 spiked/unspiked pairs are collected. The acceptable instrument diagnostic and system response check accuracy will be within ± 5 percent of target. Acceptable system response check precision will be 5 percent RSD.

6.0 QUALITY ASSURANCE/QUALITY CONTROL

Specific Quality Assurance/Quality Control (QA/QC) procedures were strictly followed during this test program to ensure the production of useful and valid data throughout the course of the project. A detailed presentation of QC procedures for all sampling and analysis activities can be found in the Site Specific Test Plan and Quality Assurance Project Plan for this project. This section reports all QC results so that the data quality can be ascertained.

In summary, a high degree of data quality was maintained throughout the project. All train leak checks met the QC criteria as specified in the methods. Isokinetic sampling rates were kept within 10% of 100% for all test runs. Acceptable spike recoveries and close agreement between duplicate analyses were shown for the sample analyses. The data completeness was better than 95%.

6.1 Sampling QC Results

The following sections discuss the QC results of the sampling methods employed during this project.

6.1.1 Leak Checks

Tables 6-1 and 6-2 list the pre- and post-test and port change leak checks results for the chip dryer and furnace tests. The acceptance criterion that all post-test leak checks must be less than 0.02 cfm or 4 percent of the average sampling rate (which ever is less) at the highest vacuum achieved during sampling was met for all test runs.

Table 6-1. Summary of Dioxin/Furan Test Leak Check Results

6.1.3 Meter Box Calibrations

All dry gas meters are fully calibrated every six months against an EPA approved intermediate standard. The full calibration is used to correct the actual metered sample volume to the true sample volume. To verify the full calibration, a post-test calibration is performed. The full and post-test calibrations must be within 5% to meet ERG's internal QA/QC acceptance criterion. As shown in Table 6-4, the dry gas meters used for this testing met this criterion.

Table 6-4. Dry Gas Meter Post-Test Calibration Results

Sampling Train[1]	Meter Box #	Full Calibration Factor	Post-Test Calibration Factor	Post-Test[2] Deviation, %
D/F CD Outlet	A-38	0.981	0.978	-0.30
D/F CD Inlet	A-40	0.98	0.979	-0.10
HCl CD Outlet	A-37	0.988	0.995	-0.70
HCl CD Inlet	A-39	0.994	0.974	-2.00
D/F RF Outlet	A-37	0.988	0.995	-0.70
D/F RF Inlet	A-39	0.994	0.974	-2.00
HCl RF Outlet	A-38	0.981	0.978	-0.30
HCl RF Inlet	A-40	0.98	0.979	-0.10

[1]CD=Chip Dryer, RF=Reverberatory Furnace

[2]$\frac{\text{Post-Full}}{\text{Full}} \times 100$

6.1.4 Field Blank Results

Field Blanks are collected to determine the level, if any, of sample contamination resulting from the exposure of the sampling train to ambient conditions in the vicinity of the sampling locations or to sample "carry over" from one run to the next. A field blank train for each test method and for each location was assembled as if for sampling, leak checked at the

sampling location, left at the sampling location for the duration of a test run and then recovered. The samples were returned to the laboratory for analysis along with the test samples. The results of the analysis for the Method 26A field blanks are shown in Table 6-5. A small amount of HCl was detected in the Chip Dryer field blank, but represents less than 1% of the amount detected in most of the test samples and less than 5% of that detected in all samples. Because the level of contamination was so low, no blank corrections were made on the emission results. No HCl above the instrument detection limit was detected in the furnace field blanks.

Table 6-5. Method 26A Field Blank Analysis Results, µg Detected

Location	µg HCl Detected
Chip Dryer Inlet	20.0
Chip Dryer Outlet	Not Required
Reverberatory Furnace Inlet	< 14.0
Reverberatory Furnace Outlet	< 14.0

Table 6-6 shows the results of the analysis of the D/F field blanks. The levels detected in the blank are less than 1% of that detected for any congener in the chip dryer inlet samples and less than 1% for most and less than 5% for all detected in the chip dryer outlet samples except for OCDD and OCDF. The levels detected in the furnace inlet field blank were less than 1% for most congeners and less than 5% for all except for 2,3,7,8-TCDD and 1,2,3,7,8-TCDD which were less than 10%. Trace amounts of all but three congeners were detected in the furnace outlet field blank. Of the ones detected all but seven were less than 5 times the detection limit and the others were less than 10 times the detection limit. All but six of the congeners were at levels equivalent to those found in the furnace outlet samples and all were detected at levels less than one nanogram. Since the levels detected were insignificant, no blank correction to the data was performed.

Table 6-6. Method 23 Field Blank Analysis Results, ng Detected

Congener	Chip Dryer Inlet	Furnace Inlet	Furnace Outlet
2,3,7,8 -TCDD	<0.006	0.07	<0.004
1,2,3,7,8-PeCDD	0.04	0.48	0.02

1,2,3,7,8,9-HxCDF	0.02	0.15	<0.007
1,2,3,4,6,7,8-HpCDF	1.2	6.1	0.43
1,2,3,4,7,8,9-HpCDF	0.17	0.72	<0.05
1,2,3,4,6,7,8,9-OCDF	0.41	1.5	0.31

6.1.5 FTIR Sampling Quality Control

FTIR sampling system quality control procedures used in this test program were:

- Sampling system leak check;
- Dynamic spiking (also analytical quality control); and
- Monitoring of all pertinent system temperatures and flow rates.

Sampling system leak checks were carried out before and after each run. The leak check procedure used is identical to that given in EPA Method 320. The sample gas inlet to the probe was covered and the total sample flow rate rotameter was monitored to observe zero flow (i.e., indicator ball sits on bottom of scale). In all cases in this program, the system passed both before and after run leak checks for all runs performed.

Dynamic spiking was carried out to test the complete FTIR sampling and analysis system. Spiking was carried out twice daily on both inlet and outlet for HCl, and three EPA Method 301 validation tests were carried out. The Method 301 tests were carried out on the following locations:

- Chip dryer outlet;
- Furnace hood inlet; and
- outlet.

Method 301 validation results are given in Section 2.5.2.1. Daily spiking results are given below in Section 6.2.4.

To insure that the sampling system was performing correctly during all measurement operations, selected temperatures and flows were monitored during each run. Temperature data were recorded every 15 minutes on a data sheet. Sample flows were monitored but not recorded. The following data were monitored or recorded:

- Inlet/outlet stack temperature;
- Inlet/outlet probe temperature;
- Inlet/outlet filter temperature;
- Inlet/outlet heat-traced sample line temperature;
- Inlet/outlet main sample pump head temperature;

- FTIR sample pump head temperature;
- Sample pump enclosure temperature;
- Sample manifold temperature;
- Controller electronics box temperature;
- Heated sample line jumper temperature(2);
- Main sample flow rate;
- FTIR sample flow rate; and
- Excess sample flow rate.

FTIR cell temperature was controlled at 185°C sample gas temperature (not cell wall temperature), and cell pressure was recorded. No unusual readings of any parameter were found during testing.

6.2 Analytical Quality Control Results

6.2.1 D/F Analytical Quality Control

All quality control procedures specified in the test method were followed. Blanks were used to determine analytical contamination, calibration standards were used for instrument calibration and linearity checks, internal standards were used to determine isomer recoveries and adjust response factors for matrix effects, surrogate standards were used to measure the collection efficiency of the sampling methodology and an alternate standard was used as a column efficiency check.

6.2.1.1 D/F Quality Control Blanks

Reagent blanks of 500 mL of each liquid reagent used at the test site were saved for analysis. Each reagent blank was of the same lot as was used during the sampling program.

Each lot number and reagent grade was recorded on the field blank label and in the laboratory notebook (acetone, methylene chloride, toluene, filter, XAD-2®). Two reagent blanks were collected in the field. The analysis results showed the absence of any analytes, at the detection limit, for approximately half of the congeners with the remaining being detected at less than 5 times the detection limit. These insignificant amounts are most likely due to laboratory contamination.

6.2.1.2 Quality Control Standards

Recoveries of the internal standards must be between 40 to 130% for the tetra- through hexachlorinated compounds and in the range of 25 to 130% for the hepta- and octachlorinated homologs. These requirements were met for all of the D/F samples except for the following: chip dryer inlet Run 1, isotopically labeled HpCDD (134%).

Surrogate standard recoveries must be between 70 to 130%. The recoveries of all standards met this requirement except for the following: isotopically labeled HxCDD for chip dryer outlet run 1 (158%), chip dryer outlet run 2 (137%) and chip dryer outlet run 3 (142%). These % recoveries were all just outside of the recovery limits and will not have an effect on the analysis results.

6.2.2 HCl Analytical Quality Control

The IC is calibrated with a minimum of three concentrations, not including zero. A correlation coefficient of greater than or equal to 0.995 must be achieved to have an acceptable calibration. At least 10 percent of the total number of samples are analyzed in duplicate. Ion concentrations in the duplicates must agree to within ± 20 percent. All QC results were within the acceptance criteria

Reagent blanks were collected in the field and returned to the laboratory for analysis. HCl, as Cl^{-1}, was not detected in any of the blanks at the detection limit.

Every sample was analyzed in duplicated with the relative percent difference for every sample duplicate less than 5.

A matrix spike and matrix spike duplicate analysis was performed on the chip dryer outlet run 1 sample. The percent recoveries were 106 and 104, respectively.

6.2.3 Quality Control for Gravimetric Procedures

All quality control procedures specified in the test method are followed. All field reagent blanks were processed and analyzed as specified in the test method. Prior to each gravimetric determination, the balance calibration was verified using a series of certified weights covering the range of weights encountered for the samples.

6.2.4 FTIR Analytical Quality Control

Dynamic analyte spiking was used for quality control/quality assurance of the complete sampling and analysis system. Dynamic spiking is continuous spiking of the sample gas to provide information on system response, sample matrix effects, and potential sampling system biases. Spiking was accomplished by direct introduction of a certified gas standard.

Gaseous spiking was carried out by metering the spike gas into the sample stream at a known rate. A sulfur hexafluoride dilution tracer was used to directly measure the fraction of spike gas spiked into the sample. EPA Method 320 limits the dilution of the sample gas to 10 percent.

Before any testing was started at a given site, an initial "snapshot" of the stack gas is taken with the FTIR measurement and analysis system to determine the true sample matrix. If any target analytes are present at significantly higher levels than expected, adjustments were made to the cell pathlength and/or the spectral analysis regions used for quantitative analysis. These adjustments minimized interferences due to unexpectedly high levels of detected analytes.

FTIR method performance is gauged from the results of the QA/QC. All spiking tests met Method 301 criteria (i.e., 50 percent relative standard deviation (RSD) and accuracy of within ± 30 percent). The acceptable instrument diagnostic and system response check accuracy will be within ± 6 percent of target.

Analytical QC checks for the FTIR system consisted of the following:

- Dynamic spiking of HCl;
- direct measurement of a HCl gas standard;
- direct measurement of a CO gas standard; and
- direct measurement of a CH_4, NO_x, and CO_2 standard.

Dynamic spiking runs were conducted twice daily: before and after testing. Three spiked/unspiked data pairs were collected. Statistical calculations consistent with EPA Method 301 were performed on the data. Recovery of 70-130 percent and less than 50 percent RSD were the acceptance criteria. Table 6-6 summarizes the dynamic spiking results. All dynamic spiking tests met the above acceptance criteria. In all runs, sample gas was diluted 10 percent or less.

Direct instrumental measurement of HCl, CO, and a CH_4, NO_x and CO_2 mixture was conducted before and after daily testing activities. Acceptance criteria are normally ±6 percent of target, using EPA protocol gases. However, since the HCl standard was obtained at a ±5 percent analytical tolerance, the acceptance criteria was set at ±10 percent. FTIR NO_x is measured as NO + NO_2. Examination of Tables 6-7 through 6-9 shows that all QC checks met the above criteria.

Table 6-6. QC Spiking Results

Run	Date	Time	Inlet/outlet	% Recovery
1	12/5/97	AM	outlet	97.61
1	12/5/97	AM	inlet	112.85
2	12/5/97	PM	outlet	102.62

Overview

The samples and associated QC samples were extracted and analyzed according to procedures described in Method 23 (6/93). Any particular difficulties encountered during the sample handling by Triangle Laboratories will be discussed in the QC Remarks section below. This report contains results only from the Method 23 dioxin/furan analyses of ten M23 samples.

Quality Control Samples

A laboratory method blank, identified as the TLI Blank, was prepared along with the samples. A TLI Cleanup Blank was also processed along with the samples to prove that contamination was not introduced during the cleanup procedures.

Quality Control Remarks

This release of this particular set of Eastern Research Group analytical data by Triangle Laboratories was authorized by the Quality Control Chemist who has reviewed each sample data package following a series of inspections/reviews. When applicable, general deviations from acceptable QC requirements are identified below and comments are made on the effect of these deviations upon the validity and reliability of the results. Specific QC issues associated with this particular project are:

Sample receipt: Twenty-five M23 samples were received from Eastern Research Group in good condition on December 17, 1997 at ambient temperature and stored in a refrigerator at 4 °C. Samples CAA-206 and CAA-207 were not included in the shipment.

Sample Preparation Laboratory: None

Mass Spectrometry: None

Data Review: Due to the limitations of the software, the "CAA" portion of the sample identification numbers was not listed on the reports.

The ion abundance ratios for the 1234678-HpCDF internal standards and 1234789-HpCDF surrogate standards in samples 177/182-184/209 and 193-196 were outside QC limits, most likely due to matrix-related interferents in these samples. The percent recovery of the 1234678-HpCDF internal standard is significantly lower than the recoveries of the other internal standards. However, the percent recoveries for all internal standards are sufficient to quantitate the associated analyte concentrations in the samples.

Other Comments: No 2,3,7,8-substituted target analytes were detected in the TLI Blank or TLI Cleanup Blank above the target detection limit (TDL).

The analytical data presented in this report are consistent with the guidelines of EPA Method 23 (6/93). Any exceptions have been discussed in the QC Remarks section of this case narrative with emphasis on their effect on the data. Should Eastern Research Group have any questions or comments regarding this data package, please feel free to contact our Project Scientist, Amy Boehm, at 919/544-5729 ext. 268.

LIST OF CERTIFICATIONS AND ACCREDITATIONS

ENVIRONMENTAL

American Association for Laboratory Accreditation. Accredidation pending. Certificate Number 0226-01. Accreditation for technical competence in Environmental Testing.(Including Waste Water, Sol/Haz Waste, Pulp/Paper, and Air Matrices) Parameters are AOX/TOX, and Dioxin/Furan. Method 1613 for Drinking Water.

State of Alabama, Department of Environmental Management. Expires December 31, 1998. Laboratory I.D. # 40950. Dioxin in drinking water.

State of Alaska, Department of Environmental Conservation. Expires December 21, 1998. Certificate number OS-00397. Dioxin in drinking water.

State of Arizona, Department of Health Services. Expires May 26, 1998. Certificate #AZ0423. Drinking Water for Dioxin, Dioxin in WW and S/H Waste.

State of Arkansas, Department of Pollution Control and Ecology. Expires February 18, 1998. Pulp/paper, soil, water, and Hazardous Waste for Dioxin/Furan; AOX/TOX, Volatiles, Semi-volatiles, and Metals.

State of California, Department of Health Services. Expires August 31, 1999. Certificate #1922. Selected Metals in Waste Water; Volatiles, Semi-volatiles, and Dioxin/furan in WW and Sol/Haz Waste. Dioxin in drinking water.

State of Connecticut, Department of Health Services. Expires September 30, 1999. Registration # PH-0117. Dioxin in drinking water.

Delaware Health and Social Services. Expires December 31, 1998. Certificate #NC 140. Dioxin in drinking water.

Florida Department of Health and Rehabilitative Services. Expires June 30, 1998.Dioxin in DW. Drinking Water ID HRS# 87424. Metals, Extractable Organics (GC/MS), Pesticides/PCB's (GC) and Volatiles (GC/MS) in Environmental Samples. Environmental water ID HRS# E87411.

Triangle Laboratories, Inc.
801 Capitola Drive
Durham, NC 27713-4411
919-544-5729
P.O. Box 13485
Research Triangle Park, NC 27709-3485
Fax # 919-544-5491

Hawaii Department of Health. Expires March 1, 1998. Dioxin in drinking water. "Accepted" status for regulatory purposes .

Idaho Department of Health and Welfare. Expires December 31, 1998. Dioxin in drinking water.

State of Kansas, Department of Health and Environment. Expires January 31, 1998. Environmental Analyses/Non portable Water and Solid and Hazardous Waste. Method 1613 for drinking water. ID #'s - Drinking water and/or pollution control - E-215. Solid or Hazardous Waste - E-1209.

Commonwealth of Kentucky, Department for Environmental Protection. Expires December 31, 1998. ID#90060. Dioxin in drinking water.

Maryland Department of Health and Mental Hygiene. Expires September 30, 1998. Certification #235. Drinking water by Method 1613A.

State of Michigan, Department of Public Health. Expires June 3, 1998. Drinking water by Method 1613.

Mississippi State Department of Health. No expiration date. Dioxin in drinking water.

Montana Department of Health and Environmental Services. Expires December 31, 1998. Dioxin in drinking water.

State of New Jersey, Department of Environmental Protection and Energy. Expires June 30, 1998. ID #67851. BNAs and Volatiles. Dioxin in drinking water.

State of New Mexico, Environment Department. Recertification pending. Dioxin in drinking water.

New York State Department of Health. Expires April 1, 1998. ID #11026. Environmental Analyses of non-potable Water, Solid and Hazardous Waste. Method 1613 in DW.

State of North Carolina, Department of Environment Health and Natural Resources Expires August 31, 1999. Certificate # 37751. Dioxin in drinking water.

State of North Carolina, Department of Environment, Health, and Natural Resources, Division of Environmental Management. Expires December 31, 2000. Certificate # 485. Metals, pesticides & PCBs, semi-volatiles and volatiles; TCLP.

North Dakota State Department of Health and Consolidated Laboratories. Expires December 31, 1998. Certificate # R-076. Effective October 4, 1993. Dioxin in drinking water.

Revised 1/6/98 RM
y:certific\certlist.mem

Oklahoma Department of Environmental Quality. Expires August 31, 1998. Laboratory #9612. Dioxin by 1613A, 8290 and 8280.

State of South Carolina, Department of Health and Environmental Control. Expires April 1, 1998. Certificate number #99040001 (drinking water). Expires August 31, 1999. Certificate number #99040002 (other parameters). Dioxin/Furans, BNA, Volatiles, and PCBs/pesticides under Clean Water Act, 2,3,7,8-TCDD for Drinking Water, and Organic extractables for Solid and Hazardous Waste.

State of Tennessee. Department of Environment and Conservation. Expires February 5, 1999. ID #02992. Method 1613 Drinking water only.

U.S. Department of Agriculture Soil Permit. Expires September 30, 2001. Permit No. S-3790. Under the authority of the Federal Plant Pest Act, permission is granted to receive foreign soil samples for use in laboratory analysis.

U.S. Army Corps of Engineers. Recertification Pending. Validated to perform methods 8280 & 8290 for Lockbourne Landfill Site Investigation, Defense Distribution Depot Projects, and assorted projects for the USACE North Pacific Division Laboratory.

U.S. EPA Region V. Expires November 14, 1999. Dioxin in drinking water.

U.S. EPA Region VIII, for the State of Wyoming. Expires November 12, 1998. Dioxin in drinking water.

State of Utah, Department of Health. Expires December 31, 1998. Certificate Number E-166. Certification for the following parameters: Semi-Volatiles and Volatiles under RCRA; Volatiles under Clean Water Act; Dioxin/furans by Method 8280; Drinking water for Dioxin by Method 1613; Metals including Mercury and Microwave Digestion.

Commonwealth of Virginia, Department of General Services, Division of Consolidated Laboratory Services. Expires June 30, 1998. ID # 00341. Dioxin in drinking water.

State of Washington, Department of Ecology. Expires September 11, 1998. Lab Accreditation Number C067. Scope of Accreditation applies to water analyses for Polychlorinated Dibenzo-p-dioxins and Polychlorinated Dibenzofurans, BNA Extr (Semivolatile) Organics and Purgeable (Volatile) Organics.

State of Washington, Department of Health. Expires April 30, 1998. Dioxin in drinking water. Lab I.D. 129

State of West Virginia, Department of Health. Expires December 31, 1998. Certificate No. 9923(C). Dioxin in drinking water.

State of Wisconsin, Department of Natural Resources. Expires August 31, 1998. Laboratory ID Number 999869530. Certification for the following categories of Organics: Purgeable, Base/Neutral, Acid, PCBs, and Dioxin. Expires November 14, 1999. Laboratory ID 999869530. Dioxin in drinking water.

PHARMACEUTICAL

Drug Enforcement Agency (DEA). Expires November 30, 1998. Registration number RT01195835. Controlled substance registration for schedules 1,2,3,3N,4,5.

N.C. Department of Human Resources. Expires October 31, 1998. Registration number NC-PT 0000 0031. North Carolina controlled substances registration. Application submitted for renewal.

Food & Drug Administration (FDA) Registration. Expires June 1998. ID #'s 001500 1053481. Annual registration of drug establishment. Annual registration of drug establishment.

OTHER

Clinical Laboratory Improvement Amendments (CLIA) Registration. Expires May 30, 1999. ID # 34D0705123. Department of Health & Human Services. Health Care Financing Administration.

U.S. EPA Large Quantity Hazardous Waste Generator. No expiration date. EPA ID #NCD982156879. Permit indicates that the laboratory is a large generator of hazardous waste.

North Carolina General License for Radiation Protection. No. expiration date. License No. 032-875-OG. The general license applies only to radioactive material contained in devices which have been manufactured and labeled in accordance with specific requirements.

Gross weight of sample container + sample before/after aliquot removal.

Comments: Batched with Project 44376.

Project # 44376A, sample # 2 - Acid layer was still dirty after the fourth Shake. SBm 12/31/97.

_____ Initials: _____ Date: __/__/__

Initials of both SPIKER AND OBSERVER must be entered. XXXXX = Gross Weight not provided for WATER Samples.

Method 23 Sample Calculations:

Analyte Concentration

The concentration or amount of any analyte is calculated using the following expression.

$$Amt_{(\sigma)} = \frac{A_\sigma * Q_\beta}{A_\beta * RRF_{(\sigma)} * W}$$

Where:

$Amt_{(\sigma)}$	=	amount of a given analyte, expressed in nanograms (ng) or picograms (pg).
A_σ	=	integrated current for the characteristic ions of the analyte
A_β	=	integrated current of the characteristic ions of the corresponding internal standard
Q_β	=	amount of internal standard added to the sample before extraction
$RRF_{(\sigma)}$	=	mean analyte relative response factor from the initial calibration
W	=	sample weight or volume (W = 1.0 for Method 23 samples)

Detection Limits

The detection limit reported for a target analyte that is not detected or presents an analyte response that is less than 2.5 times the background level is calculated by using the following expression. The area of the analyte is replaced by the noise level measured in a region of the chromatogram clear of genuine GC signals multiplied by an empirically determined factor. The detection limits represent the maximum possible concentration of a target analyte that could be present without being detected.

$$DL_{(\sigma)} = \frac{2 * 2.5 * (F * H) * Q_\beta}{A_\beta * RRF_{(\sigma)} * W}$$

Where:

$DL_{(\sigma)}$	=	estimated detection limit for a target analyte, expressed in ng or pg
2.5	=	minimum response required for a GC signal
F	=	an empirical number that approximates the area to height ratio for a GC signal. (F = 3.7 for all dioxin/furan analyses)
H	=	height of the noise
A_β	=	integrated current of the characteristic ions of the corresponding internal standard
Q_β	=	amount of internal standard added to the sample before extraction
$RRF_{(\sigma)}$	=	mean analyte relative response factor from the initial calibration
W	=	sample weight or volume

Data Flags

In order to assist with data interpretation, data qualifier flags are used on the final reports. Please note that all data qualifier flags are subjective and are applied as consistently as possible. Each flag has been reviewed by two independent Chemists and the impact of the data qualifier flag on the quality of the data discussed above. The most commonly used flags are:

A **'B'** flag is used to indicate that an analyte has been detected in the laboratory method blank as well as in an associated field sample. The 'B' flag is used only when the concentration of analyte found in the sample is less than 20 times that found in the associated blank. This flag denotes possible contribution of background laboratory contamination to the concentration or amount of that analyte detected in the field sample.

An **'E'** flag is used to indicate a concentration based on an analyte to internal standard ratio which exceeds the range of the calibration curve. Values which are outside the calibration curve are estimates only.

An **'I'** flag is used to indicate labeled standards have been interfered with on the GC column by coeluting, interferent peaks. The interference may have caused the standard's area to be overestimated. All quantitations relative to this standard, therefore, may be underestimated.

A **'J'** flag is used to indicate a concentration based on an analyte to internal standard ratio which is below the calibration curve. Values which are outside the calibration curve are estimates only.

A **'PR'** flag is used to indicate that a GC peak is poorly resolved. This resolution problem may be seen as two closely eluting peaks without a reasonable valley between the peak tops, overly broad peaks, or peaks whose shapes vary greatly from a normal distribution. The concentrations or amounts reported for such peaks are most likely overestimated.

A **'Q'** flag is used to indicate the presence of QC ion instabilities caused by quantitative interferences.

An **'RO'** flag is used to indicate that a labeled standard has an ion abundance ratio that is outside of the acceptable QC limits, most likely due to a coeluting interference. This may have caused the percent recovery of the standard to be overestimated. All quantitations versus this standard, therefore, may be underestimated.

An **'S'** flag indicates that the response of a specific PCDD/PCDF isomer has exceeded the normal dynamic range of the mass spectrometer detection system. The corresponding signal is saturated and the reported analyte concentration is a 'minimum estimate'. When the 'S' qualifier is used in the reporting of 'totals', there is saturation of one (not necessarily from a specific isomer) or more saturated signals for a given class of

compounds. Results for saturated analytes are reported as greater than the upper calibration limit.

A 'U' flag is used to indicate that a specific isomer cannot be resolved from a large, co-eluting interferent GC peak. The specific isomer is reported as not detected as a valid concentration cannot be determined. The calculated detection limit, therefore, should be considered an underestimated value.

A 'V' flag is used to indicate that, although the percent recovery of a labeled standard may be below a specific QC limit, the signal-to-noise ratio of the peak is greater than ten-to-one. The standard is considered reliably quantifiable. All quantitations derived from the standard are considered valid as well.

An 'X' flag is used to indicate that a polychlorodibenzofuran (PCDF) peak has eluted at the same time as the associated diphenyl ether (DPE) and that the DPE peak intensity is at least ten percent of the total PCDF peak intensity. Total PCDF values are flagged 'X' if the total DPE contribution to the total PCDF value is greater than ten percent. All PCDF peaks that are significantly influenced by the presence of DPE peaks are either reported as "estimated maximum possible concentration (EMPC) values without regard to the isotopic abundance ratio, or are included in the detection limit value depending on the analytical method

Initial ....Date...

Data Review By: CM 1/9/98 Calculated Noise Area: 1.00

The Total Area for each peak with an ion abundance ratio outside ratio limits has been recalculated according to method requirements.

Initial ....Date....

Data Review By: CM 1/9/98 Calculated Noise Area: 1.00

The Total Area for each peak with an ion abundance ratio outside ratio limits has been recalculated according to method requirements.

Printed: 10:15 01/09/98

Initial ....Date.

Data Review By: CM 1/9/98 Calculated Noise Area: 1.00

The Total Area for each peak with an ion abundance ratio outside ratio limits has been recalculated according to method requirements.

Printed: 10:15 01/09/98

Initial ....Date...

Data Review By: CM 1/9/98 Calculated Noise Area: 1.00

The Total Area for each peak with an ion abundance ratio outside ratio limits has been recalculated according to method requirements.

Printed: 10:15 01/09/98

Initial ....Date...

Data Review By: CM 1/9/98 Calculated Noise Area: 1.00

The Total Area for each peak with an ion abundance ratio outside ratio limits has been recalculated according to method requirements.

Printed: 10:16 01/09/98

Initial ....Date...

Data Review By: CM 1/9/98 Calculated Noise Area: 1.00

The Total Area for each peak with an ion abundance ratio outside ratio limits has been recalculated according to method requirements.

Printed: 10:16 01/09/98

Initial ....Date...

Data Review By: CM 1/9/98 Calculated Noise Area: 1.22

The Total Area for each peak with an ion abundance ratio outside ratio limits has been recalculated according to method requirements.

Printed: 10:16 01/09/98

Initial ....Date...

Data Review By: CM 1/9/98 Calculated Noise Area: 0.83

The Total Area for each peak with an ion abundance ratio outside ratio limits has been recalculated according to method requirements.

Initial ....Date...

Data Review By: CM 1/9/98 Calculated Noise Area: 1.00

The Total Area for each peak with an ion abundance ratio outside ratio limits has been recalculated according to method requirements.

Initial ....Date...

Data Review By: CM 1/9/98 Calculated Noise Area: 1.00

The Total Area for each peak with an ion abundance ratio outside ratio limits has been recalculated according to method requirements.

Initial ....Date...

Data Review By: CM 1.9.98 Calculated Noise Area: 1.00

The Total Area for each peak with an ion abundance ratio outside ratio limits has been recalculated according to method requirements.

TRIANGLE LABS

CASE NARRATIVE

Analysis of Samples for the Presence of

Polychlorinated Dibenzo-*p*-Dioxins and Dibenzofurans by

High-Resolution Chromatography / High-Resolution Mass Spectrometry

Method 23 (6/93)

Date:	January 15, 1998
Client ID:	Eastern Research Group
P.O. Number:	
TLI Project Number:	44376

This report should only be reproduced in full. Any partial reproduction of this report requires permission from Triangle Laboratories, Inc.

Fax # 919-544-5491

Overview

The samples and associated QC samples were extracted and analyzed according to procedures described in Method 23 (6/93). Any particular difficulties encountered during the sample handling by Triangle Laboratories will be discussed in the QC Remarks section below. This report contains results only from the Method 23 dioxin/furan analysis of nine M23 samples.

Quality Control Samples

A laboratory method blank, identified as the TLI Blank, was prepared along with the samples.

Quality Control Remarks

This release of this particular set of Eastern Research Group analytical data by Triangle Laboratories was authorized by the Quality Control Chemist who has reviewed each sample data package following a series of inspections/reviews. When applicable, general deviations from acceptable QC requirements are identified below and comments are made on the effect of these deviations upon the validity and reliability of the results. Specific QC issues associated with this particular project are:

Sample receipt: Nineteen M23 trains were received from Eastern Research Group in good condition on December 17, 1997 at ambient temperature and stored in a refrigerator at 4 °C.

Sample Preparation Laboratory: Samples109-112, 113-116, 117-120/216/217/218, 121-124/219, 129-132, 133-136, and 137-140 were processed through additional cleanup due to a yellow residue present after concentration. A cleanup blank, identified as the CleanUp Blk, was prepared along with the samples.

Mass Spectrometry: None

Data Review: The analyses of samples 105-108, 109-112, 113-116, 121-124/219, 117-120/216/217/218, and 125-128 exhibit the presence of saturated analyte signals (signals outside the dynamic range of the instrument). The affected analytes are flagged "S" on the quantitation report. The results for these analytes are reported as greater than the upper calibration limit for that analyte, and should be considered a minimum estimate of the actual concentration present in the sample.

Other Comments: No 2,3,7,8-substituted target analytes were detected in the TLI Blank above the target detection limit (TDL).

The analytical data presented in this report are consistent with the guidelines of EPA Method 23 (6/93). Any exceptions have been discussed in the QC Remarks section of this case narrative with emphasis on their effect on the data. Should Eastern Research Group have any questions or comments regarding this data package, please feel free to contact our Project Scientist, Amy J. Boehm, at 919/544-5729 ext. 268.

LIST OF CERTIFICATIONS AND ACCREDITATIONS

ENVIRONMENTAL

American Association for Laboratory Accreditation. Accredidation pending. Certificate Number 0226-01. Accreditation for technical competence in Environmental Testing.(Including Waste Water, Sol/Haz Waste, Pulp/Paper, and Air Matrices) Parameters are AOX/TOX, and Dioxin/Furan. Method 1613 for Drinking Water.

State of Alabama, Department of Environmental Management. Expires December 31, 1998. Laboratory I.D. # 40950. Dioxin in drinking water.

State of Alaska, Department of Environmental Conservation. Expires December 21, 1998. Certificate number OS-00397. Dioxin in drinking water.

State of Arizona, Department of Health Services. Expires May 26, 1998. Certificate #AZ0423. Drinking Water for Dioxin, Dioxin in WW and S/H Waste.

State of Arkansas, Department of Pollution Control and Ecology. Expires February 18, 1998. Pulp/paper, soil, water, and Hazardous Waste for Dioxin/Furan; AOX/TOX, Volatiles, Semi-volatiles, and Metals.

State of California, Department of Health Services. Expires August 31, 1999. Certificate #1922. Selected Metals in Waste Water; Volatiles, Semi-volatiles, and Dioxin/furan in WW and Sol/Haz Waste. Dioxin in drinking water.

State of Connecticut, Department of Health Services. Expires September 30, 1999. Registration # PH-0117. Dioxin in drinking water.

Delaware Health and Social Services. Expires December 31, 1998. Certificate #NC 140. Dioxin in drinking water.

Florida Department of Health and Rehabilitative Services. Expires June 30, 1998.Dioxin in DW. Drinking Water ID HRS# 87424. Metals, Extractable Organics (GC/MS), Pesticides/PCB's (GC) and Volatiles (GC/MS) in Environmental Samples. Environmental water ID HRS# E87411.

Hawaii Department of Health. Expires March 1, 1998. Dioxin in drinking water. "Accepted" status for regulatory purposes .

Idaho Department of Health and Welfare. Expires December 31, 1998. Dioxin in drinking water.

State of Kansas, Department of Health and Environment. Expires January 31, 1998. Environmental Analyses/Non portable Water and Solid and Hazardous Waste. Method 1613 for drinking water. ID #'s - Drinking water and/or pollution control - E-215. Solid or Hazardous Waste - E-1209.

Commonwealth of Kentucky, Department for Environmental Protection. Expires December 31, 1998. ID#90060. Dioxin in drinking water.

Maryland Department of Health and Mental Hygiene. Expires September 30, 1998. Certification #235. Drinking water by Method 1613A.

State of Michigan, Department of Public Health. Expires June 3, 1998. Drinking water by Method 1613.

Mississippi State Department of Health. No expiration date. Dioxin in drinking water.

Montana Department of Health and Environmental Services. Expires December 31, 1998. Dioxin in drinking water.

State of New Jersey, Department of Environmental Protection and Energy. Expires June 30, 1998. ID #67851. BNAs and Volatiles. Dioxin in drinking water.

State of New Mexico, Environment Department. Recertification pending. Dioxin in drinking water.

New York State Department of Health. Expires April 1, 1998. ID #11026. Environmental Analyses of non-potable Water, Solid and Hazardous Waste. Method 1613 in DW.

State of North Carolina, Department of Environment Health and Natural Resources Expires August 31, 1999. Certificate # 37751. Dioxin in drinking water.

State of North Carolina, Department of Environment, Health, and Natural Resources, Division of Environmental Management. Expires December 31, 2000. Certificate # 485. Metals, pesticides & PCBs, semi-volatiles and volatiles; TCLP.

North Dakota State Department of Health and Consolidated Laboratories. Expires December 31, 1998. Certificate # R-076. Effective October 4, 1993. Dioxin in drinking water.

Oklahoma Department of Environmental Quality. Expires August 31, 1998. Laboratory #9612. Dioxin by 1613A, 8290 and 8280.

State of South Carolina, Department of Health and Environmental Control. Expires April 1, 1998. Certificate number #99040001 (drinking water). Expires August 31, 1999. Certificate number #99040002 (other parameters). Dioxin/Furans, BNA, Volatiles, and PCBs/pesticides under Clean Water Act, 2,3,7,8-TCDD for Drinking Water, and Organic extractables for Solid and Hazardous Waste.

State of Tennessee. Department of Environment and Conservation. Expires February 5, 1999. ID #02992. Method 1613 Drinking water only.

U.S. Department of Agriculture Soil Permit. Expires September 30, 2001. Permit No. S-3790. Under the authority of the Federal Plant Pest Act, permission is granted to receive foreign soil samples for use in laboratory analysis.

U.S. Army Corps of Engineers. Recertification Pending. Validated to perform methods 8280 & 8290 for Lockbourne Landfill Site Investigation, Defense Distribution Depot Projects, and assorted projects for the USACE North Pacific Division Laboratory.

U.S. EPA Region V. Expires November 14, 1999. Dioxin in drinking water.

U.S. EPA Region VIII, for the State of Wyoming. Expires November 12, 1998. Dioxin in drinking water.

State of Utah, Department of Health. Expires December 31, 1998. Certificate Number E-166. Certification for the following parameters: Semi-Volatiles and Volatiles under RCRA; Volatiles under Clean Water Act; Dioxin/furans by Method 8280; Drinking water for Dioxin by Method 1613; Metals including Mercury and Microwave Digestion.

Commonwealth of Virginia, Department of General Services, Division of Consolidated Laboratory Services. Expires June 30, 1998. ID # 00341. Dioxin in drinking water.

State of Washington, Department of Ecology. Expires September 11, 1998. Lab Accreditation Number C067. Scope of Accreditation applies to water analyses for Polychlorinated Dibenzo-p-dioxins and Polychlorinated Dibenzofurans, BNA Extr (Semivolatile) Organics and Purgeable (Volatile) Organics.

State of Washington, Department of Health. Expires April 30, 1998. Dioxin in drinking water. Lab I.D. 129

State of West Virginia, Department of Health. Expires December 31, 1998. Certificate No. 9923(C). Dioxin in drinking water.

State of Wisconsin, Department of Natural Resources. Expires August 31, 1998. Laboratory ID Number 999869530. Certification for the following categories of Organics: Purgeable, Base/Neutral, Acid, PCBs, and Dioxin. Expires November 14, 1999. Laboratory ID 999869530. Dioxin in drinking water.

PHARMACEUTICAL

Drug Enforcement Agency (DEA). Expires November 30, 1998. Registration number RT01195835. Controlled substance registration for schedules 1,2,3,3N,4,5.

N.C. Department of Human Resources. Expires October 31, 1998. Registration number NC-PT 0000 0031. North Carolina controlled substances registration. Application submitted for renewal.

Food & Drug Administration (FDA) Registration. Expires June 1998. ID #'s 001500 1053481. Annual registration of drug establishment. Annual registration of drug establishment.

OTHER

Clinical Laboratory Improvement Amendments (CLIA) Registration. Expires May 30, 1999. ID # 34D0705123. Department of Health & Human Services, Health Care Financing Administration.

U.S. EPA Large Quantity Hazardous Waste Generator. No expiration date. EPA ID #NCD982156879. Permit indicates that the laboratory is a large generator of hazardous waste.

North Carolina General License for Radiation Protection. No. expiration date. License No. 032-875-OG. The general license applies only to radioactive material contained in devices which have been manufactured and labeled in accordance with specific requirements.

Data Flags

In order to assist with data interpretation, data qualifier flags are used on the final reports. Please note that all data qualifier flags are subjective and are applied as consistently as possible. Each flag has been reviewed by two independent Chemists and the impact of the data qualifier flag on the quality of the data discussed above. The most commonly used flags are:

A **'B'** flag is used to indicate that an analyte has been detected in the laboratory method blank as well as in an associated field sample. The 'B' flag is used only when the concentration of analyte found in the sample is less than 20 times that found in the associated blank. This flag denotes possible contribution of background laboratory contamination to the concentration or amount of that analyte detected in the field sample.

An **'E'** flag is used to indicate a concentration based on an analyte to internal standard ratio which exceeds the range of the calibration curve. Values which are outside the calibration curve are estimates only.

An **'I'** flag is used to indicate labeled standards have been interfered with on the GC column by coeluting, interferent peaks. The interference may have caused the standard's area to be overestimated. All quantitations relative to this standard, therefore, may be underestimated.

A **'J'** flag is used to indicate a concentration based on an analyte to internal standard ratio which is below the calibration curve. Values which are outside the calibration curve are estimates only.

A **'PR'** flag is used to indicate that a GC peak is poorly resolved. This resolution problem may be seen as two closely eluting peaks without a reasonable valley between the peak tops, overly broad peaks, or peaks whose shapes vary greatly from a normal distribution. The concentrations or amounts reported for such peaks are most likely overestimated.

A **'Q'** flag is used to indicate the presence of QC ion instabilities caused by quantitative interferences.

An **'RO'** flag is used to indicate that a labeled standard has an ion abundance ratio that is outside of the acceptable QC limits, most likely due to a coeluting interference. This may have caused the percent recovery of the standard to be overestimated. All quantitations versus this standard, therefore, may be underestimated.

An **'S'** flag indicates that the response of a specific PCDD/PCDF isomer has exceeded the normal dynamic range of the mass spectrometer detection system. The corresponding signal is saturated and the reported analyte concentration is a 'minimum estimate'. When the 'S' qualifier is used in the reporting of 'totals', there is saturation of one (not necessarily from a specific isomer) or more saturated signals for a given class of

compounds. Results for saturated analytes are reported as greater than the upper calibration limit.

A **'U'** flag is used to indicate that a specific isomer cannot be resolved from a large, co-eluting interferent GC peak. The specific isomer is reported as not detected as a valid concentration cannot be determined. The calculated detection limit, therefore, should be considered an underestimated value.

A **'V'** flag is used to indicate that, although the percent recovery of a labeled standard may be below a specific QC limit, the signal-to-noise ratio of the peak is greater than ten-to-one. The standard is considered reliably quantifiable. All quantitations derived from the standard are considered valid as well.

An **'X'** flag is used to indicate that a polychlorodibenzofuran (PCDF) peak has eluted at the same time as the associated diphenyl ether (DPE) and that the DPE peak intensity is at least ten percent of the total PCDF peak intensity. Total PCDF values are flagged 'X' if the total DPE contribution to the total PCDF value is greater than ten percent. All PCDF peaks that are significantly influenced by the presence of DPE peaks are either reported as "estimated maximum possible concentration (EMPC) values without regard to the isotopic abundance ratio, or are included in the detection limit value depending on the analytical method

Method 23 Sample Calculations:

Analyte Concentration

The concentration or amount of any analyte is calculated using the following expression.

$$Amt_{(\sigma)} = \frac{A_\sigma * Q_\beta}{A_\beta * RRF_{(\sigma)} * W}$$

Where:

$Amt_{(\sigma)}$	=	amount of a given analyte, expressed in nanograms (ng) or picograms (pg).
A_σ	=	integrated current for the characteristic ions of the analyte
A_β	=	integrated current of the characteristic ions of the corresponding internal standard
Q_β	=	amount of internal standard added to the sample before extraction
$RRF_{(\sigma)}$	=	mean analyte relative response factor from the initial calibration
W	=	sample weight or volume (W = 1.0 for Method 23 samples)

Detection Limits

The detection limit reported for a target analyte that is not detected or presents an analyte response that is less than 2.5 times the background level is calculated by using the following expression. The area of the analyte is replaced by the noise level measured in a region of the chromatogram clear of genuine GC signals multiplied by an empirically determined factor. The detection limits represent the maximum possible concentration of a target analyte that could be present without being detected.

$$DL_{(\sigma)} = \frac{2 * 2.5 * (F * H) * Q_\beta}{A_\beta * RRF_{(\sigma)} * W}$$

Where:

$DL_{(\sigma)}$	=	estimated detection limit for a target analyte, expressed in ng or pg
2.5	=	minimum response required for a GC signal
F	=	an empirical number that approximates the area to height ratio for a GC signal. (F = 3.7 for all dioxin/furan analyses)
H	=	height of the noise
A_β	=	integrated current of the characteristic ions of the corresponding internal standard
Q_β	=	amount of internal standard added to the sample before extraction
$RRF_{(\sigma)}$	=	mean analyte relative response factor from the initial calibration
W	=	sample weight or volume

Printed: 11:48 01/10/98

Initial ....Date...

Data Review By: CSH 1/10/98 Calculated Noise Area: 2.19

The Total Area for each peak with an ion abundance ratio outside
atio limits has been recalculated according to method requirements.

Page No. 1 Listing of T980152B.dbf
01/10/98 Matched GC Peaks / Ratio / Ret. Time

Column Description.....	"Why" Code Description.....	QC Log Desc.....
M_Z -Nominal Ion Mass(es)	WL-Below Retention Time Window	A-Peak Added
..RT. -Retention Time (mm:ss)	WH-Above Retention Time Window	K-Peak Kept
Rat.1 -Ratio of M/M+2 Ions	SN-Below Signal to Noise Level	D-Peak Deleted
OK -RO=Ratio Outside Limits	<M-Below Method Detection Limit	T-Time Changed
Rel.RT-Relative Retention Time	NL-Channel Specific Noise Level	M-Peak Area Changed
		N-Name Changed
		X-Ether Interference

Initial ....Date...

Data Review By: [illegible] 1/15/98 Calculated Noise Area: 2.00

The Total Area for each peak with an ion abundance ratio outside ratio limits has been recalculated according to method requirements.

Initial ....Date...

Data Review By: GP 1/12/98 Calculated Noise Area: 2.00

The Total Area for each peak with an ion abundance ratio outside
atio limits has been recalculated according to method requirements.

Triangle Laboratories, Inc.®
801 Capitola Drive • Durham, North Carolina 27713
Phone: (919) 544-5729 • Fax: (919) 544-5491

Printed: 09:26 01/15/98

Initial ....Date...

Data Review By: [illegible] 1/15/98 Calculated Noise Area: 2.00

The Total Area for each peak with an ion abundance ratio outside
ratio limits has been recalculated according to method requirements.

Initial ....Date...

Data Review By: SM 1/11/98 Calculated Noise Area: 2.00

The Total Area for each peak with an ion abundance ratio outside
atio limits has been recalculated according to method requirements.

Initial ....Date...

Data Review By: GSS 1/11/98 Calculated Noise Area: 2.00

The Total Area for each peak with an ion abundance ratio outside ratio limits has been recalculated according to method requirements.

Phone: (919) 544-5729 • Fax: (919) 544-5491

Printed: 09:27 01/15/98

Initial ....Date...

Data Review By: GHH 1/15/98 Calculated Noise Area: 2.00

The Total Area for each peak with an ion abundance ratio outside ratio limits has been recalculated according to method requirements.

Initial ....Date...

Data Review By: [illegible] 1/11/98 Calculated Noise Area: 2.00

The Total Area for each peak with an ion abundance ratio outside ratio limits has been recalculated according to method requirements.

Initial ....Date...

Data Review By: [illegible] 1/11/98 Calculated Noise Area: 2.00

The Total Area for each peak with an ion abundance ratio outside
ratio limits has been recalculated according to method requirements.

Initial ....Date...

Data Review By: GH 1/15/98 Calculated Noise Area: 2.00

The Total Area for each peak with an ion abundance ratio outside ratio limits has been recalculated according to method requirements.

Initial ....Date...

Data Review By: [illegible] 1/15/97 Calculated Noise Area: 1.20

The Total Area for each peak with an ion abundance ratio outside ratio limits has been recalculated according to method requirements.

Initial ....Date...

Data Review By: GH 1/11/98 Calculated Noise Area: 2.00

The Total Area for each peak with an ion abundance ratio outside ratio limits has been recalculated according to method requirements.

Column Description.....	"Why" Code Description.....	QC Log Desc.....
M_Z -Nominal Ion Mass(es)	WL-Below Retention Time Window	A-Peak Added
..RT. -Retention Time (mm:ss)	WH-Above Retention Time Window	K-Peak Kept
Rat.1 -Ratio of M/M+2 Ions	SN-Below Signal to Noise Level	D-Peak Deleted
OK -RO=Ratio Outside Limits	<M-Below Method Detection Limit	T-Time Changed
Rel.RT-Relative Retention Time	NL-Channel Specific Noise Level	M-Peak Area Changed
		N-Name Changed
		X-Ether Interference

CASE NARRATIVE

Analysis of Samples for the Presence of

Chloride by

Ion Chromatography

METHOD 26

Date : January 27, 1998

Client ID : Eastern Research Group

TLI Project Number : 44369

This report should only be reproduced in full. Any partial reproduction of this report requires permission from Triangle Laboratories, Inc.

Triangle Laboratories, Inc.

Objective: Analysis of thirty-nine impinger samples for chloride by Method 26

Method: Thirty-nine impinger samples were received by Triangle Laboratories, Inc. on December 17, 1997 without coolant in good condition. The samples were stored at 4°C prior to analysis. This report pertains only to the analysis of two of the samples for chloride. The samples were analyzed for chloride content by ion chromatography using Method 26 with suppressed conductivity detection. The results reported relate only to the items tested.

The analysis conditions are listed below:

Instrument: Dionex DX300 Ion Chromatograph with a PED-II Conductivity Detector
Eluent flow: 1.5 mL/min. (1.8 mM sodium carbonate/1.7mM sodium bicarbonate)
Suppressor: Anion self-regenerating suppressor-1
Sample Loop: 25 uL
Detection: Conductivity - suppressed ion
Data Recording: Dionex AI 450 software

Report:

Enclosed with the case narrative are copies of the client paperwork, sample log-in sheets, and log book pages. The data are reported as quantitation reports and chromatograms. A seven point calibration curve was performed ranging from 0.5 ppm to 100 ppm both before and after sample analysis. Reported concentrations are mean values determined from duplicate analyses.

Results:

Due to instrument problems, a six point calibration curve from 1 ppm to 100 ppm was used for the chlorine analyses. Because of this, chlorine samples whose concentrations were calculated as being below 1 ppm were reported as less than 1 ppm. Samples in which chloride was not detected were reported as detection limits.

* Due to the levels of chloride present, samples CAA-15, CAA-19, CAA-35, CAA-51, CAA-55, and CAA-63 were analyzed at dilutions.

Samples CAA-03 and CAA-04 were used to analyze matrix spikes and matrix spike duplicates. The matrix spike and matrix spike duplicate sample recoveries were within QC criteria for the chloride spikes. The high recoveries of the chlorine spikes may be a matrix effect. Its cause is
* being investigated.

The data in this package has been judged to be valid according to the guidelines of Method 26 except as noted above. Should you have any questions, please feel free to contact our Project Scientist, Amy Boehm, at (919) 544-5729, Ext. 268.

LIST OF CERTIFICATIONS AND ACCREDITATIONS

ENVIRONMENTAL

American Association for Laboratory Accreditation. Accredidation pending. Certificate Number 0226-01. Accreditation for technical competence in Environmental Testing.(Including Waste Water, Sol/Haz Waste, Pulp/Paper, and Air Matrices) Parameters are AOX/TOX, and Dioxin/Furan. Method 1613 for Drinking Water.

State of Alabama, Department of Environmental Management. Expires December 31, 1998. Laboratory I.D. # 40950. Dioxin in drinking water.

State of Alaska, Department of Environmental Conservation. Expires December 21, 1998. Certificate number OS-00397. Dioxin in drinking water.

State of Arizona, Department of Health Services. Expires May 26, 1998. Certificate #AZ0423. Drinking Water for Dioxin, Dioxin in WW and S/H Waste.

State of Arkansas, Department of Pollution Control and Ecology. Expires February 18, 1998. Pulp/paper, soil, water, and Hazardous Waste for Dioxin/Furan; AOX/TOX, Volatiles, Semi-volatiles, and Metals.

State of California, Department of Health Services. Expires August 31, 1999. Certificate #1922. Selected Metals in Waste Water; Volatiles, Semi-volatiles, and Dioxin/furan in WW and Sol/Haz Waste. Dioxin in drinking water.

State of Connecticut, Department of Health Services. Expires September 30, 1999. Registration # PH-0117. Dioxin in drinking water.

Delaware Health and Social Services. Expires December 31, 1998. Certificate #NC 140. Dioxin in drinking water.

Florida Department of Health and Rehabilitative Services. Expires June 30, 1998. Dioxin in DW. Drinking Water ID HRS# 87424. Metals, Extractable Organics (GC/MS), Pesticides/PCB's (GC) and Volatiles (GC/MS) in Environmental Samples. Environmental water ID HRS# E87411.

Idaho Department of Health and Welfare. Expires December 31, 1998. Dioxin in drinking water.

State of Kansas, Department of Health and Environment. Expires January 31, 1998. Environmental Analyses/Non portable Water and Solid and Hazardous Waste. Method 1613 for drinking water. ID #'s - Drinking water and/or pollution control - E-215. Solid or Hazardous Waste - E-1209.

Commonwealth of Kentucky, Department for Environmental Protection. Expires December 31, 1998. ID#90060. Dioxin in drinking water.

Maryland Department of Health and Mental Hygiene. Expires September 30, 1998. Certification #235. Drinking water by Method 1613A.

State of Michigan, Department of Public Health. Expires June 3, 1998. Drinking water by Method 1613.

Mississippi State Department of Health. No expiration date. Dioxin in drinking water.

Montana Department of Health and Environmental Services. Expires December 31, 1998. Dioxin in drinking water.

State of New Jersey, Department of Environmental Protection and Energy. Expires June 30, 1998. ID #67851. BNAs and Volatiles. Dioxin in drinking water.

State of New Mexico, Environment Department. Recertification pending. Dioxin in drinking water.

New York State Department of Health. Expires April 1, 1998. ID #11026. Environmental Analyses of non-potable Water, Solid and Hazardous Waste. Method 1613 in DW.

State of North Carolina, Department of Environment Health and Natural Resources Expires August 31, 1999. Certificate # 37751. Dioxin in drinking water.

State of North Carolina, Department of Environment, Health, and Natural Resources, Division of Environmental Management. Expires December 31, 2000. Certificate # 485. Metals, pesticides & PCBs, semi-volatiles and volatiles; TCLP.

North Dakota State Department of Health and Consolidated Laboratories. Expires December 31, 1998. Certificate # R-076. Effective October 4, 1993. Dioxin in drinking water.

Revised 1/20/98 RM
y:certific\certlist.mem

Oklahoma Department of Environmental Quality. Expires August 31, 1998. Laboratory #9612. Dioxin by 1613A, 8290 and 8280.

State of South Carolina, Department of Health and Environmental Control. Expires April 1, 1998. Certificate number #99040001 (drinking water). Expires August 31, 1999. Certificate number #99040002 (other parameters). Dioxin/Furans, BNA, Volatiles, and PCBs/pesticides under Clean Water Act, 2,3,7,8-TCDD for Drinking Water, and Organic extractables for Solid and Hazardous Waste.

State of Tennessee. Department of Environment and Conservation. Expires February 5, 1999. ID #02992. Method 1613 Drinking water only.

U.S. Department of Agriculture Soil Permit. Expires September 30, 2001. Permit No. S-3790. Under the authority of the Federal Plant Pest Act, permission is granted to receive foreign soil samples for use in laboratory analysis.

U.S. Army Corps of Engineers. Recertification Pending. Validated to perform methods 8280 & 8290 for Lockbourne Landfill Site Investigation, Defense Distribution Depot Projects, and assorted projects for the USACE North Pacific Division Laboratory.

U.S. EPA Region V. Expires November 14, 1999. Dioxin in drinking water.

U.S. EPA Region VIII, for the State of Wyoming. Expires November 12, 1998. Dioxin in drinking water.

State of Utah, Department of Health. Extended by State to March 31, 1998. Certificate Number E-166. Certification for the following parameters: Semi-Volatiles and Volatiles under RCRA; Volatiles under Clean Water Act; Dioxin/furans by Method 8280; Drinking water for Dioxin by Method 1613; Metals including Mercury and Microwave Digestion.

Commonwealth of Virginia, Department of General Services, Division of Consolidated Laboratory Services. Expires June 30, 1998. ID # 00341. Dioxin in drinking water.

State of Washington, Department of Ecology. Expires September 11, 1998. Lab Accreditation Number C067. Scope of Accreditation applies to water analyses for Polychlorinated Dibenzo-p-dioxins and Polychlorinated Dibenzofurans, BNA Extr (Semivolatile) Organics and Purgeable (Volatile) Organics.

State of Washington, Department of Health. Expires April 30, 1998. Dioxin in drinking water. Lab I.D. 129

State of West Virginia, Department of Health. Expires January 31, 1998. Certificate No. 9923(C). Dioxin in drinking water.

State of Wisconsin, Department of Natural Resources. Expires August 31, 1998. Laboratory ID Number 999869530. Certification for the following categories of Organics: Purgeable, Base/Neutral, Acid, PCBs, and Dioxin. Expires November 14, 1999. Laboratory ID 999869530. Dioxin in drinking water.

PHARMACEUTICAL

Drug Enforcement Agency (DEA). Expires November 30, 1998. Registration number RT01195835. Controlled substance registration for schedules 1,2,3,3N,4,5.

N.C. Department of Human Resources. Expires October 31, 1998. Registration number NC-PT 0000 0031. North Carolina controlled substances registration. Application submitted for renewal.

Food & Drug Administration (FDA) Registration. Expires June 1998. ID #'s 001500 1053481. Annual registration of drug establishment. Annual registration of drug establishment.

OTHER

Clinical Laboratory Improvement Amendments (CLIA) Registration. Expires May 30, 1999. ID # 34D0705123. Department of Health & Human Services, Health Care Financing Administration.

U.S. EPA Large Quantity Hazardous Waste Generator. No expiration date. EPA ID #NCD982156879. Permit indicates that the laboratory is a large generator of hazardous waste.

North Carolina General License for Radiation Protection. No. expiration date. License No. 032-875-OG. The general license applies only to radioactive material contained in devices which have been manufactured and labeled in accordance with specific requirements.

PROJECT COMMUNICATION TRACKING FORM

TLI project Number: 44369

Use this form to record all exchanges of information between production units as well as personnel handling this project. Decisions, corrective actions and recommendations must also appear on this tracking document.

Date	Name	Comment / Decision / Resolution / Action / Observation
1-6-98	LDJ	MS/MSD was performed on sample 194-52-1 (CAA-03). 3ml of sample and 3ml of 100 ppm chloride Std.
1-6-98	LDJ	The following samples had dilutions 194-52-7 = 2 fold dilution 194-52-8 = 2 fold dilution 194-52-16 = 20 fold dilution 194-52-20 = 20 fold dilution 194-52-22 = 80 fold dilution 194-52-26 = 20 fold dilution
1-9-98	LDJ	MS/MSD was performed on sample 194-52-2 (CAA-04) 3ml of sample and 3ml of 100ppm chloride std.
1-26-98	LDJ	2 Fold Dilution → 3ml of sample and 3ml of HPLC water. 20 Fold Dilution → 250µl of sample and 5ml of HPLC water.

* THE BALANCE CALIBRATION DATA SEEMED TO CHANGE MARKEDLY FROM 12-21 TO 12-22. THE DIFFERENCE IN THE READING USING A 100G WEIGHT WAS .0046 GRAMS. SINCE THE BEAKERS I WEIGHED BACK ON 12-22-97 ALL WEIGH AROUND 100G, I SUBTRACTED .0046G FROM ALL THESE MEASUREMENTS MADE ON 12-22 SO THEY WOULD LINE UP WITH WHAT WAS DONE ON PREVIOUS DAYS.

EXAMPLE: REFERENCE BEAKER WT.S:

12-18-97 ⇒ 110.2901
12-19-97 ⇒ 110.2901
12-21-97 ⇒ 110.2900
12-22-97 ⇒ 110.2945 - .0046 = 110.2899
