On September 30 and October 8 and 9, 1975, the State Department of Ecology requested EPA's concurrence in the State's sub-delegation of the NSPS program to four local air pollution control agencies. After reviewing the State's request, the Regional Administrator determined that the subdelegations meet all the requirements outlined in EPA's delegation of February 28, 1975. Therefore, the Regional Administrator on December 5, 1975, concurred in the subdelegations to the four local agencies listed below with the stipulation that all the conditions placed on the original delegation to the State shall also apply to the sub-delegations to the local agencies. EPA is today amending 40 CFR 60.4 to reflect the State's sub-delegations.

The amended § 60.4 provides that all reports, requests, applications, submittals and communications required pursuant to Part 60 which were previously to be sent to the Director of the State of Washington Department of Ecology (DOE) will now be sent to the Puget Sound Air Pollution Control Agency (PSAPCA), the Northwest Air Pollution Authority (NWAPA), the Spokane County Air Pollution Authority (SCAPA) or the Southwest Air Pollution Control Authority (SAPCA) as appropriate. The amended section is set forth below.

The Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegations which are reflected by the administrative amendment were effective on September 30 to the NWAPA, October 7 to the PSAPCA and October 8 to the SCAPA and the SAPCA, and it serves no useful purpose to delay the technical change of the addition of the local agency addresses to the Code of Federal Regulations.

This rulemaking is effective immediately, and is issued under the authority of Section 111 of the Clean Air Act, as amended. 42 U.S.C. 1857c-6.

Dated: January 24, 1976.

STANLEY W. LEGRO,
Assistant Administrator
for Enforcement.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

1. In § 60.4, paragraph (b) is amended by revising subparagraph (WW) to read as follows:

§ 60.4 Address.

(b)
(WW) (i) Washington; State of Washington, Department of Ecology, Olympia, Washington 98504.

(ii) Northwest Air Pollution Authority, 207 Pioneer Building, Second and Pine Streets, Mount Vernon, Washington 98273.

(iii) Puget Sound Air Pollution Control Agency, 410 West Harrison Street, Seattle, Washington 98119.

(iv) Spokane County Air Pollution Control Authority, North 811 Jefferson, Spokane, Washington 99201.

(v) Southwest Air Pollution Control Authority, Suite 7601 H, NE Hazel Dell Avenue, Vancouver, Washington 98665.

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Delegation of Authority to State of Oregon

Pursuant to the delegation of authority for the standards of performance for new stationary sources (NSPS) to the State of Oregon on November 10, 1975, EPA is today amending 40 CFR 60.4, Address, to reflect this delegation. A Notice announcing this delegation is published today at 41 FR 7750 in the FEDERAL REGISTER. The amended § 60.4 which adds the address of the State of Oregon Department of Environmental Quality to which all reports, requests, applications, submittals, and communications pursuant to this part must be addressed, is set forth below.

The Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegation which is reflected by this administrative amendment was effective on November 10, 1975 and it serves no purpose to delay the technical change of this addition of the State address to the Code of Federal Regulations.

This rulemaking is effective immediately, and is issued under the authority of Section 111 of the Clean Air Act, as amended. 42 U.S.C. 1857c-6.

Dated: February 11, 1976.

STANLEY W. LEGRO,
Assistant Administrator for
Enforcement.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Delegation of Authority to Commonwealth of Virginia

Pursuant to the delegation of authority for the standards of performance for new stationary sources (NSPS) to the Commonwealth of Virginia on December 30, 1975, EPA is today amending 40 CFR 60.4, *Address*, to reflect this delegation. A Notice announcing this delegation is published today at 41 FR 8416 in the FEDERAL REGISTER. The amended § 60.4, which adds the address of the Virginia State Air Pollution Control Board to which all reports, requests, applications, submittals, and communications to the Administrator pursuant to this part must also be addressed, is set forth below.

The Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegation which is reflected by this administrative amendment was effective on December 30, 1975, and it serves no purpose to delay the technical change of this addition of the State address to the Code of Federal Regulations.

This rulemaking is effective immediately, and is issued under the authority of section 111 of the Clean Air Act, as amended. 42 U.S.C. 1857c-6.

[FRL 509-3]

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Ferroalloy Production Facilities

On October 21, 1974 (39 FR 37470), under section 111 of the Clean Air Act, as amended, the Environmental Protection Agency (EPA) proposed standards of performance for new and modified ferroalloy production facilities. Interested persons participated in the rulemaking by submitting comments to EPA. The comments have been carefully considered, and where determined by the Administrator to be appropriate, changes have been made to the regulations as promulgated.

The standards limit emissions of particulate matter and carbon monoxide from ferroalloy electric submerged arc furnaces. The purpose of the standards is to require effective capture and control of emissions from the furnace and tapping station by application of best systems of emission reduction. For ferroalloy furnaces the best system of emission reduction for particulate matter is a well-designed hood in combination with a fabric filter collector or venturi scrubber. For some alloys the best system is an electrostatic precipitator preceded by wet gas conditioning or a venturi scrubber. The standard for carbon monoxide requires only that the gas stream be flared or combusted in some other manner.

The environmental impact of these standards is beneficial since the increase in emissions due to growth of the industry will be minimized. Also, the standards will remove the incentive for plants to locate in areas with less stringent regulations.

Upon evaluation of the costs associated with the standards and their economic impact, EPA concluded that the costs are reasonable and should not bar entry into the market or expansion of facilities. In addition, the standards will require at most a minimal increase in power consumption over that required to comply with the restrictions of most State regulations.

SUMMARY OF REGULATION

The promulgated standards limit particulate matter and carbon monoxide emissions from the electric submerged arc furnace and limit particulate matter emissions from dust-handling equipment. Emissions of particulate matter from the control device are limited to less than 0.45 kg/MW-hr (0.99 lb/MW-hr) for furnaces producing high-silicon alloys (in general) and to less than 0.23 kg/MW-hr (0.51 lb/MW-hr) for furnaces producing chrome and manganese alloys. For both product groups, emissions from the control device must be less than 15 percent opacity. The regulation requires that the collection hoods capture all emissions generated within the furnace and capture all tapping emissions for at least 60 percent of the tap-

ping time. The concentration of carbon monoxide in any gas stream discharged to the atmosphere must be less than 20 volume percent. Emissions from dust-handling equipment may not equal or exceed 10 percent opacity. Any owner or operator of a facility subject to this regulation must continuously monitor volumetric flow rates through the collection system and must continuously monitor the opacity of emissions from the control device.

SUMMARY OF COMMENTS

Eighteen comment letters were received on the proposed standards of performance. Copies of the comment letters and a report which contains a summary of the issues and EPA's responses are available for public inspection and copying at the U.S. Environmental Protection Agency, Public Information Reference Unit (EPA Library), Room 2922, 401 M Street, S.W., Washington, D.C. Copies of the report also may be obtained upon written request from the EPA Public Information Center (PM-215), 401 M Street, S.W., Washington, D.C. 20460 (specify—Supplemental Information on Standards of Performance for Ferroalloy Production Facilities). In addition to the summary of the issues and EPA's responses, the report contains a reevaluation of the opacity standard in light of revisions to Reference Method 9 which were published in the *FEDERAL REGISTER* November 12, 1974 (39 FR 39872).

The bases for the proposed standards are presented in "Background Information for Standards of Performance: Electric Submerged Arc Furnaces for Production of Ferroalloys" (EPA 450/2-74-018a, b). Copies of this document are available on request from the Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, North Carolina 27711, Attention: Mr. Don R. Goodwin.

SIGNIFICANT COMMENTS AND CHANGES TO THE PROPOSED REGULATION

Most of the comment letters contained multiple comments. The more significant comments and the differences between the proposed and the final regulations are discussed below. In addition to the discussed changes, several paragraphs were reworded and some sections were reorganized.

(1) *Mass standard.* Several commenters questioned the representativeness of the data used to demonstrate the achievability of the 0.23 kg/MW-hr (0.51 lb/MW-hr) standard proposed for facilities producing chrome and manganese alloys. Specifically, the commenters were concerned that sampling only a limited number of compartments or control devices serving a furnace, nonisokinetic sampling of some facilities, and the procedures used to determine the total gas volume flow from open fabric filter collectors would bias the data low. For these reasons, the commenters argued that the standard should be 0.45 kg/MW-hr (0.99 lb/MW-hr) for all alloys. As additional support for their position, they claimed that control equipment vendors will not

guarantee that their equipment will achieve 0.23 kg/MW-hr (0.51 lb/MW-hr).³⁵

Because of these comments, EPA thoroughly reevaluated the bases for the two mass standards of performance and concluded that the standards are achievable by best systems of emission reduction. For open ferroalloy electric submerged arc furnaces, the best system of emission reduction is a well-designed canopy hood that minimizes the volume of induced air and a well-designed and properly operated fabric filter collector or high-energy venturi scrubber. In a few cases, an electrostatic precipitator preceded by a venturi scrubber or wet gas conditioning is a best system. In EPA's opinion, revising the standard upward to 0.45 kg/MW-hr (0.99 lb/MW-hr) would allow installation of systems other than the best. Therefore, the promulgated standard of performance for furnaces producing chrome and manganese alloys is 0.23 kg/MW-hr (0.51 lb/MW-hr). The standard for furnaces producing the specified high-silicon alloys is 0.45 kg/MW-hr (0.99 lb/MW-hr). The rationale for establishing the standards at these levels is summarized below.

The reevaluation of the data bases for the standards showed that the emission test procedures used did not significantly bias the results. Therefore, contrary to the commenter's concerns, the procedures did not result in emission limitations lower than those achievable by best systems of emission reduction. The deviations and assumptions made in the test procedures were based on consideration of the particle size of the emissions, an evaluation of the performance of the control systems, and factors affecting the induction of air into open fabric filter collectors.

EPA tests, and allows testing of, a representative number of stacks or compartments in a control device because subsections of a well-designed and properly operating control device will perform equivalently. Evaluation of the control system and the condition of the control device by EPA engineers at the time of the emission test showed that sections not tested were of equivalent design and in operating condition equivalent to or better than the tested sections. Thus, the performance of the non-tested portions of the control device are considered to be equivalent to or better than the performance of the sections emission tested. In addition, the particle size of emissions from well-controlled ferroalloy furnaces was investigated by EPA and was found to consist of particles of less than two micrometers aerodynamic diameter for all alloys. The mass and, hence, inertia of these particles are negligible; therefore, they follow the motion of the gas stream. For emissions of this size distribution, concentrations determined by nonisokinetic sampling would not be significantly different than those measured by isokinetic sampling.

EPA determined the total gas volume flow rate from the open fabric filter collectors by measuring the inlet volume flow rate and the volume of air induced into the collector. The inlet gas volumes

to the collectors were measured during each run of each test; but the volume of air induced into the collector was determined once during the emission test. The total gas volume flow from the collector was calculated as the sum of the inlet gas volume and the induced air volume. Although the procedures used were not ideal, the reported gas volumes are considered to be reasonably representative of the total gas volumes from the facility. This conclusion is based on the fact that the quantity of air induced around the bags in an open collector is primarily dependent on the open area and the temperature of the inlet gas stream and the ambient air. Therefore, equivalent air volumes are drawn into the collector under similar meteorological and inlet gas conditions. During the periods of emission testing at the facilities, meteorological conditions were uniform and the volume of induced air was expected to be constant. Consequently, measurement of the induced air volume once during the emission test was expected to be sufficient for calculating the total gas volume flow from the collector.

Since conducting the test in question, EPA has gained additional experience and has concluded that in general it is preferable to measure the total gas volume flow during each run of a performance test. This conclusion, however, does not invalidate the use of the test data obtained by the less optimum procedure of a single determination of induced air volume. EPA evaluated possible variations in the amount of air induced into the collector by performing enthalpy balances using reported temperature data. The induced air volumes were calculated assuming adiabatic mixing (no heat transfer by inlet gases to collector) and, hence, are conservatively high estimates. The calculated induced air volumes did differ from the single measured values; however, the effect on the mass emission rate for the collectors was not significant. EPA, therefore, concluded that the use of single measurements of the induced air volume did not affect the level of the standards.

Another issue of concern to commenters is the reluctance of control equipment vendors to guarantee reduction of emissions to less than 0.23 kg/MW-hr (0.51 lb/MW-hr). It is EPA's opinion that this reluctance does not demonstrate the unachievability of the standard. The vendors' reluctance to guarantee this level is not surprising considering the variables which are beyond their control. Specifically, they rarely have any control over the design of the fume collection systems for the furnace and tapping station. Fabric filter collectors tend to control the concentration of particulate matter in the effluent. The mass rate of emissions from the collector is determined by the total volumetric flow rate from the control device, which is not determined by vendors. Further, because of limited experience with emission testing to evaluate the performance of open fabric filter collectors, vendors cannot effectively evaluate the performance of these systems over the guarantee

period. For vendors, establishment of the performance guarantee level is also complicated by the fact that the performance of the collector is contingent upon its being properly operated and maintained.

Standards of performance are necessarily based on data from a limited number of best-controlled facilities and on engineering judgments regarding performance of the control systems. For this reason, there is a possibility of arriving at different conclusions regarding the performance capabilities of these systems. Consequently, the question of vendors' reluctance to guarantee their equipment to achieve 0.23 kg/MW-hr (0.51 lb/MW-hr) was considered along with the results of additional recent emission tests on fabric filter collectors. Recognizing that the data base for the standards was limited and that a number of well-controlled facilities had started operation since completion of the original study, EPA obtained additional data to better evaluate the performance of emission control systems of interest. Under the authority of section 114 of the Clean Air Act, EPA requested copies of all emission data for well-controlled furnaces operated by 10 ferroalloy producers. Data were received for five well-controlled facilities. In general, these facilities had close fitting water cooled canopy hoods, and tapping fumes were collected and sent to the control device along with the furnace emissions.

The emission data submitted by the industry show that properly operating compartments of open fabric filter collectors have effluent concentrations of less than 0.009 g/dscm (0.004 gr/dscf). For these recently constructed facilities, the reported mass emission rates were less than 0.12 kg/MW-hr (0.24 lb/MW-hr) for 15 MW capacity silicon metal furnaces. Evaluation of possible errors in the data and uncertainties in the test procedures showed that emissions may have been as high as 0.20 kg/MW-hr (0.45 lb/MW-hr) in some cases. These emission rates were achieved by design of the collection hood to minimize the quantity of induced air. The data submitted by the industry showed that gas volumes from well-hooded large silicon metal furnaces can be reduced to 50 percent of the volumes from typically hooded large silicon furnaces. Based on the data obtained from the industry, a large well-hooded and well-controlled silicon metal furnace is expected to have an emission rate of less than 0.45 kg/MW-hr (0.99 lb/MW-hr).

In EPA's study of the ferroalloy industry, it was determined that emissions from production of high-silicon alloys would be more difficult to control than chrome and manganese emissions due to the finer size distribution of the particles and significantly larger gas volumes from the furnace. Comparison of the gas volumes reported by the industry from silicon metal production with gas volumes from typically hooded furnaces producing chrome and manganese alloys shows that the original conclusion is still valid. Due to the lower gas volumes

associated with their production, a lower mass emission rate is still expected for chrome and manganese alloys. In addition, EPA emission tests in the original study on a number of tightly hooded open furnaces demonstrated emissions can be controlled to less than 0.23 kg/MW-hr (0.51 lb/MW-hr). Emissions were reduced to these levels by control of induced air volumes and by use of a well-designed and properly operated fabric filter collector or venturi scrubber.

Just before promulgation of the standards, members of the Ferroalloy Association informed EPA that future supplies of chrome and manganese ores will be finer and more friable than those in use during development of the standard. The industry representatives claimed that use of finer ores will affect furnace operations and prevent new furnaces from complying with the 0.23 kg/MW-hr (0.51 lb/MW-hr) standard. Although the representatives submitted statements concerning the effect of finer ores on furnace operating conditions, no data were provided to show the effect of ore size on emissions. EPA evaluated the material submitted and concluded that furnace operating problems associated with use of fine ores can be controlled by operation and maintenance procedures. With proper operation of the furnace, use of finer ores should not affect the achievability of the standard, and relaxation of the 0.23 kg/MW-hr (0.51 lb/MW-hr) standard is not justified. This evaluation is discussed in detail in Chapter II of the supplemental information document. If and when factual information is presented to EPA which clearly demonstrates that use of finer chrome and manganese ores does prevent a properly operated new furnace, which is equipped with the best demonstrated system of emission reduction (considering costs), from meeting the 0.23 kg/MW-hr (0.51 lb/MW-hr) standard, EPA will propose a revision to the standard. The best system of emission reduction (considering costs) is considered to be a well-designed collection hood in combination with a well-designed fabric filter collector or high-energy venturi scrubber.

The emission data obtained by EPA and the data provided by the industry show that the standards of performance for both product groups are achievable and the required control system clearly is adequately demonstrated. The question of the achievability of and the validity of the data basis for both the 0.23 kg/MW-hr (0.51 lb/MW-hr) and 0.45 kg/MW-hr (0.99 lb/MW-hr) standards is discussed in more detail in Chapter II of the supplemental information document.

(2) *Control device opacity standard.* On November 12, 1974 (39 FR 39872), after proposal of the standards for ferroalloy facilities, Method 9 was revised to require that compliance with opacity standards be determined by averaging sets of 24 consecutive observations taken at 15-second intervals (six-minute averages). The proposed opacity standard which limited emissions from the control

device to less than 20 percent has been revised in the regulation promulgated herein to require that emissions be less than 15 percent opacity in order to retain the intended level of control.

(3) *Control system capture requirements.* Ten commenters criticized fume capture requirements for the furnace and tapping station control systems on two basic points. The arguments were: (1) EPA lacks the statutory authority to regulate emissions within the building, and (2) the standards are not technically feasible at all times.

EPA has the statutory authority under section 111 of the Act to regulate any new stationary source which "emits or may emit any air pollutant." EPA does not agree with the opinion of the commenters that section 111 of the Act expressly or implicitly limits the Agency to regulation only of pollutants which are emitted directly into the atmosphere. Particulate matter emissions escaping capture by the furnace control system ultimately will be discharged to the atmosphere outside of the shop; therefore, they may be regulated under section 111 of the Act. Standards which regulate pollutants at the point of emission inside the building allow assessment of the control system without interference from nonregulated sources located in the same building. In addition, by requiring evaluation of emissions before their dilution, the standards will result in better control of the furnace emissions and will regulate affected ferroalloy facilities more uniformly than would standards limiting emissions from the shop.

EPA believes the standards on the furnace and tapping station collection hoods are achievable because the standards are based on observations of normal operations at well-controlled facilities. The commenters who argued that the standards are not technically feasible at all times cited examples of abnormal operations which would preclude achieving the standards. For example, several commenters cited the fact that violent reactions due to imbalances in the alloy chemistry occasionally can generate more emissions than the hood was designed to capture. If the capture system is well-designed, well-maintained, and properly operated, only failures of the process to operate in the normal or usual manner would cause the capacity of the system to be exceeded. Such operating periods are malfunctions, and, therefore, compliance with the standards of performance would not be determined during these periods. Performance tests under 40 CFR 60.8(c) are conducted only during representative conditions, and periods of start-up, shutdown, and malfunctions are not considered representative conditions.

Five commenters discussed other operating conditions which they believed would preclude a source from complying with the tapping station standard. These conditions included blowing taps, period of poling the tarhole, and periods of removal of metal and slag from the spout. The commenters argued that blowing taps should be exempted from the standard and the tapping station standard

should be replaced with an opacity standard or emissions from the shop. The comments were reviewed and EPA concluded that exemption of blowing taps is justified. The regulation promulgated herein exempts blowing taps from the tapping station standard and includes a definition of blowing tap. EPA believes that conditions which result in plugging of the tarhole and metal in the spout are malfunctions because they are unavoidable failures of the process to operate in the normal or usual manner. Discussions with experts in the ferroalloy industry, revealed that these conditions are not predictable conditions for which a preventative maintenance or operation program could be established. As malfunctions, these periods are not subject to the standards, and a performance test would not be conducted during such periods. Therefore, the suggested revision to the standard to exempt these periods is not necessary because of the existing provisions of 40 CFR 60.8(c) and 60.11. In EPA's judgment, both the furnace and tapping station standards are achievable for all normal process operations at facilities with well-designed, well-maintained, and properly operated emission collection systems.

The promulgated regulation retains the proposed fume capture requirements, but the regulation has been revised to be more enforceable than the proposed capture requirements, which could have been enforced only on an infrequent basis. The regulation has been reorganized to clarify that unlike the opacity standards, the collection system capture requirements (visible emission limitations) are subject to demonstration of compliance during the performance test. To provide a means for routine enforcement of the capture requirements, continuous monitoring of the volumetric flow rate(s) through the collection system is required for each affected furnace. An owner or operator may comply with this requirement either by installing a flow rate monitoring device in an appropriate location in the exhaust duct or by calculating the flow rate through the system from fan operating data. During the performance test, the baseline operating flow rate(s) will be established for the affected electric submerged arc furnace. The regulation establishes emission capture standards which are applicable only during the performance test of the affected facility. At all other times, the operating volumetric flow rate(s) shall be maintained at or greater than the established baseline values for the furnace load. Use of lower volumetric flow rates than the established values constitutes unacceptable operation and maintenance of the affected facility. These provisions of the promulgated regulation will ensure continuous monitoring of the operations of the emission capture system and will simplify enforcement of the emission capture requirements.

The requirements for monitoring volumetric flow rates will add negligible additional costs to the total costs of complying with the standards of performance. Flow rate monitoring devices

of sufficient accuracy to meet the requirements of § 60.265(c) can be installed for \$600-\$4000 depending on the flow profile of the area being monitored and the complexity of the monitoring device. A suitable strip chart recorder can be installed for less than \$600. The alternative provisions allowing calculation of the volumetric flow rate(s) through the control system from continuous monitoring of fan operations will result in no additional costs because the industry presently monitors fan operations.

(4) *Monitoring of operations.* The promulgated regulation requires reporting to the Administrator any product changes that will result in a change in the applicable standard of performance for the affected electric submerged arc furnace. This requirement is necessary because electric submerged arc furnaces may be converted to production of alloys other than the original design alloys by physical alterations to the furnace, changes to the electrode spacing, changes in the transformer capacity, and changes in the materials charged to the furnace. Thus, the emission rate from the electric submerged arc furnace and the standard of performance (which is dependent on the alloy produced) may change during the lifetime of the facility. Conversion of the furnace to production of alloys with significantly different emission rates, such as changes between the product groups for the two standards, may result in the facility exceeding the applicable standard. Consequently, the reporting requirement was added to ensure continued compliance with the applicable standards of performance. These reports of product changes will afford the Administrator an opportunity to determine whether a performance test should be conducted and will simplify enforcement of the regulation. As with the requirements applicable under the proposed regulation, the performance test still must be conducted while the electric submerged arc furnace is producing the design alloy whose emissions are the most difficult to control of the product family. Subsequent product changes within the product family will not cause the facility to exceed the standard.

(5) *Test methods and procedures.* Section 60.266(d) of the promulgated regulation requires the owner or operator to design and construct the control device to allow measurement of emissions and flow rates using applicable test methods and procedures. This provision permits the use of open pressurized fabric filter collectors (and other control devices) whose emissions cannot be measured by reference methods currently in Appendix A to this part, if compliance with the promulgated standard can be demonstrated by an alternative procedure. EPA has not specified a single test procedure for emission testing of open pressurized fabric filter collectors because of the large variations in the design of these collectors. Test procedures can be developed on a case-by-case basis, however. Provisions in 40 CFR 60.8(b) allow the owner or operator upon approval by the Administrator to use an "alternative" or

"equivalent" test procedure to show compliance with the standards. EPA would like to emphasize that development of the "alternative" or "equivalent" test procedure is the responsibility of any owner or operator who elects to use a control device not amenable to testing by Method 5 of Appendix A to this part. The procedures of an "alternative" test method for demonstration of compliance are dependent on specific design features and condition of the collector and the capabilities of the sampling equipment. Consequently, procedures acceptable for demonstration of compliance will vary with specific situations. General guidance on possible approaches to sampling of emissions from pressurized fabric filter collectors is provided in Chapter IV of the supplemental information document.

Due to the costs of testing, the owner or operator should obtain EPA approval for a specific test procedure or other means for determining compliance before construction of a new source. Under the provisions of § 60.6, the owner or operator of a new facility may request review of the acceptability of proposed plans for construction and testing of control systems which are not amenable to sampling by Reference Method 5. If an acceptable "alternative" test procedure is not developed by the owner or operator, then total enclosure of the pressurized fabric filter collector and testing by Method 5 is required.

Effective date. In accordance with section 111 of the Act, these regulations prescribing standards of performance for ferroalloy production facilities are effective May 4, 1976, and apply to electric submerged arc furnaces and their associated dust-handling equipment, the construction or modification of which was commenced after October 21, 1974.

(Secs. 111 and 114 of the Clean Air Act, amended by Sec. 4(a) of Pub. L. 91-604, 84 Stat. 1678 (42 U.S.C. 1857c-6, 1857c-9).)

Dated: April 23, 1976.

RUSSELL E. TRAIN,
Administrator.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

1. The table of sections is amended by adding subpart Z as follows:

Subpart Z—Standards of Performance for Ferroalloy Production Facilities

Sec.
60.260 Applicability and designation of affected facility.
60.261 Definitions.
60.262 Standard for particulate matter.
60.263 Standard for carbon monoxide.
60.264 Emission monitoring.
60.265 Monitoring of operations.
60.266 Test methods and procedures.

2. Part 60 is amended by adding subpart Z as follows:

Subpart Z—Standards of Performance for Ferroalloy Production

§ 60.260 Applicability and designation of affected facility.

The provisions of this subpart are applicable to the following affected facilities: Electric submerged arc furnaces which produce silicon metal, ferrosilicon,

calcium silicon, silicomanganese zirconium, ferrochrome silicon, silvery iron, high-carbon ferrochrome, charge chrome standard ferromanganese, silicomanganese, ferromanganese silicon, or calcium carbide; and dust-handling equipment.

§ 60.261 Definitions.

As used in this subpart, all terms not defined herein shall have the meaning given them in the Act and in subpart A of this part.

(a) "Electric submerged arc furnace" means any furnace wherein electrical energy is converted to heat energy by transmission of current between electrodes partially submerged in the furnace charge.

(b) "Furnace charge" means any material introduced into the electric submerged arc furnace and may consist of, but is not limited to, ores, slag, carbonaceous material, and limestone.

(c) "Product change" means any change in the composition of the furnace charge that would cause the electric submerged arc furnace to become subject to a different mass standard applicable under this subpart.

(d) "Slag" means the more or less completely fused and vitrified matter separated during the reduction of a metal from its ore.

(e) "Tapping" means the removal of slag or product from the electric submerged arc furnace under normal operating conditions such as removal of metal under normal pressure and movement by gravity down the spout into the ladle.

(f) "Tapping period" means the time duration from initiation of the process of opening the tap hole until plugging of the tap hole is complete.

(g) "Furnace cycle" means the time period from completion of a furnace product tap to the completion of the next consecutive product tap.

(h) "Tapping station" means that general area where molten product or slag is removed from the electric submerged arc furnace.

(i) "Blowing tap" means any tap in which an evaluation of gas forces or projects jets of flame or metal sparks beyond the ladle, runner, or collection hood.

(j) "Furnace power input" means the resistive electrical power consumption of an electric submerged arc furnace as measured in kilowatts.

(k) "Dust-handling equipment" means any equipment used to handle particulate matter collected by the air pollution control device (and located at or near such device) serving any electric submerged arc furnace subject to this subpart.

(l) "Control device" means the air pollution control equipment used to remove particulate matter generated by an electric submerged arc furnace from an effluent gas stream.

(m) "Capture system" means the equipment (including hoods, ducts, fans, dampers, etc.) used to capture or transport particulate matter generated by an affected electric submerged arc furnace to the control device.

(n) "Standard ferromanganese" means that alloy as defined by A.S.T.M. designation A99-66.

(o) "Silicomanganese" means that alloy as defined by A.S.T.M. designation A483-66.

(p) "Calcium carbide" means material containing 70 to 85 percent calcium carbide by weight.

(q) "High-carbon ferrochrome" means that alloy as defined by A.S.T.M. designation A101-66 grades HC1 through HC6.

(r) "Charge chrome" means that alloy containing 52 to 70 percent by weight chromium, 5 to 8 percent by weight carbon, and 3 to 6 percent by weight silicon.

(s) "Silvery iron" means any ferro-silicon, as defined by A.S.T.M. designation 100-69, which contains less than 30 percent silicon.

(t) "Ferrochrome silicon" means that alloy as defined by A.S.T.M. designation A482-66.

(u) "Silicomanganese zirconium" means that alloy containing 60 to 65 percent by weight silicon, 1.5 to 2.5 percent by weight calcium, 5 to 7 percent by weight zirconium, 0.75 to 1.25 percent by weight aluminum, 5 to 7 percent by weight manganese, and 2 to 3 percent by weight barium.

(v) "Calcium silicon" means that alloy as defined by A.S.T.M. designation A495-64.

(w) "Ferrosilicon" means that alloy as defined by A.S.T.M. designation A100-69 grades A, B, C, D, and E which contains 50 or more percent by weight silicon.

(x) "Silicon metal" means any silicon alloy containing more than 96 percent silicon by weight.

(y) "Ferromanganese silicon" means that alloy containing 63 to 66 percent by weight manganese, 28 to 32 percent by weight silicon, and a maximum of 0.08 percent by weight carbon.

§ 60.262 Standard for particulate matter.

(a) On and after the date on which the performance test required to be conducted by § 60.8 is completed, no owner or operator subject to the provisions of this subpart shall cause to be discharged into the atmosphere from any electric submerged arc furnace any gases which:

(1) Exit from a control device and contain particulate matter in excess of 0.45 kg/MW-hr (0.99 lb/MW-hr) while silicon metal, ferrosilicon, calcium silicon, or silicomanganese zirconium is being produced.

(2) Exit from a control device and contain particulate matter in excess of 0.23 kg/MW-hr (0.51 lb/MW-hr) while high-carbon ferrochrome, charge chrome, standard ferromanganese, silicomanganese, calcium carbide, ferrochrome silicon, ferromanganese silicon, or silvery iron is being produced.

(3) Exit from a control device and exhibit 15 percent opacity or greater.

(4) Exit from an electric submerged arc furnace and escape the capture system and are visible without the aid of instruments. The requirements under this subparagraph apply only during periods when flow rates are being established under § 60.265(d).

(5) Escape the capture system at the tapping station and are visible without the aid of instruments for more than 40 percent of each tapping period. There are no limitations on visible emissions under this subparagraph when a blowing tap occurs. The requirements under this subparagraph apply only during periods when flow rates are being established under § 60.265(d).

(b) On and after the date on which the performance test required to be conducted by § 60.8 is completed, no owner or operator subject to the provisions of this subpart shall cause to be discharged into the atmosphere from any dust-handling equipment any gases which exhibit 10 percent opacity or greater.

§ 60.263 Standard for carbon monoxide.

(a) On and after the date on which the performance test required to be conducted by § 60.8 is completed, no owner or operator subject to the provisions of this subpart shall cause to be discharged into the atmosphere from any electric submerged arc furnace any gases which contain, on a dry basis, 20 or greater volume percent of carbon monoxide. Combustion of such gases under conditions acceptable to the Administrator constitutes compliance with this section. Acceptable conditions include, but are not limited to, flaring of gases or use of gases as fuel for other processes.

§ 60.264 Emission monitoring.

(a) The owner or operator subject to the provisions of this subpart shall install, calibrate, maintain and operate a continuous monitoring system for measurement of the opacity of emissions discharged into the atmosphere from the control device(s).

(b) For the purpose of reports required under § 60.7(c), the owner or operator shall report as excess emissions all six-minute periods in which the average opacity is 15 percent or greater.

(c) The owner or operator subject to the provisions of this subpart shall submit a written report of any product change to the Administrator. Reports of product changes must be postmarked not later than 30 days after implementation of the product change.

§ 60.265 Monitoring of operations.

(a) The owner or operator of any electric submerged arc furnace subject to the provisions of this subpart shall maintain daily records of the following information:

(1) Product being produced.

(2) Description of constituents of furnace charge, including the quantity, by weight.

(3) Time and duration of each tapping period and the identification of material tapped (slag or product.)

(4) All furnace power input data obtained under paragraph (b) of this section.

(5) All flow rate data obtained under paragraph (c) of this section or all fan motor power consumption and pressure drop data obtained under paragraph (e) of this section.

(b) The owner or operator subject to the provisions of this subpart shall install, calibrate, maintain, and operate a device to measure and continuously record the furnace power input. The furnace power input may be measured at the output or input side of the transformer. The device must have an accuracy of ± 5 percent over its operating range.

(c) The owner or operator subject to the provisions of this subpart shall install, calibrate, and maintain a monitoring device that continuously measures and records the volumetric flow rate through each separately ducted hood of the capture system, except as provided under paragraph (e) of this section. The owner or operator of an electric submerged arc furnace that is equipped with a water cooled cover which is designed to contain and prevent escape of the generated gas and particulate matter shall monitor only the volumetric flow rate through the capture system for control of emissions from the tapping station. The owner or operator may install the monitoring device(s) in any appropriate location in the exhaust duct such that reproducible flow rate monitoring will result. The flow rate monitoring device must have an accuracy of ± 10 percent over its normal operating range and must be calibrated according to the manufacturer's instructions. The Administrator may require the owner or operator to demonstrate the accuracy of the monitoring device relative to Methods 1 and 2 of Appendix A to this part.

(d) When performance tests are conducted under the provisions of § 60.8 of this part to demonstrate compliance with the standards under §§ 60.262(a) (4) and (5), the volumetric flow rate through each separately ducted hood of the capture system must be determined using the monitoring device required under paragraph (c) of this section. The volumetric flow rates must be determined for furnace power input levels at 50 and 100 percent of the nominal rated capacity of the electric submerged arc furnace. At all times the electric submerged arc furnace is operated, the owner or operator shall maintain the volumetric flow rate at or above the appropriate levels for that furnace power input level determined during the most recent performance test. If emissions due to tapping are captured and ducted separately from emissions of the electric submerged arc furnace, during each tapping period the owner or operator shall maintain the exhaust flow rates through the capture system over the tapping station at or above the levels established during the most recent performance test. Operation at lower flow rates may be considered by the Administrator to be unacceptable operation and maintenance of the affected facility. The owner or operator may request that these flow rates be reestablished by conducting new performance tests under § 60.8 of this part.

(e) The owner or operator may as an alternative to paragraph (c) of this section determine the volumetric flow rate through each fan of the capture system from the fan power consumption, pressure drop across the fan and the fan per-

formance curve. Only data specific to the operation of the affected electric submerged arc furnace are acceptable for demonstration of compliance with the requirements of this paragraph. The owner or operator shall maintain on file a permanent record of the fan performance curve (prepared for a specific temperature) and shall:

(1) Install, calibrate, maintain, and operate a device to continuously measure and record the power consumption of the fan motor (measured in kilowatts), and

(2) Install, calibrate, maintain, and operate a device to continuously measure and record the pressure drop across the fan. The fan power consumption and pressure drop measurements must be synchronized to allow real time comparisons of the data. The monitoring devices must have an accuracy of ± 5 percent over their normal operating ranges.

(f) The volumetric flow rate through each fan of the capture system must be determined from the fan power consumption, fan pressure drop, and fan performance curve specified under paragraph (e) of this section, during any performance test required under § 60.8 of this part to demonstrate compliance with the standards under §§ 60.262(a) (4) and (5). The owner or operator shall determine the volumetric flow rate at a representative temperature for furnace power input levels of 50 and 100 percent of the nominal rated capacity of the electric submerged arc furnace. At all times the electric submerged arc furnace is operated, the owner or operator shall maintain the fan power consumption and fan pressure drop at levels such that the volumetric flow rate is at or above the levels established during the most recent performance test for that furnace power input level. If emissions due to tapping are captured and ducted separately from emissions of the electric submerged arc furnace, during each tapping period the owner or operator shall maintain the fan power consumption and fan pressure drop at levels such that the volumetric flow rate is at or above the levels established during the most recent performance test. Operation at lower flow rates may be considered by the Administrator to be unacceptable operation and maintenance of the affected facility. The owner or operator may request that these flow rates be reestablished by conducting new performance tests under § 60.8 of this part. The Administrator may require the owner or operator to verify the fan performance curve by monitoring necessary fan operating parameters and determining the gas volume moved relative to Methods 1 and 2 of Appendix A to this part.

(g) All monitoring devices required under paragraphs (c) and (e) of this section are to be checked for calibration annually in accordance with the procedures under § 60.13(b).

§ 60.266 Test methods and procedures.

(a) Reference methods in Appendix A of this part, except as provided in § 60.8 (b), shall be used to determine compliance with the standards prescribed in § 60.262 and § 60.263 as follows:

(1) Method 5 for the concentration of particulate matter and the associated moisture content except that the heating systems specified in paragraphs 2.1.2 and 2.1.4 of Method 5 are not to be used when the carbon monoxide content of the gas stream exceeds 10 percent by volume, dry basis.

(2) Method 1 for sample and velocity traverses.

(3) Method 2 for velocity and volumetric flow rate.

(4) Method 3 for gas analysis, including carbon monoxide.

(b) For Method 5, the sampling time for each run is to include an integral number of furnace cycles. The sampling time for each run must be at least 60 minutes and the minimum sample volume must be 1.8 dscm (64 dscf) when sampling emissions from open electric submerged arc furnaces with wet scrubber control devices, sealed electric submerged arc furnaces, or semi-enclosed electric submerged arc furnaces. When sampling emissions from other types of installations, the sampling time for each run must be at least 200 minutes and the minimum sample volume must be 5.7 dscm (200 dscf). Shorter sampling times or smaller sampling volumes, when necessitated by process variables or other factors, may be approved by the Administrator.

(c) During the performance test, the owner or operator shall record the maxi-

mum open hood area (in hoods with segmented or otherwise moveable sides) under which the process is expected to be operated and remain in compliance with all standards. Any future operation of the hooding system with open areas in excess of the maximum is not permitted.

(d) The owner or operator shall construct the control device so that volumetric flow rates and particulate matter emissions can be accurately determined by applicable test methods and procedures.

(e) During any performance test required under § 60.8 of this part, the owner or operator shall not allow gaseous diluents to be added to the effluent gas stream after the fabric in an open pressurized fabric filter collector unless the total gas volume flow from the collector is accurately determined and considered in the determination of emissions.

(f) When compliance with § 60.263 is to be attained by combusting the gas stream in a flare, the location of the sampling site for particulate matter is to be upstream of the flare.

(g) For each run, particulate matter emissions, expressed in kg/hr (lb/hr), must be determined for each exhaust stream at which emissions are quantified using the following equation:

$$E_a = C \cdot Q$$

where:

E_a = Emissions of particulate matter in kg/hr (lb/hr).

C = Concentration of particulate matter in kg/dscm (lb/dscf) as determined by Method 5.

Q = Volumetric flow rate of the effluent gas stream in dscm/hr (dscf/hr) as determined by Method 2.

(h) For Method 5, particulate matter emissions from the affected facility, expressed in kg/MW-hr (lb/MW-hr) must be determined for each run using the following equation:

$$E = \frac{\sum_{i=1}^N E_i}{p}$$

where:

E = Emissions of particulate from the affected facility, in kg/MW-hr (lb/MW-hr).

N = Total number of exhaust streams at which emissions are quantified.

E_i = Emission of particulate matter from each exhaust stream in kg/hr (lb/hr), as determined in paragraph (g) of this section.

p = Average furnace power input during the sampling period, in megawatts as determined according to § 60.263 (b).

(Secs. 111 and 114 of the Clean Air Act, as amended by sec. 4(a) of Pub. L. 91-604, 84 Stat. 1678 (42 U.S.C. 1857c-6, 1857c-9))

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCE
Delegation of Authority to Commonwealth of Massachusetts

Pursuant to the delegation of authority for the standards of performance for new stationary sources (NSPS) to the Commonwealth of Massachusetts on January 23, 1976, EPA is today amending 40 CFR 60.4, "Address," to reflect this delegation. A notice announcing this delegation is published in the Notices section of today's FEDERAL REGISTER. The amended § 60.4, which adds the address of the Massachusetts Department of Environmental Quality Engineering, Division of Air Quality Control, to which all reports, requests, applications, submittals, and communications to the Administrator pursuant to this part must also be addressed, is set forth below.

The Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive bur-

dens are imposed on the parties affected. The delegation which is reflected by this administrative amendment was effective on January 23, 1976, and it serves no purpose to delay the technical change of this addition of the State address to the Code of Federal Regulations.

This rulemaking is effective immediately, and is issued under the authority of Section 111 of the Clean Air Act, as amended.

42 U.S.C. 1857c-6.

Dated May 3, 1976.

STANLEY W. LEGRO,
Assistant Administrator
for Enforcement.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

1. In § 60.4 paragraph (b) is amended by revising subparagraph (W) to read as follows:

§ 60.4 Address.

(b) . . .

(W) Massachusetts Department of Environmental Quality Engineering, Division of Air Quality Control, 600 Washington Street, Boston, Massachusetts 02111.

[FR Doc.76-13822 Filed 5-12-76;8:45 am]

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Delegation of Authority to State of New Hampshire

Pursuant to the delegation of authority for the standards of performance for new stationary sources (NSPS) to the State of New Hampshire on February 17, 1976, EPA is today amending 40 CFR 60.4, "Address," to reflect this delegation. A Notice announcing this delegation is published in the Notices section of today's FEDERAL REGISTER. The amended § 60.4, which adds the address of the New Hampshire Air Pollution Control Agency to which all reports, requests, applications, submittals, and communications to the Administrator pursuant to this part must also be addressed, is set forth below.

The Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegation which is reflected by this administrative amendment was effective on February 17, 1976, and it serves no purpose to delay the technical change of this addition of the State address to the Code of Federal Regulations.

RULES AND REGULATIONS

This rulemaking is effective immediately, and is issued under the authority of Section 111 of the Clean Air Act, as amended.

42 U.S.C. 1857c-6.

Dated: May 3, 1976.

STANLEY W. LEGRO,
Assistant Administrator
of Enforcement.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

1. In § 60.4 paragraph (b) is amended by revising subparagraph (EE) to read as follows:

§ 60.4 Address.

(b) . . .

(EE) New Hampshire Air Pollution Control Agency, Department of Health and Welfare, State Laboratory Building, Hazen Drive, Concord, New Hampshire 03301.

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Ferroalloy Production Facilities.

Correction

In FR Doc. 76-12814 appearing at page 18498 in the FEDERAL REGISTER of Tuesday, May 4, 1976 the following corrections should be made:

1. On page 18498, second column, last paragraph designated "(1)", second line, fourth word should read "representativeness".

2. On page 18501, first column, the subpart heading immediately preceding the text, should read "Subpart Z—Standards of Performance for Ferroalloy Production Facilities".

3. On page 18501, in § 60.280, second column, fourth line from the top, the third word should read "silicomanga-".

4. On page 18501, second column, in § 60.261 (i), second line, third word should read "evolution".

5. On page 18503, third column, in § 60.266(h) the equation should have appeared as follows:

$$E = \frac{\sum_{n=1}^N E_n}{p}$$

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Delegation of Authority to State of California on Behalf of Ventura County and Northern Sonoma County Air Pollution Control Districts

Pursuant to the delegation of authority for the standards of performance for new stationary sources (NSPS) to the State of California on behalf of the Ventura County Air Pollution Control District and the Northern Sonoma County Air Pollution Control District, dated February 2, 1976, EPA is today amending 40 CFR 60.4, Address, to reflect this delegation. A Notice announcing this delegation is published today in the Notice section of this issue. The amended § 60.4 is set forth below. It adds the addresses of the Ventura County and Northern Sonoma County Air Pollution Control Districts, to which must be addressed all reports, requests, applications, submittals, and communications pursuant to this part by sources subject to the NSPS located within these Air Pollution Control Districts.

The Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegation which is reflected by this administrative amendment was effective on February 2, 1976, and it serves no purpose to delay the technical change of this addition of the Air Pollution Control District addresses to the Code of Federal Regulations.

This rulemaking is effective immediately.

(Sec. 111 of the Clean Air Act, as amended [42 U.S.C. 1857c-6]).

Dated: May 3, 1976.

STANLEY W. LEGRO,
Assistant Administrator
for Enforcement.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

1. Section 60.4(b) is amended by revising subparagraph F to read as follows:

§ 60.4 Address.

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Delegation of Authority to State of Utah

Pursuant to the delegation of authority for the standards of performance for twelve (12) categories of new stationary sources (NSPS) to the State of Utah on May 13, 1976, EPA is today amending 40 CFR 60.4, Address, to reflect this delegation. A Notice announcing this delegation is published today in the FEDERAL REGISTER. The amended § 60.4, which adds the address of the Utah Air Conservation Committee to which all reports, requests, applications, submittals, and communications to the Administrator pursuant to this part must also be addressed, is set forth below.

The Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegation which is reflected by this administrative amendment was effective on May 13, 1976, and it serves no purpose to delay the technical change of this addition of the State address to the Code of Federal Regulations.

This rulemaking is effective immediately, and is issued under the authority of section 111 of the Clean Air Act, as amended, 42 U.S.C. 1857c-6.

Dated: June 10, 1976.

STANLEY W. LEGRO,
Assistant Administrator
for Enforcement.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

NEW SOURCE REVIEW

Delegation of Authority to the State of Georgia

The amendments below institute certain address changes for reports and applications required from operators of new sources. EPA has delegated to the State of Georgia authority to review new and modified sources. The delegated authority includes the reviews under 40 CFR Part 52 for the prevention of significant deterioration. It also includes the review under 40 CFR Part 60 for the standards of performance for new stationary sources and review under 40 CFR Part 61 for national emission standards for hazardous air pollutants.

A notice announcing the delegation of authority is published elsewhere in the Notices section this issue of the *FEDERAL REGISTER*. These amendments provide that all reports, requests, applications, submittals, and communications previously required for the delegated reviews will now be sent instead to the Environmental Protection Division, Georgia Department of Natural Resources, 270 Washington Street SW., Atlanta, Georgia 30334, instead of EPA's Region IV.

The Regional Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegation which is reflected by this administrative amendment was effective on May 3, 1976, and it serves no purpose to delay the technical change of this addition of the State address to the Code of Federal regulations.

This rulemaking is effective immediately, and is issued under the authority of Sections 101, 110, 111, 112 and 301 of the Clean Air Act, as amended 42 U.S.C. 1857, 1857C-5, 6, 7 and 1857g.

Dated: June 11, 1976.

JACK E. RAVAN,
Regional Administrator.

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

DELEGATION OF AUTHORITY TO THE STATE OF GEORGIA

Part 60 of Chapter I, Title 40, Code of Federal Regulations, is amended as follows:

2. In § 60.4, paragraph (b) (L) is revised to read as follows:

§ 60.4 Address.

(b) . . .

(L) State of Georgia, Environmental Protection Division, Department of Natural Resources, 270 Washington Street, S.W., Atlanta, Georgia 30334.

FEDERAL REGISTER, VOL. 41, NO. 120-

39 SUBCHAPTER C—AIR PROGRAMS [FRL 574-3]

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Delegation of Authority to State of California on Behalf of Fresno, Mendocino, San Joaquin, and Sacramento County Air Pollution Control Districts

Pursuant to the delegation of authority for the standards of performance for new stationary sources (NSPS) to the State of California on behalf of the Fresno County Air Pollution Control District, the Mendocino County Air Pollution Control District, the San Joaquin County Air Pollution Control District, and the Sacramento County Air Pollution Control District, dated March 29, 1976, EPA is today amending 40 CFR 60.4, Address, to reflect this delegation. A Notice announcing this delegation is published today in the Notice Section of this issue. The amended § 60.4 is set forth below. It adds the addresses of the Fresno County, Mendocino County, San Joaquin County, and Sacramento County Air Pollution Control Districts, to which must be addressed all reports, requests, applications, submittals, and communications pursuant to this part by sources subject to the NSPS located within these Air Pollution Control Districts.

The Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegation which is reflected by this administrative amendment was effective on March 29, 1976, and it serves no purpose to delay the technical change of this addition of the Air Pollution Control District addresses to the Code of Federal Regulations.

This rulemaking is effective immediately, and is issued under the authority of section 111 of the Clean Air Act, as amended [42 U.S.C. 1857c-6].

Dated: June 15, 1976.

STANLEY W. LEGRO,
Assistant Administrator
for Enforcement.

Part 60 of Chapter I, Title 40, of the Code of Federal Regulations, is amended as follows:

1. In § 60.4, paragraph (b) is amended by revising subparagraph F to read as follows:

§ 60.4 Address.

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Delegation of Authority to State of California on Behalf of Madera County Air Pollution Control District

Pursuant to the delegation of authority for the standards of performance for new stationary sources (NSPS) to the State of California on behalf of the Madera County Air Pollution Control District, dated May 12, 1976, EPA is today amending 40 CFR 60.4 Address, to reflect this delegation. A Notice announcing this delegation is published in the Notices Section of this issue of the FEDERAL REGISTER, Environmental Protection Agency, FRL 596-8. The amended § 60.4 is set forth below. It adds the address of the Madera County Air Pollution Control District, to which must be addressed all reports, requests, applications, submittals, and communications pursuant to this part by sources subject to the NSPS located within this Air Pollution Control District.

The Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegation which is reflected by this administrative amendment was effective on May 12, 1976, and it serves no purpose to delay the technical change of this addition of the Air Pollution Control District address to the Code of Federal Regulations.

This rulemaking is effective immediately, and is issued under the authority of Section 111 of the Clean Air Act, as amended [42 U.S.C. 1857c-6].

Dated: July 27, 1976.

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Revision to Emission Monitoring Requirements

On October 6, 1975 (40 FR 46250), under section 111 of the Clean Air Act, as amended, the Environmental Protection Agency (EPA) promulgated emission monitoring requirements and revisions to the performance testing methods in 40 CFR Part 60. The provisions of § 60.13(i) allow the Administrator to approve alternatives to monitoring procedures or requirements only upon written application by an owner or operator of an affected facility; monitoring equipment manufacturers would not be allowed to apply for approval of alternative monitoring equipment. Since EPA did not intend to prevent monitoring equipment manufacturers from applying for approval of alternative monitoring equipment, § 60.13(i) is being revised. As revised, any person will be allowed to make application to the Administrator for approval of alternative monitoring procedures or requirements.

This revision does not add new requirements, rather it provides greater flexibility for approval of alternative equipment and procedures. This revision is effective (date of publication).

(Sections 111, 114, and 301(a) of the Clean Air Act, as amended by sec. 4(a) of Pub. L. 91-604, 84 Stat. 1878 and by sec. 15(c) (2) of Pub. L. 91-604, 84 Stat. 1713 (42 U.S.C. 1857-6, 1857-9, and 1857g(a)).)

Dated: August 13, 1976.

RUSSELL E. TRAIN,
Administrator.

In 40 CFR Part 60, Subpart A is amended as follows:

1. Section 60.13 is amended by revising paragraph (i) as follows:

§ 60.13 Monitoring requirements.

(i) After receipt and consideration of written application, the Administrator may approve alternatives to any monitoring procedures or requirements of this part including, but not limited to the following:

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Delegation of Authority to State of California on Behalf of Stanislaus County Air Pollution Control District; Delegation of Authority to State of California on Behalf of Sacramento County Air Pollution Control District; Correction

Pursuant to the delegation of authority for the standards of performance for new stationary sources (NSPS) to the State of California on behalf of the Stanislaus County Air Pollution Control District, dated July 2, 1976, EPA is today amending 40 CFR 60.4 Address, to reflect this delegation. A notice announcing this delegation is published today at 41 FR 40108. The amended § 60.4 is set forth below. It adds the address of the Stanislaus County Air Pollution Control District, to which must be addressed all reports, requests, applications, submittals, and communications pursuant to this part by sources subject to the NSPS located within this Air Pollution Control District.

On July 8, 1976, EPA amended 40 CFR 60.4, Address to reflect delegation of authority for NSPS to the State of California on behalf of the Sacramento County Air Pollution Control District. By letter of July 30, 1976, Colin T. Greenlaw, M.D., Sacramento County Air Pollution Control Officer, notified EPA that the address published at 41 FR 27967 was incorrect. Therefore, EPA is today also amending 40 CFR 60.4, Address to reflect the correct address for the Sacramento County Air Pollution Control District.

The Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegations which are reflected by this administrative amendment were effective on July 2, 1976 and March 29, 1976, and it serves no purpose to delay the technical change of these additions of the Air Pollution Control Districts addresses to the Code of Federal Regulations.

This rulemaking is effective immediately, and is issued under the authority of Section 111 of the Clean Air Act, as amended (42 U.S.C. 1857c-6)

Dated: September 8, 1976.

L. RUSSELL FREEMAN,
Acting Regional Administrator,
Region IX, EPA.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

1. In § 60.4 paragraph (b) (f) is revised to read as follows:

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

PART 61—NATIONAL EMISSION STANDARDS FOR HAZARDOUS AIR POLLUTANTS

Reports and Applications From Operators of New Sources; Address Changes

DELEGATION OF AUTHORITY TO THE STATE OF ALABAMA

The amendments below institute certain address changes for reports and applications required from operators of new sources. EPA has delegated to the State of Alabama authority to review new and modified sources. The delegated authority includes the review under 40 CFR Part 60 for the standards of performance for new stationary sources and review under 40 CFR Part 61 for national emission standards for hazardous air pollutants.

A notice announcing the delegation of authority is published elsewhere in this issue of the FEDERAL REGISTER. These amendments provide that all reports, requests, applications, submittals, and communications previously required for the delegated reviews will now be sent instead to the Air Pollution Control Division, Alabama Air Pollution Control Commission, 645 South McDonough Street, Montgomery, Alabama 36104, instead of EPA's Region IV.

The Regional Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegation which is reflected by this administrative amendment was effective on August 5, 1976, and it serves no purpose to delay the technical change of this addition of the State address to the Code of Federal Regulations.

This rulemaking is effective immediately, and is issued under the authority of sections 111, 112, and 301 of the Clean Air Act, as amended 42 U.S.C. 1857, 1857c-5, 6, 7 and 1857g.

Dated: September 9, 1976.

JACK E. LAVAN,
Regional Administrator.

Part 60 of Chapter I, Title 40, Code of Federal Regulations, is amended as follows:

1. In § 60.4, paragraph (b) is amended by revising subparagraph (B) to read as follows:

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Delegation of Authority to the State of Indiana

Pursuant to the delegation of authority to implement the standards of performance for new stationary sources (NSPS) to the State of Indiana on April 21, 1976, EPA is today amending 40 CFR 60.4, Address, to reflect this delegation. A notice announcing this delegation is published Thursday, September 30, 1976 (41 FR 43237). The amended § 60.4, which adds the address of the Indiana Air Pollution Control Board to that list of addresses to which all reports, requests, applications, submittals, and communications to the Administrator pursuant to this part must be sent, is set forth below.

The Administrator finds good cause for foregoing prior notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegation which is reflected by this administrative amendment was effective on April 21, 1976, and it serves no purpose to delay the technical change of this addition of the State address to the Code of Federal Regulations.

This rulemaking is effective immediately.

(Sec. 111 of the Clean Air Act, as amended, 42 U.S.C. 1857c-6.)

PART 61—NATIONAL EMISSION STANDARDS FOR HAZARDOUS AIR POLLUTANTS

Delegation of Authority to State of North Dakota

Pursuant to the delegation of authority for the standards of performance for new sources (NSPS) and national emission standards for hazardous air pollutants (NESHAPS) to the State of North Dakota on August 30, 1976, EPA is today amending respectively 40 CFR 60.4 and 61.04 Address, to reflect this delegation. A notice announcing this delegation is published today in the notices section. The amended §§ 60.4 and 61.04 which add the address of the North Dakota State Department of Health to which all reports, requests, applications, submittals, and communications to the Administrator pursuant to these parts must also be addressed, are set forth below.

The Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegation which is reflected by this administrative amendment was effective on August 30, 1976, and it serves no purpose to delay the technical change of this addition to the State address to the Code of Federal Regulations.

This rulemaking is effective immediately, and is issued under the authority of sections 111 and 112 of the Clean Air Act, as amended, (42 U.S.C. 1857c-6 and -7).

Dated: October 1, 1976.

JOHN A. GREEN,
Regional Administrator.

SUBCHAPTER C—AIR PROGRAMS

[FRL 639-3]

PART 60—STANDARDS OF PERFORMANCE
FOR NEW STATIONARY SOURCES

Amendments to Subpart D

Standards of performance for fossil fuel-fired steam generators of more than 73 megawatts (250 million Btu per hour) heat input rate are provided under Subpart D of 40 CFR Part 60. Subpart D is amended herein to revise the application of the standards of performance for facilities burning wood residues in combination with fossil fuel.

Subpart D contains standards for particulate matter, sulfur dioxide, nitrogen oxides, and visible emissions from steam generators. These standards, except for the one applicable to visible emissions, are based on heat input. For sulfur dioxide, there are separate standards for liquid fossil fuel-fired and solid fossil fuel-fired facilities with provisions for a prorated standard when combinations of different fossil fuels are fired. There is no sulfur dioxide standard for gaseous fossil fuel-fired facilities since they emit negligible amounts of sulfur dioxide.

To date, there have been two ways for a source owner or operator to comply with the sulfur dioxide standard: (1) By firing low sulfur fossil fuels or (2) by using flue gas desulfurization systems. Complying with the standard by firing low sulfur fossil fuel requires an adequate supply of fuel with a sulfur content low enough to meet the standard. However, it would be possible for the owner or operator to fire, for example, a relatively high sulfur fossil fuel with a very low sulfur fossil fuel (e.g. natural gas) to obtain a fuel mixture which would meet the standard. The low sulfur fuel adds to the heat input but not to the sulfur dioxide emissions and, thereby, has an overall fuel sulfur reduction effect. In the past, the application of Subpart D permitted the heat content of fossil fuels but not wood residue to be used in determining compliance with the standards for particulate matter, sulfur dioxide and nitrogen oxides; the amendment made herein will allow the heat content of wood residue to be used for determining compliance with the standards. The amendment does not change the scope of applicability of Subpart D; all steam generating units constructed after August 17, 1971, and capable of firing fossil fuel at a heat input rate of more than 73 megawatts (250 million Btu per hour) are subject to Subpart D.

RATIONALE FOR THE AMENDMENTS

Wood residue, which includes bark, sawdust, chips, etc., is not a fossil fuel and thus has not been allowed for use as a dilution agent in complying with the sulfur dioxide standard for steam generators. Several companies have requested that EPA revise Subpart D to permit blending of wood residue with high sulfur fossil fuels. This would enable them to obtain a fuel mixture low enough in sulfur to comply with the sulfur dioxide standard. Since Subpart D allows the blending of high and low sulfur fossil fuels, EPA has concluded that it is reasonable to extend application of this principle to wood residue which, although not a fossil fuel, does have low sulfur content.

Several companies have expressed interest in constructing steam generators which continuously fire wood residue in combination with fossil fuel. New facilities will comply with the standards for less cost than at present because they will be able to use wood residue, a valuable source of energy, as an alternative to expensive low sulfur fossil fuels. Also, using wood residue as a fuel supplement instead of low sulfur fossil fuels will re-

RULES AND REGULATIONS

sult in substantial savings in the consumption of scarce natural gas and oil resources, and will relieve what would otherwise be a substantial solid waste disposal problem. Consumption of energy and raw material resources will be reduced further by minimizing the need for flue gas desulfurization systems at new facilities. There will be no adverse environmental impact; neither sulfur dioxide nor nitrogen oxides emissions will increase as a result of this action. Considering the beneficial, environmental, energy, and economic impacts, it is reasonable to permit wood residue to be fired as a low sulfur fuel to aid in compliance with the standards for fossil fuel-fired steam generators.

In making this amendment, EPA recognizes that affected facilities which burn substantially more wood residue than fossil fuel may have difficulty complying with the 43 nanogram per joule standard for particulate matter (0.1 pound per million Btu). There is not sufficient information available at this time to determine what level of particulate matter emissions is achievable; however, EPA is continuing to gather information on this question. If EPA determines that the particulate matter standard is not achievable, appropriate changes will be made to the standard. Any change would be proposed for public comment; however, in the interim, owners and operators will be subject to the 43 nanogram per joule standard.

'F' FACTOR DETERMINATION

New facilities firing wood residue in combination with fossil fuel will be subject to the emission and fuel monitoring requirements of § 60.45 (as revised on October 6, 1975, 40 FR 46250). The 'F' factors listed in § 60.45(f)(4), which are used for converting continuous monitoring data and performance test data into units of the standard, presently apply only to fossil fuels. Therefore, 'F' factors for bark and wood residue have been added to § 60.45(f)(4). Any owner or operator who elects to calculate his own 'F' factor must obtain approval of the Administrator.

INTERNATIONAL SYSTEM OF UNITS

In accordance with the objective to implement national use of the metric system, EPA presents numerical values in both metric units and English units in its regulations and technical publications. In an effort to simplify use of the metric units of measurements, EPA now uses the International System of Units (SI) as set forth in a publication by the American Society for Testing and Materials entitled "Standard for Metric Practice" (Designation: E 380-76). The following amendments to Subpart D reflect the use of SI units.

MISCELLANEOUS

Since these amendments are expected to have limited applicability, no environmental impact statement is required for this rulemaking pursuant to section 1(b) of the "Procedures for the Voluntary

Preparation of Environmental Impact Statements" (39 FR 37419).

This action is effective on November 22, 1976. The Agency finds that good cause exists for not publishing this action as a notice of proposed rulemaking and for making it effective immediately upon publication because:

1. The action is expected to have limited applicability.
2. The action will remove an existing restriction on operations without increasing emissions and will have beneficial environmental, energy, and economic effects.
3. The action is not technically controversial and does not alter the overall substantive content of Subpart D.
4. Immediate effectiveness of the action will enable affected parties to proceed promptly and with certainty in conducting their affairs.

(Secs. 111, 114 and 301(a) of the Clean Air Act, as amended by section 4(a) of Pub.L. 91-604, 84 Stat. 1678, and by section 15(c)(2) of Pub.L. 91-604, 84 Stat. 1713 (42 U.S.C. 1857c-6, 1857c-9, 1857g(a)).)

Date: November 15, 1976.

JOHN QUARLES,
Acting Administrator.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

1. Section 60.40 is amended by revising the designation of affected facility and by substituting the International System (SI) of Units as follows:

§ 60.40 Applicability and designation of affected facility.

(a) The affected facilities to which the provisions of this subpart apply are:

(1) Each fossil fuel-fired steam generating unit of more than 73 megawatts heat input rate (250 million Btu per hour).

(2) Each fossil fuel and wood residue-fired steam generating unit capable of firing fossil fuel at a heat input rate of more than 73 megawatts (250 million Btu per hour).

(b) Any change to an existing fossil fuel-fired steam generating unit to accommodate the use of combustible materials, other than fossil fuels as defined in this subpart, shall not bring that unit under the applicability of this subpart.

2. Section 60.41 is amended by adding paragraphs (d) and (e) as follows:

§ 60.41 Definitions.

(d) "Fossil fuel and wood residue-fired steam generating unit" means a furnace or boiler used in the process of burning fossil fuel and wood residue for the purpose of producing steam by heat transfer.

(e) "Wood residue" means bark, sawdust, slabs, chips, shavings, mill trim, and other wood products derived from wood processing and forest management operations.

3. Section 60.42 is amended by revising paragraph (a)(1) and by substituting SI units in paragraph (a)(1) as follows:

§ 60.42 Standard for particulate matter.

(a) * * *

(1) Contain particulate matter in excess of 43 nanograms per joule heat input (0.10 lb per million Btu) derived from fossil fuel or fossil fuel and wood residue.

4. Section 60.43 is amended by revising paragraphs (a)(1) and (a)(2), by substituting SI units in paragraphs (a)(1) and (a)(2), and by revising the formula in paragraph (b) as follows:

§ 60.43 Standard for sulfur dioxide.

(a) * * *

(1) 340 nanograms per joule heat input (0.80 lb per million Btu) derived from liquid fossil fuel or liquid fossil fuel and wood residue.

(2) 520 nanograms per joule heat input (1.2 lb per million Btu) derived from solid fossil fuel or solid fossil fuel and wood residue.

(b) When different fossil fuels are burned simultaneously in any combination, the applicable standard (in ng/J) shall be determined by proration using the following formula:

$$PS_{SO_2} = \frac{y(340) + z(520)}{y + z}$$

where:

PS_{SO_2} is the prorated standard for sulfur dioxide when burning different fuels simultaneously, in nanograms per joule heat input derived from all fossil fuels fired or from all fossil fuels and wood residue fired,
y is the percentage of total heat input derived from liquid fossil fuel, and
z is the percentage of total heat input derived from solid fossil fuel.

5. Section 60.44 is amended by revising paragraphs (a)(1), (a)(2), and (a)(3); by substituting SI units in paragraphs (a)(1), (a)(2), and (a)(3); and by revising paragraph (b) as follows:

§ 60.44 Standard for nitrogen oxides.

(a) * * *

(1) 86 nanograms per joule heat input (0.20 lb per million Btu) derived from gaseous fossil fuel or gaseous fossil fuel and wood residue.

(2) 130 nanograms per joule heat input (0.30 lb per million Btu) derived from liquid fossil fuel or liquid fossil fuel and wood residue.

(3) 300 nanograms per joule heat input (0.70 lb per million Btu) derived from solid fossil fuel or solid fossil fuel and wood residue (except lignite or a solid fossil fuel containing 25 percent, by weight, or more of coal refuse).

(b) When different fossil fuels are burned simultaneously in any combination, the applicable standards (in ng/J) shall be determined by proration. Compliance shall be determined by using the following formula:

RULES AND REGULATIONS

$$PSNO_x = \frac{x(86) + y(130) + z(300)}{x + y + z}$$

where:

PSNO_x is the prorated standard for nitrogen oxides when burning different fuels simultaneously, in nanograms per joule heat input derived from all fossil fuels fired or from all fossil fuels and wood residue fired,
 x is the percentage of total heat input derived from gaseous fossil fuel,
 y is the percentage of total heat input derived from liquid fossil fuel, and
 z is the percentage of total heat input derived from solid fossil fuel (except lignite or a solid fossil fuel containing 25 percent, by weight, or more of coal refuse).

When lignite or a solid fossil fuel containing 25 percent, by weight, or more of coal refuse is burned in combination with gaseous, liquid, other solid fossil fuel, or wood residue, the standard for nitrogen oxides does not apply.

6. Section 60.45 is amended by substituting SI units in paragraphs (e), (f) (1), (f) (2), (f) (4) (i), (f) (4) (ii), (f) (4) (iii), (f) (4) (iv), (f) (5), and (f) (5) (ii), by adding paragraphs (f) (4) (v) and (f) (5) (iii), and by revising paragraph (f) (6) as follows:

§ 60.45 Emission and fuel monitoring.

(e) An owner or operator required to install continuous monitoring systems under paragraphs (b) and (c) of this section shall for each pollutant monitored use the applicable conversion procedure for the purpose of converting continuous monitoring data into units of the applicable standards (nanograms per joule, pounds per million Btu) as follows:

(f)

(1) E = pollutant emissions, ng/J (lb/million Btu).

(2) C = pollutant concentration, ng/dscm (lb/dscf), determined by multiplying the average concentration (ppm) for each one-hour period by 4.15×10^{-4} M ng/dscm per ppm (2.59×10^{-3} M lb/dscf per ppm) where M = pollutant molecular weight, g/g-mole (lb/lb-mole). M = 64.07 for sulfur dioxide and 46.01 for nitrogen oxides.

(4)

(i) For anthracite coal as classified according to A.S.T.M. D 388-66, $F = 2.723 \times 10^{-7}$ dscm/J (10,140 dscf/million Btu) and $F_c = 0.532 \times 10^{-7}$ scm CO_2 /J (1,980 scf CO_2 /million Btu).

(ii) For subbituminous and bituminous coal as classified according to A.S.T.M. D 388-66, $F = 2.637 \times 10^{-7}$ dscm/J (9,820 dscf/million Btu) and $F_c = 0.486 \times 10^{-7}$ scm CO_2 /J (1,810 scf CO_2 /million Btu).

(iii) For liquid fossil fuels including crude, residual, and distillate oils, $F = 2.476 \times 10^{-7}$ dscm/J (9,220 dscf/million Btu) and $F_c = 0.384$ scm CO_2 /J (1,430 scf CO_2 /million Btu).

(iv) For gaseous fossil fuels, $F = 2.347 \times 10^{-7}$ dscm/J (8,740 dscf/million Btu).

For natural gas, propane, and butane fuels, $F_c = 0.279 \times 10^{-7}$ scm CO_2 /J (1,040 scf CO_2 /million Btu) for natural gas, 0.322×10^{-7} scm CO_2 /J (1,200 scf CO_2 /million Btu) for propane, and 0.338×10^{-7} scm CO_2 /J (1,260 scf CO_2 /million Btu) for butane.

(v) For bark $F = 1.076$ dscm/J (9,575 dscf/million Btu) and $F_c = 0.217$ dscm/J (1,927 dscf/million Btu). For wood residue other than bark $F = 1.038$ dscm/J

(9,233 dscf/million Btu) and $F_c = 0.207$ dscm/J (1,842 dscf/million Btu).

(5) The owner or operator may use the following equation to determine an F factor (dscm/J or dscf/million Btu) on a dry basis (if it is desired to calculate F on a wet basis, consult the Administrator) or F_c factor (scm CO_2 /J, or scf CO_2 /million Btu) on either basis in lieu of the F or F_c factors specified in paragraph (f) (4) of this section:

$$F = \frac{227.0(\%H) + 95.7(\%C) + 35.4(\%S) + 8.6(\%N) - 28.5(\%O)}{GCV}$$

(SI units)

$$F = \frac{10^6[3.64(\%H) + 1.53(\%C) + 0.57(\%S) + 0.14(\%N) - 0.46(\%O)]}{GCV}$$

(English units)

$$F_c = \frac{20.0(\%C)}{GCV}$$

(SI units)

$$F_c = \frac{321 \times 10^6(\%C)}{GCV}$$

(English units)

(i)

(ii) GCV is the gross calorific value (kJ/kg, Btu/lb) of the fuel combusted, determined by the A.S.T.M. test methods D 2015-66(72) for solid fuels and D 1826-64(70) for gaseous fuels as applicable.

(iii) For affected facilities which fire both fossil fuels and nonfossil fuels, the F or F_c value shall be subject to the Administrator's approval.

(6) For affected facilities firing combinations of fossil fuels or fossil fuels and wood residue, the F or F_c factors determined by paragraphs (f) (4) or (f) (5) of this section shall be prorated in accordance with the applicable formula as follows:

$$F = \sum_{i=1}^n X_i F_i \text{ or } F_c = \sum_{i=1}^n X_i (F_c)_i$$

where:

X_i = the fraction of total heat input derived from each type of fuel (e.g. natural gas, bituminous coal, wood residue, etc.)

F_i or $(F_c)_i$ = the applicable F or F_c factor for each fuel type determined in accordance with paragraphs (f) (4) and (f) (5) of this section.

n = the number of fuels being burned in combination.

7. Section 60.46 is amended by substituting SI units in paragraphs (b) and (f) and paragraph (g) is revised as follows:

§ 60.46 Test methods and procedures.

(b) For Method 5, Method 1 shall be used to select the sampling site and the number of traverse sampling points. The sampling time for each run shall be at least 60 minutes and the minimum sampling volume shall be 0.85 dscm (30 dscf) except that smaller sampling times or volumes, when necessitated by process

variables or other factors, may be approved by the Administrator. The probe and filter holder heating systems in the sampling train shall be set to provide a gas temperature no greater than 433°K (320°F).

(f) For each run using the methods specified by paragraphs (a) (3), (a) (4), and (a) (5) of this section, the emissions expressed in ng/J (lb/million Btu) shall be determined by the following procedure:

$$E = CF \frac{20.9}{20.9 - \text{percent } O_2}$$

where:

(1) E = pollutant emission ng/J (lb/million Btu).

(2) C = pollutant concentration, ng/dscm (lb/dscf), determined by method 5, 6, or 7.

(3) Percent O_2 = oxygen content by volume (expressed as percent), dry basis. Percent oxygen shall be determined by using the integrated or grab sampling and analysis procedures of Method 3 as applicable.

The sample shall be obtained as follows:

(g) When combinations of fossil fuels or fossil fuel and wood residue are fired, the heat input, expressed in watts (Btu/hr), is determined during each testing period by multiplying the gross calorific value of each fuel fired (in J/kg or Btu/lb) by the rate of each fuel burned (in kg/sec or lb/hr). Gross calorific values are determined in accordance with A.S.T.M. methods D 2015-66(72) (solid fuels), D 240-64(73) (liquid fuels), or D 1826-64(7) (gaseous fuels) as applicable. The method used to determine calorific value of wood residue must be approved by the Administrator. The owner or operator shall determine the rate of fuels burned during each testing period by suitable methods and shall confirm the

RULES AND REGULATIONS

rate by a material balance over the steam generation system.

(Sections 111, 114, and 301(a) of the Clean Air Act as amended by section 4(a) of Pub. L. 91-604, 84 Stat. 1678 and by section 15(c) (2) of Pub. L. 91-604, 84 Stat. 1713 (42 U.S.C. 1857c-6, 1857c-9, 1857g(a)).

50 Title 40—Protection of Environment

CHAPTER I—ENVIRONMENTAL

PROTECTION AGENCY

[FRL 639-2]

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Amendments to Reference Methods 13A and 13B

On August 6, 1975 (40 FR 33151), the Environmental Protection Agency (EPA) Promulgated Reference Methods 13A and 13B in Appendix A to 40 CFR Part 60. Methods 13A and 13B prescribe testing and analysis procedures for fluoride emissions from stationary sources. After promulgation of the methods, EPA continued to evaluate them and as a result has determined the need for certain amendments to improve the accuracy and precision of the methods.

Methods 13A and 13B require assembly of the fluoride sampling train so that the filter is located either between the third and fourth impingers or in an optional location between the probe and first impinger. They also specify that a fritted glass disc be used to support the filter. Since promulgation of the methods, EPA has found that when a glass frit filter support is used in the optional filter location, some of the fluoride sample is retained on the glass. Although no tests have been performed, it is believed that fluoride retention may also occur if a sintered metal frit filter support is used. However, in tests performed using a 20 mesh stainless steel screen as a filter support no fluoride retention was noted. Therefore, to eliminate the possibility of fluoride retention, sections 5.1.5 and 7.1.3 of Methods 13A and 13B are being revised to require the use of a 20 mesh stainless steel screen filter support if the filter is located between the probe and first impinger. If the filter is located in the normal position between the third and fourth impingers, the glass frit filter support may still be used.

In addition to the changes to sections 5.1.5 and 7.1.3, a few corrections are also being made. The amendments promulgated herein are effective on November 29, 1976. EPA finds that good cause exists for not publishing this action as a notice of proposed rulemaking and for making it effective immediately upon publication because:

1. The action is intended to improve the accuracy and precision of Methods 13A and 13B and does not alter the overall substantive content of the methods or the stringency of standards of performance for fluoride emissions.

2. The amended methods may be used immediately in source testing for fluoride emissions.

Dated: November 17, 1976.

JOHN QUARLES,
Acting Administrator.

In Part 60 of Chapter I, Title 40 of the Code of Federal Regulations, Appendix A is amended as follows:

1. Reference Method 13A is amended as follows:

(a) In section 3., the phrase "300 µg/liter" is corrected to read "300 mg/liter" and the parenthetical phrase "(see section 7.3.6)" is corrected to read "(see section 7.3.4)".

(b) Section 5.1.5 is revised to read as follows:

5.1.5 Filter holder—If located between the probe and first impinger, borosilicate glass with a 20 mesh stainless steel screen filter support and a silicone rubber gasket; neither a glass frit filter support nor a sintered metal filter support may be used if the filter is in front of the impingers. If located between the third and fourth impingers, borosilicate glass with a glass frit filter support and a silicone rubber gasket. Other materials of construction may be used with approval from the Administrator, e.g., if probe liner is stainless steel, then filter holder may be stainless steel. The holder design shall provide a positive seal against leakage from the outside or around the filter.

(c) Section 7.1.3 is amended by revising the first two sentences of the sixth paragraph to read as follows:

7.1.3 Preparation of collection train. . . .
Assemble the train as shown in Figure 13A-1 with the filter between the third and fourth impingers. Alternatively, the filter may be placed between the probe and first impinger if a 20 mesh stainless steel screen is used for the filter support. . . .

(d) In section 7.3.4, the reference in the first paragraph to "section 7.3.6" is corrected to read "section 7.3.5".

2. Reference Method 13B is amended as follows:

(a) In the third line of section 3, the phrase "300µg/liter" is corrected to read "300 mg/liter".

(b) Section 5.1.5 is revised to read as follows:

5.1.5 Filter holder—If located between the probe and first impinger, borosilicate glass with a 20 mesh stainless steel screen filter support and a silicone rubber gasket; neither a glass frit filter support nor a sintered metal filter support may be used if the filter is in front of the impingers. If located between the third and fourth impingers, borosilicate glass with a glass frit filter support and a silicone rubber gasket. Other materials of construction may be used with approval from the Administrator, e.g., if probe liner is stainless steel, then filter holder may be stainless steel. The holder design shall provide a positive seal against leakage from the outside or around the filter.

(c) Section 7.1.3 is amended by revising the first two sentences of the sixth paragraph to read as follows:

7.1.3 Preparation of collection train. . . .
Assemble the train as shown in Figure 13A-1 (Method 13A) with the filter between the third and fourth impingers. Alternatively, the filter may be placed between the probe and first impinger if a 20 mesh stainless steel screen is used for the filter support. . . .

(d) In section 7.3.4, the reference in the first paragraph to "section 7.3.6" is corrected to read "section 7.3.5".

(Secs. 111, 114, and 301(a) Clean Air Act, as amended by sec. 4(a) of Pub. L. 91-604, 84 Stat. 1678 and by sec. 15(c) (2) of Pub. L. 91-604, 84 Stat. 1713 (42 U.S.C. 1857c-6, 1957c-9, and 1857g(2)).)

Title 40—Protection of Environment
CHAPTER I—ENVIRONMENTAL
PROTECTION AGENCY
SUBCHAPTER C—AIR PROGRAMS
[FRL 651-5]

PART 60—STANDARDS OF PERFORM-
ANCE FOR NEW STATIONARY SOURCES

Delegation of Authority to Pima County
Health Department On Behalf of Pima
County Air Pollution Control District

Pursuant to the delegation of author-
ity for the standards of performance for
new stationary sources (NSPS) to the
Pima County Health Department on be-
half of the Pima County Air Pollution
Control District, dated October 7, 1976,
EPA is today amending 40 CFR 60.4
Address, to reflect this delegation. A
document announcing this delegation
is published today at 41 FR in the Notices
section of this issue. The amended
§ 60.4 is set forth below. It adds the ad-
dress of the Pima County Air Pollution
Control District, to which must be ad-
dressed all reports, requests, applications,
submittals, and communications pursu-
ant to this part by sources subject to the
NSPS located within this Air Pollution
Control District.

The Administrator finds good cause for
foregoing prior public notice and for
making this rulemaking effective imme-
diately in that it is an administrative
change and not one of substantive con-
tent. No additional substantive burdens
are imposed on the parties affected. The
delegation which is reflected by this ad-
ministrative amendment was effective on
October 7, 1976 and it serves no purpose
to delay the technical change on this
addition of the Air Pollution Control
District's address to the Code of Federal
Regulations.

This rulemaking is effective immedi-
ately, and is issued under the authority
of Section 111 of the Clean Air Act, as
amended (42 U.S.C. 1867c-6).

Dated: November 19, 1976.

R. L. O'CONNELL,
Acting Regional Administrator,
Environmental Protection
Agency, Region IX.

Part 60 of Chapter I, Title 40 of the
Code of Federal Regulations is amended
as follows:

1. In § 60.4 paragraph (b) is amended
by adding subparagraph D to read as
follows:

§ 60.4 Address.

• • • • •

(3) • • • • •

(A)-(C) • • • • •

D—Arizona

Pima County Air Pollution Control Dis-
trict, 151 West Congress Street, Tucson, AZ
85701.

RULES AND REGULATIONS

[FRL 657-3]

PART 60—STANDARDS OF PERFORM-
ANCE FOR NEW STATIONARY SOURCES

Delegation of Authority to State of Califor-
nia on Behalf of San Diego County Air
Pollution Control District

Pursuant to the delegation of authority
for the standards of performance for
new stationary sources (NSPS) to the
State of California on behalf of the San
Diego County Air Pollution Control Dis-
trict, dated November 8, 1976, EPA is
today amending 40 CFR 60.4 Address, to
reflect this delegation. A Notice announc-
ing this delegation is published in the
Notices section of this issue, under EPA
(FR Doc. 76-36929 at page 54798). The
amended § 60.4 is set forth below. It adds
the address of the San Diego County Air
Pollution Control District, to which must
be addressed all reports, requests, appli-
cations, submittals, and communications
pursuant to this part by sources subject
to the NSPS located within this Air Pol-
lution Control District.

The Administrator finds good cause
for foregoing prior public notice and for
making this rulemaking effective imme-
diately in that it is an administrative
change and not one of substantive con-
tent. No additional substantive burdens
are imposed on the parties affected. The
delegation which is reflected in this ad-
ministrative amendment was effective on
November 8, 1976 and it serves no pur-
pose to delay the technical change on
this addition of the Air Pollution Control
District's address to the Code of Federal
Regulations.

This rulemaking is effective immedi-
ately, and is issued under the authority
of section 111 of the Clean Air Act, as
amended (42 U.S.C. 1857c-6).

Dated: November 26, 1976.

SHELIA M. PRINDIRVILLE,
Acting Regional Administrator,
Environmental Protection
Agency, Region IX.

Part 60 of Chapter I, Title 40 of the
Code of Federal Regulations is amended
as follows:

1. In § 60.4 paragraph (b) is amended
by revising subparagraph F to read as
follows:

§ 60.4 Address.

• • • • •

RULES AND REGULATIONS

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES**Delegation of Authority to the State of Ohio**

Pursuant to the delegation of authority to implement the standards of performance for new stationary sources (NSPS) to the State of Ohio on August 4, 1976, EPA is today amending 40 CFR 60.4. Address to reflect this delegation. A Notice announcing this delegation is published in the Notices section of this issue of the FEDERAL REGISTER (FR Doc. 76-37487). The amended § 60.4 is set forth below which adds the addresses of the Agencies in Ohio which assist the State in the delegated authority to that list of addresses to which all reports, requests, applications, submittals, and communications to the Administrator pursuant to this part must be sent.

The Administrator finds good cause for foregoing prior notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegation which is reflected by this administrative amendment was effective on August 4, 1976, and it serves no purpose to delay the technical change of this addition of the addresses to the Code of Federal Regulations.

This rulemaking is effective immediately, and is issued under the authority of section 111 of the Clean Air Act, as amended.

(42 U.S.C. 1857c-6.)

Dated: December 10, 1976.

GEORGE R. ALEXANDER, JR.,
Regional Administrator.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

1. In § 60.4, paragraph (b) is amended by revising subparagraph KK, to read as follows:

§ 60.4 Address.

(b) . . .

(A)-(JJ) . . .

(KK) Ohio—

Medina, Summit and Portage Counties; Director, Air Pollution Control, 177 South Broadway, Akron, Ohio, 44308.

Stark County; Director, Air Pollution Control Division, Canton City Health Department, City Hall, 218 Cleveland Avenue SW, Canton, Ohio, 44702.

Butler, Clermont, Hamilton and Warren Counties; Superintendent, Division of Air Pollution Control, 2400 Beekman Street, Cincinnati, Ohio, 45214.

Cuyahoga County; Commissioner, Division of Air Pollution Control, Department of Public Health and Welfare, 2735 Broadway Avenue, Cleveland, Ohio, 44115.

Lorain County; Control Officer, Division of Air Pollution Control, 200 West Erie Avenue, 7th Floor, Lorain, Ohio, 44052.

Belmont, Carroll, Columbiana, Harrison, Jefferson, and Monroe Counties; Director, North Ohio Valley Air Authority (NOVAA), 814 Adams Street, Steubenville, Ohio, 43952.

Clark, Darke, Greene, Miami, Montgomery, and Preble Counties; Supervisor, Regional Air Pollution Control Agency (RAPCA), Montgomery County Health Department, 451 West Third Street, Dayton, Ohio, 45402.

Lucas County and the City of Rossford (in Wood County); Director, Toledo Pollution Control Agency, 26 Main Street, Toledo, Ohio, 43605.

Adams, Brown, Lawrence, and Scioto Counties; Engineer-Director, Air Division, Portsmouth City Health Department, 740 Second Street, Portsmouth, Ohio, 45662.

Allen, Ashland, Auglaize, Crawford, Defiance, Erie, Fulton, Hancock, Hardin, Henry, Huron, Knox, Marion, Mercer, Morrow, Ottawa, Paulding, Putnam, Richland, Sandusky, Seneca, Van Wert, Williams, Wood (except City of Rossford), and Wyandot Counties; Ohio Environmental Protection Agency, Northwest District Office, 111 West Washington Street, Bowling Green, Ohio, 43402.

Ashtabula, Geauga, Lake, Mahoning, Trumbull, and Wayne Counties; Ohio Environmental Protection Agency, Northeast District Office, 2110 East Aurora Road, Twinsburg, Ohio, 44087.

Athens, Coshocton, Gallia, Guernsey, Highland, Hocking, Holmes, Jackson, Meigs, Morgan, Muskingum, Noble, Perry, Pike, Ross, Tuscarawas, Vinton, and Washington Counties; Ohio Environmental Protection Agency, Southeast District Office, Route 3, Box 603, Logan, Ohio, 43138.

Champaign, Clinton, Logan, and Shelby Counties; Ohio Environmental Protection Agency, Southwest District Office, 7 East Fourth Street, Dayton, Ohio, 45402.

Delaware, Fairfield, Fayette, Franklin, Licking, Madison, Pickaway, and Union Counties; Ohio Environmental Protection Agency, Central District Office, 369 East Broad Street, Columbus, Ohio, 43215.

SUBCHAPTER C—AIR PROGRAMS

DELEGATION OF AUTHORITY—NEW SOURCE REVIEW

Delegation of Authority to the State of North Carolina

The amendments below institute certain address changes for reports and applications required from operators of new sources. EPA has delegated to the State of North Carolina authority to review new and modified sources. The delegated authority includes the reviews under 40 CFR Part 52 for the prevention of significant deterioration. It also includes the reviews under 40 CFR Part 60 for the standards of performance for new stationary sources and reviews under 40 CFR Part 61 for national emission standards for hazardous air pollutants.

A notice announcing the delegation of authority is published elsewhere in this issue of the FEDERAL REGISTER. These amendments provide that all reports, requests, applications, submittals, and communications previously required for the delegated reviews will now be sent instead to the North Carolina Environmental Management Commission, Department of Natural and Economic Resources, Division of Environmental Management, P.O. Box 27687, Raleigh, North Carolina 27611. Attention: Air Quality Section, instead of EPA's Region IV.

The Regional Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegation which is reflected by this administrative amendment was effective on November 24, 1976, and it serves no purpose to delay the technical change of this addition of the State address to the Code of Federal Regulations.

This rulemaking is effective immediately, and is issued under the authority of Sections 101, 110, 111, 112, and 301 of the Clean Air Act, as amended, 42 U.S.C. 1857, 1857c-5, 6, 7 and 1857g.

Dated: December 21, 1976.

JOHN A. LITTLE,
Deputy Regional Administrator.

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

2. Part 60 of Chapter I, Title 40, Code of Federal Regulations, is amended as follows: In § 60.4, paragraph (b) is amended by revising subparagraph (II) to read as follows:

§ 60.1 Address.

(b) . . .

(A)-(HH) . . .

(II) North Carolina Environmental Management Commission, Department of Natural and Economic Resources, Division of Environmental Management, P.O. Box 27687, Raleigh, North Carolina 27611. Attention: Air Quality Section.

SUBCHAPTER C—AIR PROGRAMS

[FRL 664-3]

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Delegation of Authority to State of Nebraska

Pursuant to the delegation of authority for the Standards of Performance for New Stationary Sources (NSPS), to the State of Nebraska on November 24, 1975, the Environmental Protection Agency (EPA) is today amending 40 CFR 60.4, [Address.], to reflect this delegation. A notice announcing this delegation is published (December 30, 1976), in the FEDERAL REGISTER. Effective immediately all requests, reports, applications, submittals, and other communications concerning the 12 source categories of the

RULES AND REGULATIONS

NSPS which were promulgated December 23, 1971, and March 8, 1974, shall be sent to Nebraska Department of Environmental Control (DEC), P.O. Box 94653, State House Station, Lincoln, Nebraska 68509. However, reports required pursuant to 40 CFR 60.7(a) shall be sent to EPA, Region VII, 1735 Baltimore, Kansas City, Missouri 64108, as well as to the State.

The Regional Administrator finds good cause for forgoing prior public notice and making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. This delegation, which is reflected by this administrative amendment, was effective on November 24, 1975, and it serves no purpose to delay the technical change of this addition of the State address to the Code of Federal Regulations.

This rulemaking is effective immediately, and is issued under the authority of Section 111 of the Clean Air Act, as amended.

(42 U.S.C. 1857c-6.)

Dated: December 20, 1976.

JEROME H. SVORE,
Regional Administrator.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

1. In § 60.4 paragraph (b) is amended by revising subparagraph (CC) to read as follows:

§ 60.4 Address.

(b)

(A)-(BB)

(CC) Nebraska Department of Environmental Control, P.O. Box 94653, State House Station, Lincoln, Nebraska 68509.

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Delegation of Authority to the State of Iowa

Pursuant to the delegation of authority for New Source Performance Standards (NSPS) to the State of Iowa on June 6, 1975, the Environmental Protection Agency is today amending 40 CFR 60.4, [Address.] to reflect this delegation. A notice announcing this delegation is published (December 30, 1976), in the FEDERAL REGISTER.

The amended § 60.4 provides that all reports, requests, applications, submittals, and other communications required for the 11 source categories of the NSPS, which were delegated to the State, shall be sent to the Iowa Department of Environmental Quality (DEQ), 3920 Delaware Avenue, P.O. Box 3326, Des Moines, Iowa 50316. However, reports required pursuant to 40 CFR 60.7(a) shall be sent to EPA, Region VII, 1735 Baltimore, Kansas City, Missouri 64108, as well as to the State.

The Regional Administrator finds good cause to forgo prior public notice and make this rulemaking effective immediately in that it is an administrative change and not one of substantive content. The delegation was effective June 6, 1975, and it serves no purpose to delay the technical change of the addition of the State address to the Code of Federal Regulations.

This rulemaking is effective immediately and is issued under the authority of Section 111 of the Clean Air Act, as amended.

(42 U.S.C. 1857c-6.)

Dated: December 20, 1976.

JEROME H. SVORE,
Regional Administrator.

Part 60 of Chapter 1, Title 40 of the Code of Federal Regulations is amended as follows:

1. In § 60.4, paragraph (b) is amended by revising subparagraph Q, to read as follows:

§ 60.4 Address.

(b)
(A)-(P)
(Q) State of Iowa, Department of Environmental Quality, 3920 Delaware, P.O. Box 3326, Des Moines, Iowa 50316.

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCE Delegation of Authority to State of Vermont

Pursuant to the delegation of authority for the Standards of Performance for New Stationary Sources (NSPS) to the State of Vermont on September 3, 1976, EPA is today amending 40 CFR 60.4, Address, to reflect this delegation. A notice announcing this delegation is published today in the FEDERAL REGISTER. (See FR Doc. 77-546 appearing in the Notices section of this issue). The amended § 60.4, which adds the address of the Vermont Agency of Environmental Protection to which all reports, requests, applications, submittals, and communications to the Administrator pursuant to this part must also be addressed, is set forth below.

The Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegation which is reflected by this administrative amendment was effective on September 3, 1976, and it serves no purpose to delay the technical change of this addition to the State address to the Code of Federal Regulations.

This rulemaking is effective immediately, and is issued under the authority of Section 111 of the Clean Air Act, as amended. 42 U.S.C. 1857c-6.

Dated: December 17, 1976.

JOHN A. S. MCGLENNON,
Regional Administrator.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

1. In § 60.4 paragraph (b) is amended by revising subparagraph (UU) to read as follows:

§ 60.4 Address.

(b)
(UU)—State of Vermont, Agency of Environmental Protection, Box 489, Montpelier, Vermont 05602.

NEW SOURCE REVIEW

Delegation of Authority to the State of
South Carolina

The amendments below institute certain address changes for reports and applications required from operators of new sources. EPA has delegated to the State of South Carolina authority to review new and modified sources. The delegated authority includes the reviews under 40 CFR Part 52 for the prevention of significant deterioration. It also includes the review under 40 CFR Part 60 for the standards of performance for new stationary sources and review under 40 CFR Part 61 for national emission standards for hazardous air pollutants.

A notice announcing the delegation of authority is published elsewhere in the notices section of this issue of the *FEDERAL REGISTER*. These amendments provide that all reports, requests, applications, submittals, and communications previously required for the delegated reviews will now be sent to the Office of Environmental Quality Control, Department of Health and Environmental Control, 2600 Bull Street, Columbia, South Carolina 29201, instead of EPA's Region IV.

The Regional Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegation which is reflected by this administrative amendment was effective on October 19, and it serves no purpose to delay the technical change of this addition of the State address to the Code of Federal Regulations.

This rulemaking is effective immediately, and is issued under the authority of sections 101, 110, 111, 112, and 301 of the Clean Air Act, as amended, 42 U.S.C. 1857c-5, 6, 7 and 1857g.

Dated: January 11, 1977.

JOHN A. LITTLE,
Acting Regional Administrator.

ENVIRONMENTAL PROTECTION
AGENCY

[FRL 675-4]

AIR PROGRAMS—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Receipt of Application and Approval of
Alternative Performance Test Method

On January 26, 1976 (41 FR 3826), the Environmental Protection Agency (EPA) promulgated standards of performance for new primary aluminum reduction plants under 40 CFR Part 60. The standards limit air emissions of gaseous and particulate fluorides from new and modified primary aluminum reduction plants. The owners or operators of affected facilities are required to determine compliance with these standards by conducting a performance test as specified in Appendix A—Reference Methods, Method 13A or 13B, "Determination of Total Fluoride Emissions from Stationary Sources" published in the *FEDERAL REGISTER* August 6, 1975 (40 FR 33157). As provided in 40 CFR 60.8(b), (2) and (3), the Administrator may approve the use of an equivalent test method or may approve the use of an alternative method if the method has been shown to be adequate for the determination of compliance with the standard. Method 13A specified that total fluorides be determined by the SPADNS Zirconium Lake colorimetric method, and Method 13B specified that this determination be made by the specific ion electrode method.

On September 3, 1976, EPA received written application for approval of equivalency for a third analytical technique from Kaiser Aluminum and Chemical Corporation, Oakland, California. Specifically, the application requested approval of ASTM Method D 3270-73T, "Tentative Method of Analysis for Fluoride Content of the Atmosphere and Plant Tissues," 1974 Annual Book of ASTM Standards—Part 26.

Specific guidelines for the determination of method equivalency have not been established by EPA. However, EPA has completed a technical review of the application and has determined that the ASTM method will produce results adequate for the determination of compliance with the standards of performance for new primary aluminum plants. Therefore, EPA approves the ASTM method as an alternative to the analytical procedures specified in paragraph 7.3 "Analysis" of Method 13A or 13B for aluminum plants, pursuant to 40 CFR 60.8(b)(3).

Dated: January 18, 1977.

ROGER STRELOW,
Assistant Administrator
for Air and Waste Management.

Title 40--Protection of Environment

CHAPTER I--ENVIRONMENTAL
PROTECTION AGENCY

[FRL 669-4]

PART 60--STANDARDS OF PERFORMANCE
FOR NEW STATIONARY SOURCESRevisions to Emission Monitoring
Requirements and to Reference Methods

On October 6, 1975 (40 FR 46250), under sections 111, 114, and 301 of the Clean Air Act, as amended, the Environmental Protection Agency (EPA) promulgated emission monitoring requirements and revisions to the performance testing Reference Methods in 40 CFR Part 60. Since that time, EPA has determined that there is a need for a number of revisions to clarify the requirements. Each of the revisions being made in 40 CFR Part 60 are discussed as follows:

1. *Section 60.13*. Paragraph (c) (3) has been rewritten to clarify that not only new monitoring systems but also upgraded monitoring systems must comply with applicable performance specifications.

Paragraph (e) (1) is revised to provide that data recording is not required more frequently than once every six minutes (rather than the previously required ten seconds) for continuous monitoring systems measuring the opacity of emissions. Since reports of excess emissions are based upon review of six-minute averages, more frequent data recording is not required in order to satisfy these monitoring requirements.

2. *Section 60.45*. Paragraphs (a) through (e) have been reorganized for clarification. In addition, restrictions on use of continuous monitoring systems for measuring oxygen on a wet basis have been removed. Prior to this revision, only dry basis oxygen monitoring equipment was acceptable. Procedures for use of wet basis oxygen monitoring equipment have been approved by EPA and were published in the FEDERAL REGISTER as an alternative procedure (41 FR 44838).

Also deleted from § 60.45 are restrictions on the location of a carbon dioxide (CO₂) continuous monitoring system downstream of wet scrubber flue gas desulfurization equipment. At the time the regulations were promulgated (October 6, 1975), EPA thought that limestone scrubbers were operated under conditions that could cause significant generation or absorption of CO₂ by the scrubbing solution which would cause errors in the monitoring results. EPA investigated this potential problem and concluded that lime or limestone scrubbers under typical conditions of operation do not significantly alter the concentration of CO₂ in the flue gas and would not introduce significant errors into the monitoring results. Lime scrubbers operate at a pH level between 7 and 8 which will maximize SO₂ absorption and minimize CO₂ absorption. Thus, the effect of CO₂ loss on the emission results is expected to be minimal. The exact amount of CO₂ loss, if any, during the scrubber operation has not been deter-

mined since it is dependent upon the operating conditions for a particular facility. Although each percent of CO₂ absorption will result in a positive bias of 7.1 percent (at a stack concentration of 14 percent CO₂) in the final emission results, i.e. the indicated results may be higher than actual stack concentrations, the actual bias is expected to be very small since the amount of CO₂ absorption will be much less than one percent.

In flue gases from limestone scrubbers, there exists a possibility of the addition of CO₂ from the scrubbing reaction to the CO₂ from the fuel combustion. Every two molecules of SO₂ reacting with the limestone will produce a molecule of CO₂. Limestone scrubbers are typically operated at an approximate temperature of 50° C under acidic conditions. At these operating conditions the amount of CO₂ generated in a 90 percent efficiency scrubber is 1350 ppm or 0.135 percent CO₂. This will introduce a negative bias of 1 to 1.5 percent for a CO₂ level of 8 to 15 percent. This amount of potential error compares favorably with systems previously approved. Therefore, EPA is removing the restrictions which limited the installation of carbon dioxide continuous monitoring systems to a location upstream of the scrubber.

Several other revisions are being made to paragraphs (a), (b), (c), and (e) of Subpart D which improve the clarity or further define the intent of the regulations. Paragraph (d) has been reserved for later addition of fuel monitoring provisions.

3. *Performance Specification 1*. Paragraph 6.2 has been rewritten to clarify requirements that must be met by continuous opacity monitor manufacturers. Manufacturers must certify that at least one analyzer from each month's production was tested and meets all applicable requirements. If any requirements are not met, the production for the month must be resampled according to military standard 105D (MIL-STD-105D) and retested. Previously the regulation required that each unit of production had to be tested. Copies of MIL-STD-105D may be purchased from the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

4. *Performance Specification 2*. Figure 2-3 of Performance Specification 2 has been corrected to properly define the term "mean differences." The corrections in the operations now conform with the statistical definitions of the specifications.

5. *General*. These amendments provide optional monitoring procedures that may be selected by an owner or operator of a facility affected by the monitoring requirements of 40 CFR Part 60. Certain editorial clarifications are also included. Proposal of these amendments is not necessary because the changes are either interpretative in nature, or represent minor changes in instrumentation testing and data recording, or allow a wider selection of equipment to be used. These changes will have no effect upon the number of emission sources that must be monitored or the quality of the resultant

emission data. The changes are consistent with recent determinations of the Administrator with respect to use of alternative continuous monitoring systems.

6. *Effective date*. These revisions become effective March 2, 1977.

(Secs. 111, 114, 301(a), Clean Air Act, as amended, Pub. L. 91-604, 84 Stat. 1678 (42 U.S.C. 1857c-6, 1857c-9, 1857g(a)).)

NOTE.—The Environmental Protection Agency has determined that this document does not contain a major proposal requiring preparation of an Inflation Impact Statement under Executive Order 11821 and OMB Circular A-107.

Dated: January 19, 1977.

JOHN QUARLES,
Acting Administrator.

In 40 CFR Part 60 Subpart A, Subpart D, and Appendix B are amended as follows:

Subpart A—General Provisions

1. Section 60.13 is amended by revising paragraphs (c) (3) and (e) (1) as follows:

§ 60.13 Monitoring requirements.

(c) * * *

(3) All continuous monitoring systems referenced by paragraph (c) (2) of this section shall be upgraded or replaced (if necessary) with new continuous monitoring systems, and the new or improved systems shall be demonstrated to comply with applicable performance specifications under paragraph (c) (1) of this section on or before September 11, 1979.

(e) * * *

(1) All continuous monitoring systems referenced by paragraphs (c) (1) and (c) (2) of this section for measuring opacity of emissions shall complete a minimum of one cycle of sampling and analyzing for each successive ten-second period and one cycle of data recording for each successive six-minute period.

Subpart D—Standards of Performance for
Fossil Fuel-Fired Steam Generators

2. Section 60.45 is amended by revising paragraphs (a), (b), (c), and (e) and by reserving paragraph (d) as follows:

§ 60.45 Emission and fuel monitoring.

(a) Each owner or operator shall install, calibrate, maintain, and operate continuous monitoring systems for measuring the opacity of emissions, sulfur dioxide emissions, nitrogen oxides emissions, and either oxygen or carbon dioxide except as provided in paragraph (b) of this section.

(b) Certain of the continuous monitoring system requirements under paragraph (a) of this section do not apply to owners or operators under the following conditions:

(1) For a fossil fuel-fired steam generator that burns only gaseous fossil fuel, continuous monitoring systems for measuring the opacity of emissions and sulfur dioxide emissions are not required.

RULES AND REGULATIONS

(2) For a fossil fuel-fired steam generator that does not use a flue gas desulfurization device, a continuous monitoring system for measuring sulfur dioxide emissions is not required if the owner or operator monitors sulfur dioxide emissions by fuel sampling and analysis under paragraph (d) of this section.

(3) Notwithstanding § 60.13(b), installation of a continuous monitoring system for nitrogen oxides may be delayed until after the initial performance tests under § 60.8 have been conducted. If the owner or operator demonstrates during the performance test that emissions of nitrogen oxides are less than 70 percent of the applicable standards in § 60.44, a continuous monitoring system for measuring nitrogen oxides emissions is not required. If the initial performance test results show that nitrogen oxide emissions are greater than 70 percent of the applicable standard, the owner or operator shall install a continuous monitoring system for nitrogen oxides within one year after the date of the initial performance tests under § 60.8 and comply with all other applicable monitoring requirements under this part.

(4) If an owner or operator does not install any continuous monitoring systems for sulfur oxides and nitrogen oxides, as provided under paragraphs (b) (1) and (b) (3) or paragraphs (b) (2) and (b) (3) of this section a continuous monitoring system for measuring either oxygen or carbon dioxide is not required.

(c) For performance evaluations under § 60.13(c) and calibration checks under § 60.13(d), the following procedures shall be used:

(1) Reference Methods 6 or 7, as applicable, shall be used for conducting performance evaluations of sulfur dioxide and nitrogen oxides continuous monitoring systems.

(2) Sulfur dioxide or nitric oxide, as applicable, shall be used for preparing calibration gas mixtures under Performance Specification 2 of Appendix B to this part.

(3) For affected facilities burning fossil fuel(s), the span value for a continuous monitoring system measuring the opacity of emissions shall be 80, 90, or 100 percent and for a continuous monitoring system measuring sulfur oxides or nitrogen oxides the span value shall be determined as follows:

[In parts per million]

Fossil fuel	Span value for sulfur dioxide	Span value for nitrogen oxides
Gas.....	(1)	500
Liquid.....	1,000	500
Solid.....	1,600	500
Combinations..	1,000y+1,500z	500(x+y)+1,000z

¹ Not applicable.

where:

x = the fraction of total heat input derived from gaseous fossil fuel, and
y = the fraction of total heat input derived from liquid fossil fuel, and
z = the fraction of total heat input derived from solid fossil fuel.

(4) All span values computed under paragraph (c)(3) of this section for burning combinations of fossil fuels shall be rounded to the nearest 500 ppm.

(5) For a fossil fuel-fired steam generator that simultaneously burns fossil fuel and nonfossil fuel, the span value of all continuous monitoring systems shall be subject to the Administrator's approval.

(d) [Reserved]

(e) For any continuous monitoring system installed under paragraph (a) of this section, the following conversion procedures shall be used to convert the continuous monitoring data into units of the applicable standards (ng/J, lb/million Btu):

(1) When a continuous monitoring system for measuring oxygen is selected, the measurement of the pollutant concentration and oxygen concentration shall each be on a consistent basis (wet or dry). Alternative procedures approved by the Administrator shall be used when measurements are on a wet basis. When measurements are on a dry basis, the following conversion procedure shall be used:

$$E = CF \left[\frac{20.9}{20.9 - \text{percent } O_2} \right]$$

where:

E, C, F, and %O₂ are determined under paragraph (f) of this section.

(2) When a continuous monitoring system for measuring carbon dioxide is selected, the measurement of the pollutant concentration and carbon dioxide concentration shall each be on a consistent basis (wet or dry) and the fol-

lowing conversion procedure shall be used:

$$E = CF \left[\frac{100}{\text{percent CO}_2} \right]$$

where:

E, C, F, and %CO₂ are determined under paragraph (f) of this section.

APPENDIX B—PERFORMANCE SPECIFICATIONS

3. Performance Specification 1 is amended by revising paragraph 6.2 as follows:

6. . . .

6.2 Conformance with the requirements of section 6.1 may be demonstrated by the owner or operator of the affected facility by testing each analyzer or by obtaining a certificate of conformance from the instrument manufacturer. The certificate must certify that at least one analyzer from each month's production was tested and satisfactorily met all applicable requirements. The certificate must state that the first analyzer randomly sampled met all requirements of paragraph 6 of this specification. If any of the requirements were not met, the certificate must show that the entire month's analyzer production was resampled according to the military standard 105D sampling procedure (MIL-STD-105D) inspection level II; was retested for each of the applicable requirements under paragraph 6 of this specification; and was determined to be acceptable under MIL-STD-105D procedures. The certificate of conformance must show the results of each test performed for the analyzers sampled during the month the analyzer being installed was produced.

4. Performance Specification 2 is amended by revising Figure 2-3 as follows:

Test No.	Date and Time	Reference Method Samples					Analyzer 1-Hour Average (ppm)*	Difference (ppm)
		SO ₂ Sample 1 (ppm)	NO Sample 1 (ppm)	NO Sample 2 (ppm)	NO Sample 3 (ppm)	NO Sample Average (ppm)		
1								
2								
3								
4								
5								
6								
7								
8								
9								
Mean reference method test value (SO ₂)		Mean reference method test value (NO _x)					Mean of the differences

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Delegation of Authority to City of Philadelphia

Pursuant to the delegation of authority for the standards of performance for new stationary sources (NSPS) to the City of Philadelphia on September 30, 1976, EPA is today amending 40 CFR 60.4, Address, to reflect this delegation. For a notice announcing this delegation, see FR Doc. 77-3712 published in the Notices section of today's FEDERAL REGISTER. The amended § 60.4, which adds the address of the Philadelphia Department of Public Health, Air Management Services, to which all reports, requests, applications, submittals, and communications to the Administrator pursuant to this part must also be addressed, is set forth below.

The Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegation which is reflected by this Administrative amendment was effective on September 30, 1976, and it serves no purpose to delay the technical change of this address to the Code of Federal Regulations.

This rulemaking is effective immediately, and is issued under the authority of section 111 of the Clean Air Act, as amended, 42 U.S.C. 1857c-6.

Dated: January 25, 1977.

A. R. MORRIS,
Acting Regional Administrator.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

1. In § 60.4, paragraph (b) is amended by revising subparagraph (NN) to read as follows:

§ 60.4 Address.

(b)
(A)-(MM)
(NN) (a) City of Philadelphia: Philadelphia Department of Public Health, Air Management Services, 801 Arch Street, Philadelphia, Pennsylvania 19107.

[FR Doc. 77-3709 Filed 2-3-77; 8:45 am]

FEDERAL REGISTER, VOL. 42, NO. 24

FRIDAY, FEBRUARY 4, 1977

59

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Region V Address; Correction

Section 60.4 paragraph (a) is corrected by changing Region V (Illinois, Indiana, Minnesota, Michigan, Ohio, Wisconsin), 1 North Wacker Drive, Chicago, Illinois 60606 to Region V (Illinois, Indiana, Minnesota, Michigan, Ohio, Wisconsin), 230 South Dearborn Street, Chicago, Illinois 60604.

Dated: March 21, 1977.

GEORGE R. ALEXANDER, Jr.,
Regional Administrator.

[FR Doc. 77-9406 Filed 3-29-77; 8:45 am]

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Delegation of Authority to the State of Wisconsin

Pursuant to the delegation of authority for the standards of performance for new stationary sources (NSPS) to the State of Wisconsin on September 28, 1976, EPA is today amending 40 CFR 60.4, Address, to reflect this delegation. A Notice announcing this delegation is published today, March 30, 1977, at 42 FR 16845 in this FEDERAL REGISTER. The amended § 60.4, which adds the address of the Wisconsin Department of Natural Resources to which all reports, requests, applications, submittals, and communications to the Administrator pursuant to this part must also be addressed, is set forth below.

The Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegation which is reflected by this administrative amendment was effective on September 28, 1976 and it serves no purpose to delay the technical change of this addition of the State address to the Code of Federal Regulations.

This rulemaking is effective immediately, and is issued under the authority of section 111 of the Clean Air Act, as amended, 42 U.S.C. 1857c-6.

Dated: March 21, 1977.

GEORGE R. ALEXANDER, Jr.,
Regional Administrator.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

1. In § 60.4 paragraph (b) is amended by revising subparagraph (YY), to read as follows:

§ 60.4 Address.

(b)
(A)-(XX)
(YY) Wisconsin—
Wisconsin Department of Natural Resources,
P.O. Box 7921, Madison, Wisconsin 53707.

[FR Doc. 77-9404 Filed 3-29-77; 8:45 am]

FEDERAL REGISTER, VOL. 42, NO. 61—WEDNESDAY, MARCH 30, 1977

Title 40—Protection of Environment

CHAPTER 1—ENVIRONMENTAL PROTECTION AGENCY

[FRL 715-8]

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Compliance With Standards and Maintenance Requirements

AGENCY: Environmental Protection Agency.

ACTION: Final rule.

SUMMARY: This action amends the general provisions of the standards of performance to allow methods other than Reference Method 9 to be used as a means of measuring plume opacity. The Environmental Protection Agency (EPA) is investigating a remote sensing laser radar system of measuring plume opacity and believes it could be considered as an alternative method to Reference Method 9. This amendment would allow EPA to propose such systems as alternative methods in the future.

EFFECTIVE DATE: June 22, 1977.

FOR FURTHER INFORMATION CONTACT:

Don R. Goodwin, Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone no. 919-688-8146, ext. 271.

SUPPLEMENTARY INFORMATION: As originally expressed, 40 CFR 60.11(b) permitted the use of Reference Method 9 exclusively for determining whether a source complied with an applicable opacity standard. By this action, EPA amends § 60.11(b) so that alternative methods approved by the Administrator may be used to determine opacity.

When § 60.11(b) was originally promulgated, the visible emissions (Method 9) technique of determining plume opacity with trained visible emission observers was the only expedient and accurate method available to enforcement personnel. Recently, EPA funded the development of a remote sensing laser radar system (LIDAR) that appears to produce results adequate for determination of compliance with opacity standards. EPA is currently evaluating the equipment and is considering proposing its use as an alternative technique of measuring plume opacity.

This amendment will allow EPA to consider use of the LIDAR method of determining plume opacity and, if appropriate, to approve this method for enforcement of opacity regulations. If this method appears to be a suitable alternative to Method 9, it will be proposed in the FEDERAL REGISTER for public comment. After considering comments, EPA will determine if the new method will be an acceptable means of determining opacity compliance.

(Secs. 111, 114, 301(a), Clean Air Act, sec. 4(a) of Pub. L. 91-604, 84 Stat. 1683; sec. 4(a) of Pub. L. 91-604, 84 Stat. 1687; sec. 2 of Pub. L. No. 90-148, 81 Stat. 504 (42 U.S.C. 1857c-6, 1857c-9 and 1857g(a)).)

NOTE—Economic Impact Analysis: The Environmental Protection Agency has determined that this action does not contain a major proposal requiring preparation of an Economic Impact Analysis under Executive Orders 11821 and 11949 and OMB Circular A-107.

Dated: May 10, 1977.

DOUGLAS M. COSTLE,
Administrator.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

1. Section 60.11 is amended by revising paragraph (b) as follows:

§ 60.11 Compliance with standards and maintenance requirements.

(b) Compliance with opacity standards in this part shall be determined by conducting observations in accordance with Reference Method 9 in Appendix A of this part or any alternative method that is approved by the Administrator. Opacity readings of portions of plumes which contain condensed, uncombined water vapor shall not be used for purposes of determining compliance with opacity standards. The results of continuous monitoring by transmissometer which indicate that the opacity at the time visual observations were made was not in excess of the standard are probative but not conclusive evidence of the actual opacity of an emission, provided that the source shall meet the burden of proving that the instrument used meets (at the time of the alleged violation) Performance Specification 1 in Appendix B of this part, has been properly maintained and (at the time of the alleged violation) calibrated, and that the resulting data have not been tampered with in any way.

(Secs. 111, 114, 301(a), Clean Air Act, Sec. 4(a) of Pub. L. 91-604, 84 Stat. 1683; sec. 4(a) of Pub. L. 91-604, 84 Stat. 1687; sec. 2 of Pub. L. No. 90-148, 81 Stat. 504 (42 U.S.C. 1857c-6, 1857c-9, 1857g(a)).)

[FR Doc. 77-14562 Filed 5-20-77; 8:45 am]

Title 40—Protection of Environment

CHAPTER 1—ENVIRONMENTAL PROTECTION AGENCY

[FRL 742-8]

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Petroleum Refinery Fluid Catalytic Cracking Unit Catalyst Regenerators

AGENCY: Environmental Protection Agency.

ACTION: Final rule.

SUMMARY: This rule revises the standard which limits the opacity of omissions from new, modified, or reconstructed petroleum refinery fluid catalytic cracking unit catalyst regenerators to 30 percent, except for one six-minute period in any one hour. The revision is being made to make the standard consistent with a revision to the test method for opacity. The standard implements the Clean Air Act and is intended to require the proper operation and maintenance of fluid catalytic cracking unit catalyst regenerators.

EFFECTIVE DATE: June 24, 1976.

ADDRESSES: Copies of the comment letters and a report which contains a summary of the issues and EPA's responses are available for public inspection and copying at the U.S. Environmental Protection Agency, Public Information Reference Unit (EPA Library), Room 2922, 401 M Street SW., Washington, D.C. Copies of the report also may be obtained upon written request from the EPA Public Information Center (PM-315), Washington, D.C. 20460 (specify Comment Summary—Petroleum Refinery Fluid Catalytic Cracking Units).

FOR FURTHER INFORMATION CONTACT:

Don R. Goodwin, Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone number 919-688-8146, extension 271.

SUPPLEMENTARY INFORMATION:

BACKGROUND

On June 29, 1973, the U.S. Court of Appeals for the District of Columbia Circuit remanded to EPA the standards of performance for Portland cement plants (*Portland Cement Association v. Ruckelshaus*, 486 F.2d 375). One of the issues remanded was the use of opacity standards. On November 12, 1974, EPA responded to the remand (39 FR 39872) and on May 22, 1975, the Court affirmed the use of opacity standards (513 F.2d 506).

In the remand response, EPA reconsidered the use of opacity standards and concluded that they are a reliable, inexpensive, and useful means of ensuring that control equipment is properly maintained and operated at all times. EPA also made revisions to the general pro-

RULES AND REGULATIONS

visions of 40 CFR Part 60 and to the Reference Method 9.

EPA reevaluated the opacity standard for petroleum refinery fluid catalytic cracking unit catalyst regenerators in light of the revisions to Reference Method 9, and proposed a revision to this standard on August 30, 1976 (41 FR 36600). The revision is not the result of a reevaluation of the technical, economic and environmental basis for the standard. Consequently, the revised opacity standard will be neither more nor less stringent than the previous standard, and will be consistent with the mass emission standard (1.0 kg/1000 kg of coke burnoff).

SUMMARY OF COMMENTS AND EPA'S RESPONSES

EPA received six letters commenting on the proposed revision (three from industry and three from State and local governments). Two commenters pointed out that the basis for the original opacity standard assumed new fluid catalytic cracking units would be of 65,000 barrels per day capacity, but the proposed revision assumed new fluid catalytic cracking units would be of less than 50,000 barrels per day capacity. Two other commenters pointed out that the original standard allowed one three-minute exception from the opacity standard of performance to accommodate soot-blowing in the carbon monoxide boiler and that the proposed change to six-minute averages did not justify adding an additional exception.

A review of the basis for the original opacity standard indicates the commenters are correct. Large, new or modified fluid catalytic cracking units will more likely be in the range of 65,000 barrels per day capacity, and one exception per hour more accurately reflects the one three-minute exception allowed under the previous test method. The effect of increased capacity on the opacity of particulate mass emissions was discussed both in the FEDERAL REGISTER notice proposing revision of the opacity standard and in the background information document supporting the revision. Considering the effect on opacity of the greater capacity of a 65,000-barrel-per-day fluid catalytic cracking unit compared to a 50,000-barrel-per-day unit leads to the conclusion that the opacity standard should not be revised to 25 percent, but should remain at 30 percent opacity. Accordingly, the revised opacity standard is promulgated as 30 percent opacity with one six-minute exception period per hour.

One comment concerned § 60.11(e) of the General Provisions and questioned whether in its present form it adequately accounts for the problems of petroleum refinery fluid catalytic cracking units. Section 60.11(e) provides relief for those individual sources where, because of operating variables, opacity readings are abnormally high and cause it to exceed the standard, even though it is in compliance with the mass emission stand-

ard. The mechanism for relief is that opacity readings may be taken during initial start-up mass emission testing and a special opacity standard assigned to the source.

Petroleum refinery fluid catalytic cracking units operate continuously for periods of two years or more; and over such long periods, mass and opacity emissions gradually increase. For this reason, the mass and opacity standards were set on the basis of levels achievable at the end of the run. It is to be expected, therefore, that at the beginning of the run, both mass and opacity emissions from such units will be well below the standard, even in some cases where opacity readings are abnormally high given the mass emissions. In such cases, an individualized opacity standard based on beginning-of-run readings would not necessarily prevent the facility which still meets the mass emissions standard at the end of the run from failing an end-of-run opacity test. To alleviate this problem, EPA is adding a new § 60.106 (e) to the petroleum refinery standard which, in conjunction with §§ 60.11 (e) (2), (e) (3), and (e) (4) of the General Provisions, will permit determination of an individualized opacity standard for a fluid catalytic cracking unit during any performance test and not just the initial performance test. This will ensure that a properly operated and maintained source will not be found in violation of the opacity standard, while in compliance with the applicable mass emission standard.

The proposed amendment to § 60.102 (a) (2) specified that opacity readings of portions of plumes which contain condensed, uncombined water vapor are not to be used for determining compliance with opacity standards. Since this provision has been added to § 60.11 (b) of the General Provisions, it is not necessary to repeat it in Subpart J for petroleum refineries.

MISCELLANEOUS

The opacity standard, as modified, applies to all affected facilities for which construction or modification was commenced after June 11, 1973, the date the standard was proposed.

This revision is promulgated under the authority of sections 111, 114, and 301 (a) of the Clean Air Act, as amended by Public Law 91-604, 84 Statute 1683, 1687 (42 U.S.C. 1857c-6, 1857c-9) and Public Law 90-148, 81 Statute 504 (42 U.S.C. 1857g(a)).

NOTE.—The Environmental Protection Agency has determined that this document does not contain a major proposal requiring preparation of an Economic Impact Statement under Executive Orders 11821 and 11949, and OMB Circular R-107.

Dated: June 24, 1977.⁶⁵

DOUGLAS M. COSTLE,
Administrator.

Part 60, Chapter I of Title 40 of the Code of Federal Regulations is amended as follows:

1. Section 60.102(a) (2) is revised to read as follows:

§ 60.102 Standard for particulate matter.

(a)

(2) Gases exhibiting greater than 30 percent opacity, except for one six-minute average opacity reading in any one hour.

(Sec. 111, Pub. L. 91-604, 84 Stat. 1683 (42 U.S.C. 1857c-6); sec. 301(a), Pub. L. 90-148, 81 Stat. 504 (42 U.S.C. 1857g(a)).)

2. Section 60.105(e) (1) is revised to read as follows:

§ 60.105 Emission monitoring.

(e)

(1) Opacity. All hourly periods which contain two or more six-minute periods during which the average opacity as measured by the continuous monitoring system exceeds 30 percent.

3. Section 60.106(e) is added to read as follows:

§ 60.106 Test methods and procedures.

(e) An owner or operator of an affected facility may request the Administrator to determine opacity of emissions from the affected facility during any performance test covered under § 60.8. In such event the provisions of §§ 60.11 (e) (2), (e) (3), and (e) (4) shall apply.

(Sec. 111, 114, Pub. L. 91-604, 84 Stat. 1683, 1687 (42 U.S.C. 1857c-6, 1857c-9); sec. 301(a), Pub. L. 90-148, 81 Stat. 504 (42 U.S.C. 1857g(a)).)

[FR Doc. 77-18129 Filed 6-23-77; 8:45 am]

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Units and Abbreviations

AGENCY: Environmental Protection Agency

ACTION: Final rule

SUMMARY: This action revises the General Provisions by reorganizing the units and abbreviations and adding the International System of Units (SI). Until recently, EPA did not have a preferred system of measurement to be used in its regulations. Now the Agency is using SI units in all regulations issued under this part. This necessitates that SI units be added to the General Provisions to provide a complete listing of abbreviations used.

EFFECTIVE DATE: August 18, 1977.

FOR FURTHER INFORMATION CONTACT:

Don R. Goodwin, Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone no. 919-541-5271.

SUPPLEMENTARY INFORMATION:

BACKGROUND

Section 3 of Pub. L. 94-168, the Metric Conversion Act of 1975, declares that the policy of the United States shall be to coordinate and plan the increasing use of the metric system in the United States. On December 10, 1976, a notice was published in the *FEDERAL REGISTER* (41 FR 54018) that set forth the interpretation and modification of the International System of Units (SI) for the United States. EPA incorporates SI units in all regulations issued under 40 CFR Part 60 and provides common equivalents in parentheses where desirable. Use of SI units requires this revision of the abbreviations section (§ 60.3) of the General Provisions of 40 CFR Part 60.

REFERENCE DOCUMENTS

An explanation of the International Systems of Units was presented in the *FEDERAL REGISTER* notice mentioned above (41 FR 54018). The Environmental Protection Agency is using the Standard for Metric Practice (E 380-76) published by the American Society for Testing and Materials (A.S.T.M.) as its basic reference. This document may be obtained by sending \$4.00 to A.S.T.M., 1916 Race Street, Philadelphia, Pennsylvania 19103.

MISCELLANEOUS

As this revision has no regulatory impact, but only defines units and abbrevi-

RULES AND REGULATIONS

ations used in this part, opportunity for public participation was judged unnecessary.

(Sections 111 and 301(a) of the Clean Air Act; sec. 4(a) of Pub. L. 91-604, 84 Stat. 1683; sec. 2 of Pub. L. 90-148, 81 Stat. 504 (42 U.S.C. 1857c-6, 1857g(a)).)

NOTE:—The Environmental Protection Agency has determined that this document does not contain a major proposal requiring preparation of an Economic Impact Analysis under Executive Orders 11821 and 11949 and OMB Circular A-107.

Dated: July 8, 1977.

DOUGLAS M. COSTLE,
Administrator.

40 CFR Part 60 is amended by revising § 60.3 to read as follows:

§ 60.3 Units and abbreviations.

Used in this part are abbreviations and symbols of units of measure. These are defined as follows:

(a) System International (SI) units of measure:

A—ampere
g—gram
Hz—hertz
J—joule
K—degree Kelvin
kg—kilogram
m—meter
m³—cubic meter
mg—milligram—10⁻³ gram
mm—millimeter—10⁻³ meter
Mg—megagram—10⁶ gram
mol—mole
N—newton
ng—nanogram—10⁻⁹ gram
nm—nanometer—10⁻⁹ meter
Pa—pascal
s—second
V—volt
W—watt
Ω—ohm
μg—microgram—10⁻⁶ gram

(b) Other units of measure:

Btu—British thermal unit
°C—degree Celsius (centigrade)
cal—calorie
cfm—cubic feet per minute
cu ft—cubic feet
dcf—dry cubic feet
dcm—dry cubic meter
dcf—dry cubic feet at standard conditions
dcm—dry cubic meter at standard conditions
eq—equivalent
°F—degree Fahrenheit
ft—feet
gal—gallon
gr—grain
g—gram
g—eq—gram equivalent
hr—hour
in—inch
K—1,000
l—liter
lpm—liter per minute
lb—pound
meq—milliequivalent
min—minute

ml—milliliter
mol. wt.—molecular weight
ppb—parts per billion
ppm—parts per million
psia—pounds per square inch absolute
psig—pounds per square inch gage
°R—degree Rankine
scf—cubic feet at standard conditions
scfh—cubic feet per hour at standard conditions
scm—cubic meter at standard conditions
sec—second
sq ft—square feet
std—at standard conditions

(c) Chemical nomenclature:

CdS—cadmium sulfide
CO—carbon monoxide
CO₂—carbon dioxide
HCl—hydrochloric acid
Hg—mercury
H₂O—water
H₂S—hydrogen sulfide
H₂SO₄—sulfuric acid
N₂—nitrogen
NO—nitric oxide
NO₂—nitrogen dioxide
NO_x—nitrogen oxides
O₂—oxygen
SO₂—sulfur dioxide
SO₃—sulfur trioxide
SO_x—sulfur oxides

(d) Miscellaneous:

A.S.T.M.—American Society for Testing and Materials

(Sections 111 and 301(a) of the Clean Air Act; sec. 4(a) of Pub. L. 91-604, 84 Stat. 1683; sec. 2 of Pub. L. 90-148, 81 Stat. 504 (42 U.S.C. 1857c-6, 1857g(a)).)

[FR Doc. 77-20557 Filed 7-18-77; 8:45 am]

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES**Delegation of Authority to the State of New Jersey**

AGENCY: Environmental Protection Agency.

ACTION: Final Rule.

SUMMARY: A notice announcing EPA's delegation of authority for the New Source Performance Standards to the State of New Jersey is published at page 37387 of today's *FEDERAL REGISTER*. In order to reflect this delegation, this document amends EPA regulations to require the submission of all notices, reports, and other communications called for by the delegated regulations to the State of New Jersey rather than to EPA.

EFFECTIVE DATE: July 21, 1977.

FOR FURTHER INFORMATION CONTACT:

J. Kevin Healy, Attorney, U.S. Environmental Protection Agency, Region II, General Enforcement Branch, Enforcement Division, 26 Federal Plaza, New York, New York 10007, 212-264-1196).

SUPPLEMENTARY INFORMATION: On May 9, 1977 EPA delegated authority to the State of New Jersey to implement and enforce the New Source Performance Standards. A full account of the background to this action and of the exact terms of the delegation appear in the Notice of Delegation which is also published in today's *FEDERAL REGISTER*.

This rulemaking is effective immediately, since the Administrator has found good cause to forego prior public notice. This addition of the State of New Jersey address to the Code of Federal Regulations is a technical change and imposes no additional substantive burden on the parties affected.

Dated: July 18, 1977.

BARBARA BLUM,
Acting Administrator.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended under authority of Section 111 of the Clean Air Act (42 U.S.C. 1857c-6), as follows:

(1) In § 60.4 paragraph (b) is amended by revising subparagraph (FF) to read as follows:

§ 60.4 Address.

• • • • •
(b) • • • • •

(FF)—State of New Jersey: New Jersey Department of Environmental Protection, John Fitch Plaza, P.O. Box 2807, Trenton, New Jersey 08625.

[FR Doc. 77-21020 Filed 7-20-77; 8:45 am]

RULES AND REGULATIONS**PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES****Applicability Dates**

AGENCY: Environmental Protection Agency.

ACTION: Final rule.

SUMMARY: This action incorporates into the regulations the dates on which the standards of performance are applicable. The dates were not a part of the regulations at the time of their promulgation and considerable confusion exists over when the standards apply. This action removes the confusion and makes future enforcement of the standards easier.

EFFECTIVE DATE: August 24, 1977.

FOR FURTHER INFORMATION CONTACT:

Don. R. Goodwin, Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone 919-541-5271.

SUPPLEMENTARY INFORMATION: Section 111 of the Clean Air Act provides that "new source" under that section means "any stationary source, the construction or modification of which is commenced after the publication of regulations (or, if earlier, proposed regulations) prescribing a standard of performance which will be applicable to such source." Thus, for standards of performance under section 111, the proposal date (or, in the event there was no proposal, the promulgation date) of a standard constitutes its applicability date. While this information is contained in the "Applicability" section (§ 60.2) of the General Provisions, the Agency has not, until now, incorporated in the regulations the specific applicability date(s) for each standard.

The absence of these dates from the various regulations has led to some confusion. The most frequent mistake is for the applicability date to be confused with the effective date. The effective date is the day on which the regulation becomes law (usually the day the final regulation is published in the *FEDERAL REGISTER*). The effective date has customarily been noted in the preamble to the final regulation when it appears in the *FEDERAL REGISTER*. A regulation, then, usually becomes effective upon promulgation and applies to sources constructed or modified after the proposal date.

In view of past confusion and the growing number of regulations, including revisions and amendments, the Agency has decided to hereafter incorporate the applicability date(s) under the "Applicability and designation of affected facility" section of each subpart. This action should serve to clarify which

facilities are affected by these regulations. This amendment provides clarification of the applicability dates only for the standards promulgated to date. An applicability statement will be added to regulations under proposal and to future regulations at the time of promulgation.

MISCELLANEOUS

As this action has no regulatory impact, but only sets forth applicability dates for the purpose of clarification, public participation was judged unnecessary.

(Secs. 111 and 301(a) of the Clean Air Act; sec. 4(a) of Pub. L. 91-604, 84 Stat. 1683; sec. 2 of Pub. L. 90-148, 81 Stat. 504 (42 U.S.C. 1857c-6, 1857g(a)).)

NOTE.—The Environmental Protection Agency has determined that this document does not contain a major proposal requiring preparation of an Economic Impact Analysis under Executive Orders 11821 and 11849 and OMB Circular A-107.

Dated: July 18, 1977.

BARBARA BLUM,
Acting Administrator.

40 CFR Part 60 is amended by revising Subparts D through AA as follows:

Subpart D—Standards of Performance for Fossil-Fuel-Fired Steam Generators

1. Section 60.40 is revised as follows:

§ 60.40 Applicability and designation of affected facility.

(a) The affected facilities to which the provisions of this subpart apply are:

(1) Each fossil-fuel-fired steam generating unit of more than 73 megawatts heat input rate (250 million Btu per hour).

(2) Each fossil-fuel and wood-residue-fired steam generating unit capable of firing fossil fuel at a heat input rate of more than 73 megawatts (250 million Btu per hour).

(b) Any change to an existing fossil-fuel-fired steam generating unit to accommodate the use of combustible materials, other than fossil fuels as defined in this subpart, shall not bring that unit under the applicability of this subpart.

(c) Any facility under paragraph (a) of this section that commences construction or modification after August 17, 1971, is subject to the requirements of this subpart.

Subpart E—Standards of Performance for Incinerators

2. Section 60.50 is revised as follows:

§ 60.50 Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to each incinerator of more than 45 metric tons per day charging rate (50 tons/day), which is the affected facility.

RULES AND REGULATIONS

(b) Any facility under paragraph (a) of this section that commences construction or modification after August 17, 1971, is subject to the requirements of this subpart.

Subpart F—Standards of Performance for Portland Cement Plants

3. Section 60.60 is revised as follows:

§ 60.60 Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to the following affected facilities in portland cement plants: kiln, clinker cooler, raw mill system, finish mill system, raw mill dryer, raw material storage, clinker storage, finished product storage, conveyor transfer points, bagging and bulk loading and unloading systems.

(b) Any facility under paragraph (a) of this section that commences construction or modification after August 17, 1971, is subject to the requirements of this subpart.

Subpart G—Standards of Performance for Nitric Acid Plants

4. Section 60.70 is revised as follows:

§ 60.70 Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to each nitric acid production unit, which is the affected facility.

(b) Any facility under paragraph (a) of this section that commences construction or modification after August 17, 1971, is subject to the requirements of this subpart.

Subpart H—Standards of Performance for Sulfuric Acid Plants

5. Section 60.80 is revised as follows:

§ 60.80 Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to each sulfuric acid production unit, which is the affected facility.

(b) Any facility under paragraph (a) of this section that commences construction or modification after August 17, 1971, is subject to the requirements of this subpart.

Subpart I—Standards of Performance for Asphalt Concrete Plants

6. Section 60.90 is revised as follows:

§ 60.90 Applicability and designation of affected facility.

(a) The affected facility to which the provisions of this subpart apply is each asphalt concrete plant. For the purpose of this subpart, an asphalt concrete plant is comprised only of any combination of the following: dryers; systems for screening, handling, storing, and weighing hot aggregate; systems for loading, transferring, and storing mineral filler; systems for mixing asphalt concrete; and the loading, transfer, and storage systems associated with emission control systems.

Subpart J—Standards of Performance for Petroleum Refineries

7. Section 60.100 is revised as follows:

§ 60.100 Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to the following affected facilities in petroleum refineries: fluid catalytic cracking unit catalyst regenerators, fluid catalytic cracking unit incinerator-waste heat boilers, and fuel gas combustion devices.

(b) Any facility under paragraph (a) of this section that commences construction or modification after June 11, 1973, is subject to the requirements of this subpart.

Subpart K—Standards of Performance for Storage Vessels for Petroleum Liquids

8. Section 60.110 is revised as follows:

§ 60.110 Applicability and designation of affected facility.

(a) Except as provided in § 60.110(b), the affected facility to which this subpart applies is each storage vessel for petroleum liquids which has a storage capacity greater than 151,412 liters (40,000 gallons).

(b) This subpart does not apply to storage vessels for petroleum or condensate stored, processed, and/or treated at a drilling and production facility prior to custody transfer.

(c) Subject to the requirements of this subpart is any facility under paragraph (a) of this section which:

(1) Has a capacity greater than 151,412 liters (40,000 gallons), but not exceeding 245,000 liters (65,000 gallons), and commences construction or modification after March 8, 1974.

(2) Has a capacity greater than 245,000 liter (65,000 gallons), and commences construction or modification after June 11, 1973.

Subpart L—Standards of Performance for Secondary Lead Smelters

9. Section 60.120 is revised as follows:

§ 60.120 Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to the following affected facilities in secondary lead smelters: pot furnaces of more than 250 kg (550 lb) charging capacity, blast (cupola) furnaces, and reverberatory furnaces.

(b) Any facility under paragraph (a) of this section that commences construction or modification after June 11, 1973, is subject to the requirements of this subpart.

Subpart M—Standards of Performance for Secondary Brass and Bronze Ingot Production Plants

10. Section 60.130 is revised as follows:

§ 60.130 Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to the following affected fa-

cilities in secondary brass or bronze ingot production plants: reverberatory and electric furnaces of 1,000 kg (2,205 lb) or greater production capacity and blast (cupola) furnaces of 250 kg/hr (550 lb/hr) or greater production capacity.

(b) Any facility under paragraph (a) of this section that commences construction or modification after June 11, 1973, is subject to the requirements of this subpart.

Subpart N—Standards of Performance for Iron and Steel Plants

11. Section 60.140 is revised as follows:

§ 60.140 Applicability and designation of affected facility.

(a) The affected facility to which the provisions of this subpart apply is each basic oxygen process furnace.

(b) Any facility under paragraph (a) of this section that commences construction or modification after June 11, 1973, is subject to the requirements of this subpart.

Subpart O—Standards of Performance for Sewage Treatment Plants

12. Section 60.150 is revised as follows:

§ 60.150 Applicability and designation of affected facility.

(a) The affected facility to which the provisions of this subpart apply is each incinerator which burns the sludge produced by municipal sewage treatment facilities.

(b) Any facility under paragraph (a) of this section that commences construction or modification after June 11, 1973, is subject to the requirements of this subpart.

Subpart P—Standards of Performance for Primary Copper Smelters

13. Section 60.160 is revised as follows:

§ 60.160 Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to the following affected facilities in primary copper smelters: dryer, roaster, smelting furnace, and copper converter.

(b) Any facility under paragraph (a) of this section that commences construction or modification after October 16, 1974, is subject to the requirements of this subpart.

Subpart Q—Standards of Performance for Primary Zinc Smelters

14. Section 60.170 is revised as follows:

§ 60.170 Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to the following affected facilities in primary zinc smelters: roaster and sintering machine.

(b) Any facility under paragraph (a) of this section that commences construction or modification after October 16, 1974, is subject to the requirements of this subpart.

RULES AND REGULATIONS

Subpart R—Standards of Performance for Primary Lead Smelters

15. Section 60.180 is revised as follows:

§ 60.180 Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to the following affected facilities in primary lead smelters: sintering machine, sintering machine discharge end, blast furnace, dross reverberatory furnace, electric smelting furnace, and converter.

(b) Any facility under paragraph (a) of this section that commences construction or modification after October 16, 1974, is subject to the requirements of this subpart.

Subpart S—Standards of Performance for Primary Aluminum Reduction Plants

16. Section 60.190 is revised as follows:

§ 60.190 Applicability and designation of affected facility.

(a) The affected facilities in primary aluminum reduction plants to which this subpart applies are potroom groups and anode bake plants.

(b) Any facility under paragraph (a) of this section that commences construction or modification after October 23, 1974, is subject to the requirements of this subpart.

Subpart T—Standards of Performance for the Phosphate Fertilizer Industry: Wet-Process Phosphoric Acid Plants

17. Section 60.200 is revised as follows:

§ 60.200 Applicability and designation of affected facility.

(a) The affected facility to which the provisions of this subpart apply is each wet-process phosphoric acid plant. For the purpose of this subpart, the affected facility includes any combination of: reactors, filters, evaporators, and hotwells.

(b) Any facility under paragraph (a) of this section that commences construction or modification after October 22, 1974, is subject to the requirements of this subpart.

Subpart U—Standards of Performance for the Phosphate Fertilizer Industry: Superphosphoric Acid Plants

18. Section 60.210 is revised as follows:

§ 60.210 Applicability and designation of affected facility.

(a) The affected facility to which the provisions of this subpart apply is each superphosphoric acid plant. For the purpose of this subpart, the affected facility includes any combination of: evaporators, hotwells, acid sumps, and cooling tanks.

(b) Any facility under paragraph (a) of this section that commences construction or modification after October 22, 1974, is subject to the requirements of this subpart.

Subpart V—Standards of Performance for the Phosphate Fertilizer Industry: Diammonium Phosphate Plants

19. Section 60.220 is revised as follows:

§ 60.220 Applicability and designation of affected facility.

(a) The affected facility to which the provisions of this subpart apply is each granular diammonium phosphate plant. For the purpose of this subpart, the affected facility includes any combination of: reactors, granulators, dryers, coolers, screens, and mills.

(b) Any facility under paragraph (a) of this section that commences construction or modification after October 22, 1974, is subject to the requirements of this subpart.

Subpart W—Standards of Performance for the Phosphate Fertilizer Industry: Triple Superphosphate Plants

20. Section 60.230 is revised as follows:

§ 60.230 Applicability and designation of affected facility.

(a) The affected facility to which the provisions of this subpart apply is each triple superphosphate plant. For the purpose of this subpart, the affected facility includes any combination of: mixers, curing belts (dens), reactors, granulators, dryers, cookers, screens, mills, and facilities which store run-of-pile triple superphosphate.

(b) Any facility under paragraph (a) of this section that commences construction or modification after October 22, 1974, is subject to the requirements of this subpart.

Subpart X—Standards of Performance for the Phosphate Fertilizer Industry: Granular Triple Superphosphate Storage Facilities

21. Section 60.240 is revised as follows:

§ 60.240 Applicability and designation of affected facility.

(a) The affected facility to which the provisions of this subpart apply is each granular triple superphosphate storage facility. For the purpose of this subpart, the affected facility includes any combination of: storage or curing piles, conveyors, elevators, screens, and mills.

(b) Any facility under paragraph (a) of this section that commences construction or modification after October 22, 1974, is subject to the requirements of this subpart.

Subpart Y—Standards of Performance for Coal Preparation Plants

22. Section 60.250 is revised as follows:

§ 60.250 Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to any of the following affected facilities in coal preparation plants which process more than 200 tons per day: thermal dryers, pneumatic coal-cleaning equipment (air tables), coal processing and conveying equipment (including breakers and crushers), coal

storage systems, and coal transfer and loading systems.

(b) Any facility under paragraph (a) of this section that commences construction or modification after October 21, 1974, is subject to the requirements of this subpart.

Subpart Z—Standards of Performance for Ferroalloy Production Facilities

23. Section 60.260 is revised as follows:

§ 60.260 Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to the following affected facilities: electric-submerged arc furnaces which produce silicon metal, ferrosilicon, calcium silicon, silicomanganese zirconium, ferrochrome silicon, silvery iron, high-carbon ferrochrome, charge chrome, standard ferromanganese, silicomanganese, ferromanganese silicon, or calcium carbide; and dust-handling equipment.

(b) Any facility under paragraph (a) of this section that commences construction or modification after October 21, 1974, is subject to the requirements of this subpart.

Subpart AA—Standards of Performance for Steel Plants: Electric Arc Furnaces

24. Section 60.270 is revised as follows:

§ 60.270 Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to the following affected facilities in steel plants: electric arc furnaces and dust-handling equipment.

(b) Any facility under paragraph (a) of this section that commences construction or modification after October 24, 1974, is subject to the requirements of this subpart.

(Secs. 111 and 801(a), Clean Air Act as amended (42 U.S.C. 1857c-6, 1857g(a)).)

No. 919-541-5271.

Dated August 8, 1977.

EDWARD F. TUERK,
Acting Assistant Administrator,
for Air and Waste Management.

In FR Doc. 76-33966, §§ 60.45(f)(4) and 60.45(f)(5) on page 51399 are corrected as follows:

§ 60.45 [Amended]

1. In § 60.45(f)(4)(iii) "F_c=0.384 scm CO₂/J" in the fourth line is corrected to read "F_c=0.384×10⁻⁷ scm CO₂/J."

$$F = 10^{-4} \frac{[227.2 (\text{pct. H}) + 95.5 (\text{pct. C}) + 35.6 (\text{pct. S}) + 8.7 (\text{pct. N}) - 28.7 (\text{pct. O})]}{\text{GCV}}$$

$$F_c = \frac{2.0 \times 10^{-4} (\text{pct. C})}{\text{GCV}}$$

(Sec. 111, 114, 301(a) of the Clean Air Act as amended [42 U.S.C. 1857c-6, 1857c-9, 1857g(a)].)

[FR Doc. 77-23402 Filed 8-12-77; 8:45 am]

2. In § 60.45(f)(4)(iv) a left parenthesis is inserted in the second line between "dscm/J" and "8,740."

3. § 60.45(f)(4)(v) is corrected to read as follows:

§ 60.45 Emission and fuel monitoring.

• • • • •

(f) • • •

(4) • • •

(v) For bark $F = 2.589 \times 10^{-7}$ dscm/J (9,640 dscf/million Btu) and $F_c = 0.500 \times 10^{-7}$ scm CO₂/J (1,860 scf CO₂/million Btu). For wood residue other than bark $F = 2.492 \times 10^{-7}$ dscm/J (9,280 dscf/million Btu) and $F_c = 0.494 \times 10^{-7}$ scm CO₂/J (1,840 scf CO₂/million Btu).

• • • • •

4. In § 60.45(f)(5) the F factor and F_c factor equations in SI units are corrected to read as follows:

FEDERAL REGISTER, VOL. 42,

NO. 157—MONDAY, AUGUST 15, 1977

Title 40—Protection of Environment

CHAPTER I—ENVIRONMENTAL
PROTECTION AGENCY

[FRL 775-4]

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

PART 61—NATIONAL EMISSION STANDARDS FOR HAZARDOUS AIR POLLUTANTS

Authority Citations; Revision

AGENCY: Environmental Protection Agency.

ACTION: Final rule.

SUMMARY: This action revises the authority citations for Standards of Performance for New Stationary Sources and National Emission Standards for Hazardous Air Pollutants. The revision adopts a method recommended by the FEDERAL REGISTER for identifying which sections are enacted under which statutory authority, making the citations more useful to the reader.

EFFECTIVE DATE: August 17, 1977.

FOR FURTHER INFORMATION CONTACT:

Don R. Goodwin, Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, N.C. 27711, telephone 919-541-5271.

SUPPLEMENTARY INFORMATION: This action is being taken in accordance with the requirements of 1 CFR 21.43 and is authorized under section 301(a) of the Clean Air Act, as amended, 42 U.S.C. 1857g(a). Because the amendments are clerical in nature and affect no substantive rights or requirements, the Administrator finds it unnecessary to propose and invite public comment.

Dated: August 12, 1977.

DOUGLAS M. COSTLE,
Administrator.

Parts 60 and 61 of Chapter I, Title 40 of the Code of Federal Regulations are revised as follows:

1. The authority citation following the table of sections in Part 60 is revised to read as follows:

AUTHORITY: Sec. 111, 301(a) of the Clean Air Act as amended (42 U.S.C. 1857c-8, 1857g(a)), unless otherwise noted.

2. Following §§ 60.10 and 60.24(g) the following authority citation is added:

(Sec. 116 of the Clean Air Act as amended (42 U.S.C. 1857d-1)).

3. Following §§ 60.7, 60.8, 60.9, 60.11, 60.13, 60.45, 60.46, 60.53, 60.54, 60.63, 60.64, 60.73, 60.74, 60.84, 60.85, 60.93, 60.105, 60.106, 60.113, 60.123, 60.133, 60.144, 60.153, 60.154, 60.165, 60.166, 60.175, 60.176, 60.185, 60.186, 60.184, 60.195, 60.203, 60.204, 60.213, 60.214, 60.223, 60.224, 60.233, 60.234, 60.243, 60.244, 60.253, 60.254, 60.264, 60.265, 60.266, 60.273, 60.274, 60.275 and Appendices A, B, C, and D, the following authority citation is added:

(Sec. 114 of the Clean Air Act as amended (42 U.S.C. 1857c-9)).

4. The authority citation following the table of sections in Part 61 is revised to read as follows:

AUTHORITY: Sec. 112, 301(a) of the Clean Air Act as amended (42 U.S.C. 1857c-7, 1857g(a)), unless otherwise noted.

5. Following § 61.16, the following authority citation is added:

(Sec. 116 of the Clean Air Act as amended (42 U.S.C. 1857d-1)).

6. Following §§ 61.09, 61.10, 61.12, 61.13, 61.14, 61.15, 61.24, 61.33, 61.34, 61.43, 61.44, 61.53, 61.54, 61.55, 61.67, 61.68, 61.69, 61.70, 61.71, and Appendices A and B, the following authority citation is added:

(Sec. 114 of the Clean Air Act as amended (42 U.S.C. 1857c-9)).

RULES AND REGULATIONS

69

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Revision to Reference Methods 1-8

AGENCY: Environmental Protection Agency.

ACTION: Final Rule.

SUMMARY: This rule revises Reference Methods 1 through 8, the detailed requirements used to measure emissions from affected facilities to determine whether they are in compliance with a standard of performance. The methods were originally promulgated December 23, 1971, and since that time several revisions became apparent which would clarify, correct and improve the methods. These revisions make the methods easier to use, and improve their accuracy and reliability.

EFFECTIVE DATE: September 19, 1977.

ADDRESSES: Copies of the comment letters are available for public inspection and copying at the U.S. Environmental Protection Agency, Public Information Reference Unit (EPA Library), Room 2922, 401 M Street, S.W., Washington, D.C. 20460. A summary of the comments and EPA's responses may be obtained upon written request from the EPA Public Information Center (PM-215), 401 M Street, S.W., Washington, D.C. 20460 (specify "Public Comment Summary: Revisions to Reference Methods 1-8 in Appendix A of Standards of Performance for New Stationary Sources").

FOR FURTHER INFORMATION CONTACT:

Don R. Goodwin, Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone No. 919-541-5271.

SUPPLEMENTARY INFORMATION: The amendments were proposed on June 8, 1976 (40 FR 23060). A total of 55 comment letters were received during the comment period—34 from industry, 15 from governmental agencies, and 6 from other interested parties. They contained numerous suggestions which were incorporated in the final revisions.

Changes common to all eight of the reference methods are: (1) the clarification of procedures and equipment specifications resulting from the comments, (2) the addition of guidelines for alternative procedures and equipment to make prior approval of the Administrator unnecessary and (3) the addition of an introduction to each reference method discussing the general use of the method and delineating the procedure for using alternative methods and equipment.

Specific changes to the methods are:

METHOD 1

1. The provision for the use of more than two traverse diameters, when specified by the Administrator, has been deleted. If one traverse diameter is in a plane containing the greatest expected concentration variation, the intended purpose of the deleted paragraph will be fulfilled.

2. Based on recent data from Fluidyne (Particulate Sampling Strategies for Large Power Plants Including Nonuniform Flow, EPA-600/2-76-170, June 1976) and Entropy Environmentalists (Determination of the Optimum Number of Traverse Points: An Analysis of Method 1 Criteria (draft), Contract No. 68-01-3172); the number of traverse points for velocity measurements has been reduced and the 2:1 length to width ratio requirement for cross-sectional layout of rectangular ducts has been replaced by a "balanced matrix" scheme.

3. Guidelines for sampling in stacks containing cyclonic flow and stacks smaller than about 0.31 meter in diameter or 0.071 m² in cross-sectional area will be published at a later date.

4. Clarification has been made as to when a check for cyclonic flow is necessary; also, the suggested procedure for determination of unacceptable flow conditions has been revised.

METHOD 2

1. The calibration of certain pitot tubes has been made optional. Appropriate construction and application guidelines have been included.

2. A detailed calibration procedure for temperature gauges has been included.

3. A leak check procedure for pitot lines has been included.

METHOD 3

1. The applicability of the method has been confined to fossil-fuel combustion processes and to other processes where it has been determined that components other than O₂, CO₂, CO, and N₂ are not present in concentrations sufficient to affect the final results.

2. Based on recent research information (Particulate Sampling Strategies for Large Power Plants Including Nonuniform Flow, EPA-600/2-76-170, June 1976), the requirement for proportional sampling has been dropped and replaced with the requirement for constant rate sampling. Proportional and constant rate sampling have been found to give essentially the same result.

3. The "three consecutive" requirement has been replaced by "any three" for the determination of molecular weight, CO₂, and O₂.

4. The equation for excess air has been revised to account for the presence of CO.

5. A clearer distinction has been made between molecular weight determination and emission rate correction factor determination.

6. Single point, integrated sampling has been included.

METHOD 4

1. The sampling time of 1 hour has been changed to a total sampling time which will span the length of time the pollutant emission rate is being determined or such time as specified in an applicable subpart of the standards.

2. The requirement for proportional sampling has been dropped and replaced with the requirement for constant rate sampling.

3. The leak check before the test run has been made optional; the leak check after the run remains mandatory.

METHOD 5

1. The following alternatives have been included in the method:

a. The use of metal probe liners.
b. The use of other materials of construction for filter holders and probe liner parts.

c. The use of polyethylene wash bottles and sample storage containers.

d. The use of desiccants other than silica gel or calcium sulfate, when appropriate.

e. The use of stopcock grease other than silicone grease, when appropriate.

f. The drying of filters and probe-filter catches at elevated temperatures, when appropriate.

g. The combining of the filter and probe washes into one container.

2. The leak check prior to a test run has been made optional. The post-test leak check remains mandatory. A method for correcting sample volume for excessive leakage rates has been included.

3. Detailed leak check and calibration procedures for the metering system have been included.

METHOD 6

1. Possible interfering agents of the method have been delineated.

2. The options of: (a) using a Method 8 impinger system, or (b) determining SO₂ simultaneously with particulate matter, have been included in the method.

3. Based on recent research data, the requirement for proportional sampling has been dropped and replaced with the requirement for constant rate sampling.

4. Tests have shown that isopropanol obtained from commercial sources occasionally has peroxide impurities that will cause erroneously low SO₂ measurements. Therefore, a test for detecting peroxides in isopropanol has been included in the method.

5. The leak check before the test run has been made optional; the leak check after the run remains mandatory.

6. A detailed calibration procedure for the metering system has been included in the method.

METHOD 7

1. For variable wave length spectrophotometers, a scanning procedure for determining the point of maximum absorbance has been incorporated as an option.

METHOD 8

1. Known interfering compounds have been listed to avoid misapplication of the method.

2. The determination of filterable particulate matter (including acid mist) simultaneously with SO₂ and SO₃ has been allowed where applicable.

3. Since occasionally some commercially available quantities of isopropanol

RULES AND REGULATIONS

have peroxide impurities that will cause erroneously high sulfuric acid mist measurements, a test for peroxides in isopropanol has been included in the method.

4. The gravimetric technique for moisture content (rather than volumetric) has been specified because a mixture of isopropyl alcohol and water will have a volume less than the sum of the volumes of its content.

5. A closer correspondence has been made between similar parts of Methods 8 and 5.

MISCELLANEOUS

Several commenters questioned the meaning of the term "subject to the approval of the Administrator" in relation to using alternate test methods and procedures. As defined in § 60.2 of subpart A, the "Administrator" includes any authorized representative of the Administrator of the Environmental Protection Agency. Authorized representatives are EPA officials in EPA Regional Offices or State, local, and regional governmental officials who have been delegated the responsibility of enforcing regulations under 40 CFR 60. These officials in consultation with other staff members familiar with technical aspects of source testing will render decisions regarding acceptable alternate test procedures.

In accordance with section 117 of the Act, publication of these methods was preceded by consultation with appropriate advisory committees, independent experts, and Federal departments and agencies.

(Secs. 111, 114 and 301(a) of the Clean Air Act, sec. 4(a) of Pub. L. No. 91-604, 84 Stat. 1683; sec. 4(a) of Pub. L. No. 91-604, 84 Stat. 1687; sec. 2 of Pub. L. No. 90-148, 81 Stat. 504 [42 U.S.C. 1857c-6, 1857c-9, 1857g(a)].)

NOTE.—The Environmental Protection Agency has determined that this document does not contain a major proposal requiring preparation of an Economic Impact Analysis under Executive Orders 11821 and 11949 and OMB Circular A-107.

Dated: August 10, 1977.

DOUGLAS M. COSTLE,
Administrator.

Part 60 of Chapter I of Title 40 of the Code of Federal Regulations is amended by revising Methods 1 through 8 of Appendix A—Reference Methods as follows:

APPENDIX A—REFERENCE METHODS

The reference methods in this appendix are referred to in § 60.8 (Performance Tests) and § 60.11 (Compliance With Standards and Maintenance Requirements) of 40 CFR Part 60, Subpart A (General Provisions). Specific uses of these reference methods are described in the standards of performance contained in the subparts, beginning with Subpart D.

Within each standard of performance, a section titled "Test Methods and Procedures" is provided to (1) identify the test methods applicable to the facility subject to the respective standard and (2) identify any special instructions or conditions to be followed when applying a method to the respective facility. Such instructions (for example, establish sampling rates, volumes, or temperatures) are to be used either in addition to, or as a substitute for procedures in a reference method. Similarly, for sources subject to emission monitoring requirements, specific instructions pertaining to any use of a reference method are provided in the subpart or in Appendix B.

Inclusion of methods in this appendix is not intended as an endorsement or denial of their applicability to sources that are not subject to standards of performance. The methods are potentially applicable to other sources; however, applicability should be confirmed by careful and appropriate evaluation of the conditions prevalent at such sources.

The approach followed in the formulation of the reference methods involves specifications for equipment, procedures, and performance. In concept, a performance specification approach would be preferable in all methods because this allows the greatest flexibility to the user. In practice, however, this approach is impractical in most cases because performance specifications cannot be established. Most of the methods described herein, therefore, involve specific equipment specifications and procedures, and only a few methods in this appendix rely on performance criteria.

Minor changes in the reference methods should not necessarily affect the validity of the results and it is recognized that alternative and equivalent methods exist. Section 60.8 provides authority for the Administrator to specify or approve (1) equivalent methods, (2) alternative methods, and (3) minor changes in the methodology of the reference methods. It should be clearly understood that unless otherwise identified all such methods and changes must have prior approval of the Administrator. An owner employing such methods or deviations from the reference methods without obtaining prior approval does so at the risk of subsequent disapproval and retesting with approved methods.

Within the reference methods, certain specific equipment or procedures are recognized as being acceptable or potentially acceptable and are specifically identified in the methods. The items identified as acceptable options may be used without approval but must be identified in the test report. The potentially approvable options are cited as "subject to the approval of the Administrator" or as "or equivalent." Such potentially approvable techniques or alternatives may be used at the discretion of the owner without prior approval. However, detailed descriptions for applying these potentially approvable techniques or alternatives are not provided in the reference methods. Also, the potentially approvable options are not necessarily acceptable in all applications. Therefore, an owner electing to use such potentially approvable techniques or alternatives is responsible for: (1) assuring that the techniques or alternatives are in fact applicable and are properly executed; (2) including a written description of the alternative method in the test report (the written method must be clear and must be capable of being performed without additional instruction, and the degree of detail should be similar to the detail contained in the reference methods); and (3) providing any rationale or supporting data necessary to show the validity of the alternative in the particular application. Failure to meet these requirements can result in the Administrator's disapproval of the alternative.

METHOD 1—SAMPLE AND VELOCITY TRAVERSES FOR STATIONARY SOURCES

1. Principle and Applicability

1.1 Principle. To aid in the representative measurement of pollutant emissions and/or total volumetric flow rate from a stationary source, a measurement site where the effluent stream is flowing in a known direction is selected, and the cross-section of the stack is divided into a number of equal areas. A traverse point is then located within each of these equal areas.

1.2 Applicability. This method is applicable to flowing gas streams in ducts, stacks, and flues. The method cannot be used when: (1) flow is cyclonic or swirling (see Section 2.4), (2) a stack is smaller than about 0.30 meter (12 in.) in diameter, or 0.071 m² (113 in.²) in cross-sectional area, or (3) the measurement site is less than two stack or duct diameters downstream or less than a half diameter upstream from a flow disturbance.

The requirements of this method must be considered before construction of a new facility from which emissions will be measured; failure to do so may require subsequent alterations to the stack or deviation from the standard procedure. Cases involving variants are subject to approval by the Administrator, U.S. Environmental Protection Agency.

2. Procedure

2.1 Selection of Measurement Site. Sampling or velocity measurement is performed at a site located at least eight stack or duct diameters downstream and two diameters upstream from any flow disturbance such as a bend, expansion, or contraction in the stack, or from a visible flame. If necessary, an alternative location may be selected, at a position at least two stack or duct diameters downstream and a half diameter upstream from any flow disturbance. For a rectangular cross section, an equivalent diameter (*D_e*) shall be calculated from the following equation, to determine the upstream and downstream distances:

$$D_e = \frac{2LW}{L+W}$$

RULES AND REGULATIONS

Figure 1-1. Minimum number of traverse points for particulate traverses.

where L =length and W =width.

2.2 Determining the Number of Traverse Points.

2.2.1 Particulate Traverses. When the eight- and two-diameter criterion can be met, the minimum number of traverse points shall be: (1) twelve, for circular or rectangular stacks with diameters (or equivalent diameters) greater than 0.61 meter (24 in.); (2) eight, for circular stacks with diameters between 0.30 and 0.61 meter (12-24 in.); (3) nine, for rectangular stacks with equivalent diameters between 0.30 and 0.61 meter (12-24 in.).

When the eight- and two-diameter criterion cannot be met, the minimum number of traverse points is determined from Figure 1-1. Before referring to the figure, however, determine the distances from the chosen measurement site to the nearest upstream and downstream disturbances, and divide each distance by the stack diameter or equivalent diameter, to determine the distance in terms of the number of duct diameters. Then, determine from Figure 1-1 the minimum number of traverse points that corresponds: (1) to the number of duct diameters upstream; and (2) to the number of diameters downstream. Select the higher of the two minimum numbers of traverse points, or a greater value, so that for circular stacks the number is a multiple of 4, and for rectangular stacks, the number is one of those shown in Table 1-1.

TABLE 1-1. Cross-sectional layout for rectangular stacks

Number of traverse points:	Matrix layout
9	3x3
12	4x3
16	4x4
20	5x4
25	5x5
30	6x5
36	6x6
42	7x6
49	7x7

RULES AND REGULATIONS

Figure 1-2. Minimum number of traverse points for velocity (nonparticulate) traverses.

2.2.2 Velocity (Non-Particulate) Traverses. When velocity or volumetric flow rate is to be determined (but not particulate matter), the same procedure as that for particulate traverses (Section 2.2.1) is followed, except that Figure 1-2 may be used instead of Figure 1-1.

2.3 Cross-Sectional Layout and Location of Traverse Points.

2.3.1 Circular Stacks. Locate the traverse points on two perpendicular diameters according to Table 1-2 and the example shown in Figure 1-3. Any equation (for examples, see Citations 2 and 3 in the Bibliography) that gives the same values as those in Table 1-2 may be used in lieu of Table 1-2.

For particulate traverses, one of the diameters must be in a plane containing the greatest expected concentration variation, e.g., after bends, one diameter shall be in the plane of the bend. This requirement becomes less critical as the distance from the disturbance increases; therefore, other diameter locations may be used, subject to approval of the Administrator.

In addition, for stacks having diameters greater than 0.61 m (24 in.) no traverse points shall be located within 2.5 centimeters (1.00 in.) of the stack walls; and for stack diameters equal to or less than 0.61 m (24 in.), no traverse points shall be located within 1.3 cm (0.50 in.) of the stack walls. To meet these criteria, observe the procedures given below.

2.3.1.1 Stacks With Diameters Greater Than 0.61 m (24 in.). When any of the traverse points as located in Section 2.3.1 fall within 2.5 cm (1.00 in.) of the stack walls, relocate them away from the stack walls to: (1) a distance of 2.5 cm (1.00 in.); or (2) a distance equal to the nozzle inside diameter, whichever is larger. These relocated traverse points (on each end of a diameter) shall be the "adjusted" traverse points.

Whenever two successive traverse points are combined to form a single adjusted traverse point, treat the adjusted point as two separate traverse points, both in the sampling (or velocity measurement) procedure, and in recording the data.

RULES AND REGULATIONS

Figure 1-3. Example showing circular stack cross section divided into 12 equal areas, with location of traverse points indicated.

(3) In stacks having tangential inlets or other duct configurations which tend to induce swirling; in these instances, the presence or absence of cyclonic flow at the sampling location must be determined. The following techniques are acceptable for this determination.

Figure 1-4. Example showing rectangular stack cross section divided into 12 equal areas, with a traverse point at centroid of each area.

Table 1-2. LOCATION OF TRAVERSE POINTS IN CIRCULAR STACKS
(Percent of stack diameter from inside wall to traverse point)

23												96.8
24												98.9

2.3.1.2 Stacks With Diameters Equal to or Less Than 0.61 m (24 in.). Follow the procedure in Section 2.3.1.1, noting only that any "adjusted" points should be relocated away from the stack walls to: (1) a distance of 1.3 cm (0.50 in.); or (2) a distance equal to the nozzle inside diameter, whichever is larger.

2.3.2 Rectangular Stacks. Determine the number of traverse points as explained in Sections 2.1 and 2.2 of this method. From Table 1-1, determine the grid configuration. Divide the stack cross-section into as many equal rectangular elemental areas as traverse points,

and then locate a traverse point at the centroid of each equal area according to the example in Figure 1-4.

The situation of traverse points being too close to the stack walls is not expected to arise with rectangular stacks. If this problem should ever arise, the Administrator must be contacted for resolution of the matter.

2.4 Verification of Absence of Cyclonic Flow. In most stationary sources, the direction of stack gas flow is essentially parallel to the stack walls. However, cyclonic flow may exist (1) after such devices as cyclones and inertial demisters following venturi scrubbers, or

Level and zero the manometer. Connect a Type 8 pitot tube to the manometer. Position the Type 8 pitot tube at each traverse point, in succession, so that the planes of the face openings of the pitot tube are perpendicular to the stack cross-sectional plane; when the Type 8 pitot tube is in this position, it is at "0° reference." Note the differential pressure (Δp) reading at each traverse point. If a null (zero) pitot reading is obtained at 0° reference at a given traverse point, an acceptable flow condition exists at that point. If the pitot reading is not zero at 0° reference, rotate the pitot tube (up to $\pm 90^\circ$ yaw angle), until a null reading is obtained. Carefully determine and record the value of the rotation angle (α) to the nearest degree. After the null technique has been applied at each traverse point, calculate the average of the absolute values of α ; assign a value of 0° to those points for which no rotation was required, and include these in the overall average. If the average value of α is greater than 10°, the overall flow condition in the stack is unacceptable and alternative methodology, subject to the approval of the Administrator, must be used to perform accurate sample and velocity traverses.

METHOD 2—DETERMINATION OF STACK GAS VELOCITY AND VOLUMETRIC FLOW RATE (TYPE S PITOT TUBE)

1. Principle and Applicability

1.1 Principle. The average gas velocity in a stack is determined from the gas density and from measurement of the average velocity head with a Type S (Stausscheibe or reverse type) pitot tube.

1.2 Applicability. This method is applicable for measurement of the average velocity of a gas stream and for quantifying gas flow.

This procedure is not applicable at measurement sites which fail to meet the criteria of Method 1, Section 2.1. Also, the method cannot be used for direct measurement in cyclonic or swirling gas streams; Section 2.4 of Method 1 shows how to determine cyclonic or swirling flow conditions. When unacceptable conditions exist, alternative procedures, subject to the approval of the Administrator, U.S. Environmental Protection Agency, must be employed to make accurate flow rate determinations; examples of such alternative procedures are: (1) to install straightening vanes; (2) to calculate the total volumetric flow rate stoichiometrically, or (3) to move to another measurement site at which the flow is acceptable.

2. Apparatus

Specifications for the apparatus are given below. Any other apparatus that has been demonstrated (subject to approval of the Administrator) to be capable of meeting the specifications will be considered acceptable.

RULES AND REGULATIONS

*SUGGESTED (INTERFERENCE FREE)
PITOT TUBE - THERMOCOUPLE SPACING

Figure 2-1. Type S pitot tube manometer assembly.

2.1 Type S Pitot Tube. The Type S pitot tube (Figure 2-1) shall be made of metal tubing (e.g., stainless steel). It is recommended that the external tubing diameter (dimension D , Figure 2-2b) be between 0.48 and 0.95 centimeters ($\frac{3}{16}$ and $\frac{3}{8}$ inch). There shall be an equal distance from the base of each leg of the pitot tube to its face-opening plane (dimensions P_A and P_B , Figure 2-2b); it is recommended that this distance be between 1.05 and 1.50 times the external tubing diameter. The face openings of the pitot tube shall, preferably, be aligned as shown in Figure 2-2; however, slight misalignments of the openings are permissible (see Figure 2-3). The Type S pitot tube shall have a known coefficient, determined as outlined in Section 4. An identification number shall be assigned to the pitot tube; this number shall be permanently marked or engraved on the body of the tube.

RULES AND REGULATIONS

Figure 2-2. Properly constructed Type S pitot tube, shown in: (a) end view; face opening planes perpendicular to transverse axis; (b) top view; face opening planes parallel to longitudinal axis; (c) side view; both legs of equal length and centerlines coincident, when viewed from both sides. Baseline coefficient values of 0.84 may be assigned to pitot tubes constructed this way.

RULES AND REGULATIONS

Figure 2-3. Types of face-opening misalignment that can result from field use or improper construction of Type S pitot tubes. These will not affect the baseline value of $\bar{C}_p(s)$ so long as α_1 and $\alpha_2 < 10^\circ$, β_1 and $\beta_2 < 5^\circ$, $z < 0.32$ cm (1/8 in.) and $w < 0.08$ cm (1/32 in.) (citation 11 in Section 6).

RULES AND REGULATIONS

A standard pitot tube may be used instead of a Type 8, provided that it meets the specifications of Sections 2.7 and 4.2; note, however, that the static and impact pressure holes of standard pitot tubes are unsuited to plugging in particulate-laden gas streams. Therefore, whenever a standard pitot tube is used to perform a traverse, adequate proof must be furnished that the openings of the pitot tube have not plugged up during the traverse period; this can be done by taking a velocity head (Δp) reading at the final traverse point, cleaning out the impact and static holes of the standard pitot tube by "back-purging" with pressurized air, and then taking another Δp reading. If the Δp readings made before and after the air purge are the same (± 5 percent), the traverse is acceptable. Otherwise, reject the run. Note that if Δp at the final traverse point is unsuitably low, another point may be selected. If "back-purging" at regular intervals is part of the procedure, then comparative Δp readings shall be taken, as above, for the last two back purges at which suitably high Δp readings are observed.

2.2 Differential Pressure Gauge. An inclined manometer or equivalent device is used. Most sampling trains are equipped with a 10-in. (water column) inclined-vertical manometer, having 0.01-in. H_2O divisions on the 0- to 1-in. inclined scale, and 0.1-in. H_2O divisions on the 1- to 10-in. vertical scale. This type of manometer (or other gauge of equivalent sensitivity) is satisfactory for the measurement of Δp values as low as 1.3 mm (0.05 in.) H_2O . However, a differential pressure gauge of greater sensitivity shall be used (subject to the approval of the Administrator), if any of the following is found to be true: (1) the arithmetic average of all Δp readings at the traverse points in the stack is less than 1.3 mm (0.05 in.) H_2O ; (2) for traverses of 12 or more points, more than 10 percent of the individual Δp readings are below 1.3 mm (0.05 in.) H_2O ; (3) for traverses of fewer than 12 points, more than one Δp reading is below 1.3 mm (0.05 in.) H_2O . Citation 18 in Section 6 describes commercially available instrumentation for the measurement of low-range gas velocities.

As an alternative to criteria (1) through (3) above, the following calculation may be performed to determine the necessity of using a more sensitive differential pressure gauge:

$$T = \frac{\sum_{i=1}^n \sqrt{\Delta p_i + K}}{\sum_{i=1}^n \sqrt{\Delta p_i}}$$

where:

Δp_i = Individual velocity head reading at a traverse point, mm H_2O (in. H_2O).
 n = Total number of traverse points.
 K = 0.13 mm H_2O when metric units are used and 0.005 in. H_2O when English units are used.

If T is greater than 1.05, the velocity head data are unacceptable and a more sensitive differential pressure gauge must be used.

NOTE.—If differential pressure gauges other than inclined manometers are used (e.g., magnetic gauges), their calibration must be checked after each test series. To check the calibration of a differential pressure gauge, compare Δp readings of the gauge with those of a gauge-oil manometer at a minimum of three points, approximately representing the range of Δp values in the stack. If, at each point, the values of Δp as read by the differential pressure gauge and gauge-oil manometer agree to within 5 percent, the differential pressure gauge shall be considered to be in proper calibration. Otherwise, the test series shall either be voided, or procedures to adjust the measured Δp values and final results shall be used, subject to the approval of the Administrator.

2.3 Temperature Gauge. A thermocouple, liquid-filled bulb thermometer, bimetallic thermometer, mercury-in-glass thermometer, or other gauge capable of measuring temperature to within 1.5 percent of the minimum absolute stack temperature shall be used. The temperature gauge shall be attached to the pitot tube such that the sensor tip does not touch any metal; the gauge shall be in an interference-free arrangement with respect to the pitot tube face openings (see Figure 2-1 and also Figure 2-7 in Section 4). Alternate positions may be used if the pitot tube-temperature gauge system is calibrated according to the procedure of Section 4. Provided that a difference of not more than 1 percent in the average velocity measurement is introduced, the tem-

perature gauge need not be attached to the pitot tube; this alternative is subject to the approval of the Administrator.

2.4 Pressure Probe and Gauge. A piezometer tube and mercury- or water-filled U-tube manometer capable of measuring stack pressure to within 2.5 mm (0.1 in.) Hg is used. The static tap of a standard type pitot tube or one leg of a Type X pitot tube with the face opening planes positioned parallel to the gas flow may also be used as the pressure probe.

2.5 Barometer. A mercury, aneroid, or other barometer capable of measuring atmospheric pressure to within 2.5 mm Hg (0.1 in. Hg) may be used. In many cases, the barometric reading may be obtained from a nearby national weather service station, in which case the station value (which is the absolute barometric pressure) shall be requested and an adjustment for elevation differences between the weather station and the sampling point shall be applied at a rate of minus 2.5 mm (0.1 in.) Hg per 30-meter (100 foot) elevation increase, or vice-versa for elevation decrease.

2.6 Gas Density Determination Equipment. Method 3 equipment, if needed (see Section 3.6), to determine the stack gas dry molecular weight, and Reference Method 4 or Method 5 equipment for moisture content determination; other methods may be used subject to approval of the Administrator.

2.7 Calibration Pitot Tube. When calibration of the Type 8 pitot tube is necessary (see Section 4), a standard pitot tube is used as a reference. The standard pitot tube shall, preferably, have a known coefficient, obtained either (1) directly from the National Bureau of Standards, Route 270, Quince Orchard Road, Gaithersburg,

Maryland, or (2) by calibration against another standard pitot tube with an NBS-traceable coefficient. Alternatively, a standard pitot tube designed according to the criteria given in 2.7.1 through 2.7.5 below and illustrated in Figure 2-4 (see also Citations 7, 8, and 17 in Section 6) may be used. Pitot tubes designed according to these specifications will have baseline coefficients of about 0.99 ± 0.01 .

2.7.1 Hemispherical (shown in Figure 2-4), ellipsoidal, or conical tip.

2.7.2 A minimum of six diameters straight run (based upon D , the external diameter of the tube) between the tip and the static pressure holes.

2.7.3 A minimum of eight diameters straight run between the static pressure holes and the centerline of the external tube, following the 90 degree bend.

2.7.4 Static pressure holes of equal size (approximately 0.1 D), equally spaced in a piezometer ring configuration.

2.7.5 Ninety degree bend, with curved or mitered junction.

2.8 Differential Pressure Gauge for Type 8 Pitot Tube Calibration. An inclined manometer or equivalent is used. If the single-velocity calibration technique is employed (see Section 4.1.2.3), the calibration differential pressure gauge shall be readable to the nearest 0.13 mm H_2O (0.005 in. H_2O). For multi-velocity calibrations, the gauge shall be readable to the nearest 0.13 mm H_2O (0.005 in. H_2O) for Δp values between 1.3 and 25 mm H_2O (0.05 and 1.0 in. H_2O), and to the nearest 1.3 mm H_2O (0.05 in. H_2O) for Δp values above 25 mm H_2O (1.0 in. H_2O). A special, more sensitive gauge will be required to read Δp values below 1.3 mm H_2O (0.05 in. H_2O) (see Citation 18 in Section 6).

Figure 2-4. Standard pitot tube design specifications.

3. Procedure

3.1 Set up the apparatus as shown in Figure 2-1: Capillary tubing or surge tanks installed between the manometer and pitot tube may be used to dampen Δp fluctuations. It is recommended, but not required, that a pretest leak-check be conducted, as follows: (1) blow through the pitot impact opening until at least 7.6 cm (3 in.) H_2O velocity pressure registers on the manometer; then, close off the impact opening. The pressure shall remain stable for at least 15 seconds; (2) do the same for the static pressure side, except using suction to obtain the minimum of 7.6 cm (3 in.) H_2O . Other leak-check procedures, subject to the approval of the Administrator, may be used.

3.2 Level and zero the manometer. Because the ma-

nometer level and zero may drift due to vibrations and temperature changes, make periodic checks during the traverse. Record all necessary data as shown in the example data sheet (Figure 2-5).

3.3 Measure the velocity head and temperature at the traverse points specified by Method 1. Ensure that the proper differential pressure gauge is being used for the range of Δp values encountered (see Section 2.2). If it is necessary to change to a more sensitive gauge, do so, and remeasure the Δp and temperature readings at each traverse point. Conduct a post-test leak-check (mandatory), as described in Section 3.1 above, to validate the traverse run.

3.4 Measure the static pressure in the stack. One reading is usually adequate.

3.5 Determine the atmospheric pressure.

Figure 2-5. Velocity traverse data.

RULES AND REGULATIONS

3.6 Determine the stack gas dry molecular weight. For combustion processes or processes that emit essentially CO_2 , O_2 , CO , and N_2 , use Method 3. For processes emitting essentially air, an analysis need not be conducted; use a dry molecular weight of 29.0. For other processes, other methods, subject to the approval of the Administrator, must be used.

3.7 Obtain the moisture content from Reference Method 4 (or equivalent) or from Method 5.

3.8 Determine the cross-sectional area of the stack or duct at the sampling location. Whenever possible, physically measure the stack dimensions rather than using blueprints.

4. Calibration

4.1 Type S Pitot Tube. Before its initial use, carefully examine the Type S pitot tube in top, side, and end views to verify that the face openings of the tube are aligned within the specifications illustrated in Figure 2-2 or 2-3. The pitot tube shall not be used if it fails to meet these alignment specifications.

After verifying the face opening alignment, measure and record the following dimensions of the pitot tube:

(a) the external tubing diameter (dimension D_t , Figure 2-2b); and (b) the base-to-opening plane distances (dimensions P_A and P_B , Figure 2-2b). If D_t is between 0.48 and 0.95 cm ($3/16$ and $3/8$ in.) and if P_A and P_B are equal and between 1.05 and 1.50 R_t , there are two possible options: (1) the pitot tube may be calibrated according to the procedure outlined in Sections 4.1.2 through 4.1.5 below, or (2) a baseline (isolated tube) coefficient value of 0.84 may be assigned to the pitot tube. Note, however, that if the pitot tube is part of an assembly, calibration may still be required, despite knowledge of the baseline coefficient value (see Section 4.1.1).

If D_t , P_A , and P_B are outside the specified limits, the pitot tube must be calibrated as outlined in 4.1.2 through 4.1.5 below.

4.1.1 Type S Pitot Tube Assemblies. During sample and velocity traverses, the isolated Type S pitot tube is not always used; in many instances, the pitot tube is used in combination with other source-sampling components (thermocouple, sampling probe, nozzle) as part of an "assembly." The presence of other sampling components can sometimes affect the baseline value of the Type S pitot tube coefficient (Citation 9 in Section 6); therefore an assigned (or otherwise known) baseline coefficient

value may or may not be valid for a given assembly. The baseline and assembly coefficient values will be identical only when the relative placement of the components in the assembly is such that aerodynamic interference effects are eliminated. Figures 2-6 through 2-8 illustrate interference-free component arrangements for Type S pitot tubes having external tubing diameters between 0.48 and 0.95 cm ($3/16$ and $3/8$ in.). Type S pitot tube assemblies that fail to meet any or all of the specifications of Figures 2-6 through 2-8 shall be calibrated according to the procedure outlined in Sections 4.1.2 through 4.1.5 below, and prior to calibration, the values of the inter-component spacings (pitot-nozzle, pitot-thermocouple, pitot-probe sheath) shall be measured and recorded.

NOTE.—Do not use any Type S pitot tube assembly which is constructed such that the impact pressure opening plane of the pitot tube is below the entry plane of the nozzle (see Figure 2-6b).

4.1.2 Calibration Setup. If the Type S pitot tube is to be calibrated, one leg of the tube shall be permanently marked A, and the other, B. Calibration shall be done in a flow system having the following essential design features:

Figure 2-6. Proper pitot tube - sampling nozzle configuration to prevent aerodynamic interference; buttonhook - type nozzle; centers of nozzle and pitot opening aligned; D_t between 0.48 and 0.95 cm ($3/16$ and $3/8$ in.).

RULES AND REGULATIONS

Figure 2-7. Proper thermocouple placement to prevent interference; D_t between 0.48 and 0.95 cm (3/16 and 3/8 in.).

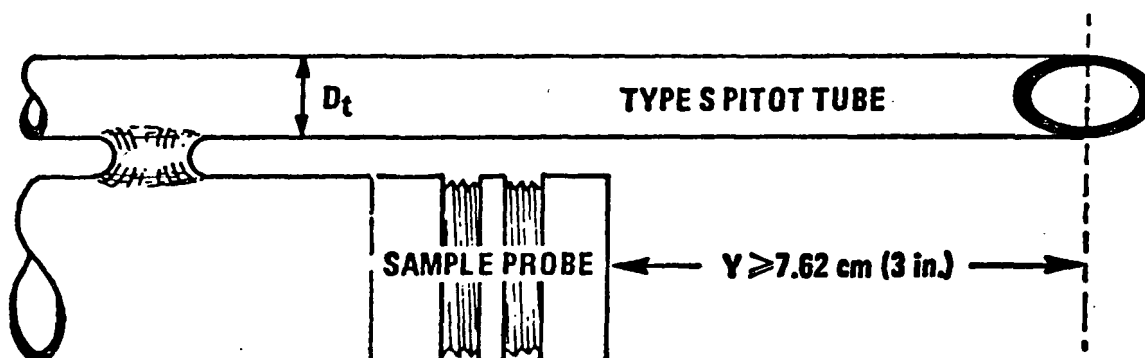

Figure 2-8. Minimum pitot-sample probe separation needed to prevent interference; D_t between 0.48 and 0.95 cm (3/16 and 3/8 in.).

4.1.2.1 The flowing gas stream must be confined to a duct of definite cross-sectional area, either circular or rectangular. For circular cross-sections, the minimum duct diameter shall be 30.5 cm (12 in.); for rectangular cross-sections, the width (shorter side) shall be at least 25.4 cm (10 in.).

4.1.2.2 The cross-sectional area of the calibration duct must be constant over a distance of 10 or more duct diameters. For a rectangular cross-section, use an equivalent diameter, calculated from the following equation, to determine the number of duct diameters:

$$D_e = \frac{2LW}{L+W}$$

Equation 2-1

where:

D_e = Equivalent diameter

L = Length

W = Width

To ensure the presence of stable, fully developed flow patterns at the calibration site, or "test section," the site must be located at least eight diameters downstream and two diameters upstream from the nearest disturbances.

NOTE.—The eight- and two-diameter criteria are not absolute; other test section locations may be used (subject to approval of the Administrator), provided that the flow at the test site is stable and demonstrably parallel to the duct axis.

4.1.2.3 The flow system shall have the capacity to generate a test-section velocity around 915 m/min (3,000

ft/min). This velocity must be constant with time to guarantee steady flow during calibration. Note that Type S pitot tube coefficients obtained by single-velocity calibration at 915 m/min (3,000 ft/min) will generally be valid to within ± 3 percent for the measurement of velocities above 305 m/min (1,000 ft/min) and to within ± 5 to 6 percent for the measurement of velocities between 180 and 305 m/min (600 and 1,000 ft/min). If a more precise correlation between C_p and velocity is desired, the flow system shall have the capacity to generate at least four distinct, time-invariant test-section velocities covering the velocity range from 180 to 1,525 m/min (600 to 5,000 ft/min), and calibration data shall be taken at regular velocity intervals over this range (see Citations 9 and 14 in Section 6 for details).

4.1.2.4 Two entry ports, one each for the standard and Type S pitot tubes, shall be cut in the test section; the standard pitot entry port shall be located slightly downstream of the Type S port, so that the standard and Type S impact openings will lie in the same cross-sectional plane during calibration. To facilitate alignment of the pitot tubes during calibration, it is advisable that the test section be constructed of plexiglas or some other transparent material.

4.1.3 Calibration Procedure. Note that this procedure is a general one and must not be used without first referring to the special considerations presented in Section 4.1.5. Note also that this procedure applies only to single-velocity calibration. To obtain calibration data for the A and B sides of the Type S pitot tube, proceed as follows:

4.1.3.1 Make sure that the manometer is properly filled and that the oil is free from contamination and is of the proper density. Inspect and leak-check all pitot lines; repair or replace if necessary.

4.1.3.2 Level and zero the manometer. Turn on the fan and allow the flow to stabilize. Seal the Type S entry port.

4.1.3.3 Ensure that the manometer is level and zeroed. Position the standard pitot tube at the calibration point (determined as outlined in Section 4.1.5.1), and align the tube so that its tip is pointed directly into the flow. Particular care should be taken in aligning the tube to avoid yaw and pitch angles. Make sure that the entry port surrounding the tube is properly sealed.

4.1.3.4 Read Δp_{std} and record its value in a data table similar to the one shown in Figure 2-9. Remove the standard pitot tube from the duct and disconnect it from the manometer. Seal the standard entry port.

4.1.3.5 Connect the Type S pitot tube to the manometer. Open the Type S entry port. Check the manometer level and zero. Insert and align the Type S pitot tube so that its A side impact opening is at the same point as was the standard pitot tube and is pointed directly into the flow. Make sure that the entry port surrounding the tube is properly sealed.

4.1.3.6 Read Δp_s and enter its value in the data table. Remove the Type S pitot tube from the duct and disconnect it from the manometer.

4.1.3.7 Repeat steps 4.1.3.3 through 4.1.3.6 above until three pairs of Δp readings have been obtained.

4.1.3.8 Repeat steps 4.1.3.3 through 4.1.3.7 above for the B side of the Type S pitot tube.

4.1.3.9 Perform calculations, as described in Section 4.1.4 below.

4.1.4 Calculations.

4.1.4.1 For each of the six pairs of Δp readings (i.e., three from side A and three from side B) obtained in Section 4.1.3 above, calculate the value of the Type S pitot tube coefficient as follows:

RULES AND REGULATIONS

PITOT TUBE IDENTIFICATION NUMBER: _____ DATE: _____

CALIBRATED BY: _____

"A" SIDE CALIBRATION				
RUN NO.	Δp_{std} cm H ₂ O (in. H ₂ O)	$\Delta p(s)$ cm H ₂ O (in. H ₂ O)	$C_p(s)$	DEVIATION $C_p(s) - \bar{C}_p(A)$
1				
2				
3				
			\bar{C}_p (SIDE A)	

"B" SIDE CALIBRATION				
RUN NO.	Δp_{std} cm H ₂ O (in. H ₂ O)	$\Delta p(s)$ cm H ₂ O (in. H ₂ O)	$C_p(s)$	DEVIATION $C_p(s) - \bar{C}_p(B)$
1				
2				
3				
			\bar{C}_p (SIDE B)	

$$\text{AVERAGE DEVIATION} = \sigma \text{ (A OR B)} = \frac{\sum_{i=1}^3 |C_p(s) - \bar{C}_p(A \text{ OR } B)|}{3} \leftarrow \text{MUST BE } \leq 0.01$$

$$|\bar{C}_p \text{ (SIDE A)} - \bar{C}_p \text{ (SIDE B)}| \leftarrow \text{MUST BE } \leq 0.01$$

Figure 2-9. Pitot tube calibration data.

$$C_p(s) = C_{p(std)} \sqrt{\frac{\Delta p_{std}}{\Delta p_s}}$$

Equation 2-2

where:

$C_p(s)$ = Type S pitot tube coefficient

$C_{p(std)}$ = Standard pitot tube coefficient; use 0.99 if the coefficient is unknown and the tube is designed

according to the criteria of Sections 2.7.1 to 2.7.5 of this method.

Δp_{std} = Velocity head measured by the standard pitot tube, cm H₂O (in. H₂O)

Δp_s = Velocity head measured by the Type S pitot tube, cm H₂O (in. H₂O)

4.1.4.2 Calculate \bar{C}_p (side A), the mean A-side coefficient, and \bar{C}_p (side B), the mean B-side coefficient; calculate the difference between these two average values.

4.1.4.3 Calculate the deviation of each of the three A-side values of $C_p(s)$ from \bar{C}_p (side A), and the deviation of each B-side value of $C_p(s)$ from \bar{C}_p (side B). Use the following equation:

$$\text{Deviation} = C_p(s) - \bar{C}_p(A \text{ or } B)$$

Equation 2-3

4.1.4.4 Calculate σ , the average deviation from the mean, for both the A and B sides of the pitot tube. Use the following equation:

$$\sigma \text{ (side A or B)} = \frac{\sum_{i=1}^3 |C_p(s) - \bar{C}_p(A \text{ or } B)|}{3}$$

Equation 2-4

4.1.4.5 Use the Type S pitot tube only if the values of σ (side A) and σ (side B) are less than or equal to 0.01 and if the absolute value of the difference between \bar{C}_p (A) and \bar{C}_p (B) is 0.01 or less.

4.1.5 Special considerations:

4.1.5.1 Selection of calibration point.

4.1.5.1.1 When an isolated Type S pitot tube is calibrated, select a calibration point at or near the center of the duct, and follow the procedures outlined in Sections 4.1.3 and 4.1.4 above. The Type S pitot coefficients so obtained, i.e., \bar{C}_p (side A) and \bar{C}_p (side B), will be valid, so long as either: (1) the isolated pitot tube is used; or (2) the pitot tube is used with other components (nozzle, thermocouple, sample probe) in an arrangement that is free from aerodynamic interference effects (see Figures 2-6 through 2-8).

4.1.5.1.2 For Type S pitot tube-thermocouple combinations (without sample probe), select a calibration point at or near the center of the duct, and follow the procedures outlined in Sections 4.1.3 and 4.1.4 above. The coefficients so obtained will be valid so long as the pitot tube-thermocouple combination is used by itself or with other components in an interference-free arrangement (Figures 2-6 and 2-8).

4.1.5.1.3 For assemblies with sample probes, the calibration point should be located at or near the center of the duct; however, insertion of a probe sheath into a small duct may cause significant cross-sectional area blockage and yield incorrect coefficient values (Citation 9 in Section 6). Therefore, to minimize the blockage effect, the calibration point may be a few inches off-center if necessary. The actual blockage effect will be negligible when the theoretical blockage, as determined by a projected-area model of the probe sheath, is 2 percent or less of the duct cross-sectional area for assemblies without external sheaths (Figure 2-10a), and 3 percent or less for assemblies with external sheaths (Figure 2-10b).

4.1.5.2 For those probe assemblies in which pitot tube-nozzle interference is a factor (i.e., those in which the pitot-nozzle separation distance fails to meet the specification illustrated in Figure 2-6a), the value of $C_p(s)$ depends upon the amount of free-space between the tube and nozzle, and therefore is a function of nozzle size. In these instances, separate calibrations shall be performed with each of the commonly used nozzle sizes in place. Note that the single-velocity calibration technique is acceptable for this purpose, even though the larger nozzle sizes (>0.635 cm or 1/4 in.) are not ordinarily used for isokinetic sampling at velocities around 915 m/min (3,000 ft/min), which is the calibration velocity; note also that it is not necessary to draw an isokinetic sample during calibration (see Citation 19 in Section 6).

4.1.5.3 For a probe assembly constructed such that its pitot tube is always used in the same orientation, only one side of the pitot tube need be calibrated (the side which will face the flow). The pitot tube must still meet the alignment specifications of Figure 2-2 or 2-3, however, and must have an average deviation (σ) value of 0.01 or less (see Section 4.1.4.4).

RULES AND REGULATIONS

Figure 2-10. Projected-area models for typical pitot tube assemblies.

4.1.6 Field Use and Recalibration.

4.1.6.1 Field Use.

4.1.6.1.1 When a Type S pitot tube (isolated tube or assembly) is used in the field, the appropriate coefficient value (whether assigned or obtained by calibration) shall be used to perform velocity calculations. For calibrated Type S pitot tubes, the A side coefficient shall be used when the A side of the tube faces the flow, and the B side coefficient shall be used when the B side faces the flow; alternatively, the arithmetic average of the A and B side coefficient values may be used, irrespective of which side faces the flow.

4.1.6.1.2 When a probe assembly is used to sample a small duct (12 to 36 in. in diameter), the probe sheath sometimes blocks a significant part of the duct cross-section, causing a reduction in the effective value of C_p . Consult Citation 9 in Section 6 for details. Conventional pitot-sampling probe assemblies are not recommended for use in ducts having inside diameters smaller than 12 inches (Citation 16 in Section 6).

4.1.6.2 Recalibration.

4.1.6.2.1 Isolated Pitot Tubes. After each field use, the pitot tube shall be carefully reexamined in top, side, and end views. If the pitot face openings are still aligned within the specifications illustrated in Figure 2-2 or 2-3, it can be assumed that the baseline coefficient of the pitot tube has not changed. If, however, the tube has been damaged to the extent that it no longer meets the specifications of Figure 2-2 or 2-3, the damage shall either be repaired to restore proper alignment of the face openings or the tube shall be discarded.

4.1.6.2.2 Pitot Tube Assemblies. After each field use, check the face opening alignment of the pitot tube, as in Section 4.1.6.2.1; also, remeasure the intercomponent spacings of the assembly. If the intercomponent spacings have not changed and the face opening alignment is acceptable, it can be assumed that the coefficient of the assembly has not changed. If the face opening alignment is no longer within the specifications of Figures 2-2 or 2-3, either repair the damage or replace the pitot tube (calibrating the new assembly, if necessary). If the intercomponent spacings have changed, restore the original spacings or recalibrate the assembly.

4.2 Standard pitot tube (if applicable). If a standard pitot tube is used for the velocity traverse, the tube shall be constructed according to the criteria of Section 2.7 and shall be assigned a baseline coefficient value of 0.99. If the standard pitot tube is used as part of an assembly,

the tube shall be in an interference-free arrangement (subject to the approval of the Administrator).

4.3 Temperature Gauges. After each field use, calibrate dial thermometers, liquid-filled bulb thermometers, thermocouple-potentiometer systems, and other gauges at a temperature within 10 percent of the average absolute stack temperature. For temperatures up to 405° C (761° F), use an ASTM mercury-in-glass reference thermometer, or equivalent, as a reference; alternatively, either a reference thermocouple and potentiometer (calibrated by NBS) or thermometric fixed points, e.g., ice bath and boiling water (corrected for barometric pressure) may be used. For temperatures above 405° C (761° F), use an NBS-calibrated reference thermocouple-potentiometer system or an alternate reference, subject to the approval of the Administrator.

If, during calibration, the absolute temperatures measured with the gauge being calibrated and the reference gauge agree within 1.5 percent, the temperature data taken in the field shall be considered valid. Otherwise, the pollutant emission test shall either be considered invalid or adjustments (if appropriate) of the test results shall be made, subject to the approval of the Administrator.

4.4 Barometer. Calibrate the barometer used against a mercury barometer.

5. Calculations

Carry out calculations, retaining at least one extra decimal figure beyond that of the acquired data. Round off figures after final calculation.

5.1 Nomenclature.

A = Cross-sectional area of stack, m² (ft²).

B_{ws} = Water vapor in the gas stream (from Method 5 or Reference Method 4), proportion by volume.

C_p = Pitot tube coefficient, dimensionless.

K_p = Pitot tube constant,

$$34.97 \frac{\text{m}}{\text{sec}} \left[\frac{(\text{g/g-mole})(\text{mm Hg})}{(^{\circ}\text{K})(\text{mm H}_2\text{O})} \right]^{1/2}$$

for the metric system and

$$85.49 \frac{\text{ft}}{\text{sec}} \left[\frac{(\text{lb/lb-mole})(\text{in. Hg})}{(^{\circ}\text{R})(\text{in. H}_2\text{O})} \right]^{1/2}$$

for the English system.

M_d = Molecular weight of stack gas, dry basis (see Section 3.6) g/g-mole (lb/lb-mole).

M_w = Molecular weight of stack gas, wet basis, g/g-mole (lb/lb-mole).

$$= M_d (1 - B_{ws}) + 18.0 B_{ws} \quad \text{Equation 2-5}$$

P_{bar} = Barometric pressure at measurement site, mm Hg (in. Hg).

P_s = Stack static pressure, mm Hg (in. Hg).

P_s = Absolute stack gas pressure, mm Hg (in. Hg).

$$= P_{bar} + P_s \quad \text{Equation 2-6}$$

P_{std} = Standard absolute pressure, 760 mm Hg (29.92 in. Hg).

Q_{sd} = Dry volumetric stack gas flow rate corrected to standard conditions, dscm/hr (dscf/hr).

t_s = Stack temperature, °C (°F).

T_s = Absolute stack temperature, °K (°R).

$$= 273 + t_s \text{ for metric} \quad \text{Equation 2-7}$$

$$= 460 + t_s \text{ for English} \quad \text{Equation 2-8}$$

T_{std} = Standard absolute temperature, 293°K (528°R)

v_s = Average stack gas velocity, m/sec (ft/sec).

Δp = Velocity head of stack gas, mm H₂O (in. H₂O).

3,600 = Conversion factor, sec/hr.

18.0 = Molecular weight of water, g/g-mole (lb-lb-mole).

5.2 Average stack gas velocity.

$$v_s = K_p C_p (\sqrt{\Delta p})^{0.775} \sqrt{\frac{T_s (a-v)}{P_s M_s}}$$

$$\quad \text{Equation 2-9}$$

5.3 Average stack gas dry volumetric flow rate.

$$Q_{sd} = 3,600 (1 - B_{ws}) v_s A \left(\frac{T_{std}}{T_s (a-v)} \right) \left(\frac{P_s}{P_{std}} \right)$$

$$\quad \text{Equation 2-10}$$

METHOD 3—GAS ANALYSIS FOR CARBON DIOXIDE, OXYGEN, EXCESS AIR, AND DRY MOLECULAR WEIGHT

1. Principle and Applicability

1.1 Principle. A gas sample is extracted from a stack, by one of the following methods: (1) single-point, grab sampling; (2) single-point, integrated sampling; or (3) multi-point, integrated sampling. The gas sample is analyzed for percent carbon dioxide (CO₂), percent oxygen (O₂), and, if necessary, percent carbon monoxide (CO). If a dry molecular weight determination is to be made, either an Orsat or a Fyrite¹ analyzer may be used for the analysis; for excess air or emission rate correction factor determination, an Orsat analyzer must be used.

1.2 Applicability. This method is applicable for determining CO₂ and O₂ concentrations, excess air, and dry molecular weight of a sample from a gas stream of a fossil-fuel combustion process. The method may also be applicable to other processes where it has been determined that compounds other than CO₂, O₂, CO, and nitrogen (N₂) are not present in concentrations sufficient to affect the results.

Other methods, as well as modifications to the procedure described herein, are also applicable for some or all of the above determinations. Examples of specific methods and modifications include: (1) a multi-point sampling method using an Orsat analyzer to analyze individual grab samples obtained at each point; (2) a method using CO₂ or O₂ and stoichiometric calculations to determine dry molecular weight and excess air; (3) assigning a value of 30.0 for dry molecular weight, in lieu of actual measurements, for processes burning natural gas, coal, or oil. These methods and modifications may be used, but are subject to the approval of the Administrator.

2. Apparatus

As an alternative to the sampling apparatus and systems described herein, other sampling systems (e.g., liquid displacement) may be used provided such systems are capable of obtaining a representative sample and maintaining a constant sampling rate, and are otherwise capable of yielding acceptable results. Use of such systems is subject to the approval of the Administrator.

2.1 Grab Sampling (Figure 3-1).
2.1.1 Probe. The probe should be made of stainless steel or borosilicate glass tubing and should be equipped with an in-stack or out-stack filter to remove particulate matter (a plug of glass wool is satisfactory for this purpose). Any other material inert to O₂, CO₂, CO, and N₂ and resistant to temperature at sampling conditions may be used for the probe; examples of such material are aluminum, copper, quartz glass and Teflon.

2.1.2 Pump. A one-way squeeze bulb, or equivalent, is used to transport the gas sample to the analyzer.

2.2 Integrated Sampling (Figure 3-2).

2.2.1 Probe. A probe such as that described in Section 2.1.1 is suitable.

¹ Mention of trade names or specific products does not constitute endorsement by the Environmental Protection Agency.

RULES AND REGULATIONS

Figure 3-1. Grab-sampling train.

Figure 3-2. Integrated gas-sampling train.

RULES AND REGULATIONS

2.2.2 Condenser. An air-cooled or water-cooled condenser, or other condenser that will not remove O_2 , CO_2 , CO , and N_2 , may be used to remove excess moisture which would interfere with the operation of the pump and flow meter.

2.2.3 Valve. A needle valve is used to adjust sample gas flow rate.

2.2.4 Pump. A leak-free, diaphragm-type pump, or equivalent, is used to transport sample gas to the flexible bag. Install a small surge tank between the pump and rate meter to eliminate the pulsation effect of the diaphragm pump on the rotameter.

2.2.5 Rate Meter. The rotameter, or equivalent rate meter, used should be capable of measuring flow rate to within ± 2 percent of the selected flow rate. A flow rate range of 50 to 1000 cm³/min is suggested.

2.2.6 Flexible Bag. Any leak-free plastic (e.g., Tedlar, Mylar, Teflon) or plastic-coated aluminum (e.g., aluminized Mylar) bag, or equivalent, having a capacity consistent with the selected flow rate and time length of the test run, may be used. A capacity in the range of 45 to 90 liters is suggested.

To leak-check the bag, connect it to a water manometer and pressurize the bag to 5 to 10 cm H₂O (2 to 4 in. H₂O). Allow to stand for 10 minutes. Any displacement in the water manometer indicates a leak. An alternative leak-check method is to pressurize the bag to 5 to 10 cm H₂O (2 to 4 in. H₂O) and allow to stand overnight. A deflated bag indicates a leak.

2.2.7 Pressure Gauge. A water-filled U-tube manometer, or equivalent, of about 28 cm (12 in.) is used for the flexible bag leak-check.

2.2.8 Vacuum Gauge. A mercury manometer, or equivalent, of at least 760 mm Hg (30 in. Hg) is used for the sampling train leak-check.

2.3 Analysis. For Orsat and Fyrite analyzer maintenance and operation procedures, follow the instructions recommended by the manufacturer, unless otherwise specified herein.

2.3.1 Dry Molecular Weight Determination. An Orsat analyzer or Fyrite type combustion gas analyzer may be used.

2.3.2 Emission Rate Correction Factor or Excess Air Determination. An Orsat analyzer must be used. For low CO_2 (less than 4.0 percent) or high O_2 (greater than 15.0 percent) concentrations, the measuring burette of the Orsat must have at least 0.1 percent subdivisions.

3. Dry Molecular Weight Determination

Any of the three sampling and analytical procedures described below may be used for determining the dry molecular weight.

3.1 Single-Point, Grab Sampling and Analytical Procedure.

3.1.1 The sampling point in the duct shall either be at the centroid of the cross section or at a point no closer to the walls than 1.00 m (3.3 ft), unless otherwise specified by the Administrator.

3.1.2 Set up the equipment as shown in Figure 3-1, making sure all connections ahead of the analyzer are tight and leak-free. If an Orsat analyzer is used, it is recommended that the analyzer be leak-checked by following the procedure in Section 5; however, the leak-check is optional.

3.1.3 Place the probe in the stack, with the tip of the probe positioned at the sampling point; purge the sampling line. Draw a sample into the analyzer and immediately analyze it for percent CO_2 and percent O_2 . Determine the percentage of the gas that is N_2 and CO by subtracting the sum of the percent CO_2 and percent O_2 from 100 percent. Calculate the dry molecular weight as indicated in Section 6.3.

3.1.4 Repeat the sampling, analysis, and calculation procedures, until the dry molecular weights of any three grab samples differ from their mean by no more than 0.3 g/g-mole (0.3 lb/lb-mole). Average these three molecular weights, and report the results to the nearest 0.1 g/g-mole (lb/lb-mole).

3.2 Single-Point, Integrated Sampling and Analytical Procedure.

3.2.1 The sampling point in the duct shall be located as specified in Section 3.1.1.

3.2.2 Leak-check (optional) the flexible bag as in Section 2.2.6. Set up the equipment as shown in Figure 3-2. Just prior to sampling, leak-check (optional) the train by placing a vacuum gauge at the condenser inlet, pulling a vacuum of at least 250 mm Hg (10 in. Hg), plugging the outlet at the quick disconnect, and then turning off the pump. The vacuum should remain stable for at least 0.5 minute. Evacuate the flexible bag. Connect the probe and place it in the stack, with the tip of the probe positioned at the sampling point; purge the sampling line. Next, connect the bag and make sure that all connections are tight and leak free.

3.2.3 Sample at a constant rate. The sampling run should be simultaneous with, and for the same total length of time as, the pollutant emission rate determination. Collection of at least 30 liters (1.00 ft³) of sample gas is recommended; however, smaller volumes may be collected, if desired.

3.2.4 Obtain one integrated flue gas sample during each pollutant emission rate determination. Within 8 hours after the sample is taken, analyze it for percent CO_2 and percent O_2 using either an Orsat analyzer or a Fyrite-type combustion gas analyzer. If an Orsat analyzer is used, it is recommended that the Orsat leak-check described in Section 5 be performed before this determination; however, the check is optional. Determine the percentage of the gas that is N_2 and CO by subtracting the sum of the percent CO_2 and percent O_2

from 100 percent. Calculate the dry molecular weight as indicated in Section 6.3.

3.2.5 Repeat the analysis and calculation procedures until the individual dry molecular weights for any three analyses differ from their mean by no more than 0.3 g/g-mole (0.3 lb/lb-mole). Average these three molecular weights, and report the results to the nearest 0.1 g/g-mole (0.1 lb/lb-mole).

3.3 Multi-Point, Integrated Sampling and Analytical Procedure.

3.3.1 Unless otherwise specified by the Administrator, a minimum of eight traverse points shall be used for circular stacks having diameters less than 0.61 m (24 in.), a minimum of nine shall be used for rectangular stacks having equivalent diameters less than 0.61 m (24 in.), and a minimum of twelve traverse points shall be used for all other cases. The traverse points shall be located according to Method 1. The use of fewer points is subject to approval of the Administrator.

3.3.2 Follow the procedures outlined in Sections 3.2.2 through 3.2.5, except for the following: traverse all sampling points and sample at each point for an equal length of time. Record sampling data as shown in Figure 3-3.

4. Emission Rate Correction Factor or Excess Air Determination

NOTE.—A Fyrite-type combustion gas analyzer is not acceptable for excess air or emission rate correction factor determination, unless approved by the Administrator. If both percent CO_2 and percent O_2 are measured, the analytical results of any of the three procedures given below may also be used for calculating the dry molecular weight.

Each of the three procedures below shall be used only when specified in an applicable subpart of the standards. The use of these procedures for other purposes must have specific prior approval of the Administrator.

4.1 Single-Point, Grab Sampling and Analytical Procedure.

4.1.1 The sampling point in the duct shall either be at the centroid of the cross-section or at a point no closer to the walls than 1.00 m (3.3 ft), unless otherwise specified by the Administrator.

4.1.2 Set up the equipment as shown in Figure 3-1, making sure all connections ahead of the analyzer are tight and leak-free. Leak-check the Orsat analyzer according to the procedure described in Section 5. This leak-check is mandatory.

TIME	TRAVERSE PT.	Q 1pm	% DEV. ^a
AVERAGE			

$$^a \% DEV = \left(\frac{Q \cdot Q_{avg}}{Q_{avg}} \right) 100 \quad (\text{MUST BE } \leq 10\%)$$

Figure 3-3. Sampling rate data.

4.1.3 Place the probe in the stack, with the tip of the probe positioned at the sampling point; purge the sampling line. Draw a sample into the analyzer. For emission rate correction factor determination, immediately analyze the sample, as outlined in Sections 4.1.4 and 4.1.5, for percent CO_2 or percent O_2 . If excess air is desired, proceed as follows: (1) immediately analyze the sample, as in Sections 4.1.4 and 4.1.5, for percent CO_2 , O_2 , and CO ; (2) determine the percentage of the gas that is N_2 by subtracting the sum of the percent CO_2 , percent O_2 , and percent CO from 100 percent; and (3) calculate percent excess air as outlined in Section 6.2.

4.1.4 To ensure complete absorption of the CO_2 , O_2 , or if applicable, CO , make repeated passes through each absorbing solution until two consecutive readings are the same. Several passes (three or four) should be made between readings. (If constant readings cannot be obtained after three consecutive readings, replace the absorbing solution.)

4.1.5 After the analysis is completed, leak-check (mandatory) the Orsat analyzer once again, as described in Section 5. For the results of the analysis to be valid, the Orsat analyzer must pass this leak test before and after the analysis. NOTE.—Since this single-point, grab sampling and analytical procedure is normally conducted in conjunction with a single-point, grab sampling and analytical procedure for a pollutant, only one analysis is ordinarily conducted. Therefore, great care must be taken to obtain a valid sample and analysis. Although in most cases only CO_2 or O_2 is required, it is recommended that both CO_2 and O_2 be measured, and that Citation 5 in the Bibliography be used to validate the analytical data.

4.2 Single-Point, Integrated Sampling and Analytical Procedure.

4.2.1 The sampling point in the duct shall be located as specified in Section 4.1.1.

4.2.2 Leak-check (mandatory) the flexible bag as in Section 2.2.6. Set up the equipment as shown in Figure 3-2. Just prior to sampling, leak-check (mandatory) the train by placing a vacuum gauge at the condenser inlet, pulling a vacuum of at least 250 mm Hg (10 in. Hg), plugging the outlet at the quick disconnect, and then

turning off the pump. The vacuum shall remain stable for at least 0.5 minute. Evacuate the flexible bag. Connect the probe and place it in the stack, with the tip of the probe positioned at the sampling point; purge the sampling line. Next, connect the bag and make sure that all connections are tight and leak free.

4.2.3 Sample at a constant rate, or as specified by the Administrator. The sampling run must be simultaneous with, and for the same total length of time as, the pollutant emission rate determination. Collect at least 30 liters (1.00 ft³) of sample gas. Smaller volumes may be collected, subject to approval of the Administrator.

4.2.4 Obtain one integrated flue gas sample during each pollutant emission rate determination. For emission rate correction factor determination, analyze the sample within 4 hours after it is taken for percent CO_2 or percent O_2 (as outlined in Sections 4.2.5 through 4.2.7). The Orsat analyzer must be leak-checked (see Section 5) before the analysis. If excess air is desired, proceed as follows: (1) within 4 hours after the sample is taken, analyze it (as in Sections 4.2.5 through 4.2.7) for percent CO_2 , O_2 , and CO ; (2) determine the percentage of the gas that is N_2 by subtracting the sum of the percent CO_2 , percent O_2 , and percent CO from 100 percent; (3) calculate percent excess air, as outlined in Section 6.2.

4.2.5 To ensure complete absorption of the CO_2 , O_2 , or if applicable, CO , make repeated passes through each absorbing solution until two consecutive readings are the same. Several passes (three or four) should be made between readings. (If constant readings cannot be obtained after three consecutive readings, replace the absorbing solution.)

4.2.6 Repeat the analysis until the following criteria are met:

4.2.6.1 For percent CO_2 , repeat the analytical procedure until the results of any three analyses differ by no more than (a) 0.3 percent by volume when CO_2 is greater than 4.0 percent or (b) 0.2 percent by volume when CO_2 is less than or equal to 4.0 percent. Average the three acceptable values of percent CO_2 and report the results to the nearest 0.1 percent.

4.2.6.2 For percent O_2 , repeat the analytical procedure until the results of any three analyses differ by no more

RULES AND REGULATIONS

than (a) 0.3 percent by volume when O_2 is less than 15.0 percent or (b) 0.2 percent by volume when O_2 is greater than 15.0 percent. Average the three acceptable values of percent O_2 and report the results to the nearest 0.1 percent.

4.2.6.3 For percent CO, repeat the analytical procedure until the results of any three analyses differ by no more than 0.3 percent. Average the three acceptable values of percent CO and report the results to the nearest 0.1 percent.

4.2.7 After the analysis is completed, leak-check (mandatory) the Orsat analyzer once again, as described in Section 5. For the results of the analysis to be valid, the Orsat analyzer must pass this leak test before and after the analysis. Note: Although in most instances only CO_2 or O_2 is required, it is recommended that both CO_2 and O_2 be measured, and that Citation 5 in the Bibliography be used to validate the analytical data.

4.3 Multi-Point, Integrated Sampling and Analytical Procedure.

4.3.1 Both the minimum number of sampling points and the sampling point location shall be as specified in Section 3.3.1 of this method. The use of fewer points than specified is subject to the approval of the Administrator.

4.3.2 Follow the procedures outlined in Sections 4.2.2 through 4.2.7, except for the following: Traverse all sampling points and sample at each point for an equal length of time. Record sampling data as shown in Figure 3-3.

5. Leak-Check Procedure for Orsat Analyzers

Moving an Orsat analyzer frequently causes it to leak. Therefore, an Orsat analyzer should be thoroughly leak-checked on site before the flue gas sample is introduced into it. The procedure for leak-checking an Orsat analyzer is:

5.1.1 Bring the liquid level in each pipette up to the reference mark on the capillary tubing and then close the pipette stopcock.

5.1.2 Raise the leveling bulb sufficiently to bring the confining liquid meniscus onto the graduated portion of the burette and then close the manifold stopcock.

5.1.3 Record the meniscus position.

5.1.4 Observe the meniscus in the burette and the liquid level in the pipette for movement over the next 4 minutes.

5.1.5 For the Orsat analyzer to pass the leak-check, two conditions must be met.

5.1.5.1 The liquid level in each pipette must not fall below the bottom of the capillary tubing during this 4-minute interval.

5.1.5.2 The meniscus in the burette must not change by more than 0.2 ml during this 4-minute interval.

5.1.6 If the analyzer fails the leak-check procedure, all rubber connections and stopcocks should be checked until the cause of the leak is identified. Leaking stopcocks must be disassembled, cleaned, and regreased. Leaking rubber connections must be replaced. After the analyzer is reassembled, the leak-check procedure must be repeated.

6. Calculations

6.1 Nomenclature.

M_d = Dry molecular weight, g/g-mole (lb/lb-mole).

%EA = Percent excess air.

% CO_2 = Percent CO_2 by volume (dry basis).

% O_2 = Percent O_2 by volume (dry basis).

%CO = Percent CO by volume (dry basis).

% N_2 = Percent N_2 by volume (dry basis).

0.264 = Ratio of O_2 to N_2 in air, v/v.

0.280 = Molecular weight of N_2 or CO, divided by 100.

0.320 = Molecular weight of O_2 divided by 100.

0.440 = Molecular weight of CO_2 divided by 100.

6.2 Percent Excess Air. Calculate the percent excess air (if applicable), by substituting the appropriate values of percent O_2 , CO, and N_2 (obtained from Section 4.1.3 or 4.2.4) into Equation 3-1.

$$\%EA = \left[\frac{\%O_2 - 0.5\%CO}{0.264\%N_2 - (\%O_2 - 0.5\%CO)} \right] 100$$

Equation 3-1

NOTE.—The equation above assumes that ambient air is used as the source of O_2 and that the fuel does not contain appreciable amounts of N_2 (as do coke oven or blast furnace gases). For those cases when appreciable amounts of N_2 are present (coal, oil, and natural gas do not contain appreciable amounts of N_2) or when oxygen enrichment is used, alternate methods, subject to approval of the Administrator, are required.

6.3 Dry Molecular Weight. Use Equation 3-2 to calculate the dry molecular weight of the stack gas

$$M_d = 0.440(\%CO_2) + 0.320(\%O_2) + 0.280(\%N_2 + \%CO)$$

Equation 3-2

NOTE.—The above equation does not consider argon in air (about 0.9 percent, molecular weight of 37.7). A negative error of about 0.4 percent is introduced. The tester may opt to include argon in the analysis using procedures subject to approval of the Administrator.

METHOD 4—DETERMINATION OF MOISTURE CONTENT IN STACK GASES

1. Principle and Applicability

1.1 Principle. A gas sample is extracted at a constant rate from the source; moisture is removed from the sample stream and determined either volumetrically or gravimetrically.

1.2 Applicability. This method is applicable for determining the moisture content of stack gas.

Two procedures are given. The first is a reference method, for accurate determinations of moisture content (such as are needed to calculate emission data). The second is an approximation method, which provides estimates of percent moisture to aid in setting isokinetic sampling rates prior to a pollutant emission measurement run. The approximation method described herein is only a suggested approach; alternative means for approximating the moisture content, e.g., drying tubes, wet bulb-dry bulb techniques, condensation techniques, stoichiometric calculations, previous experience, etc., are also acceptable.

The reference method is often conducted simultaneously with a pollutant emission measurement run; when it is, calculation of percent isokinetic, pollutant emission rate, etc., for the run shall be based upon the results of the reference method or its equivalent; these calculations shall not be based upon the results of the approximation method, unless the approximation method is shown, to the satisfaction of the Administrator, U.S. Environmental Protection Agency, to be capable of yielding results within 1 percent H_2O of the reference method.

NOTE.—The reference method may yield questionable results when applied to saturated gas streams or to streams that contain water droplets. Therefore, when these conditions exist or are suspected, a second determination of the moisture content shall be made simultaneously with the reference method, as follows: Assume that the gas stream is saturated. Attach a temperature sensor [capable of measuring to $\pm 1^\circ C$ ($2^\circ F$)] to the reference method probe. Measure the stack gas temperature at each traverse point (see Section 2.2.1) during the reference method traverse; calculate the average stack gas temperature. Next, determine the moisture percentage, either by: (1) using a psychrometric chart and making appropriate corrections if stack pressure is different from that of the chart, or (2) using saturation vapor pressure tables. In cases where the psychrometric chart or the saturation vapor pressure tables are not applicable (based on evaluation of the process), alternate methods, subject to the approval of the Administrator, shall be used.

2. Reference Method

The procedure described in Method 5 for determining moisture content is acceptable as a reference method.

2.1 Apparatus. A schematic of the sampling train used in this reference method is shown in Figure 4-1. All components shall be maintained and calibrated according to the procedure outlined in Method 5.

RULES AND REGULATIONS

Figure 4-1. Moisture sampling train-reference method.

2.1.1 Probe. The probe is constructed of stainless steel or glass tubing, sufficiently heated to prevent water condensation, and is equipped with a filter, either in-stack (e.g., a plug of glass wool inserted into the end of the probe) or heated out-stack (e.g., as described in Method 5), to remove particulate matter.

When stack conditions permit, other metals or plastic tubing may be used for the probe, subject to the approval of the Administrator.

2.1.2 Condenser. The condenser consists of four impingers connected in series with ground glass, leak-free fittings or any similarly leak-free non-contaminating fittings. The first, third, and fourth impingers shall be of the Greenburg-Smith design, modified by replacing the tip with a 1.3 centimeter ($\frac{1}{2}$ inch) ID glass tube extending to about 1.3 cm ($\frac{1}{2}$ in.) from the bottom of the flask. The second impinger shall be of the Greenburg-Smith design with the standard tip. Modifications (e.g., using flexible connections between the impingers, using materials other than glass, or using flexible vacuum lines to connect the filter holder to the condenser) may be used, subject to the approval of the Administrator.

The first two impingers shall contain known volumes of water, the third shall be empty, and the fourth shall contain a known weight of 6- to 16-mesh indicating type silica gel, or equivalent desiccant. If the silica gel has been previously used, dry at 175° C (350° F) for 2 hours. New silica gel may be used as received. A thermometer, capable of measuring temperature to within 1° C (2° F), shall be placed at the outlet of the fourth impinger, for monitoring purposes.

Alternatively, any system may be used (subject to the approval of the Administrator) that cools the sample gas stream and allows measurement of both the water that has been condensed and the moisture leaving the condenser, each to within 1 ml or 1 g. Acceptable means are to measure the condensed water, either gravimetrically or volumetrically, and to measure the moisture leaving the condenser by: (1) monitoring the temperature and pressure at the exit of the condenser and using Dalton's law of partial pressures, or (2) passing

the sample gas stream through a tared silica gel (or equivalent desiccant) trap, with exit gases kept below 20° C (68° F), and determining the weight gain.

If means other than silica gel are used to determine the amount of moisture leaving the condenser, it is recommended that silica gel (or equivalent) still be used between the condenser system and pump, to prevent moisture condensation in the pump and metering devices and to avoid the need to make corrections for moisture in the metered volume.

2.1.3 Cooling System. An ice bath container and crushed ice (or equivalent) are used to aid in condensing moisture.

2.1.4 Metering System. This system includes a vacuum gauge, leak-free pump, thermometers capable of measuring temperature to within 3° C (5.4° F), dry gas meter capable of measuring volume to within 2 percent, and related equipment as shown in Figure 4-1. Other metering systems, capable of maintaining a constant sampling rate and determining sample gas volume, may be used, subject to the approval of the Administrator.

2.1.5 Barometer. Mercury, aneroid, or other barometer capable of measuring atmospheric pressure to within 2.5 mm Hg (0.1 in. Hg) may be used. In many cases, the barometric reading may be obtained from a nearby national weather service station, in which case the station value (which is the absolute barometric pressure) shall be requested and an adjustment for elevation differences between the weather station and the sampling point shall be applied at a rate of minus 2.5 mm Hg (0.1 in. Hg) per 30 m (100 ft) elevation increase or vice versa for elevation decrease.

2.1.6 Graduated Cylinder and/or Balance. These items are used to measure condensed water and moisture caught in the silica gel to within 1 ml or 0.5 g. Graduated cylinders shall have subdivisions no greater than 2 ml. Most laboratory balances are capable of weighing to the nearest 0.5 g or less. These balances are suitable for use here.

2.2 Procedure. The following procedure is written for a condenser system (such as the impinger system de-

scribed in Section 2.1.2) incorporating volumetric analysis to measure the condensed moisture, and silica gel and gravimetric analysis to measure the moisture leaving the condenser.

2.2.1 Unless otherwise specified by the Administrator, a minimum of eight traverse points shall be used for circular stacks having diameters less than 0.61 m (24 in.), a minimum of nine points shall be used for rectangular stacks having equivalent diameters less than 0.61 m (24 in.), and a minimum of twelve traverse points shall be used in all other cases. The traverse points shall be located according to Method 1. The use of fewer points is subject to the approval of the Administrator. Select a suitable probe and probe length such that all traverse points can be sampled. Consider sampling from opposite sides of the stack (four total sampling ports) for large stacks, to permit use of shorter probe lengths. Mark the probe with heat resistant tape or by some other method to denote the proper distance into the stack or duct for each sampling point. Place known volumes of water in the first two impingers. Weigh and record the weight of the silica gel to the nearest 0.5 g, and transfer the silica gel to the fourth impinger; alternatively, the silica gel may first be transferred to the impinger, and the weight of the silica gel plus impinger recorded.

2.2.2 Select a total sampling time such that a minimum total gas volume of 0.60 scm (21 scf) will be collected, at a rate no greater than 0.021 m³/min (0.75 cfm). When both moisture content and pollutant emission rate are to be determined, the moisture determination shall be simultaneous with, and for the same total length of time as, the pollutant emission rate run, unless otherwise specified in an applicable subpart of the standards.

2.2.3 Set up the sampling train as shown in Figure 4-1. Turn on the probe heater and (if applicable) the filter heating system to temperatures of about 120° C (248° F), to prevent water condensation ahead of the condenser; allow time for the temperatures to stabilize. Place crushed ice in the ice bath container. It is recommended, but not required, that a leak check be done, as follows: Disconnect the probe from the first impinger or

RULES AND REGULATIONS

(if applicable) from the filter holder. Plug the inlet to the first impinger (or filter holder) and pull a 380 mm (15 in.) Hg vacuum; a lower vacuum may be used, provided that it is not exceeded during the test. A leakage rate in excess of 4 percent of the average sampling rate or 0.00057 m³/min (0.02 cfm), whichever is less, is unacceptable. Following the leak check, reconnect the probe to the sampling train.

2.2.4 During the sampling run, maintain a sampling rate within 10 percent of constant rate, or as specified by the Administrator. For each run, record the data required on the example data sheet shown in Figure 4-2. Be sure to record the dry gas meter reading at the beginning and end of each sampling time increment and when-

ever sampling is halted. Take other appropriate readings at each sample point, at least once during each time increment.

2.2.5 To begin sampling, position the probe tip at the first traverse point. Immediately start the pump and adjust the flow to the desired rate. Traverse the cross section, sampling at each traverse point for an equal length of time. Add more ice and, if necessary, salt to maintain a temperature of less than 20° C (68° F) at the silica gel outlet.

2.2.6 After collecting the sample, disconnect the probe from the filter holder (or from the first impinger) and conduct a leak check (mandatory) as described in Section

2.2.3. Record the leak rate. If the leakage rate exceeds the allowable rate, the tester shall either reject the test results or shall correct the sample volume as in Section 6.3 of Method 5. Next, measure the volume of the moisture condensed to the nearest ml. Determine the increase in weight of the silica gel (or silica gel plus impinger) to the nearest 0.5 g. Record this information (see example data sheet, Figure 4-3) and calculate the moisture percentage, as described in 2.3 below.

2.3 Calculations. Carry out the following calculations, retaining at least one extra decimal figure beyond that of the acquired data. Round off figures after final calculation.

	IMPINGER VOLUME, ml	SILICA GEL WEIGHT, g
FINAL		
INITIAL		
DIFFERENCE		

Figure 4-3. Analytical data - reference method.

2.3.1 Nomenclature.

B_{ws} = Proportion of water vapor, by volume, in the gas stream.
 M_w = Molecular weight of water, 18.0 g/g-mole (18.0 lb/lb-mole).
 P_m = Absolute pressure (for this method, same as barometric pressure) at the dry gas meter, mm Hg (in. Hg).
 P_{std} = Standard absolute pressure, 760 mm Hg (29.92 in. Hg).
 R = Ideal gas constant, 0.06236 (mm Hg) (m³)/(g-mole) (°K) for metric units and 21.85 (in. Hg) (ft³)/(lb-mole) (°R) for English units.
 T_m = Absolute temperature at meter, °K (°R).
 T_{std} = Standard absolute temperature, 293° K (528° R).
 V_m = Dry gas volume measured by dry gas meter, dcm (dcf).
 ΔV_m = Incremental dry gas volume measured by dry gas meter at each traverse point, dcm (dcf).
 $V_{m(std)}$ = Dry gas volume measured by the dry gas meter, corrected to standard conditions, dscm (dscf).
 $V_{ws(std)}$ = Volume of water vapor condensed corrected to standard conditions, scm (scf).
 $V_{ws(std)}$ = Volume of water vapor collected in silica gel corrected to standard conditions, scm (scf).
 V_f = Final volume of condenser water, ml.
 V_i = Initial volume, if any, of condenser water, ml.
 W_f = Final weight of silica gel or silica gel plus impinger, g.
 W_i = Initial weight of silica gel or silica gel plus impinger, g.
 Y = Dry gas meter calibration factor.
 ρ_w = Density of water, 0.9982 g/ml (0.002201 lb/ml).

2.3.2 Volume of water vapor condensed.

$$V_{ws(std)} = \frac{(V_f - V_i) \rho_w R T_{std}}{P_{std} M_w} = K_1 (V_f - V_i) \quad \text{Equation 4-1}$$

where:

$K_1 = 0.001333 \text{ m}^3/\text{ml}$ for metric units
 $= 0.04707 \text{ ft}^3/\text{ml}$ for English units

2.3.3 Volume of water vapor collected in silica gel.

$$V_{ws(std)} = \frac{(W_f - W_i) R T_{std}}{P_{std} M_w} = K_2 (W_f - W_i) \quad \text{Equation 4-2}$$

where:

$K_2 = 0.001336 \text{ m}^3/\text{g}$ for metric units
 $= 0.04716 \text{ ft}^3/\text{g}$ for English units

2.3.4 Sample gas volume.

$$V_{m(std)} = V_m Y \frac{(P_m)(T_{std})}{(P_{std})(T_m)} = K_3 Y \frac{V_m P_m}{T_m} \quad \text{Equation 4-3}$$

where:

$K_3 = 0.3858 \text{ }^\circ\text{K}/\text{mm Hg}$ for metric units
 $= 17.64 \text{ }^\circ\text{R}/\text{in. Hg}$ for English units

NOTE.—If the post-test leak rate (Section 2.2.6) exceeds the allowable rate, correct the value of V_m in Equation 4-3, as described in Section 6.3 of Method 5.

2.3.5 Moisture Content.

$$B_{ws} = \frac{V_{ws(std)} + V_{ws(std)} + V_m(std)}{V_{ws(std)} + V_{ws(std)} + V_m(std)} \quad \text{Equation 4-4}$$

NOTE.—In saturated or moisture droplet-laden gas streams, two calculations of the moisture content of the stack gas shall be made, one using a value based upon the saturated conditions (see Section 1.2), and another based upon the results of the impinger analysis. The lower of these two values of B_{ws} shall be considered correct.

2.3.6 Verification of constant sampling rate. For each time increment, determine the ΔV_m . Calculate the average. If the value for any time increment differs from the average by more than 10 percent, reject the results and repeat the run.

3. Approximation Method

The approximation method described below is presented only as a suggested method (see Section 1.2).

3.1 Apparatus.

3.1.1 Probe. Stainless steel or glass tubing, sufficiently heated to prevent water condensation and equipped with a filter (either in-stack or heated out-stack) to remove particulate matter. A plug of glass wool, inserted into the end of the probe, is a satisfactory filter.

3.1.2 Impingers. Two midjet impingers, each with 30 ml capacity, or equivalent.

3.1.3 Ice Bath. Container and ice, to aid in condensing moisture in impingers.

3.1.4 Drying Tube. Tube packed with new or regenerated 6- to 16-mesh indicating-type silica gel (or equivalent desiccant), to dry the sample gas and to protect the meter and pump.

3.1.5 Valve. Needle valve, to regulate the sample gas flow rate.

3.1.6 Pump. Leak-free, diaphragm type, or equivalent, to pull the gas sample through the train.

3.1.7 Volume meter. Dry gas meter, sufficiently accurate to measure the sample volume within 2%, and calibrated over the range of flow rates and conditions actually encountered during sampling.

3.1.8 Rate Meter. Rotameter, to measure the flow range from 0 to 3 lpm (0 to 0.11 cfm).

3.1.9 Graduated Cylinder. 25 ml.

3.1.10 Barometer. Mercury, aneroid, or other barometer, as described in Section 2.1.5 above.

3.1.11 Vacuum Gauge. At least 760 mm Hg (30 in. Hg) gauge, to be used for the sampling leak check.

3.2 Procedure.

3.2.1 Place exactly 5 ml distilled water in each impinger. Assemble the apparatus without the probe as shown in Figure 4-4. Leak check the train by placing a vacuum gauge at the inlet to the first impinger and drawing a vacuum of at least 250 mm Hg (10 in. Hg), plugging the outlet of the rotameter, and then turning off the pump. The vacuum shall remain constant for at least one minute. Carefully release the vacuum gauge before unplugging the rotameter end.

Figure 4-5. Field moisture determination - approximation method.

RULES AND REGULATIONS

3.2.2 Connect the probe, insert it into the stack, and sample at a constant rate of 2 lpm (0.071 cfm). Continue sampling until the dry gas meter registers about 30 liters (1.1 ft³) or until visible liquid droplets are carried over from the first impinger to the second. Record temperature, pressure, and dry gas meter readings as required by Figure 4-3.

3.2.3 After collecting the sample, combine the contents of the two impingers and measure the volume to the nearest 0.5 ml.

3.3 Calculations. The calculation method presented is designed to estimate the moisture in the stack gas; therefore, other data, which are only necessary for accurate moisture determinations, are not collected. The following equations adequately estimate the moisture content, for the purpose of determining isokinetic sampling rate settings.

3.3.1 Nomenclature.

B_{ws} = Approximate proportion, by volume, of water vapor in the gas stream leaving the second impinger, 0.025.

B_w = Water vapor in the gas stream, proportion by volume.

M_w = Molecular weight of water, 18.0 g/g-mole (18.0 lb/lb-mole)

P_s = Absolute pressure (for this method, same as barometric pressure) at the dry gas meter.

P_{std} = Standard absolute pressure, 760 mm Hg (29.92 in. Hg).

R = Ideal gas constant, 0.06236 (mm Hg) (m³)/(g-mole) (°K) for metric units and 21.85 (in. Hg) (ft³/lb-mole) (°R) for English units.

T_s = Absolute temperature at meter, °K (°R)

T_{std} = Standard absolute temperature, 293° K (528° R)

V_f = Final volume of impinger contents, ml.

V_i = Initial volume of impinger contents, ml.

V_w = Dry gas volume measured by dry gas meter, dcm (dscf).

$V_{w(std)}$ = Dry gas volume measured by dry gas meter, corrected to standard conditions, dscm (dscf).

$V_{w(std)}$ = Volume of water vapor condensed, corrected to standard conditions, scm (scf).

ρ_w = Density of water, 0.9982 g/ml (0.002201 lb/ml).

3.3.2 Volume of water vapor collected.

$$V_{ws} = \frac{(V_f - V_i) \rho_w R T_{std}}{P_{std} M_w} \\ = K_1 (V_f - V_i)$$

Equation 4-5

where:

$K_1 = 0.001333$ m³/ml for metric units

$= 0.04707$ ft³/ml for English units.

3.3.3 Gas volume.

$$V_{w(std)} = V_w \left(\frac{P_s}{P_{std}} \right) \left(\frac{T_{std}}{T_s} \right) \\ = K_2 \frac{V_w P_s}{T_s}$$

Equation 4-6

where:

$K_2 = 0.3858$ °K/mm Hg for metric units

$= 17.64$ °R/in. Hg for English units

3.3.4 Approximate moisture content.

$$B_{ws} = \frac{V_{ws}}{V_{ws} + V_{w(std)}} + B_{wm} \\ = \frac{V_{ws}}{V_{ws} + V_{w(std)}} + (0.025)$$

Equation 4-7

4. Calibration

4.1 For the reference method, calibrate equipment as specified in the following sections of Method 5: Section 5.3 (metering system); Section 5.5 (temperature gauges); and Section 5.7 (barometer). The recommended leak check of the metering system (Section 5.6 of Method 5) also applies to the reference method. For the approximation method, use the procedures outlined in Section 5.1.1 of Method 5 to calibrate the metering system, and the procedure of Method 5, Section 5.7 to calibrate the barometer.

METHOD 5—DETERMINATION OF PARTICULATE EMISSIONS FROM STATIONARY SOURCES

1. Principle and Applicability

1.1 Principle. Particulate matter is withdrawn isokinetically from the source and collected on a glass fiber filter maintained at a temperature in the range of 120±14° C (248±25° F) or such other temperature as specified by an applicable subpart of the standards or approved by the Administrator, U.S. Environmental Protection Agency, for a particular application. The particulate mass, which includes any material that condenses at or above the filtration temperature, is determined gravimetrically after removal of uncombined water.

1.2 Applicability. This method is applicable for the determination of particulate emissions from stationary sources.

2. Apparatus

2.1 Sampling Train. A schematic of the sampling train used in this method is shown in Figure 5-1. Complete construction details are given in APTD-0581 (Citation 2 in Section 7); commercial models of this train are also available. For changes from APTD-0581 and for allowable modifications of the train shown in Figure 5-1, see the following subsections.

The operating and maintenance procedures for the sampling train are described in APTD-0576 (Citation 3 in Section 7). Since correct usage is important in obtaining valid results, all users should read APTD-0576 and adopt the operating and maintenance procedures outlined in it, unless otherwise specified herein. The sampling train consists of the following components:

RULES AND REGULATIONS

Figure 5-1. Particulate-sampling train.

2.1.1 Probe Nozzle. Stainless steel (316) or glass with sharp, tapered leading edges. The angle of taper shall be $\leq 30^\circ$ and the taper shall be on the outside to preserve a constant internal diameter. The probe nozzle shall be of the button-hook or elbow design, unless otherwise specified by the Administrator. If made of stainless steel, the nozzle shall be constructed from seamless tubing; other materials of construction may be used, subject to the approval of the Administrator.

A range of nozzle sizes suitable for isokinetic sampling should be available, e.g., 0.32 to 1.27 cm ($\frac{1}{8}$ to $\frac{1}{2}$ in.)—or larger if higher volume sampling trains are used—inside diameter (ID) nozzles in increments of 0.16 cm ($\frac{1}{16}$ in.). Each nozzle shall be calibrated according to the procedures outlined in Section 5.

2.1.2 Probe Liner. Borosilicate or quartz glass tubing with a heating system capable of maintaining a gas temperature at the exit end during sampling of $120 \pm 14^\circ \text{C}$ ($245 \pm 25^\circ \text{F}$), or such other temperature as specified by an applicable subpart of the standards or approved by the Administrator for a particular application. (The tester may opt to operate the equipment at a temperature lower than that specified.) Since the actual temperature at the outlet of the probe is not usually monitored during sampling, probes constructed according to APTD-0581 and utilizing the calibration curves of APTD-0576 (or calibrated according to the procedure outlined in APTD-0576) will be considered acceptable.

Either borosilicate or quartz glass probe liners may be used for stack temperatures up to about 480°C (900°F); quartz liners shall be used for temperatures between 480 and 900°C (900 and $1,650^\circ \text{F}$). Both types of liners may be used at higher temperatures than specified for short periods of time, subject to the approval of the Administrator. The softening temperature for borosilicate is 820°C ($1,508^\circ \text{F}$), and for quartz it is $1,500^\circ \text{C}$ ($2,732^\circ \text{F}$).

Whenever practical, every effort should be made to use borosilicate or quartz glass probe liners. Alternatively, metal liners (e.g., 316 stainless steel, Incoloy 825, or other corrosion resistant metals) made of seamless tubing may be used, subject to the approval of the Administrator.

2.1.3 Pitot Tube. Type S, as described in Section 2.1 of Method 2, or other device approved by the Administrator. The pitot tube shall be attached to the probe (as shown in Figure 5-1) to allow constant monitoring of the stack gas velocity. The impact (high pressure) opening

plane of the pitot tube shall be even with or above the nozzle entry plane (see Method 2, Figure 2-6b) during sampling. The Type S pitot tube assembly shall have a known coefficient, determined as outlined in Section 4 of Method 2.

2.1.4 Differential Pressure Gauge. Inclined manometer or equivalent device (two), as described in Section 2.2 of Method 2. One manometer shall be used for velocity head (Δp) readings, and the other, for orifice differential pressure readings.

2.1.5 Filter Holder. Borosilicate glass, with a glass frit filter support and a silicone rubber gasket. Other materials of construction (e.g., stainless steel, Teflon, Viton) may be used, subject to approval of the Administrator. The holder design shall provide a positive seal against leakage from the outside or around the filter. The holder shall be attached immediately at the outlet of the probe (or cyclone, if used).

2.1.6 Filter Heating System. Any heating system capable of maintaining a temperature around the filter holder during sampling of $120 \pm 14^\circ \text{C}$ ($245 \pm 25^\circ \text{F}$), or such other temperature as specified by an applicable subpart of the standards or approved by the Administrator for a particular application. Alternatively, the tester may opt to operate the equipment at a temperature lower than that specified. A temperature gauge capable of measuring temperature to within 3°C (5.4°F) shall be installed so that the temperature around the filter holder can be regulated and monitored during sampling. Heating systems other than the one shown in APTD-0581 may be used.

2.1.7 Condenser. The following system shall be used to determine the stack gas moisture content: Four impingers connected in series with leak-free ground glass fittings or any similar leak-free non-contaminating fittings. The first, third, and fourth impingers shall be of the Greenburg-Smith design, modified by replacing the tip with 1.3 cm ($\frac{1}{2}$ in.) ID glass tube extending to about 1.3 cm ($\frac{1}{2}$ in.) from the bottom of the flask. The second impinger shall be of the Greenburg-Smith design with the standard tip. Modifications (e.g., using flexible connections between the impingers, using materials other than glass, or using flexible vacuum lines to connect the filter holder to the condenser) may be used, subject to the approval of the Administrator. The first and second impingers shall contain known quantities of water (Section 4.1.3), the third shall be empty, and the fourth shall contain a known weight of silica gel, or equivalent desiccant. A thermometer, capable of measuring

temperature to within 1°C (2°F) shall be placed at the outlet of the fourth impinger for monitoring purposes.

Alternatively, any system that cools the sample gas stream and allows measurement of the water condensed and moisture leaving the condenser, each to within 1 ml or 1 g may be used, subject to the approval of the Administrator. Acceptable means are to measure the condensed water either gravimetrically or volumetrically and to measure the moisture leaving the condenser by: (1) monitoring the temperature and pressure at the exit of the condenser and using Dalton's law of partial pressures; or (2) passing the sample gas stream through a tared silica gel (or equivalent desiccant) trap with exit gases kept below 20°C (68°F) and determining the weight gain.

If means other than silica gel are used to determine the amount of moisture leaving the condenser, it is recommended that silica gel (or equivalent) still be used between the condenser system and pump to prevent moisture condensation in the pump and metering devices and to avoid the need to make corrections for moisture in the metered volume.

NOTE.—If a determination of the particulate matter collected in the impingers is desired in addition to moisture content, the impinger system described above shall be used, without modification. Individual States or control agencies requiring this information shall be contacted as to the sample recovery and analysis of the impinger contents.

2.1.8 Metering System. Vacuum gauge, leak-free pump, thermometers capable of measuring temperature to within 3°C (5.4°F), dry gas meter capable of measuring volume to within 2 percent, and related equipment, as shown in Figure 5-1. Other metering systems capable of maintaining sampling rates within 10 percent of isokinetic and of determining sample volumes to within 2 percent may be used, subject to the approval of the Administrator. When the metering system is used in conjunction with a pitot tube, the system shall enable checks of isokinetic rates.

Sampling trains utilizing metering systems designed for higher flow rates than that described in APTD-0581 or APTD-0576 may be used provided that the specifications of this method are met.

2.1.9 Barometer. Mercury, aneroid, or other barometer capable of measuring atmospheric pressure to within 2.5 mm Hg (0.1 in. Hg). In many cases, the barometric reading may be obtained from a nearby national weather service station, in which case the station value (which is

¹ Mention of trade names or specific products does not constitute endorsement by the Environmental Protection Agency.

RULES AND REGULATIONS

the absolute barometric pressure) shall be requested and an adjustment for elevation differences between the weather station and sampling point shall be applied at a rate of minus 2.5 mm Hg (0.1 in. Hg) per 30 m (100 ft) elevation increase or vice versa for elevation decrease.

2.1.10 Gas Density Determination Equipment. Temperature sensor and pressure gauge, as described in Sections 2.3 and 2.4 of Method 2, and gas analyzer, if necessary, as described in Method 3. The temperature sensor shall, preferably, be permanently attached to the pitot tube or sampling probe in a fixed configuration, such that the tip of the sensor extends beyond the leading edge of the probe sheath and does not touch any metal. Alternatively, the sensor may be attached just prior to use in the field. Note, however, that if the temperature sensor is attached in the field, the sensor must be placed in an interference-free arrangement with respect to the Type S pitot tube openings (see Method 2, Figure 2-7). As a second alternative, if a difference of not more than 1 percent in the average velocity measurement is to be introduced, the temperature gauge need not be attached to the probe or pitot tube. (This alternative is subject to the approval of the Administrator.)

2.2 Sample Recovery. The following items are needed:

2.2.1 Probe-Liner and Probe-Nozzle Brushes. Nylon bristle brushes with stainless steel wire handles. The probe brush shall have extensions (at least as long as the probe) of stainless steel, Nylon, Teflon, or similarly inert material. The brushes shall be properly sized and shaped to brush out the probe liner and nozzle.

2.2.2 Wash Bottles—Two. Glass wash bottles are recommended; polyethylene wash bottles may be used at the option of the tester. It is recommended that acetone not be stored in polyethylene bottles for longer than a month.

2.2.3 Glass Sample Storage Containers. Chemically resistant, borosilicate glass bottles, for acetone washes, 500 ml or 1000 ml. Screw cap liners shall either be rubber-backed Teflon or shall be constructed so as to be leak-free and resistant to chemical attack by acetone. (Narrow mouth glass bottles have been found to be less prone to leakage.) Alternatively, polyethylene bottles may be used.

2.2.4 Petri Dishes. For filter samples, glass or polyethylene, unless otherwise specified by the Administrator.

2.2.5 Graduated Cylinder and/or Balance. To measure condensed water to within 1 ml or 1 g. Graduated cylinders shall have subdivisions no greater than 2 ml. Most laboratory balances are capable of weighing to the nearest 0.5 g or less. Any of these balances is suitable for use here and in Section 2.3.4.

2.2.6 Plastic Storage Containers. Air-tight containers to store silica gel.

2.2.7 Funnel and Rubber Policeman. To aid in transfer of silica gel to container; not necessary if silica gel is weighed in the field.

2.2.8 Funnel. Glass or polyethylene, to aid in sample recovery.

2.3 Analysis. For analysis, the following equipment is needed.

2.3.1 Glass Weighing Dishes.

2.3.2 Desiccator.

2.3.3 Analytical Balance. To measure to within 0.1 mg.

2.3.4 Balance. To measure to within 0.5 g.

2.3.5 Beakers. 250 ml.

2.3.6 Hygrometer. To measure the relative humidity of the laboratory environment.

2.3.7 Temperature Gauge. To measure the temperature of the laboratory environment.

3. Reagents

3.1 Sampling. The reagents used in sampling are as follows:

3.1.1 Filters. Glass fiber filters, without organic binder, exhibiting at least 99.95 percent efficiency (≤ 0.05 percent penetration) on 0.3-micron dioctyl phthalate smoke particles. The filter efficiency test shall be conducted in accordance with ASTM standard method D 2886-71. Test data from the supplier's quality control program are sufficient for this purpose.

3.1.2. Silica Gel. Indicating type, 6 to 16 mesh. If previously used, dry at 175° C (350° F) for 2 hours. New silica gel may be used as received. Alternatively, other types of desiccants (equivalent or better) may be used, subject to the approval of the Administrator.

3.1.3 Water. When analysis of the material caught in the impingers is required, distilled water shall be used. Run blanks prior to field use to eliminate a high blank on test samples.

3.1.4 Crushed Ice.

3.1.5 Stopcock Grease. Acetone-insoluble, heat-stable silicone grease. This is not necessary if screw-on connectors with Teflon sleeves, or similar, are used. Alternatively, other types of stopcock grease may be used, subject to the approval of the Administrator.

3.2 Sample Recovery. Acetone—reagent grade, ≤ 0.001 percent residue, in glass bottles—is required. Acetone from metal containers generally has a high residue blank and should not be used. Sometimes, suppliers transfer acetone to glass bottles from metal containers; thus, acetone blanks shall be run prior to field use and only acetone with low blank values (≤ 0.001 percent) shall be used. In no case shall a blank value of greater than 0.001 percent of the weight of acetone used be subtracted from the sample weight.

3.3 Analysis. Two reagents are required for the analysis:

3.3.1 Acetone. Same as 3.2.

3.3.2 Desiccant. Anhydrous calcium sulfate, indicating type. Alternatively, other types of desiccants may be used, subject to the approval of the Administrator.

4. Procedure

4.1 Sampling. The complexity of this method is such that, in order to obtain reliable results, testers should be trained and experienced with the test procedures.

4.1.1 Pretest Preparation. All the components shall be maintained and calibrated according to the procedure described in APTD-0576, unless otherwise specified herein.

Weigh several 200 to 300 g portions of silica gel in air-tight containers to the nearest 0.5 g. Record the total weight of the silica gel plus container, on each container. As an alternative, the silica gel need not be preweighed, but may be weighed directly in its impinger or sampling holder just prior to train assembly.

Check filters visually against light for irregularities and flaws or pinhole leaks. Label filters of the proper diameter on the back side near the edge using numbering machine ink. As an alternative, label the shipping containers (glass or plastic petri dishes) and keep the filters in these containers at all times except during sampling and weighing.

Desiccate the filters at 20±5° C (68±10° F) and ambient pressure for at least 24 hours and weigh at intervals of at least 6 hours to a constant weight, i.e., <0.5 mg change from previous weighing; record results to the nearest 0.1 mg. During each weighing the filter must not be exposed to the laboratory atmosphere for a period greater than 2 minutes and a relative humidity above 50 percent. Alternatively (unless otherwise specified by the Administrator), the filters may be oven dried at 105° C (220° F) for 2 to 3 hours, desiccated for 2 hours, and weighed. Procedures other than those described, which account for relative humidity effects, may be used, subject to the approval of the Administrator.

4.1.2 Preliminary Determinations. Select the sampling site and the minimum number of sampling points according to Method 1 or as specified by the Administrator. Determine the stack pressure, temperature, and the range of velocity heads using Method 2; it is recommended that a leak-check of the pitot lines (see Method 2, Section 3.1) be performed. Determine the moisture content using Approximation Method 4 or its alternatives for the purpose of making isokinetic sampling rate settings. Determine the stack gas dry molecular weight, as described in Method 2, Section 3.6; if integrated Method 3 sampling is used for molecular weight determination, the integrated bag sample shall be taken simultaneously with, and for the same total length of time as, the particulate sample run.

Select a nozzle size based on the range of velocity heads, such that it is not necessary to change the nozzle size in order to maintain isokinetic sampling rates. During the run, do not change the nozzle size. Ensure that the proper differential pressure gauge is chosen for the range of velocity heads encountered (see Section 2.2 of Method 2).

Select a suitable probe liner and probe length such that all traverse points can be sampled. For large stacks, consider sampling from opposite sides of the stack to reduce the length of probes.

Select a total sampling time greater than or equal to the minimum total sampling time specified in the test procedures for the specific industry such that (1) the sampling time per point is not less than 2 min. (or some greater time interval as specified by the Administrator) and (2) the sample volume taken (corrected to standard conditions) will exceed the required minimum total gas sample volume. The latter is based on an approximate average sampling rate.

It is recommended that the number of minutes sampled at each point be an integer or an integer plus one-half minute, in order to avoid timekeeping errors.

In some circumstances, e.g., batch cycles, it may be necessary to sample for shorter times at the traverse points and to obtain smaller gas sample volumes. In these cases, the Administrator's approval must first be obtained.

4.1.3 Preparation of Collection Train. During preparation and assembly of the sampling train, keep all openings where contamination can occur covered until just prior to assembly or until sampling is about to begin.

Place 100 ml of water in each of the first two impingers, leave the third impinger empty, and transfer approximately 200 to 300 g of preweighed silica gel from its container to the fourth impinger. More silica gel may be used, but care should be taken to ensure that it is not entrained and carried out from the impinger during sampling. Place the container in a clean place for later use in the sample recovery. Alternatively, the weight of the silica gel plus impinger may be determined to the nearest 0.5 g and recorded.

Using a tweezer or clean disposable surgical gloves, place a labeled (identified) and weighed filter in the filter holder. Be sure that the filter is properly centered and the gasket properly placed so as to prevent the sample gas stream from circumventing the filter. Check the filter for tears after assembly is completed.

When glass liners are used, install the selected nozzle using a Viton A O-ring when stack temperatures are less than 260° C (500° F) and an asbestos string gasket when temperatures are higher. See APTD-0576 for

details. Other connecting systems using either 316 stainless steel or Teflon ferrules may be used. When metal liners are used, install the nozzle as above or by a leak-free direct mechanical connection. Mark the probe with heat resistant tape or by some other method to denote the proper distance into the stack or duct for each sampling point.

Set up the train as in Figure 5-1, using (if necessary) a very light coat of silicone grease on all ground glass joints, greasing only the outer portion (see APTD-0576) to avoid possibility of contamination by the silicone grease. Subject to the approval of the Administrator, a glass cyclone may be used between the probe and filter holder when the total particulate catch is expected to exceed 100 mg or when water droplets are present in the stack gas.

Place crushed ice around the impingers.

4.1.4 Leak-Check Procedures.

4.1.4.1 Pretest Leak-Check. A pretest leak-check is recommended, but not required. If the tester opts to conduct the pretest leak-check, the following procedure shall be used.

After the sampling train has been assembled, turn on and set the filter and probe heating systems at the desired operating temperatures. Allow time for the temperatures to stabilize. If a Viton A O-ring or other leak-free connection is used in assembling the probe nozzle to the probe liner, leak-check the train at the sampling site by plugging the nozzle and pulling a 380 mm Hg (15 in. Hg) vacuum.

NOTE.—A lower vacuum may be used, provided that it is not exceeded during the test.

If an asbestos string is used, do not connect the probe to the train during the leak-check. Instead, leak-check the train by first plugging the inlet to the filter holder (cyclone, if applicable) and pulling a 380 mm Hg (15 in. Hg) vacuum (see Note immediately above). Then connect the probe to the train and leak-check at about 25 mm Hg (1 in. Hg) vacuum; alternatively, the probe may be leak-checked with the rest of the sampling train, in one step, at 380 mm Hg (15 in. Hg) vacuum. Leakage rates in excess of 4 percent of the average sampling rate or 0.00057 m³/min (0.02 cfm), whichever is less, are unacceptable.

The following leak-check instructions for the sampling train described in APTD-0576 and APTD-0581 may be helpful. Start the pump with bypass valve fully open and coarse adjust valve completely closed. Partially open the coarse adjust valve and slowly close the bypass valve until the desired vacuum is reached. Do not reverse direction of bypass valve; this will cause water to back up into the filter holder. If the desired vacuum is exceeded, either leak-check at this higher vacuum or end the leak check as shown below and start over.

When the leak-check is completed, first slowly remove the plug from the inlet to the probe, filter holder, or cyclone (if applicable) and immediately turn off the vacuum pump. This prevents the water in the impingers from being forced backward into the filter holder and silica gel from being entrained backward into the third impinger.

4.1.4.2 Leak-Checks During Sample Run. If, during the sampling run, a component (e.g., filter assembly or impinger) change becomes necessary, a leak-check shall be conducted immediately before the change is made. The leak-check shall be done according to the procedure outlined in Section 4.1.4.1 above, except that it shall be done at a vacuum equal to or greater than the maximum value recorded up to that point in the test. If the leakage rate is found to be no greater than 0.00057 m³/min (0.02 cfm) or 4 percent of the average sampling rate (whichever is less), the results are acceptable, and no correction will need to be applied to the total volume of dry gas metered; if, however, a higher leakage rate is obtained, the tester shall either record the leakage rate and plan to correct the sample volume as shown in Section 6.3 of this method, or shall void the sampling run.

Immediately after component changes, leak-checks are optional; if such leak-checks are done, the procedure outlined in Section 4.1.4.1 above shall be used.

4.1.4.3 Post-test Leak-Check. A leak-check is mandatory at the conclusion of each sampling run. The leak-check shall be done in accordance with the procedures outlined in Section 4.1.4.1, except that it shall be conducted at a vacuum equal to or greater than the maximum value reached during the sampling run. If the leakage rate is found to be no greater than 0.00057 m³/min (0.02 cfm) or 4 percent of the average sampling rate (whichever is less), the results are acceptable, and no correction need be applied to the total volume of dry gas metered. If, however, a higher leakage rate is obtained, the tester shall either record the leakage rate and correct the sample volume as shown in Section 6.3 of this method, or shall void the sampling run.

4.1.5 Particulate Train Operation. During the sampling run, maintain an isokinetic sampling rate (within 10 percent of true isokinetic unless otherwise specified by the Administrator) and a temperature around the filter of 120±14° C (248±25° F), or such other temperature as specified by an applicable subpart of the standards or approved by the Administrator.

For each run, record the data required on a data sheet such as the one shown in Figure 5-2. Be sure to record the initial dry gas meter reading. Record the dry gas meter readings at the beginning and end of each sampling time increment, when changes in flow rates are made, before and after each leak check, and when sampling is halted.

RULES AND REGULATIONS

Take other readings required by Figure 5-2 at least once at each sample point during each time increment and additional readings when significant changes (20 percent variation in velocity head readings) necessitate additional adjustments in flow rate. Level and zero the manometer. Because the manometer level and zero may drift due to vibrations and temperature changes, make periodic checks during the traverse.

Clean the portholes prior to the test run to minimize the chance of sampling deposited material. To begin sampling, remove the nozzle cap, verify that the filter and probe heating systems are up to temperature, and that the pitot tube and probe are properly positioned. Position the nozzle at the first traverse point with the tip pointing directly into the gas stream. Immediately start the pump and adjust the flow to isokinetic conditions. Nomographs are available, which aid in the rapid adjust-

ment of the isokinetic sampling rate without excessive computations. These nomographs are designed for use when the Type 8 pitot tube coefficient is 0.85 ± 0.02 , and the stack gas equivalent density (dry molecular weight) is equal to 29 ± 4 . APTD-0576 details the procedure for using the nomographs. If C_p and M_d are outside the above stated ranges do not use the nomographs unless appropriate steps (see Citation 7 in Section 7) are taken to compensate for the deviations.

Figure. 5-2. Particulate field data.

When the stack is under significant negative pressure (height of impinger stem), take care to close the coarse adjust valve before inserting the probe into the stack to prevent water from backing into the filter holder. If necessary, the pump may be turned on with the coarse adjust valve closed.

When the probe is in position, block off the openings around the probe and porthole to prevent unrepresentative dilution of the gas stream.

Traverse the stack cross-section, as required by Method 1 or as specified by the Administrator, being careful not to bump the probe nozzle into the stack walls when sampling near the walls or when removing or inserting the probe through the portholes; this minimizes the chance of extracting deposited material.

During the test run, make periodic adjustments to keep the temperature around the filter holder at the proper level; add more ice and, if necessary, salt to maintain a temperature of less than 20° C (68° F) at the condenser/silica gel outlet. Also, periodically check the level and zero of the manometer.

If the pressure drop across the filter becomes too high, making isokinetic sampling difficult to maintain, the filter may be replaced in the midst of a sample run. It is recommended that another complete filter assembly be used rather than attempting to change the filter itself. Before a new filter assembly is installed, conduct a leak-check (see Section 4.1.4.2). The total particulate weight shall include the summation of all filter assembly catches.

A single train shall be used for the entire sample run, except in cases where simultaneous sampling is required in two or more separate ducts or at two or more different locations within the same duct, or, in cases where equipment failure necessitates a change of trains. In all other situations, the use of two or more trains will be subject to the approval of the Administrator.

Note that when two or more trains are used, separate analyses of the front-half and (if applicable) impinger catches from each train shall be performed, unless (identical) multiple trains are used on all trains, in which case, the front-half catches from the individual trains may be combined (as may the impinger catches) and one analysis of front-half catch and one analysis of impinger catch may be performed. Consult with the Administrator for details concerning the calculation of results when two or more trains are used.

At the end of the sample run, turn off the coarse adjust valve, remove the probe and nozzle from the stack, turn off the pump, record the final dry gas meter reading, and conduct a post-test leak-check, as outlined in Section 4.1.4.3. Also, leak-check the pitot lines as described in Method 2, Section 3.1; the lines must pass this leak-check, in order to validate the velocity head data.

4.1.6 Calculation of Percent Isokinetic. Calculate percent isokinetic (see Calculations, Section 6) to determine whether the run was valid or another test run should be made. If there was difficulty in maintaining isokinetic rates due to source conditions, consult with the Administrator for possible variance on the isokinetic rates.

4.2. Sample Recovery. Proper cleanup procedure begins as soon as the probe is removed from the stack at the end of the sampling period. Allow the probe to cool. When the probe can be safely handled, wipe off all external particulate matter near the tip of the probe nozzle and place a cap over it to prevent losing or gaining particulate matter. Do not cap off the probe tip tightly while the sampling train is cooling down as this would create a vacuum in the filter holder, thus drawing water from the impingers into the filter holder.

Before moving the sample train to the cleanup site, remove the probe from the sample train, wipe off the

silicone grease, and cap the open outlet of the probe. Be careful not to lose any condensate that might be present. Wipe off the silicone grease from the filter inlet probe. The probe was fastened to the cap. Remove the umbilical cord from the last impinger and cap the impinger. If a flexible line is used between the first impinger or condenser and the filter holder, disconnect the line at the filter holder and let any condensed water or liquid drain into the impingers or condenser. After wiping off the silicone grease, cap off the filter holder outlet and impinger inlet. Either ground-glass stoppers, plastic caps, or serum caps may be used to close these openings.

Transfer the probe and filter-impinger assembly to the cleanup area. This area should be clean and protected from the wind so that the chances of contaminating or losing the sample will be minimized.

Save a portion of the acetone used for cleanup as a blank. Take 200 ml of this acetone directly from the wash bottle being used and place it in a glass sample container labeled "acetone blank."

Inspect the train prior to and during disassembly and note any abnormal conditions. Treat the samples as follows:

Container No. 1. Carefully remove the filter from the filter holder and place it in its identified petri dish container. Use a pair of tweezers and/or clean disposable surgical gloves to handle the filter. If it is necessary to fold the filter, do so such that the particulate cake is inside the fold. Carefully transfer to the petri dish any particulate matter and/or filter fibers which adhere to the filter holder gasket, by using a dry nylon bristle brush and/or a sharp-edged blade. Seal the container.

Container No. 2. Taking care to see that dust on the outside of the probe or other exterior surfaces does not get into the sample, quantitatively recover particulate matter or any condensate from the probe nozzle, probe

RULES AND REGULATIONS

fitting, probe liner, and front half of the filter holder by washing these components with acetone and placing the wash in a glass container. Distilled water may be used instead of acetone when approved by the Administrator and shall be used when specified by the Administrator; in these cases, save a water blank and follow the Administrator's directions on analysis. Perform the acetone rinses as follows:

Carefully remove the probe nozzle and clean the inside surface by rinsing with acetone from a wash bottle and brushing with a nylon bristle brush. Brush until the acetone rinse shows no visible particles, after which make a final rinse of the inside surface with acetone.

Brush and rinse the inside parts of the Swagelok fitting with acetone in a similar way until no visible particles remain.

Rinse the probe liner with acetone by tilting and rotating the probe while squirting acetone into its upper end so that all inside surfaces will be wetted with acetone. Let the acetone drain from the lower end into the sample container. A funnel (glass or polyethylene) may be used to aid in transferring liquid washes to the container. Follow the acetone rinse with a probe brush. Hold the probe in an inclined position, squirt acetone into the upper end as the probe brush is being pushed with a twisting action through the probe; hold a sample container underneath the lower end of the probe, and catch any acetone and particulate matter which is brushed from the probe. Run the brush through the probe three times or more until no visible particulate matter is carried out with the acetone or until none remains in the probe liner on visual inspection. With stainless steel or other metal probes, run the brush through in the above prescribed manner at least six times since metal probes have small crevices in which particulate matter can be entrapped. Rinse the brush with acetone, and quantitatively collect these washings in the sample container. After the brushing, make a final acetone rinse of the probe as described above.

It is recommended that two people be used to clean the probe to minimize sample losses. Between sampling runs, keep brushes clean and protected from contamination.

After ensuring that all joints have been wiped clean of silicone grease, clean the inside of the front half of the filter holder by rubbing the surfaces with a nylon bristle brush and rinsing with acetone. Rinse each surface three times or more if needed to remove visible particulate. Make a final rinse of the brush and filter holder. Carefully rinse out the glass cyclone, also (if applicable). After all acetone washings and particulate matter have been collected in the sample container, tighten the lid on the sample container so that acetone will not leak out when it is shipped to the laboratory. Mark the height of the fluid level to determine whether or not leakage occurred during transport. Label the container to clearly identify its contents.

Container No. 3. Note the color of the indicating silica gel to determine if it has been completely spent and make a notation of its condition. Transfer the silica gel from the fourth impinger to its original container and seal. A funnel may make it easier to pour the silica gel without spilling. A rubber policeman may be used as an aid in removing the silica gel from the impinger. It is not necessary to remove the small amount of dust particles that may adhere to the impinger wall and are difficult to remove. Since the gain in weight is to be used for moisture calculations, do not use any water or other liquids to transfer the silica gel. If a balance is available in the field, follow the procedure for container No. 3 in Section 4.3.

Impinger Water. Treat the impingers as follows: Make a notation of any color or film in the liquid catch. Measure the liquid which is in the first three impingers to within ± 1 ml by using a graduated cylinder or by weighing it to within ± 0.5 g by using a balance (if one is available). Record the volume or weight of liquid present. This information is required to calculate the moisture content of the effluent gas.

Discard the liquid after measuring and recording the volume or weight, unless analysis of the impinger catch is required (see Note, Section 2.1.7).

If a different type of condenser is used, measure the amount of moisture condensed either volumetrically or gravimetrically.

Whenever possible, containers should be shipped in such a way that they remain upright at all times.

4.3 Analysis. Record the data required on a sheet such as the one shown in Figure 5-3. Handle each sample container as follows:

Container No. 1. Leave the contents in the shipping container or transfer the filter and any loose particulate from the sample container to a tared glass weighing dish. Desiccate for 24 hours in a desiccator containing anhydrous calcium sulfate. Weigh to a constant weight and report the results to the nearest 0.1 mg. For purposes of this Section, 4.3, the term "constant weight" means a difference of no more than 0.5 mg or 1 percent of total weight less tare weight, whichever is greater, between two consecutive weighings, with no less than 6 hours of desiccation time between weighings.

Figure 5-3. Analytical data.

RULES AND REGULATIONS

Alternatively, the sample may be oven dried at 105° C (220° F) for 2 to 3 hours, cooled in the desiccator, and weighed to a constant weight, unless otherwise specified by the Administrator. The tester may also opt to oven dry the sample at 105° C (220° F) for 2 to 3 hours, weigh the sample, and use this weight as a final weight.

Container No. 2. Note the level of liquid in the container and confirm on the analysis sheet whether or not leakage occurred during transport. If a noticeable amount of leakage has occurred, either void the sample or use methods, subject to the approval of the Administrator, to correct the final results. Measure the liquid in this container either volumetrically to ± 1 ml or gravimetrically to ± 0.5 g. Transfer the contents to a tared 250-ml beaker and evaporate to dryness at ambient temperature and pressure. Desiccate for 24 hours and weigh to a constant weight. Report the results to the nearest 0.1 mg.

Container No. 3. Weigh the spent silica gel (or silica gel plus impinger) to the nearest 0.5 g using a balance. This step may be conducted in the field.

"Acetone Blank" Container. Measure acetone in this container either volumetrically or gravimetrically. Transfer the acetone to a tared 250-ml beaker and evaporate to dryness at ambient temperature and pressure. Desiccate for 24 hours and weigh to a constant weight. Report the results to the nearest 0.1 mg.

NOTE.—At the option of the tester, the contents of Container No. 2 as well as the acetone blank container may be evaporated at temperatures higher than ambient. If evaporation is done at an elevated temperature, the temperature must be below the boiling point of the solvent; also, to prevent "bumping," the evaporation process must be closely supervised, and the contents of the beaker must be swirled occasionally to maintain an even temperature. Use extreme care, as acetone is highly flammable and has a low flash point.

5. Calibration

Maintain a laboratory log of all calibrations.

5.1 Probe Nozzle. Probe nozzles shall be calibrated before their initial use in the field. Using a micrometer, measure the inside diameter of the nozzle to the nearest

0.025 mm (0.001 in.). Make three separate measurements using different diameters each time, and obtain the average of the measurements. The difference between the high and low numbers shall not exceed 0.1 mm (0.004 in.). When nozzles become nicked, dented, or corroded, they shall be reshaped, sharpened, and recalibrated before use. Each nozzle shall be permanently and uniquely identified.

5.2 Pitot Tube. The Type 8 pitot tube assembly shall be calibrated according to the procedure outlined in Section 4 of Method 2.

5.3 Metering System. Before its initial use in the field, the metering system shall be calibrated according to the procedure outlined in APTD-0576. Instead of physically adjusting the dry gas meter dial readings to correspond to the wet test meter readings, calibration factors may be used to mathematically correct the gas meter dial readings to the proper values. Before calibrating the metering system, it is suggested that a leak-check be conducted. For metering systems having diaphragm pumps, the normal leak-check procedure will not detect leakages within the pump. For these cases the following leak-check procedure is suggested: make a 10-minute calibration run at 0.00057 m³/min (0.02 cfm); at the end of the run, take the difference of the measured wet test meter and dry gas meter volumes; divide the difference by 10 to get the leak rate. The leak rate should not exceed 0.00057 m³/min (0.02 cfm).

After each field use, the calibration of the metering system shall be checked by performing three calibration runs at a single, intermediate orifice setting (based on the previous field test), with the vacuum set at the maximum value reached during the test series. To adjust the vacuum, insert a valve between the wet test meter and the inlet of the metering system. Calculate the average value of the calibration factor. If the calibration has changed by more than 5 percent, recalibrate the meter over the full range of orifice settings, as outlined in APTD-0576.

Alternative procedures, e.g., using the orifice meter coefficients, may be used, subject to the approval of the Administrator.

NOTE.—If the dry gas meter coefficient values obtained before and after a test series differ by more than 5 percent, the test series shall either be voided, or calculations for the test series shall be performed using whichever meter coefficient value (i.e., before or after) gives the lower value of total sample volume.

5.4 Probe Heater Calibration. The probe heating system shall be calibrated before its initial use in the field according to the procedure outlined in APTD-0576. Probes constructed according to APTD-0581 need not be calibrated if the calibration curves in APTD-0576 are used.

5.5 Temperature Gauges. Use the procedure in Section 4.3 of Method 2 to calibrate in-stack temperature gauges. Dial thermometers, such as are used for the dry gas meter and condenser outlet, shall be calibrated against mercury-in-glass thermometers.

5.6 Leak Check of Metering System Shown in Figure 5-1. That portion of the sampling train from the pump to the orifice meter should be leak checked prior to initial use and after each shipment. Leakage after the pump will result in less volume being recorded than is actually sampled. The following procedure is suggested (see Figure 5-4): Close the main valve on the meter box. Insert a one-hole rubber stopper with rubber tubing attached into the orifice exhaust pipe. Disconnect and vent the low side of the orifice manometer. Close off the low side orifice tap. Pressurize the system to 13 to 18 cm (6 to 7 in.) water column by blowing into the rubber tubing. Pinch off the tubing and observe the manometer for one minute. A loss of pressure on the manometer indicates a leak in the meter box; leaks, if present, must be corrected.

5.7 Barometer. Calibrate against a mercury barometer.

6. Calculations

Carry out calculations, retaining at least one extra decimal figure beyond that of the acquired data. Round off figures after the final calculation. Other forms of the equations may be used as long as they give equivalent results.

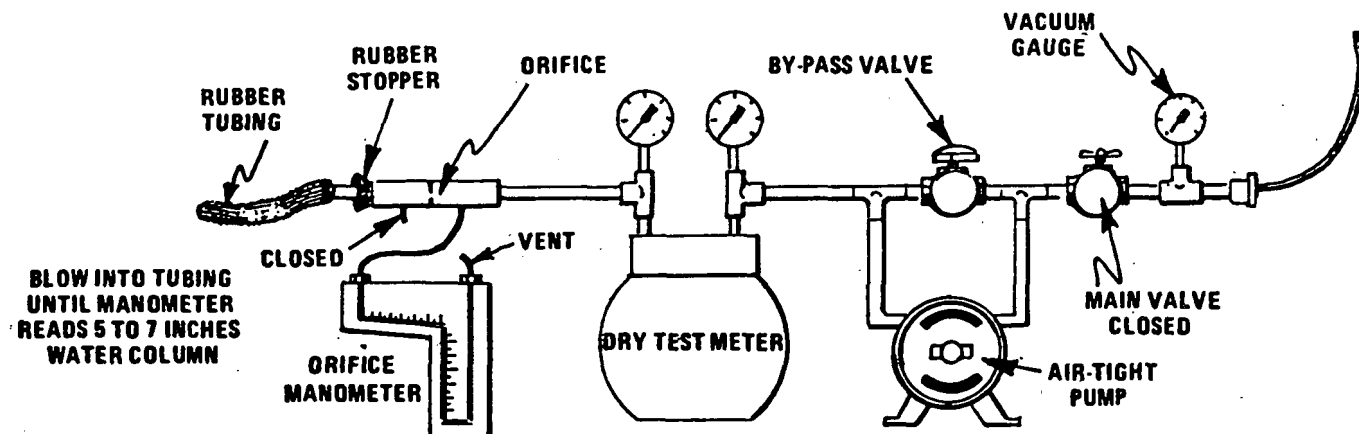

Figure 5-4. Leak check of meter box.

6.1 Nomenclature

- A_n = Cross-sectional area of nozzle, m² (ft²).
- B_w = Water vapor in the gas stream, proportion by volume.
- C_a = Acetone blank residue concentrations, mg/g.
- C_p = Concentration of particulate matter in stack gas, dry basis, corrected to standard conditions, g/dscm (g/dscf).
- I = Percent of isokinetic sampling.
- L_a = Maximum acceptable leakage rate for either a pretest leak check or for a leak check following a component change; equal to 0.00057 m³/min (0.02 cfm) or 4 percent of the average sampling rate, whichever is less.
- L_i = Individual leakage rate observed during the leak check conducted prior to the i^{th} component change ($i=1, 2, 3, \dots, n$), m³/min (cfm).
- L_p = Leakage rate observed during the post-test leak check, m³/min (cfm).
- m_a = Total amount of particulate matter collected, mg.
- M_w = Molecular weight of water, 18.0 g/g-mole (18.0 lb/lb-mole).
- m_s = Mass of residue of acetone after evaporation, mg.
- P_{bar} = Barometric pressure at the sampling site, mm Hg (in. Hg).
- P_t = Absolute stack gas pressure, mm Hg (in. Hg).
- P_{std} = Standard absolute pressure, 760 mm Hg (29.92 in. Hg).

- R = Ideal gas constant, 0.06236 mm Hg-m³/°K-g-mole (21.85 in. Hg-ft³/°R-lb-mole).
- T_a = Absolute average dry gas meter temperature (see Figure 5-2), °K (°R).
- T_s = Absolute average stack gas temperature (see Figure 5-2), °K (°R).
- T_{std} = Standard absolute temperature, 293° K (528° R).
- V_a = Volume of acetone blank, ml.
- V_w = Volume of acetone used in wash, ml.
- V_{t1} = Total volume of liquid collected in impingers and silica gel (see Figure 5-3), ml.
- V_{t2} = Volume of gas sample as measured by dry gas meter, dcm (dcf).
- $V_{m(std)}$ = Volume of gas sample measured by the dry gas meter, corrected to standard conditions, dscm (dscf).
- $V_{w(std)}$ = Volume of water vapor in the gas sample, corrected to standard conditions, scm (scf).
- V_s = Stack gas velocity, calculated by Method 2, Equation 2-9, using data obtained from Method 5, m/sec (ft/sec).
- W_s = Weight of residue in acetone wash, mg.
- Y = Dry gas meter calibration factor.
- ΔH = Average pressure differential across the orifice meter (see Figure 5-2), mm H₂O (in. H₂O).
- ρ_a = Density of acetone, mg/ml (see label on bottle).
- ρ_w = Density of water, 0.9982 g/ml (0.002201 lb/ml).
- t = Total sampling time, min.

t_1 = Sampling time interval, from the beginning of a run until the first component-change, min.

t_2 = Sampling time interval, between two successive component changes, beginning with the interval between the first and second changes, min.

t_n = Sampling time interval, from the final (n^{th}) component change until the end of the sampling run, min.

13.6 = Specific gravity of mercury.

60 = Sec/min.

100 = Conversion to percent.

6.2 Average dry gas meter temperature and average orifice pressure drop. See data sheet (Figure 5-2).

6.3 Dry Gas Volume. Correct the sample volume measured by the dry gas meter to standard conditions (20° C, 760 mm Hg or 68° F, 29.92 in. Hg) by using Equation 5-1.

$$V_{m(std)} = V_m Y \left(\frac{T_{std}}{T_m} \right) \left[\frac{P_{bar} + \frac{\Delta H}{13.6}}{P_{std}} \right]$$

$$= K_1 V_m Y \frac{P_{bar} + (\Delta H/13.6)}{T_m}$$

Equation 5-1

RULES AND REGULATIONS

where:
 $m_1 = 0.3548^\circ \text{K/mm Hg}$ for metric units
 $= 17.64^\circ \text{R/in. Hg}$ for English units

NOTE.—Equation 5-1 can be used as written unless the leakage rate observed during any of the mandatory leak checks (i.e., the post-test leak check or leak checks conducted prior to component changes) exceeds B_s . If B_p or L_i exceeds B_s , Equation 5-1 must be modified as follows:

(a) Case I. No component changes made during sampling run. In this case, replace V_m in Equation 5-1 with the expression;

$$V_m = (L_p - L_s)\theta$$

(b) Case II. One or more component changes made during the sampling run. In this case, replace V_m in Equation 5-1 by the expression:

$$\left[V_m - (L_i - L_s)\theta_i - \sum_{i=2}^n (L_i - L_s)\theta_i - (L_p - L_s)\theta_p \right]$$

and substitute only for those leakage rates (L_i or L_p) which exceed L_s .

6.4 Volume of water vapor.

$$V_{w(sld)} = V_1 \left(\frac{P_w}{M_w} \right) \left(\frac{RT_{std}}{P_{std}} \right) = K_3 V_1$$

where:
 $K_3 = 0.001333 \text{ m}^3/\text{ml}$ for metric units
 $= 0.04707 \text{ ft}^3/\text{ml}$ for English units.

6.5 Moisture Content.

$$B_{ws} = \frac{V_{w(sld)}}{V_m(sld) + V_{w(sld)}}$$

Equation 5-3

$$I = \frac{100 T_s [K_3 V_1 + (V_m/T_m) (P_{bar} + \Delta H/13.6)]}{60 \theta v_s P_s A_s}$$

Equation 5-7

where:
 $K_4 = 0.003454 \text{ mm Hg} \cdot \text{m}^3/\text{ml} \cdot ^\circ \text{K}$ for metric units
 $= 0.002669 \text{ in. Hg} \cdot \text{ft}^3/\text{ml} \cdot ^\circ \text{R}$ for English units.

6.11.2 Calculation From Intermediate Values.

$$I = \frac{T_s V_m(sld) P_{std} 100}{T_{std} v_s \theta A_s P_s 60 (1 - B_{ws})}$$

$$= K_4 \frac{T_s V_m(sld)}{P_s V_s A_s \theta (1 - B_{ws})}$$

Equation 5-8

where:
 $K_4 = 4.320$ for metric units
 $= 0.09450$ for English units.

6.12 Acceptable Results. If 90 percent $\leq I \leq 110$ percent, the results are acceptable. If the results are low in comparison to the standard and I is beyond the acceptable range, or, if I is less than 90 percent, the Administrator may opt to accept the results. Use Citation 4 to make judgments. Otherwise, reject the results and repeat the test.

NOTE.—In saturated or water droplet-laden gas streams, two calculations of the moisture content of the stack gas shall be made, one from the impinger analysis (Equation 5-3), and a second from the assumption of saturated conditions. The lower of the two values of B_{ws} shall be considered correct. The procedure for determining the moisture content based upon assumption of saturated conditions is given in the Note of Section 1.3 of Method 4. For the purposes of this method, the average stack gas temperature from Figure 5-2 may be used to make this determination, provided that the accuracy of the in-stack temperature sensor is $\pm 1^\circ \text{C}$ (2°F).

METHOD 6—DETERMINATION OF SULFUR DIOXIDE EMISSIONS FROM STATIONARY SOURCES

1. Principle and Applicability

1.1 Principle. A gas sample is extracted from the sampling point in the stack. The sulfuric acid mist (including sulfur trioxide) and the sulfur dioxide are separated. The sulfur dioxide fraction is measured by the barium-thorin titration method.

1.2 Applicability. This method is applicable for the determination of sulfur dioxide emissions from stationary sources. The minimum detectable limit of the method has been determined to be 3.4 milligrams (mg) of SO_2/m^3 ($2.12 \times 10^{-7} \text{ lb/ft}^3$). Although no upper limit has been established, tests have shown that concentrations as high as 80,000 mg/m^3 of SO_2 can be collected efficiently in two midjet impingers, each containing 15 milliliters of 3 percent hydrogen peroxide, at a rate of 1.0 lpm for 20 minutes. Based on theoretical calculations, the upper concentration limit in a 20-liter sample is about 93,300 mg/m^3 .

Possible interferences are free ammonia, water-soluble cations, and fluorides. The cations and fluorides are removed by glass wool filters and an isopropanol bubbler, and hence do not affect the SO_2 analysis. When samples are being taken from a gas stream with high concentrations of very fine metallic fumes (such as in inlets to control devices), a high-efficiency glass fiber filter must be used in place of the glass wool plug (i.e., the one in the probe) to remove the cation interferences.

Free ammonia interferes by reacting with SO_2 to form particulate sulfite and by reacting with the indicator. If free ammonia is present (this can be determined by knowledge of the process and noticing white particulate matter in the probe and isopropanol bubbler), alternative methods, subject to the approval of the Administrator, U.S. Environmental Protection Agency, are required.

2. Apparatus

RULES AND REGULATIONS

Figure 6-1. SO₂ sampling train.

2.1 Sampling. The sampling train is shown in Figure 6-1, and component parts are discussed below. The tester has the option of substituting sampling equipment described in Method 8 in place of the midget impinger equipment of Method 6. However, the Method 8 train must be modified to include a heated filter between the probe and isopropanol impinger, and the operation of the sampling train and sample analysis must be at the flow rates and solution volumes defined in Method 8.

The tester also has the option of determining SO₂ simultaneously with particulate matter and moisture determinations by (1) replacing the water in a Method 5 impinger system with 3 percent peroxide solution, or (2) by replacing the Method 5 water impinger system with a Method 8 isopropanol-filter-peroxide system. The analysis for SO₂ must be consistent with the procedure in Method 8.

2.1.1 Probe. Borosilicate glass, or stainless steel (other materials of construction may be used, subject to the approval of the Administrator), approximately 6-mm inside diameter, with a heating system to prevent water condensation and a filter (either in-stack or heated out-stack) to remove particulate matter, including sulfuric acid mist. A plug of glass wool is a satisfactory filter.

2.1.2 Bubbler and Impingers. One midget bubbler, with medium-coarse glass frit and borosilicate or quartz glass wool packed in top (see Figure 6-1) to prevent sulfuric acid mist carryover, and three 20-ml midget impingers. The bubbler and midget impingers must be connected in series with leak-free glass connectors. Silicone grease may be used, if necessary, to prevent leakage.

At the option of the tester, a midget impinger may be used in place of the midget bubbler. Other collection absorbers and flow rates may be used, but are subject to the approval of the Administrator. Also, collection efficiency must be shown to be at least 99 percent for each test run and must be documented in the report. If the efficiency is found to be acceptable after a series of three tests, further documentation is not required. To conduct the efficiency test, an extra absorber must be added and analyzed separately. This extra absorber must not contain more than 1 percent of the total SO₂.

2.1.3 Glass Wool. Borosilicate or quartz.

2.1.4 Stopcock Grease. Acetone-insoluble, heat-stable silicone grease may be used, if necessary.

2.1.5 Temperature Gauge. Dial thermometer, or equivalent, to measure temperature of gas leaving impinger train to within 1° C (2° F).

2.1.6 Drying Tube. Tube packed with 6- to 16-mesh indicating type silica gel, or equivalent, to dry the gas

sample and to protect the meter and pump. If the silica gel has been used previously, dry at 175° C (350° F) for 2 hours. New silica gel may be used as received. Alternatively, other types of desiccants (equivalent or better) may be used, subject to approval of the Administrator.

2.1.7 Valve. Needle valve, to regulate sample gas flow rate.

2.1.8 Pump. Leak-free diaphragm pump, or equivalent, to pull gas through the train. Install a small tank between the pump and rate meter to eliminate the pulsation effect of the diaphragm pump on the rotameter.

2.1.9 Rate Meter. Rotameter, or equivalent, capable of measuring flow rate to within 2 percent of the selected flow rate of about 1000 cc/min.

2.1.10 Volume Meter. Dry gas meter, sufficiently accurate to measure the sample volume within 2 percent, calibrated at the selected flow rate and conditions actually encountered during sampling, and equipped with a temperature gauge (dial thermometer, or equivalent) capable of measuring temperature to within 3° C (5.4° F).

2.1.11 Barometer. Mercury, aneroid, or other barometer capable of measuring atmospheric pressure to within 2.5 mm Hg (0.1 in. Hg). In many cases, the barometric reading may be obtained from a nearby national weather service station, in which case the station value (which is the absolute barometric pressure) shall be requested and an adjustment for elevation differences between the weather station and sampling point shall be applied at a rate of minus 2.5 mm Hg (0.1 in. Hg) per 30 m (100 ft) elevation increase or vice versa for elevation decrease.

2.1.12 Vacuum Gauge. At least 760 mm Hg (30 in. Hg) gauge, to be used for leak check of the sampling train.

2.2 Sample Recovery.

2.2.1 Wash bottles. Polyethylene or glass, 500 ml, two.

2.2.2 Storage Bottles. Polyethylene, 100 ml, to store impinger samples (one per sample).

2.3 Analysis.

2.3.1 Pipettes. Volumetric type, 5-ml, 20-ml (one per sample), and 25-ml sizes.

2.3.2 Volumetric Flasks. 100-ml size (one per sample) and 100-ml size.

2.3.3 Burettes. 5- and 50-ml sizes.

2.3.4 Erlenmeyer Flasks. 250 ml-size (one for each sample, blank, and standard).

2.3.5 Dropping Bottle. 125-ml size, to add indicator.

2.3.6 Graduated Cylinder. 100-ml size.

2.3.7 Spectrophotometer. To measure absorbance at 852 nanometers.

3. Reagents

Unless otherwise indicated, all reagents must conform to the specifications established by the Committee on Analytical Reagents of the American Chemical Society. Where such specifications are not available, use the best available grade.

3.1 Sampling.

3.1.1 Water. Deionized, distilled to conform to ASTM specification D1193-74, Type 3. At the option of the analyst, the KMnO₄ test for oxidizable organic matter may be omitted when high concentrations of organic matter are not expected to be present.

3.1.2 Isopropanol, 80 percent. Mix 80 ml of isopropanol with 20 ml of deionized, distilled water. Check each lot of isopropanol for peroxide impurities as follows: shake 10 ml of isopropanol with 10 ml of freshly prepared 10 percent potassium iodide solution. Prepare a blank by similarly treating 10 ml of distilled water. After 1 minute, read the absorbance at 352 nanometers on a spectrophotometer. If absorbance exceeds 0.1, reject alcohol for use.

Peroxides may be removed from isopropanol by redistilling or by passage through a column of activated alumina; however, reagent grade isopropanol with suitably low peroxide levels may be obtained from commercial sources. Rejection of contaminated lots may, therefore, be a more efficient procedure.

3.1.3 Hydrogen Peroxide, 3 Percent. Dilute 30 percent hydrogen peroxide 1:9 (v/v) with deionized, distilled water (80 ml is needed per sample). Prepare fresh daily.

3.1.4 Potassium Iodide Solution, 10 Percent. Dissolve 10.0 grams KI in deionized, distilled water and dilute to 100 ml. Prepare when needed.

3.2 Sample Recovery.

3.2.1 Water. Deionized, distilled, as in 3.1.1.

3.2.2 Isopropanol, 80 Percent. Mix 80 ml of isopropanol with 20 ml of deionized, distilled water.

3.3 Analysis.

3.3.1 Water. Deionized, distilled, as in 3.1.1.

3.3.2 Isopropanol, 100 percent.

3.3.3 Thorin Indicator. 1-(o-arsenophenylazo)-2-naphthol-3,6-disulfonic acid, disodium salt, or equivalent. Dissolve 0.20 g in 100 ml of deionized, distilled water.

3.3.4 Barium Perchlorate Solution. 0.0100 N. Dissolve 1.95 g of barium perchlorate trihydrate [Ba(ClO₄)₃·3H₂O] in 200 ml distilled water and dilute to 1 liter with isopropanol. Alternatively, 1.22 g of [BaCl₂·2H₂O] may be used instead of the perchlorate. Standardize as in Section 5.5.

RULES AND REGULATIONS

3.3.5 Sulfuric Acid Standard, 0.0100 N. Purchase or standardize to ± 0.0002 N against 0.0100 N NaOH which has previously been standardized against potassium acid phthalate (primary standard grade).

4. Procedure.

4.1 Sampling.

4.1.1 Preparation of collection train. Measure 15 ml of 80 percent isopropanol into the midjet bubbler and 15 ml of 3 percent hydrogen peroxide into each of the first two midjet impingers. Leave the final midjet impinger dry. Assemble the train as shown in Figure 6-1. Adjust probe heater to a temperature sufficient to prevent water condensation. Place crushed ice and water around the impingers.

4.1.2 Leak-check procedure. A leak check prior to the sampling run is optional; however, a leak check after the sampling run is mandatory. The leak-check procedure is as follows:

With the probe disconnected, place a vacuum gauge at the inlet to the bubbler and pull a vacuum of 250 mm (10 in.) Hg; plug or pinch off the outlet of the flow meter, and then turn off the pump. The vacuum shall remain stable for at least 30 seconds. Carefully release the vacuum gauge before releasing the flow meter end to prevent back flow of the impinging fluid.

Other leak-check procedures may be used, subject to the approval of the Administrator, U.S. Environmental Protection Agency. The procedure used in Method 5 is not suitable for diaphragm pumps.

4.1.3 Sample collection. Record the initial dry gas meter reading and barometric pressure. To begin sampling, position the tip of the probe at the sampling point, connect the probe to the bubbler, and start the pump. Adjust the sample flow to a constant rate of approximately 1.0 liter/min as indicated by the rotameter. Maintain this constant rate (± 10 percent) during the entire sampling run. Take readings (dry gas meter, temperatures at dry gas meter and at impinger outlet and rate meter) at least every 5 minutes. Add more ice during the run to keep the temperature of the gases leaving the last impinger at 20°C (68°F) or less. At the conclusion of each run, turn off the pump, remove probe from the stack, and record the final readings. Conduct a leak check as in Section 4.1.2. (This leak check is mandatory.) If a leak is found, void the test run. Drain the ice bath, and purge the remaining part of the train by drawing clean ambient air through the system for 15 minutes at the sampling rate.

Clean ambient air can be provided by passing air through a charcoal filter or through an extra midjet impinger with 15 ml of 3 percent H_2O_2 . The tester may opt to simply use ambient air, without purification.

4.2 Sample Recovery. Disconnect the impingers after purging. Discard the contents of the midjet bubbler. Pour the contents of the midjet impingers into a leak-free polyethylene bottle for shipment. Rinse the three midjet impingers and the connecting tubes with deionized, distilled water, and add the washings to the same storage container. Mark the fluid level. Seal and identify the sample container.

4.3 Sample Analysis. Note level of liquid in container, and confirm whether any sample was lost during shipment; note this on analytical data sheet. If a noticeable amount of leakage has occurred, either void the sample or use methods, subject to the approval of the Administrator, to correct the final results.

Transfer the contents of the storage container to a 100-ml volumetric flask and dilute to exactly 100 ml with deionized, distilled water. Pipette a 20-ml aliquot of this solution into a 250-ml Erlenmeyer flask, add 80 ml of 100 percent isopropanol and two to four drops of thorin indicator, and titrate to a pink endpoint using 0.0100 N barium perchlorate. Repeat and average the titration volumes. Run a blank with each series of samples. Replicate titrations must agree within 1 percent or 0.2 ml, whichever is larger.

(NOTE.—Protect the 0.0100 N barium perchlorate solution from evaporation at all times.)

5. Calibration

5.1 Metering System.

5.1.1 Initial Calibration. Before its initial use in the field, first leak check the metering system (drying tube, needle valve, pump, rotameter, and dry gas meter) as

follows: place a vacuum gauge at the inlet to the drying tube and pull a vacuum of 250 mm (10 in.) Hg; plug or pinch off the outlet of the flow meter, and then turn off the pump. The vacuum shall remain stable for at least 30 seconds. Carefully release the vacuum gauge before releasing the flow meter end.

Next, calibrate the metering system (at the sampling flow rate specified by the method) as follows: connect an appropriately sized wet test meter (e.g., 1 liter per revolution) to the inlet of the drying tube. Make three independent calibration runs, using at least five revolutions of the dry gas meter per run. Calculate the calibration factor, Y (wet test meter calibration volume divided by the dry gas meter volume, both volumes adjusted to the same reference temperature and pressure), for each run, and average the results. If any Y value deviates by more than 2 percent from the average, the metering system is unacceptable for use. Otherwise, use the average as the calibration factor for subsequent test runs.

5.1.2 Post-Test Calibration Check. After each field test series, conduct a calibration check as in Section 5.1.1 above, except for the following variations: (a) the leak check is not to be conducted, (b) three, or more revolutions of the dry gas meter may be used, and (c) only two independent runs need be made. If the calibration factor does not deviate by more than 5 percent from the initial calibration factor (determined in Section 5.1.1), then the dry gas meter volumes obtained during the test series are acceptable. If the calibration factor deviates by more than 5 percent, recalibrate the metering system as in Section 5.1.1, and for the calculations, use the calibration factor (initial or recalibration) that yields the lower gas volume for each test run.

5.2 Thermometers. Calibrate against mercury-in-glass thermometers.

5.3 Rotameter. The rotameter need not be calibrated but should be cleaned and maintained according to the manufacturer's instruction.

5.4 Barometer. Calibrate against a mercury barometer.

5.5 Barium Perchlorate Solution. Standardize the barium perchlorate solution against 25 ml of standard sulfuric acid to which 100 ml of 100 percent isopropanol has been added.

6. Calculations

Carry out calculations, retaining at least one extra decimal figure beyond that of the acquired data. Round off figures after final calculation.

6.1 Nomenclature.

C_{SO_2} = Concentration of sulfur dioxide, dry basis corrected to standard conditions, mg/dscm (lb/dscf).

N = Normality of barium perchlorate titrant, milliequivalents/ml.

P_{bar} = Barometric pressure at the exit orifice of the dry gas meter, mm Hg (in. Hg).

P_{std} = Standard absolute pressure, 760 mm Hg (29.92 in. Hg).

T_m = Average dry gas meter absolute temperature, $^\circ\text{K}$ ($^\circ\text{R}$).

T_{std} = Standard absolute temperature, 293°K (528°R).

V_m = Volume of sample aliquot titrated, ml.

V_m = Dry gas volume as measured by the dry gas meter, dcm (dcf).

$V_{m(\text{std})}$ = Dry gas volume measured by the dry gas meter, corrected to standard conditions, dscm (dscf).

V_{soln} = Total volume of solution in which the sulfur dioxide sample is contained, 100 ml.

V_t = Volume of barium perchlorate titrant used for the sample, ml (average of replicate titrations).

V_{t0} = Volume of barium perchlorate titrant used for the blank, ml.

Y = Dry gas meter calibration factor.

32.03 = Equivalent weight of sulfur dioxide.

6.2 Dry sample gas volume, corrected to standard conditions.

$$V_{m(\text{std})} = V_m Y \left(\frac{T_{\text{std}}}{T_m} \right) \left(\frac{P_{\text{bar}}}{P_{\text{std}}} \right) = K_1 Y \frac{V_m P_{\text{bar}}}{T_m}$$

Equation 6-1

where:

$$K_1 = 0.3858^\circ\text{K/mm Hg for metric units.}$$

$$= 17.64^\circ\text{R/in. Hg for English units.}$$

6.3 Sulfur dioxide concentration.

$$C_{\text{SO}_2} = K_2 \frac{(V_t - V_{t0}) N \left(\frac{V_{\text{soln}}}{V_m} \right)}{V_{m(\text{std})}}$$

Equation 6-2

where:

$$K_2 = 32.03 \text{ mg/meq. for metric units.}$$

$$= 7.061 \times 10^{-3} \text{ lb/meq. for English units.}$$

METHOD 7—DETERMINATION OF NITROGEN OXIDE EMISSIONS FROM STATIONARY SOURCES

1. Principle and Applicability

1.1 Principle. A grab sample is collected in an evacuated flask containing a dilute sulfuric acid-hydrogen peroxide absorbing solution, and the nitrogen oxides, except nitrous oxide, are measured colorimetrically using the phenoldisulfonic acid (PDS) procedure.

1.2 Applicability. This method is applicable to the measurement of nitrogen oxides emitted from stationary sources. The range of the method has been determined to be 2 to 400 milligrams NO_x (as NO_2) per dry standard cubic meter, without having to dilute the sample.

2. Apparatus

2.1 Sampling (see Figure 7-1). Other grab sampling systems or equipment, capable of measuring sample volume to within ± 2.0 percent and collecting a sufficient sample volume to allow analytical reproducibility to within ± 5 percent, will be considered acceptable alternatives, subject to approval of the Administrator, U.S. Environmental Protection Agency. The following equipment is used in sampling:

2.1.1 Probe. Borosilicate glass tubing, sufficiently heated to prevent water condensation and equipped with an in-stack or out-stack filter to remove particulate matter (a plug of glass wool is satisfactory for this purpose). Stainless steel or Teflon® tubing may also be used for the probe. Heating is not necessary if the probe remains dry during the purging period.

* Mention of trade names or specific products does not constitute endorsement by the Environmental Protection Agency.

RULES AND REGULATIONS

Figure 7-1. Sampling train, flask valve, and flask.

2.1.2 Collection Flask. Two-liter borosilicate, round bottom flask, with short neck and 24/40 standard taper opening, protected against implosion or breakage.

2.1.3 Flask Valve. T-bore stopcock connected to a 24/40 standard taper joint.

2.1.4 Temperature Gauge. Dial-type thermometer, or other temperature gauge, capable of measuring 1° C (2° F) intervals from -5 to 50° C (25 to 125° F).

2.1.5 Vacuum Line. Tubing capable of withstanding a vacuum of 75 mm Hg (3 in. Hg) absolute pressure, with "T" connection and T-bore stopcock.

2.1.6 Vacuum Gauge. U-tube manometer, 1 meter (36 in.), with 1-mm (0.1 in.) divisions, or other gauge capable of measuring pressure to within ±2.5 mm Hg (0.10 in. Hg).

2.1.7 Pump. Capable of evacuating the collection flask to a pressure equal to or less than 75 mm Hg (3 in. Hg) absolute.

2.1.8 Squeeze Bulb. One-way.

2.1.9 Volumetric Pipette. 25 ml.

2.1.10 Stopcock and Ground Joint Grease. A high-vacuum, high-temperature chlorofluorocarbon grease is required. Halocarbon 25-58 has been found to be effective.

2.1.11 Barometer. Mercury, aneroid, or other barometer capable of measuring atmospheric pressure to within 2.5 mm Hg (0.1 in. Hg). In many cases, the barometric reading may be obtained from a nearby national weather service station, in which case the station value (which is the absolute barometric pressure) shall be requested and an adjustment for elevation differences between the weather station and sampling point shall be applied at a rate of minus 2.5 mm Hg (0.1 in. Hg) per 30 m (100 ft) elevation increase, or vice versa for elevation decrease.

2.2 Sample Recovery. The following equipment is required for sample recovery:

2.2.1 Graduated Cylinder. 50 ml with 1-ml divisions.

2.2.2 Storage Containers. Leak-free polyethylene bottles.

2.2.3 Wash Bottle. Polyethylene or glass.

2.2.4 Glass Stirring Rod.

2.2.5 Test Paper for Indicating pH. To cover the pH range of 7 to 14.

2.3 Analysis. For the analysis, the following equipment is needed:

2.3.1 Volumetric Pipettes. Two 1 ml, two 2 ml, one 3 ml, one 4 ml, two 10 ml, and one 25 ml for each sample and standard.

2.3.2 Porcelain Evaporating Dishes. 175- to 250-ml capacity with lip for pouring, one for each sample and each standard. The Coors No. 45006 (shallow-form, 195 ml) has been found to be satisfactory. Alternatively, polymethyl pentene beakers (Nalgae No. 1203, 150 ml), or glass beakers (150 ml) may be used. When glass beakers are used, etching of the beakers may cause solid matter to be present in the analytical step: the solids should be removed by filtration (see Section 4.3).

2.3.3 Steam Bath. Low-temperature ovens or thermostatically controlled hot plates kept below 70° C (160° F) are acceptable alternatives.

2.3.4 Dropping Pipette or Dropper. Three required.

2.3.5 Polyethylene Policeman. One for each sample and each standard.

2.3.6 Graduated Cylinder. 100 ml with 1-ml divisions.

2.3.7 Volumetric Flasks. 50 ml (one for each sample), 100 ml (one for each sample and each standard, and one for the working standard KNO₃ solution), and 1000 ml (one).

2.3.8 Spectrophotometer. To measure absorbance at 410 nm.

2.3.9 Graduated Pipette. 10 ml with 0.1-ml divisions.

2.3.10 Test Paper for Indicating pH. To cover the pH range of 7 to 14.

2.3.11 Analytical Balance. To measure to within 0.1 mg.

3. Reagents

Unless otherwise indicated, it is intended that all reagents conform to the specifications established by the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available; otherwise, use the best available grade.

3.1 Sampling. To prepare the absorbing solution, cautiously add 2.8 ml concentrated H₂SO₄ to 1 liter of deionized, distilled water. Mix well and add 6 ml of 3 percent hydrogen peroxide, freshly prepared from 30 percent hydrogen peroxide solution. The absorbing solution should be used within 1 week of its preparation. Do not expose to extreme heat or direct sunlight.

3.2 Sample Recovery. Two reagents are required for sample recovery:

3.2.1 Sodium Hydroxide (1N). Dissolve 40 g NaOH in deionized, distilled water and dilute to 1 liter.

3.2.2 Water. Deionized, distilled to conform to ASTM specification D1193-74, Type 3. At the option of the

analyst, the KMnO₄ test for oxidizable organic matter may be omitted when high concentrations of organic matter are not expected to be present.

3.3 Analysis. For the analysis, the following reagents are required:

3.3.1 Fuming Sulfuric Acid. 15 to 18 percent by weight free sulfur trioxide. HANDLE WITH CAUTION.

3.3.2 Phenol. White solid.

3.3.3 Sulfuric Acid. Concentrated, 95 percent minimum assay. HANDLE WITH CAUTION.

3.3.4 Potassium Nitrate. Dried at 105 to 110° C (220 to 230° F) for a minimum of 2 hours just prior to preparation of standard solution.

3.3.5 Standard KNO₃ Solution. Dissolve exactly 2.198 g of dried potassium nitrate (KNO₃) in deionized, distilled water and dilute to 1 liter with deionized, distilled water in a 1,000-ml volumetric flask.

3.3.6 Working Standard KNO₃ Solution. Dilute 10 ml of the standard solution to 100 ml with deionized, distilled water. One milliliter of the working standard solution is equivalent to 100 µg nitrogen dioxide (NO₂).

3.3.7 Water. Deionized, distilled as in Section 3.2.2.

3.3.8 Phenoldisulfonic Acid Solution. Dissolve 25 g of pure white phenol in 150 ml concentrated sulfuric acid on a steam bath. Cool, add 75 ml fuming sulfuric acid, and heat at 100° C (212° F) for 2 hours. Store in a dark, stoppered bottle.

4. Procedures

4.1 Sampling.

4.1.1 Pipette 25 ml of absorbing solution into a sample flask, retaining a sufficient quantity for use in preparing the calibration standards. Insert the flask valve stopper into the flask with the valve in the "purge" position. Assemble the sampling train as shown in Figure 7-1 and place the probe at the sampling point. Make sure that all fittings are tight and have been properly greased with a high-vacuum, high-temperature chlorofluorocarbon-based stopcock grease. Turn the flask valve and the pump valve to their "evacuate" positions. Evacuate the flask to 75 mm Hg (3 in. Hg) absolute pressure, or less. Evacuation to a pressure approaching the vapor pressure of water at the existing temperature is desirable. Turn the pump valve to its "vent" position and turn off the pump. Check for leakage by observing the manometer for any pressure fluctuation. (Any variation

RULES AND REGULATIONS

greater than 10 mm Hg (0.4 in. Hg) over a period of 1 minute is not acceptable, and the flask is not to be used until the leakage problem is corrected. Pressure in the flask is not to exceed 75 mm Hg (3 in. Hg) absolute at the time sampling is commenced. Record the volume of the flask and valve (V_f), the flask temperature (T_f), and the barometric pressure. Turn the flask valve counterclockwise to its "purge" position and do the same with the pump valve. Purge the probe and the vacuum tube using the squeeze bulb. If condensation occurs in the probe and the flask valve area, heat the probe and purge until the condensation disappears. Next, turn the pump valve to its "vent" position. Turn the flask valve clockwise to its "evacuate" position and record the difference in the mercury levels in the manometer. The absolute internal pressure in the flask (P_f) is equal to the barometric pressure less the manometer reading. Immediately turn the flask valve to the "sample" position and permit the gas to enter the flask until pressures in the flask and sample line (i.e., duct, stack) are equal. This will usually require about 15 seconds; a longer period indicates a "plug" in the probe, which must be corrected before sampling is continued. After collecting the sample, turn the flask valve to its "purge" position and disconnect the flask from the sampling train. Shake the flask for at least 5 minutes.

4.1.2 If the gas being sampled contains insufficient oxygen for the conversion of NO to NO₂ (e.g., an applicable subpart of the standard may require taking a sample of a calibration gas mixture of NO in N₂), then oxygen shall be introduced into the flask to permit this conversion. Oxygen may be introduced into the flask by one of three methods: (1) Before evacuating the sampling flask, flush with pure cylinder oxygen, then evacuate flask to 75 mm Hg (3 in. Hg) absolute pressure or less; or (2) inject oxygen into the flask after sampling; or (3) terminate sampling with a minimum of 50 mm Hg (2 in. Hg) vacuum remaining in the flask, record this final pressure, and then vent the flask to the atmosphere until the flask pressure is almost equal to atmospheric pressure.

4.2 Sample Recovery. Let the flask set for a minimum of 18 hours and then shake the contents for 2 minutes. Connect the flask to a mercury-filled U-tube manometer. Open the valve from the flask to the manometer and record the flask temperature (T_f), the barometric pressure, and the difference between the mercury levels in the manometer. The absolute internal pressure in the flask (P_f) is the barometric pressure less the manometer reading. Transfer the contents of the flask to a leak-free polyethylene bottle. Rinse the flask twice with 5-ml portions of deionized, distilled water and add the rinse water to the bottle. Adjust the pH to between 9 and 12 by adding sodium hydroxide (1 N), dropwise (about 25 to 35 drops). Check the pH by dipping a stirring rod into the solution and then touching the rod to the pH test paper. Remove as little material as possible during this step. Mark the height of the liquid level so that the container can be checked for leakage after transport. Label the container to clearly identify its contents. Seal the container for shipping.

4.3 Analysis. Note the level of the liquid in container and confirm whether or not any sample was lost during shipment; note this on the analytical data sheet. If a noticeable amount of leakage has occurred, either void the sample or use methods, subject to the approval of the Administrator, to correct the final results. Immediately prior to analysis, transfer the contents of the shipping container to a 50-ml volumetric flask, and rinse the container twice with 5-ml portions of deionized, distilled water. Add the rinse water to the flask and dilute to the mark with deionized, distilled water; mix thoroughly. Pipette a 25-ml aliquot into the porcelain evaporating dish. Return any unused portion of the sample to the polyethylene storage bottle. Evaporate the 25-ml aliquot to dryness on a steam bath and allow to cool. Add 2 ml phenoldisulfonic acid solution to the dried residue and triturate thoroughly with a polyethylene policeman. Make sure the solution contacts all the residue. Add 1 ml deionized, distilled water and four drops of concentrated sulfuric acid. Heat the solution on a steam bath for 3 minutes with occasional stirring. Allow the solution to cool, add 20 ml deionized, distilled water, mix well by stirring, and add concentrated ammonium hydroxide, dropwise, with constant stirring, until the pH is 10 (as determined by pH paper). If the sample contains solids, these must be removed by filtration (centrifugation is an acceptable alternative, subject to the approval of the Administrator), as follows: filter through Whatman No. 41 filter paper into a 100-ml volumetric flask; rinse the evaporating dish with three 5-ml portions of deionized, distilled water; filter these three rinses. Wash the filter with at least three 15-ml portions of deionized, distilled water. Add the filter washings to the contents of the volumetric flask and dilute to the mark with deionized, distilled water. If solids are absent, the solution can be transferred directly to the 100-ml volumetric flask and diluted to the mark with deionized, distilled water. Mix the contents of the flask thoroughly, and measure the absorbance at the optimum wavelength used for the standards (Section 5.2.1), using the blank solution as a zero reference. Dilute the sample and the blank with equal volumes of deionized, distilled water if the absorbance exceeds A_4 , the absorbance of the 400- μ g NO₂ standard (see Section 5.2.2).

5. Calibration

5.1 Flask Volume. The volume of the collection flask-flask valve combination must be known prior to sampling. Assemble the flask and flask valve and fill with

water, to the stopcock. Measure the volume of water to ± 10 ml. Record this volume on the flask.

5.2 Spectrophotometer Calibration

5.2.1 Optimum Wavelength Determination. For both fixed and variable wavelength spectrophotometers, calibrate against standard certified wavelength of 410 nm, every 8 months. Alternatively, for variable wavelength spectrophotometers, scan the spectrum between 400 and 415 nm using a 200- μ g NO₂ standard solution (see Section 5.2.2). If a peak does not occur, the spectrophotometer is probably malfunctioning, and should be repaired. When a peak is obtained within the 400 to 415 nm range, the wavelength at which this peak occurs shall be the optimum wavelength for the measurement of absorbance for both the standards and samples.

5.2.2 Determination of Spectrophotometer Calibration Factor K_c . Add 0.0, 1.0, 2.0, 3.0, and 4.0 ml of the KNO₃ working standard solution (1 ml=100- μ g NO₂) to a series of five porcelain evaporating dishes. To each, add 25 ml of absorbing solution, 10 ml deionized, distilled water, and sodium hydroxide (1N), dropwise, until the pH is between 9 and 12 (about 25 to 35 drops each). Beginning with the evaporation step, follow the analysis procedure of Section 4.3, until the solution has been transferred to the 100-ml volumetric flask and diluted to the mark. Measure the absorbance of each solution at the optimum wavelength, as determined in Section 5.2.1. This calibration procedure must be repeated on each day that samples are analyzed. Calculate the spectrophotometer calibration factor as follows:

$$K_c = 100 \frac{A_1 + 2A_2 + 3A_3 + 4A_4}{A_1^2 + A_2^2 + A_3^2 + A_4^2}$$

Equation 7-1

where:

K_c = Calibration factor

A_1 = Absorbance of the 100- μ g NO₂ standard

A_2 = Absorbance of the 200- μ g NO₂ standard

A_3 = Absorbance of the 300- μ g NO₂ standard

A_4 = Absorbance of the 400- μ g NO₂ standard

5.3 Barometer. Calibrate against a mercury barometer.

5.4 Temperature Gauge. Calibrate dial thermometers against mercury-in-glass thermometers.

5.5 Vacuum Gauge. Calibrate mechanical gauges, if used, against a mercury manometer such as that specified in 2.1.6.

5.6 Analytical Balance. Calibrate against standard weights.

6. Calculations

Carry out the calculations, retaining at least one extra decimal figure beyond that of the acquired data. Round off figures after final calculations.

6.1 Nomenclature

A = Absorbance of sample.

C = Concentration of NO₂ as NO₂, dry basis, corrected to standard conditions, mg/dscm (lb/dscf).

F = Dilution factor (i.e., 25/5, 25/10, etc., required only if sample dilution was needed to reduce the absorbance into the range of calibration).

K_c = Spectrophotometer calibration factor.

m = Mass of NO₂ as NO₂ in gas sample, μ g.

P_f = Final absolute pressure of flask, mm Hg (in. Hg).

P_{std} = Initial absolute pressure of flask, mm Hg (in. Hg).

P_{std} = Standard absolute pressure, 760 mm Hg (29.92 in. Hg).

T_f = Final absolute temperature of flask, °K (°R).

T_i = Initial absolute temperature of flask, °K (°R).

T_{std} = Standard absolute temperature, 293°K (528°R).

V_{std} = Sample volume at standard conditions (dry basis), ml.

V_f = Volume of flask and valve, ml.

V_s = Volume of absorbing solution, 25 ml.

$25/25$ = aliquot factor. (If other than a 25-ml aliquot was used for analysis, the corresponding factor must be substituted).

6.2 Sample volume, dry basis, corrected to standard conditions.

$$V_{sc} = \frac{T_{std}}{P_{std}} (V_f - V_o) \left[\frac{P_f}{T_f} - \frac{P_i}{T_i} \right]$$

$$= K_1 (V_f - 25 \text{ ml}) \left[\frac{P_f}{T_f} - \frac{P_i}{T_i} \right]$$

Equation 7-2

where:

$$K_1 = 0.3858 \frac{^\circ\text{K}}{\text{mm Hg}} \text{ for metric units}$$

$$= 17.64 \frac{^\circ\text{R}}{\text{in. Hg}} \text{ for English units}$$

6.3 Total μ g NO₂ per sample.

$$m = 2 K_c A F$$

Equation 7-3

NOTE.—If other than a 25-ml aliquot is used for analysis, the factor 2 must be replaced by a corresponding factor.

6.4 Sample concentration, dry basis, corrected to standard conditions.

$$C = K_2 \frac{m}{V_{sc}}$$

Equation 7-4

where:

$$K_2 = 10^3 \frac{\text{mg/m}^3}{\mu\text{g/ml}} \text{ for metric units}$$

$$= 6.243 \times 10^{-5} \frac{\text{lb/scf}}{\mu\text{g/ml}} \text{ for English units}$$

6. Hamil, H. F. and R. E. Thomas. Collaborative Study of Method for the Determination of Nitrogen Oxide Emissions from Stationary Sources (Nitric Acid Plants). Southwest Research Institute report for Environmental Protection Agency. Research Triangle Park, N.C. May 8, 1974.

METHOD 8—DETERMINATION OF SULFURIC ACID MIST AND SULFUR DIOXIDE EMISSIONS FROM STATIONARY SOURCES

1. Principle and Applicability

1.1 Principle. A gas sample is extracted isokinetically from the stack. The sulfuric acid mist (including sulfur trioxide) and the sulfur dioxide are separated, and both fractions are measured separately by the barium-thorin titration method.

1.2 Applicability. This method is applicable for the determination of sulfuric acid mist (including sulfur trioxide, and in the absence of other particulate matter) and sulfur dioxide emissions from stationary sources. Collaborative tests have shown that the minimum detectable limits of the method are 0.05 milligrams/cubic meter (0.03 $\times 10^{-7}$ pounds/cubic foot) for sulfur trioxide and 1.2 mg/m³ (0.74 10^{-7} lb/ft³) for sulfur dioxide. No upper limits have been established. Based on theoretical calculations for 200 milliliters of 3 percent hydrogen peroxide solution, the upper concentration limit for sulfur dioxide in a 1.0 m³ (35.3 ft³) gas sample is about 12,500 mg/m³ (7.7 $\times 10^{-4}$ lb/ft³). The upper limit can be extended by increasing the quantity of peroxide solution in the impingers.

Possible interfering agents of this method are fluorides, free ammonia, and dimethyl aniline. If any of these interfering agents are present (this can be determined by knowledge of the process), alternative methods, subject to the approval of the Administrator, are required.

Filterable particulate matter may be determined along with SO₂ and SO₃ (subject to the approval of the Administrator); however, the procedure used for particulate matter must be consistent with the specifications and procedures given in Method 5.

2. Apparatus

2.1 Sampling. A schematic of the sampling train used in this method is shown in Figure 8-1; it is similar to the Method 5 train except that the filter position is different and the filter holder does not have to be heated. Commercial models of this train are available. For those who desire to build their own, however, complete construction details are described in APTD-0581. Changes from the APTD-0581 document and allowable modifications to Figure 8-1 are discussed in the following subsections.

The operating and maintenance procedures for the sampling train are described in APTD-0576. Since correct usage is important in obtaining valid results, all users should read the APTD-0576 document and adopt the operating and maintenance procedures outlined in it, unless otherwise specified herein. Further details and guidelines on operation and maintenance are given in Method 5 and should be read and followed whenever they are applicable.

2.1.1 Probe Nozzle. Same as Method 5, Section 2.1.1.

2.1.2 Probe Liner. Borosilicate or quartz glass, with a heating system to prevent visible condensation during sampling. Do not use metal probe liners.

2.1.3 Pitot Tube. Same as Method 5, Section 2.1.3.

RULES AND REGULATIONS

Figure 8-1. Sulfuric acid mist sampling train.

2.1.4 Differential Pressure Gauge. Same as Method 5, Section 2.1.4.

2.1.5 Filter Holder. Borosilicate glass, with a glass frit filter support and a silicone rubber gasket. Other gasket materials, e.g., Teflon or Viton, may be used subject to the approval of the Administrator. The holder design shall provide a positive seal against leakage from the outside or around the filter. The filter holder shall be placed between the first and second impingers. Note: Do not heat the filter holder.

2.1.6 Impingers—Four, as shown in Figure 8-1. The first and third shall be of the Greenburg-Smith design with standard tips. The second and fourth shall be of the Greenburg-Smith design, modified by replacing the insert with an approximately 13 millimeter (0.5 in.) ID glass tube, having an unobstructed tip located 13 mm (0.5 in.) from the bottom of the flask. Similar collection systems, which have been approved by the Administrator, may be used.

2.1.7 Metering System. Same as Method 5, Section 2.1.8.

2.1.8 Barometer. Same as Method 5, Section 2.1.9.

2.1.9 Gas Density Determination Equipment. Same as Method 5, Section 2.1.10.

2.1.10 Temperature Gauge. Thermometer, or equivalent, to measure the temperature of the gas leaving the impinger train to within 1° C (2° F).

2.2 Sample Recovery.

2.2.1 Wash Bottles. Polyethylene or glass, 500 ml. (two).

2.2.2 Graduated Cylinders. 250 ml, 1 liter. (Volumetric flasks may also be used.)

2.2.3 Storage Bottles. Leak-free polyethylene bottles, 1000 ml size (two for each sampling run).

2.2.4 Trip Balance. 500-gram capacity, to measure to ± 0.5 g (necessary only if a moisture content analysis is to be done).

2.3 Analysis.

2.3.1 Pipettes. Volumetric 25 ml, 100 ml.

2.3.2 Burette. 60 ml.

2.3.3 Erlenmeyer Flask. 250 ml. (one for each sample blank and standard).

2.3.4 Graduated Cylinder. 100 ml.

2.3.5 Trip Balance. 500 g capacity, to measure to ± 0.5 g.

2.3.6 Dropping Bottle. To add indicator solution, 125-ml size.

3. Reagents

Unless otherwise indicated, all reagents are to conform to the specifications established by the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Otherwise, use the best available grade.

3.1 Sampling.

3.1.1 Filters. Same as Method 5, Section 3.1.1.

3.1.2 Silica Gel. Same as Method 5, Section 3.1.2.

3.1.3 Water. Deionized, distilled to conform to ASTM specification D1193-74, Type 3. At the option of the analyst, the $KMnO_4$ test for oxidizable organic matter may be omitted when high concentrations of organic matter are not expected to be present.

3.1.4 Isopropanol. 80 Percent. Mix 800 ml of isopropanol with 200 ml of deionized, distilled water.

NOTE.—Experience has shown that only A.C.S. grade isopropanol is satisfactory. Tests have shown that isopropanol obtained from commercial sources occasionally has peroxide impurities that will cause ex-

cessionably high sulfuric acid mist measurement. Use the following test for detecting peroxides in each lot of isopropanol: Shake 10 ml of the isopropanol with 10 ml of freshly prepared 10 percent potassium iodide solution. Prepare a blank by similarly treating 10 ml of distilled water. After 1 minute, read the absorbance on a spectrophotometer at 352 nanometers. If the absorbance exceeds 0.1, the isopropanol shall not be used. Peroxides may be removed from isopropanol by redistilling, or by passage through a column of activated alumina. However, reagent-grade isopropanol with suitably low peroxide levels is readily available from commercial sources; therefore, rejection of contaminated lots may be more efficient than following the peroxide removal procedure.

3.1.5 Hydrogen Peroxide, 3 Percent. Dilute 100 ml of 30 percent hydrogen peroxide to 1 liter with deionized, distilled water. Prepare fresh daily.

3.1.6 Crushed Ice.

3.2 Sample Recovery.

3.2.1 Water. Same as 3.1.3.

3.2.2 Isopropanol, 80 Percent. Same as 3.1.4.

3.3 Analysis.

3.3.1 Water. Same as 3.1.3.

3.3.2 Isopropanol, 100 Percent.

3.3.3 Thorin Indicator. 1-(o-arsenophenylazo)-2-naphthol-3, 6-disulfonic acid, disodium salt, or equivalent. Dissolve 0.20 g in 100 ml of deionized, distilled water.

3.3.4 Barium Perchlorate (0.0100 Normal). Dissolve 1.85 g of barium perchlorate trihydrate ($Ba(ClO_4)_3 \cdot 3H_2O$) in 200 ml deionized, distilled water, and dilute to 1 liter with isopropanol; 1.22 g of barium chloride dihydrate ($BaCl_2 \cdot 2H_2O$) may be used instead of the barium perchlorate. Standardize with sulfuric acid as in Section 5.2. This solution must be protected against evaporation at all times.

RULES AND REGULATIONS

3.3.5 Sulfuric Acid Standard (0.0100 N). Purchase or standardize to ± 0.0002 N against 0.0100 N NaOH that has previously been standardized against primary standard potassium acid phthalate.

4. Procedure

4.1.1 Pretest Preparation. Follow the procedure outlined in Method 5, Section 4.1.1; filters should be inspected, but need not be desiccated, weighed, or identified. If the effluent gas can be considered dry, i.e., moisture free, the silica gel need not be weighed.

4.1.2 Preliminary Determinations. Follow the procedure outlined in Method 5, Section 4.1.2.

4.1.3 Preparation of Collection Train. Follow the procedure outlined in Method 5, Section 4.1.3 (except for the second paragraph and other obviously inapplicable parts) and use Figure 8-1 instead of Figure 5-1. Replace the second paragraph with: Place 100 ml of 80 percent isopropanol in the first impinger, 100 ml of 3 percent hydrogen peroxide in both the second and third im-

impingers; retain a portion of each reagent for use as a blank solution. Place about 200 g of silica gel in the fourth impinger.

NOTE.—If moisture content is to be determined by impinger analysis, weigh each of the first three impingers (plus absorbing solution) to the nearest 0.5 g and record these weights. The weight of the silica gel (or silica gel plus container) must also be determined to the nearest 0.5 g and recorded.

4.1.4 Pretest Leak-Check Procedure. Follow the basic procedure outlined in Method 5, Section 4.1.4.1, noting that the probe heater shall be adjusted to the minimum temperature required to prevent condensation, and also that verbiage such as, "• • • plugging the inlet to the filter holder • • •" shall be replaced by, "• • • plugging the inlet to the first impinger • • •". The pretest leak-check is optional.

4.1.5 Train Operation. Follow the basic procedures outlined in Method 5, Section 4.1.5, in conjunction with the following special instructions. Data shall be recorded

on a sheet similar to the one in Figure 8-2. The sampling rate shall not exceed 0.030 m³/min (1.0 cfm) during the run. Periodically during the test, observe the connecting line between the probe and first impinger for signs of condensation. If it does occur, adjust the probe heater setting upward to the minimum temperature required to prevent condensation. If component changes become necessary during a run, a leak-check shall be done immediately before each change, according to the procedure outlined in Section 4.1.2 of Method 5 (with appropriate modifications, as mentioned in Section 4.1.4 of this method); record all leak rates. If the leakage rate(s) exceed the specified rate, the tester shall either void the run or shall plan to correct the sample volume as outlined in Section 6.3 of Method 5. Immediately after component changes, leak-checks are optional. If these leak-checks are done, the procedure outlined in Section 4.1.4.1 of Method 5 (with appropriate modifications) shall be used.

SCHEMATIC OF STACK CROSS SECTION

[illegible]

Figure 8-2. Field data.

After turning off the pump and recording the final readings at the conclusion of each run, remove the probe from the stack. Conduct a post-test (mandatory) leak-check as in Section 4.1.4.3 of Method 5 (with appropriate modification) and record the leak rate. If the post-test leakage rate exceeds the specified acceptable rate, the tester shall either correct the sample volume, as outlined in Section 8.3 of Method 5, or shall end the run.

Drain the ice bath and, with the probe disconnected, purge the remaining part of the train, by drawing clean ambient air through the system for 15 minutes at the average flow rate used for sampling.

NOTE.—Clean ambient air can be provided by passing air through a charcoal filter. At the option of the tester, ambient air (without cleaning) may be used.

4.1.6 Calculation of Percent Isokinetic. Follow the procedure outlined in Method 5, Section 4.1.6.

4.2 Sample Recovery.

4.2.1 Container No. 1. If a moisture content analysis

is to be done, weigh the first impinger plus contents to the nearest 0.5 g and record this weight.

Transfer the contents of the first impinger to a 250-ml graduated cylinder. Rinse the probe, first impinger, all connecting glassware before the filter, and the front half of the filter holder with 80 percent isopropanol. Add the rinse solution to the cylinder. Dilute to 250 ml with 80 percent isopropanol. Add the filter to the solution, mix, and transfer to the storage container. Protect the solution against evaporation. Mark the level of liquid on the container and identify the sample container.

4.2.2 Container No. 2. If a moisture content analysis is to be done, weigh the second and third impingers (plus contents) to the nearest 0.5 g and record these weights. Also, weigh the spent silica gel (or silica gel plus impinger) to the nearest 0.5 g.

Transfer the solutions from the second and third impingers to a 1000-ml graduated cylinder. Rinse all connecting glassware (including back half of filter holder) between the filter and silica gel impinger with deionized,

distilled water, and add this rinse water to the cylinder. Dilute to a volume of 1000 ml with deionized, distilled water. Transfer the solution to a storage container. Mark the level of liquid on the container. Seal and identify the sample container.

4.3 Analysis.

Note the level of liquid in containers 1 and 2, and confirm whether or not any sample was lost during shipment; note this on the analytical data sheet. If a noticeable amount of leakage has occurred, either void the sample or use methods, subject to the approval of the Administrator, to correct the final results.

4.3.1 Container No. 1. Shake the container holding the isopropanol solution and the filter. If the filter breaks up, allow the fragments to settle for a few minutes before removing a sample. Pipette a 100-ml aliquot of this solution into a 250-ml Erlenmeyer flask, add 2 to 4 drops of thorin indicator, and titrate to a pink endpoint using 0.010N N barium perchlorate. Repeat the titration with a second aliquot of sample and average the titration

RULES AND REGULATIONS

values. Replicate titrations must agree within 1 percent or 0.2 ml, whichever is greater.

4.3.2 Container No. 2. Thoroughly mix the solution in the container holding the contents of the second and third impingers. Pipette a 10-ml aliquot of sample into a 250-ml Erlenmeyer flask. Add ml of isopropanol, 2 to 4 drops of thion indicator, and titrate to a pink endpoint using 0.0100 N barium perchlorate. Repeat the titration with a second aliquot of sample and average the titration values. Replicate titrations must agree within 1 percent or 0.2 ml, whichever is greater.

4.3.3 Blanks. Prepare blanks by adding 2 to 4 drops of thion indicator to 100 ml of 80 percent isopropanol. Titrate the blanks in the same manner as the samples.

5. Calibration

5.1 Calibrate equipment using the procedures specified in the following sections of Method 5: Section 5.3 (metering system); Section 5.5 (temperature gauges); Section 5.7 (barometer). Note that the recommended leak-check of the metering system, described in Section 5.6 of Method 5, also applies to this method.

5.2 Standardize the barium perchlorate solution with 25 ml of standard sulfuric acid, to which 100 ml of 100 percent isopropanol has been added.

6. Calculations

Note.—Carry out calculations retaining at least one extra decimal figure beyond that of the acquired data. Round off figures after final calculation.

6.1 Nomenclature.

- A_n —Cross-sectional area of nozzle, m^2 (ft^2).
- B_{std} —Water vapor in the gas stream, proportion by volume.
- CH_3SO_4 —Sulfuric acid (including SO_3) concentration, g/dscm (lb/dscf).
- C_{SO_2} —Sulfur dioxide concentration, g/dscm (lb/dscf).
- I —Percent of isokinetic sampling.
- N —Normality of barium perchlorate titrant, g equivalents/liter.
- P_{bar} —Barometric pressure at the sampling site, mm Hg (in. Hg).
- P_s —Absolute stack gas pressure, mm Hg (in. Hg).
- P_{std} —Standard absolute pressure, 760 mm Hg (29.92 in. Hg).
- T_m —Average absolute dry gas meter temperature (see Figure 8-2), °K (°F).
- T_s —Average absolute stack gas temperature (see Figure 8-2), °K (°F).
- T_{std} —Standard absolute temperature, 273° K (32° F).
- V_s —Volume of sample aliquot titrated, 100 ml for H_2SO_4 and 10 ml for SO_3 .
- V_{li} —Total volume of liquid collected in impingers and silica gel, ml.
- V_m —Volume of gas sample as measured by dry gas meter, dcm (dcf).
- $V_{m(Std)}$ —Volume of gas sample measured by the dry gas meter corrected to standard conditions, dcm (dcf).
- v_s —Average stack gas velocity, calculated by Method 2, Equation 2-9, using data obtained from Method 8, m/sec (ft/sec).
- V_{soln} —Total volume of solution in which the sulfuric acid or sulfur dioxide sample is contained, 250 ml or 1,000 ml, respectively.
- V_t —Volume of barium perchlorate titrant used for the sample, ml.
- $V_{t,bl}$ —Volume of barium perchlorate titrant used for the blank, ml.
- Y —Dry gas meter calibration factor.
- ΔH —Average pressure drop across orifice meter, mm (in.) H_2O .
- θ —Total sampling time, min.
- 13.6—Specific gravity of mercury.
- 60—sec/min.
- 100—Conversion to percent.

6.2 Average dry gas meter temperature and average orifice pressure drop. See data sheet (Figure 8-2).

6.3 Dry Gas Volume. Correct the sample volume measured by the dry gas meter to standard conditions (20° C and 760 mm Hg or 68° F and 29.92 in. Hg) by using Equation 8-1.

$$V_{m(Std)} = V_m Y \left(\frac{T_{std}}{T_m} \right) \frac{P_{bar} + \left(\frac{\Delta H}{13.6} \right)}{P_{std}} \\ = K_1 V_m Y \frac{P_{bar} + (\Delta H/13.6)}{T_m}$$

Equation 8-1

where:
 $K_1 = 0.3856$ °K/mm Hg for metric units.
 $= 17.64$ °R/in. Hg for English units.

Note.—If the leak rate observed during any mandatory leak-checks exceeds the specified acceptable rate, the tester shall either correct the value of V_m in Equation 8-1 (as described in Section 6.3 of Method 5), or shall invalidate the test run.

6.4 Volume of Water Vapor and Moisture Content. Calculate the volume of water vapor using Equation 5-2 of Method 5; the weight of water collected in the impingers and silica gel can be directly converted to milliliters (the specific gravity of water is 1 g/ml). Calculate the moisture content of the stack gas, using Equation 5-3 of Method 5. The "Note" in Section 6.5 of Method 5 also applies to this method. Note that if the effluent gas stream can be considered dry, the volume of water vapor and moisture content need not be calculated.

6.5 Sulfuric acid mist (including SO_3) concentration.

$$C_{H_2SO_4} = K_2 \frac{N(V_t - V_{t,bl}) \left(\frac{V_{soln}}{V_s} \right)}{V_{m(Std)}} \quad \text{Equation 8-2}$$

where:

$K_2 = 0.04904$ g/milliequivalent for metric units.
 $= 1.081 \times 10^{-4}$ lb/meq for English units.

6.6 Sulfur dioxide concentration.

$$C_{SO_2} = K_3 \frac{N(V_t - V_{t,bl}) \left(\frac{V_{soln}}{V_s} \right)}{V_{m(Std)}} \quad \text{Equation 8-3}$$

where:

$K_3 = 0.03203$ g/meq for metric units.
 $= 7.081 \times 10^{-4}$ lb/meq for English units.

6.7 Isokinetic Variation.

6.7.1 Calculation from raw data.

$$I = \frac{100 T_s [K_4 V_{li} + (V_m/T_m) P_{bar} + \Delta H/13.6]}{60 \theta V_s P_s A_n} \quad \text{Equation 8-4}$$

where:

$K_4 = 0.003464$ mm Hg·m³/ml·°K for metric units.
 $= 0.002676$ in. Hg·ft³/ml·°R for English units.

6.7.2 Calculation from intermediate values.

$$I = \frac{T_s V_m (Std) P_{std} 100}{T_{std} v_s \theta A_n P_s 60 (1 - B_{std})} \\ = K_5 \frac{T_s V_m (Std)}{P_s v_s A_n \theta (1 - B_{std})} \quad \text{Equation 8-5}$$

where:

$K_5 = 4.320$ for metric units.
 $= 0.09450$ for English units.

6.8 Acceptable Results. If 90 percent $\leq I \leq 110$ percent, the results are acceptable. If the results are low in comparison to the standards and I is beyond the acceptable range, the Administrator may opt to accept the results. Use Citation 4 in the Bibliography of Method 5 to make judgments. Otherwise, reject the results and repeat the test.

PROTECTION AGENCY

[FRL 784-7]

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

PART 61—NATIONAL EMISSION STANDARDS FOR HAZARDOUS AIR POLLUTANTS

Delegation of Authority; New Source Review; State of Montana

AGENCY: Environmental Protection Agency.

ACTION: Final rule.

SUMMARY: This rule will change the address to which reports and applications must be sent by operators of new sources in the State of Montana. The address change is the result of delegation of authority to the State of Montana for New Source Performance Standards (40 CFR Part 60) and National Emissions Standards for Hazardous Air Pollutants (40 CFR Part 61).

ADDRESS: Any questions or comments should be sent to Director, Enforcement Division, Environmental Protection Agency, 1860 Lincoln Street, Denver, Colo. 80295.

FOR FURTHER INFORMATION CONTACT:

Mr. Irwin L. Dickstein, 303-337-3868.

SUPPLEMENTARY INFORMATION: The amendments below institute certain address changes for reports and applications required from operators of new sources. EPA has delegated to the State of Montana authority to review new and modified sources. The delegated authority includes the review under 40 CFR Part 60 for the standards of performance for new stationary sources and review under 40 CFR Part 61 for national emission standards for hazardous air pollutants.

A Notice announcing the delegation of authority is published today in the *FEDERAL REGISTER* (42 FR 44573). The amendments provide that all reports, requests, applications, submittals, and communications previously required for the delegated reviews will now be sent to the Montana Department of Health and Environmental Sciences instead of EPA's Region VIII.

The Regional Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegation which is reflected by this administrative amendment was effective on May 18, 1977, and it serves no purpose to delay the technical change of this addition of the State address to the Code of Federal Regulations.

This rulemaking is effective immediately, and is issued under the authority of sections 111 and 112 of the Clean Air

RULES AND REGULATIONS

Act, as amended, 42 U.S.C. 1857, 1857c-5, 6, 7 and 1857g.

Dated: August 17, 1977.

JOHN A. GREEN,
Regional Administrator.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

1. In § 60.4 paragraph (b) is amended by revising subparagraph (BB) to read as follows:

§ 60.4 Address.

• • • • •
 (b) • • • • •

(BB) State of Montana, Department of Health and Environmental Services, Cogswell Building, Helena, Mont. 59601.

Part 61 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

2. In § 61.04 paragraph (b) is amended by revising subparagraph (BB) to read as follows:

§ 61.04 Address.

• • • • •
 (b) • • • • •

(BB) State of Montana, Department of Health and Environmental Sciences, Cogswell Building, Helena, Mont. 59601.

Applicability Dates; Correction

AGENCY: Environmental Protection Agency.

ACTION: Correction.

SUMMARY: This document corrects the final rule that appeared at page 37935 in the *FEDERAL REGISTER* of Monday, July 25, 1977 (FR Doc. 77-21230).

EFFECTIVE DATE: September 7, 1977.

FOR FURTHER INFORMATION CONTACT:

Don R. Goodwin, Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, N.C. 27711, telephone No. 919-541-5271.

Dated: August 31, 1977.

EDWARD F. TUERK,
Acting Assistant Administrator,
for Air and Waste Management.

In FR Doc. 77-21230 appearing at page 37935 in the *FEDERAL REGISTER* of Monday, July 25, 1977, the following corrections are made to §§ 60.250(b) and 60.270(b) on page 37938:

1. The applicability date in § 60.250(b) is corrected to October 24, 1974.

2. The applicability date in § 60.270(b) is corrected to October 21, 1974.

(Sec. 111, 301(a) of the Clean Air Act as amended (42 U.S.C. 1857c-6, 1857g(a)).)

CHAPTER I—ENVIRONMENTAL PROTECTION AGENCY

SUBCHAPTER C—AIR PROGRAMS

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Emission Guideline for Sulfuric Acid Mist

AGENCY: Environmental Protection Agency (EPA).

ACTION: Final rule.

SUMMARY: This action establishes emission guidelines and times for compliance for control of sulfuric acid mist emissions from existing sulfuric acid plants. Standards of performance have been issued for emissions of sulfuric acid mist, a designated pollutant, from new, modified, and reconstructed sulfuric acid plants. The Clean Air Act requires States to control emissions of designated pollutants from existing sources, and this rulemaking initiates the States' action and provides them guidelines for what will be acceptable by EPA.

DATES: State plans providing for the control of sulfuric acid mist from existing plants are due for submission to the Administrator on July 18, 1978. The Administrator has four months from the date required for submission of the plans, or until November 18, 1978, to take action to approve or disapprove the plan or portions of it.

ADDRESSES: Copies of the final guideline document are available by writing to the EPA Public Information Center (PM-215), 401 M Street SW., Washington, D.C. 20460. "Final Guidance Document: Control of Sulfuric Acid Mist Emissions From Existing Sulfuric Acid Production Units," June 1977, should be specified when requesting the document. A summary of the comments and EPA's responses may be obtained at the same address. Copies of the comment letters responding to the proposed rulemaking published in the *FEDERAL REGISTER* on November 4, 1976 (41 FR 48706) are available for public inspection and copying at the U.S. Environmental Protection Agency, Public Information Reference Unit (EPA Library), Room 2922, 401 M Street SW., Washington, D.C. 20460.

FOR FURTHER INFORMATION CONTACT:

Don R. Goodwin, Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, N.C. 27711; telephone: 919-541-5271.

SUPPLEMENTARY INFORMATION: On November 4, 1976 (41 FR 48706) EPA proposed an emission guideline for sulfuric acid mist emissions from existing sulfuric acid plants and announced the availability of a draft guideline document for public comment. A discussion of the background and comments received follows:

BACKGROUND

Section 111(d) of the Clean Air Act requires that "designated" pollutants controlled under standards of performance for new stationary sources by section 111(b) of the Act must also be controlled at existing sources in the same source category. New source standards of performance for sulfuric acid mist were promulgated December 23, 1971 (36 FR 24876). Sulfuric acid mist is considered a designated pollutant; therefore, it must be controlled under the provisions of section 111(d).

As a step toward implementing the requirements of section 111(d), Subpart B of Part 60, entitled "State Plans for the Control of Certain Pollutants From Existing Facilities," was published on November 17, 1975 (40 FR 53340).

Subpart B provides that once a standard of performance for the control of a designated pollutant from a new source category is promulgated, the Administrator will then publish a draft emission guideline and guideline document applicable to the control of the same pollutant from designated (existing) facilities. For health-related pollutants, the emission guideline will be proposed and subsequently be promulgated while emission guidelines for welfare-related pollutants will appear only in the applicable guideline document. Sulfuric acid mist is considered a health-related pollutant; therefore, the proposed emission guideline and the announcement that the draft guideline document was available for public inspection and comment appeared in the *FEDERAL REGISTER* November 4, 1976.

Subpart B also provides nine months for the States to develop and submit plans for control of the designated pollutant from the date that the notice of availability of a final guideline is published; thus, the States will have nine months from this date to develop their plans for the control of sulfuric acid mist at designated facilities within the State.

Another provision of Subpart B is that which provides the Administrator the option of either approving or disapproving the State submitted plan or portions of it within four months after the date required for submission. If the plan or a portion of it is disapproved, the Administrator is required to promulgate a new plan or a replacement of the inadequate portions of the plan. These and related provisions of Subpart B are essentially patterned after section 110 of the Act and 40 CFR Part 51 which sets forth the requirements for adoption and submission of State implementation plans under section 110 of the Act.

COMMENTS AND RESPONSES

During the 60-day comment period following the publication of the proposed emission guidelines on November 4, 1976, eleven comment letters were received; four from State pollution control agencies, five from industry and two from other government agencies. None of the comments warranted a change in the emission guideline nor did any com-

ments justify any significant changes in the guideline document.

One commenter believed that sulfuric acid mist is included within the definition of sulfur oxides as contained in the Air Quality Criteria for Sulfur Oxides; therefore, it is subject to control as a criteria pollutant under State implementation plans, section 110 of the Clean Air Act, and not as a designated pollutant under section 111(d) of the Act. EPA does not agree with this comment. Sulfuric acid mist is only one of a number of related compounds noted in the criteria document defining sulfur oxides. Sulfuric acid mist is not listed and regulated in and of itself. In addition, although some designated pollutants controlled under section 111(d) may occur in particulate as well as gaseous form and thus may be controlled to some degree under State implementation plan regulations requiring control of particulate matter, specific rather than incidental control of such pollutants is required under section 111(d).

Several commenters were concerned that the emission guideline was not based on the health and welfare effects of sulfuric acid mist or on such other factors as plant site location and the hazard of cumulative impacts where emissions from other sources interacted. Another commenter noted that since the toxicological effects of exposure to sulfuric acid mist are a function of concentration and time, a daily maximum time-weighted average concentration limitation should be considered.

These comments appear to be based on a misunderstanding of the intent and purpose of section 111(d) of the Act. In the preamble to the section 111(d) procedural regulation (40 FR 53340), it is stated that section 111(d) requires emission controls based on the general principle of the application of the best adequately demonstrated control technology, considering costs, rather than controls based directly on health or welfare effects or on other factors such as those mentioned in the comments. Section 111(b) (1) (A) of the Act requires the Administrator to list categories of sources once it is determined that they may contribute to the endangerment of public health or welfare. While this is a prerequisite for the development of standards under section 111(d), the emission guideline is technology-based rather than tied specifically to protection of health or welfare. The States, in developing regulations for the control of sulfuric acid mist, have the prerogative under 40 CFR 60.24 (f) and (g) to develop standards which may be based on health or welfare considerations or on any other relevant factors.

Some of the comments addressed the stringency of the emission guideline. One commenter considered the emission guideline inflexible to the point where its application will be too stringent in some areas and inadequate in others. Another commenter thought the guideline document indicated that facilities using elemental sulfur as feedstock can meet more rigid emission standards and that the

RULES AND REGULATIONS

emission guidelines should include more stringent standards for these facilities.

EPA has provided a great deal of flexibility in developing emission standards for the control of designated pollutants under Subpart B of Part 60. Specifically, 40 CFR 60.24(b) provides that nothing under Subpart B precludes any State from adopting or enforcing more stringent emission standards than those specified in the guideline document. On the other hand, 40 CFR Part 60.24(f) provides that States, "on a case-by-case basis for particular designated facilities, or classes of facilities . . . may provide for the application of less stringent emission standards than those otherwise required . . ." provided certain conditions are demonstrated by the State. The conditions include unreasonable cost of control resulting from plant age, location or basic process design, physical impossibility of installing necessary control equipment, and other factors specific to the facility that make the application of a less stringent standard significantly more reasonable. To include more stringent standards for facilities using elemental sulfur as feedstock would cause an unacceptable economic burden for those sources which have already installed efficient emission control equipment to meet a State regulation. To require these sources to retrofit additional emission control equipment to meet a more stringent standard would be inequitable.

MISCELLANEOUS

NOTE.—The Environmental Protection Agency has determined that this document does not contain a major proposal requiring preparation of an Economic Impact Analysis under Executive Order 11821 and 11949 and OMB Circular A-107.

Dated: September 22, 1977.

DOUGLAS M. COSTLE,
Administrator.

Part 60 of Chapter I of Title 40 of the Code of Federal Regulations is amended by adding Subpart C as follows:

Subpart C—Emission Guidelines and Compliance Times

- Sec. 60.30 Scope.
- 60.31 Definitions.
- 60.32 Designated facilities.
- 60.33 Emission guidelines.
- 60.34 Compliance times.

AUTHORITY: Sections 111(d), 301(a) of the Clean Air Act as amended (42 U.S.C. 1857c-6 and 1857g(a)), and additional authority as noted below.

Subpart C—Emission Guidelines and Compliance Times

§ 60.30 Scope.

This subpart contains emission guidelines and compliance times for the control of certain designated pollutants from certain designated facilities in accord-

ance with section 111(d) of the Act and Subpart B.

§ 60.31 Definitions.

Terms used but not defined in this subpart have the meaning given them in the Act and in Subparts A and B of this part.

§ 60.32 Designated facilities.

(a) Sulfuric acid production units. The designated facility to which §§ 60.33 (a) and 60.34(a) apply is each existing "sulfuric acid production unit" as defined in § 60.81(a) of Subpart H.

§ 60.33 Emission guidelines.

(a) Sulfuric acid production units. The emission guideline for designated facilities is 0.25 gram sulfuric acid mist (as measured by Reference Method 8, of Appendix A) per kilogram of sulfuric acid produced (0.5 lb/ton), the production being expressed as 100 percent H_2SO_4 .

§ 60.34 Compliance times.

(a) Sulfuric acid production units. Planning, awarding of contracts, and installation of equipment capable of attaining the level of the emission guideline established under § 60.33(a) can be accomplished within 17 months after the effective date of a State emission standard for sulfuric acid mist.

[FRL 793-4]

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Amendments to General Provisions and Copper Smelter Standards

AGENCY: Environmental Protection Agency (EPA).

ACTION: Final rule.

SUMMARY: This rule clarifies that excess emissions during periods of startup, shutdown, and malfunction are not considered a violation of a standard. This rule also clarifies that excess emissions for no more than 1.5 percent of the time during a quarter will not be considered indicative of a potential violation of the new source performance standard for primary copper smelters provided the affected facility and the air pollution control equipment are maintained and operated consistent with good air pollution control practice.

EFFECTIVE DATE: November 1, 1977.

FOR FURTHER INFORMATION CONTACT:

Don R. Goodwin, Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, North Carolina 27711.

SUPPLEMENTARY INFORMATION:

BACKGROUND

EPA promulgated standards of performance for primary copper, zinc and lead smelters on January 15, 1976. On March 5, 1976, Kennecott Copper Corporation filed a petition with the United States Court of Appeals for the District of Columbia Circuit requesting that EPA reconsider the standards for copper smelters. EPA proposed to make two clarifying amendments to the standards, and Kennecott agreed to withdraw its court challenge providing these amendments were made. The amendments being made are in response to the following two issues raised in the Kennecott court appeal:

(1) The standards of performance fail to provide for excessive emissions during periods of startup, shutdown, and malfunction.

(2) The standards of performance prescribe averaging times too short to accommodate the normal fluctuations in sulfur dioxide emissions inherent in smelting operations.

EXCESS EMISSIONS DURING STARTUP, SHUTDOWN AND MALFUNCTION

For all sources covered under 40 CFR Part 60, compliance with numerical emission limits must be determined through performance tests. 40 CFR 60.8(c) exempts periods of startup, shutdown, and malfunction from performance tests. By implication this means compliance with numerical emission limits cannot be determined during periods of startup, shutdown, and malfunction. EPA and Kennecott have agreed that for clarification

RULES AND REGULATIONS

MISCELLANEOUS

purposes this should be specifically stated in the regulation. Therefore, an amendment to this effect is being made in 40 CFR 60.8(c).

This exemption from compliance with numerical emission limits during startup, shutdown and malfunction, however, does not exempt the owner or operator from compliance with the requirements of 40 CFR 60.11(d) which says: "At all times, including periods of startup, shutdown, and malfunction, owners and operators shall, to the extent practicable, maintain and operate any affected facility including associated air pollution control equipment in a manner consistent with good air pollution control practice for minimizing emissions."

AVERAGING TIMES

Kennecott alleged that a six-hour averaging time is not long enough to average out periods of excessive emissions of sulfur dioxide which normally occur at smelters equipped with best control technology. According to Kennecott, the six-hour averaging period simply does not mask emission variations caused by normal fluctuations in gas strengths and volumes.

A performance test to determine compliance with the numerical emission limit included in the standard of performance consists of the arithmetic average of three consecutive six-hour emission tests. EPA's analysis of the emission data presented in the background document ("Background Information for New Source Performance Standards: Primary Copper, Zinc, and Lead Smelters," October 1974) supporting the standards of performance for copper smelters indicates that the possibility of a performance test exceeding the standard of performance under normal conditions is extremely low, less than 0.15 percent. This same analysis, however, indicates that the possibility of emissions averaged over a single six-hour period exceeding the numerical emission limit included in the standard of performance during normal operation is about 1.5 percent. To reconcile this situation with the excess emission reporting requirements, which currently require all six-hour periods in excess of the level of the sulfur dioxide standard to be reported as excess emissions, 40 CFR 60.165 is being amended to provide that if emissions exceed the level of the standard for no more than 1.5 percent of the six-hour averaging periods during a quarter, they will not be considered indicative of potential violation of 40 CFR 60.11(d); i.e., indicative of improper maintenance or operation. This exemption applies, however, only if the owner or operator maintains and operates the affected facility and air pollution control equipment in a manner consistent with good air pollution control practice for minimizing emissions during these periods. This ensures that the control equipment will be operated and emissions will be minimized during this time. Excess emissions during periods of startup, shutdown, and malfunction are not considered part of the 1.5 percent.

The Administrator finds that good cause exists for omitting prior notice and public comment on these amendments and for making them immediately effective because they simply clarify the existing regulations and impose no additional substantive requirements.

NOTE.—The EPA has determined that this document does not contain a major proposal requiring preparation of an Economic Impact Statement under Executive Orders 11821 and 11949, and OMB Circular R-107.

Dated: October 25, 1977.

DOUGLAS M. COSTLE,
Administrator.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

1. In § 60.8, paragraph (c) is amended to read as follows:

§ 60.8 Performance tests.

(c) Performance tests shall be conducted under such conditions as the Administrator shall specify to the plant operator based on representative performance of the affected facility. The owner or operator shall make available to the Administrator such records as may be necessary to determine the conditions of the performance tests. Operations during periods of startup, shutdown, and malfunction shall not constitute representative conditions for the purpose of a performance test nor shall emissions in excess of the level of the applicable emission limit during periods of startup, shutdown, and malfunction be considered a violation of the applicable emission limit unless otherwise specified in the applicable standard.

2. In § 60.165, paragraph (d)(2) is amended to read as follows:

§ 60.165 Monitoring of operations.

(d) * * *

(2) Sulfur dioxide. All six-hour periods during which the average emissions of sulfur dioxide, as measured by the continuous monitoring system installed under § 60.163, exceed the level of the standard. The Administrator will not consider emissions in excess of the level of the standard for less than or equal to 1.5 percent of the six-hour periods during the quarter as indicative of a potential violation of § 60.11(d) provided the affected facility, including air pollution control equipment, is maintained and operated in a manner consistent with good air pollution control practice for minimizing emissions during these periods. Emissions in excess of the level of the standard during periods of startup, shutdown, and malfunction are not to be included within the 1.5 percent.

(Secs. 111, 114, and 301(a) of the Clean Air Act as amended (42 U.S.C. 1857c-6, 1857c-9, 1857g(a)).)

FEDERAL REGISTER, VOL. 42, NO. 210

TUESDAY, NOVEMBER 1, 1977

RULES AND REGULATIONS

75

[FRL 781-7]

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Amendment to Subpart O: Sewage Sludge Incinerators

AGENCY: Environmental Protection Agency.

ACTION: Final rule.

SUMMARY: This rule revises the applicability of the standard of performance for sewage sludge incinerators to cover any incinerator that burns wastes containing more than 10 percent sewage sludge (dry basis) produced by municipal sewage treatment plants, or charges more than 1000 kg (2205 lb) per day municipal sewage sludge (dry basis). The State of Alaska requested that EPA revise the standard because incinerators small enough to meet the needs of small communities in Alaska and comply with the particulate matter standard are too costly, and land disposal is not feasible in areas with permafrost and high water tables. The intended effect of the revision is to exempt from the standard small incinerators for the combined disposal of municipal wastes and sewage sludge when land disposal, which is normally a cheaper and preferable alternative, is infeasible due to permafrost, high water tables, or other conditions.

DATES: This amendment is effective November 10, 1977, as required by § 111(b)(1)(B) of the Clean Air Act as amended.

FOR FURTHER INFORMATION CONTACT:

Don R. Goodwin, Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone 919-541-5271.

SUPPLEMENTARY INFORMATION: On January 26, 1977 (42 FR 4863), EPA published a proposed amendment to Subpart O of 40 CFR Part 60. An error in that proposal necessitated a correction notice that was published on February 18, 1977 (42 FR 10019). The proposed amendment exempted any sewage sludge incinerator located at a municipal waste treatment plant having a dry sludge capacity below 140 kg/hr (300 lb/hr), and where it would not be feasible to dispose of the sludge by land application or in a sanitary landfill because of freezing conditions. Prompting this amendment was a request by the State of Alaska which noted (1) the limited availability of small sludge incinerators which can meet the particulate matter standard, and (2) the difficulty of using landfills as an alternative means of sewage sludge disposal in some Alaskan communities because of perma-

frost conditions.

During the comment period on that proposal, four comment letters were received. Copies of these letters and a summary of the comments with EPA's responses are available for public inspection and copying at the EPA Public Information Reference Unit, Room 2922 (EPA Library), 401 M Street SW., Washington, D.C. In addition, copies of the comment summary and Agency responses may be obtained upon written request from the Public Information Center (PM-215), Environmental Protection Agency, 401 M Street SW., Washington, D.C. 20460 (specify Public Comment Summary: Amendment to Standards of Performance for Sewage Treatment Plants).

One commenter requested that industrial sludge incineration also be exempted by this revision. Only incinerators which burn sludge produced by municipal sewage treatment plants are covered by Subpart O. Incineration of industrial sludges are not covered because they may involve special metal, toxic and radioactive waste problems which were not addressed by the original study for developing the standard.

Three other commenters questioned the applicability of the proposed amendment. One questioned the need for the proposed exemption, arguing that small incinerators with control devices sufficient to meet the existing particulate emission standard of 0.65 g/kg dry sludge input are commercially available and should be used. Two others recommended wording to broaden the proposed exemption. They suggested that the amendment as proposed is too restrictive, considering the conditions faced by small communities in Alaska. One noted that high water-table levels severely limit land disposal of sludge in many areas. The other made a similar comment but attributed the problem to high rainfall as well.

Based upon these comments, EPA re-evaluated the need for the proposed exemption. EPA recognizes that at least one type of incinerator (the fluidized-bed type) can be constructed in size categories of less than 140 kg/hr (300 lb/hr) and with emission control equipment capable of achieving the existing standard. However, separate sludge disposal by an incinerator dedicated exclusively to sewage sludge is unduly costly for a small community. This conclusion is based on data contained in two EPA publications: A Guide to the Selection of Cost-Effective Wastewater Treatment Systems (EPA-430/9-75-002), and Municipal Sludge Management: EPA Construction Grants Program—An Overview of the Sludge Management Situation (EPA-430/9-76-009). Sludge incineration costs, especially those for operation and maintenance, were compared for sewage treatment plants of 1 and 10 million gallons per day (mgd) capacity. Costs for a 1 mgd plant (about 1000 kg of dry sludge per day) were 100 to 300 percent higher than those for a 10 mgd facility. A small, remote community which already incinerates its other municipal wastes would bear the heaviest burden if forced to incinerate its sewage sludge separately.

In most instances, neither municipal waste nor sewage sludge incinerators are constructed because land disposal is a more cost-effective alternative. The co-incineration of sewage sludge with solid waste should be a cost-effective and energy-efficient disposal alternative whenever land disposal options are not reasonably available. Since high water table levels, high annual precipitation, freezing conditions, and other factors limit or preclude the land application or sanitary landfilling of sludge, EPA has decided to broaden the exemption. Only freezing conditions were considered in the proposed exemption. However, an exemption based on these additional factors would be difficult to enforce due to climatic variability.

In order to make the exemption sufficiently broad and readily enforceable, EPA has decided to exempt incinerators that burn not more than 1000 kg per day of sewage sludge from municipal sewage treatment plants provided that the sewage sludge (dry basis) does not comprise, by weight, more than 10 percent of the total waste burned. The exemption provides relief only when sewage sludge is co-incinerated with municipal wastes, since any incinerator combusting more than 10 percent sewage sludge is affected by the emission standard regardless of the amount of sludge combusted. This approach, is based principally on the economics of sewage waste disposal and applies to any small community faced with very difficult land disposal conditions. It allows disposal of small quantities of sewage sludge in incinerators primarily combusting municipal refuse.

Currently, sludge incineration for small communities is 50 to 100 percent more costly per ton of dry sludge than land application or sanitary landfilling. Even though EPA is proposing criteria for landfill design and operation, the costs of incineration are expected to remain significantly higher. Thus, it is expected that this exemption will not cause a shift to incineration, but will only pro-

RULES AND REGULATIONS

vide relief in areas where land disposal is either infeasible or very costly.

The purpose of the amendment is to relieve small communities (<9,000 population) of the burden of constructing separate incinerators for municipal wastes and sewage sludge in areas where land disposal is not feasible. Co-incineration of sewage sludge with solid wastes is less costly than separate sludge incineration and provides an energy benefit in lower auxiliary fuel consumption. Without this amendment, any co-incineration facility would have been considered a sludge incinerator under Subpart O.

Since sludge incineration costs decline as the quantities disposed of increase, this amendment limits the exemption to co-incineration units burning not more than 1000 kg (2205 lb) dry sludge per day. At an average generation rate of 0.11 kg (0.25 lb) dry sludge per person per day, the 1000 kg limit represents a population of approximately 9,000 persons. The 10 percent sludge allowance in such co-incineration is based on the fact that an average community generates about 14 times as much solid waste per person as dry sludge. Thus the 10 percent allowance should easily permit a small community to co-incinerate all its sludge and solid waste in one facility.

This amendment does not affect the applicability of the National Emission Standard for Mercury under 40 CFR Part 61. However, significant mercury wastes are usually not found in sewage sludge from small communities, but are more commonly found in metropolitan wastes from industrial activity.

It should be noted that standards of performance for new sources established under section 111 of the Clean Air Act reflect emission limits achievable with the best adequately demonstrated systems of emission reduction considering the cost of such systems. State implementation plans (SIPs) approved or promulgated under section 110 of the Act, on the other hand, must provide for the attainment and maintenance of national ambient air quality standards (NAAQS) designed to protect public health and welfare. For that purpose SIPs must in some cases require greater emission reductions than those required by standards of performance for new sources.

States are free under section 116 of the Act to establish even more stringent emission limits than those necessary to attain or maintain the NAAQS under section 110 or those for new sources established under section 111. Thus, new sources may in some cases be subject to limitations more stringent than EPA's standards of performance under section 111, and prospective owners and operators of new sources should be aware of this possibility in planning for such facilities.

NOTE.—The Environmental Protection Agency has determined that this document does not contain a major proposal requiring preparation of an Economic Impact Analysis

under Executive Orders 11821 and 11949 and OMB Circular A-107.

Dated: November 3, 1977.

DOUGLAS M. COSTLE,
Administrator.

In 40 CFR Part 60, Subpart O is amended by revising § 60.150 and § 60.153 as follows:

§ 60.150 Applicability and designation of affected facility.

(a) The affected facility is each incinerator that combusts wastes containing more than 10 percent sewage sludge (dry basis) produced by municipal sewage treatment plants, or each incinerator that charges more than 1000 kg (2205 lb) per day municipal sewage sludge (dry basis).

(b) Any facility under paragraph (a) of this section that commences construction or modification after June 11, 1973, is subject to the requirements of this subpart.

§ 60.153 Monitoring of operations.

(a) The owner or operator of any sludge incinerator subject to the provisions of this subpart shall:

(1) Install, calibrate, maintain, and operate a flow measuring device which can be used to determine either the mass or volume of sludge charged to the incinerator. The flow measuring device shall have an accuracy of ± 5 percent over its operating range.

(2) Provide access to the sludge charged so that a well mixed representative grab sample of the sludge can be obtained.

(3) Install, calibrate, maintain, and operate a weighing device for determining the mass of any municipal solid waste charged to the incinerator when sewage sludge and municipal solid waste are incinerated together. The weighing device shall have an accuracy of ± 5 percent over its operating range.

(Sections 111, 114, 301(a) of the Clean Air Act as amended [42 U.S.C. 1857c-6, 1857c-9, 1857g(a)].)

Title 40—Protection of Environment

CHAPTER I—ENVIRONMENTAL
PROTECTION AGENCY

SUBCHAPTER C—AIR PROGRAMS

[FRL 803-8]

PART 60—STANDARDS OF PERFORMANCE
FOR NEW STATIONARY SOURCES

Opacity Provisions for Fossil-Fuel-Fired
Steam Generators

AGENCY: Environmental Protection Agency (EPA).

ACTION: Final rule.

SUMMARY: This rule revises the format of the opacity standard and establishes reporting requirements for excess emissions of opacity for fossil-fuel-fired steam generators. This action is needed to make the standard and reporting requirements conform to changes in the Reference Method for determining opacity which were promulgated on November 12, 1974, (39 FR 39872). The intended effect is to limit opacity of emissions in order to insure proper operation and maintenance of facilities subject to standards of performance.

EFFECTIVE DATE: This rule is effective on December 5, 1977.

ADDRESSES: A summary of the public comments received on the September 10, 1975 (40 FR 42028), proposed rule with EPA's responses is available for public inspection and copying at the EPA Public Information Reference Unit (EPA Library), room 2922, 401 M Street SW., Washington, D.C. 20460. In addition, copies of the comment summary may be obtained by writing to the EPA Public Information Center (PM-215), Washington, D.C. 20460 (specify: "Public Comment Summary: Steam Generator Opacity Exception (40 FR 42028)").

FOR FURTHER INFORMATION CONTACT:

Don R. Goodwin, Director, Emission Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, N.C. 27711, telephone: 919-541-5271.

SUPPLEMENTARY INFORMATION: The standards of performance for fossil-fuel-fired steam generators as promulgated under Subpart D of Part 60 in December 23, 1971, (36 FR 24876) allow emissions up to 20 percent opacity, except 40 percent is allowed for two minutes in any hour. On October 15, 1973, (38 FR 28564) a provision was added to Subpart D which required reporting as excess emissions all hourly periods during which there were three or more one-minute periods when average opacity exceeds 20 percent. Changes to the opacity provisions of Subpart A, General Provisions, and to Reference Method 9, Visual Determination of the Opacity of Emissions from Stationary Sources, were promulgated on November 12, 1974 (39

RULES AND REGULATIONS

FR 39872). Among these changes is a requirement that opacity be determined by averaging 24 readings taken at 15-second intervals. Because of this change, the Agency reassessed the opacity standard originally promulgated under Subpart D, and on September 10, 1975, proposed amendments to the opacity standard and reporting requirements. Specifically, these amendments would have deleted the permissible exemption (two minutes per hour of emissions of 40 percent opacity) for gaseous and solid fossil fuels.

The proposed amendment to the opacity provisions was based on a review of available data particularly with respect to the challenge to the opacity standards for coal-fired steam generators (*Essex Chemical Corp. et al. v. Ruckelshaus, Appalachian Power Co., et al. vs. EPA*, 486 F.2d 427, September 10, 1973). Information available at that time indicated that the two-minute exception allowed under § 60.42(a)(2) was unnecessary for large steam generators fired with solid and gaseous fossil fuels.

Interested parties were invited to submit comments. A total of 10 interested parties, including State agencies, electric utility firms, and industrial firms submitted comments. Following a review of the proposed amendments and consideration of the comments, the amendments have been revised and are being promulgated today.

While no information was submitted to show that the exception is needed for large utility steam generators equipped with conventional "cold side" electrostatic precipitators or with scrubbers or fabric filters, commenters contended that the two-minute exception is needed for industrial boilers and for all units equipped with so-called "hot side" electrostatic precipitators, (i.e., precipitators installed upstream of the air heater where temperatures are 590K to 700K). For industrial boilers in the size range of 73 to 220 MW (250 x 10⁶ to 750 x 10⁶ BTU per hour) heat input, commenters stated that the frequency of soot blowing would have to be increased significantly over present practices if the exception were deleted. More frequent soot blowing would increase costs and energy requirements considerably without any decrease in particulate emissions. Operators of "hot side" precipitators pointed out that where hot side precipitators are used, soot-blowing opacity exceptions are necessary to allow cleaning of the air heater. They noted that since the air heaters are downstream of "hot side" precipitators, any particulate which is removed by soot-blowing will be released with exhaust gases and will contribute to opacity.

EPA has concluded that for steam generators designed for compliance with the particulate matter standard of performance, there are legitimate reasons for providing a limited exception to the opacity standard, and thus, while the format of the opacity standard is revised,

the opacity exemption for coal-fired units is retained. The exception could be deleted for gaseous fossil fuel, but since opacity is not a problem from gas-fired units, there is no need to further complicate the regulation by deleting the exception for gas. The two-minute exception could be deleted for very large coal-fired units (>220 MW heat input) that are not equipped with hot side precipitators, but again the deletion would have little effect and would needlessly complicate the regulation.

Section 60.42(a)(2) is amended by expressing the two-minute 40 percent opacity exception in terms of a six-minute 27 percent average opacity (a weighted average of two minutes at 40 percent opacity and four minutes at 20 percent opacity) for consistency with Reference Method 9. This change does not alter the stringency of the standard. In addition, § 60.45(g)(1) which was reserved on October 6, 1975, (40 FR 46250) pending resolution of the opacity exception, is added to require reporting as excess emissions any six-minute period during which the average opacity of emissions exceeds 20 percent opacity, except for the one permissible six-minute period per hour of up to 27 percent opacity.

NOTE.—The Environmental Protection Agency has determined that this document does not contain a major proposal requiring preparation of an Economic Impact Analysis under Executive Orders 11821 and 11949 and OMB Circular A-107.

Dated: November 23, 1977.

DOUGLAS M. COSTLE,
Administrator.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

1. Section 60.42(a)(2) is revised as follows:

§ 60.42 Standard for particulate matter.

(a) * * *

(2) Exhibit greater than 20 percent opacity except for one six-minute period per hour of not more than 27 percent opacity.

(Sec. 111, 301(a), Clean Air Act as amended (42 U.S.C. 7411, 7601).)

2. Section 60.45(g)(1) is added as follows:

§ 60.45 Emission and fuel monitoring.

(g) * * *

(1) **Opacity.** Excess emissions are defined as any six-minute period during which the average opacity of emissions exceeds 20 percent opacity, except that one six-minute average per hour of up to 27 percent opacity need not be reported.

(Sec. 111, 114, 301(a), Clean Air Act as amended (42 U.S.C. 7411, 7414, 7601).)

RULES AND REGULATIONS

77

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Delegation of Authority to the
Commonwealth of Puerto Rico

AGENCY: Environmental Protection Agency.

ACTION: Final rule.

SUMMARY: A notice announcing EPA's delegation of authority for the New Source Performance Standards to the Commonwealth of Puerto Rico is published at page 62196 of today's **FEDERAL REGISTER**. In order to reflect this delegation, this document amends EPA regulations to require the submission of all notices, reports, and other communications called for by the delegated regulations to the Commonwealth of Puerto Rico as well as to EPA.

EFFECTIVE DATE: December 9, 1977.

FOR FURTHER INFORMATION CONTACT:

J. Kevin Healy, Attorney, U.S. Environmental Protection Agency, Region II, General Enforcement Branch, Enforcement Division, 26 Federal Plaza, New York, N.Y. 10007, 212-264-1196.

SUPPLEMENTARY INFORMATION: By letter dated January 13, 1977 EPA delegated authority to the Commonwealth of Puerto Rico to implement and enforce the New Source Performance Standards. The Commonwealth accepted this delegation by letter dated October 17, 1977. A full account of the background to this action and of the exact terms of the delegation appears in the Notice of Delegation which is also published in today's **FEDERAL REGISTER**.

This rulemaking is effective immediately, since the Administrator has found good cause to forgo prior public notice. This addition of the Commonwealth of Puerto Rico address to the Code of Federal Regulations is a technical change and imposes no additional substantive burden on the parties affected.

Dated: November 22, 1977.

ECKARDT C. BECK,
Regional Administrator.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

(1) In § 60.4 paragraph (b) is amended by revising subparagraph (BBB) to read as follows:

§ 60.4 Address.

(b) * * *

(AAA) * * *

(BBB)—Commonwealth of Puerto Rico: Commonwealth of Puerto Rico Environmental Quality Board, P.O. Box 11785, Santurce, P.R. 00910.

[FR Doc. 77-35162 Filed 12-8-77; 8:45 am]

FEDERAL REGISTER, VOL. 42, NO. 237

FRIDAY, DECEMBER 9, 1977

Title 40—Protection of Environment

CHAPTER I—ENVIRONMENTAL PROTECTION AGENCY

[FRL 838-3]

AIR POLLUTION

Delegation of Authority to the State of Minnesota for Prevention of Significant Deterioration; Inspections, Monitoring and Entry; Standards of Performance for New Stationary Sources; and National Emission Standards for Hazardous Air Pollutants

AGENCY: Environmental Protection Agency.

ACTION: Final rule.

SUMMARY: The amendment below institutes an address change for the implementation of technical and administrative review and enforcement of Prevention of Significant Deterioration provisions; Inspections, Monitoring and Entry provisions; Standards of Performance for New Stationary Sources; and National Emission Standards for Hazardous Air Pollutants. The notice announcing the delegation of authority is published elsewhere in this issue of the **FEDERAL REGISTER**.

EFFECTIVE DATE: October 6, 1977.

ADDRESSES: This amendment provides that all reports, requests, applications, and communications required for the delegated authority will no longer be sent to the U.S. Environmental Protection Agency, Region V Office, but will be sent instead to: Minnesota Pollution Control Agency, Division of Air Quality, 1935 West County Road B-2, Roseville, Minn. 55113.

FOR FURTHER INFORMATION, CONTACT:

Joel Morbito, Air Programs Branch, U.S. Environmental Protection Agency, Region V, 230 South Dearborn St., Chicago, Ill. 60604, 312-353-2205.

SUPPLEMENTARY INFORMATION: The Regional Administrator finds good cause for forgoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegations which are granted by this administrative amendment were effective October 6, 1977, and it serves no purpose to delay the technical change of this addition of the State address to the Code of Federal Regulations. This rulemaking is effective immediately and is issued under authority of sections 101, 110, 111, 112, 114, 160-169 of the Clean Air Act, as amended (42 U.S.C. 7401, 7410, 7411, 7412, 7414, 7470-79,

7491). Accordingly, 40 CFR Parts 52, 60 and 61 are amended as follows:

PART 52—APPROVAL AND PROMULGATION OF IMPLEMENTATION PLANS

Subpart Y—Minnesota

1. Section 52.1224 is amended by adding a new paragraph (b) (5) as follows:

§ 52.1224 General requirements.

(b) * * *

(5) Authority of the Regional Administrator to make available information and data was delegated to the Minnesota Pollution Control Agency effective October 6, 1977.

2. Section 52.1234 is amended by adding a new paragraph (c) as follows:

§ 52.1234 Significant deterioration of air quality.

(c) All applications and other information required pursuant to § 52.21 from sources located in the State of Minnesota shall be submitted to the Minnesota Pollution Control Agency, Division of Air Quality, 1935 West County Road B-2, Roseville, Minn. 55113.

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Subpart A—General Provisions

1. Section 60.4 is amended by adding a new paragraph (b) (Y) as follows:

§ 60.4 Address.

(b) * * *

(Y) Minnesota Pollution Control Agency, Division of Air Quality, 1935 West County Road B-2, Roseville, Minn. 55113.

FEDERAL REGISTER, VOL. 42, NO. 1

TUESDAY, JANUARY 3, 1978

**PART 60—STANDARDS OF PERFORMANCE
FOR NEW STATIONARY SOURCES**

Revision of Reference Method 11

AGENCY: Environmental Protection Agency (EPA).

ACTION: Final rule.

SUMMARY: This action revises reference method 11, the method for determining the hydrogen sulfide content of fuel gas streams. The revision is made because EPA found that interferences resulting from the presence of mercaptans in some refinery fuel gases can lead to erroneous test data when the current method is used. This revision eliminates the problem of mercaptan interference and insures the accuracy of the test data.

EFFECTIVE DATE: January 10, 1978.

ADDRESSES: Copies of the comment letters responding to the proposed revision published in the *FEDERAL REGISTER* on May 23, 1977 (42 FR 26222), and a summary of the comments with EPA's responses are available for public inspection and copying at the U.S. Environmental Protection Agency, Public Information Reference Unit (EPA Library), Room 2922, 401 M Street SW., Washington, D.C. 20460. A copy of the summary of comments and EPA's responses may be obtained by writing the Emission Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, N.C. 27711. When requesting this document, "Comments and Responses Summary: Revision of Reference Method 11," should be specified.

FOR FURTHER INFORMATION CONTACT:

Don R. Goodwin, Director, Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, N.C. 27711, telephone 919-541-5271.

SUPPLEMENTARY INFORMATION: On March 8, 1974, the Environmental Protection Agency promulgated standards of performance limiting emissions of sulfur dioxide from new, modified, and reconstructed fuel gas combustion devices at petroleum refineries. At the same time, reference method 11 was promulgated as the performance test method for measuring H₂S in the fuel gases. It was found after the promulgation of method 11 that interference resulting from the presence of mercaptans in some refinery fuel gases can lead to erroneous test results in those cases where mercaptans were present in significant concentrations.

Following studies of the problems related to reference method 11, it was decided to revise the method and the revision was proposed in the *FEDERAL REGISTER* on May 23, 1977. The major change in the proposed revision from the original promulgation was a substitution of a new absorbing solution that is essentially free from mercaptan interference. New sections were also added which described the range and sensitivity, interferences, and precision and accuracy of the revision.

There were seven comments received concerning the proposed revision. Five were received from industry, one from a local environmental control agency and one from a research laboratory. None of the comments warranted any significant changes of the proposed revision. The final revision differs from the revision proposed on May 23, 1977, in only one respect: Phenylarsine oxide standard solution has been included as an acceptable titrant in lieu of sodium thiosulfate.

The effective date of this regulation is January 10, 1978, because section 111(b)(1)(B) of the Clean Air Act provides that standards of performance or revisions of them become effective upon promulgation.

NOTE.—The Environmental Protection Agency has determined that this document does not contain a major proposal requiring preparation of an economic impact analysis under Executive Orders 11821 and 11949 and OMB Circular A-107.

Dated: December 29, 1977.

DOUGLAS M. COSTLE,
Administrator.

Part 60 of Chapter I of Title 40 of the Code of Federal Regulations is amended by revising Method 11 of Appendix A—Reference Methods as follows:

APPENDIX A.—REFERENCE METHODS

METHOD 11—DETERMINATION OF HYDROGEN SULFIDE CONTENT OF FUEL GAS STREAMS IN PETROLEUM REFINERIES

1. Principle and applicability. 1.1 *Principle.* Hydrogen sulfide (H₂S) is collected from a source in a series of midjet impingers and absorbed in pH 3.0 cadmium sulfate (CdSO₄) solution to form cadmium sulfide (CdS). The latter compound is then measured iodometrically. An impinger containing hydrogen peroxide is included to remove SO₂ as an interfering species. This method is a revision of the H₂S method originally published in the *FEDERAL REGISTER*, Volume 39, No. 47, dated Friday, March 8, 1974.

1.2 *Applicability.* This method is applicable for the determination of the hydrogen sulfide content of fuel gas streams at petroleum refineries.

2. *Range and sensitivity.* The lower limit of detection is approximately 8 mg/m³ (6 ppm). The maximum of the range is 740 mg/m³ (520 ppm).

3. *Interferences.* Any compound that reduces iodine or oxidizes iodide ion will interfere in this procedure, provide it is collected in the cadmium sulfate impingers. Sulfur dioxide in concentrations of up to 2,600 mg/m³ is eliminated by the hydrogen peroxide solution. Thiols precipitate with hydrogen sulfide. In the absence of H₂S, only co-traces of thiols are collected. When methane- and ethane-thiols at a total level of 300 mg/m³ are present in addition to H₂S, the results vary from 2 percent low at an H₂S concentration of 400 mg/m³ to 14 percent high at an H₂S concentration of 100 mg/m³. Carbon oxysulfide at a concentration of 20 percent does not interfere. Certain carbonyl-containing compounds react with iodine and produce recurring end points. However, acetaldehyde and acetone at concentrations of 1 and 3 percent, respectively, do not interfere.

Entrained hydrogen peroxide produces a negative interference equivalent to 100 percent of that of an equimolar quantity of hydrogen sulfide. Avoid the ejection of hydrogen peroxide into the cadmium sulfate impingers.

4. *Precision and accuracy.* Collaborative testing has shown the within-laboratory coefficient of variation to be 2.2 percent and the overall coefficient of variation to be 5 percent. The method bias was shown to be -4.8 percent when only H₂S was present. In the presence of the interferences cited in section 3, the bias was positive at low H₂S concentrations and negative at higher concentrations. At 230 mg H₂S/m³, the level of the compliance standard, the bias was +2.7 percent. Thiols had no effect on the precision.

5. Apparatus.

5.1 Sampling apparatus.

5.1.1 *Sampling line.* Six to 7 mm (¼ in.) Teflon¹ tubing to connect the sampling train to the sampling valve.

5.1.2 *Impingers.* Five midjet impingers, each with 30 ml capacity. The internal diameter of the impinger tip must be 1 mm ±0.05 mm. The impinger tip must be positioned 4 to 6 mm from the bottom of the impinger.

5.1.3 *Glass or Teflon connecting tubing for the impingers.*

5.1.4 *Ice bath container.* To maintain absorbing solution at a low temperature.

5.1.5 *Drying tube.* Tube packed with 6- to 16-mesh indicating-type silica gel, or equivalent, to dry the gas sample and protect the meter and pump. If the silica gel has been used previously, dry at 175° C (350° F) for 2 hours. New silica gel may be used as received. Alternatively, other types of desiccants (equivalent or better) may be used, subject to approval of the Administrator.

NOTE.—Do not use more than 30 g of silica gel. Silica gel absorbs gases such as propane from the fuel gas stream, and use of excessive amounts of silica gel could result in errors in the determination of sample volume.

5.1.6 *Sampling valve.* Needle valve or equivalent to adjust gas flow rate. Stainless steel or other corrosion-resistant material.

5.1.7 *Volume meter.* Dry gas meter, sufficiently accurate to measure the sample volume within 2 percent, calibrated at the selected flow rate (~1.0 liter/min) and conditions actually encountered during sampling. The meter shall be equipped with a temperature gauge (dial thermometer or equivalent) capable of measuring temperature to within 3° C (5.4° F). The gas meter should have a petcock, or equivalent, on the outlet connector which can be closed during the leak check. Gas volume for one revolution of the meter must not be more than 10 liters.

¹ Mention of trade names of specific products does not constitute endorsement by the Environmental Protection Agency.

RULES AND REGULATIONS

8.1.8 Flow meter. Rotameter or equivalent, to measure flow rates in the range from 0.5 to 2 liters/min (1 to 4 cfh).

8.1.9 Graduated cylinder, 25 ml size.

8.1.10 Barometer. Mercury, aneroid, or other barometer capable of measuring atmospheric pressure to within 2.5 mm Hg (0.1 in. Hg). In many cases, the barometric reading may be obtained from a nearby National Weather Service station, in which case, the station value (which is the absolute barometric pressure) shall be requested and an adjustment for elevation differences between the weather station and the sampling point shall be applied at a rate of minus 2.5 mm Hg (0.1 in. Hg) per 30 m (100 ft) elevation increase or vice-versa for elevation decrease.

8.1.11 U-tube manometer, 0-30 cm water column. For leak check procedure.

8.1.12 Rubber squeeze bulb. To pressurize train for leak check.

8.1.13 Tee, pinchclamp, and connecting tubing. For leak check.

8.1.14 Pump. Diaphragm pump, or equivalent. Insert a small surge tank between the pump and rate meter to eliminate the pulsation effect of the diaphragm pump on the rotameter. The pump is used for the air purge at the end of the sample run; the pump is not ordinarily used during sampling, because fuel gas streams are usually sufficiently pressurized to force sample gas through the train at the required flow rate. The pump need not be leak-free unless it is used for sampling.

8.1.15 Needle valve or critical orifice. To set air purge flow to 1 liter/min.

8.1.16 Tube packed with active carbon. To filter air during purge.

8.1.17 Volumetric flask. One 1,000 ml.

8.1.18 Volumetric pipette. One 15 ml.

8.1.19 Pressure-reduction regulator. Depending on the sampling stream pressure, a pressure-reduction regulator may be needed to reduce the pressure of the gas stream entering the Teflon sample line to a safe level.

8.1.20 Cold trap. If condensed water or amine is present in the sample stream, a corrosion-resistant cold trap shall be used immediately after the sample tap. The trap shall not be operated below 0° C (32° F) to avoid condensation of C₁ or C₂ hydrocarbons.

8.2 Sample recovery.

8.2.1 Sample container. Iodine flask, glass-stoppered; 500 ml size.

8.2.2 Pipette. 50 ml volumetric type.

8.2.3 Graduated cylinders. One each 25 and 250 ml.

8.2.4 Flasks. 125 ml, Erlenmeyer.

8.2.5 Wash bottle.

8.2.6 Volumetric flasks. Three 1,000 ml.

8.3 Analysis.

8.3.1 Flask. 500 ml glass-stoppered iodine flask.

8.3.2 Burette. 50 ml.

8.3.3 Flask. 125 ml, Erlenmeyer.

8.3.4 Pipettes, volumetric. One 25 ml; two each 50 and 100 ml.

8.3.5 Volumetric flasks. One 1,000 ml; two 500 ml.

8.3.6 Graduated cylinders. One each 10 and 100 ml.

8. Reagents. Unless otherwise indicated, it is intended that all reagents conform to the specifications established by the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Otherwise, use best available grade.

8.1 Sampling.

8.1.1 Cadmium sulfate absorbing solution. Dissolve 41 g of 3CdSO₄·8H₂O and 15 ml of 0.1 M sulfuric acid in a 1-liter volumetric flask that contains approximately ¾ liter of deionized distilled water. Dilute to volume with deionized water. Mix thoroughly. pH should be 3±0.1. Add 10 drops of Dow-Corning Antifoam B. Shake well before use. If Antifoam B is not used, the alternate acidified iodine extraction procedure (section 7.2.2) must be used.

8.1.2 Hydrogen peroxide, 3 percent. Dilute 30 percent hydrogen peroxide to 3 percent as needed. Prepare fresh daily.

8.1.3 Water. Deionized, distilled to conform to ASTM specifications D1193-72, Type 3. At the option of the analyst, the KMnO₄ test for oxidizable organic matter may be omitted when high concentrations of organic matter are not expected to be present.

8.2 Sample recovery.

8.2.1 Hydrochloric acid solution (HCl), 3M. Add 240 ml of concentrated HCl (specific gravity 1.19) to 500 ml of deionized, distilled water in a 1-liter volumetric flask. Dilute to 1 liter with deionized water. Mix thoroughly.

8.2.2 Iodine solution 0.1 N. Dissolve 24 g of potassium iodide (KI) in 30 ml of deionized, distilled water. Add 12.7 g of resublimed iodine (I₂) to the potassium iodide solution. Shake the mixture until the iodine is completely dissolved. If possible, let the solution stand overnight in the dark. Slowly dilute the solution to 1 liter with deionized, distilled water, with swirling. Filter the solution if it is cloudy. Store solution in a brown-glass reagent bottle.

8.2.3 Standard iodine solution, 0.01 N. Pipette 100.0 ml of the 0.1 N iodine solution into a 1-liter volumetric flask and dilute to volume with deionized, distilled water. Standardize daily as in section 8.1.1. This solution must be protected from light. Reagent bottles and flasks must be kept tightly stoppered.

8.3 Analysis.

8.3.1 Sodium thiosulfate solution, standard 0.1 N. Dissolve 24.8 g of sodium thiosulfate pentahydrate (Na₂S₂O₅·5H₂O) or 15.8 g of anhydrous sodium thiosulfate (Na₂S₂O₃) in 1 liter of deionized, distilled water and add 0.01 g of anhydrous sodium carbonate (Na₂CO₃) and 0.4 ml of chloroform (CHCl₃) to stabilize. Mix thoroughly by shaking or by aerating with nitrogen for approximately 15 minutes and store in a glass-stoppered, reagent bottle. Standardize as in section 8.1.2.

8.3.2 Sodium thiosulfate solution, standard 0.01 N. Pipette 50.0 ml of the standard 0.1 N thiosulfate solution into a volumetric flask and dilute to 500 ml with distilled water.

Note.—A 0.01 N phenylarsine oxide solution may be prepared instead of 0.01 N thiosulfate (see section 6.3.3).

8.3.3 Phenylarsine oxide solution, standard 0.01 N. Dissolve 1.80 g of phenylarsine oxide (C₆H₅AsD) in 150 ml of 0.3 N sodium hydroxide. After settling, decant 140 ml of this solution into 800 ml of distilled water. Bring the solution to pH 6-7 with 6N hydrochloric acid and dilute to 1 liter. Standardize as in section 8.1.3.

8.3.4 Starch indicator solution. Suspend 10 g of soluble starch in 100 ml of deionized, distilled water and add 15 g of potassium hydroxide (KOH) pellets. Stir until dissolved, dilute with 900 ml of deionized distilled water and let stand for 1 hour. Neutralize the alkali with concentrated hydrochloric acid, using an indicator paper similar to Alkacid test ribbon, then add 2 ml of glacial acetic acid as a preservative.

Note.—Test starch indicator solution for decomposition by titrating, with 0.01 N iodine solution, 4 ml of starch solution in 200 ml of distilled water that contains 1 g potassium iodide. If more than 4 drops of the 0.01 N iodine solution are required to obtain the blue color, a fresh solution must be prepared.

7. Procedure.

7.1 Sampling.

7.1.1 Assemble the sampling train as shown in figure 11-1, connecting the five midjet impingers in series. Place 15 ml of 3 percent hydrogen peroxide solution in the first impinger. Leave the second impinger empty. Place 15 ml of the cadmium sulfate absorbing solution in the third, fourth, and fifth impingers. Place the impinger assembly in an ice bath container and place crushed ice around the impingers. Add more ice during the run, if needed.

7.1.2 Connect the rubber bulb and manometer to first impinger, as shown in figure 11-1. Close the petcock on the dry gas meter outlet. Pressurize the train to 25-cm water pressure with the bulb and close off tubing connected to rubber bulb. The train must hold a 25-cm water pressure with not more than a 1-cm drop in pressure in a 1-minute interval. Stopcock grease is acceptable for sealing ground glass joints.

Note.—This leak check procedure is optional at the beginning of the sample run, but is mandatory at the conclusion. Note also that if the pump is used for sampling, it is recommended (but not required) that the pump be leak-checked separately, using a method consistent with the leak-check procedure for diaphragm pumps outlined in section 4.1.2 of reference method 6, 40 CFR Part 60, Appendix A.

7.1.3 Purge the connecting line between the sampling valve and first impinger, by disconnecting the line from the first impinger, opening the sampling valve, and allowing process gas to flow through the line for a minute or two. Then, close the sampling valve and reconnect the line to the impinger train. Open the petcock on the dry gas meter outlet. Record the initial dry gas meter reading.

7.1.4 Open the sampling valve and then adjust the valve to obtain a rate of approximately 1 liter/min. Maintain a constant (±10 percent) flow rate during the test. Record the meter temperature.

7.1.5 Sample for at least 10 min. At the end of the sampling time, close the sampling valve and record the final volume and temperature readings. Conduct a leak check as described in Section 7.1.2 above.

7.1.6 Disconnect the impinger train from the sampling line. Connect the charcoal tube and the pump, as shown in figure 11-1. Purge the train (at a rate of 1 liter/min) with clean ambient air for 15 minutes to ensure that all H₂S is removed from the hydrogen peroxide. For sample recovery, cap the open ends and remove the impinger train to a clean area that is away from sources of heat. The area should be well lighted, but not exposed to direct sunlight.

7.2 Sample recovery.

7.2.1 Discard the contents of the hydrogen peroxide impinger. Carefully rinse the contents of the third, fourth, and fifth impingers into a 500 ml iodine flask.

RULES AND REGULATIONS

Figure 11-1. H₂S sampling train.

NOTE.—The impingers normally have only a thin film of cadmium sulfide remaining after a water rinse. If Antifoam B was not used or if significant quantities of yellow cadmium sulfide remain in the impingers, the alternate recovery procedure described below must be used.

7.2.2 Pipette exactly 50 ml of 0.01 N iodine solution into a 125 ml Erlenmeyer flask. Add 10 ml of 3 M HCl to the solution. Quantitatively rinse the acidified iodine into the iodine flask. Stopper the flask immediately and shake briefly.

7.2.2 (Alternate). Extract the remaining cadmium sulfide from the third, fourth, and fifth impingers using the acidified iodine solution. Immediately after pouring the acidified iodine into an impinger, stopper it and shake for a few moments, then transfer the liquid to the iodine flask. Do not transfer any rinse portion from one impinger to another; transfer it directly to the iodine flask. Once the acidified iodine solution has been poured into any glassware containing cadmium sulfide, the container must be tightly stoppered at all times except when adding more solution, and this must be done as quickly and carefully as possible. After adding any acidified iodine solution to the iodine flask, allow a few minutes for absorption of the H₂S before adding any further rinses. Repeat the iodine extraction until all cadmium sulfide is removed from the impingers. Extract that part of the connecting glassware that contains visible cadmium sulfide.

Quantitatively rinse all of the iodine from the impingers, connectors, and the beaker into the iodine flask using deionized, distilled water. Stopper the flask and shake briefly.

7.2.3 Allow the iodine flask to stand about 30 minutes in the dark for absorption of the H₂S into the iodine, then complete the titration analysis as in section 7.3.

NOTE.—Caution! Iodine evaporates from acidified iodine solutions. Samples to which acidified iodine have been added may not be stored, but must be analyzed in the time schedule stated in section 7.2.3.

7.2.4 Prepare a blank by adding 45 ml of cadmium sulfate absorbing solution to an iodine flask. Pipette exactly 50 ml of 0.01 N iodine solution into a 125-ml Erlenmeyer flask. Add 10 ml of 3 M HCl. Follow the same impinger extracting and quantitative rinsing procedure carried out in sample analysis. Stopper the flask, shake briefly, let stand 30 minutes in the dark, and titrate with the samples.

NOTE.—The blank must be handled by exactly the same procedure as that used for the samples.

7.3 Analysis.

NOTE.—Titration analyses should be conducted at the sample-cleanup area in order to prevent loss of iodine from the sample. Titration should never be made in direct sunlight.

7.3.1 Using 0.01 N sodium thiosulfate solution (or 0.01 N phenylarsine oxide, if applicable), rapidly titrate each sample in an iodine flask using gentle mixing, until solution is light yellow. Add 4 ml of starch indicator solution and continue titrating slowly until the blue color just disappears. Record V_T , the volume of sodium thiosulfate solution used, or V_{As} , the volume of phenylarsine oxide solution used (ml).

7.3.2 Titrate the blanks in the same manner as the samples. Run blanks each day until replicate values agree within 0.05 ml. Average the replicate titration values which agree within 0.05 ml.

8. Calibration and standards.

8.1 Standardizations.

8.1.1 Standardize the 0.01 N iodine solution daily as follows: Pipette 25 ml of the iodine solution into a 125 ml Erlenmeyer flask. Add 2 ml of 3 M HCl. Titrate rapidly with standard 0.01 N thiosulfate solution or with 0.01 N phenylarsine oxide until the solution is light yellow, using gentle mixing. Add four drops of starch indicator solution and continue titrating slowly until the blue color just disappears. Record V_T , the volume of thiosulfate solution used, or V_{As} , the volume of phenylarsine oxide solution used (ml). Repeat until replicate values agree within 0.05 ml. Average the replicate titration values which agree within 0.05 ml and calculate the exact normality of the iodine solution using equation 9.3. Repeat the standardization daily.

8.1.2 Standardize the 0.1 N thiosulfate solution as follows: Oven-dry potassium dichromate ($K_2Cr_2O_7$) at 180 to 200° C (360 to 390° F). Weigh to the nearest milligram, 2 g of potassium dichromate. Transfer the dichromate to a 500 ml volumetric flask, dissolve in deionized, distilled water and dilute to exactly 500 ml. In a 500 ml iodine flask, dissolve approximately 3 g of potassium iodide (KI) in 45 ml of deionized, distilled water, then add 10 ml of 3 M hydrochloric acid solution. Pipette 50 ml of the dichromate solution into this mixture. Gently swirl the solution once and allow it to stand in the dark for 5 minutes. Dilute the solution with 100 to 200 ml of deionized distilled water, washing down the sides of the flask with part of the water. Titrate with 0.1 N thiosulfate until the solution is light yellow. Add 4 ml of starch indicator and continue titrating slowly to a green end point. Record V_s , the volume of thiosulfate solution used (ml). Repeat until replicate analyses agree within 0.05 ml. Calculate the normality using equation 9.1. Repeat the standardization each week, or after each test series, whichever time is shorter.

8.1.3 Standardize the 0.01 N Phenylarsine oxide (if applicable) as follows: oven dry potassium dichromate ($K_2Cr_2O_7$) at 180 to 200° C (360 to 390° F). Weigh to the nearest milligram, 2 g of the $K_2Cr_2O_7$; transfer the dichromate to a 500 ml volumetric flask, dissolve in deionized, distilled water, and dilute to exactly 500 ml. In a 500 ml iodine flask, dissolve approximately 0.3 g of potassium iodide (KI) in 45 ml of deionized, distilled water, add 10 ml of 3 M hydrochloric acid. Pipette 5 ml of the $K_2Cr_2O_7$ solution into the iodine flask. Gently swirl the contents of the flask once and allow to stand in the dark for 5 minutes. Dilute the solution with 100 to 200 ml of deionized, distilled water, washing down the sides of the flask with part of the water. Titrate with 0.01 N phenylarsine oxide until the solution is light yellow. Add 4 ml of starch indicator and continue titrating slowly to a green end point. Record V_{As} , the volume of phenylarsine oxide used (ml). Repeat until replicate analyses agree within 0.05 ml. Calculate the normality using equation 9.2. Repeat the standardization each week or after each test series, whichever time is shorter.

RULES AND REGULATIONS

8.2 Sampling train calibration. Calibrate the sampling train components as follows:

8.2.1 Dry gas meter:

8.2.1.1 Initial calibration. The dry gas meter shall be calibrated before its initial use in the field. Proceed as follows: First, assemble the following components in series: Drying tube, needle valve, pump, rotameter, and dry gas meter. Then, leak-check the system as follows: Place a vacuum gauge (at least 760 mm Hg) at the inlet to the drying tube and pull a vacuum of 250 mm (10 in.) Hg; plug or pinch off the outlet of the flow meter, and then turn off the pump. The vacuum shall remain stable for at least 30 seconds. Carefully release the vacuum gauge before releasing the flow meter end.

Next, calibrate the dry gas meter (at the sampling flow rate specified by the method) as follows: Connect an appropriately sized wet test meter (e.g., 1 liter per revolution) to the inlet of the drying tube. Make three independent calibration runs, using at least five revolutions of the dry gas meter per run. Calculate the calibration factor, Y (wet test meter calibration volume divided by the dry gas meter volume, both volumes adjusted to the same reference temperature and pressure), for each run, and average the results. If any Y value deviates by more than 2 percent from the average, the dry gas meter is unacceptable for use. Otherwise, use the average as the calibration factor for subsequent test runs.

8.2.1.2 Post-test calibration check. After each field test series, conduct a calibration check as in section 8.2.1.1. above, except for the following variations: (a) The leak check is not to be conducted, (b) three or more revolutions of the dry gas meter may be used, and (3) only two independent runs need be made. If the calibration factor does not deviate by more than 5 percent from the initial calibration factor (determined in section 8.2.1.1.), then the dry gas meter volumes obtained during the test series are acceptable. If the calibration factor deviates by more than 5 percent, recalibrate the dry gas meter as in section 8.2.1.1., and for the calculations, use the calibration factor (initial or recalibration) that yields the lower gas volume for each test run.

8.2.2 Thermometers. Calibrate against mercury-in-glass thermometers.

8.2.3 Rotameter. The rotameter need not be calibrated, but should be cleaned and maintained according to the manufacturer's instruction.

8.2.4 Barometer. Calibrate against a mercury barometer.

9. Calculations. Carry out calculations retaining at least one extra decimal figure beyond that of the acquired data. Round off results only after the final calculation.

9.1 Normality of the Standard (~0.1 N) Thiosulfate Solution.

$$N_s = 2.039 W/V_s$$

where:

W = Weight of $K_2Cr_2O_7$ used, g.

V_s = Volume of $Na_2S_2O_3$ solution used, ml.

N_s = Normality of standard thiosulfate solution, g-eq/liter.

2.039 = Conversion factor

(6 eq. I_2 /mole $K_2Cr_2O_7$) (1,000 ml/liter)/= (294.2 g $K_2Cr_2O_7$ /mole) (10 aliquot factor)

9.2 Normality of Standard Phenylarsine Oxide Solution (if applicable).

$$N_A = 0.2039 W/V_A$$

where:

W = Weight of $K_2Cr_2O_7$ used, g.

V_A = Volume of C_6H_5AsO used, ml.

N_A = Normality of standard phenylarsine oxide solution, g-eq/liter.

0.2039 = Conversion factor

(6 eq. I_2 /mole $K_2Cr_2O_7$) (1,000 ml/liter)/ (294.2 g $K_2Cr_2O_7$ /mole) (10 aliquot factor)

9.3 Normality of Standard Iodine Solution.

$$N_I = N_T V_T / V_I$$

where:

N_I = Normality of standard iodine solution, g-eq/liter.

V_I = Volume of standard iodine solution used, ml.

N_T = Normality of standard (~0.01 N) thiosulfate solution; assumed to be 0.1 N_s , g-eq/liter.

V_T = Volume of thiosulfate solution used, ml.

NOTE.—If phenylarsine oxide is used instead of thiosulfate, replace N_T and V_T in Equation 9.3 with N_A and V_A , respectively (see sections 8.1.1 and 8.1.3).

9.4 Dry Gas Volume. Correct the sample volume measured by the dry gas meter to standard conditions (20° C) and 760 mm Hg.

$$V_{m(std)} = V_m Y [(T_{std}/T_m) (P_{bar}/P_{std})]$$

where:

$V_{m(std)}$ = Volume at standard conditions of gas sample through the dry gas meter, standard liters.

V_m = Volume of gas sample through the dry gas meter (meter conditions), liters.

T_{std} = Absolute temperature at standard conditions, 293° K.

T_m = Average dry gas meter temperature, °K.

P_{bar} = Barometric pressure at the sampling site, mm Hg.

P_{std} = Absolute pressure at standard conditions, 760 mm Hg.

Y = Dry gas meter calibration factor.

9.5 Concentration of H_2S . Calculate the concentration of H_2S in the gas stream at standard conditions using the following equation:

$$C_{H_2S} = K[(V_{IT}N_I - V_{IT}N_T) \text{ sample} - (V_{IT}N_I - V_{IT}N_T) \text{ blank}] / V_{m(std)}$$

where (metric units):

C_{H_2S} = Concentration of H_2S at standard conditions, mg/dscm.

K = Conversion factor = 17.04×10^3

(34.07 g/mole H_2S) (1,000 liters/m³) (1,000 mg/g)/=(1,000 ml/liter) (2 H_2S eq/mole)

V_{IT} = Volume of standard iodine solution = 50.0 ml.

N_I = Normality of standard iodine solution, g-eq/liter.

V_{IT} = Volume of standard (~0.01 N) sodium thiosulfate solution, ml.

N_T = Normality of standard sodium thiosulfate solution, g-eq/liter.

$V_{m(std)}$ = Dry gas volume at standard conditions, liters.

NOTE.—If phenylarsine oxide is used instead of thiosulfate, replace N_T and V_{IT} in Equation 9.5 with N_A and V_{AT} , respectively (see Sections 7.3.1 and 8.1.3).

10. Stability. The absorbing solution is stable for at least 1 month. Sample recovery and analysis should begin within 1 hour of sampling to minimize oxidation of the acidified cadmium sulfide. Once iodine has been added to the sample, the remainder of the analysis procedure must be completed according to sections 7.2.2 through 7.3.2.

SUBCHAPTER C—AIR PROGRAMS

[FRL 846-7]

NEW SOURCE REVIEW

Delegation of Authority to the Commonwealth of Kentucky

AGENCY: Environmental Protection Agency.

ACTION: Final rule.

SUMMARY: The amendments below institute certain address changes for reports and applications required from operators of new sources. EPA has delegated to the Commonwealth of Kentucky authority to review new and modified sources. The delegated authority includes the reviews under 40 CFR Part 52 for the prevention of significant deterioration. It also includes the review under 40 CFR Part 60 for the standards of performance for new stationary sources and reviewed under 40 CFR Part 61 for national emission standards for hazardous air pollutants. A notice announcing the delegation of authority was published in the Notices section of a previous issue of the FEDERAL REGISTER. These amendments provide that all reports, requests, applications, submittals, and communications previously required for the delegated reviews will now be sent to the Division of Air Pollution Control, Department for Natural Resources and Environmental Protection, West Frankfort Office Complex, U.S. 127, Frankfort, Ky. 40601, instead of EPA's Region IV.

EFFECTIVE DATE: January 25, 1978.

FOR FURTHER INFORMATION, CONTACT:

John Eagles, Air Programs Branch, Environmental Protection Agency, Region IV, 345 Courtland Street NE., Atlanta, Ga. 30308, phone 404-881-2864.

SUPPLEMENTARY INFORMATION: The Regional Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegation which is reflected by this administrative amendment was effective on April 12, 1977, and it serves no purpose to delay the technical change of this addition of the state address to the Code of Federal Regulations.

(Secs. 101, 110, 111, 112, 301, Clean Air Act, as amended, (42 U.S.C. 7401, 7410, 7411, 7412, 7601).)

Dated: January 10, 1978.

JOHN C. WHITE,
Regional Administrator.

RULES AND REGULATIONS

PART 52—APPROVAL AND PROMULGATION OF IMPLEMENTATION PLANS

Part 52 of Chapter I, Title 40, Code of Federal Regulations, is amended as follows:

Subpart S—Kentucky

1. Section 52.920(c) is amended by adding a new paragraph (c)(11) as follows:

§ 52.920 Identification of plan.

(c) * * *

(11) Letters requesting delegation of Federal authority for the administrative and technical portions of the Prevention of Significant Deterioration program were submitted on May 5 and July 13, 1976 by the Secretary of the Department for Natural Resources and Environmental Protection.

2. Section 52.931 is amended by adding a new paragraph (c) as follows:

§ 52.931 Significant deterioration of air quality.

(c) All applications and other information required pursuant to § 52.21 from sources located in the Commonwealth of Kentucky shall be submitted to the Division of Air Pollution Control, Department for Natural Resources and Environmental Protection, West Frankfort Office Complex, U.S. 127, Frankfort, Ky. 40601, instead of the EPA Region IV office.

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Part 60 of Chapter I, Title 40, Code of Federal Regulations, is amended as follows:

3. In § 60.4, paragraph (b)(S) is added as follows:

§ 60.4 Address.

(b) * * *

(S) Division of Air Pollution Control, Department for Natural Resources and Environmental Protection, U.S. 127, Frankfort, Ky. 40601.

PART 61—NATIONAL EMISSION STANDARDS FOR HAZARDOUS AIR POLLUTANTS

Part 61 of Chapter I, Title 40, Code of Federal Regulations, is amended as follows:

4. In § 61.04, paragraph (b)(S) is added as follows:

§ 61.04 Address.

(b) * * *

(S) Division of Air Pollution Control, Department for Natural Resources and Environmental Protection, U.S. 127, Frankfort, Ky. 40601.

CHAPTER I—ENVIRONMENTAL PROTECTION
AGENCYSUBCHAPTER C—AIR PROGRAMS
[FRL 856-1]PART 60—STANDARDS OF PERFORMANCE
FOR NEW STATIONARY SOURCES

Delegation of Authority to State of Delaware

AGENCY: Environmental Protection
Agency.

ACTION: Final rule.

SUMMARY: This document amends
regulations concerning air programs to
reflect delegation to the State of Dela-
ware of authority to implement and
enforce certain Standards of Perfor-
mance for New Stationary Sources.EFFECTIVE DATE: February 16,
1978.FOR FURTHER INFORMATION
CONTACT:Stephen R. Wassersug, Director, En-
forcement Division, Environmental
Protection Agency, Region III, 6th
and Walnut Streets, Philadelphia,
Pa. 19106, 215-597-4171.

SUPPLEMENTARY INFORMATION:

I. BACKGROUND

On September 7, 1977, the State of Delaware requested delegation of authority to implement and enforce certain Standards of Performance for New Stationary Sources. The request was reviewed and on September 30, 1977 a letter was sent to Pierre S. DuPont IV, Governor, State of Delaware, approving the delegation and outlining its conditions. The approval letter specified that if Governor DuPont or any other representatives had any objections to the conditions of delegation they were to respond within ten (10) days after receipt of the letter. As of this date, no objections have been received.

II. REGULATIONS AFFECTED BY THIS
DOCUMENT

Pursuant to the delegation of authority for certain Standards of Performance for New Stationary Sources to the State of Delaware, EPA is today amending 40 CFR 60.4, *Address*, to reflect this delegation. A Notice announcing this delegation (was) published on February 15, 1978, in the *FEDERAL REGISTER*. The amended § 60.4, which adds the address of the Delaware Department of Natural Resources and Environmental Control, to which all reports, requests, applications, submittals, and communications to the Administrator pursuant to this part must also be addressed, is set forth below.

III. GENERAL

The Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegation which is reflected by this administrative amendment was effective on September 30, 1977, and it serves no purpose to delay the technical change of this address to the Code of Federal Regulations.

This rulemaking is effective immediately, and is issued under the authority of Section 111 of the Clean Air Act, as amended, 42 U.S.C. 1857c-6.

Dated: January 31, 1978.

JACK J. SCHRAMM,
Regional Administrator.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

1. In § 60.4, paragraph (b) is amended by revising subparagraph (I) to read as follows:

§ 60.4 *Address.*

• • • • •

(b) • • •

(A)-(H) • • •

(I) State of Delaware (for fossil fuel-fired steam generators; incinerators; nitric acid plants; asphalt concrete plants; storage vessels for petroleum liquids; and sewage treatment plants only): Delaware Department of Natural Resources and Environmental Control, Edward Tatnall Building, Dover, Del. 19901.

[FRL 833-11]

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Kraft Pulp Mills

AGENCY: Environmental Protection Agency.

ACTION: Final rule.

SUMMARY: The standards limit emissions of total reduced sulfur (TRS) and particulate matter from new, modified, and reconstructed kraft pulp mills. The standards implement the Clean Air Act and are based on the Administrator's determination that emissions from kraft pulp mills contribute significantly to air pollution. The intended effect of these standards is to require new, modified, and reconstructed kraft pulp mills to use the best demonstrated system of continuous emission reduction.

EFFECTIVE DATE: February 23, 1978.

ADDRESSES: The Standards Support and Environmental Impact Statement (SSEIS) may be obtained from the U.S. EPA Library (MD-35), Research Triangle Park, N.C. 27711 (specify "Standards Support and Environmental Impact Statement, Volume 2: Promulgated Standards of Performance for Kraft Pulp Mills" (EPA-450/2-76-014b)). Copies of all comment letters received from interested persons participating in this rulemaking are available for inspection and copying during normal business hours at EPA's Public Information Reference Unit, Room 2922 (EPA Library), 401 M Street SW., Washington, D.C.

FOR FURTHER INFORMATION CONTACT:

Don R. Goodwin, Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, N.C. 27711, telephone No. 919-541-5271.

SUPPLEMENTARY INFORMATION: On September 24, 1976 (41 FR 42012), standards of performance were proposed for new, modified, and reconstructed kraft pulp mills under section 111 of the Clean Air Act, as amended. The significant comments that were received during the public comment period have been carefully reviewed and considered and, where determined by the Administrator to be appropriate, changes have been included in this notice of final rulemaking.

THE STANDARDS

The standards limit emissions of particulate matter from three affected facilities at kraft pulp mills. The limits are: 0.10 gram per dry standard cubic meter (g/dscm) at 8 percent oxygen for recovery furnaces, 0.10 gram per kilogram of black liquor solids (dry weight) (g/kg BLS) for smelt dissolving tanks, 0.15 g/dscm at 10 percent oxygen for lime kilns when burning gas, and 0.30 g/dscm at 10 percent oxygen for lime kilns when burning oil. Visible emissions from recovery furnaces are limited to 35 percent opacity.

The standards also limit emissions of TRS from eight affected facilities at kraft pulp mills. The limits are: 5 parts per million (ppm) by volume at 10 percent oxygen from the digester systems, multiple-effect evaporator systems, brown stock washer systems, black liquor oxidation systems, and condensate stripper systems; 5 ppm by volume at 8 percent oxygen from straight kraft recovery furnaces, 8 ppm by volume at 10 percent oxygen from lime kilns; and 25 ppm by volume at 8 percent oxygen from cross recovery furnaces, which are defined as furnaces burning at least 7 percent neutral sulfite semi-chemical (NSSC) liquor and having a green liquor sulfidity of at least 28 percent. In addition, TRS emissions from smelt dissolving tanks are limited to 0.0084 g/kg BLS.

The proposed TRS standard for the lime kiln has been changed, a separate TRS standard for cross recovery furnaces has been developed, and the proposed format of the standards for smelt dissolving tanks, digesters, multiple-effect evaporators, brown stock washers, black liquor oxidation and condensate strippers have been changed. The TRS, particulate matter and opacity standards for the other facilities, however, are essentially the same as those proposed.

It should be noted that standards of performance for new sources established under section 111 of the Clean Air Act reflect emission limits achievable with the best adequately demonstrated technological system of continuous emission reduction considering the cost of achieving such emission reductions and any nonair quality health, environmental, and energy impacts. State implementation plans (SIP's) approved or promulgated under section 110 of the Act, on the other hand, must provide for the attainment and maintenance of national ambient air quality standards (NAAQS) designed to protect public health and welfare. For that purpose SIP's must in some cases require greater emission reductions than those required by standards of performance for new sources. Section 173(2) of the Clean Air Act, as amended in 1977, requires, among other things, that a new

or modified source constructed in an area which exceeds the NAAQS must reduce emissions to the level which reflects the "lowest achievable emission rate" for such category of source, unless the owner or operator demonstrates that the source cannot achieve such an emission rate. In no event can the emission rate exceed any applicable standard of performance.

A similar situation may arise when a major emitting facility is to be constructed in a geographic area which falls under the prevention of significant deterioration of air quality provisions of the Act (Part C). These provisions require, among other things, that major emitting facilities to be constructed in such areas are to be subject to best available control technology. The term "best available control technology" (BACT) means "an emission limitation based on the maximum degree of reduction of each pollutant subject to regulation under this Act emitted from or which results from any major emitting facility, which the permitting authority, on a case-by-case basis, taking into account energy, environmental, and economic impacts and other costs, determines it achievable for such facility through application of production processes and available methods, systems, and techniques, including fuel cleaning or treatment or innovative fuel combustion techniques for control of each such pollutant. In no event shall application of 'best available control technology' result in emissions of any pollutants which will exceed the emissions allowed by any applicable standard established pursuant to section 111 or 112 of this Act."

Standards of performance should not be viewed as the ultimate in achievable emission control and should not preclude the imposition of a more stringent emission standard, where appropriate. For example, cost of achievement may be an important factor in determining standards of performance applicable to all areas of the country (clean as well as dirty). Costs must be accorded far less weight in determining the "lowest achievable emission rate" for new or modified sources locating in areas violating statutorily-mandated health and welfare standards. Although there may be emission control technology available that can reduce emissions below those levels required to comply with standards of performance, this technology might not be selected as the basis of standards of performance due to costs associated with its use. This in no way should preclude its use in situations where cost is a lesser consideration, such as determination of the "lowest achievable emission rate."

In addition, States are free under section 116 of the Act to establish even more stringent emission limits than

RULES AND REGULATIONS

those established under section 111 or those necessary to attain or maintain the NAAQS under section 110. Thus, new sources may in some cases be subject to limitations more stringent than standards of performance under section 111, and prospective owners and operators of new sources should be aware of this possibility in planning for such facilities.

ENVIRONMENTAL AND ECONOMIC IMPACT

The promulgated standards will reduce particulate emissions about 50 percent below requirements of the average existing State regulations. TRS emissions will be reduced by about 80 percent below requirements of the average existing State regulations, and this reduction will prevent odor problems from arising at most new kraft pulp mills. The secondary environmental impacts of the promulgated standard will be slight increases in water demand and wastewater treatment requirements. The energy impact of the promulgated standards will be small, increasing national energy consumption in 1980 by the equivalent of only 1.4 million barrels per year of No. 6 oil. The economic impact will be small with fifth-year annualized costs being estimated at \$33 million.

PUBLIC PARTICIPATION

Prior to proposal of the standards, interested parties were advised by public notice in the FEDERAL REGISTER of a meeting of the National Air Pollution Control Techniques Advisory Committee. In addition, copies of the proposed standards and the Standards Support and Environmental Impact Statement (SSEIS) were distributed to members of the kraft pulp industry and several environmental groups at the time of proposal. The public comment period extended from September 24, 1976, to March 14, 1977, and resulted in 42 comment letters with 28 of these letters coming from the industry, 12 from various regulatory agencies, and two from U.S. citizens. Several comments resulted in changes to the proposed standards. A detailed discussion of the comments and changes which resulted is presented in Volume 2 of the SSEIS. A summary is presented here.

SIGNIFICANT COMMENTS AND CHANGES MADE IN THE PROPOSED REGULATIONS

Most of the comment letters received contained multiple comments. The most significant comments and changes made to the proposed regulations are discussed below.

IMPACTS OF THE PROPOSED STANDARDS

Several commenters expressed concern about the increased energy consumption which would result from

compliance with proposed standards. These commenters felt that this would conflict with the Department of Energy's goal to reduce total energy consumption in the pulp and paper industry by 14 percent. This factor was considered in the analysis of the energy impact associated with the standards and is discussed in the SSEIS. Although the standards will increase the difficulty of attaining this energy reduction goal, the 4.3 percent increase in energy usage that will be required by new, modified, or reconstructed kraft pulp mills to comply with the standards is considered reasonable in comparison to the benefits which will result from the corresponding reduction in TRS and particulate matter emissions.

EMISSION CONTROL TECHNOLOGY

Most of the comments received regarding emission control technology concerned the application of this technology to either lime kilns or recovery furnaces. A few comments, however, expressed concern with the use of the oxygen correction factor included in the proposed standards for both lime kilns and recovery furnaces. These commenters pointed out that adjusting the concentration of particulate matter and TRS emissions to 10 percent oxygen for lime kilns and 8 percent oxygen for recovery furnaces only when the oxygen concentration exceeded these values effectively placed more stringent standards on the most energy-efficient operators. To ensure that the standard is equitable for all operators, these commenters suggested that the measured particulate matter and TRS concentrations should always be adjusted to 10 percent oxygen for the lime kiln and 8 percent oxygen for the recovery furnace.

These comments are valid. Requiring a lime kiln or recovery furnace with a low oxygen concentration to meet the same emission concentration as a lime kiln or recovery furnace with a high oxygen concentration would effectively place a more stringent emission limit on the kiln or furnace with the low oxygen concentration. Consequently, the promulgated standards require correction of particulate matter and TRS concentrations to 10 percent or 8 percent oxygen, as appropriate, in all cases.

Lime Kilns. Numerous comments were received on the emission control technology for lime kilns. The main points questioned by the commenters were: (a) Whether caustic scrubbing is effective in reducing TRS emissions from lime kilns; (b) whether an overdesign of the mud washing facilities at lime kiln E was responsible for the lower TRS emissions observed at this lime kiln; and (c) the adequacy of the data base used in developing the TRS standard.

The effectiveness of caustic scrubbing is substantiated by comparison of TRS emissions during brief periods when caustic was not being added to the scrubber at lime kiln E, with TRS emissions during normal operation at lime kiln E when caustic is being added to the scrubber. These observations clearly indicate that TRS emissions would be higher if caustic was not used in the scrubber. The ability of caustic scrubbing to reduce TRS emissions is also substantiated by the experience at another kraft pulp mill which was able to reduce TRS emissions from its lime kiln from 40-50 ppm to about 20 ppm merely by adding caustic to the scrubber. These factors, coupled with the emission data showing higher TRS emissions from those lime kilns which employed only efficient mud washing and good lime kiln process control, clearly show that caustic scrubbing reduces TRS emissions.

The mud washing facilities at lime kiln E are larger than those at other kraft pulp mills of equivalent pulp capacity. This "overdesign" resulted from initial plans of the company to process lime mud from waste water treatment. These waste water treatment plans were later abandoned. Since the quality or efficiency of mud washing has been shown to be a significant factor in reducing TRS emissions from lime kilns, the larger mud washing facilities at lime kiln E undoubtedly contributed to the low TRS emissions observed at this kiln. With the data available, however, it is not possible to separate the relative contribution of these mud washing facilities to the low TRS emissions observed from the relative contributions of good process operation of the lime kiln and caustic scrubbing.

Comments questioning the adequacy of the data base used in developing the standards for lime kilns were mainly directed toward the following points: the TRS standard was based on only one lime kiln; sampling losses which may have occurred during testing were not taken into account; and no lime kiln met both the TRS standard and the particulate standard.

As mentioned above, the TRS standard is based upon the emission control system installed at lime kiln E (i.e., efficient mud washing, good lime kiln process operation, and caustic scrubbing). While it is true that no other lime kiln in the United States is currently achieving the TRS emission levels observed at lime kiln E, there is no other lime kiln in the United States which is using the same emission control system that is employed at this facility. As discussed in the SSEIS, an analysis of the various parameters influencing TRS emissions from lime kilns indicates that this system of emission reduction could be applied to

RULES AND REGULATIONS

all new, modified, or reconstructed lime kilns and achieve the same reduction in emissions as observed at lime kiln E. Section 111 of the Clean Air Act requires that "standards of performance reflect the degree of emission reduction achievable through the application of the best system of continuous emission reduction which (taking into consideration the cost of achieving such emission reduction, and any nonair quality health and environmental impact and energy requirements) the Administrator determines has been adequately demonstrated for that category of sources." Litigation of standards of performance has resulted in clarification of the term "adequately demonstrated." In *Portland Cement Association v. Ruckelshaus* (486 F. 2d 375, D.C. Circuit, 1973), the standards of performance were viewed by the Court as "technology-forcing." Thus, while a system of emission reduction must be available for use to be considered adequately demonstrated, it does not have to be in routine use. However, in order to ensure that the numerical emission limit selected was consistent with proper operation and maintenance of the emission control system on lime kiln E, continuous monitoring data was examined. This analysis indicated that an emission source test of lime kiln E would have found TRS emission above 5 ppm greater than 5 percent of the time. This analysis also indicated, however, that it was very unlikely that an emission source test of lime kiln E would have found TRS emissions above 8 ppm. Thus, it appeared that the 5 ppm TRS numerical emission limit included in the proposed standard for lime kilns was too stringent. Accordingly, the numerical emission limit included in the promulgated TRS standard for lime kilns has been revised to 8 ppm. As discussed later in this preamble, consistent with this change in the numerical emission limit, the excess emissions allowance included within the emission monitoring requirements has been eliminated.

This does not reflect a change in the basis for the standard. The standard is still based on the best system of emission reduction, considering costs, for controlling TRS emissions from lime kilns (i.e., efficient mud washing, good lime kiln process operation, and caustic scrubbing). This system, or one equivalent to it, will still be required to comply with the standard.

Since proposal of the standards, sample losses of up to 20 percent during emission source testing have been confirmed. Although these losses were not considered in selecting the numerical emission limit included in the proposed TRS emission standard, they have been considered in selecting the numerical emission limit included in the promulgated standard. Also, since the amount of sample loss that

occurs within the TRS emission measurement system during source testing can be determined, procedures have been added to Reference Method 16 requiring determination of these losses during each source test and adjustment of the emission data obtained to take these losses into account.

With regard to the ability of a lime kiln to comply with both the TRS emission standard and the particulate emission standard simultaneously, caustic scrubbing will tend to increase particulate emissions due to release of sodium fume from the scrubbing liquor. Compared to the concentration of particulate matter permitted in the gases discharged to the atmosphere, however, the potential contribution of sodium fume from caustic scrubbing is quite small. Consequently, with proper operation and maintenance, sodium fume due to caustic scrubbing will not cause particulate emissions from a lime kiln to exceed the numerical emission limit included in the promulgated standard.

Recovery Furnace. A number of comments were received regarding both the proposed TRS emission standard and the proposed particulate emission standard for recovery furnaces. Basically, the major issue was whether a cross recovery furnace could comply with the 5 ppm TRS standard or whether a separate standard was necessary.

Review of the data and information submitted with these comments indicates that the operation of cross recovery furnaces is substantially different from that of straight kraft recovery furnaces. The sulfidity of the black liquor burned in cross recovery furnaces and the heat content of the liquor, both of which are significant factors influencing TRS emissions, are considerably different from the levels found in straight kraft recovery furnaces.

Analysis of the data indicated that TRS emissions were generally less than 25 ppm, with only occasional excursions exceeding this level. Consequently, the promulgated TRS emission standard has been revised to include a separate TRS numerical emission limit of 25 ppm for cross recovery furnaces.

Smelt Dissolving Tank. Numerous comments were received concerning the format of the proposed TRS and particulate emission standards for smelt dissolving tanks. These comments pointed out that standards in terms of emissions per unit of air-dried pulp were inequitable for kraft pulp mills which produced low-yield pulps since both TRS and particulate emissions from the smelt dissolving tanks are proportional to the tons of black liquor solids fed into the tanks. The black liquor solids produced per ton of air-dried pulp, however, can vary sub-

stantially from mill to mill. A standard in terms of emissions per unit of air-dried pulp, therefore, requires greater control of emissions at kraft pulp mills which use low-yield pulps (higher solids-to-pulp ratio).

Review of these comments does indeed indicate that the format of the proposed standards was inequitable. The format of the promulgated standards, therefore, has been revised to emissions per unit of black liquor solids fed to the smelt dissolving tanks. Since the percent solids and black liquor flow rate to the recovery furnace is routinely monitored at kraft pulp mills, the weight of black liquor solids corresponding to a particular emissions period will be easy to determine.

Brown Stock Washers. Several comments expressed concern about combustion of the high volume-low TRS concentration gases discharged from brown stock washers and black liquor oxidation facilities in recovery furnaces without facing a serious risk of explosions. As discussed in the SSEIS, information obtained from two kraft pulp mill operators indicates that this practice is both safe and reliable when it is accompanied by careful engineering and operating practices. Danger of an explosion occurring is essentially eliminated by introducing the gases high in the furnace. Since some older furnaces do not have the capability to accept large volumes of gases at higher combustion ports, this practice may not be safe for some existing furnaces. In addition, the costs associated with altering these furnaces to accept these gases are frequently prohibitive. Consequently, the promulgated standards include an exemption for new, modified, or reconstructed brown stock washers and black liquor oxidation facilities within existing kraft pulp mills where combustion of these gases in an existing facility is not feasible from a safety or economic standpoint.

CONTINUOUS MONITORING

Numerous comments were received concerning the proposed continuous monitoring requirements. Generally, these comments questioned the requirement to install TRS monitors in light of the absence of performance specifications for these monitors.

At the time of proposal of the standards, both EPA and the kraft pulp mill industry were engaged in developing performance specifications for TRS continuous emission monitoring systems. It was expected that this work would lead to performance specifications for these monitoring systems by the time the standards of performance were promulgated. Unfortunately, this is not the case. In a joint EPA/industry effort, the compatibility of various TRS emission monitoring

RULES AND REGULATIONS

methods with Reference Method 16, which is the performance test method to determine TRS emissions, is still under study. There is little doubt but that these TRS emission monitoring systems will be shown to be compatible with Reference Method 16, and that performance specifications for these systems will be developed. Consequently, the promulgated standards include TRS continuous emission monitoring requirements. These requirements, however, will not become effective until performance specifications for TRS continuous emission monitoring systems have been developed. To accommodate this situation, not only for the promulgated standards for kraft pulp mills, but also for standards of performance that may be developed in the future that may also face this situation, section 60.13 of the General Provisions for subpart 60 is amended to provide that continuous monitoring systems need not be installed until performance specifications for these systems are promulgated under Appendix B to subpart 60. This will ensure that all facilities which are covered by standards of performance will eventually install continuous emission monitoring systems where required.

EXCESS EMISSIONS

Numerous comments were received which were concerned with the excess emission allowances and the reporting requirements for excess emissions. In general, these comments reflected a lack of understanding with regard to the concept of excess emissions. Consequently, a brief review of this concept is appropriate.

Standards of performance have two major objectives. The first is installation of the best system of emission reduction, considering costs; and the second is continued proper operation and maintenance of the system throughout its useful life. Since the numerical emission limit included in standards of performance is selected to reflect the performance of the best system of emission reduction under conditions of proper operation and maintenance, the performance test, under 40 CFR 60.8 represents the ability of the source to meet these objectives. Performance tests, however, are often time consuming and complex. As a result, while the performance test is an excellent mechanism for achieving these objectives, it is rather cumbersome and inconvenient for routinely achieving these objectives. Therefore, the Agency believes that continuous monitors must play an important role in meeting these objectives.

Excess emissions are defined as emissions exceeding the numerical emission limit included in a standard of performance. Continuous emission monitoring, therefore, identifies periods of excess emissions and when com-

bined with the requirement that these periods be reported to EPA, it provides the Agency with a useful mechanism for achieving the previously mentioned objectives.

Continuous emission monitoring, however, will identify all periods of excess emissions, including those which are not the result of improper operation and maintenance. Excess emissions due to start-ups, shutdowns, and malfunctions, for example, are unavoidable or beyond the control of an owner or operator and cannot be attributed to improper operation and maintenance. Similarly, excess emissions as a result of some inherent variability or fluctuation within a process which influences emissions cannot be attributed to improper operation and maintenance, unless these fluctuations could be controlled by more carefully attending to those process operating parameters during routine operation which have little effect on operation of the process, but which may have a significant effect on emissions.

To quantify the potential for excess emissions due to inherent variability in a process, continuous monitoring data are used whenever possible to calculate an excess emission allowance. For TRS emissions at kraft pulp mills, this allowance is defined as follows. If a calendar quarter is divided into discrete contiguous 12-hour time periods, the excess emission allowance is expressed as the percentage of these time periods. Excess emissions may occur as the result of unavoidable variability within the kraft pulping process. Thus, the excess emissions allowance represents the potential for excess emissions under conditions of proper operation and maintenance in the absence of start-ups, shutdowns and malfunctions, and is used as a guideline or screening mechanism for interpreting the data generated by the excess emission reporting requirements.

Although the excess emission reporting requirements provide a mechanism for achieving the objective of proper operation and maintenance of the best system of emission reduction, this mechanism is not necessarily a direct indicator of improper operation and maintenance. Consequently, excess emission reports must be reviewed and interpreted for proper decisionmaking.

In general, the comments received concerning the excess emission reporting requirements questioned: (1) The adequacy of the TRS excess emission allowance for lime kilns and (2) the lack of a TRS excess emission allowance for recovery furnaces.

With regard to the adequacy of the TRS excess emissions allowance for lime kilns, a reevaluation of the TRS emission data from lime kiln E led the Agency to the conclusion that, for a TRS emission limit of 5 ppm, an

excess emission allowance of 6 percent was appropriate. However, a similar analysis also indicates that an excess emission allowance is not appropriate at a TRS emission level of 8 ppm. Accordingly, the excess emission reporting requirements included in the promulgated standard for lime kilns contains no excess emission allowance. This does not represent a change in the basis of the standard. The standard will still require installation of the best system of emission reduction, considering costs (i.e., efficient mud washing, good lime kiln process operation, and caustic scrubbing; or an alternative system equivalent to the performance of this system).

With regard to the lack of a TRS excess emission allowance for recovery furnaces, at the time of proposal of the standards, no TRS continuous emission monitoring data were available from a well-controlled and well operated recovery furnace which could be used to determine an excess emission allowance. Several months of TRS continuous emission monitoring data, however, were submitted with the comments received from the operator of recovery furnace D concerning this point.

A review of the data indicates that, while some of the excursions of TRS emissions above 5 ppm reflected either improper operation and maintenance, or start-ups, shutdowns, or malfunctions, most of these excursions reflected unavoidable normal variability in the operation of a kraft pulp mill recovery furnace. Discounting those excursions in emissions from the data which were due to improper operation and maintenance, or start-ups, shutdowns, or malfunctions indicates that an excess emission allowance of 1 percent is appropriate for all recovery furnaces.

Including an excess emissions allowance in the promulgated standards for recovery furnaces, but not for lime kilns, is a reversal of the proposed requirements. Including such an allowance for recovery furnaces but not for lime kilns, however, is consistent with the nature of the different emission control systems which were selected as the bases for these standards. The emission control system upon which the TRS standard for recovery furnaces is based consists of black liquor oxidation and good process operation of the recovery furnace for direct recovery furnaces, and good process operation alone for indirect recovery furnaces. Neither of these emission control systems are particularly well suited to controlling fluctuations in the kraft pulping process. Thus, fluctuations in the process tend to pass through the emission control system and show up as fluctuations in TRS emissions.

The emission control system upon which the TRS standard for lime kilns

RULES AND REGULATIONS

is based consists of efficient mud washing, good process operation of the lime kiln, and caustic scrubbing of the gases discharged from the lime kiln. As with the emission control system upon which the standard for recovery furnaces is based, the first two emission control techniques (i.e., mud washing and good process operation) are not particularly well suited to controlling fluctuations in the kraft pulping process. The third emission control technique, however, caustic scrubbing, is an "add-on" emission control technique that can be designed to accommodate fluctuations in TRS emissions and minimize or essentially eliminate these fluctuations.

EMISSION TESTING

A few comments were received which questioned the validity of the results obtained by Reference Method 16, due to sample losses and sulfur dioxide (SO₂) interference.

With regard to the validity of the results obtained by Reference Method 16, as mentioned earlier, during the emission testing program, it was not widely known that sample losses could occur within the TRS emission measurement system. Since proposal of the standards, however, sample losses of up to 20 percent during emission source testing have been confirmed. Although these losses were not considered in selecting the numerical emission limits included in the proposed TRS emission standards, they have been considered in selecting the numerical emission limit included in the promulgated standards. Also, since the amount of sample loss that occurs within the TRS emission measurement system during source testing can be determined, procedures have been added to Reference Method 16 requiring determination of these losses during each source test and adjustment of the emission data obtained to take these losses into account. This will ensure that the TRS emission data obtained during a performance test are accurate.

It has also been confirmed that high concentrations of SO₂ will interfere with the determination of TRS emissions to some extent. At this point, however, it is not known what SO₂ concentration levels will result in a significant loss of accuracy in determining TRS emissions. The ability of a citrate scrubber to selectively remove SO₂ prior to measurement of TRS emissions is now being tested. In addition, various chromatographic columns might exist which would effectively resolve this problem. As soon as an appropriate technique is developed to overcome this problem, Reference Method 16 will be amended.

This problem of SO₂ interference will not present major difficulties to the use of Reference Method 16. Relatively high SO₂ concentration levels were observed in only one EPA emission source test. Accordingly, high SO₂ concentration levels are probably not a frequent occurrence within kraft pulp mills. More importantly, however, high SO₂ concentrations only interfere with the determination of methyl mercaptan in the emission measurement system outlined in Reference Method 16. Since methyl mercaptan is usually only a small contributor to total TRS emissions, neglecting methyl mercaptan where this interference occurs should not seriously affect the determination of TRS emissions. Consequently, Reference Method 16 can be used to enforce the promulgated standards without major difficulties.

Miscellaneous: The effective date of this regulation is February 24, 1976. Section 111(b)(1)(B) of the Clean Air Act provides that standards of performance or revisions of them become effective upon promulgation and apply to affected facilities, construction or modification of which was commenced after the date of proposal (September 24, 1976).

NOTE.—An economic assessment has been prepared as required under section 317 of the Act. This also satisfies the requirements of Executive Orders 11821 and OMB Circular A-107.

Dated: February 10, 1978.

BARBARA BLUM,
Acting Administrator.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

Subpart A—General Provisions

1. Section 60.13 is amended to clarify the provisions in paragraph (a) by revising paragraph (a) to read as follows:

§ 60.13 Monitoring requirements.

(a) For the purposes of this section, all continuous monitoring systems required under applicable subparts shall be subject to the provisions of this section upon promulgation of performance specifications for continuous monitoring system under Appendix B to this part, unless:

- (1) The continuous monitoring system is subject to the provisions of paragraphs (c)(2) and (c)(3) of this section, or
- (2) otherwise specified in an applicable subpart or by the Administrator.

2. Part 60 is amended by adding subpart BB as follows:

Subpart BB—Standards of Performance for Kraft Pulp Mills

- Sec.
60.280 Applicability and designation of affected facility.
60.281 Definitions.

- 60.282 Standard for particulate matter.
60.283 Standard for total reduced sulfur (TRS).
60.284 Monitoring of emissions and operations.
60.285 Test methods and procedures.

AUTHORITY: Secs. 111, 301(a) of the Clean Air Act, as amended [42 U.S.C. 7411, 7601(a)], and additional authority as noted below.

Subpart BB—Standards of Performance for Kraft Pulp Mills

60.280 Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to the following affected facilities in kraft pulp mills: digester system, brown stock washer system, multiple-effect evaporator system, black liquor oxidation system, recovery furnace, smelt dissolving tank, lime kiln, and condensate stripper system. In pulp mills where kraft pulping is combined with neutral sulfite semichemical pulping, the provisions of this subpart are applicable when any portion of the material charged to an affected facility is produced by the kraft pulping operation.

(b) Any facility under paragraph (a) of this section that commences construction or modification after September 24, 1976, is subject to the requirements of this subpart.

§ 60.281 Definitions.

As used in this subpart, all terms not defined herein shall have the same meaning given them in the Act and in Subpart A.

(a) "Kraft pulp mill" means any stationary source which produces pulp from wood by cooking (digesting) wood chips in a water solution of sodium hydroxide and sodium sulfide (white liquor) at high temperature and pressure. Regeneration of the cooking chemicals through a recovery process is also considered part of the kraft pulp mill.

(b) "Neutral sulfite semichemical pulping operation" means any operation in which pulp is produced from wood by cooking (digesting) wood chips in a solution of sodium sulfite and sodium bicarbonate, followed by mechanical defibrating (grinding).

(c) "Total reduced sulfur (TRS)" means the sum of the sulfur compounds hydrogen sulfide, methyl mercaptan, dimethyl sulfide, and dimethyl disulfide, that are released during the kraft pulping operation and measured by Reference Method 16.

(d) "Digester system" means each continuous digester or each batch digester used for the cooking of wood in white liquor, and associated flash tank(s), below tank(s), chip steamer(s), and condenser(s).

(e) "Brown stock washer system" means brown stock washers and associated knotters, vacuum pumps, and fil-

RULES AND REGULATIONS

trate tanks used to wash the pulp following the digester system.

(f) "Multiple-effect evaporator system" means the multiple-effect evaporators and associated condenser(s) and hotwell(s) used to concentrate the spent cooking liquid that is separated from the pulp (black liquor).

(g) "Black liquor oxidation system" means the vessels used to oxidize, with air or oxygen, the black liquor, and associated storage tank(s).

(h) "Recovery furnace" means either a straight kraft recovery furnace or a cross recovery furnace, and includes the direct-contact evaporator for a direct-contact furnace.

(i) "Straight kraft recovery furnace" means a furnace used to recover chemicals consisting primarily of sodium and sulfur compounds by burning black liquor which on a quarterly basis contains 7 weight percent or less of the total pulp solids from the neutral sulfite semichemical process or has green liquor sulfidity of 28 percent or less.

(j) "Cross recovery furnace" means a furnace used to recover chemicals consisting primarily of sodium and sulfur compounds by burning black liquor which on a quarterly basis contains more than 7 weight percent of the total pulp solids from the neutral sulfite semichemical process and has a green liquor sulfidity of more than 28 percent.

(k) "Black liquor solids" means the dry weight of the solids which enter the recovery furnace in the black liquor.

(l) "Green liquor sulfidity" means the sulfidity of the liquor which leaves the smelt dissolving tank.

(m) "Smelt dissolving tank" means a vessel used for dissolving the smelt collected from the recovery furnace.

(n) "Lime kiln" means a unit used to calcine lime mud, which consists primarily of calcium carbonate, into quicklime, which is calcium oxide.

(o) "Condensate stripper system" means a column, and associated condensers, used to strip, with air or steam, TRS compounds from condensate streams from various processes within a kraft pulp mill.

§ 60.282 Standard for particulate matter.

(a) On and after the date on which the performance test required to be conducted by § 60.8 is completed, no owner or operator subject to the provisions of this subpart shall cause to be discharged into the atmosphere:

(1) From any recovery furnace any gases which:

(i) Contain particulate matter in excess of 0.10 g/dscm (0.044 gr/dscf) corrected to 8 percent oxygen.

(ii) Exhibit 35 percent opacity or greater.

(2) From any smelt dissolving tank any gases which contain particulate

matter in excess of 0.1 g/kg black liquor solids (dry weight) [0.2 lb/ton black liquor solids (dry weight)].

(3) From any lime kiln any gases which contain particulate matter in excess of:

(i) 0.15 g/dscm (0.067 gr/dscf) corrected to 10 percent oxygen, when gaseous fossil fuel is burned.

(ii) 0.30 g/dscm (0.13 gr/dscf) corrected to 10 percent oxygen, when liquid fossil fuel is burned.

§ 60.283 Standard for total reduced sulfur (TRS).

(a) On and after the date on which the performance test required to be conducted by § 60.8 is completed, no owner or operator subject to the provisions of this subpart shall cause to be discharged into the atmosphere:

(1) From any digester system, brown stock washer system, multiple-effect evaporator system, black liquor oxidation system, or condensate stripper system any gases which contain TRS in excess of 5 ppm by volume on a dry basis, corrected to 10 percent oxygen, unless the following conditions are met:

(i) The gases are combusted in a lime kiln subject to the provisions of paragraph (a)(5) of this section; or

(ii) The gases are combusted in a recovery furnace subject to the provisions of paragraphs (a)(2) or (a)(3) of this section; or

(iii) The gases are combusted with other waste gases in an incinerator or other device, or combusted in a lime kiln or recovery furnace not subject to the provisions of this subpart, and are subjected to a minimum temperature of 1200° F. for at least 0.5 second; or

(iv) It has been demonstrated to the Administrator's satisfaction by the owner or operator that incinerating the exhaust gases from a new, modified, or reconstructed black liquor oxidation system or brown stock washer system in an existing facility is technologically or economically not feasible. Any exempt system will become subject to the provisions of this subpart if the facility is changed so that the gases can be incinerated.

(2) From any straight kraft recovery furnace any gases which contain TRS in excess of 5 ppm by volume on a dry basis, corrected to 8 percent oxygen.

(3) From any cross recovery furnace any gases which contain TRS in excess of 25 ppm by volume on a dry basis, corrected to 8 percent oxygen.

(4) From any smelt dissolving tank any gases which contain TRS in excess of 0.0084 g/kg black liquor solids (dry weight) [0.0168 lb/ton liquor solids (dry weight)].

(5) From any lime kiln any gases which contain TRS in excess of 8 ppm by volume on a dry basis, corrected to 10 percent oxygen.

§ 60.284 Monitoring of emissions and operations.

(a) Any owner or operator subject to the provisions of this subpart shall install, calibrate, maintain, and operate the following continuous monitoring systems:

(1) A continuous monitoring system to monitor and record the opacity of the gases discharged into the atmosphere from any recovery furnace. The span of this system shall be set at 70 percent opacity.

(2) Continuous monitoring systems to monitor and record the concentration of TRS emissions on a dry basis and the percent of oxygen by volume on a dry basis in the gases discharged into the atmosphere from any lime kiln, recovery furnace, digester system, brown stock washer system, multiple-effect evaporator system, black liquor oxidation system, or condensate stripper system, except where the provisions of § 60.283(a)(1)(iii) or (iv) apply. These systems shall be located downstream of the control device(s) and the span(s) of these continuous monitoring system(s) shall be set:

(i) At a TRS concentration of 30 ppm for the TRS continuous monitoring system, except that for any cross recovery furnace the span shall be set at 50 ppm.

(ii) At 20 percent oxygen for the continuous oxygen monitoring system.

(b) Any owner or operator subject to the provisions of this subpart shall install, calibrate, maintain, and operate the following continuous monitoring devices:

(1) A monitoring device which measures the combustion temperature at the point of incineration of effluent gases which are emitted from any digester system, brown stock washer system, multiple-effect evaporator system, black liquor oxidation system, or condensate stripper system where the provisions of § 60.283(a)(1)(iii) apply. The monitoring device is to be certified by the manufacturer to be accurate within ± 1 percent of the temperature being measured.

(2) For any lime kiln or smelt dissolving tank using a scrubber emission control device:

(i) A monitoring device for the continuous measurement of the pressure loss of the gas stream through the control equipment. The monitoring device is to be certified by the manufacturer to be accurate to within a gage pressure of ± 500 pascals (ca. ± 2 inches water gage pressure).

(ii) A monitoring device for the continuous measurement of the scrubbing liquid supply pressure to the control equipment. The monitoring device is to be certified by the manufacturer to be accurate within ± 15 percent of design scrubbing liquid supply pressure. The pressure sensor or tap is to

RULES AND REGULATIONS

be located close to the scrubber liquid discharge point. The Administrator may be consulted for approval of alternative locations.

(c) Any owner or operator subject to the provisions of this subpart shall, except where the provisions of § 60.283(a)(1)(iv) or § 60.283(a)(4) apply.

(1) Calculate and record on a daily basis 12-hour average TRS concentrations for the two consecutive periods of each operating day. Each 12-hour average shall be determined as the arithmetic mean of the appropriate 12 contiguous 1-hour average total reduced sulfur concentrations provided by each continuous monitoring system installed under paragraph (a)(2) of this section.

(2) Calculate and record on a daily basis 12-hour average oxygen concentrations for the two consecutive periods of each operating day for the recovery furnace and lime kiln. These 12-hour averages shall correspond to the 12-hour average TRS concentrations under paragraph (c)(1) of this section and shall be determined as an arithmetic mean of the appropriate 12 contiguous 1-hour average oxygen concentrations provided by each continuous monitoring system installed under paragraph (a)(2) of this section.

(3) Correct all 12-hour average TRS concentrations to 10 volume percent oxygen, except that all 12-hour average TRS concentration from a recovery furnace shall be corrected to 8 volume percent using the following equation:

$$C_{\text{corr}} = C_{\text{meas}} \times (21 - X/21 - Y)$$

where:

C_{corr} = the concentration corrected for oxygen.

C_{meas} = the concentration uncorrected for oxygen.

X = the volumetric oxygen concentration in percentage to be corrected to (8 percent for recovery furnaces and 10 percent for lime kilns, incinerators, or other devices).

Y = the measured 12-hour average volumetric oxygen concentration.

(d) For the purpose of reports required under § 60.7(c), any owner or operator subject to the provisions of this subpart shall report periods of excess emissions as follows:

(1) For emissions from any recovery furnace periods of excess emissions are:

(i) All 12-hour averages of TRS concentrations above 5 ppm by volume for straight kraft recovery furnaces and above 25 ppm by volume for cross recovery furnaces.

(ii) All 6-minute average opacities that exceed 35 percent.

(2) For emissions from any lime kiln, periods of excess emissions are all 12-hour average TRS concentration above 8 ppm by volume.

(3) For emissions from any digester system, brown stock washer system,

multiple-effect evaporator system, black liquor oxidation system, or condensate stripper system periods of excess emissions are:

(i) All 12-hour average TRS concentrations above 5 ppm by volume unless the provisions of § 60.283(a)(1)(i), (ii), or (iv) apply; or

(ii) All periods in excess of 5 minutes and their duration during which the combustion temperature at the point of incineration is less than 1200° F. where the provisions of § 60.283(a)(1)(ii) apply.

(e) The Administrator will not consider periods of excess emissions reported under paragraph (d) of this section to be indicative of a violation of § 60.11(d) provided that:

(1) The percent of the total number of possible contiguous periods of excess emissions in a quarter (excluding periods of startup, shutdown, or malfunction and periods when the facility is not operating) during which excess emissions occur does not exceed:

(i) One percent for TRS emissions from recovery furnaces.

(ii) Six percent for average opacities from recovery furnaces.

(2) The Administrator determines that the affected facility, including air pollution control equipment, is maintained and operated in a manner which is consistent with good air pollution control practice for minimizing emissions during periods of excess emissions.

§ 60.285 Test methods and procedures.

(a) Reference methods in Appendix A of this part, except as provided under § 60.8(b), shall be used to determine compliance with § 60.282(a) as follows:

(1) Method 5 for the concentration of particulate matter and the associated moisture content,

(2) Method 1 for sample and velocity traverses,

(3) When determining compliance with § 60.282(a)(2), Method 2 for velocity and volumetric flow rate,

(4) Method 3 for gas analysis, and

(5) Method 9 for visible emissions.

(b) For Method 5, the sampling time for each run shall be at least 60 minutes and the sampling rate shall be at least 0.85 dscm/hr (0.53 dscf/min) except that shorter sampling times, when necessitated by process variables or other factors, may be approved by the Administrator. Water shall be used as the cleanup solvent instead of acetone in the sample recovery procedure outlined in Method 5.

(c) Method 17 (in-stack filtration) may be used as an alternate method for Method 5 for determining compliance with § 60.282(a)(1)(i): *Provided*, That a constant value of 0.009 g/dscm (0.004 gr/dscf) is added to the results of Method 17 and the stack tempera-

ture is no greater than 205° C (ca. 400° F). Water shall be used as the cleanup solvent instead of acetone in the sample recovery procedure outlined in Method 17.

(d) For the purpose of determining compliance with § 60.283(a)(1), (2), (3), (4), and (5), the following reference methods shall be used:

(1) Method 16 for the concentration of TRS,

(2) Method 3 for gas analysis, and

(3) When determining compliance with § 60.283(a)(4), use the results of Method 2, Method 16, and the black liquor solids feed rate in the following equation to determine the TRS emission rate.

$$E = (C_{\text{H}_2\text{S}}F_{\text{H}_2\text{S}} + C_{\text{MeSH}}F_{\text{MeSH}} + C_{\text{DMS}}F_{\text{DMS}} + C_{\text{DMDS}}F_{\text{DMDS}}) (Q_{\text{sc}}) / \text{BLS}$$

Where:

E = mass of TRS emitted per unity of black liquor solids (g/kg) (lb/ton)

$C_{\text{H}_2\text{S}}$ = average concentration of hydrogen sulfide (H_2S) during the test period, PPM.

C_{MeSH} = average concentration of methyl mercaptan (MeSH) during the test period, PPM.

C_{DMS} = average concentration of dimethyl sulfide (DMS) during the test period, PPM.

C_{DMDS} = average concentration of dimethyl disulfide (DMDS) during the test period, PPM.

$F_{\text{H}_2\text{S}}$ = 0.001417 g/m³ PPM for metric units
= 0.08844 lb/ft³ PPM for English units

F_{MeSH} = 0.00200 g/m³ PPM for metric units
= 0.1248 lb/ft³ PPM for English units

F_{DMS} = 0.002583 g/m³ PPM for metric units
= 0.1612 lb/ft³ PPM for English units

F_{DMDS} = 0.003917 g/m³ PPM for metric units
= 0.2445 lb/ft³ PPM for English units

Q_{sc} = dry volumetric stack gas flow rate corrected to standard conditions, dscm/hr (dscf/hr)

BLS = black liquor solids feed rate, kg/hr (lb/hr)

(4) When determining whether a furnace is straight kraft recovery furnace or a cross recovery furnace, TAPPI Method T.624 shall be used to determine sodium sulfide, sodium hydroxide and sodium carbonate. These determinations shall be made three times daily from the green liquor and the daily average values shall be converted to sodium oxide (Na_2O) and substituted into the following equation to determine the green liquor sulfidity:

$$\text{GLS} = 100 \quad C_{\text{Na}_2\text{S}}^3 / C_{\text{Na}_2\text{S}}^2 + C_{\text{NaOH}} + C_{\text{Na}_2\text{CO}_3}$$

Where:

GLS = percent green liquor sulfidity

$C_{\text{Na}_2\text{S}}$ = average concentration of Na_2S expressed as Na_2O (mg/l)

C_{NaOH} = average concentration of NaOH expressed as Na_2O (mg/l)

$C_{\text{Na}_2\text{CO}_3}$ = average concentration of Na_2CO_3 expressed as Na_2O (mg/l)

(e) All concentrations of particulate matter and TRS required to be measured by this section from lime kilns or incinerators shall be corrected to 10 volume percent oxygen and those concentrations from recovery furnaces

RULES AND REGULATIONS

shall be corrected to 8 volume percent oxygen. These corrections shall be made in the manner specified in § 60.284(c)(3).

APPENDIX A—REFERENCE METHODS

(3) Method 16 and Method 17 are added to Appendix A as follows:

METHOD 16. SEMICONTINUOUS DETERMINATION OF SULFUR EMISSIONS FROM STATIONARY SOURCES

Introduction

The method described below uses the principle of gas chromatographic separation and flame photometric detection. Since there are many systems or sets of operating conditions that represent usable methods of determining sulfur emissions, all systems which employ this principle, but differ only in details of equipment and operation, may be used as alternative methods, provided that the criteria set below are met.

1. Principle and Applicability.

1.1 Principle. A gas sample is extracted from the emission source and diluted with clean dry air. An aliquot of the diluted sample is then analyzed for hydrogen sulfide (H₂S), methyl mercaptan (MeSH), dimethyl sulfide (DMS) and dimethyl disulfide (DMDS) by gas chromatographic (GC) separation and flame photometric detection (FPD). These four compounds are known collectively as total reduced sulfur (TRS).

1.2 Applicability. This method is applicable for determination of TRS compounds from recovery furnaces, lime kilns, and smelt dissolving tanks at kraft pulp mills.

2. Range and Sensitivity.

2.1 Range. Coupled with a gas chromatographic system utilizing a ten milliliter sample size, the maximum limit of the FPD for each sulfur compound is approximately 1 ppm. This limit is expanded by dilution of the sample gas before analysis. Kraft mill gas samples are normally diluted tenfold (9:1), resulting in an upper limit of about 10 ppm for each compound.

For sources with emission levels between 10 and 100 ppm, the measuring range can be best extended by reducing the sample size to 1 milliliter.

2.2 Using the sample size, the minimum detectable concentration is approximately 80 ppb.

3. Interferences.

3.1 Moisture Condensation. Moisture condensation in the sample delivery system, the analytical column, or the FPD burner block can cause losses or interferences. This potential is eliminated by heating the sample line, and by conditioning the sample with dry dilution air to lower its dew point below the operating temperature of the GC/FPD analytical system prior to analysis.

3.2 Carbon Monoxide and Carbon Dioxide. CO and CO₂ have substantial desensitizing effect on the flame photometric detector even after 9:1 dilution. Acceptable systems must demonstrate that they have eliminated this interference by some procedure such as eluting these compounds before any of the compounds to be measured. Compliance with this requirement can be demonstrated by submitting chromatograms of calibration gases with and without CO, in the diluent gas. The CO₂ level should be approximately 10 percent for the case with CO₂ present. The two chromatograms should show agreement within the precision limits of Section 4.1.

3.3 Particulate Matter. Particulate matter in gas samples can cause interference by eventual clogging of the analytical system. This interference must be eliminated by use of a probe filter.

3.4 Sulfur Dioxide. SO₂ is not a specific interferent but may be present in such large amounts that it cannot be effectively separated from other compounds of interest. The procedure must be designed to eliminate this problem either by the choice of separation columns or by removal of SO₂ from the sample.

Compliance with this section can be demonstrated by submitting chromatograms of calibration gases with SO₂ present in the same quantities expected from the emission source to be tested. Acceptable systems shall show baseline separation with the amplifier attenuation set so that the reduced sulfur compound of concern is at least 50 percent of full scale. Base line separation is defined as a return to zero \pm percent in the interval between peaks.

4. Precision and Accuracy.

4.1 GC/FPD and Dilution System Calibration Precision. A series of three consecutive injections of the same calibration gas, at any dilution, shall produce results which do not vary by more than ± 3 percent from the mean of the three injections.

4.2 GC/FPD and Dilution System Calibration Drift. The calibration drift determined from the mean of three injections made at the beginning and end of any 8-hour period shall not exceed \pm percent.

4.3 System Calibration Accuracy. The complete system must quantitatively transport and analyze with an accuracy of 20 percent. A correction factor is developed to adjust calibration accuracy to 100 percent.

5. Apparatus (See Figure 16-1).

5.1.1 Probe. The probe must be made of inert material such as stainless steel or glass. It should be designed to incorporate a filter and to allow calibration gas to enter the probe at or near the sample entry point. Any portion of the probe not exposed to the stack gas must be heated to prevent moisture condensation.

5.1.2 Sample Line. The sample line must be made of Teflon,¹ no greater than 1.3 cm (1/2) inside diameter. All parts from the probe to the dilution system must be thermostatically heated to 120° C.

5.1.3 Sample Pump. The sample pump shall be a leakless Teflon-coated diaphragm type or equivalent. If the pump is upstream of the dilution system, the pump head must be heated to 120° C.

5.2 Dilution System. The dilution system must be constructed such that all sample contacts are made of inert materials (e.g., stainless steel or Teflon). It must be heated to 120° C. and be capable of approximately a 9:1 dilution of the sample.

5.3 Gas Chromatograph. The gas chromatograph must have at least the following components:

5.3.1 Oven. Capable of maintaining the separation column at the proper operating temperature $\pm 1^\circ$ C.

5.3.2 Temperature Gauge. To monitor column oven, detector, and exhaust temperature $\pm 1^\circ$ C.

5.3.3 Flow System. Gas metering system to measure sample, fuel, combustion gas, and carrier gas flows.

¹ Mention of trade names or specific products does not constitute endorsement by the Environmental Protection Agency.

5.3.4 Flame Photometric Detector.

5.3.4.1 Electrometer. Capable of full scale amplification of linear ranges of 10⁻⁶ to 10⁻⁴ amperes full scale.

5.3.4.2 Power Supply. Capable of delivering up to 750 volts.

5.3.4.3 Recorder. Compatible with the output voltage range of the electrometer.

5.4 Gas Chromatograph Columns. The column system must be demonstrated to be capable of resolving the four major reduced sulfur compounds: H₂S, MeSH, DMS, and DMDS. It must also demonstrate freedom from known interferences.

To demonstrate that adequate resolution has been achieved, the tester must submit a chromatograph of a calibration gas containing all four of the TRS compounds in the concentration range of the applicable standard. Adequate resolution will be defined as base line separation of adjacent peaks when the amplifier attenuation is set so that the smaller peak is at least 50 percent of full scale. Base line separation is defined in Section 3.4. Systems not meeting this criteria may be considered alternate methods subject to the approval of the Administrator.

5.5 Calibration System. The calibration system must contain the following components:

5.5.1 Tube Chamber. Chamber of glass or Teflon of sufficient dimensions to house permeation tubes.

5.5.2 Flow System. To measure air flow over permeation tubes at ± 2 percent. Each flowmeter shall be calibrated after a complete test series with a wet test meter. If the flow measuring device differs from the wet test meter by 5 percent, the completed test shall be discarded. Alternatively, the tester may elect to use the flow data that would yield the lowest flow measurement. Calibration with a wet test meter before a test is optional.

5.5.3 Constant Temperature Bath. Device capable of maintaining the permeation tubes at the calibration temperature within $\pm 0.1^\circ$ C.

5.5.4 Temperature Gauge. Thermometer or equivalent to monitor bath temperature within $\pm 1^\circ$ C.

6. Reagents.

6.1 Fuel. Hydrogen (H₂) prepurified grade or better.

6.2 Combustion Gas. Oxygen (O₂) or air, research purity or better.

6.3 Carrier Gas. Prepurified grade or better.

6.4 Diluent. Air containing less than 50 ppb total sulfur compounds and less than 10 ppm each of moisture and total hydrocarbons. This gas must be heated prior to mixing with the sample to avoid water condensation at the point of contact.

6.5 Calibration Gases. Permeation tubes, one each of H₂S, MeSH, DMS, and DMDS, gravimetrically calibrated and certified at some convenient operating temperature. These tubes consist of hermetically sealed FEP Teflon tubing in which a liquified gaseous substance is enclosed. The enclosed gas permeates through the tubing wall at a constant rate. When the temperature is constant, calibration gases covering a wide range of known concentrations can be generated by varying and accurately measuring the flow rate of diluent gas passing over the tubes. These calibration gases are used to calibrate the GC/FPD system and the dilution system.

7. Pretest Procedures. The following procedures are optional but would be helpful in preventing any problem which might occur later and invalidate the entire test.

RULES AND REGULATIONS

7.1 After the complete measurement system has been set up at the site and deemed to be operational, the following procedures should be completed before sampling is initiated.

7.1.1 Leak Test. Appropriate leak test procedures should be employed to verify the integrity of all components, sample lines, and connections. The following leak test procedure is suggested: For components upstream of the sample pump, attach the probe end of the sample line to a manometer or vacuum gauge, start the pump and pull greater than 50 mm (2 in.) Hg vacuum, close off the pump outlet, and then stop the pump and ascertain that there is no leak for 1 minute. For components after the pump, apply a slight positive pressure and check for leaks by applying a liquid (detergent in water, for example) at each joint. Bubbling indicates the presence of a leak.

7.1.2 System Performance. Since the complete system is calibrated following each test, the precise calibration of each component is not critical. However, these components should be verified to be operating properly. This verification can be performed by observing the response of flowmeters or of the GC output to changes in flow rates or calibration gas concentrations and ascertaining the response to be within predicted limits. In any component, or if the complete system fails to respond in a normal and predictable manner, the source of the discrepancy should be identified and corrected before proceeding.

8. Calibration. Prior to any sampling run, calibrate the system using the following procedures. (If more than one run is performed during any 24-hour period, a calibration need not be performed prior to the second and any subsequent runs. The calibration must, however, be verified as prescribed in Section 10, after the last run made within the 24-hour period.)

8.1 General Considerations. This section outlines steps to be followed for use of the GC/FPD and the dilution system. The procedure does not include detailed instructions because the operation of these systems is complex, and it requires a understanding of the individual system being used. Each system should include a written operating manual describing in detail the operating procedures associated with each component in the measurement system. In addition, the operator should be familiar with the operating principles of the components, particularly the GC/FPD. The citations in the Bibliography at the end of this method are recommended for review for this purpose.

8.2 Calibration Procedure. Insert the permeation tubes into the tube chamber. Check the bath temperature to assure agreement with the calibration temperature of the tubes within $\pm 0.1^\circ\text{C}$. Allow 24 hours for the tubes to equilibrate. Alternatively equilibration may be verified by injecting samples of calibration gas at 1-hour intervals. The permeation tubes can be assumed to have reached equilibrium when consecutive hourly samples agree within the precision limits of Section 4.1.

Vary the amount of air flowing over the tubes to produce the desired concentrations for calibrating the analytical and dilution systems. The air flow across the tubes must at all times exceed the flow requirement of the analytical systems. The concentration in parts per million generated by a tube containing a specific permeant can be calculated as follows:

$$C = K \frac{P}{L} \quad \text{Equation 16-1}$$

where:

C=Concentration of permeant produced in ppm.

P=Permeation rate of the tube in $\mu\text{g}/\text{min}$.
M=Molecular weight of the permeant (g/g-mole).

L=Flow rate, l/min, of air over permeant @ 20°C , 760 mm Hg.

K=Gas constant at 20°C and 760 mm Hg=24.04 l/g mole.

8.3 Calibration of analysis system. Generate a series of three or more known concentrations spanning the linear range of the FPD (approximately 0.05 to 1.0 ppm) for each of the four major sulfur compounds. Bypassing the dilution system, inject these standards into the GC/FPD analyzers and monitor the responses. Three injections for each concentration must yield the precision described in Section 4.1. Failure to attain this precision is an indication of a problem in the calibration or analytical system. Any such problem must be identified and corrected before proceeding.

8.4 Calibration Curves. Plot the GC/FPD response in current (amperes) versus their causative concentrations in ppm on log-log coordinate graph paper for each sulfur compound. Alternatively, a least squares equation may be generated from the calibration data.

8.5 Calibration of Dilution System. Generate a known concentration of hydrogen sulfide using the permeation tube system. Adjust the flow rate of diluent air for the first dilution stage so that the desired level of dilution is approximated. Inject the diluted calibration gas into the GC/FPD system and monitor its response. Three injections for each dilution must yield the precision described in Section 4.1. Failure to attain this precision in this step is an indication of a problem in the dilution system. Any such problem must be identified and corrected before proceeding. Using the calibration data for H_2S (developed under 8.3) determine the diluted calibration gas concentration in ppm. Then calculate the dilution factor as the ratio of the calibration gas concentration before dilution to the diluted calibration gas concentration determined under this paragraph. Repeat this procedure for each stage of dilution required. Alternatively, the GC/FPD system may be calibrated by generating a series of three or more concentrations of each sulfur compound and diluting these samples before injecting them into the GC/FPD system. This data will then serve as the calibration data for the unknown samples and a separate determination of the dilution factor will not be necessary. However, the precision requirements of Section 4.1 are still applicable.

9. Sampling and Analysis Procedure.

9.1 Sampling. Insert the sampling probe into the test port making certain that no dilution air enters the stack through the port. Begin sampling and dilute the sample approximately 9:1 using the dilution system. Note that the precise dilution factor is that which is determined in paragraph 8.5. Condition the entire system with sample for a minimum of 15 minutes prior to commencing analysis.

9.2 Analysis. Aliquots of diluted sample are injected into the GC/FPD analyzer for analysis.

9.2.1 Sample Run. A sample run is composed of 16 individual analyses (injects) performed over a period of not less than 3 hours or more than 6 hours.

9.2.2 Observation for Clogging of Probe. If reductions in sample concentrations are observed during a sample run that cannot be explained by process conditions, the sampling must be interrupted to determine if the sample probe is clogged with particulate matter. If the probe is found to be clogged, the test must be stopped and the results up to that point discarded. Testing may resume after cleaning the probe or replacing it with a clean one. After each run, the sample probe must be inspected and, if necessary, dismantled and cleaned.

10. Post-Test Procedures.

10.1 Sample Line Loss. A known concentration of hydrogen sulfide at the level of the applicable standard, ± 20 percent, must be introduced into the sampling system at the opening of the probe in sufficient quantities to insure that there is an excess of sample which must be vented to the atmosphere. The sample must be transported through the entire sampling system to the measurement system in the normal manner. The resulting measured concentration should be compared to the known value to determine the sampling system loss. A sampling system loss of more than 20 percent is unacceptable. Sampling losses of 0-20 percent must be corrected for by dividing the resulting sample concentration by the fraction of recovery. The known gas sample may be generated using permeation tubes. Alternatively, cylinders of hydrogen sulfide mixed in air may be used provided they are traceable to permeation tubes. The optional pretest procedures provide a good guideline for determining if there are leaks in the sampling system.

10.2 Recalibration. After each run, or after a series of runs made within a 24-hour period, perform a partial recalibration using the procedures in Section 8. Only H_2S (or other permeant) need be used to recalibrate the GC/FPD analysis system (8.3) and the dilution system (8.5).

10.3 Determination of Calibration Drift. Compare the calibration curves obtained prior to the runs, to the calibration curves obtained under paragraph 10.1. The calibration drift should not exceed the limits set forth in paragraph 4.2. If the drift exceeds this limit, the intervening run or runs should be considered not valid. The tester, however, may instead have the option of choosing the calibration data set which would give the highest sample values.

11. Calculations.

11.1 Determine the concentrations of each reduced sulfur compound detected directly from the calibration curves. Alternatively, the concentrations may be calculated using the equation for the least square line.

11.2 Calculation of TRS. Total reduced sulfur will be determined for each analysis made by summing the concentrations of each reduced sulfur compound resolved during a given analysis.

$$\text{TRS} = \text{I} (\text{H}_2\text{S}, \text{MeSH}, \text{DMS}, 2\text{DMDS})\text{d}$$

Equation 16-2

where:

TRS=Total reduced sulfur in ppm, wet basis.

H_2S =Hydrogen sulfide, ppm.

MeSH=Methyl mercaptan, ppm.

DMS=Dimethyl sulfide, ppm.

DMDS=Dimethyl disulfide, ppm.

d=Dilution factor, dimensionless.

RULES AND REGULATIONS

11.3 Average TRS. The average TRS will be determined as follows:

$$\text{Average TRS} = \frac{\sum_{i=1}^N \text{TRS}_i}{N(1-B_{wo})}$$

Average TRS = Average total reduced sulfur in ppm, dry basis.

TRS_i = Total reduced sulfur in ppm as determined by Equation 16-2.

N = Number of samples.

B_{wo} = Fraction of volume of water vapor in the gas stream as determined by method 4—Determination of Moisture in Stack Gases (36 FR 24887).

11.4 Average concentration of individual reduced sulfur compounds.

$$C = \frac{\sum_{i=1}^N S_i}{N}$$

Equation 16-3

where:

S_i = Concentration of any reduced sulfur compound from the *i*th sample injection, ppm.

C = Average concentration of any one of the reduced sulfur compounds for the entire run, ppm.

N = Number of injections in any run period.

12. Example System. Described below is a system utilized by EPA in gathering NSPS data. This system does not now reflect all the latest developments in equipment and column technology, but it does represent one system that has been demonstrated to work.

12.1 Apparatus.

12.1.1 Sampling System.

12.1.1.1 Probe. Figure 16-1 illustrates the probe used in lime kilns and other sources where significant amounts of particulate matter are present. The probe is designed with the deflector shield placed between the sample and the gas inlet holes and the glass wool plugs to reduce clogging of the filter and possible adsorption of sample gas. The exposed portion of the probe between the sampling port and the sample line is heated with heating tape.

12.1.1.2 Sample Line. 1/4 inch inside diameter Teflon tubing, heated to 120° C. This temperature is controlled by a thermostatic heater.

12.1.1.3 Sample Pump. Leakless Teflon coated diaphragm type or equivalent. The pump head is heated to 120° C by enclosing it in the sample dilution box (12.2.4 below).

12.1.2 Dilution System. A schematic diagram of the dynamic dilution system is given in Figure 16-2. The dilution system is constructed such that all sample contacts are made of inert materials. The dilution system which is heated to 120° C must be capable of a minimum of 9:1 dilution of sample. Equipment used in the dilution system is listed below:

12.1.2.1 Dilution Pump. Model A-150 Kohmyhr Teflon positive displacement type, nonadjustable 150 cc/min. ±2.0 percent, or equivalent, per dilution stage. A 9:1 dilution of sample is accomplished by com-

binning 150 cc of sample with 1,350 cc of clean dry air as shown in Figure 16-2.

12.1.2.2 Valves. Three-way Teflon solenoid or manual type.

12.1.2.3 Tubing. Teflon tubing and fittings are used throughout from the sample probe to the GC/FPD to present an inert surface for sample gas.

12.1.2.4 Box. Insulated box, heated and maintained at 120° C, of sufficient dimensions to house dilution apparatus.

12.1.2.5 Flowmeters. Rotameters or equivalent to measure flow from 0 to 1500 ml/min ±1 percent per dilution stage.

12.1.3 Gas Chromatograph Columns. Two types of columns are used for separation of low and high molecular weight sulfur compounds:

12.1.3.1 Low Molecular Weight Sulfur Compounds Column (GC/FPD-I).

12.1.3.1 Separation Column. 11 m by 2.16 mm (36 ft by 0.085 in) inside diameter Teflon tubing packed with 30/60 mesh Teflon coated with 5 percent polyphenyl ether and 0.05 percent orthophosphoric acid, or equivalent (see Figure 16-3).

12.1.3.1.2 Stripper or Precolumn. 0.6 m by 2.16 mm (2 ft by 0.085 in) inside diameter Teflon tubing packed as in 5.3.1.

12.1.3.1.3 Sample Valve. Teflon 10-port gas sampling valve, equipped with a 10 ml sample loop, actuated by compressed air (Figure 16-3).

12.1.3.1.4 Oven. For containing sample valve, stripper column and separation column. The oven should be capable of maintaining an elevated temperature ranging from ambient to 100° C, constant within ±1° C.

12.1.3.1.5 Temperature Monitor. Thermocouple pyrometer to measure column oven, detector, and exhaust temperature ±1° C.

12.1.3.1.6 Flow System. Gas metering system to measure sample flow, hydrogen flow, and oxygen flow (and nitrogen carrier gas flow).

12.1.3.1.7 Detector. Flame photometric detector.

12.1.3.1.8 Electrometer. Capable of full scale amplification of linear ranges of 10⁻⁹ to 10⁻⁴ amperes full scale.

12.1.3.1.9 Power Supply. Capable of delivering up to 750 volts.

12.1.3.1.10 Recorder. Compatible with the output voltage range of the electrometer.

12.1.3.2 High Molecular Weight Compounds Column (GC/FPD-II).

12.1.3.2.1 Separation Column. 3.05 m by 2.16 mm (10 ft by 0.085 in) inside diameter Teflon tubing packed with 30/60 mesh Teflon coated with 10 percent Triton X-305, or equivalent.

12.1.3.2.2 Sample Valve. Teflon 6-port gas sampling valve equipped with a 10 ml sample loop, actuated by compressed air (Figure 16-3).

12.1.3.2.3 Other Components. All components same as in 12.1.3.1.4 to 12.1.3.1.10.

12.1.4 Calibration. Permeation tube system (figure 16-4).

12.1.4.1 Tube Chamber. Glass chamber of sufficient dimensions to house permeation tubes.

12.1.4.2 Mass Flowmeters. Two mass flowmeters in the range 0-3 l/min. and 0-10 l/min. to measure air flow over permeation tubes at ±2 percent. These flowmeters shall be cross-calibrated at the beginning of each test. Using a convenient flow rate in the measuring range of both flowmeters, set and monitor the flow rate of gas over the permeation tubes. Injection of calibration

gas generated at this flow rate as measured by one flowmeter followed by injection of calibration gas at the same flow rate as measured by the other flowmeter should agree within the specified precision limits. If they do not, then there is a problem with the mass flow measurement. Each mass flowmeter shall be calibrated prior to the first test with a wet test meter and thereafter, at least once each year.

12.1.4.3 Constant Temperature Bath. Capable of maintaining permeation tubes at certification temperature of 30° C. within ±0.1° C.

12.2 Reagents

12.2.1 Fuel. Hydrogen (H₂) prepurified grade or better.

12.2.2 Combustion Gas. Oxygen (O₂) research purity or better.

12.2.3 Carrier Gas. Nitrogen (N₂) prepurified grade or better.

12.2.4 Diluent. Air containing less than 50 ppb total sulfur compounds and less than 10 ppm each of moisture and total hydrocarbons, and filtered using MSA filters 46727 and 79030, or equivalent. Removal of sulfur compounds can be verified by injecting dilution air only, described in Section 8.3.

12.2.5 Compressed Air. 60 psig for GC valve actuation.

12.2.6 Calibrated Gases. Permeation tubes gravimetrically calibrated and certified at 30.0° C.

12.3 Operating Parameters.

12.3.1 Low-Molecular Weight Sulfur Compounds. The operating parameters for the GC/FPD system used for low molecular weight compounds are as follows: nitrogen carrier gas flow rate of 50 cc/min, exhaust temperature of 110° C, detector temperature of 105° C, oven temperature of 40° C, hydrogen flow rate of 80 cc/min, oxygen flow rate of 20 cc/min, and sample flow rate between 20 and 80 cc/min.

12.3.2 High-Molecular Weight Sulfur Compounds. The operating parameters for the GC/FPD system for high molecular weight compounds are the same as in 12.3.1 except: oven temperature of 70° C, and nitrogen carrier gas flow of 100 cc/min.

12.4 Analysis Procedure.

12.4.1 Analysis. Aliquots of diluted sample are injected simultaneously into both GC/FPD analyzers for analysis. GC/FPD-I is used to measure the low-molecular weight reduced sulfur compounds. The low molecular weight compounds include hydrogen sulfide, methyl mercaptan, and dimethyl sulfide. GC/FPD-II is used to resolve the high-molecular weight compound. The high-molecular weight compound is dimethyl disulfide.

12.4.1.1 Analysis of Low-Molecular Weight Sulfur Compounds. The sample valve is actuated for 3 minutes in which time an aliquot of diluted sample is injected into the stripper column and analytical column. The valve is then deactivated for approximately 12 minutes in which time, the analytical column continues to be flushed, the stripper column is backflushed, and the sample loop is refilled. Monitor the responses. The elution time for each compound will be determined during calibration.

12.4.1.2 Analysis of High-Molecular Weight Sulfur Compounds. The procedure is essentially the same as above except that no stripper column is needed.

METHOD 17. DETERMINATION OF PARTICULATE EMISSIONS FROM STATIONARY SOURCES (IN-STACK FILTRATION METHOD)

Introduction

Particulate matter is not an absolute quantity; rather, it is a function of temperature and pressure. Therefore, to prevent variability in particulate matter emission regulations and/or associated test methods, the temperature and pressure at which particulate matter is to be measured must be carefully defined. Of the two variables (i.e., temperature and pressure), temperature has the greater effect upon the amount of particulate matter in an effluent gas stream; in most stationary source categories, the effect of pressure appears to be negligible.

In method 5, 250° F is established as a nominal reference temperature. Thus, where Method 5 is specified in an applicable subpart of the standards, particulate matter is defined with respect to temperature. In order to maintain a collection temperature of 250° F, Method 5 employs a heated glass

sample probe and a heated filter holder. This equipment is somewhat cumbersome and requires care in its operation. Therefore, where particulate matter concentrations (over the normal range of temperature associated with a specified source category) are known to be independent of temperature, it is desirable to eliminate the glass probe and heating systems, and sample at stack temperature.

This method describes an in-stack sampling system and sampling procedures for use in such cases. It is intended to be used only when specified by an applicable subpart of the standards, and only within the applicable temperature limits (if specified), or when otherwise approved by the Administrator.

1. Principle and Applicability.

1.1 Principle. Particulate matter is withdrawn isokinetically from the source and collected on a glass fiber filter maintained at stack temperature. The particulate mass is determined gravimetrically after removal of uncombined water.

1.2 Applicability. This method applies to the determination of particulate emissions from stationary sources for determining compliance with new source performance standards, only when specifically provided for in an applicable subpart of the standards. This method is not applicable to stacks that contain liquid droplets or are saturated with water vapor. In addition, this method shall not be used as written if the projected cross-sectional area of the probe extension-filter holder assembly covers more than 5 percent of the stack cross-sectional area (see Section 4.1.2).

2. Apparatus.

2.1 Sampling Train. A schematic of the sampling train used in this method is shown in Figure 17-1. Construction details for many, but not all, of the train components are given in APTD-0581 (Citation 2 in Section 7); for changes from the APTD-0581 document and for allowable modifications to Figure 17-1, consult with the Administrator.

Figure 17-1. Particulate-Sampling Train, Equipped with In-Stack Filter.

RULES AND REGULATIONS

The operating and maintenance procedures for many of the sampling train components are described in APTD-0576 (Citation 3 in Section 7). Since correct usage is important in obtaining valid results, all users should read the APTD-0576 document and adopt the operating and maintenance procedures outlined in it, unless otherwise specified herein. The sampling train consists of the following components:

2.1.1 Probe Nozzle. Stainless steel (316) or glass, with sharp, tapered leading edge. The angle of taper shall be 030° and the taper shall be on the outside to preserve a constant internal diameter. The probe nozzle shall be of the button-hook or elbow design, unless otherwise specified by the Administrator. If made of stainless steel, the nozzle shall be constructed from seamless tubing. Other materials of construction may be used subject to the approval of the Administrator.

A range of sizes suitable for isokinetic sampling should be available, e.g., 0.32 to 1.27 cm ($\frac{1}{8}$ to $\frac{1}{2}$ in.)—or larger if higher volume sampling trains are used—inside diameter (ID) nozzles in increments of 0.16 cm ($\frac{1}{16}$ in.). Each nozzle shall be calibrated according to the procedures outlined in Section 5.1.

2.1.2 Filter Holder. The in-stack filter holder shall be constructed of borosilicate or quartz glass, or stainless steel; if a gasket is used, it shall be made of silicone rubber, Teflon, or stainless steel. Other holder and gasket materials may be used subject to the approval of the Administrator. The filter holder shall be designed to provide a positive seal against leakage from the outside or around the filter.

2.1.3 Probe Extension. Any suitable rigid probe extension may be used after the filter holder.

2.1.4 Pitot Tube. Type S, as described in Section 2.1 of Method 2, or other device approved by the Administrator; the pitot tube shall be attached to the probe extension to allow constant monitoring of the stack gas velocity (see Figure 17-1). The impact (high pressure) opening plane of the pitot tube shall be even with or above the nozzle entry plane during sampling (see Method 2, Figure 2-6b). It is recommended: (1) that the pitot tube have a known baseline coefficient, determined as outlined in Section 4 of Method 2; and (2) that this known coefficient be preserved by placing the pitot tube in an interference-free arrangement with respect to the sampling nozzle, filter holder, and temperature sensor (see Figure 17-1). Note that the 1.9 cm (0.75 in) free-space between the nozzle and pitot tube shown in Figure 17-1, is based on a 1.3 cm (0.5 in) ID nozzle. If the sampling train is designed for sampling at higher flow rates than that described in APTD-0581, thus necessitating the use of larger sized nozzles, the free-space shall be 1.9 cm (0.75 in) with the largest sized nozzle in place.

Source-sampling assemblies that do not meet the minimum spacing requirements of Figure 17-1 (or the equivalent of these requirements, e.g., Figure 2-7 of Method 2) may be used; however, the pitot tube coefficients of such assemblies shall be determined by calibration, using methods subject to the approval of the Administrator.

2.1.5 Differential Pressure Gauge. Inclined manometer or equivalent device (two), as described in Section 2.2 of Method 2. One manometer shall be used for velocity head (Δp) readings, and the other, for orifice differential pressure readings.

2.1.6 Condenser. It is recommended that the impinger system described in Method 5 be used to determine the moisture content of the stack gas. Alternatively, any system that allows measurement of both the water condensed and the moisture leaving the condenser, each to within 1 ml or 1 g, may be used. The moisture leaving the condenser can be measured either by: (1) monitoring the temperature and pressure at the exit of the condenser and using Dalton's law of partial pressures; or (2) passing the sample gas stream through a silica gel trap with exit gases kept below 20° C (68° F) and determining the weight gain.

Flexible tubing may be used between the probe extension and condenser. If means other than silica gel are used to determine the amount of moisture leaving the condenser, it is recommended that silica gel still be used between the condenser system and pump to prevent moisture condensation in the pump and metering devices and to avoid the need to make corrections for moisture in the metered volume.

2.1.7 Metering System. Vacuum gauge, leak-free pump, thermometers capable of measuring temperature to within 3° C (5.4° F), dry gas meter capable of measuring volume to within 2 percent, and related equipment, as shown in Figure 17-1. Other metering systems capable of maintaining sampling rates within 10 percent of isokinetic and of determining sample volumes to within 2 percent may be used, subject to the approval of the Administrator. When the metering system is used in conjunction with a pitot tube, the system shall enable checks of isokinetic rates.

Sampling trains utilizing metering systems designed for higher flow rates than that described in APTD-0581 or APTD-0576 may be used provided that the specifications of this method are met.

2.1.8 Barometer. Mercury, aneroid, or other barometer capable of measuring atmospheric pressure to within 2.5 mm Hg (0.1 in. Hg). In many cases, the barometric reading may be obtained from a nearby national weather service station, in which case the station value (which is the absolute barometric pressure) shall be requested and an adjustment for elevation differences between the weather station and sampling point shall be applied at a rate of minus 2.5 mm Hg (0.1 in. Hg) per 30 m (100 ft) elevation increase or vice versa for elevation decrease.

2.1.9 Gas Density Determination Equipment. Temperature sensor and pressure gauge, as described in Sections 2.3 and 2.4 of Method 2, and gas analyzer, if necessary, as described in Method 3.

The temperature sensor shall be attached to either the pitot tube or to the probe extension, in a fixed configuration. If the temperature sensor is attached in the field; the sensor shall be placed in an interference-free arrangement with respect to the Type S pitot tube openings (as shown in Figure 17-1 or in Figure 2-7 of Method 2). Alternatively, the temperature sensor need not be attached to either the probe extension or pitot tube during sampling, provided that a difference of not more than 1 percent in the average velocity measurement is introduced. This alternative is subject to the approval of the Administrator.

2.2 Sample Recovery.

2.2.1 Probe Nozzle Brush. Nylon bristle brush with stainless steel wire handle. The brush shall be properly sized and shaped to brush out the probe nozzle.

2.2.2 Wash Bottles—Two. Glass wash bottles are recommended; polyethylene wash bottles may be used at the option of the tester. It is recommended that acetone not be stored in polyethylene bottles for longer than a month.

2.2.3 Glass Sample Storage Containers. Chemically resistant, borosilicate glass bottles, for acetone washes, 500 ml or 1000 ml. Screw cap liners shall either be rubber-backed Teflon or shall be constructed so as to be leak-free and resistant to chemical attack by acetone. (Narrow mouth glass bottles have been found to be less prone to leakage.) Alternatively, polyethylene bottles may be used.

2.2.4 Petri Dishes. For filter samples; glass or polyethylene, unless otherwise specified by the Administrator.

2.2.5 Graduated Cylinder and/or Balance. To measure condensed water to within 1 ml or 1 g. Graduated cylinders shall have subdivisions no greater than 2 ml. Most laboratory balances are capable of weighing to the nearest 0.5 g or less. Any of these balances is suitable for use here and in Section 2.3.4.

2.2.6 Plastic Storage Containers. Air tight containers to store silica gel.

2.2.7 Funnel and Rubber Policeman. To aid in transfer of silica gel to container; not necessary if silica gel is weighed in the field.

2.2.8 Funnel. Glass or polyethylene, to aid in sample recovery.

2.3 Analysis.

2.3.1 Glass Weighing Dishes.

2.3.2 Desiccator.

2.3.3 Analytical Balance. To measure to within 0.1 mg.

2.3.4 Balance. To measure to within 0.5 mg.

2.3.5 Beakers. 250 ml.

2.3.6 Hygrometer. To measure the relative humidity of the laboratory environment.

2.3.7 Temperature Gauge. To measure the temperature of the laboratory environment.

3. Reagents.

3.1 Sampling.

3.1.1 Filters. The in-stack filters shall be glass mats or thimble fiber filters, without organic binders, and shall exhibit at least 99.95 percent efficiency (00.05 percent penetration) on 0.3 micron dioctyl phthalate smoke particles. The filter efficiency tests shall be conducted in accordance with ASTM standard method D 2986-71. Test data from the supplier's quality control program are sufficient for this purpose.

3.1.2 Silica Gel. Indicating type; 6- to 16-mesh. If previously used, dry at 175° C (350° F) for 2 hours. New silica gel may be used as received. Alternatively, other types of desiccants (equivalent or better) may be used, subject to the approval of the Administrator.

3.1.3 Crushed Ice.

3.1.4 Stopcock Grease. Acetone-insoluble, heat-stable silicone grease. This is not necessary if screw-on connectors with Teflon sleeves, or similar, are used. Alternatively, other types of stopcock grease may be used, subject to the approval of the Administrator.

3.2 Sample Recovery. Acetone, reagent grade, 00.001 percent residue, in glass bottles. Acetone from metal containers generally has a high residue blank and should not be used. Sometimes, suppliers transfer acetone to glass bottles from metal containers. Thus, acetone blanks shall be run prior to field use and only acetone with low blank

RULES AND REGULATIONS

values (00.001 percent) shall be used. In no case shall a blank value of greater than 0.001 percent of the weight of acetone used be subtracted from the sample weight.

3.3 Analysis.

3.3.1 Acetone. Same as 3.2.

3.3.2 Desiccant. Anhydrous calcium sulfate, indicating type. Alternatively, other types of desiccants may be used, subject to the approval of the Administrator.

4. Procedure.

4.1 Sampling. The complexity of this method is such that, in order to obtain reliable results, testers should be trained and experienced with the test procedures.

4.1.1 Pretest Preparation. All components shall be maintained and calibrated according to the procedure described in APTD-0576, unless otherwise specified herein.

Weigh several 200 to 300 g portions of silica gel in air-tight containers to the nearest 0.5 g. Record the total weight of the silica gel plus container, on each container. As an alternative, the silica gel need not be preweighed, but may be weighed directly in its impinger or sampling holder just prior to train assembly.

Check filters visually against light for irregularities and flaws or pinhole leaks. Label filters of the proper size on the back side near the edge using numbering machine ink. As an alternative, label the shipping containers (glass or plastic petri dishes) and keep the filters in these containers at all times except during sampling and weighing.

Desiccate the filters at $20 \pm 5.6^\circ \text{C}$ ($68 \pm 10^\circ \text{F}$) and ambient pressure for at least 24 hours and weigh at intervals of at least 6 hours to a constant weight, i.e., 00.5 mg change from previous weighing; record results to the nearest 0.1 mg. During each weighing the filter must not be exposed to the laboratory atmosphere for a period greater than 2 minutes and a relative humidity above 50 percent. Alternatively (unless otherwise specified by the Administrator), the filters may be oven dried at 105°C (220°F) for 2 to 3 hours, desiccated for 2 hours, and weighed. Procedures other than those described, which account for relative humidity effects, may be used, subject to the approval of the Administrator.

4.1.2 Preliminary Determinations. Select the sampling site and the minimum number of sampling points according to Method 1 or as specified by the Administrator. Make a

projected-area model of the probe extension-filter holder assembly, with the pitot tube face openings positioned along the centerline of the stack, as shown in Figure 17-2. Calculate the estimated cross-section blockage, as shown in Figure 17-2. If the blockage exceeds 5 percent of the duct cross sectional area, the tester has the following options: (1) a suitable out-of-stack filtration method may be used instead of in-stack filtration; or (2) a special in-stack arrangement, in which the sampling and velocity measurement sites are separate, may be used; for details concerning this approach, consult with the Administrator (see also Citation 10 in Section 7). Determine the stack pressure, temperature, and the range of velocity heads using Method 2; it is recommended that a leak-check of the pitot lines (see Method 2, Section 3.1) be performed. Determine the moisture content using Approximation Method 4 or its alternatives for the purpose of making isokinetic sampling rate settings. Determine the stack gas dry molecular weight, as described in Method 2, Section 3.6; if integrated Method 3 sampling is used for molecular weight determination, the integrated bag sample shall be taken simultaneously with, and for the same total length of time as, the particular sample run.

RULES AND REGULATIONS

$$\text{ESTIMATED BLOCKAGE (\%)} = \left[\frac{\text{SHADED AREA}}{\text{DUCT AREA}} \right] \times 100$$

Figure 17-2. Projected-area model of cross-section blockage (approximate average for a sample traverse) caused by an in-stack filter holder-probe extension assembly.

RULES AND REGULATIONS

Select a nozzle size based on the range of velocity heads, such that it is not necessary to change the nozzle size in order to maintain isokinetic sampling rates. During the run, do not change the nozzle size. Ensure that the proper differential pressure gauge is chosen for the range of velocity heads encountered (see Section 2.2 of Method 2).

Select a probe extension length such that all traverse points can be sampled. For large stacks, consider sampling from opposite sides of the stack to reduce the length of probes.

Select a total sampling time greater than or equal to the minimum total sampling time specified in the test procedures for the specific industry such that (1) the sampling time per point is not less than 2 minutes (or some greater time interval if specified by the Administrator), and (2) the sample volume taken (corrected to standard conditions) will exceed the required minimum total gas sample volume. The latter is based on an approximate average sampling rate.

It is recommended that the number of minutes sampled at each point be an integer or an integer plus one-half minute, in order to avoid timekeeping errors.

In some circumstances, e.g., batch cycles, it may be necessary to sample for shorter times at the traverse points and to obtain smaller gas sample volumes. In these cases, the Administrator's approval must first be obtained.

4.1.3 Preparation of Collection Train. During preparation and assembly of the sampling train, keep all openings where contamination can occur covered until just prior to assembly or until sampling is about to begin.

If impingers are used to condense stack gas moisture, prepare them as follows: place 100 ml of water in each of the first two impingers, leave the third impinger empty, and transfer approximately 200 to 300 g of preweighed silica gel from its container to the fourth impinger. More silica gel may be used, but care should be taken to ensure that it is not entrained and carried out from the impinger during sampling. Place the container in a clean place for later use in the sample recovery. Alternatively, the weight of the silica gel plus impinger may be determined to the nearest 0.5 g and recorded.

If some means other than impingers is used to condense moisture, prepare the condenser (and, if appropriate, silica gel for condenser outlet) for use.

Using a tweezer or clean disposable surgical gloves, place a labeled (identified) and

weighed filter in the filter holder. Be sure that the filter is properly centered and the gasket properly placed so as not to allow the sample gas stream to circumvent the filter. Check filter for tears after assembly is completed. Mark the probe extension with heat resistant tape or by some other method to denote the proper distance into the stack or duct for each sampling point.

Assemble the train as in Figure 17-1, using a very light coat of silicone grease on all ground glass joints and greasing only the outer portion (see APTD-0576) to avoid possibility of contamination by the silicone grease. Place crushed ice around the impingers.

4.1.4 Leak Check Procedures.

4.1.4.1 Pretest Leak-Check. A pretest leak-check is recommended, but not required. If the tester opts to conduct the pretest leak-check, the following procedure shall be used.

After the sampling train has been assembled, plug the inlet to the probe nozzle with a material that will be able to withstand the stack temperature. Insert the filter holder into the stack and wait approximately 5 minutes (or longer, if necessary) to allow the system to come to equilibrium with the temperature of the stack gas stream. Turn on the pump and draw a vacuum of at least 380 mm Hg (15 in. Hg); note that a lower vacuum may be used, provided that it is not exceeded during the test. Determine the leakage rate. A leakage rate in excess of 4 percent of the average sampling rate or 0.00057 m³/min. (0.02 cfm), whichever is less, is unacceptable.

The following leak-check instructions for the sampling train described in APTD-0576 and APTD-0581 may be helpful. Start the pump with by-pass valve fully open and coarse adjust valve completely closed. Partially open the coarse adjust valve and slowly close the by-pass valve until the desired vacuum is reached. Do not reverse direction of by-pass valve. If the desired vacuum is exceeded, either leak-check at this higher vacuum or end the leak-check as shown below and start over.

When the leak-check is completed, first slowly remove the plug from the inlet to the probe nozzle and immediately turn off the vacuum pump. This prevents water from being forced backward and keeps silica gel from being entrained backward.

4.1.4.2 Leak-Checks During Sample Run. If, during the sampling run, a component (e.g., filter assembly or impinger) change becomes necessary, a leak-check shall be conducted immediately before the change is

made. The leak-check shall be done according to the procedure outlined in Section 4.1.4.1 above, except that it shall be done at a vacuum equal to or greater than the maximum value recorded up to that point in the test. If the leakage rate is found to be no greater than 0.00057 m³/min (0.02 cfm) or 4 percent of the average sampling rate (whichever is less), the results are acceptable, and no correction will need to be applied to the total volume of dry gas metered; if, however, a higher leakage rate is obtained, the tester shall either record the leakage rate and plan to correct the sample volume as shown in Section 6.3 of this method, or shall void the sampling run.

Immediately after component changes, leak-checks are optional; if such leak-checks are done, the procedure outlined in Section 4.1.4.1 above shall be used.

4.1.4.3 Post-Test Leak-Check. A leak-check is mandatory at the conclusion of each sampling run. The leak-check shall be done in accordance with the procedures outlined in Section 4.1.4.1, except that it shall be conducted at a vacuum equal to or greater than the maximum value reached during the sampling run. If the leakage rate is found to be no greater than 0.00057 m³/min (0.02 cfm) or 4 percent of the average sampling rate (whichever is less), the results are acceptable, and no correction need be applied to the total volume of dry gas metered. If, however, a higher leakage rate is obtained, the tester shall either record the leakage rate and correct the sample volume as shown in Section 6.3 of this method, or shall void the sampling run.

4.1.5 Particulate Train Operation. During the sampling run, maintain a sampling rate such that sampling is within 10 percent of true isokinetic, unless otherwise specified by the Administrator.

For each run, record the data required on the example data sheet shown in Figure 17-3. Be sure to record the initial dry gas meter reading. Record the dry gas meter readings at the beginning and end of each sampling time increment, when changes in flow rates are made, before and after each leak check, and when sampling is halted. Take other readings required by Figure 17-3 at least once at each sample point during each time increment and additional readings when significant changes (20 percent variation in velocity head readings) necessitate additional adjustments in flow rate. Level and zero the manometer. Because the manometer level and zero may drift due to vibrations and temperature changes, make periodic checks during the traverse.

SCHEMATIC OF STACK CROSS SECTION

[illegible]

Figure 17-3. Particulate field data.

RULES AND REGULATIONS

RULES AND REGULATIONS

Clean the portholes prior to the test run to minimize the chance of sampling the deposited material. To begin sampling, remove the nozzle cap and verify that the pitot tube and probe extension are properly positioned. Position the nozzle at the first traverse point with the tip pointing directly into the gas stream. Immediately start the pump and adjust the flow to isokinetic conditions. Nomographs are available, which aid in the rapid adjustment to the isokinetic sampling rate without excessive computations. These nomographs are designed for use when the Type S pitot tube coefficient is 0.85 ± 0.02 , and the stack gas equivalent density (dry molecular weight) is equal to 29 ± 4 . APTD-0576 details the procedure for using the nomographs. If C_p and M_g are outside the above stated ranges, do not use the nomographs unless appropriate steps (see Citation 7 in Section 7) are taken to compensate for the deviations.

When the stack is under significant negative pressure (height of impinger stem), take care to close the coarse adjust valve before inserting the probe extension assembly into the stack to prevent water from being forced backward. If necessary, the pump may be turned on with the coarse adjust valve closed.

When the probe is in position, block off the openings around the probe and porthole to prevent unrepresentative dilution of the gas stream.

Traverse the stack cross section, as required by Method 1 or as specified by the Administrator, being careful not to bump the probe nozzle into the stack walls when sampling near the walls or when removing or inserting the probe extension through the portholes, to minimize chance of extracting deposited material.

During the test run, take appropriate steps (e.g., adding crushed ice to the impinger ice bath) to maintain a temperature of less than 20°C (68°F) at the condenser outlet; this will prevent excessive moisture losses. Also, periodically check the level and zero of the manometer.

If the pressure drop across the filter becomes too high, making isokinetic sampling difficult to maintain, the filter may be replaced in the midst of a sample run. It is recommended that another complete filter holder assembly be used rather than attempting to change the filter itself. Before a new filter holder is installed, conduct a leak check, as outlined in Section 4.1.4.2. The total particulate weight shall include the summation of all filter assembly catches.

A single train shall be used for the entire sample run, except in cases where simultaneous sampling is required in two or more separate ducts or at two or more different locations within the same duct, or, in cases where equipment failure necessitates a change of trains. In all other situations, the use of two or more trains will be subject to the approval of the Administrator. Note that when two or more trains are used, a separate analysis of the collected particulate from each train shall be performed, unless identical nozzle sizes were used on all trains, in which case the particulate catches from the individual trains may be combined and a single analysis performed.

At the end of the sample run, turn off the pump, remove the probe extension assembly from the stack, and record the final dry gas meter reading. Perform a leak-check, as outlined in Section 4.1.4.3. Also, leak-check the pitot lines as described in Section 3.1 of Method 2; the lines must pass this leak-

check, in order to validate the velocity head data.

4.1.6 Calculation of Percent Isokinetic. Calculate percent isokinetic (see Section 6.11) to determine whether another test run should be made. If there is difficulty in maintaining isokinetic rates due to source conditions, consult with the Administrator for possible variance on the isokinetic rates.

4.2 Sample Recovery. Proper cleanup procedure begins as soon as the probe extension assembly is removed from the stack at the end of the sampling period. Allow the assembly to cool.

When the assembly can be safely handled, wipe off all external particulate matter near the tip of the probe nozzle and place a cap over it to prevent losing or gaining particulate matter. Do not cap off the probe tip tightly while the sampling train is cooling down as this would create a vacuum in the filter holder, forcing condenser water backward.

Before moving the sample train to the cleanup site, disconnect the filter holder-probe nozzle assembly from the probe extension; cap the open inlet of the probe extension. Be careful not to lose any condensate, if present. Remove the umbilical cord from the condenser outlet and cap the outlet. If a flexible line is used between the first impinger (or condenser) and the probe extension, disconnect the line at the probe extension and let any condensed water or liquid drain into the impingers or condenser. Disconnect the probe extension from the condenser; cap the probe extension outlet. After wiping off the silicone grease, cap off the condenser inlet. Ground glass stoppers, plastic caps, or serum caps (whichever are appropriate) may be used to close these openings.

Transfer both the filter holder-probe nozzle assembly and the condenser to the cleanup area. This area should be clean and protected from the wind so that the chances of contaminating or losing the sample will be minimized.

Save a portion of the acetone used for cleanup as a blank. Take 200 ml of this acetone directly from the wash bottle being used and place it in a glass sample container labeled "acetone blank."

Inspect the train prior to and during disassembly and note any abnormal conditions. Treat the samples as follows:

Container No. 1. Carefully remove the filter from the filter holder and place it in its identified petri dish container. Use a pair of tweezers and/or clean disposable surgical gloves to handle the filter. If it is necessary to fold the filter, do so such that the particulate cake is inside the fold. Carefully transfer to the petri dish any particulate matter and/or filter fibers which adhere to the filter holder gasket, by using a dry Nylon bristle brush and/or a sharp-edged blade. Seal the container.

Container No. 2. Taking care to see that dust on the outside of the probe nozzle or other exterior surfaces does not get into the sample, quantitatively recover particulate matter or any condensate from the probe nozzle, fitting, and front half of the filter holder by washing these components with acetone and placing the wash in a glass container. Distilled water may be used instead of acetone when approved by the Administrator and shall be used when specified by the Administrator; in these cases, save a water blank and follow Administrator's directions on analysis. Perform the acetone rinses as follows:

Carefully remove the probe nozzle and clean the inside surface by rinsing with acetone from a wash bottle and brushing with a Nylon bristle brush. Brush until acetone rinse shows no visible particles, after which make a final rinse of the inside surface with acetone.

Brush and rinse with acetone the inside parts of the fitting in a similar way until no visible particles remain. A funnel (glass or polyethylene) may be used to aid in transferring liquid washes to the container. Rinse the brush with acetone and quantitatively collect these washings in the sample container. Between sampling runs, keep brushes clean and protected from contamination.

After ensuring that all joints are wiped clean of silicone grease (if applicable), clean the inside of the front half of the filter holder by rubbing the surfaces with a Nylon bristle brush and rinsing with acetone. Rinse each surface three times or more if needed to remove visible particulate. Make final rinse of the brush and filter holder. After all acetone washings and particulate matter are collected in the sample container, tighten the lid on the sample container so that acetone will not leak out when it is shipped to the laboratory. Mark the height of the fluid level to determine whether or not leakage occurred during transport. Label the container to clearly identify its contents.

Container No. 3. If silica gel is used in the condenser system for moisture content determination, note the color of the gel to determine if it has been completely spent; make a notation of its condition. Transfer the silica gel back to its original container and seal. A funnel may make it easier to pour the silica gel without spilling, and a rubber policeman may be used as an aid in removing the silica gel. It is not necessary to remove the small amount of dust particles that may adhere to the walls and are difficult to remove. Since the gain in weight is to be used for moisture calculations, do not use any water or other liquids to transfer the silica gel. If a balance is available in the field, follow the procedure for Container No. 3 under "Analysis."

Condenser Water. Treat the condenser or impinger water as follows: make a notation of any color or film in the liquid catch. Measure the liquid volume to within ± 1 ml by using a graduated cylinder or, if a balance is available, determine the liquid weight to within ± 0.5 g. Record the total volume or weight of liquid present. This information is required to calculate the moisture content of the effluent gas. Discard the liquid after measuring and recording the volume or weight.

4.3 Analysis. Record the data required on the example sheet shown in Figure 17-4. Handle each sample container as follows:

Container No. 1. Leave the contents in the shipping container or transfer the filter and any loose particulate from the sample container to a tared glass weighing dish. Desiccate for 24 hours in a desiccator containing anhydrous calcium sulfate. Weigh to a constant weight and report the results to the nearest 0.1 mg. For purposes of this Section, 4.3, the term "constant weight" means a difference of no more than 0.5 mg or 1 percent of total weight less tare weight, whichever is greater, between two consecutive weighings, with no less than 6 hours of desiccation time between weighings.

Alternatively, the sample may be oven dried at the average stack temperature or

RULES AND REGULATIONS

105° C (220° F), whichever is less, for 2 to 3 hours, cooled in the desiccator, and weighed to a constant weight, unless otherwise speci-

fied by the Administrator. The tester may also opt to oven dry the sample at the average stack temperature or 105° C (220° F),

whichever is less, for 2 to 3 hours, weigh the sample, and use this weight as a final weight.

Figure 17-4. Analytical data.

RULES AND REGULATIONS

Container No. 2. Note the level of liquid in the container and confirm on the analysis sheet whether or not leakage occurred during transport. If a noticeable amount of leakage has occurred, either void the sample or use methods, subject to the approval of the Administrator, to correct the final results. Measure the liquid in this container either volumetrically to ± 1 ml or gravimetrically to ± 0.5 g. Transfer the contents to a tared 250-ml beaker and evaporate to dryness at ambient temperature and pressure. Desiccate for 24 hours and weigh to a constant weight. Report the results to the nearest 0.1 mg.

Container No. 3. This step may be conducted in the field. Weigh the spent silica gel (or silica gel plus impinger) to the nearest 0.5 g using a balance.

"Acetone Blank" Container. Measure acetone in this container either volumetrically or gravimetrically. Transfer the acetone to a tared 250-ml beaker and evaporate to dryness at ambient temperature and pressure. Desiccate for 24 hours and weigh to a constant weight. Report the results to the nearest 0.1 mg.

NOTE.—At the option of the tester, the contents of Container No. 2 as well as the acetone blank container may be evaporated at temperatures higher than ambient. If evaporation is done at an elevated temperature, the temperature must be below the boiling point of the solvent; also, to prevent "bumping," the evaporation process must be closely supervised, and the contents of the beaker must be swirled occasionally to maintain an even temperature. Use extreme care, as acetone is highly flammable and has a low flash point.

5. Calibration. Maintain a laboratory log of all calibrations.

5.1 Probe Nozzle. Probe nozzles shall be calibrated before their initial use in the field. Using a micrometer, measure the inside diameter of the nozzle to the nearest

0.025 mm (0.001 in.). Make three separate measurements using different diameters each time, and obtain the average of the measurements. The difference between the high and low numbers shall not exceed 0.1 mm (0.004 in.). When nozzles become nicked, dented, or corroded, they shall be reshaped, sharpened, and recalibrated before use. Each nozzle shall be permanently and uniquely identified.

5.2 Pitot Tube. If the pitot tube is placed in an interference-free arrangement with respect to the other probe assembly components, its baseline (isolated tube) coefficient shall be determined as outlined in Section 4 of Method 2. If the probe assembly is not interference-free, the pitot tube assembly coefficient shall be determined by calibration, using methods subject to the approval of the Administrator.

5.3 Metering System. Before its initial use in the field, the metering system shall be calibrated according to the procedure outlined in APTD-0576. Instead of physically adjusting the dry gas meter dial readings to correspond to the wet test meter readings, calibration factors may be used to mathematically correct the gas meter dial readings to the proper values.

Before calibrating the metering system, it is suggested that a leak-check be conducted. For metering systems having diaphragm pumps, the normal leak-check procedure will not detect leakages within the pump. For these cases the following leak-check procedure is suggested: make a 10-minute calibration run at $0.00057 \text{ m}^3/\text{min}$ (0.02 cfm); at the end of the run, take the difference of the measured wet test meter and dry gas meter volumes; divide the difference by 10, to get the leak rate. The leak rate should not exceed $0.00057 \text{ m}^3/\text{min}$ (0.02 cfm).

After each field use, the calibration of the metering system shall be checked by performing three calibration runs at a single, intermediate orifice setting (based on the

previous field test), with the vacuum set at the maximum value reached during the test series. To adjust the vacuum, insert a valve between the wet test meter and the inlet of the metering system. Calculate the average value of the calibration factor. If the calibration has changed by more than 5 percent, recalibrate the meter over the full range of orifice settings, as outlined in APTD-0576.

Alternative procedures, e.g., using the orifice meter coefficients, may be used, subject to the approval of the Administrator.

NOTE.—If the dry gas meter coefficient values obtained before and after a test series differ by more than 5 percent, the test series shall either be voided, or calculations for the test series shall be performed using whichever meter coefficient value (i.e., before or after) gives the lower value of total sample volume.

5.4 Temperature Gauges. Use the procedure in Section 4.3 of Method 2 to calibrate in-stack temperature gauges. Dial thermometers, such as are used for the dry gas meter and condenser outlet, shall be calibrated against mercury-in-glass thermometers.

5.5 Leak Check of Metering System Shown in Figure 17-1. That portion of the sampling train from the pump to the orifice meter should be leak checked prior to initial use and after each shipment. Leakage after the pump will result in less volume being recorded than is actually sampled. The following procedure is suggested (see Figure 17-5). Close the main valve on the meter box. Insert a one-hole rubber stopper with rubber tubing attached into the orifice exhaust pipe. Disconnect and vent the low side of the orifice manometer. Close off the low side orifice tap. Pressurize the system to 13 to 18 cm (5 to 7 in.) water column by blowing into the rubber tubing. Pinch off the tubing and observe the manometer for one minute. A loss of pressure on the manometer indicates a leak in the meter box; leaks, if present, must be corrected.

Figure 17-5. Leak check of meter box.

RULES AND REGULATIONS

5.6 Barometer. Calibrate against a mercury barometer.

6. Calculations. Carry out calculations, retaining at least one extra decimal figure beyond that of the acquired data. Round off figures after the final calculation. Other forms of the equations may be used as long as they give equivalent results.

6.1 Nomenclature.

A_n = Cross-sectional area of nozzle, m^2 (ft^2).
 B_{ws} = Water vapor in the gas stream, proportion by volume.
 C_a = Acetone blank residue concentration, mg/g .
 c_p = Concentration of particulate matter in stack gas, dry basis, corrected to standard conditions, $g/dscm$ ($g/dscf$).
 I = Percent of isokinetic sampling.
 L_a = Maximum acceptable leakage rate for either a pretest leak check or for a leak check following a component change; equal to $0.00057 m^3/min$ ($0.02 cfm$) or 4 percent of the average sampling rate, whichever is less.
 L_o = Individual leakage rate observed during the leak check conducted prior to the "i" component change ($i = 1, 2, 3 \dots n$), m^3/min (cfm).
 L_p = Leakage rate observed during the post-test leak check, m^3/min (cfm).
 m_n = Total amount of particulate matter collected, mg .
 M_w = Molecular weight of water, $18.0 g/g\text{-mole}$ ($18.0 lb/lb\text{-mole}$).
 m_a = Mass of residue of acetone after evaporation, mg .
 P_{bar} = Barometric pressure at the sampling site, mm Hg ($in.$ Hg).
 P_s = Absolute stack gas pressure, mm Hg ($in.$ Hg).
 P_{std} = Standard absolute pressure, $760 mm$ Hg ($29.92 in.$ Hg).
 R = Ideal gas constant, $0.06236 mm$ Hg- $m^3/K\text{-g-mole}$ ($21.85 in.$ Hg- $ft^3/R\text{-lb-mole}$).
 T_m = Absolute average dry gas meter temperature (see Figure 17-3), $^{\circ}K$ ($^{\circ}R$).
 T_s = Absolute average stack gas temperature (see Figure 17-3), $^{\circ}K$ ($^{\circ}R$).
 T_{std} = Standard absolute temperature, $293^{\circ}K$ ($528^{\circ}R$).
 V_a = Volume of acetone blank, ml .
 V_{av} = Volume of acetone used in wash, ml .
 V_k = Total volume of liquid collected in impingers and silica gel (see Figure 17-4), ml .
 V_m = Volume of gas sample as measured by dry gas meter, dcm ($dscf$).
 $V_{m(std)}$ = Volume of gas sample measured by the dry gas meter, corrected to standard conditions, $dscm$ ($dscf$).
 $V_{w(std)}$ = Volume of water vapor in the gas sample, corrected to standard conditions, scm (scf).
 v_s = Stack gas velocity, calculated by Method 2, Equation 2-9, using data obtained from Method 17, m/sec (ft/sec).
 W_a = Weight of residue in acetone wash, mg .
 Y = Dry gas meter calibration coefficient.
 ΔH = Average pressure differential across the orifice meter (see Figure 17-3), mm H_2O ($in.$ H_2O).
 ρ_a = Density of acetone, mg/ml (see label on bottle).
 ρ_w = Density of water, $0.9982 g/ml$ ($0.002201 lb/ml$).
 θ = Total sampling time, min .
 θ_i = Sampling time interval, from the beginning of a run until the first component change, min .
 θ_{i+1} = Sampling time interval, between two successive component changes, beginning with the interval between the first and second changes, min .

θ_s = Sampling time interval, from the final (n) component change until the end of the sampling run, min .

13.6 = Specific gravity of mercury.

60 = Sec/min.

100 = Conversion to percent.

6.2 Average dry gas meter temperature and average orifice pressure drop. See data sheet (Figure 17-3).

6.3 Dry Gas Volume. Correct the sample volume measured by the dry gas meter to standard conditions ($20^{\circ} C$, $760 mm$ Hg or $68^{\circ} F$, $29.92 in.$ Hg) by using Equation 17-1.

$$V_{m(std)} = V_m Y \left(\frac{T_{std}}{T_m} \right) \left[\frac{P_{bar} + \frac{\Delta H}{13.6}}{P_{std}} \right]$$

$$= K_1 V_m Y \frac{P_{bar} + (\Delta H/13.6)}{T_m}$$

Equation 17-1

where:

$K_1 = 0.3858^{\circ} K/mm$ Hg for metric units;
 $17.64^{\circ} R/in.$ Hg for English units.

NOTE.—Equation 17-1 can be used as written unless the leakage rate observed during any of the mandatory leak checks (i.e., the post-test leak check or leak checks conducted prior to component changes) exceeds L_a . If L_o or L_p exceeds L_a , Equation 17-1 must be modified as follows:

(a) Case I. No component changes made during sampling run. In this case, replace V_m in Equation 17-1 with the expression:

$$[V_m - (L_o - L_a)\theta]$$

(b) Case II. One or more component changes made during the sampling run. In this case, replace V_m in Equation 17-1 by the expression:

$$[V_m - (L_1 - L_a)\theta_1 - \sum_{i=2}^n (L_i - L_a)\theta_i - (L_p - L_a)\theta_p]$$

and substitute only for those leakage rates (L_o or L_p) which exceed L_a .

6.4 Volume of water vapor.

$$V_{w(std)} = V_{lc} \left(\frac{\rho_w}{M_w} \right) \left(\frac{RT_{std}}{P_{std}} \right) = K_2 V_{lc}$$

Equation 17-2

where:

$K_2 = 0.001333 m^3/ml$ for metric units; $0.04707 ft^3/ml$ for English units.

6.5 Moisture Content.

$$B_{ws} = \frac{V_{w(std)}}{V_{m(std)} + V_{w(std)}}$$

Equation 17-3

6.6 Acetone Blank Concentration.

$$C_a = \frac{m_a}{V_a \rho_a}$$

Equation 17-4

6.7 Acetone Wash Blank.

$$W_a = C_a V_{av} \rho_a$$

Equation 17-5

6.8 Total Particulate Weight. Determine the total particulate catch from the sum of the weights obtained from containers 1 and 2 less the acetone blank (see Figure 17-4).

NOTE.—Refer to Section 4.1.5 to assist in calculation of results involving two or more filter assemblies or two or more sampling trains.

6.9 Particulate Concentration.

$$c_p = (0.001 g/mg) (m_n / V_{m(std)})$$

Equation 17-6

6.10 Conversion Factors:

From	To	Multiply by
scf	m^3	0.02832
g/ft^3	gr/ft^3	15.43
g/ft^3	lb/ft^3	2.205×10^{-3}
g/ft^3	g/m^3	35.31

6.11 Isokinetic Variation.

6.11.1 Calculation from Raw Data.

$$I = \frac{100 T_s [K_3 V_{lc} + (V_m Y / T_m) (P_{bar} + \Delta H/13.6)]}{60 v_s P_s A_n}$$

Equation 17-7

where:

$K_3 = 0.003454 mm$ Hg- $m^3/ml\text{-}^{\circ}K$ for metric units; $0.002669 in.$ Hg- $ft^3/ml\text{-}^{\circ}R$ for English units.

6.11.2 Calculation from Intermediate Values.

$$I = \frac{T_s V_{m(std)} P_{std} 100}{T_{std} v_s \theta A_n P_s 60 (1 - B_{ws})}$$

$$= K_4 \frac{T_s V_{m(std)}}{P_s v_s A_n \theta (1 - B_{ws})}$$

Equation 17-8

where:

$K_4 = 4.320$ for metric units; 0.09450 for English units.

6.12 Acceptable Results. If 90 percent 010110 percent, the results are acceptable. If the results are low in comparison to the standard and I is beyond the acceptable range, or if I is less than 90 percent, the Administrator may opt to accept the results. Use Citation 4 in Section 7 to make judgments. Otherwise, reject the results and repeat the test.

7. Bibliography.

RULES AND REGULATIONS

83

Title 40—Protection of Environment

[FRL 848-2]

CHAPTER I—ENVIRONMENTAL PROTECTION AGENCY

PART 60—STANDARDS OF PERFOR- MANCE FOR NEW STATIONARY SOURCES

PART 61—NATIONAL EMISSION STANDARDS FOR HAZARDOUS AIR POLLUTANTS

Revision of Authority Citations

AGENCY: Environmental Protection Agency (EPA).

ACTION: Final rule.

SUMMARY: This action amends the authority citations for Standards of Performance for New Stationary Sources and National Emission Standards for Hazardous Pollutants. The amendment adopts the redesignation of classification numbers as changed in the 1977 amendments to the Clean Air Act. As amended, the Act formerly classified to 42 U.S.C. 1857 et seq. has been transferred and is now classified to 42 U.S.C. 7401 et seq.

EFFECTIVE DATE: March 3, 1978.

FOR FURTHER INFORMATION CONTACT:

Don R. Goodwin, Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, N.C. 27711 telephone 919-541-5271.

SUPPLEMENTARY INFORMATION: This action is being taken in accordance with the requirements of 1 CFR 21.43 and is authorized under section 301(a) of the Clean Air Act, as amended, 42 U.S.C. 7601(a). Because the amendments are clerical in nature and affect no substantive rights or requirements, the Administrator finds it unnecessary to propose and invite public comment.

Dated: February 24, 1978.

DOUGLAS M. COSTLE,
Administrator.

Parts 60 and 61 of Chapter I, Title 40 of the Code of Federal Regulations are revised as follows:

1. The authority citation following the table of sections in Part 60 is revised to read as follows:

AUTHORITY: Sec. 111, 301(a) of the Clean Air Act as amended (42 U.S.C. 7411, 7601(a)), unless otherwise noted.

§§ 60.10 and 60.24 [Amended]

2. Following §§ 60.10 and 60.24(g) the following authority citation is added: (Sec. 116 of the Clean Air Act as amended (42 U.S.C. 7416)).

1. Addendum to Specifications for Incinerator Testing at Federal Facilities. PHS, NCAPC. December 8, 1967.

FEDERAL REGISTER, VOL. 43, NO. 43

FRIDAY, MARCH 3, 1978

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Lignite-Fired Steam Generators

AGENCY: Environmental Protection Agency (EPA).

ACTION: Final rule.

SUMMARY: This final rule establishes standards of performance for new or modified lignite-fired steam generators with heat input rates greater than 73 megawatts (250 million Btu per hour) and limits emissions of nitrogen oxides to 260 ng/J of heat input except that 340 ng/J of heat input is allowed from cyclone-fired units which are fired with lignite mined in North Dakota, South Dakota, or Montana. Steam generators contribute significantly to air pollution, and the intended effect of this final rule is to require new steam generators which burn lignite to use the best control system for reducing emissions of nitrogen oxides.

EFFECTIVE DATE: March 7, 1978.

ADDRESSES: The "Standards Support and Environmental Impact Statement (SSEIS), Volume 2: Promulgated Standards of Performance for Lignite-Fired Steam Generators" (EPA-450/2-76-030b) may be obtained by writing the U.S. EPA Library (MD-35), Research Triangle Park, N.C. 27711. Volume 1 of the SSEIS, "Proposed Standards of Performance for Lignite-Fired Steam Generators" (EPA-450/2-76-030a), is also available at the same address. Please specify both the title and EPA number of the document desired. These documents and all public comments may be inspected at the Public Information Reference Unit (EPA Library), Room 2922, 401 M Street SW., Washington, D.C.

FOR FURTHER INFORMATION CONTACT:

Don R. Goodwin, Director, Emission Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, N.C. 27711, telephone 919-541-5271.

SUPPLEMENTARY INFORMATION: On December 23, 1971 (36 FR 24877), EPA established under Subpart D of 40 CFR Part 60 standards of performance for new steam generators with heat input rates greater than 73 megawatts (250 million Btu per hour). Steam generators which burn lignite were exempted from the emission standards for nitrogen oxides (NO_x) because too little operating experience was available to adequately characterize NO_x emissions. (Lignite-fired steam generators were not exempted from the standards for sulfur oxides and particulate matter, however.) Since 1971, EPA has gathered additional information on lignite-fired facilities, and on December 22, 1976 (41 FR 55791), the Agency proposed to amend Subpart D by establishing a standard of performance of 260 nanograms per joule (ng/J) of heat input (0.6 pound per million Btu) for NO_x emissions from new lignite-fired steam generators. Supporting information for the proposed standard was published in Volume 1 of the SSEIS for lignite-fired steam generators. After reviewing issues raised during the public comment period which followed the proposal, EPA decided to promulgate standards which will permit the limited use of cyclone-fired facilities to burn lignite mined in North Dakota, South Dakota, and Montana (which causes severe fouling and slagging in pulverized-fired units). Supporting information for these final standards of performance appears in Volume 2 of the SSEIS.

FINAL STANDARDS

NO_x emissions from lignite-fired steam generators are limited to 260 ng/J of heat input (0.6 lb/10⁶ Btu) except that 340 ng/J (0.8 lb/10⁶ Btu) is allowed from cyclone-fired steam generators burning lignite mined in North Dakota, South Dakota, and Montana. Both standards apply only to boilers which burn lignite, with heat input rates greater than 73 megawatts (250 million Btu per hour), and for which construction or modification began after December 21, 1976.

RATIONALE FOR FINAL STANDARDS

The NO_x standard originally proposed by EPA, 260 ng/J, may have prevented the use of cyclone-fired boilers, since it has not been demonstrated that emissions from these units can be consistently controlled to levels below 260 ng/J. During the public comment period, several commenters argued that the utilization of cyclone-fired boilers is necessary to

overcome the serious fouling and slagging problems which develop whenever the sodium content of the lignite burned exceeds about 5 percent, by weight. These high sodium content reserves are believed to be widespread, especially in North Dakota, and the utilities claim that their low sodium content reserves are being rapidly depleted. The commenters said that cyclones have inherently lower fouling and slagging rates than other large boiler designs because much less ash is carried through the boiler convective passes. In addition, they contended that in the Dakotas there has actually been very little operating experience with pulverized-fired boilers, the alternative to large cyclones, and it is doubtful that these units can burn high sodium lignite without experiencing severe problems. Thus, the commenters concluded that the proposed standard might restrict the use of valuable resources of high sodium lignite fuel by prohibiting the utilization of cyclone-fired boilers. The commenters also argued that the proposed standard would place an economic burden on the electric power utilities which burn lignite by limiting competitive bidding for new boilers.

EPA agrees that at present there is too little operating experience with pulverized- or cyclone-fired boilers to be able to predict their reliability when burning high sodium lignite. Furthermore, the Agency does not want to establish a standard which might inhibit future efforts to find a successful way to burn this troublesome fuel. Consequently, EPA has established a separate nitrogen oxides emission standard of 340 ng/J (0.8 lb/10⁶ Btu) for new cyclone-fired boilers which burn North Dakota, South Dakota, or Montana lignite. This standard will permit the limited utilization of cyclone-fired boilers and assure the continued use of our country's abundant resources of lignite. Lignite mined in Texas, the only other known major lignite formation, generally has low sodium content and has been successfully burned in pulverized-fired units for years. The standard is supported by emission test data and other information contained in Volume I of the SSEIS. Nitrogen oxides emissions from pulverized-fired boilers will be limited to 260 ng/J (0.6 lb/10⁶ Btu), as originally proposed.

Cyclone-fired boilers could account for 10 to 20 percent of all new lignite-fired steam generators, based on EPA estimates of lignite consumption for the year 1980. EPA estimates that NO_x emissions from new cyclone-fired boilers may be reduced by as much as 20 percent as a result of the standard. The combined effect of both standards will be to reduce total NO_x emissions from all new boilers which burn lignite by about 25 percent.

RULES AND REGULATIONS

It should be noted that standards of performance for new sources established under section 111 of the Clean Air Act reflect the degree of emission limitation achievable through application of the best adequately demonstrated technological system of continuous emission reduction (taking into consideration the cost of achieving such emission reduction, any non-air quality health and environmental impact and energy requirements). State implementation plans (SIPs) approved or promulgated under section 110 of the Act, on the other hand, must provide for the attainment and maintenance of national ambient air quality standards (NAAQS) designed to protect public health and welfare. For that purpose, SIPs must in some cases require greater emission reductions than those required by standards of performance for new sources. Section 173 of the Act requires, among other things, that a new or modified source constructed in an area which exceeds the NAAQS must reduce emissions to the level which reflects the "lowest achievable emission rate" for such category of source as defined in section 171(3), unless the owner or operator demonstrates that the source cannot achieve such an emission rate. In no event can the emission rate exceed any applicable standard of performance.

A similar situation may arise when a major emitting facility is to be constructed in a geographic area which falls under the prevention of significant deterioration of air quality provisions of the Act (Part C). These provisions require, among other things, that major emitting facilities to be constructed in such areas are to be subject to best available control technology. The term "best available control technology" (BACT) means "an emission limitation based on the maximum degree of reduction of each pollutant subject to regulation under this Act emitted from or which results from any major emitting facility, which the permitting authority, on a case-by-case basis, taking into account energy, environmental, and economic impacts and other costs, determines is achievable for such facility through application of production processes and available methods, systems, and techniques, including fuel cleaning or treatment or innovative fuel combustion techniques for control of each such pollutant. In no event shall application of 'best available control technology' result in emissions of any pollutants which will exceed the emissions allowed by any applicable standard established pursuant to section 111 or 112 of this Act."

Standards of performance should not be viewed as the ultimate in achievable emission control and should not preclude the imposition of

a more stringent emission standard, where appropriate. For example, while cost of achievement may be an important factor in determining standards of performance applicable to all areas of the country (clean as well as dirty), costs must be accorded far less weight in determining the "lowest achievable emission rate" for new or modified sources locating in areas violating statutorily-mandated health and welfare standards. Although there may be emission control technology available that can reduce emissions below those levels required to comply with standards of performance, this technology might not be selected as the basis of standards of performance due to costs associated with its use. This in no way should preclude its use in situations where cost is a lesser consideration, such as determination of the "lowest achievable emission rate."

In addition, States are free under section 116 of the Act to establish even more stringent emission limits than those established under section 111 or those necessary to attain or maintain the NAAQS under section 110. Thus, new sources may in some cases be subject to limitations more stringent than EPA's standards of performance under section 111, and prospective owners and operators of new sources should be aware of this possibility in planning for such facilities.

ENVIRONMENTAL AND ECONOMIC IMPACTS

The impact of the NO_x emission standards will be most significant in North Dakota and Texas where most new lignite-fired boilers will be located. Although ambient NO_x levels in these areas are now low, emission regulations are important because: (1) The standards will maintain low ambient NO_x concentrations in areas where population and industrial growth is expected in the future; (2) the standards will reduce the potential for development of rural smog which can form in regions having initially low ambient NO_x concentrations; and (3) the standards will reduce long distance transport of NO_x to areas having air pollution problems. In addition, since nationwide levels of NO_x are expected to rise in the future despite NO_x control regulations, the NO_x emission standards for lignite-fired boilers will help to alleviate this problem.

The standards will cause total NO_x emissions from all new lignite-fired steam generators to be reduced by about 25 percent. By comparison, NO_x emissions would have been reduced by about 29 percent if the use of cyclones had been restricted by the standard originally proposed. Thus, the continued use of cyclone-fired boilers will have only a minor adverse impact on air quality.

The NO_x emission standards will have no impact on water pollution,

solid waste disposal, sulfur dioxide and particulate emissions, or energy consumption at new lignite-fired steam generators. In addition, the standards will not prohibit the use of any lignite reserves or adversely affect any other natural resources. Additional information about the environmental impact of the standards appears in Volumes 1 and 2 of the SSEIS.

The NO_x emission standards will cause capital costs for new lignite-fired plants to increase by, at most, only 0.5 percent and operating costs will rise even less. Therefore, capital and operating expenses will rise only nominally. Since the price consumers pay for electric power is generally proportional to the electric utility's operating costs, consumer power price increases will be negligible. The boiler manufacturers will experience no significant market disadvantages because the standards effectively permit the sale of all boiler designs and provide no sales advantages for any manufacturer. The small increases in capital costs resulting from the standards will not affect the boiler industry's overall sales. More information about the economic impact of the standards can be found in Volumes 1 and 2 of the SSEIS.

PUBLIC COMMENTS

Seventeen comment letters were received during the public comment period. Many of the comments were critical of the information EPA used to support restriction of the cyclone-fired boiler. In particular, these arguments were made: (1) None of the pulverized-fired boilers which EPA tested operate reliably when burning lignite with a sodium content above about 5 percent; (2) the front-wall-fired plant cited by EPA has never burned lignite with an 8 percent sodium content for an extended period of time, as EPA has reported. Also, the plant's capacity factor has averaged about 72 percent, not 86 percent as stated by EPA; (3) although it is true that a North Dakota electric utility has recently agreed to purchase two tangentially-fired boilers, these units are guaranteed to burn lignite containing no more than 4.8 percent sodium. Also, the decision to purchase these boilers may have been influenced by the utility's concern that EPA might prohibit the use of cyclones; (4) recent experiments by the Energy Research and Development Administration have demonstrated that cyclone-fired boilers have significantly lower ash deposition rates than pulverized-fired boilers. This confirms arguments that cyclones have much lower fouling and slagging potentials when burning high sodium content lignite.

EPA agrees that there has not been enough successful operating experience with pulverized-fired boilers

RULES AND REGULATIONS

which burn high sodium content lignite to justify eliminating cyclones from the market. Consequently, the Agency has decided to establish a separate NO_x emission standard for cyclones burning Dakota lignite which permits their use.

Another issue raised during the comment period concerned the potentially high NO_x emissions which could occur when Texas lignite with a high nitrogen content is burned. It was argued that these emissions could exceed the standard even if the best system of emission reduction were employed. In support of this contention, a commenter submitted data which indicate that the fuel-nitrogen content of Texas lignites ranges well above expected values. EPA has determined, however, that these data were accumulated around the turn of the century and are inconsistent with present-day values. Information from the Bureau of Economic Geology at the University of Texas and the Texas Railroad Commission indicates that Texas lignite nitrogen contents are typically low and should not cause NO_x emissions from a well controlled plant to exceed the standard.

These and all other comments are discussed in detail in Volume 2, Chapter 2 of the SSEIS.

The effective date of this regulation is (date of publication), because section 111(b)(1)(B) of the Clean Air Act provides that standards of performance or revisions thereof become effective upon promulgation.

NOTE.—The Environmental Protection Agency has determined that this document does not contain a major proposal requiring preparation of an Economic Impact Analysis under Executive Orders 11821 and 11949 and OMB Circular A-107.

Dated: March 2, 1978.

DOUGLAS M. COSTLE,
Administrator.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended by revising Subparts A and D as follows:

Subpart A—General Provisions

1. Section 60.2 is amended by substituting the International System of Units (SI) in paragraph (1) as follows:

§ 60.2 Definitions.

(1) "Standard conditions" means a temperature of 293 K (68° F) and a pressure of 101.3 kilopascals (29.92 in Hg).

Subpart D—Standards of Performance for Fossil Fuel-Fired Steam Generators

2. Section 60.40 is amended by revising paragraph (c) and by adding paragraph (d) as follows:

§ 60.40 Applicability and designation of affected facility.

(c) Except as provided in paragraph (d) of this section, any facility under paragraph (a) of this section that commenced construction or modification after August 17, 1971, is subject to the requirements of this subpart.

(d) The requirements of §§ 60.44(a)(4), (a)(5), (b), and (d), and 60.45(f)(4)(vi) are applicable to lignite-fired steam generating units that commenced construction or modification after December 22, 1976.

3. Section 60.41 is amended by adding paragraph (f) as follows:

§ 60.41 Definitions.

(f) "Coal" means all solid fuels classified as anthracite, bituminous, subbituminous, or lignite by the American Society for Testing Material. Designation D 388-66.

4. Section 60.44 is amended by adding paragraphs (a)(4) and (a)(5), by revising paragraph (b), and by adding paragraphs (c) and (d) as follows:

§ 60.44 Standard for nitrogen oxides.

(4) 260 nanograms per joule heat input (0.60 lb per million Btu) derived from lignite or lignite and wood residue (except as provided under paragraph (a)(5) of this section).

(5) 340 nanograms per joule heat input (0.80 lb per million Btu) derived from lignite which is mined in North Dakota, South Dakota, or Montana and which is burned in a cyclone-fired unit.

(b) Except as provided under paragraphs (c) and (d) of this section, when different fossil fuels are burned simultaneously in any combination, the applicable standard (in ng/J) is determined by proration using the following formula:

$$PS_{NOx} = \frac{w(260) + x(86) + y(130) + z(300)}{w + x + y + z}$$

where:

PS_{NOx} = is the prorated standard for nitrogen oxides when burning different fuels simultaneously, in nanograms per joule heat input derived from all fossil fuels fired or from all fossil fuels and wood residue fired;

w = is the percentage of total heat input derived from lignite;

x = is the percentage of total heat input derived from gaseous fossil fuel;

y = is the percentage of total heat input derived from liquid fossil fuel; and

z = is the percentage of total heat input derived from solid fossil fuel (except lignite).

(c) When a fossil fuel containing at least 25 percent, by weight, of coal refuse is burned in combination with gaseous, liquid, or other solid fossil

fuel or wood residue, the standard for nitrogen oxides does not apply.

(d) Cyclone-fired units which burn fuels containing at least 25 percent of lignite that is mined in North Dakota, South Dakota, or Montana remain subject to paragraph (a)(5) of this section regardless of the types of fuel combusted in combination with that lignite.

(Sections 111 and 301(a) of the Clean Air Act, as amended (42 U.S.C. 7411, and 7601).)

5. Section 60.45 is amended by adding paragraph (f)(4)(vi) as follows:

§ 60.45 Emission and fuel monitoring.

(f) . . .

(4) . . .

(vi) For lignite coal as classified according to A.S.T.M. D 388-66, $F = 2.659 \times 10^{-7}$ dscm/J (9900 dscf/million Btu) and $F_c = 0.516 \times 10^{-7}$ scm CO₂/J (1920 scf CO₂/million Btu).

(Sections 111, 114, and 301(a) of the Clean Air Act, as amended (42 U.S.C. 7411, 7414, and 7601).)

CHAPTER I—ENVIRONMENTAL
PROTECTION AGENCY

SUBCHAPTER C—AIR PROGRAMS

[FRL 835-21]

PART 60—STANDARDS OF PERFOR-
MANCE FOR NEW STATIONARY
SOURCES

Lime Manufacturing Plants

AGENCY: Environmental Protection
Agency (EPA).

ACTION: Final rule.

SUMMARY: This rule establishes standards of performance which limit emissions of particulate matter from new, modified, and reconstructed lime manufacturing plants. The standards implement the Clean Air Act and are based on the Administrator's determination that lime manufacturing plant emissions contribute significantly to air pollution. The intended effect of setting these standards is to require, new, modified, and reconstructed lime manufacturing plants to use the best demonstrated system of continuous emission reduction.

EFFECTIVE DATE: March 7, 1978.

ADDRESSES: A support document entitled, "Standard Support and Environmental Impact Statement, Volume II: Promulgated Standards of Performance for Lime Manufacturing Plants" (EPA-450/2-77-007b), October 1977, has been prepared and is available. This document includes summary economic and environmental impact statements as well as EPA's responses to the comments on the proposed standards. Also available is the supporting volume for the proposed standards entitled, "Standard Support and Environmental Impact Statement, Volume I: Proposed Standards of Performance for Lime Manufacturing Plants" (EPA-450/2-77-007a), April 1977. Copies of these documents can be ordered by addressing a request to the EPA Library (MD-35), Research Triangle Park, N.C. 27711. The title and number for each or both of the documents should be specified when ordering. These documents as well as copies of the comment letters responding to the proposed rulemaking published in the FEDERAL REGISTER on May 3, 1977 (42 FR 22506) are available for public inspection and copying at the U.S. Environmental Protection Agency, Public Information Reference Unit (EPA Library), Room 2922, 401 M Street SW., Washington, D.C. 20460.

FOR FURTHER INFORMATION
CONTACT:

Don R. Goodwin, Director, Emission

Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, N.C. 27711, telephone 919-541-5271.

SUPPLEMENTARY INFORMATION: There are two minor changes in the standards from those proposed on May 3, 1977. The first of these is the specific exclusion of lime production units at kraft pulp mills [§60.340(b)]. Emission standards for kraft pulp mills were proposed in the FEDERAL REGISTER on September 24, 1976, which cover emissions from the lime production units at these mills.

The second change is the addition of §60.344(c) (Test methods and procedures). The addition recommends a testing technique which would more accurately test exhaust gases from hydrators in those cases where high moisture content is a problem.

During the 60-day comment period following publication of the proposed emission standards in the FEDERAL REGISTER on May 3, 1977, 23 comment letters were received, 10 from industry, 7 from State or local pollution control agencies, and 6 from other government agencies. In addition, on June 16, 1977, a public meeting was held at the EPA facility at Research Triangle Park, N.C., that provided an opportunity for oral presentations and comments on the standards. None of the comments warranted a change of the emission standards nor did any comments justify any significant changes in the standards support document.

Major comments focused on three areas: (1) criticism of the testing procedures and the supporting emission data, (2) the opacity standard, and (3) the requirement for continuous monitoring. These and other comments are summarized and addressed in Volume II of the standards support document.

The most significant of the three areas of comments was the questioning of the testing procedures and the data base. More specifically, it was asserted that when data were gathered upon which to base the standard, standard testing procedures were not followed in every case, which consequently biased the data. A careful review of the procedures and the resulting data revealed that, although there were minor miscalculations, the errors did not affect the emission standards that were set.

The opacity standard (10 percent), was questioned because it was thought to be too stringent and in a range where observer error would result in unfair violation decisions. A review of the opacity data indicated that of the 1,056 six-minute averages of opacity, less than one percent exceeded the visible emission level of 10 percent, thus EPA considers the 10 percent opacity standard reasonable. As for observer error, as indicated in the introduction to Reference Method 9

(Part 60, Appendix A), the accuracy of the method and any potential error must be taken into account when determining possible violations of the standards.

Some commenters questioned the requirement for continuous monitoring of multiple stack baghouses, believing it to be unnecessary and excessively expensive to place a monitor on each stack. In establishing the continuous monitoring requirement, it was not the intention of EPA that emission monitors be installed at each stack at a multiple stack baghouse. The proposed regulation has been revised to reflect this intent. It is believed that in most cases one monitor, or two in certain situations, can be installed to simultaneously monitor emissions from several stacks. With such a monitoring system, the plant must demonstrate that representative emissions are monitored on a continuous basis.

It should be noted that standards of performance for new sources established under section 111 of the Clean Air Act reflect the degree of emission limitation achievable through application of the best adequately demonstrated technological system of continuous emission reduction (taking into consideration the cost of achieving such emission reduction, any nonair quality health and environmental impact and energy requirements). State implementation plans (SIPs) approved or promulgated under section 110 of the Act, on the other hand, must provide for the attainment and maintenance of national ambient air quality standards (NAAQS) designed to protect public health and welfare. For that purpose, SIPs must in some cases require greater emission reductions than those required by standards of performance for new sources. Section 173 of the Act requires, among other things, that a new or modified source constructed in an area which exceeds the NAAQS must reduce emissions to the level which reflects the "lowest achievable emission rate" for such category of source. In no event can the emission rate exceed any applicable standard of performance.

A similar situation may arise when a major emitting facility is to be constructed in a geographic area which falls under the prevention of significant deterioration of air quality provisions of the Act (part C). These provisions require, among other things, that major emitting facilities to be constructed in such areas are to be subject to best available control technology for all pollutants regulated under the Act. The term "best available control technology" (BACT), as defined in section 169(3), means "an emission limitation based on the maximum degree of reduction of each pollutant subject to regulation under this Act emitted from or which results

RULES AND REGULATIONS

from any major emitting facility, which the permitting authority, on a case-by-case basis, taking into account energy, environmental, and economic impacts and other costs, determines is achievable for such facility through application of production processes and available methods, systems, and techniques, including fuel cleaning or treatment or innovative fuel combustion techniques for control of each such pollutant. In no event shall application of 'best available control technology' result in emissions of any pollutants which will exceed the emissions allowed by any applicable standard established pursuant to section 111 or 112 of this Act."

Standards of performance should not be viewed as the ultimate in achievable emission control and should not preclude the imposition of a more stringent emission standard, where appropriate. For example while cost of achievement may be an important factor in determining standards of performance applicable to all areas of the country (clean as well as dirty), statutorily, costs do not play such a role in determining the "lowest achievable emission rate" for new or modified sources locating in areas violating statutorily-mandated health and welfare standards. Although there may be emission control technology available that can reduce emissions below those levels required to comply with standards of performance, this technology might not be selected as the basis of standards of performance due to costs associated with its use. This in no way should preclude its use in situations where cost is a lesser consideration, such as determination of the "lowest achievable emission rate."

In addition, States are free under section 116 of the Act to establish even more stringent emission limits than those established under section 111 or those necessary to attain or maintain the NAAQS under section 110. Thus, new sources may in some cases be subject to limitations more stringent than EPA's standards of performance under section 111, and prospective owners and operators of new sources should be aware of this possibility in planning for such facilities.

MISCELLANEOUS: The effective date of this regulation is March 7, 1978. Section 111(b)(1)(B) of the Clean Air Act provides that standards of performance or revisions of them become effective upon promulgation and apply to affected facilities, construction or modification of which was commenced after the date of proposal (May 3, 1977).

NOTE.—The Environmental Protection Agency has determined that this document does not contain a major proposal requiring an Economic Impact Analysis under Executive Orders 11821 and 11949 and OMB Circular A-107.

Dated: March 1, 1978.

DOUGLAS M. COSTLE,
Administrator.

Part 60 of Chapter I of Title 40 of the Code of Regulations is amended as follows:

1. By adding subpart HH as follows:

Subpart HH—Standards of Performance for Lime Manufacturing Plants

Sec.

60.340 Applicability and designation of affected facility.

60.341 Definitions.

60.342 Standard for particulate matter.

60.343 Monitoring of emissions and operations.

60.344 Test methods and procedures.

AUTHORITY: Sec. 111 and 301(a) of the Clean Air Act, as amended (42 U.S.C. 7411, 7601), and additional authority as noted below.

§ 60.340 Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to the following affected facilities used in the manufacture of lime: rotary lime kilns and lime hydrators.

(b) The provisions of this subpart are not applicable to facilities used in the manufacture of lime at kraft pulp mills.

(c) Any facility under paragraph (a) of this section that commences construction or modification after May 3, 1977, is subject to the requirements of this part.

§ 60.341 Definitions.

As used in this subpart, all terms not defined herein shall have the same meaning given them in the Act and in subpart A of this part.

(a) "Lime manufacturing plant" includes any plant which produces a lime product from limestone by calcination. Hydration of the lime product is also considered to be part of the source.

(b) "Lime product" means the product of the calcination process including, but not limited to, calcitic lime, dolomitic lime, and dead-burned dolomite.

(c) "Rotary lime kiln" means a unit with an inclined rotating drum which is used to produce a lime product from limestone by calcination.

(d) "Lime hydrator" means a unit used to produce hydrated lime product.

§ 60.342 Standard for particulate matter.

(a) On and after the date on which the performance test required to be conducted by § 60.8 is completed, no owner or operator subject to the provisions of this subpart shall cause to be discharged into the atmosphere:

(1) From any rotary lime kiln any gases which:

(i) Contain particulate matter in excess of 0.15 kilogram per megagram of limestone feed (0.30 lb/ton).

(ii) Exhibit 10 percent opacity or greater.

(2) From any lime hydrator any gases which contain particulate matter in excess of 0.075 kilogram per megagram of lime feed (0.15 lb/ton).

§ 60.343 Monitoring of emissions and operations.

(a) The owner or operator subject to the provisions of this subpart shall install, calibrate, maintain, and operate a continuous monitoring system, except as provided in paragraph (b) of this section, to monitor and record the opacity of a representative portion of the gases discharged into the atmosphere from any rotary lime kiln. The span of this system shall be set at 40 percent opacity.

(b) The owner or operator of any rotary lime kiln using a wet scrubbing emission control device subject to the provisions of this subpart shall not be required to monitor the opacity of the gases discharged as required in paragraph (a) of this section, but shall install, calibrate, maintain, and operate the following continuous monitoring devices:

(1) A monitoring device for the continuous measurement of the pressure loss of the gas stream through the scrubber. The monitoring device must be accurate within ± 250 pascals (one inch of water).

(2) A monitoring device for the continuous measurement of the scrubbing liquid supply pressure to the control device. The monitoring device must be accurate within ± 5 percent of design scrubbing liquid supply pressure.

(c) The owner or operator of any lime hydrator using a wet scrubbing emission control device subject to the provisions of this subpart shall install, calibrate, maintain, and operate the following continuous monitoring devices:

(1) A monitoring device for the continuous measuring of the scrubbing liquid flow rate. The monitoring device must be accurate within ± 5 percent of design scrubbing liquid flow rate.

(2) A monitoring device for the continuous measurement of the electric current, in amperes, used by the scrubber. The monitoring device must be accurate within ± 10 percent over its normal operating range.

(d) For the purpose of conducting a performance test under § 60.8, the owner or operator of any lime manufacturing plant subject to the provisions of this subpart shall install, calibrate, maintain, and operate a device for measuring the mass rate of limestone feed to any affected rotary lime

Title 40—Protection of Environment

CHAPTER I—ENVIRONMENTAL PROTECTION AGENCY

SUBCHAPTER C—AIR PROGRAMS

[FRL 836-1]

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Petroleum Refinery Claus Sulfur Recovery Plants

AGENCY: Environmental Protection Agency (EPA).

ACTION: Final rule.

SUMMARY: This rule establishes standards of performance which will limit emissions of sulfur dioxide (SO_2) and reduced sulfur compounds from new, modified, and reconstructed petroleum refinery Claus sulfur recovery plants. The standards implement the Clean Air Act and are based on the Administrator's determination that emissions from petroleum refinery Claus sulfur recovery plants contribute significantly to air pollution. The intended effect of the standards is to require new, modified, and reconstructed petroleum refinery Claus sulfur recovery plants to use the best technological system of continuous emission reduction.

EFFECTIVE DATE: March 15, 1978.

ADDRESSES: Copies of the standard support documents are available on request from the U.S. EPA Library (MD-35), Research Triangle Park, N.C. 27711. The requestor should specify "Standards Support and Environmental Impact Statement, Volume I: Proposed Standards of Performance for Petroleum Refinery Sulfur Recovery Plants" (EPA-450/2-76-016a) and/or "Standards Support and Environmental Impact Statement, Volume II: Promulgated Standards of Performance for Petroleum Refinery Sulfur Recovery Plants" (EPA-450/2-76-016b). Comment letters responding to the proposed rules published in the FEDERAL REGISTER on October 4, 1976 (41 FR 43866), are available for public inspection and copying at the U.S. Environmental Protection Agency, Public Information Reference Unit (EPA Library), Room 2922, 401 M Street SW., Washington, D.C.

Don R. Goodwin, Emission Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, N.C. 27711, telephone number 919-541-5271.

kiln and the mass rate of lime feed to any affected lime hydrator. The measuring device used must be accurate to within ± 5 percent of the mass rate over its operating range.

(e) For the purpose of reports required under §60.7(c), periods of excess emissions that shall be reported are defined as all six-minute periods during which the average opacity of the plume from any lime kiln subject to paragraph (a) of this subpart is 10 percent or greater.

(Sec. 114 of the Clean Air Act, as amended (42 U.S.C. 7414).)

§ 60.344 Test methods and procedures.

(a) Reference methods in Appendix A of this part, except as provided under §60.8(b), shall be used to determine compliance with §60.322(a) as follows:

(1) Method 5 for the measurement of particulate matter,

(2) Method 1 for sample and velocity traverses,

(3) Method 2 for velocity and volumetric flow rate,

(4) Method 3 for gas analysis,

(5) Method 4 for stack gas moisture, and

(6) Method 9 for visible emissions.

(b) For Method 5, the sampling time for each run shall be at least 60 minutes and the sampling rate shall be at least 0.85 std m^3/h , dry basis (0.53 dscf/min), except that shorter sampling times, when necessitated by process variables or other factors, may be approved by the Administrator.

(c) Because of the high moisture content (40 to 85 percent by volume) of the exhaust gases from hydrators, the Method 5 sample train may be modified to include a calibrated orifice immediately following the sample nozzle when testing lime hydrators. In this configuration, the sampling rate necessary for maintaining isokinetic conditions can be directly related to exhaust gas velocity without a correction for moisture content. Extra care should be exercised when cleaning the sample train with the orifice in this position following the test runs.

(Sec. 114 of the Clean Air Act, as amended (42 U.S.C. 7414).)

[FR Doc. 78-5974 Filed 3-6-78; 8:45 am]

FEDERAL REGISTER, VOL. 43, NO. 45

TUESDAY, MARCH 7, 1978

SUPPLEMENTARY INFORMATION:

SUMMARY

On October 4, 1976 (41 FR 43866), EPA proposed standards of performance for new petroleum refinery Claus sulfur recovery plants under section 111 of the Clean Air Act, as amended. The promulgated standards are essentially the same as those proposed, although an exemption for small petroleum refineries has been included in the promulgated standards. The standards are based on the use of tail gas scrubbing systems which have been determined to be the best technological system of continuous emission reduction, taking into consideration the cost of achieving such emission reduction, any nonair quality, health, and environmental impact and energy requirements. Compliance with these standards will increase the overall sulfur recovery efficiency of a typical refinery Claus sulfur recovery plant to about 99.9 percent, compared to a recovery efficiency of about 94 percent for an uncontrolled refinery Claus sulfur recovery plant, or a recovery efficiency of about 99 percent for a Claus sulfur recovery plant complying with typical State emission control regulations for these plants.

The promulgated standards will apply to: (1) any Claus sulfur recovery plant with a sulfur production capacity of more than 20 long tons per day (LTD) which is associated with a small petroleum refinery (i.e., a petroleum refinery having a crude oil processing capacity of 50,000 barrels per stream day (BSD) or less which is owned or controlled by a refiner whose total combined crude oil processing capacity is 137,500 BSD or less) and (2) any size Claus sulfur recovery plant associated with a large petroleum refinery. Specifically, the standards limit the concentration of sulfur dioxide (SO_2) in the gases discharged into the atmosphere to 0.025 percent by volume at zero percent oxygen on a dry basis. Where the emission control system installed to comply with these standards discharges residual emissions of hydrogen sulfide (H_2S), carbonyl sulfide (COS), and carbon disulfide (CS_2), the standards limit the concentration of H_2S and the total concentration of H_2S , COS and CS_2 (calculated as SO_2) in the gases discharged into the atmosphere to 0.0010 percent and 0.030 percent by volume at zero percent oxygen on a dry basis, respectively.

Compliance with these standards will reduce nationwide sulfur dioxide emissions by some 55,000 tons per year by 1980. This reduction will be achieved without any significant adverse impact on other aspects of environmental quality, such as solid waste disposal, water pollution, or noise. This reduction in emissions will also be accompanied by a reduction in the

RULES AND REGULATIONS

growth of national energy consumption equivalent to about 90,000 barrels of fuel oil per year by 1980.

The economic impact of the promulgated standards is reasonable. They will result in an increase in the annual operating costs of the petroleum refining industry by some \$16 million per year in 1980. An individual refiner who installs alternative II controls will need to increase his prices from 0.1 to 1 percent to maintain his profitability.

It should be noted that standards of performance for new sources established under section 111 of the Act reflect the degree of emission limitation achievable through application of the best adequately demonstrated technological system of continuous emission reduction (taking into consideration the cost of achieving such emission reduction, any nonair quality health and environmental impact and energy requirements). State implementation plans (SIPs) approved or promulgated under section 110 of the Act, on the other hand, must provide for the attainment and maintenance of national ambient air quality standards (NAAQS) designed to protect public health and welfare. For that purpose, SIPs must in some cases require greater emission reduction than those required by standards of performance for new sources. Section 173(2) of the Act requires, among other things, that a new or modified source constructed in an area which exceeds the NAAQS must reduce emissions to the level which reflects the "lowest achievable emission rate" for such category of source, unless the owner or operator demonstrates that the source cannot achieve such an emission rate. In no event can the emission rate exceed any applicable standard of performance.

A similar situation may arise when a major emitting facility is to be constructed in a geographic area which falls under the prevention of significant deterioration of air quality provisions of the Act (part C). These provisions require, among other things, that major emitting facilities to be constructed in such areas are to be subject to the best available control technology. The term "best available control technology" (BACT) means "an emission limitation based on the maximum degree of reduction of each pollutant subject to regulation under this Act emitted from or which results from any major emitting facility, which the permitting authority, on a case-by-case basis, taking into account energy, environmental, and economic impacts and other costs, determines is achievable for such facility through application of production processes and available methods, systems, and techniques, including fuel cleaning or treatment or innovative fuel combustion techniques for control of each such pollutant. In no event shall appli-

cation of 'best available control technology' result in emissions of any pollutants which will exceed the emissions allowed by any applicable standard established pursuant to section 111 or 112 of this Act."

Standards of performance should not be viewed as the ultimate in achievable emission control and should not preclude the imposition of a more stringent emission standard, where appropriate. For example, while cost of achievement may be an important factor in determining standards of performance applicable to all areas of the country (clean as well as dirty), costs must be accorded far less weight in determining the "lowest achievable emission rate" for new or modified sources locating in areas violating statutorily-mandated health and welfare standards. Although there may be emission control technology available that can reduce emissions below those levels required to comply with standards of performance, this technology might not be selected as the basis of standards of performance due to costs associated with its use. This in no way should preclude its use in situations where cost is a lesser consideration, such as determination of the "lowest achievable emission rate."

In addition, States are free under section 116 of the Act to establish even more stringent emission limits than those established under section 111 or those necessary to attain or maintain the NAAQS under section 110. Thus, new sources may in some cases be subject to limitations more stringent than standards of performance under section 111, and prospective owners and operators of new sources should be aware of this possibility in planning for such facilities.

PUBLIC PARTICIPATION

Prior to proposal of the standards, interested parties were advised by public notice in the FEDERAL REGISTER of a meeting of the National Air Pollution Control Techniques Advisory Committee to discuss the standards recommended for proposal. This meeting was open to the public and each person attending was given ample opportunity to comment on the standards recommended for proposal. The standards were proposed on October 4, 1976, and copies of the proposed standards and the Standards Support and Environmental Impact Statement (SSEIS) were distributed to members of the petroleum refining industry and several environmental groups at this time. The public comment period extended from October 4, 1976, to December 3, 1976.

Twenty-two comment letters were received on the proposed standards of performance. These comments have been carefully considered and, where determined to be appropriate by the

Administrator, changes have been made in the standards which were proposed.

MAJOR COMMENTS

Comments on the proposed standards were received from several oil industry representatives, State and local air pollution control agencies, a vendor of emission source testing equipment, and several Federal agencies. These comments covered four major areas: the costs of implementing the standards, the ability of emission control technology to meet the standards, the environmental impacts of the standards, and the energy impacts of the standards.

COSTS

The major comments concerning costs were that the costs of the emission control systems required to meet the standards were underestimated, that these costs were excessive; and that small sulfur recovery plants, or small petroleum refineries should be exempt from the standard.

The basic cost data used to develop the cost estimates were obtained from petroleum refinery sources. No specific data or information was provided in the public comments, however, which would indicate that these costs are significantly in error.

In the preamble to the proposed standards, comments were specifically invited concerning the impact of the standards on the small refiner. After considering these comments, EPA has concluded that some relief from the standards is appropriate. The major factor involved in this decision was a consideration of the cost effectiveness of the standards on large and small refiners. The incremental cost per incremental unit of sulfur emissions that must be controlled to meet the standards is substantially greater for the small refiner than for the large refiner. Furthermore, the impact of these costs on the small refiner is more severe than the impact on the large refiner, because the small refiner cannot readily pass on the cost of emission control equipment. Consequently, as discussed in volume II of the Standards Support and Environmental Impact Statement (SSEIS), the promulgated standards include a lower size cutoff for small petroleum refineries and Claus sulfur recovery plants. Claus sulfur recovery plants with a sulfur production capacity of 20 long tons per day or less associated with a petroleum refinery with a crude oil processing capacity of 50,000 BSD or less, which is owned or controlled by a refiner whose total combined crude oil processing capacity is 137,500 BSD or less, are exempt from the standards. This definition of a small petroleum refinery is consistent with that included in section 211 of the Clean Air Act, as amended.

RULES AND REGULATIONS

EMISSION CONTROL TECHNOLOGY

A major concern of many commenters was the limited amount of source test data used in support of the numerical emission limits included in the standards and the fact that some of these data were collected at refineries where the emission control system was operating below design capacity. Also, some commenters questioned the ability of the alternative II emission control systems to continuously operate at a 99.9 percent control efficiency because of the adverse impact of Claus sulfur recovery plant fluctuations and CO₂-rich waste gas streams.

In arriving at the numerical emissions limits included in the standards, source test data collected by a local agency at times when the emission control systems were operating at normal capacities, information from vendors of emission control equipment, published literature on emission control technology, and contractor reports on the performance of emission control technology were considered, in addition to the data collected during EPA's source tests. Based on the information and data from these sources and the lack of any new information and data submitted by the commenters, no change in the emission limits of the standards is warranted. Furthermore, the numerical emission limits in the standards contain an adequate safety margin to allow for increased emissions due to Claus sulfur recovery plant fluctuations.

With respect to the potential adverse impact of high CO₂ gas streams, this is not likely to impair the overall emission control system efficiency since high CO₂ gas streams are seldom found in the gases treated in refinery Claus sulfur recovery plants.

ENVIRONMENTAL IMPACT

Several commenters felt that the assessment of the environmental impact of the standards was, in some cases, biased and not always clear. One of these commenters suggested that a thorough environmental impact statement should be prepared to clarify the impacts of the standards.

Litigation involving standards of performance has established that preparation of a formal environmental impact statement under the National Environmental Policy Act is not necessary for actions under section 111 of the Clean Air Act. While a formal environmental impact statement is not prepared, the beneficial as well as the adverse impacts of standards of performance are considered. The promulgated standards will significantly reduce emissions of sulfur from petroleum refineries without resulting in any significant adverse environmental, energy, or economic impacts.

Other commenters felt that standards based on 99 percent control (al-

ternative I) would be essentially as environmentally beneficial as standards based on 99.9 percent control and would be less costly to the public. This argument was based on the premise that most State regulations do not require control of Claus sulfur plant emissions at the 99 percent level as claimed in volume I of the SSEIS. Hence, standards based on alternative I would significantly reduce national sulfur emissions from refinery Claus sulfur recovery plants.

A review of State regulations for controlling emissions from refinery sulfur recovery plants has shown that the majority of the States with the largest petroleum refining capacities require 99 percent control of emissions from new and existing sulfur recovery plants. Since refinery sulfur recovery plant growth will likely occur in these States, the conclusion that standards based on 99 percent control would have little or no beneficial impact is essentially correct.

ENERGY IMPACT

Several commenters questioned the conclusion that compliance with standards based on alternative II could lead to an energy savings, compared to standards based on alternative I. A review of the information and data available confirms this conclusion. In any case, the important consideration is whether the energy impact of the standards is reasonable. No information was submitted which would indicate that the energy impact of the standards is unreasonable.

OTHER CONSIDERATIONS

At proposal comments were requested relative to EPA's decision to regulate reduced sulfur compound emissions, which are designated pollutants, without implementing section 111(d) of the Clean Air Act at this time. The one commenter who responded to this issue was in agreement with this decision.

As discussed in both the preamble to the proposed standards and volumes I and II of the SSEIS, petroleum refinery Claus sulfur recovery plants are sources of SO_x emissions, not reduced sulfur compound emissions. One of the emission control technologies for reducing SO_x emissions, however, first converts these emissions to reduced sulfur compounds and then controls these compounds. Consequently, this technology may discharge residual emissions of reduced sulfur compounds to the atmosphere.

Currently, there are about 30 refinery Claus sulfur recovery plants in the United States which have installed reduction emission control systems to reduce SO_x emissions. A review of these plants indicates that these emission control systems are well designed and well maintained and operated.

Emissions of reduced sulfur compounds are less than 0.050 percent (i.e., 500 ppm), which is only slightly higher than the numerical emission limit included in the promulgated standard. Thus, there is little to gain at this time by requiring States to develop regulations limiting emissions from these sources. Consequently, section 111(d) will not be implemented until resources permit, taking into consideration other requirements of the Clean Air Act, as amended, which EPA must implement.

Several commenters were concerned that Reference Method 15 might not be practical for use in a refinery environment. The basis for most of these objections was that the commenters thought this method was being proposed as a continuous monitoring method. However, Reference Method 15 was not proposed for use as a continuous monitoring method. Performance specifications for continuous monitors for reduced sulfur compounds have not been developed and therefore such monitors are not required to be installed until performance specifications for these monitors are proposed and promulgated under Appendix B of 40 CFR Part 60.

Reference Method 15 has been revised to allow greater flexibility in operating details and equipment choice. The user is now permitted to design his own sampling and analysis system as long as he preserves the operating principle of gas chromatography with flame photometric detection and meets the design and performance criteria.

MISCELLANEOUS

The effective date of this regulation is March 15, 1978. Section 111(b)(1)(B) of the Clean Air Act provides that standards of performance or revisions of them become effective upon promulgation and apply to affected facilities, construction or modification of which was commenced after the date of proposal (October 4, 1976).

ECONOMIC IMPACT ASSESSMENT: An economic assessment has been prepared as required under section 317 of the Act. This also satisfies the requirements of Executive Orders 11821 and 11949 and OMB Circular A-107.

Dated: March 1, 1978.

DOUGLAS M. COSTLE,
Administrator.

1. Section 60.100 is amended as follows:

§ 60.100 Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to the following affected facilities in petroleum refineries: fluid catalytic cracking unit catalyst regenerators, fuel gas combustion devices, and all Claus sulfur recovery plants except Claus plants of 20 long

RULES AND REGULATIONS

tons per day (LTD) or less associated with a small petroleum refinery. The Claus sulfur recovery plant need not be physically located within the boundaries of a petroleum refinery to be an affected facility, provided it processes gases produced within a petroleum refinery.

(b) Any fluid catalytic cracking unit catalyst regenerator of fuel gas combustion device under paragraph (a) of this section which commences construction or modification after June 11, 1973, or any Claus sulfur recovery plant under paragraph (a) of this section which commences construction or modification after October 4, 1976, is subject to the requirements of this part.

(Secs. 111 and 301(a), Clean Air Act, as amended (42 U.S.C. 7411, 7601 (a)), and additional authority as noted below.)

2. Section 60.101 is amended as follows:

§ 60.101 Definitions.

(i) "Claus sulfur recovery plant" means a process unit which recovers sulfur from hydrogen sulfide by a vapor-phase catalytic reaction of sulfur dioxide and hydrogen sulfide.

(j) "Oxidation control system" means an emission control system which reduces emissions from sulfur recovery plants by converting these emissions to sulfur dioxide.

(k) "Reduction control system" means an emission control system which reduces emissions from sulfur recovery plants by converting these emissions to hydrogen sulfide.

(l) "Reduced sulfur compounds" mean hydrogen sulfide (H_2S), carbonyl sulfide (COS) and carbon disulfide (CS_2).

(m) "Small petroleum refinery" means a petroleum refinery which has a crude oil processing capacity of 50,000 barrels per stream day or less, and which is owned or controlled by a refinery with a total combined crude oil processing capacity of 137,500 barrels per stream day or less.

3. Section 60.102 is amended by revising paragraph (a) introductory text and paragraph (b) as follows:

§ 60.102 Standard for particulate matter.

(a) On and after the date on which the performance test required to be conducted by § 60.8 is completed, no owner or operator subject to the provisions of this subpart shall discharge or cause the discharge into the atmosphere from any fluid catalytic cracking unit catalyst regenerator:

- (1) * * *
- (2) * * *

(b) Where the gases discharged by the fluid catalytic cracking unit catalyst regenerator pass through an in-

cinerator or waste heat boiler in which auxiliary or supplemental liquid or solid fossil fuel is burned, particulate matter in excess of that permitted by paragraph (a)(1) of this section may be emitted to the atmosphere, except that the incremental rate of particulate matter emissions shall not exceed 43.0 g/MJ (0.10 lb/million Btu) of heat input attributable to such liquid or solid fossil fuel.

4. Section 60.104 is amended as follows:

§ 60.104 Standard for sulfur dioxide.

(a) On and after the date on which the performance test required to be conducted by § 60.8 is completed, no owner or operator subject to the provisions of this subpart shall:

(1) Burn in any fuel gas combustion device any fuel gas which contains hydrogen sulfide in excess of 230 mg/dscm (0.10 gr/dscf), except that the gases resulting from the combustion of fuel gas may be treated to control sulfur dioxide emissions provided the owner or operator demonstrates to the satisfaction of the Administrator that this is as effective in preventing sulfur dioxide emissions to the atmosphere as restricting the H_2 concentration in the fuel gas to 230 mg/dscm or less. The combustion in a flare of process upset gas, or fuel gas which is released to the flare as a result of relief valve leakage, is exempt from this paragraph.

(2) Discharge or cause the discharge of any gases into the atmosphere from any Claus sulfur recovery plant containing in excess of:

(i) 0.025 percent by volume of sulfur dioxide at zero percent oxygen on a dry basis if emissions are controlled by an oxidation control system, or a reduction control system followed by incineration, or

(ii) 0.030 percent by volume of reduced sulfur compounds and 0.0010 percent by volume of hydrogen sulfide calculated as sulfur dioxide at zero percent oxygen on a dry basis if emissions are controlled by a reduction control system not followed by incineration.

(b) [Reserved]

5. Section 60.105 is amended as follows:

§ 60.105 Emission monitoring.

(a) * * *

(2) An instrument for continuously monitoring and recording the concentration of carbon monoxide in gases discharged into the atmosphere from fluid catalytic cracking unit catalyst regenerators. The span of this continuous monitoring system shall be 1,000 ppm.

(3) * * *

(4) An instrument for continuously monitoring and recording concentrations of hydrogen sulfide in fuel gases

burned in any fuel gas combustion device. If compliance with § 60.104(a)(1) is achieved by removing H_2S from the fuel gas before it is burned; fuel gas combustion devices having a common source of fuel gas may be monitored at one location, if monitoring at this location accurately represents the concentration of H_2S in the fuel gas burned. The span of this continuous monitoring system shall be 300 ppm.

(5) An instrument for continuously monitoring and recording concentrations of SO_2 in the gases discharged into the atmosphere from any Claus sulfur recovery plant if compliance with § 60.104(a)(2) is achieved through the use of an oxidation control system or a reduction control system followed by incineration. The span of this continuous monitoring system shall be sent at 500 ppm.

(6) An instrument(s) for continuously monitoring and recording the concentration of H_2S and reduced sulfur compounds in the gases discharged into the atmosphere from any Claus sulfur recovery plant if compliance with § 60.104(a)(2) is achieved through the use of a reduction control system not followed by incineration. The span(s) of this continuous monitoring system(s) shall be set at 20 ppm for monitoring and recording the concentration of H_2S and 600 ppm for monitoring and recording the concentration of reduced sulfur compounds.

(e) * * *

(1) * * *

(2) Carbon monoxide. All hourly periods during which the average carbon monoxide concentration in the gases discharged into the atmosphere from any fluid catalytic cracking unit catalyst regenerator subject to § 60.103 exceeds 0.050 percent by volume.

(3) Sulfur dioxide. (i) Any three-hour period during which the average concentration of H_2S in any fuel gas combusted in any fuel gas combustion device subject to § 60.104(a)(1) exceeds 230 mg/dscm (0.10 gr/dscf), if compliance is achieved by removing H_2S from the fuel gas before it is burned; or any three-hour period during which the average concentration of SO_2 in the gases discharged into the atmosphere from any fuel gas combustion device subject to § 60.104(a)(1) exceeds the level specified in § 60.104(a)(1), if compliance is achieved by removing SO_2 from the combusted fuel gases.

(ii) Any twelve-hour period during which the average concentration of SO_2 in the gases discharged into the atmosphere from any Claus sulfur recovery plant subject to § 60.104(a)(2) exceeds 250 ppm at zero percent oxygen on a dry basis if compliance with § 60.104(b) is achieved through the use of an oxidation control system.

RULES AND REGULATIONS

or a reduction control system followed by incineration; or any twelve-hour period during which the average concentration of H_2S , or reduced sulfur compounds in the gases discharged into the atmosphere of any Claus sulfur plant subject to § 60.104(a)(2) (b) exceeds 10 ppm or 300 ppm, respectively, at zero percent oxygen and on a dry basis if compliance is achieved through the use of a reduction control system not followed by incineration.

6. Section 60.106 is amended as follows:

§ 60.106 Test methods and procedures.

(c) For the purpose of determining compliance with § 60.104(a)(1), Method 11 shall be used to determine the concentration of H_2S and Method 6 shall be used to determine the concentration of SO_2 .

(1) If Method 11 is used, the gases sampled shall be introduced into the sampling train at approximately atmospheric pressure. Where refinery fuel gas lines are operating at pressures substantially above atmosphere, this may be accomplished with a flow control valve. If the line pressure is high enough to operate the sampling train without a vacuum pump, the pump may be eliminated from the sampling train. The sample shall be drawn from a point near the centroid of the fuel gas line. The minimum sampling time shall be 10 minutes and the minimum sampling volume 0.01 dscm (0.35 dscf) for each sample. The arithmetic average of two samples of equal sampling time shall constitute one run. Samples shall be taken at approximately 1-hour intervals. For most fuel gases, sample times exceeding 20 minutes may result in depletion of the collecting solution, although fuel gases containing low concentrations of hydrogen sulfide may necessitate sampling for longer periods of time.

(2) If Method 6 is used, Method 1 shall be used for velocity traverses and Method 2 for determining velocity and volumetric flow rate. The sampling site for determining SO_2 concentration by Method 6 shall be the same as for determining volumetric flow rate by Method 2. The sampling point in the duct for determining SO_2 concentration by Method 6 shall be at the centroid of the cross section if the cross sectional area is less than $5 m^2$ ($54 ft^2$) or at a point no closer to the walls than 1 m (39 inches) if the cross sectional area is $5 m^2$ or more and the centroid is more than 1 meter from the wall. The sample shall be extracted at a rate proportional to the gas velocity at the sampling point. The minimum sampling time shall be 10 minutes and the minimum sampling volume 0.01 dscm (0.35 dscf) for each sample. The arithmetic average of two

samples of equal sampling time shall constitute one run. Samples shall be taken at approximately 1-hour intervals.

(d) For the purpose of determining compliance with § 60.104(a)(2), Method 6 shall be used to determine the concentration of SO_2 and Method 15 shall be used to determine the concentration of H_2S and reduced sulfur compounds.

(1) If Method 6 is used, the procedure outlined in paragraph (c)(2) of this section shall be followed except that each run shall span a minimum of four consecutive hours of continuous sampling. A number of separate samples may be taken for each run, provided the total sampling time of these samples adds up to a minimum of four consecutive hours. Where more than one sample is used, the average SO_2 concentration for the run shall be calculated as the time weighted average of the SO_2 concentration for each sample according to the formula:

$$C_R = \sum_{i=1}^N C_{Si} \frac{t_{Si}}{T}$$

Where:

C_R = SO_2 concentration for the run.

N = Number of samples.

C_{Si} = SO_2 concentration for sample i .

t_{Si} = Continuous sampling time of sample i .

T = Total continuous sampling time of all N samples.

(2) If Method 15 is used, each run shall consist of 16 samples taken over a minimum of three hours. The sampling point shall be at the centroid of the cross section of the duct if the cross sectional area is less than $5 m^2$ ($54 ft^2$) or at a point no closer to the walls than 1 m (39 inches) if the cross sectional area is $5 m^2$ or more and the centroid is more than 1 meter from the wall. To insure minimum residence time for the sample inside the sample lines, the sampling rate shall be at least 3 liters/minute ($0.1 ft^3/min$). The SO_2 equivalent for each run shall be calculated as the arithmetic average of the SO_2 equivalent of each sample during the run. Reference Method 4 shall be used to determine the moisture content of the gases. The sampling point for Method 4 shall be adjacent to the sampling point for Method 15. The sample shall be extracted at a rate proportional to the gas velocity at the sampling point. Each run shall span a minimum of four consecutive hours of continuous sampling. A number of separate samples may be taken for each run provided the total sampling time of these samples adds up to a minimum of four consecutive hours. Where more than one sample is used, the average moisture content for the run shall be calculated as the time weighted average of the moisture content of each sample according to the formula:

$$B_{wv} = \sum_{i=1}^N B_{wi} \left[\frac{t_{wi}}{T} \right]$$

B_{wv} = Proportion by volume of water vapor in the gas stream for the run.

N = Number of samples.

B_{wi} = Proportion by volume of water vapor in the gas stream for the sample i .

t_{wi} = Continuous sampling time for sample i .

T = Total continuous sampling time of all N samples.

(Sec. 114 of the Clean Air Act, as amended [42 U.S.C. 7414]).

APPENDIX A—REFERENCE METHODS

7. Appendix A is amended by adding a new reference method as follows:

METHOD 15. DETERMINATION OF HYDROGEN SULFIDE, CARBONYL SULFIDE, AND CARBON DISULFIDE EMISSIONS FROM STATIONARY SOURCES

INTRODUCTION

The method described below uses the principle of gas chromatographic separation and flame photometric detection (FPD). Since there are many systems or sets of operating conditions that represent usable methods of determining sulfur emissions, all systems which employ this principle, but differ only in details of equipment and operation, may be used as alternative methods, provided that the criteria set below are met.

1. Principle and applicability

1.1 Principle. A gas sample is extracted from the emission source and diluted with clean dry air. An aliquot of the diluted sample is then analyzed for hydrogen sulfide (H_2S), carbonyl sulfide (COS), and carbon disulfide (CS_2) by gas chromatographic (GC) separation and flame photometric detection (FPD).

1.2 Applicability. This method is applicable for determination of the above sulfur compounds from tail gas control units of sulfur recovery plants.

2. Range and sensitivity

2.1 Range. Coupled with a gas chromatographic system utilizing a 1-milliliter sample size, the maximum limit of the FPD for each sulfur compound is approximately 10 ppm. It may be necessary to dilute gas samples from sulfur recovery plants hundred-fold (99:1) resulting in an upper limit of about 1000 ppm for each compound.

2.2 The minimum detectable concentration of the FPD is also dependent on sample size and would be about 0.5 ppm for a 1 ml sample.

3. Interferences

3.1 Moisture Condensation. Moisture condensation in the sample delivery system, the analytical column, or the FPD burner block can cause losses or interferences. This potential is eliminated by heating the sample line, and by conditioning the sample with dry dilution air to lower its dew point below the operating temperature of the GC/FPD analytical system prior to analysis.

3.2 Carbon Monoxide and Carbon Dioxide. CO and CO_2 have substantial desensitizing

RULES AND REGULATIONS

effects on the flame photometric detector even after 9:1 dilution. (Acceptable systems must demonstrate that they have eliminated this interference by some procedure such as eluting CO and CO₂ before any of the sulfur compounds to be measured.) Compliance with this requirement can be demonstrated by submitting chromatograms of calibration gases with and without CO₂ in the diluent gas. The CO₂ level should be approximately 10 percent for the case with CO₂ present. The two chromatographs should show agreement within the precision limits of section 4.1.

3.3 Elemental Sulfur. The condensation of sulfur vapor in the sampling line can lead to eventual coating and even blockage of the sample line. This problem can be eliminated along with the moisture problem by heating the sample line.

4. Precision

4.1 Calibration Precision. A series of three consecutive injections of the same calibration gas, at any dilution, shall produce results which do not vary by more than ± 13 percent from the mean of the three injections.

4.2 Calibration Drift. The calibration drift determined from the mean of three injections made at the beginning and end of any 8-hour period shall not exceed ± 5 percent.

5. Apparatus

5.1.1 Probe. The probe must be made of inert material such as stainless steel or glass. It should be designed to incorporate a filter and to allow calibration gas to enter the probe at or near the sample entry point. Any portion of the probe not exposed to the stack gas must be heated to prevent moisture condensation.

5.1.2 The sample line must be made of Teflon, no greater than 1.3 cm ($\frac{1}{2}$ in.) inside diameter. All parts from the probe to the dilution system must be thermostatically heated to 120° C.

5.1.3 Sample Pump. The sample pump shall be a leakless Teflon coated diaphragm type or equivalent. If the pump is upstream of the dilution system, the pump head must be heated to 120° C.

5.2 Dilution System. The dilution system must be constructed such that all sample contacts are made of inert material (e.g. stainless steel or Teflon). It must be heated to 120° C and be capable of approximately a 9:1 dilution of the sample.

5.3 Gas Chromatograph. The gas chromatograph must have at least the following components:

5.3.1 Oven. Capable of maintaining the separation column at the proper operating temperature $\pm 1^\circ$ C.

5.3.2 Temperature Gauge. To monitor column oven, detector, and exhaust temperature $\pm 1^\circ$ C.

5.3.3 Flow System. Gas metering system to measure sample, fuel, combustion gas, and carrier gas flows.

5.3.4 Flame Photometric Detector.

5.3.4.1 Electrometer. Capable of full scale amplification of linear ranges of 10^{-9} to 10^{-11} amperes full scale.

5.3.4.2 Power Supply. Capable of delivering up to 750 volts.

5.3.4.3 Recorder. Compatible with the output voltage range of the electrometer.

¹Mention of trade names or specific products does not constitute an endorsement by the Environmental Protection Agency.

5.4 Gas Chromatograph Columns. The column system must be demonstrated to be capable of resolving three major reduced sulfur compounds: H₂S, COS, and CS₂.

To demonstrate that adequate resolution has been achieved the tester must submit a chromatograph of a calibration gas containing all three reduced sulfur compounds in the concentration range of the applicable standard. Adequate resolution will be defined as base line separation of adjacent peaks when the amplifier attenuation is set so that the smaller peak is at least 50 percent of full scale. Base line separation is defined as a return to zero ± 5 percent in the interval between peaks. Systems not meeting this criteria may be considered alternate methods subject to the approval of the Administrator.

5.5.1 Calibration System. The calibration system must contain the following components.

5.5.2 Flow System. To measure air flow over permeation tubes at ± 2 percent. Each flowmeter shall be calibrated after a complete test series with a wet test meter. If the flow measuring device differs from the wet test meter by 5 percent, the completed test shall be discarded. Alternatively, the tester may elect to use the flow data that would yield the lowest flow measurement. Calibration with a wet test meter before a test is optional.

5.5.3 Constant Temperature Bath. Device capable of maintaining the permeation tubes at the calibration temperature within $\pm 1.1^\circ$ C.

5.5.4 Temperature Gauge. Thermometer or equivalent to monitor bath temperature within $\pm 1^\circ$ C.

6. Reagents

6.1 Fuel. Hydrogen (H₂) prepurified grade or better.

6.2 Combustion Gas. Oxygen (O₂) or air, research purity or better.

6.3 Carrier Gas. Prepurified grade or better.

6.4 Diluent. Air containing less than 0.5 ppm total sulfur compounds and less than 10 ppm each of moisture and total hydrocarbons.

6.5 Calibration Gases. Permeation tubes, one each of H₂S, COS, and CS₂, gravimetrically calibrated and certified at some convenient operating temperature. These tubes consist of hermetically sealed FEP Teflon tubing in which a liquified gaseous substance is enclosed. The enclosed gas permeates through the tubing wall at a constant rate. When the temperature is constant, calibration gases covering a wide range of known concentrations can be generated by varying and accurately measuring the flow rate of diluent gas passing over the tubes. These calibration gases are used to calibrate the GC/FPD system and the dilution system.

7. Pretest Procedures

The following procedures are optional but would be helpful in preventing any problem which might occur later and invalidate the entire test.

7.1 After the complete measurement system has been set up at the site and deemed to be operational, the following procedures should be completed before sampling is initiated.

7.1.1 Leak Test. Appropriate leak test procedures should be employed to verify the integrity of all components, sample lines, and connections. The following leak test procedure is suggested:

For components upstream of the sample pump, attach the probe end of the sample line to a manometer or vacuum gauge, start the pump and pull greater than 50 mm (2 in.) Hg vacuum, close off the pump outlet, and then stop the pump and ascertain that there is no leak for 1 minute. For components after the pump, apply a slight positive pressure and check for leaks by applying a liquid (detergent in water, for example) at each joint. Bubbling indicates the presence of a leak.

7.1.2 System Performance. Since the complete system is calibrated following each test, the precise calibration of each component is not critical. However, these components should be verified to be operating properly. This verification can be performed by observing the response of flowmeters or of the GC output to changes in flow rates or calibration gas concentrations and ascertaining the response to be within predicted limits. If any component or the complete system fails to respond in a normal and predictable manner, the source of the discrepancy should be identified and corrected before proceeding.

8. Calibration

Prior to any sampling run, calibrate the system using the following procedures. (If more than one run is performed during any 24-hour period, a calibration need not be performed prior to the second and any subsequent runs. The calibration must, however, be verified as prescribed in section 10, after the last run made within the 24-hour period.)

8.1 General Considerations. This section outlines steps to be followed for use of the GC/FPD and the dilution system. The procedure does not include detailed instructions because the operation of these systems is complex, and it requires an understanding of the individual system being used. Each system should include a written operating manual describing in detail the operating procedures associated with each component in the measurement system. In addition, the operator should be familiar with the operating principles of the components; particularly the GC/FPD. The citations in the Bibliography at the end of this method are recommended for review for this purpose.

8.2 Calibration Procedure. Insert the permeation tubes into the tube chamber. Check the bath temperature to assure agreement with the calibration temperature of the tubes within $\pm 0.1^\circ$ C. Allow 24 hours for the tubes to equilibrate. Alternatively equilibration may be verified by injecting samples of calibration gas at 1-hour intervals. The permeation tubes can be assumed to have reached equilibrium when consecutive hourly samples agree within the precision limits of section 4.1.

Vary the amount of air flowing over the tubes to produce the desired concentrations for calibrating the analytical and dilution systems. The air flow across the tubes must at all times exceed the flow requirement of the analytical systems. The concentration in parts per million generated by a tube containing a specific permeant can be calculated as follows:

$$C = K \times P_r / ML$$

Equation 15-1

where:

C = Concentration of permeant produced in ppm.

P_r = Permeation rate of the tube in $\mu\text{g}/\text{min}$.

RULES AND REGULATIONS

M=Molecular weight of the permeant: g/g-mole.

L=Flow rate, l/min, of air over permeant @ 20°C, 760 mm Hg.

K=Gas constant at 20°C and 760 mm Hg=24.04 l/g mole.

8.3 Calibration of analysis system. Generate a series of three or more known concentrations spanning the linear range of the FPD (approximately 0.05 to 1.0 ppm) for each of the four major sulfur compounds. Bypassing the dilution system, inject these standards in to the GC/FPD analyzers and monitor the responses. Three injects for each concentration must yield the precision described in section 4.1. Failure to attain this precision is an indication of a problem in the calibration or analytical system. Any such problem must be identified and corrected before proceeding.

8.4 Calibration Curves. Plot the GC/FPD response in current (amperes) versus their causative concentrations in ppm on log-log coordinate graph paper for each sulfur compound. Alternatively, a least squares equation may be generated from the calibration data.

8.5 Calibration of Dilution System. Generate a known concentration of hydrogen sulfide using the permeation tube system. Adjust the flow rate of diluent air for the first dilution stage so that the desired level of dilution is approximated. Inject the diluted calibration gas into the GC/FPD system and monitor its response. Three injections for each dilution must yield the precision described in section 4.1. Failure to attain this precision in this step is an indication of a problem in the dilution system. Any such problem must be identified and corrected before proceeding. Using the calibration data for H₂S (developed under 8.3) determine the diluted calibration gas concentration in ppm. Then calculate the dilution factor as the ratio of the calibration gas concentration before dilution to the diluted calibration gas concentration determined under this paragraph. Repeat this procedure for each stage of dilution required. Alternatively, the GC/FPD system may be calibrated by generating a series of three or more concentrations of each sulfur compound and diluting these samples before injecting them into the GC/FPD system. This data will then serve as the calibration data for the unknown samples and a separate determination of the dilution factor will not be necessary. However, the precision requirements of section 4.1 are still applicable.

9. Sampling and Analysis Procedure

9.1 Sampling. Insert the sampling probe into the test port making certain that no dilution air enters the stack through the port. Begin sampling and dilute the sample approximately 9:1 using the dilution system. Note that the precise dilution factor is that which is determined in paragraph 8.5. Condition the entire system with sample for a minimum of 15 minutes prior to commencing analysis.

9.2 Analysis. Aliquots of diluted sample are injected into the GC/FPD analyzer for analysis.

9.2.1 Sample Run. A sample run is composed of 16 individual analyses (injects) performed over a period of not less than 3 hours or more than 6 hours.

9.2.2 Observation for Clogging of Probe. If reductions in sample concentrations are observed during a sample run that cannot be explained by process conditions, the sampling must be interrupted to determine if

the sample probe is clogged with particulate matter. If the probe is found to be clogged, the test must be stopped and the results up to that point discarded. Testing may resume after cleaning the probe or replacing it with a clean one. After each run, the sample probe must be inspected and, if necessary, dismantled and cleaned.

10. Post-Test Procedures

10.1 Sample Line Loss. A known concentration of hydrogen sulfide at the level of the applicable standard, ± 20 percent, must be introduced into the sampling system at the opening of the probe in sufficient quantities to ensure that there is an excess of sample which must be vented to the atmosphere. The sample must be transported through the entire sampling system to the measurement system in the normal manner. The resulting measured concentration should be compared to the known value to determine the sampling system loss. A sampling system loss of more than 20 percent is unacceptable. Sampling losses of 0-20 percent must be corrected by dividing the resulting sample concentration by the fraction of recovery. The known gas sample may be generated using permeation tubes. Alternatively, cylinders of hydrogen sulfide mixed in air may be used provided they are traceable to permeation tubes. The optional pretest procedures provide a good guideline for determining if there are leaks in the sampling system.

10.2 Recalibration. After each run, or after a series of runs made within a 24-hour period, perform a partial recalibration using the procedures in section 8. Only H₂S (or other permeant) need be used to recalibrate the GC/FPD analysis system (8.3) and the dilution system (8.5).

10.3 Determination of Calibration Drift. Compare the calibration curves obtained prior to the runs, to the calibration curves obtained under paragraph 10.1. The calibration drift should not exceed the limits set forth in paragraph 4.2. If the drift exceeds this limit, the intervening run or runs should be considered not valid. The tester, however, may instead have the option of choosing the calibration data set which would give the highest sample values.

11. Calculations

11.1 Determine the concentrations of each reduced sulfur compound detected directly from the calibration curves. Alternatively, the concentrations may be calculated using the equation for the least squares line.

11.2 Calculation of SO₂ Equivalent. SO₂ equivalent will be determined for each analysis made by summing the concentrations of each reduced sulfur compound resolved during the given analysis.

$$\text{SO}_2 \text{ equivalent} = \Sigma (\text{H}_2\text{S}, \text{COS}, 2 \text{CS}_2) d$$

Equation 15-2

where:

SO₂ equivalent=The sum of the concentration of each of the measured compounds (COS, H₂S, CS₂) expressed as sulfur dioxide in ppm.

H₂S=Hydrogen sulfide, ppm.

COS=Carbonyl sulfide, ppm.

CS₂=Carbon disulfide, ppm.

d=Dilution factor, dimensionless.

11.3 Average SO₂ equivalent will be determined as follows:

$$\text{Average SO}_2 \text{ equivalent} = \frac{\Sigma \text{SO}_2 \text{ equiv.}_i}{N(1 - Bwo)}$$

Equation 15-3

where:

Average SO₂ equivalent_i=Average SO₂ equivalent in ppm, dry basis.

Average SO₂ equivalent_i=SO₂ in ppm as determined by Equation 15-2.

N=Number of analyses performed.

Bwo=Fraction of volume of water vapor in the gas stream as determined by Method 4—Determination of Moisture in Stack Gases (36 FR 24887).

12. Example System

Described below is a system utilized by EPA in gathering NSPS data. This system does not now reflect all the latest developments in equipment and column technology, but it does represent one system that has been demonstrated to work.

12.1 Apparatus.

12.1.1 Sample System.

12.1.1.1 Probe. Stainless steel tubing, 6.35 mm (1/4 in.) outside diameter, packed with glass wool.

12.1.1.2 Sample Line. 1/8 inch inside diameter Teflon tubing heated to 120°C. This temperature is controlled by a thermostatic heater.

12.1.1.3 Sample Pump. Leakless Teflon coated diaphragm type or equivalent. The pump head is heated to 120°C by enclosing it in the sample dilution box (12.2.4 below).

12.1.2 Dilution System. A schematic diagram of the dynamic dilution system is given in Figure 15-2. The dilution system is constructed such that all sample contacts are made of inert materials. The dilution system which is heated to 120°C must be capable of a minimum of 9:1 dilution of sample. Equipment used in the dilution system is listed below:

12.1.2.1 Dilution Pump. Model A-150 Kohmyhr Teflon positive displacement type, nonadjustable 150 cc/min. ± 2.0 percent, or equivalent, per dilution stage. A 9:1 dilution of sample is accomplished by combining 150 cc of sample with 1350 cc of clean dry air as shown in Figure 15-2.

12.1.2.2 Valves. Three-way Teflon solenoid or manual type.

12.1.2.3 Tubing. Teflon tubing and fittings are used throughout from the sample probe to the GC/FPD to present an inert surface for sample gas.

12.1.2.4 Box. Insulated box, heated and maintained at 120°C, of sufficient dimensions to house dilution apparatus.

12.1.2.5 Flowmeters. Rotameters or equivalent to measure flow from 0 to 1500 ml/min. ± 1 percent per dilution stage.

12.1.3.0 Gas Chromatograph.

12.1.3.1 Column—1.83 m (6 ft.) length of Teflon tubing, 2.16 mm (0.085 in.) inside diameter, packed with deactivated silica gel, or equivalent.

12.1.3.2 Sample Valve. Teflon six port gas sampling valve, equipped with a 1 ml sample loop, actuated by compressed air (Figure 15-1).

12.1.3.3 Oven. For containing sample valve, stripper column and separation column. The oven should be capable of maintaining an elevated temperature ranging from ambient to 100°C, constant within $\pm 1^\circ\text{C}$.

CHAPTER I—ENVIRONMENTAL
PROTECTION AGENCY

[FRL 870-4]

PART 60—STANDARDS OF PERFOR-
MANCE FOR NEW STATIONARY
SOURCES

Amendments to Reference Methods
1-8; Correction

AGENCY: Environmental Protection
Agency.

ACTION: Correction.

SUMMARY: This document corrects
typographical errors to certain Refer-
ence Methods and makes amendments
to others for purposes of clarification.
These Reference Methods were pub-
lished as final rules in the *FEDERAL
REGISTER* for Thursday, 42 FR 41754,
August 18, 1977, in FR Doc. 77-13608.

EFFECTIVE DATE: March 23, 1978.

FOR FURTHER INFORMATION
CONTACT:

Don R. Goodwin, Emission Stan-
dards and Engineering Division
(MD-13), Environmental Protection
Agency, Research Triangle Park,
N.C. 27711, telephone 919-541-5271.

SUPPLEMENTARY INFORMATION:
After publication of revisions to Refer-
ence Methods 1-8 on August 18, 1977,
we found many typographical errors.
We also received comments which
showed that the procedures in Refer-
ence Methods 1, 4, 6, and 7 needed ad-
ditional clarification or revision. Addi-
tional explanation of the procedures
to be used are provided by this correc-

FEDERAL REGISTER, VOL. 43, NO. 51

WEDNESDAY, MARCH 15, 1978

12.1.3.4 Temperature Monitor. Thermo-
couple pyrometer to measure column oven,
detector, and exhaust temperature $\pm 1^\circ\text{C}$.

12.1.3.5 Flow System. Gas metering
system to measure sample flow, hydrogen
flow, oxygen flow and nitrogen carrier gas
flow.

12.1.3.6 Detector. Flame photometric de-
tector.

12.1.3.7 Electrometer. Capable of full scale
amplification of linear ranges of 10^{-6} to 10^{-4}
amperes full scale.

12.1.3.8 Power Supply. Capable of deliver-
ing up to 750 volts.

12.1.3.9 Recorder. Compatible with the
output voltage range of the electrometer.

12.1.4 Calibration. Permeation tube
system (Figure 15-3).

12.1.4.1 Tube Chamber. Glass chamber of
sufficient dimensions to house permeation
tubes.

12.1.4.2 Mass Flowmeters. Two mass flow-
meters in the range 0-3 l/min. and 0-10 l/
min. to measure air flow over permeation
tubes at ± 2 percent. These flowmeters shall
be cross-calibrated at the beginning of each
test. Using a convenient flow rate in the
measuring range of both flowmeters, set
and monitor the flow rate of gas over the
permeation tubes. Injection of calibration
gas generated at this flow rate as measured
by one flowmeter followed by injection of
calibration gas at the same flow rate as mea-
sured by the other flowmeter should agree
within the specified precision limits. If they
do not, then there is a problem with the
mass flow measurement. Each mass flow-
meter shall be calibrated prior to the first
test with a wet test meter and thereafter at
least once each year.

12.1.4.3 Constant Temperature Bath. Ca-
pable of maintaining permeation tubes at
certification temperature of 30°C within
 $\pm 0.1^\circ\text{C}$.

12.2 Reagents.

12.2.1 Fuel. Hydrogen (H_2) prepurified
grade or better.

12.2.2 Combustion Gas. Oxygen (O_2) re-
search purity or better.

12.2.3 Carrier Gas. Nitrogen (N_2) prepuri-
fied grade or better.

12.2.4 Diluent. Air containing less than 0.5
ppm total sulfur compounds and less than
10 ppm each of moisture and total hydro-
carbons, and filtered using MSA filters
46727 and 79030, or equivalent. Removal of
sulfur compounds can be verified by inject-
ing dilution air only, described in section
8.3.

12.2.5 Compressed Air. 60 psig for GC
valve actuation.

12.2.6 Calibration Gases. Permeation
tubes gravimetrically calibrated and certi-
fied at 30.0°C .

12.3 Operating Parameters. The operating
parameters for the GC/FPD system are as
follows: nitrogen carrier gas flow rate of 100
cc/min, exhaust temperature of 110°C , de-
tector temperature 105°C , oven tempera-
ture of 40°C , hydrogen flow rate of 80 cc/
minute, oxygen flow rate of 20 cc/minute,
and sample flow rate of 80 cc/minute.

12.4 Analysis. The sample valve is actu-
ated for 1 minute in which time an aliquot
of diluted sample is injected onto the sepa-
ration column. The valve is then deactivated
for the remainder of analysis cycle in which
time the sample loop is refilled and the sep-
aration column continues to be foreflushed.
The elution time for each compound will be
determined during calibration.

RULES AND REGULATIONS

tion notice. In addition to the errors in the methods themselves, two typographical errors were discovered in the preamble. On page 41754, under "Method 7," the phrase "variable wave length" is corrected to read "single and double-beam." On page 41755, under "Method 8," the word "content" (in point No. 4) is corrected to read "components."

NOTE—The Environmental Protection Agency has determined that this document does not contain a major proposal requiring preparation of an Economic Impact Analysis.

Dated: March 13, 1978.

DAVID A. HAWKINS,
Assistant Administrator
for Air and Waste Management.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

APPENDIX A—REFERENCE METHODS

In Method 1 of Appendix A, Sections 2.3.1, 2.3.2, and 2.4 and Table 1-1 are amended as follows:

1. In Section 2.3.1, the word "adcording" in the second line is corrected to read "according."

2. In Section 2.3.2, insert after the first paragraph the following:

If the tester desires to use more than the minimum number of traverse points, expand the "minimum number of traverse points" matrix (see Table 1-1) by adding the extra traverse points along one or the other or both legs of the matrix; the final matrix need not be balanced. For example, if a 4x3 "minimum number of points" matrix were expanded to 36 points, the final matrix could be 9x4 or 12x3, and would not necessarily have to be 6x6. After constructing the final matrix, divide the stack cross-section into as many equal rectangular, elemental areas as traverse points, and locate a traverse point at the centroid of each equal area.

3. In Section 2.4, the word "travsrse" in the fifteenth line of the second paragraph is corrected to read "traverse."

4. In Table 1-1, move the words "Number of traverse points" to the left, so that they are centered above the numbers listed in the left-hand column.

In Method 2 of Appendix A, Sections 2.1, 2.2, 2.4, 3.2, 4.1, 4.1.2, 4.1.4.1, 4.1.5.2, and 6 are amended as follows:

1. In Section 2.1, "±" is inserted in front of the "5 percent" in the fourteenth line of the third paragraph.

2. In Section 2.2, "measurmen t" in the next-to-the last line of the first paragraph is corrected to read "measurement."

3. In Section 2.4, "Type X" in the fifth line is corrected to read "Type S."

4. In Section 3.2, "ma" in the first line is corrected to read "ma-."

5. In Section 4.1, "R_i" in the seventh line of the second paragraph is replaced with "D_i."

6. In Section 4.1.2, "B." is inserted between the words "other," and "Calibration."

7. In Section 4.1.4.1, "C_{pw}=Type S pitot tube coefficient" is corrected to read "C_{pw}=Type S pitot tube coefficient."

8. In Section 4.1.5.2, the words "pitot-nozzel" in the third line are corrected to read "pitot-nozzle."

9. In Section 6, Citations 9, 13, and 18 are amended as follows:

a. In No. 9, the word "Tiangle" is corrected to read "Triangle."

b. In No. 13, the "s" in "Techniques" is deleted.

c. In No. 18, the word "survey" is corrected to read "Survey."

In Method 3 of Appendix A, Sections 1.2, 3.2.4, 4.2.6.2, 6.2, and 7 are amended as follows:

1. In Section 1.2, the title "U. S. Environmental Protection Agency" is inserted at the end of the second paragraph.

2. In Section 3.2.4, "CO" in the tenth line is corrected to read "CO₂."

3. In Section 4.2.6.2(b), the phrase "or equal to" is inserted between "than" and "15.0."

4. In Section 6.2, Equation 3-1 is corrected to read as follows:

$$SEA = \left[\frac{SO_2 - 0.55 CO}{0.264 \ln_2 - 1 \ln_2 - 0.55 CO} \right] 100$$

5. In Section 7, Bibliography, No. 2, the word "with" is inserted between the words "Sampling" and "Plastic."

In Method 4 of Appendix A, Sections 2.1.2, 2.2.1, 2.2.3, 2.3.1, 3.1.8, 3.2.1, 3.3.1, 3.3.3, 3.3.4, and Figure 4-2 are amended as follows:

1. In Section 2.1.2, the word "neasurement" in the third line of the third paragraph is corrected to read "measurement."

2. In Section 2.2.1, the word "travers" in the sixth line is corrected to read "traverse."

3. In Section 2.2.3, the work "eak" in the last sentence is corrected to read "leak."

4. In Figure 4-2, the word "ocation" in the second line on top of the figure, is corrected to read "Location."

5. In Section 2.3.1, "M_w" is changed to read "M_v" and "P_v" is changed to read "P_w."

6. In Section 3.1.8, "31 pm" is corrected to read "3 lpm."

7. In Section 3.2.1, delete all of first paragraph except the first sentence and insert the following:

Leak check the sampling train as follows: Temporarily insert a vacuum gauge at or near the probe inlet; then, plug the probe inlet and pull a vacuum of at least 250 mm Hg (10 in. Hg). Note, the time rate of change of the dry gas meter dial; alternatively, a rotameter (0-40 cc/min) may be tem-

porarily attached to the dry gas meter outlet to determine the leakage rate. A leak rate not in excess of 2 percent of the average sampling rate is acceptable.

NOTE—Carefully release the probe inlet plug before turning off the pump.

8. In Section 3.3.1, add the following definition to the list:

Y = Dry gas meter calibration factor.

Also, "o_w" is corrected to read "p_w".

9. In Section 3.3.3, Equation 4-6 is corrected to read as follows:

$$V_{sc}(std) = V_s \left(\frac{P_s}{P_{std}} \right) \left(\frac{T_{std}}{T_s} \right) - K_2 V \frac{P_s}{P_o}$$

10. In Section 3.3.4, Equation 4-7 is corrected to read as follows:

$$B_{sc} = \frac{V_{sc}(std)}{V_{sc}(std) + V_{n}(std)} + B_{sc} = \frac{V_{sc}(std)}{V_{sc}(std) + V_{n}(std)} + (0.025)$$

In Method 5 of Appendix A, Sections 2.1.1, 2.2.4, 4.1.2, 4.1.4.2, 4.2, 6.1, 6.3, 6.11.1, and 6.11.2 are amended as follows:

1. In Section 2.1.1, the word "proble" in the fourth line is corrected to read "probe."

2. In Section 2.2.4, "pol0-" is corrected to read "poly-".

3. In Section 4.1.2, the sentence "The sampling time at each point shall be the same." is inserted at the end of the fifth paragraph.

4. In Section 4.1.4.2, the word "It" in the seventh line is corrected to read "it."

5. In Section 4.2, the word "nylon" in the seventh, ninth, and thirteenth paragraphs is corrected to read "Nylon."

6. In Section 6.1 Nomenclature, "C_a=Acetone blank residue concentrations, mg/g" is corrected to read "C_a=Acetone blank residue concentration, mg/g" and "V_a" is changed to read "V_w."

7. In Section 6.3, page 41782, "m₁=0.3858 °K/mm Hg for metric units" is corrected to read "K₁=0.3858 °K/mm Hg for metric units."

8. In Section 6.11.1, Equation 5-7 is corrected to read as follows:

$$I = \frac{100 \cdot I_1 \cdot I_2 \cdot V_{1c} + (V_2 \cdot Y \cdot I_2) (P_{bar} + 29.913.6)}{60 \cdot C_1 \cdot V_s \cdot A_n}$$

9. In Section 6.11.2, the second form of Equation 5-8 is corrected to read as follows:

$$= V_s \frac{V_{sc}(std)}{V_s \cdot V_{sc}(std) \cdot (1 - Y)}$$

In Method 6 of Appendix A, Sections 2.1, 2.1.6, 2.1.7, 2.1.8, 2.1.11, 2.1.12, 2.3.2, 3.3.4, 4.1.2, 4.1.3, and 5.1.1 are amended as follows:

RULES AND REGULATIONS

1. In Section 2.1, the word "peroxide" in the fourth line of the second paragraph is corrected to read "peroxide."

2. In Section 2.1.6, the word "sillic" in the third line is corrected to read "silica."

3. In Section 2.1.7, the word "value", which appears twice is corrected to read "valve."

4. In Section 2.1.8, the word "disphragm" is corrected to read "diaphragm" and the word "surge" is inserted between the words "small" and "tank."

5. In Section 2.1.11, the word "ameroid" is corrected to read "aneroid."

6. In Section 2.1.12, the phrase "and Rotameter." is inserted after the phrase "Vacuum Gauge" and the phrase "and 0-40 cc/min rotameter" is inserted between the words "gauge" and "to."

7. In Section 2.3.2, the phrase "and 100-ml size" is corrected to read "and 1000-ml size."

8. In Section 3.3.4, the word "sopropanol" in the fourth line is corrected to read "isopropanol."

9. In Section 4.1.3, delete the last sentence of the last paragraph. Also delete the second paragraph and replace it with the following paragraphs:

Temporarily attach a suitable (e.g., 0-40 cc/min) rotameter to the outlet of the dry gas meter and place a vacuum gauge at or near the probe inlet. Plug the probe inlet, pull a vacuum of at least 250 mm Hg (10 in. Hg), and note the flow rate as indicated by the rotameter. A leakage rate not in excess of 2 percent of the average sampling rate is acceptable.

NOTE: Carefully release the probe inlet plug before turning off the pump.

It is suggested (not mandatory) that the pump be leak-checked separately, either prior to or after the sampling run. If done prior to the sampling run, the pump leak-check shall precede the leak check of the sampling train described immediately above; if done after the sampling run, the pump leak-check shall follow the train leak-check. To leak check the pump, proceed as follows: Disconnect the drying tube from the probe-impinger assembly. Place a vacuum gauge at the inlet to either the drying tube or the pump, pull a vacuum of 250 mm (10 in.) Hg, plug or pinch off the outlet of the flow meter and then turn off the pump. The vacuum should remain stable for at least 30 seconds.

10. In Section 4.1.3, the sentence "If a leak is found, void the test run" on the sixteenth line is corrected to read

"If a leak is found, void the test run, or use procedures acceptable to the Administrator to adjust the sample volume for the leakage."

11. In Section 5.1.1, the word "or" on the sixth line is corrected to read "of."

In Method 7 of Appendix A, Sections

2.3.2, 2.3.7, 4.2, 4.3, 5.2.1, 5.2.2, 6 and 7 are amended as follows:

1. In Section 2.3.2, a semicolon replaces the comma between the words "step" and "the."

2. In Section 2.3.7, the phrase "(one for each sample)" in the first line is corrected to read "(one for each sample and each standard)."

3. In Section 4.2, the letter "n" in the seventh line is corrected to read "in."

4. In Section 4.3, the word "poylethylene" in the seventeenth line is corrected to read "polyethylene."

5. In Section 5.2.1, delete the entire section and insert the following:

Optimum Wavelength Determination. Calibrate the wavelength scale of the spectrophotometer every 6 months. The calibration may be accomplished by using an energy source with an intense line emission such as a mercury lamp, or by using a series of glass filters spanning the measuring range of the spectrophotometer. Calibration materials are available commercially and from the National Bureau of Standards. Specific details on the use of such materials should be supplied by the vendor; general information about calibration techniques can be obtained from general reference books on analytical chemistry. The wavelength scale of the spectrophotometer must read correctly within ± 5 nm at all calibration points; otherwise, the spectrophotometer shall be repaired and recalibrated. Once the wavelength scale of the spectrophotometer is in proper calibration, use 410 nm as the optimum wavelength for the measurement of the absorbance of the standards and samples.

Alternatively, a scanning procedure may be employed to determine the proper measuring wavelength. If the instrument is a double-beam spectrophotometer, scan the spectrum between 400 and 415 nm using a 300 μ g NO₂ standard solution in the sample cell and a blank solution in the reference cell. If a peak does not occur, the spectrophotometer is probably malfunctioning and should be repaired. When a peak is obtained within the 400 to 415 nm range, the wavelength at which this peak occurs shall be the optimum wavelength for the measurement of absorbance of both the standards and the samples. For a single-beam spectrophotometer, follow the scanning procedure described above, except that the blank and standard solutions shall be scanned separately. The optimum wavelength shall be the wavelength at which the maximum difference in absorbance between the standard and the blank occurs.

6. In Section 5.2.2, delete the first seven lines and insert the following:

Determination of Spectrophotometer Calibration Factor K_c. Add 0.0 ml, 2 ml, 4 ml, 6 ml, and 8 ml of the KNO₃ working standard solution (1 ml=100 μ g NO₂) to a series of five 50-ml volumetric flasks. To each flask, add 25 ml of absorbing solution, 10 ml deionized, distilled water, and sodium hydroxide (1 N) dropwise until the pH is be-

tween 9 and 12 (about 25 to 35 drops each). Dilute to the mark with deionized, distilled water. Mix thoroughly and pipette a 25-ml aliquot of each solution into a separate porcelain evaporating dish.

7. In Section 6.1, the word "Hass" in the tenth line is corrected to read "Mass."

8. In Section 7, the word "Vna" in (1) is corrected to read "Van." The word "determination" in (6) is corrected to read "Determination."

In Method 8 of Appendix A, Sections 1.2, 2.32, 4.1.4, 4.2.1, 4.3.2, 6.1, and 6.7.1 are amended as follows:

1. In Section 1.2, the phrase "U.S. EPA," is inserted in the fifth line of the second paragraph between the words "Administrator," and "are." Also, delete the third paragraph and insert the following:

Filterable particulate matter may be determined along with SO₂ and SO₃ (subject to the approval of the Administrator) by inserting a heated glass fiber filter between the probe and isopropanol impinger (see Section 2.1 of Method 6). If this option is chosen, particulate analysis is gravimetric only; H₂SO₄ acid mist is not determined separately.

RULES AND REGULATIONS

Title 40—Protection of Environment

CHAPTER I—ENVIRONMENTAL PROTECTION AGENCY

(FRL 841-6)

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Basic Oxygen Process Furnaces: Opacity Standard

AGENCY: Environmental Protection Agency.

ACTION: Final rule.

SUMMARY: This action establishes an opacity standard for basic oxygen process furnace (BOPF) facilities. In March 1974 (39 FR 9308), EPA promulgated a standard limiting the concentration of particulate matter emissions from BOPF's, however, an opacity standard was not promulgated at that time because of insufficient data to define variations in visible emissions from well-controlled facilities. An opacity standard had been proposed on June 11, 1973 (38 FR 15406) and was repropoed on March 2, 1977 (42 FR 12130). Additional data have provided the basis for the opacity standard which will help insure that control equipment is properly operated and maintained. Like the concentration standard, this opacity standard applies to BOPF facilities the construction or modification of which was commenced after June 11, 1973 since both standards were proposed on that date.

EFFECTIVE DATE: April 13, 1978.

ADDRESS: The public comments received may be inspected and copies at the Public Information Reference Unit (EPA Library), Room 2922, 401 M Street SW., Washington, D.C.

FOR FURTHER INFORMATION:

Don R. Goodwin, Emission Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone No. 919-541-5271.

SUPPLEMENTARY INFORMATION:

COMMENTS

A total of 10 comment letters were received—4 from industry, 5 from governmental agencies, and 1 from an environmental interest group. The significant comments received and EPA's responses are presented here.

Three commenters expressed the need for establishing an opacity standard for fugitive emissions. Fugitive emissions occur when off gases from the furnace are not completely cap-

tured by the furnace hood (which ducts waste gases to the control device). During some operations, the fugitive emissions can be significant. The fugitive emissions escape to the atmosphere through roof monitors.

EPA recognizes that fugitive emissions from BOPF shops are an important problem. However, it was not within the scope of this evaluation to consider an opacity standard for fugitive emissions. The particulate concentration standard covers only stack emissions. The purpose of the opacity standard for stack emissions is to serve as a means for enforcement personnel to insure that the particulate matter control system is being properly operated and maintained. EPA will be reviewing the standards of performance for new BOPF's in accordance with the 1977 amendments to the Clean Air Act. This review will address the need for limits on fugitive emissions as well as any revisions of the particulate concentration and opacity standards.

It should be noted that the absence of standards for fugitive emissions under this part does not preclude the establishment of standards as part of the new source review (NSR) and prevention of significant deterioration (PSD) programs of the Agency or as part of the programs of State and local agencies.

Two commenters questioned how the standard would apply to BOPF shops that have plenums to exhaust the emissions from more than one furnace into a single control device. They reasoned that if the production cycles overlap, it would be impossible to determine when an opacity of greater than 10 percent (but less than 20 percent) was attributable to a violation by one furnace or an acceptable emission by another furnace during oxygen blowing. EPA was aware that this situation would occur during the development of the opacity standard. Several of the plants at which visible emission tests were conducted had a single control device serving more than one furnace. The furnace production cycle data were recorded and it was not difficult to correlate the opacity data with the production cycle. Enforcement personnel can evaluate a plant's operation (length of cycle, degree of overlapping, etc.) prior to completing an inspection and correctly identify probable violations from a correlation of their opacity readings with the plant's production and monitoring records. Correlation of the data and the synchronization requirements described later will prevent the enforcement problems described by the commenters. Promulgation of an unduly complex standard that addresses the peculiarities of every BOPF installation would complicate rather than simplify enforcement. Although it is unlikely that two furnaces will be si-

2. In Section 2.3.2, the word "Burette" is corrected to read "Burette."

3. In Section 4.1.4, the stars " * " are corrected to read as periods " . . . ".

4. In Section 4.2.1, the word "het" on the eighth line of the second paragraph is corrected to read "the."

5. In Section 4.3.2, the number "40" is inserted in the fourth line between the words "Add" and "ml."

6. In Section 6.1, Nomenclature, the following are corrected to read as shown with subscripts " $C_{H_2SO_4}$, C_{SO_2} , P_{bar} , P_{std} , T_{std} , $V_{m(std)}$, and V_{sols} ."

7. In Section 6.7.1, Equation 8-4 is corrected to read as follows:

$$I = \frac{100 T_s [K_s V_{sc} - (V_s V/T_s)(P_{bar} + 4N/13.6)]}{60 V_s P_s A_n}$$

(Secs. 111, 114, 301(a), Clean Air Act, as amended (42 U.S.C. 7411, 7414, 7601).)

[FR Doc. 78-7686 Filed 3-22-78; 8:45 am]

FEDERAL REGISTER, VOL 43, NO. 57

THURSDAY, MARCH 23, 1978

RULES AND REGULATIONS

multaneously started on a blow, production data should be examined for such peculiarities before drawing any conclusions from the opacity data.

Other issues raised include the effect of oxygen "reblows" on the standard and a request for a more lenient monitoring requirement. One industry commenter claimed that there would be a "significant" number of production cycles with more than one opacity reading greater than 10 percent due to the blowing of additional oxygen (after the initial oxygen blow) into a furnace to obtain the proper composition. The opacity standard, however, is based on 73 hours of BOPF operation during which numerous reblows occurred. It was found that although the opacities could be very large at these times, they were of short enough duration that the six-minute average was still 10 percent or less.

EPA agrees with the comment that the requirement for reporting of instantaneous scrubber differential and water supply pressures that are less than 10 percent of the average maintained during the most recent performance test needs further clarification. The requirement has been revised so that any deviation of more than 10 percent over a three hour averaging period must be reported. The three hour averaging period was chosen since it is the minimum duration of a performance test. Thus instantaneous monitoring device measurements caused by routing process fluctuations will not be reported. The reports needed are the periods of time when the average scrubber pressure drop is below the level used to demonstrate compliance at the time of the performance test. In addition, the requirement for a water pressure monitor has been retained (despite the comment that it will not indicate a plugged water line) since it will perform the function of assuring that the water pumps have not shut down. A flow monitoring device was not specified because they are susceptible to plugging.

To provide for the use of certain partial combustion systems on BOPFs, new requirements have been added to the monitoring section and two clarifications added to the test methods and procedures section. A partial combustion system uses a closed hood to limit gas combustion and exhaust gas volumes. To recover combustible exhaust gases, the system may be designed to duct its emissions away from the stack to a gas holding tank during part of the steel production cycle. Steel plants in this country may begin to make more use of this approach due to its significant energy benefits. This type of control/recovery system presents two problems for enforcement personnel. First is the problem of knowing

when the diversion of exhaust gases from the stack occurs. The new requirements of paragraphs (a), (b)(3), and (b)(4) of §60.143 address this question. Second is the problem of how to sample or observe stack emissions. New provisions under §60.144 clarify this question for determining the opacity of emissions (paragraph (a)(5)) and for determining the concentration of emissions (paragraph (c)).

In addition to addressing the problem posed by exhaust gas diversion, the new requirements of paragraphs (a), (b)(3), and (b)(4) of §60.143 are also designed to minimize errors in recording the time and duration of the steel production cycle for all types of BOPFs. Accurate records are essential for determining compliance with the opacity standard. Likewise the synchronization of daily logs with the chart recorders of monitoring devices is necessary for determining that acceptable operation and maintenance procedures are being used as required by paragraph (d) of §60.11.

An alternative to the manual method of synchronization under paragraph (b)(3) of §60.143 which may minimize costs of this requirement would be to have the chart recorder automatically mark the beginning and end of the steel production cycle and any period of gas diversion from the stack. Such marking could be electrically relayed from the production equipment and exhaust duct damper operation in order to be fully automatic. Source owners or operators who wish to employ this method or equivalent methods in lieu of the synchronization procedure prescribed by the regulations may submit their plans to the Administrator for approval under paragraph 60.13(i).

The concentration standard promulgated in March, 1974, applies to both top and bottom-blown BOPFs. In developing the proposed opacity standard, data from both types of BOPFs were considered. Scrubber-controlled top and bottom-blown BOPFs were demonstrated capable of meeting the opacity limits proposed and here promulgated. Thus the promulgated opacity standard applies to bottom as well as top-blown BOPFs.

Although there was no announced intentions to utilize electrostatic precipitators (ESPs) as a control device (rather than venturi scrubbers), during the development of the proposed standard, one industry commenter asserted that ESPs may become more attractive in the future, especially in the semi-arid regions of the West where the water and energy demands of scrubbers are not easily met. If a BOPF furnace is constructed with an ESP control device, the establishment of a site-specific opacity standard may be necessary. Upon request by the owner or operator of the BOPF

furnace, a determination will be made by EPA pursuant to §60.11(e) if performance tests demonstrate compliance with the mass concentration standard.

MISCELLANEOUS

It should be noted that standards of performance for new sources established under section 111 of the Act reflect emission limits achievable with the best adequately demonstrated technological system of continuous emission reduction (taking into consideration the cost of achieving such emission reduction, and any nonair quality health and environmental impact and energy requirements). State implementation plans (SIPs) approved or promulgated under section 110 of the Act, on the other hand, must provide for the attainment and maintenance of national ambient air quality standards (NAAQS) designed to protect public health and welfare. For that purpose, SIPs must in some cases require greater emission reductions than those required by standards of performance for new sources. Section 173(2) of the Clean Air Act, requires, among other things, that a new or modified source constructed in an area which exceeds the NAAQS must reduce emissions to the level which reflects the "lowest achievable emission rate" for such category of source, unless the owner or operator demonstrates that the source cannot achieve such an emission rate. In no event can the emission rate exceed any applicable standard of performance.

A similar situation may arise when a major emitting facility is to be constructed in a geographic area which falls under the prevention of significant deterioration of air quality provisions of the Act (Part C). These provisions require, among other things, that major emitting facilities to be constructed in such areas are to be subject to best available control technology. The term "best available control technology" (BACT) means "an emission limitation based on the maximum degree of reduction of each pollutant subject to regulation under this Act emitted from or which results from any major emitting facility, which the permitting authority, on a case-by-case basis, taking into account energy, environmental, and economic impacts and other costs, determines is achievable for such facilities through application of production processes and available methods, systems, and techniques, including fuel cleaning or treatment or innovative fuel combustion techniques for control of each such pollutant. In no event shall application of 'best available control technology' result in emissions of any pollutants which will exceed the emissions allowed by any applicable standard established pursuant to section 111 or 112 of this Act."

RULES AND REGULATIONS

Standards of performance should not be viewed as the ultimate in achievable emission control and should not preclude the imposition of a more stringent emission standard, where appropriate. For example, while cost of achievement may be an important factor in determining standards of performance applicable to all areas of the country (clean as well as dirty), costs must be accorded for less weight in determining the "lowest achievable emission rate for the new or modified sources locating in areas violating statutorily-mandated health and welfare standards. Although there may be emission control technology available that can reduce emissions below the level required to comply with standards of performance, this technology might be selected as the basis of standards of performance due to costs associated with its use. This in no way should preclude its use in situations where cost is a lesser consideration, such as determination of the "lowest achievable emission rate." Furthermore, since partial combustion systems and bottom blown BOPFs have been shown to be inherently less polluting, more stringent emission limits may be placed on such sources for the purposes of defining "best available control technology" (under Prevention of Significant Deterioration regulation) and "lowest achievable emission rate" in non-attainment areas.

In addition, States are free under section 116 of the Act to establish even more stringent emission limits than those established under section 111 or those necessary to attain or maintain the NAAQS under section 110. Thus, new sources may in some cases be subject to limitations more stringent than standards of performance under section 111, and prospective owners and operators of new sources should be aware of this possibility in planning for such facilities.

The effective date of this regulation is (date of publication), because section 111(b)(1)(B) of the Clean Air Act provides that standards of performance or revisions thereof become effective upon promulgation.

The opacity standard, like the concentration standard, applies to BOPFs which commenced construction or modification after June 11, 1973. That is the date on which both standards were originally proposed. The opacity standard will add no new control burden to the sources affected, but will provide an effective means of monitoring the compliance of these facilities. The relief provided under § 60.11(e) insures that the opacity standard requires no greater reduction in emissions than the concentration standard.

NOTE.—The Environmental Protection Agency has determined that this document does not contain a major proposal requiring

preparation of an Economic Impact Analysis under Executive Orders 11821 and 11949 and OMB Circular A-107.

Dated: April 4, 1978.

DOUGLAS M. COSTLE,
Administrator.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

Subpart N—Standards of Performance for Iron and Steel Plants

1. Section 60.141 is amended by adding paragraph (c) as follows:

§ 60.141 Definitions.

(c) "Startup means the setting into operation for the first steel production cycle of a relined BOPF or a BOPF which has been out of production for a minimum continuous time period of eight hours.

2. Section 60.142 is amended by adding paragraph (a)(2) as follows:

§ 60.142 Standard for particulate matter.

(a)
(2) Exit from a control device and exhibit 10 percent opacity or greater, except that an opacity of greater than 10 percent but less than 20 percent may occur once per steel production cycle.

(Secs. 111, 301(a), Clean Air Act as amended (42 U.S.C. 7411, 7601).)

3. A new § 60.143 is added as follows:

§ 60.143 Monitoring of operations.

(a) The owner or operator of an affected facility shall maintain a single time-measuring instrument which shall be used in recording daily the time and duration of each steel production cycle, and the time and duration of any diversion of exhaust gases from the main stack servicing the BOPF.

(b) The owner or operator of any affected facility that uses venturi scrubber emission control equipment shall install, calibrate, maintain, and continuously operate monitoring devices as follows:

(1) A monitoring device for the continuous measurement of the pressure loss through the venturi constriction of the control equipment. The monitoring device is to be certified by the manufacturer to be accurate within ± 250 Pa (± 1 inch water).

(2) A monitoring device for the continuous measurement of the water supply pressure to the control equipment. The monitoring device is to be certified by the manufacturer to be accurate within ± 5 percent of the design water supply pressure. The monitoring device's pressure sensor or pressure

tap must be located close to the water discharge point. The Administrator may be consulted for approval of alternative locations for the pressure sensor or tap.

(3) All monitoring devices shall be synchronized each day with the time-measuring instrument used under paragraph (a) of this section. The chart recorder error directly after synchronization shall not exceed 0.08 cm ($\frac{1}{2}$ inch).

(4) All monitoring devices shall use chart recorders which are operated at a minimum chart speed of 3.8 cm/hr (1.5 in/hr).

(5) All monitoring devices are to be recalibrated annually, and at other times as the Administrator may require, in accordance with the procedures under § 60.13(b)(3).

(c) Any owner or operator subject to requirements under paragraph (b) of this section shall report for each calendar quarter all measurements over any three-hour period that average more than 10 percent below the average levels maintained during the most recent performance test conducted under § 60.8 in which the affected facility demonstrated compliance with the standard under § 60.142(a)(1). The accuracy of the respective measurements, not to exceed the values specified in paragraphs (b)(1) and (b)(2) of this section, may be taken into consideration when determining the measurement results that must be reported.

4. Section 60.144 is amended by adding paragraphs (a)(5) and (c) as follows:

§ 60.144 Test methods and procedures.

(a)
(5) Method 9 for visible emissions. For the purpose of this subpart, opacity observations taken at 15-second intervals immediately before and after a diversion of exhaust gases from the stack may be considered to be consecutive for the purpose of computing an average opacity for a six-minute period. Observations taken during a diversion shall not be used in determining compliance with the opacity standard.

(c) Sampling of flue gases during each steel production cycle shall be discontinued whenever all flue gases are diverted from the stack and shall be resumed after each diversion period.

(Secs. 111, 114, 301(a), Clean Air Act as amended (42 U.S.C. 7411, 7414, 7601).)

FEDERAL REGISTER, VOL 43, NO. 72
THURSDAY, APRIL 13, 1978

Title 40—Protection of Environment

(FRL 882-6)

**CHAPTER I—ENVIRONMENTAL
PROTECTION AGENCY****Subchapter C—Air Programs****PART 60—STANDARDS OF PERFORMANCE
FOR NEW STATIONARY
SOURCES****Delegation of Authority to State/
Local Air Pollution Control Agencies
in Arizona, California, and
Nevada**

AGENCY: Environmental Protection Agency.

ACTION: Final Rulemaking.

SUMMARY: The Environmental Protection Agency (EPA) is amending 40 CFR 60.4 Address by adding addresses of agencies to reflect new delegations of authority from EPA to certain state/local air pollution control agencies in Arizona, California, and Nevada. EPA has delegated authority to these agencies, as described in a notice appearing elsewhere in today's FEDERAL REGISTER, in order to implement and enforce the standards of performance for new stationary sources.

EFFECTIVE DATE: May 16, 1978.

**FOR FURTHER INFORMATION
CONTACT:**

Gerald Katz (E-4-3), Environmental Protection Agency, 215 Fremont Street, San Francisco, Calif. 94105, 415-556-8005.

SUPPLEMENTARY INFORMATION: Pursuant to delegation of authority for the standards of performance for new stationary sources (NSPS) to State/Local air pollution control agencies in Arizona, California, and Nevada from March 30, 1977 to January 30, 1978, EPA is today amending 40 CFR 60.4 Address, to reflect these actions. A Notice announcing this delegation is published elsewhere in today's FEDERAL REGISTER. The amended § 60.4 is set forth below. It adds the address of the air pollution control agencies, to which must be addressed all reports, requests, applications, submittals, and communications pursuant to this part by sources subject to the NSPS located within these agencies' jurisdictions.

The Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegation actions which are reflected in this administrative amendment were effective on the

RULES AND REGULATIONS

dates of delegation and it serves no purpose to delay the technical change on these additions of the air pollution control agencies' addresses to the Code of Federal Regulations.

(Sec. 111, Clean Air Act, as amended (42 U.S.C. 7411).)

Dated: April 5, 1978.

SHEILA M. PRINDIVILLE,
Acting Regional Administrator,
Environmental Protection
Agency, Region IX.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

1. In § 60.4 paragraph (b) is amended by revising subparagraphs D, F, and DD to read as follows:

§ 60.4 Address.

(b) * * *

(D) Arizona:

Title 40—Protection of the Environment

CHAPTER I—ENVIRONMENTAL PROTECTION AGENCY

SUBCHAPTER C—AIR PROGRAMS

[FRL 907-2]

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Grain Elevators

AGENCY: Environmental Protection Agency (EPA).

ACTION: Final rule.

SUMMARY: The standards limit emissions of particulate matter from new, modified, and reconstructed grain elevators. The standards implement the Clean Air Act and are based on the Administrator's determination that emissions from grain elevators contribute significantly to air pollution. The intended effect of these standards is to require new, modified, and reconstructed grain elevators to use the best demonstrated system of continuous emission reduction, considering costs, nonair quality health, environmental and energy impacts.

EFFECTIVE DATE: August 3, 1978.

ADDRESSES: Copies of the standards support documents are available on request from the U.S. EPA Library (MD-35), Research Triangle Park, N.C. 27711, telephone 919-541-2777 or (FTS) 629-2777. The requester should specify "Standards Support and Environmental Impact Statement, Volume 1: Proposed Standards of Performance for Grain Elevator Industry," (EPA-450-77-001a) and/or "Standards Support and Environmental Impact Statement, Volume 2: Promulgated Standards of Performance for Grain Elevator Industry," (EPA-450/2-77-001b). Copies of all comment letters received from interested persons participating in this rulemaking are available for inspection and copying during normal business hours at EPA's Public Information Reference Unit, Room 2922, EPA Library, 401 M Street SW., Washington, D.C.

FOR FURTHER INFORMATION CONTACT:

Don R. Goodwin, Director Emission Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, N.C. 27711, telephone 919-541-5271.

SUPPLEMENTARY INFORMATION: On January 13, 1977, standards of performance were proposed for the grain elevator industry (42 FR 2842) under

the authority of section 111 of the Clean Air Act. Public comments were requested on the proposal in the FEDERAL REGISTER publication. Approximately 2,000 comments were received from grain elevator operators, vendors of equipment, Congressmen, State and local air pollution control agencies, other Federal agencies, and individual U.S. citizens. Most of these comments reflected a general misunderstanding of the proposed standards and were very general in nature. A number of comments, however, contained a significant amount of useful data and information. Due to the time required to review these comments, the standards were suspended on June 24, 1977. This action was necessary to avoid creating legal uncertainties for those grain elevator operators who might have undertaken various expansion or alteration projects before promulgation of final standards.

On August 7, 1977, Congress amended the Clean Air Act. These amendments contained a provision specifically exempting country grain elevators with less than 2.5 million bushels of grain storage capacity from standards of performance developed under section 111 of the Act.

Following review of the public comments, a draft of the final standards was developed consistent with the adopted amendments to the Clean Air Act. A report responding to the major issues raised in the public comments and containing the draft final standards was mailed on August 15, 1977, to each individual, agriculture association, equipment vendor, State and local government, and member of Congress who submitted comments. Comments were requested on the draft final standards by October 15, 1977. One hundred comments were received, and the final standards reflect a thorough evaluation of these comments.

The proposed standards are reinstated elsewhere in this issue of the FEDERAL REGISTER.

THE STANDARDS

The promulgated standards apply only to new, modified, or reconstructed grain elevators with a permanent grain storage capacity of more than 88,100 m³ (ca. 2.5 million U.S. bushels) and new, modified, or reconstructed grain storage elevators at wheat flour mills, wet corn mills, dry corn mills (human consumption), rice mills, or soybean oil extraction plants with a permanent grain storage capacity of more than 35,200 m³ (ca. 1 million U.S. bushels).

The standards limit particulate matter emissions from nine types of affected facilities at grain elevators by limiting the visibility of emissions released to the atmosphere. The affected facilities are each truck loading sta-

tion, truck unloading station, railcar loading station, railcar unloading station, barge or ship loading station, barge or ship unloading station, grain dryer, all grain handling operations and each emission control device.

The standards can be summarized as follows:

(a) Truck loading station—visible emissions may not exceed 10 percent opacity.

(b) Truck unloading station, railcar loading station, and railcar unloading station—visible emissions may not exceed 5 percent opacity.

(c) Ship or barge loading station—visible emissions may not exceed 20 percent opacity.

(d) Ship or barge unloading station—specified equipment or its equivalent must be used.

(e) Grain dryer—visible emissions may not exceed 0 percent opacity.

(f) All grain handling operations—visible emissions may not exceed 0 percent opacity.

(g) Emission control devices—visible emissions may not exceed 0 percent opacity; and the concentration of particulate matter in the exhaust gas discharged to the atmosphere may not exceed 0.023 g/dscm (ca. 0.01 gr/dscf).

These standards are different from those proposed in the following areas. The visible emission limits for truck unloading stations and railcar loading and unloading stations have been increased from 0 percent opacity to 5 percent opacity. The visible emission limit for barge and ship loading has been increased from 10 percent opacity during normal loading and 15 percent opacity during "topping off" loading, to 20 percent opacity during all loading operations. The applicability of the visible emission standards for column grain dryers has been narrowed from dryers with perforated plate hole sizes of greater than 0.084 inch diameter to dryers with perforated plate hole sizes of greater than 0.094 inch diameter.

The August 1977 amendments to the Clean Air Act authorize the promulgation of design, equipment, work practice, or operational standards if development of a numerical emission limit is not feasible. Numerical emission limits may not be feasible where emissions are not confined or where emissions cannot be measured due to technological or economic limitations. Observation of visible emissions at barge unloading stations led to the conclusion that a numerical emission limit is not feasible for this facility. The visible emissions data showed an extremely wide range with some 6 minute averages above 65 percent opacity. Because of this wide range of visible emissions, an opacity numerical emission limit cannot be established that would ensure the use of the best

RULES AND REGULATIONS

system of continuous emission reduction. An equipment standard, therefore, rather than an emission standard is being promulgated for barge and ship unloading stations.

Another change from the proposed standards is that section 60.14 (modification) of the general provisions has been clarified to ensure that only capital expenditures which are spent directly on an affected facility are used to determine whether the annual asset guideline repair allowance percentage is exceeded. The annual asset guideline repair allowance percentage has been defined to be 6.5 percent.

The remaining change from the proposed standards is that four types of alterations at grain elevators have been exempted from consideration as modifications. The exempted alterations are:

(1) The addition of gravity load-out spouts to existing grain storage or grain transfer bins.

(2) The installation of automatic grain weighing scales.

(3) Replacement of motor and drive units driving existing grain handling equipment.

(4) The installation of permanent storage capacity with no increase in hourly grain handling capacity.

ENVIRONMENTAL AND ECONOMIC IMPACTS

The promulgated standards will reduce uncontrolled particulate matter emission from new grain elevators by more than 99 percent and will reduce particulate matter emissions by 70 to 90 percent compared to emission limits contained in State or local air pollution regulations. This reduction in emissions will result in a significant reduction of ambient air concentration levels of particulate matter in the vicinity of grain elevators. The maximum 24-hour average ambient air particulate matter concentration at a distance of 0.3 kilometer (km) from a typical grain elevator, for example, will be reduced by 50 to 80 percent below the ambient air concentration that would result from control of emissions to the level of the typical State or local air pollution regulations.

Several of the changes to the proposed standards reduce the estimated primary impact of the proposed standards in terms of reducing emissions of particulate matter from grain elevators. The promulgated standards, for example, apply only to large grain elevators. These changes will permit more emissions of particulate matter to the atmosphere. It was estimated that the proposed standards would have reduced national particulate matter emissions by approximately 21,000 metric tons over the next 5 years; it is now estimated that the promulgated standards will reduce particulate

matter emissions by 11,000 metric tons over the next 5 years.

The secondary environmental impacts associated with the promulgated standards will be a small increase in solid waste handling and disposal and a small increase in noise pollution. A relatively minor amount of particulate matter, sulfur dioxide and nitrogen oxide emissions will be discharged into the atmosphere from steam/electric power plants supplying the additional electrical energy required to operate the emission control devices needed to comply with the promulgated standards. The energy impact associated with the promulgated standards will be small and will lead to an increase in national energy consumption in 1981 by the equivalent of only 1,600 m³ (ca. 10,000 barrels) per year of No. 6 fuel oil.

Based on information contained in the comments submitted during the public comment periods, approximately 200 grain terminal elevators and grain storage elevators at grain processing plants will be covered by the promulgated standards over the next 5 years. The total incremental costs required to control emissions at these grain elevators to comply with the promulgated standards, above the costs necessary to control emissions at these elevators to comply with State or local air pollution control regulations, is \$15 million in capital costs over this 5-year period and \$3 million in annualized costs in the fifth year. Based on this estimate of the national economic impact, the promulgated standards will have no significant effect on the supply and demand for grain products, or on the growth of the domestic grain industry.

PUBLIC PARTICIPATION

Prior to proposal of the standards, interested parties were advised by public notice in the FEDERAL REGISTER of a meeting of the National Air Pollution Control Techniques Advisory Committee. In addition, copies of the proposed standards and the Standards Support and Environmental Impact Statement (SSEIS) supporting these standards were distributed to members of the grain elevator industry and several environmental groups at the time of proposal. The public comment period extended from January 13, to May 14, 1977. During this period 1,817 comments were received from grain elevator operators, vendors of equipment, Congressmen, State and local air pollution control agencies, other Federal agencies, and individual U.S. citizens.

Due to the time required to review these comments, the proposed standards were suspended on June 24, 1977. This action was necessary to avoid creating legal uncertainties for those

grain elevator operators who might have undertaken various expansion or alteration projects before promulgation of final standards.

Following review of the public comments, a draft of the final standards was developed consistent with the August, 1977, amendments to the Clean Air Act. A report responding to the major issues raised in the public comments and containing the draft final standards was mailed on August 15, 1977, to each individual, agriculture association, equipment vendor, State and local government, and member of Congress who submitted comments. Comments were requested on the draft final standards by October 15, 1977.

One hundred and one comments were received and the final standards reflect a thorough evaluation of these comments. Several comments resulted in changes to the proposed standards. A detailed discussion of the comments and changes made to the proposed standards is contained in volume 2 of the SSEIS, which was distributed along with a copy of the final standards to all interested parties prior to today's promulgation of final standards.

SIGNIFICANT COMMENTS

Most of the comment letters received by EPA contained multiple comments. The most significant comments and changes made to the proposed standards are discussed below:

NEED FOR STANDARDS

Numerous commenters questioned whether grain elevators should be regulated since the industry is a small contributor to nationwide emissions of particulate matter and grain dust is not hazardous or toxic.

The standards were proposed under section 111 of the Clean Air Act. This section of the act requires that standards of performance be established for new stationary sources which contribute to air pollution. Existing sources are not affected unless they are reconstructed, or modified in such a way as to increase emissions. The overriding purpose of standards of performance is to prevent new air pollution problems from developing by requiring maximum feasible control of emissions from new, modified, or reconstructed sources at the time of their construction. This is helpful in attaining and maintaining the National Ambient Air Quality Standard (NAAQS) for suspended particulate matter.

The Report of the Committee on Public Works of the United States Senate in September 1970 (Senate Report No. 91-1196), listed grain elevators as a source for which standards of performance should be developed. In addition, a study of 200 industrial cat-

RULES AND REGULATIONS

egories of sources, which were evaluated to develop a long-range plan for setting standards of performance for particulate matter, ranked grain elevators relatively high. The categories were ranked in order of priority based on potential decrease in emissions. Various grain handling operations ranked as follows: Grain processing—4; grain transfer—6; grain cleaning and screening—8; and grain drying—33. Therefore, grain elevators are a significant source of particulate matter emissions and standards of performance have been developed for this source category.

Many commenters felt, however, that it was unreasonable to require small country elevators to comply with the proposed standards because of their remote location and small amount of emissions. This sentiment was reflected in the 1977 amendments to the Clean Air Act which exempted country elevators with a grain storage capacity of less than 88,100 m³ (ca. 2.5 million U.S. bushels) from standards of performance. Consequently, the scope of the proposed standards has been narrowed and the promulgated standards apply only to new, modified, or reconstructed facilities within grain elevators with a permanent storage capacity in excess of 88,100 m³.

A number of commenters also felt small flour mills should not be covered by standards of performance because they are also small sources of particulate matter emissions and handle less grain than some country elevators which were exempted from standards of performance by the 1977 amendments to the Clean Air Act. These processors are considered to be relatively small sources of particulate matter emissions that are best regulated by State and local regulations. Consequently, grain storage elevators at wheat flour mills, wet corn mills, dry corn mills (human consumption), rice mills, and soybean oil extraction plants with a storage capacity of less than 35,200 m³ (ca. 1 million U.S. bushels) of grain are exempt from the promulgated standards.

With regard to the hazardous nature or toxicity of grain dust, the promulgated standards should not be interpreted to imply that grain dust is considered hazardous or toxic, but merely that the grain elevator industry is considered a significant source of particulate matter emissions. Studies indicate that, as a general class, particulate matter causes adverse health and welfare effects. In addition, some studies indicate that dust from grain elevators causes adverse health effects to elevator workers and that grain dust emissions are a factor contributing to an increased incidence of asthma attacks in the general population living in the vicinity of grain elevators.

EMISSION CONTROL TECHNOLOGY

A number of commenters were concerned with the reasonableness of the emission control technology which was used as the basis for the proposed standards limiting emissions from railcar unloading stations and grain dryers.

A number of commenters believed it was unreasonable to base the standards on a four-sided shed to capture emissions from railcar unloading stations at grain elevators which use unit trains. The data supporting the proposed standards were based on observations of visible emissions at a grain elevator which used this type of shed to control emissions from the unloading of railcars. This grain elevator, however, did not use unit trains. Based on information included in a number of comments, the lower rail rate for grain shipped by unit trains places a limit on the amount of time a grain elevator can hold the unit train. The additional time required to uncouple and recouple each car individually could cause a grain elevator subject to the proposed standards to exceed this time limit and thus lose the cost benefit gained by the use of unit trains. In light of this fact, the proposed visible emission limit for railcar unloading is considered unreasonable. The promulgated standards, therefore, are based upon the use of a two-sided shed for railcar unloading stations. This change in the control technology resulted in a change to the visible emission limit for railcar unloading stations and is discussed later.

A number of comments were received concerning the proposed standard for column dryers. The proposed standards would have permitted the maximum hole size in the perforated plates used in column dryers to be no larger than 2.1 mm (0.084 inch) in diameter for the dryer to automatically be in compliance with the standard. A few comments contained visible emission data taken by certified opacity observers which indicated that column dryers with perforated plates containing holes of 2.4 mm (0.094 inch) diameter could meet a 0-percent opacity emission limit. Other comments indicated that sorghum cannot be dried in column dryers with a hole size smaller than 2.4 mm (0.094 inch) diameter without plugging problems. In light of these data and information, the specification of 2.1 mm diameter holes is considered unreasonable and the promulgated standards apply only to column dryers containing perforated plates with hole sizes greater than 2.4 mm in diameter.

STRINGENCY OF THE STANDARDS

Many commenters questioned whether the standards for various affected facilities could be achieved even

if the best system of emission reduction were installed, maintained, and properly operated. These commenters pointed out that a number of variables can affect the opacity of visible emissions during unloading, handling, and loading of grain and they questioned whether enough opacity observation had been taken to assure that the standards could be attained under all operating conditions. The variables mentioned most frequently were wind speed and type, dustiness, and moisture content of grain.

It is true that wind speed could have some effect on the opacity of visible emissions. A well-designed capture system should be able to compensate for this effect to a certain extent, although some dust may escape if wind speed is too high. Compliance with standards of performance, however, is determined only under conditions representative of normal operation, and judgment by State and Federal enforcement personnel will take wind conditions into account in enforcing the standards.

It is also true that the type, dustiness, and moisture content of grain affect the amount of particulate matter emissions generated during unloading, handling, and loading of grain. A well-designed capture system, however, should be designed to capture dust under adverse conditions and should, therefore, be able to compensate for these variables.

In developing the data base for the proposed standards, over 60 plant visits were made to grain terminal and storage elevators. Various grain unloading, handling, and loading operations were inspected under a wide variety of conditions. Consequently, the standards were not based on conjecture or surmise, but on observations of visible emissions by certified opacity observers at well-controlled existing grain elevators operating under routine conditions. Not all grain elevators were visited, however, and not all operations within grain elevators were inspected under all conditions. Thus, while the proposed standards were based upon a sufficiently broad data base to allow extrapolation of the data, particular attention was paid to those comments submitted during the public comment period which included visible emission data taken by certified observers from operations at grain elevators which were using the same emission control systems the proposed standards were based upon. Evaluation of these data indicates that the visible emission limit for truck unloading stations and railcar loading stations should be 5 percent opacity instead of 0 percent opacity which was proposed. The promulgated standards, therefore, limit visible emissions from these facilities to 5 percent opacity.

RULES AND REGULATIONS

As discussed earlier, the emission control technology selected as the basis for the visible emissions standard for railcar unloading has been changed from a four-sided shed to a two-sided shed. Visible emission data included with the public comments indicate that emissions from a two-sided shed will not exceed 5 percent opacity. Consequently, the promulgated standards limit visible emissions from railcar unloading stations to 5 percent opacity.

A number of commenters also indicated that the opacity limit included in the proposed standards for barge loading was too stringent. One commenter indicated that the elevator operator had no control over when the "topping off" operation commenced because the ship captain and the stevedores decide when to start "topping off." Several State agencies commented that the standards should be at least 20 percent opacity. Based on these comments, the standards for barge and ship loading operations have been increased to 20 percent opacity during all loading operations. The comments indicate that this standard will still require use of the emission control technology upon which the proposed standards were based.

Data included with the public comments confirm that a visible emission limit of 0 percent opacity is appropriate for grain handling equipment, grain dryers, and emission control equipment. Consequently, the visible emission limits for these facilities have not been changed.

OPACITY

Many commenters misunderstood the concept of opacity and how it is used to measure visible emissions. Other commenters stated that opacity measurements were not accurate below 10 to 15 percent opacity and a standard below these levels was unenforceable.

Opacity is a measure of the degree to which particulate matter or other visible emissions reduce the transmission of light and obscure the view of an object in the background. Opacity is expressed on a scale of 0 to 100 percent with a totally opaque plume assigned a value of 100 percent opacity. The concept of opacity has been used in the field of air pollution control since the turn of the century. The concept has been upheld in courts throughout the country as a reasonable and effective means of measuring visible emissions.

Opacity for purposes of determining compliance with the standard is not determined with instruments but is determined by a qualified observer following a specific procedure. Studies have demonstrated that certified ob-

servers can accurately determine the opacity of visible emissions. To become certified, an individual must be trained and must pass an examination demonstrating his ability to accurately assign opacity levels to visible emissions. To remain certified, this training must be repeated every 6 months.

In accordance with method 9, the procedure followed in making opacity determinations requires that an observer be located in a position where he has a clear view of the emission source with the sun at his back. Instantaneous opacity observations are recorded every 15 seconds for 6 minutes (24 observations). These observations are recorded in 5 percent increments (i.e., 0, 5, 10, etc.). The arithmetic average of the 24 observations, rounded off to the nearest whole number (i.e., 0.4 would be rounded off to 0), is the value of the opacity used for determining compliance with visible emission standards. Consequently, a 0 percent opacity standard does not necessarily mean there are no visible emissions. It means either that visible emissions during a 6-minute period are not sufficient to cause a certified observer to record them as 5 percent opacity, or that the average of the twenty-four 15-second observations is calculated to be less than 0.5 percent. Consequently, although emissions released into the atmosphere from an emission source may be visible to a certified observer, the source may still be found in compliance with a 0 percent opacity standard.

Similarly, a 5-percent opacity standard permits visible emissions to exceed 5 percent opacity occasionally. If, for example, a certified observer recorded the following twenty-four 15-second observations over a 6-minute period: 7 observations at 0 percent opacity; 11 observations at 5 percent opacity; 3 observations at 10 percent opacity; and 3 observations at 15 percent opacity, the average opacity would be calculated as 5.4 percent. This value would be rounded off to 5 percent opacity and the source would be in compliance with a 5 percent opacity standard.

Some of the commenters felt the proposed standards were based only on one 6-minute reading of the opacity of visible emissions at various grain elevator facilities. None of the standards were based on a single 6-minute reading of opacity. Each of the standards were based on the highest opacity readings recorded over a period of time, such as 2 or 4 hours, at a number of grain elevators.

A number of commenters also felt the visible emission standards were too stringent in light of the maximum absolute error of 7.5 percent opacity associated with a single opacity observation. The methodology used to develop and enforce visible emission standards,

however, takes into account this observer error. As discussed above, visible emission standards are based on observations recorded by certified observers at well-controlled existing facilities operating under normal conditions. When feasible, such observations are made under conditions which yield the highest opacity readings such as the use of a highly contrasting background. These readings then serve as the basis for establishing the standards. By relying on the highest observations, the standards inherently reflect the highest positive error introduced by the observers.

Observer error is also taken into account in enforcement of visible emission standards. A number of observations are normally made before an enforcement action is initiated. Statistically, as the number of observations increases, the error associated with these observations taken as a group decreases. Thus, while the absolute positive error associated with a single opacity observation may be 7.5 percent, the error associated with a number of opacity observations, taken to form the basis for an enforcement action, may be considerably less than 7.5 percent.

ECONOMIC IMPACT

Several commenters felt the estimated economic impact of the proposed standards was too low. Some commenters questioned the ventilation flow rate volumes used in developing these estimates. The air evacuation flow rates and equipment costs used in estimating the costs associated with the standards, however, were based on information obtained from grain elevator operators during visits to facilities which were being operated with visible emissions meeting the proposed standards. These air evacuation flow rates and equipment costs were also checked against equipment vendor estimates and found to be in reasonable agreement. These ventilation flow rates, therefore, are compatible with the opacity standards. Thus, the unit cost estimates developed for the proposed standards are considered reasonably accurate.

Many commenters felt that the total cost required to reduce emissions to the levels necessary to comply with the visible emission standards should be assigned to the standards. The relevant costs, however, are those incremental costs required to comply with these standards above the costs required to comply with existing State or local air pollution regulations. While it is true that some States have no regulations, other States have regulations as stringent as the promulgated standards. Consequently, an estimate of the costs required to comply with the typical or average State regu-

RULES AND REGULATIONS

lation, which lies between these extremes, is subtracted from the total cost of complying with the standards to identify the cost impact directly associated with these standards.

Most State and local regulations, for example, require aspiration of truck dump pit grates and installation of cyclones to remove particulate matter from the aspirated air before release to the atmosphere. The promulgated standards would require the addition of a bifold door and the use of a fabric filter baghouse instead of a cyclone. The cost associated with the promulgated standards, therefore, is only the cost of the bifold doors and the difference in cost between a fabric filter baghouse and a cyclone.

In conclusion, the unit cost estimates developed for the proposed standards are essentially correct and generally reflect the costs associated with the promulgated standards. As a result, the economic impact of the promulgated standards on an individual grain elevator is considered to be about the same as that of the proposed standards. The maximum additional cost that would be imposed on most grain elevators subject to compliance with the promulgated standards will probably be less than a cent per bushel. The impact of these additional costs imposed on an individual grain elevator will be small.

Based on information contained in comments submitted by the National Grain and Feed Association, approximately 200 grain terminal elevators and grain storage elevators at grain processing plants will be covered by the standards over the next 5 years. Consequently, over this 5-year period the total incremental costs to control emissions at these grain elevators to comply with the promulgated standards, above the costs to control emissions at these elevators to comply with State or local air pollution control requirements, is \$15 million in capital costs and \$3 million in annualized costs in the 5th year. Based on this estimate of the national economic impact, the promulgated standards will have no significant effect on the supply and demand of grain or grain products, or on the growth of the domestic grain industry.

ENERGY IMPACT

A number of commenters believed that the energy impact associated with the proposed standards had been underestimated and that the true impact would be much greater. As pointed out above, the major reason for this disagreement is probably due to the fact that these commenters assigned the full impact of air pollution control to the proposed standards, whereas the impact associated with compliance with existing State and local air pollu-

tion control requirements should be subtracted. In the example discussed above concerning costs, the additional energy requirements associated with the promulgated standards is simply the difference in energy required to operate a fabric filter baghouse compared to a cyclone.

For emission control equipment such as cyclones and fabric filter baghouses, energy consumption is directly proportional to the pressure drop across the equipment. It was assumed that the pressure drop across a cyclone required to comply with existing State and local requirements would be about 80 percent of that across a fabric filter baghouse required to comply with the promulgated standards. This is equivalent to an increase in energy consumption required to operate air pollution control equipment of about 25 percent. This represents an increase of less than 5 percent in the total energy consumption of a grain elevator.

Assuming 200 grain elevators become subject to the promulgated standards over the next 5 years, this energy impact will increase national energy consumption by less than 1,600 m³ (ca. 10,000 U.S. barrels) per year in 1982. This amounts to less than 2 percent of the capacity of a large marine oil tanker and is an insignificant increase in energy consumption.

MODIFICATION

Many commenters were under the mistaken impression that all existing grain elevators would have to comply with the proposed standards and that retrofit of air pollution control equipment on existing facilities within grain elevators would be required. This is not the case. The proposed standards would have applied only to new, modified, or reconstructed facilities within grain elevators. Similarly, the promulgated standards apply only to new, modified, or reconstructed facilities and not existing facilities.

Modified facilities are only subject to the standards if the modification results in increased emissions to the atmosphere from that facility. Furthermore, any alteration which is considered routine maintenance or repair is not considered a modification. Where an alteration is considered a modification, only those facilities which are modified have to comply with the standards, not the entire grain elevator. Consequently, the standards apply only to major alterations of individual facilities at existing grain elevators which result in increased emissions to the atmosphere, not to alterations which are considered routine maintenance and repair. Major alterations that do not result in increased emissions, such as alterations where existing air pollution

control equipment is upgraded to maintain emissions at their previous level, are not considered modifications.

The following examples illustrate how the promulgated standards apply to a grain elevator under various circumstances. The proposed standards would have applied in the same way.

(1) If a completely new grain elevator were built, all affected facilities would be subject to the standards.

(2) If a truck unloading station at an existing grain elevator were modified by making a capital expenditure to increase unloading capacity and this resulted in increased emissions to the atmosphere in terms of pounds per hour, then only that affected facility (i. e., the modified truck unloading station) would be subject to the standards. The remaining facilities within the grain elevator would not be subject to the standards.

(3) If a grain elevator contained three grain dryers and one grain dryer were replaced with a new grain dryer, only the new grain dryer would be subject to the standards.

The initial assessment of the potential for modification of existing facilities concluded that few modifications would occur. The few modifications that were considered likely to take place would involve primarily the upgrading of existing country grain elevators into high throughput grain elevator terminals. A large number of commenters, however, indicated that they believed many modifications would occur and that many existing grain elevators would be required to comply with the standards.

To resolve this confusion and clarify the meaning of modification, a meeting was held with representatives of the grain elevator industry to identify various alterations to existing facilities that might be considered modifications. A list of alterations was developed which frequently occur within grain elevators, primarily to reduce labor costs or to increase grain handling capacity, although not necessarily annual grain throughput. The impact of considering four of these alterations as modifications, subject to compliance with the standards, was viewed as unreasonable. Consequently, they are exempted from consideration as modifications in the promulgated standards.

In particular, the four alterations within grain elevators which are specifically exempt from the promulgated standards are (1) The addition of gravity load-out spouts to existing grain storage or grain transfer bins; (2) the addition of electronic automatic grain weighing scales which increases hourly grain handling capacity; (3) the replacement of motors and drive trains driving existing grain handling equipment with larger motors and drive

RULES AND REGULATIONS

trains which increases hourly grain handling capacity; and (4) the addition of grain storage capacity with no increase in hourly grain handling capacity.

If the first alteration were considered a modification, this could require installation of a load-out shed thereby requiring substantial reinforcement of the grain storage or grain transfer bin to support the weight of emission control equipment. In light of the relatively small expenditure usually required to install additional gravity load-out spouts to existing grain storage or transfer bins, and the relatively large expenditure that would be required to install a load-out shed or to reinforce the storage or transfer bin, consideration of this sort of alteration within an existing grain elevator as a modification was viewed as unreasonable.

Under the general modification regulation which applies to all standards of performance, alteration two, the addition of electronic automatic grain weighing scales, would be considered a change in the method of operation of the affected facility if it were to increase the hourly grain throughput. If this alteration were to increase emissions to the atmosphere and require a capital expenditure, the grain receiving or loading station whose method of operation had changed (i.e., increased grain throughput), would be considered a modified facility subject to the standards. Consideration of this type of alteration, which would result in only minor changes to a facility, is viewed as unreasonable in light of the relatively high expenditure this could require for existing grain elevators to comply with the standards.

Alterations three and four, replacement of existing motors and drives with larger motors and drives and addition of grain storage capacity with no increase in the hourly grain handling capacity, would probably not be considered modifications under the general modification regulation. Since it is quite evident that there was considerable confusion concerning modifications, however, alterations three and four, along with alterations one and two discussed above, are specifically exempt from consideration as modifications in the promulgated standards.

The modification provisions in 40 CFR 60.14(e) exempt certain physical or operational changes from being considered as modifications, even though an increase in emission rate occurs. Under 40 CFR 60.14(e)(2), if an increase in production rate of an existing facility can be accomplished without a capital expenditure on the stationary source containing that facility, the change is not considered a modification.

A capital expenditure is defined as any amount of money exceeding the product of the Internal Revenue Service (IRS) "annual asset guideline repair allowance percentage" times the basis of the facility, as defined by section 1012 of the Internal Revenue Code. In the case of grain elevators, the IRS has not listed an annual asset guideline repair allowance percentage. Following discussions with the IRS, the Department of Agriculture, and the grain elevator industry, the Agency determined that 6.5 percent is the appropriate percentage for the grain elevator industry. If the capital expenditures required to increase the production rate of an existing facility do not exceed the amount calculated under the IRS formula, the change in the facility is not considered a modification. If the expenditures exceed the calculated amount, the change in operation is considered a modification and the facility must comply with NSPS.

Often a physical or operational change to an existing facility to increase production rate will result in an increase in the production rate of another existing facility, even though it did not undergo a physical or operational change. For example, if new electronic weighing scales were added to a truck unloading station to increase grain receipts, the production rate and emission rate would increase at the unloading station. This could result in an increase in production rate and emission rate at other existing facilities (e.g., grain handling operations) even though physical or operational changes did not occur. Under the present wording of the regulation, expenditures made throughout a grain elevator to adjust for increased production rate would have to be considered in determining if a capital expenditure had been made on each facility whose operation is altered by the production increase. If the capital expenditure made on the truck unloading station were considered to be made on each existing facility which increased its production rate, it is possible that the alterations on each such facility would qualify as modifications. Each facility would, therefore, have to meet the applicable NSPS.

Such a result is inconsistent with the intent of the regulation. The Agency intended that only capital expenditures made for the changed facility are to be considered in determining if the change is a modification. Related expenditures on other existing facilities are not to be considered in the calculation. To clarify the regulation, the phrase "the stationary source containing" is being deleted. Because this is a clarification of intent and not a change in policy, the amendment is

being promulgated as a final regulation without prior proposal.

PERFORMANCE TEST

Several commenters were concerned about the costs of conducting performance tests on fabric filter baghouses. These commenters stated that the costs involved might be a very substantial portion of the costs of the fabric filter baghouse itself, and several baghouses may be installed at a moderately sized grain elevator. The commenters suggested that a fabric filter baghouse should be assumed to be in compliance without a performance test if it were properly sized. In addition, the opacity standards could be used to demonstrate compliance.

It would not be wise to waive performance tests in all cases. Section 60.8(b) already provides that a performance test may be waived if "the owner or operator of a source has demonstrated by other means to the Administrator's satisfaction that the affected facility is in compliance with the standard." Since performance tests are heavily weighed in court proceedings, performance test requirements must be retained to insure effective enforcement.

SAFETY CONSIDERATIONS

In December 1977, and January 1978, several grain elevators exploded. Allegations were made by various individuals within the grain elevator industry contending that Federal air pollution control regulations were contributing to an increase in the risk of dust explosions at grain elevators by requiring that building doors and windows be closed and by concentrating grain dust in emission control systems. Investigation of these allegations indicates they are false.

There were no Federal regulations specifically limiting dust emissions from grain elevators which were in effect at the time of these grain elevator explosions. A number of State and local air pollution control agencies, however, have adopted regulations which limit particulate matter emissions from grain elevators. Many of these regulations were developed by States and included in their implementation plans for attaining and maintaining the NAAQS for particulate matter. Particulate matter, as a general class, can cause adverse health effects; and the NAAQS, which were promulgated on April 30, 1971, were established at levels necessary to protect the public health and welfare.

Although compliance with State or local air pollution control regulations, or the promulgated standards of performance, can be achieved in some instances by closing building doors and windows, this is not the objective of these regulations and is not an accept-

RULES AND REGULATIONS

able means of compliance. The objective of State and local regulations and the promulgated standards of performance is that dust be captured at those points within grain elevators where it is generated through the use of effective hoods or enclosures with air aspiration, and removed from the grain elevator to an air pollution control device. This is the basis for the promulgated standards of performance. Compliance with air pollution control regulations and the promulgated standards of performance does not require that windows and doors in buildings be closed to prevent escape of dust and this practice may in fact be a major safety hazard.

Fabric filter baghouses have been used for many years to collect combustible dusts such as wheat flour. There have been extremely few incidences of dust explosions or fires caused by such emission control devices in the flour industry. In the grain elevator industry, no air pollution control device has been identified as the cause of a grain elevator explosion. Consequently, fabric filter baghouses, or emission control devices in general, which are properly designed, operated, and maintained will not contribute to an increased risk of dust explosions at grain elevators.

These conclusions were supported at a joint meeting between representatives of EPA; the Federal Grain Inspection Service (FGIS) of the Department of Agriculture; the Occupational Safety and Health Administration (OSHA); the grain elevator industry; and the fire insurance industry. Installation and use of properly designed, operated, and maintained air pollution control systems were found to be consistent with State and local air pollution regulations, OSHA regulations, and national fire codes. Chapter 6 of the National Fire Code for Grain Elevators and Bulk Grain Handling Facilities (NFPA No. 61-B), which was prepared by the National Fire Protection Association, for example, recommends that "dust shall be collected at all dust producing points within the processing facilities." The code then goes on to specially recommend that all elevator boots, automatic scales, scale hoppers, belt loaders, belt discharges, trippers, and discharge heads, and all machinery such as cleaners, scalpings, and similar devices be provided with enclosures or dust hoods and air aspiration.

Consequently, compliance with existing State or local air pollution regulations, or the promulgated standards of performance, will not increase the risk of dust explosions at grain elevators if the approach taken to meet these regulations is capture and control of dust at those points within an elevator where it is generated. If, how-

ever, the approach taken is merely to close doors, windows, and other openings to trap dust within the grain elevator, or the air pollution control equipment is allowed to deteriorate to the point where it is no longer effective in capturing dust as it is generated, then ambient concentrations of dust within the elevator will increase and the risk of explosion will also increase.

The House Subcommittee on Compensation, Health, and Safety is currently conducting oversight hearings to determine if something needs to be done to prevent these disastrous grain elevator explosions. The FGIS, EPA, and OSHA testified at these oversight hearings on January 24 and 25, 1978. The testimony indicated that dust should be captured and collected in emission control devices in order to reduce the incidence of dust explosions at grain elevators, protect the health of employees from such ailments as "farmer's lung," and prevent air pollution. Consequently, properly operated and maintained air pollution control equipment will not increase the risk of grain elevator explosions.

MISCELLANEOUS

It should be noted that standards of performance for new sources established under section 111 of the Clean Air Act reflect the degree of emission limitation achievable through application of the best adequately demonstrated technological system of continuous emission reduction (taking into consideration the cost of achieving such emission reduction, any nonair quality health and environmental impact and energy requirements). State implementation plans (SIP's) approved or promulgated under section 110 of the act, on the other hand, must provide for the attainment and maintenance of national ambient air quality standards (NAAQS) designed to protect public health and welfare. For that purpose, SIP's must in some cases require greater emission reductions than those required by standards of performance for new sources. Section 173 of the act requires, among other things, that a new or modified source constructed in an area in violation of the NAAQS must reduce emissions to the level which reflects the "lowest achievable emission rate" for such category of source as defined in section 171(3). In no event can the emission rate exceed any applicable standard of performance.

A similar situation may arise when a major emitting facility is to be constructed in a geographic area which falls under the prevention of significant deterioration of air quality provisions of the act (part C). These provisions require, among other things, that major emitting facilities to be

constructed in such areas are to be subject to best available control technology for all pollutants regulated under the act. The term "best available control technology" (BACT), as defined in section 169(3), means "an emission limitation based on the maximum degree of reduction of each pollutant subject to regulation under this act emitted from or which results from any major emitting facility, which the permitting authority, on a case-by-case basis, taking into account energy, environmental, and economic impacts and other costs, determines is achievable for such facility through application of production processes and available methods, systems, and techniques, including fuel cleaning or treatment or innovative fuel combustion techniques for control of each such pollutant. In no event shall application of 'best available control technology' result in emissions of any pollutants which will exceed the emissions allowed by any applicable standard established pursuant to sections 111 or 112 of this Act."

Standards of performance should not be viewed as the ultimate in achievable emission control and should not preclude the imposition of a more stringent emission standard, where appropriate. For example, while cost of achievement may be an important factor in determining standards of performance applicable to all areas of the country (clean as well as dirty), statutorily, costs do not play such a role in determining the "lowest achievable emission rate" for new or modified sources locating in areas violating statutorily mandated health and welfare standards. Although there may be emission control technology available that can reduce emissions below those levels required to comply with standards of performance, this technology might not be selected as the basis of standards of performance due to costs associated with its use. This in no way should preclude its use in situations where cost is a lesser consideration, such as determination of the "lowest achievable emission rate."

In addition, States are free under section 116 of the act to establish even more stringent emission limits than those established under section 111 or those necessary to attain or maintain the NAAQS under section 110. Thus, new sources may in some cases be subject to limitations more stringent than standards of performance under section 111, and prospective owners and operators of new sources should be aware of this possibility in planning for such facilities.

ECONOMIC IMPACT ASSESSMENT

An economic assessment has been prepared as required under section 317 of the Act."

RULES AND REGULATIONS

Dated: July 26, 1978.

DOUGLAS M. COSTLE,
Administrator.

Part 60 of chapter I, title 40 of the Code of Federal Regulations is amended as follows:

Subpart A—General Provisions

1. Section 60.2 is amended by revising paragraph (v). The revised paragraph reads as follows:

§ 60.2 Definitions.

(v) "Particulate matter" means any finely divided solid or liquid material, other than uncombined water, as measured by the reference methods specified under each applicable subpart, or an equivalent or alternative method.

§ 60.14 [Amended]

2. Section 60.14 is amended by deleting the words "the stationary source containing" from paragraph (e)(2).
3. Part 60 is amended by adding subpart DD as follows:

Subpart DD—Standards of Performance for Grain Elevators

- Sec.
- 60.300 Applicability and designation of affected facility.
 - 60.301 Definitions.
 - 60.302 Standard for particulate matter.
 - 60.303 Test methods and procedures.
 - 60.304 Modification.

AUTHORITY: Secs. 111 and 301(a) of the Clean Air Act, as amended (42 U.S.C. 7411, 7601(a)), and additional authority as noted below.

Subpart DD—Standards of Performance for Grain Elevators

§ 60.300 Applicability and designation of affected facility.

(a) The provisions of this subpart apply to each affected facility at any grain terminal elevator or any grain storage elevator, except as provided

under § 60.304(b). The affected facilities are each truck unloading station, truck loading station, barge and ship unloading station, barge and ship loading station, railcar loading station, railcar unloading station, grain dryer, and all grain handling operations.

(b) Any facility under paragraph (a) of this section which commences construction, modification, or reconstruction after (date of reinstatement of proposal) is subject to the requirements of this part.

§ 60.301 Definitions.

As used in this subpart, all terms not defined herein shall have the meaning given them in the act and in subpart A of this part.

(a) "Grain" means corn, wheat, sorghum, rice, rye, oats, barley, and soybeans.

(b) "Grain elevator" means any plant or installation at which grain is unloaded, handled, cleaned, dried, stored, or loaded.

(c) "Grain terminal elevator" means any grain elevator which has a permanent storage capacity of more than 88,100 m³ (ca. 2.5 million U.S. bushels), except those located at animal food manufacturers, pet food manufacturers, cereal manufacturers, breweries, and livestock feedlots.

(d) "Permanent storage capacity" means grain storage capacity which is inside a building, bin, or silo.

(e) "Railcar" means railroad hopper car or boxcar.

(f) "Grain storage elevator" means any grain elevator located at any wheat flour mill, wet corn mill, dry corn mill (human consumption), rice mill, or soybean oil extraction plant which has a permanent grain storage capacity of 35,200 m³ (ca. 1 million bushels).

(g) "Process emission" means the particulate matter which is collected by a capture system.

(h) "Fugitive emission" means the particulate matter which is not collected by a capture system and is released directly into the atmosphere from an affected facility at a grain elevator.

(i) "Capture system" means the equipment such as sheds, hoods, ducts, fans, dampers, etc. used to collect particulate matter generated by an affected facility at a grain elevator.

(j) "Grain unloading station" means that portion of a grain elevator where the grain is transferred from a truck, railcar, barge, or ship to a receiving hopper.

(k) "Grain loading station" means that portion of a grain elevator where the grain is transferred from the elevator to a truck, railcar, barge, or ship.

(l) "Grain handling operations" include bucket elevators or legs (excluding legs used to unload barges or ships), scale hoppers and surge bins

(garners), turn heads, scalpers, cleaners, trippers, and the headhouse and other such structures.

(m) "Column dryer" means any equipment used to reduce the moisture content of grain in which the grain flows from the top to the bottom in one or more continuous packed columns between two perforated metal sheets.

(n) "Rack dryer" means any equipment used to reduce the moisture content of grain in which the grain flows from the top to the bottom in a cascading flow around rows of baffles (racks).

(o) "Unloading leg" means a device which includes a bucket-type elevator which is used to remove grain from a barge or ship.

§ 60.302 Standard for particulate matter.

(a) On and after the 60th day of achieving the maximum production rate at which the affected facility will be operated, but no later than 180 days after initial startup, no owner or operator subject to the provisions of this subpart shall cause to be discharged into the atmosphere any gases which exhibit greater than 0 percent opacity from any:

(1) Column dryer with column plate perforation exceeding 2.4 mm diameter (ca. 0.094 inch).

(2) Rack dryer in which exhaust gases pass through a screen filter coarser than 50 mesh.

(b) On and after the date on which the performance test required to be conducted by § 60.8 is completed, no owner or operator subject to the provisions of this subpart shall cause to be discharged into the atmosphere from any affected facility except a grain dryer any process emission which:

(1) Contains particulate matter in excess of 0.023 g/dscm (ca. 0.01 gr/dscf).

(2) Exhibits greater than 0 percent opacity.

(c) On and after the 60th day of achieving the maximum production rate at which the affected facility will be operated, but no later than 180 days after initial startup, no owner or operator subject to the provisions of this subpart shall cause to be discharged into the atmosphere any fugitive emission from:

(1) Any individual truck unloading station, railcar unloading station, or railcar loading station, which exhibits greater than 5 percent opacity.

(2) Any grain handling operation which exhibits greater than 0 percent opacity.

(3) Any truck loading station which exhibits greater than 10 percent opacity.

(4) Any barge or ship loading station which exhibits greater than 20 percent opacity.

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Amendments to Kraft Pulp Mills Standard and Reference Method 16

AGENCY: Environmental Protection Agency (EPA).

ACTION: Final rule.

SUMMARY: This action amends the standards of performance for Kraft pulp mills by adding a provision for determining compliance of affected facilities which use a control system incorporating a process other than combustion. This amendment is necessary because the standards would place control systems other than combustion at a disadvantage. The intent of this amendment is to remove any preclusion of new and improved control systems. This action also amends Reference Method 16 to insure that the testing procedure is consistent with the promulgated standards.

EFFECTIVE DATE: August 7, 1978.

FOR FURTHER INFORMATION
CONTACT:

Don R. Goodwin, Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, N.C. 27711, telephone 919-541-5271.

SUPPLEMENTARY INFORMATION: Standards of performance for Kraft pulp mills were promulgated on February 23, 1978. On March 31, 1978, the National Council for Air and Stream Improvement (NCASI) requested two changes to these standards to prevent their interpretation in a manner which was inconsistent with their intent. The purpose of these amendments, therefore, is to clarify the intent of the standards.

OXYGEN CORRECTION FACTORS

In § 60.283(a)(1), the percent oxygen to which TRS emissions must be corrected was specified. The purpose of this specification was to provide a consistent basis for the determination of TRS emissions. Ten percent was selected because it reflected the observed oxygen concentrations on facilities controlled by the best system of emission reduction which was incineration. The NCASI pointed out, howev-

er, that the specification of a 10-percent oxygen level on sources which characteristically contain higher levels would effectively discourage the development of control technologies other than incineration.

The purpose of an emission standard is to reduce total emissions to the atmosphere. If an emission control technique should evolve which is capable of achieving the same mass rate of emissions from a given facility, use of that technique should be permitted. The standard, as written, could have inhibited the development of new technologies, if misinterpreted. Therefore, to remove this potential source of misinterpretation, § 60.283(a)(1)(v) has been added to the standard to provide for correction to untreated oxygen concentration in the case of brown stock washers, black liquor oxidation systems, or digester systems.

REFERENCE METHOD 16

The second point of concern to the NCASI was the correction factor to be applied for sampling system losses contained in the post-test procedures (paragraph 10.1) of method 16. The specific concern was the specification that a test gas be introduced at the beginning of the probe to determine sample loss in the sampling train. The data base for the promulgated standard considered only TRS losses in the sampling train, not the probe or probe filter. Consequently, the post-test procedures are amended to require the determination of sampling train losses by introducing the test gas after the probe filter consistent with the data base supporting the promulgated standards.

MISCELLANEOUS

The Administrator finds that good cause exists for omitting prior notice and public comment on these amendments and for making them immediately effective because they simply clarify the existing regulations and impose no additional substantive requirements.

Section 317 of the Clean Air Act requires the Administrator to prepare an economic impact assessment for revisions determined by the Administrator to be substantial. Since the costs associated with the proposed amendments would have a negligible impact on consumer costs, the Administrator has determined that the proposed amendments are not substantial and do not require preparation of an economic impact assessment.

Dated: August 1, 1978.

DOUGLAS M. COSTLE,
Administrator.

Part 60 of chapter I, title 40 of the Code of Federal Regulations is amended to read as follows:

(d) The owner or operator of any barge or ship unloading station shall operate as follows:

(1) The unloading leg shall be enclosed from the top (including the receiving hopper) to the center line of the bottom pulley and ventilation to a control device shall be maintained on both sides of the leg and the grain receiving hopper.

(2) The total rate of air ventilated shall be at least 32.1 actual cubic meters per cubic meter of grain handling capacity (ca. 40 ft³/bu).

(3) Rather than meet the requirements of subparagraphs (1) and (2), of this paragraph the owner or operator may use other methods of emission control if it is demonstrated to the Administrator's satisfaction that they would reduce emissions of particulate matter to the same level or less.

§ 60.303 Test methods and procedures.

(a) Reference methods in appendix A of this part, except as provided under § 60.8(b), shall be used to determine compliance with the standards prescribed under § 60.302 as follows:

(1) Method 5 or method 17 for concentration of particulate matter and associated moisture content;

(2) Method 1 for sample and velocity traverses;

(3) Method 2 for velocity and volumetric flow rate;

(4) Method 3 for gas analysis; and

(5) Method 9 for visible emissions.

(b) For method 5, the sampling probe and filter holder shall be operated without heaters. The sampling time for each run, using method 5 or method 17, shall be at least 60 minutes. The minimum sample volume shall be 1.7 dscm (ca. 60 dscf).

(Sec. 114, Clean Air Act, as amended (42 U.S.C. 7414).)

§ 60.304 Modifications.

(a) The factor 6.5 shall be used in place of "annual asset guidelines repair allowance percentage," to determine whether a capital expenditure as defined by § 60.2(bb) has been made to an existing facility.

(b) The following physical changes or changes in the method of operation shall not by themselves be considered a modification of any existing facility:

(1) The addition of gravity loadout spouts to existing grain storage or grain transfer bins.

(2) The installation of automatic grain weighing scales.

(3) Replacement of motor and drive units driving existing grain handling equipment.

(4) The installation of permanent storage capacity with no increase in hourly grain handling capacity.

[FRL 987-8]

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Delegation of Authority for State of Rhode Island

AGENCY: Environmental Protection Agency (EPA).

ACTION: Amendment.

SUMMARY: The delegation of authority to the State of Rhode Island for the standards of performance for new stationary sources (NSPS) was made on March 31, 1978. This amendment which adds the address of the Rhode Island Department of Environmental Management, reflects this delegation. A notice announcing this delegation is published today in the FEDERAL REGISTER.

EFFECTIVE DATE: October 16, 1978.

FOR FURTHER INFORMATION
CONTACT:

John Courcier, Air Branch, EPA
Region I, Room 2113, JFK Federal
Building, Boston, Mass. 02203, 617-
223-4448.

SUPPLEMENTARY INFORMATION:
Under the delegation of authority for the standards of performance for new stationary sources (NSPS) to the State of Rhode Island on March 31, 1978, EPA is today amending 40 CFR 60.4, Address, to reflect this delegation. A notice announcing this delegation is published today elsewhere in this (43 part of the FEDERAL REGISTER. The amended § 60.4, which adds the address of the Rhode Island Department of Environmental Management to which all reports, requests, applications, submittals, and communications to the Administrator pursuant to this part must also be addressed, is set forth below.

The Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective

immediately in that it is an administrative change and not one of substantive content. No additional burdens are imposed on the parties affected. The delegation which is reflected by this administrative amendment was effective on March 31, 1978, and it serves no purpose to delay the technical change of this addition of the State address to the Code of Federal Regulations.

This rulemaking is effective immediately, and is issued under the authority of section 111 of the Clean Air Act, as amended, 42 U.S.C. 7412.

Dated: September 18, 1978.

WILLIAM R. ADAMS, Jr.,
Regional Administrator,
Region I.

Part 60 of chapter I, title 40 of the Code of Federal Regulations is amended as follows:

1. In § 60.4 paragraph (b) is amended by adding subparagraph (OO) to read as follows:

§ 60.4 Address

(b) . . .

(OO) State of Rhode Island, Department of Environmental Management, 83 Park Street, Providence, R.I. 02908

[FR Doc. 78-29105 Filed 10-13-78; 9:49 am]

FEDERAL REGISTER, VOL. 43, NO. 200

MONDAY, OCTOBER 16, 1978

1. In § 60.283, paragraph (a)(1) is amended to read as follows:

§ 60.283 Standard for total reduced sulfur (TRS).

(a) . . .

(1) . . .

(v) The gases from the digester system, brown stock washer system, condensate stripper system, or black liquor oxidation system are controlled by a means other than combustion. In this case, these systems shall not discharge any gases to the atmosphere which contain TRS in excess of 5 ppm by volume on a dry basis, corrected to the actual oxygen content of the untreated gas stream.

2. In appendix A, paragraph 10.1 of method 16 is amended to read as follows:

10. POST-TEST PROCEDURES

10.1 Sample line loss. A known concentration of hydrogen sulfide at the level of the applicable standard, ± 20 percent, must be introduced into the sampling system in sufficient quantities to insure that there is an excess of sample which must be vented to the atmosphere. The sample must be introduced immediately after the probe and filter and transported through the remainder of the sampling system to the measurement system in the normal manner. The resulting measured concentration should be compared to the known value to determine the sampling system loss.

For sampling losses greater than 20 percent in a sample run, the sample run is not to be used when determining the arithmetic mean of the performance test. For sampling losses of 0-20 percent, the sample concentration must be corrected by dividing the sample concentration by the fraction of recovery. The fraction of recovery is equal to one minus the ratio of the measured concentration to the known concentration of hydrogen sulfide in the sample line loss procedure. The known gas sample may be generated using permeation tubes. Alternatively, cylinders of hydrogen sulfide mixed in air may be used provided they are traceable to permeation tubes. The optional pretest procedures provide a good guideline for determining if there are leaks in the sampling system.

(Sec. 111, 301(a)), Clean Air Act as amended (42 U.S.C. 7411, 7601(a)).

RULES AND REGULATIONS

93

Title 40—Protection of Environment

CHAPTER I—ENVIRONMENTAL PROTECTION AGENCY

(FRL 1012-2)

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Appendix A—Reference Method 16

AGENCY: Environmental Protection Agency.

ACTION: Amendment.

SUMMARY: This action amends Reference Method 16 for determining total reduced sulfur emissions from stationary sources. The amendment corrects several typographical errors and improves the reference method by requiring the use of a scrubber to prevent potential interference from high SO₂ concentrations. These changes assure more accurate measurement of total reduced sulfur (TRS) emissions but do not substantially change the reference method.

SUPPLEMENTARY INFORMATION: On February 23, 1978 (43 FR 7575), Appendix A—Reference Method 16 appeared with several typographical errors or omissions. Subsequent comments noted these and also suggested that the problem of high SO₂ concentrations could be corrected by using a scrubber to remove these high concentrations. This amendment corrects the errors of the original publication and slightly modifies Reference Method 16 by requiring the use of a scrubber to prevent potential interference from high SO₂ concentrations.

Reference Method 16 is the reference method specified for use in determining compliance with the promulgated standards of performance for kraft pulp mills. The data base used to develop the standards for kraft pulp mills has been examined and this additional requirement to use a scrubber to prevent potential interference from high SO₂ concentrations does not require any change to these standards of performance. The data used to develop these standards was not gathered from kraft pulp mills with high SO₂ concentrations; thus, the problem of SO₂ interference was not present in the data base. The use of a scrubber to prevent this potential interference in the future, therefore, is completely consistent with this data base and the promulgated standards.

The increase in the cost of determining compliance with the standards of performance for kraft pulp mills, as a result of this additional requirement to use a scrubber in Reference Method 16, is negligible. At most, this additional requirement could increase the cost of a performance test by about 50 dollars.

Because these corrections and additions to Reference Method 16 are minor in nature, impose no additional substantive requirements, or do not require a change in the promulgated standards of performance for kraft pulp mills, these amendments are promulgated directly.

EFFECTIVE DATE: January 12, 1979.

Dated: January 2, 1979.

DOUGLAS M. COSTLE,
Administrator.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

APPENDIX A—REFERENCE METHODS

In Method 16 of Appendix A, Sections 3.4, 4.1, 4.3, 5, 5.5.2, 6, 8.3, 9.2, 10.3, 11.3, 12.1, 12.1.1.3, 12.1.3.1, 12.1.3.1.2, 12.1.3.2, 12.1.3.2.3, and 12.2 are amended as follows:

1. In subsection 3.4, at the end of the first paragraph, add: "In the example system, SO₂ is removed by a citrate buffer solution prior to GC injection. This scrubber will be used when SO₂ levels are high enough to prevent baseline separation from the reduced sulfur compounds."

2. In subsection 4.1, change "± 3 percent" to "± 5 percent."

3. In subsection 4.3, delete both sentences and replace with the following: "Losses through the sample transport system must be measured and a correction factor developed to adjust the calibration accuracy to 100 percent."

4. After Section 5 and before subsection 5.1.1 insert "5.1. Sampling."

5. In Section 5, add the following subsection: "5.3 SO₂ Scrubber. The SO₂ scrubber is a midjet impinger packed with glass wool to eliminate entrained mist and charged with potassium citrate-citric acid buffer." Then increase all numbers from 5.3 up to and including 5.5.4 by 0.1, e.g., change 5.3 to 5.4, etc.

6. In subsection 5.5.2, the word "lowest" in the fourth sentence is replaced with "lower."

7. In Section 6, add the following subsection: "6.6 Citrate Buffer. Dissolve 300 grams of potassium citrate and 41 grams of anhydrous citric acid in 1 liter of deionized water. 284 grams of sodium citrate may be substituted for the potassium citrate."

8. In subsection 8.3, in the second sentence, after "Bypassing the dilution system," insert "but using the SO₂ scrubber," before finishing the sentence.

9. In subsection 9.2, replace sentence with the following: "Aliquots of diluted sample pass through the SO₂ scrubber, and then are injected into the GC/FPD analyzer for analysis."

10. In subsection 10.3, "paragraph" in the second sentence is corrected with "subsection."

11. In subsection 11.3 under B_{so} definition, insert "Reference" before "Method 4."

12. In subsection 12.1.1.3 "(12.2.4 below)" is corrected to "(12.1.2.4 below)."

13. In subsection 12.1, add the following subsection: "12.1.3 SO₂ Scrubber. Midjet impinger with 15 ml of potassium citrate buffer to absorb SO₂ in the sample." Then renumber existing section 12.1.3 and following subsections through and including 12.1.4.3 as 12.1.4 through 12.1.5.3.

14. The second subsection listed as "12.1.3.1" (before corrected in above amendment) should be "12.1.4.1.1."

15. In subsection 12.1.3.1 (amended above to 12.1.4.1) correct "GC/FPD-1" to "GC/FPD-I."

16. In subsection 12.1.3.1.2 (amended above to 12.1.4.1.2) omit "Packed as in 5.3.1." and put a period after "tubing."

17. In subsection 12.1.3.2 (amended above to 12.1.4.2) correct "GC/FPD-11" to "GC/FPD-II."

18. In subsection 12.1.3.2.3 (amended above to 12.1.4.2.3) the phrase "12.1.3.1.4. to 12.1.3.1.10" is corrected to read "12.1.4.1.5 to 12.1.4.1.10."

19. In subsection 12.2, add the following subsection: "12.2.7 Citrate Buffer. Dissolve 300 grams of potassium citrate and 41 grams of anhydrous citric acid in 1 liter of deionized water. 284 grams of sodium citrate may be substituted for the potassium citrate."

(Sec. 111, 301(a) of the Clean Air Act as amended (42 U.S.C. 7411, 7601 (a))).

Title 40—Protection of Environment

CHAPTER I—ENVIRONMENTAL
PROTECTION AGENCY

(FRL 1017-7)

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY
SOURCESWood Residue-Fired Steam
Generators

APPLICABILITY DETERMINATION

AGENCY: Environmental Protection
Agency.

ACTION: Notice of Determination.

RULES AND REGULATIONS

SUMMARY: This notice presents the results of a performance review of particulate matter control systems on wood residue-fired steam generators. On November 22, 1976 (41 FR 51397), EPA amended the standards of performance of new fossil-fuel-fired steam generators to allow the heat content of wood residue to be included with the heat content of fossil-fuel when determining compliance with the standards. EPA stated in the preamble that there were some questions about the feasibility of units burning a large portion of wood residue to achieve the particulate matter standard and announced that this would be reviewed. This review has been completed, and EPA concludes that the particulate matter standard can be achieved, therefore, no revision is necessary.

ADDRESSES: The document which presents the basis for this notice may be obtained from the Public Information Center (PM-215), U.S. Environmental Protection Agency, Washington, D.C. 20460 (specify "Wood Residue-Fired Steam Generator Particulate Matter Control Assessment," EPA-450/2-78-044.)

The document may be inspected and copied at the Public Information Reference Unit (EPA Library), Room 2922, 401 M Street, S.W., Washington, D.C.

FOR FURTHER INFORMATION
CONTACT:

Don R. Goodwin, Director, Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone number (919) 541-5271.

SUPPLEMENTARY INFORMATION: On November 22, 1976, standards under 40 CFR Part 60, Subpart D for new fossil-fuel-fired steam generators were amended (41 FR 51397) to clarify that the standards apply to each fossil-fuel and wood residue-fired steam generating unit capable of firing fossil-fuel at a heat input of more than 73 megawatts (250 million Btu per hour). The primary objective of this amendment is to allow the heat input provided by wood residue to be used as a dilution agent in the calculations necessary to determine sulfur dioxide emissions. EPA recognized in the preamble of the amendment that questions remained concerning the ability of affected facilities which burn substantially more wood residue than fossil-fuel to comply with the standard for particulate matter. The preamble also stated that EPA was continuing to gather information on this question. The discussion that follows summarizes the results of EPA's examination of available information.

INTRODUCTION

Wood residue is a waste by-product of the pulp and paper industry which consists of bark, sawdust, slabs, chips, shavings, and mill trims. Disposal of this waste prior to the 1960's consisted mostly of incineration in Dutch ovens or open air tepees. Since then the advent of the spreader stoker boiler and the increasing costs of fossil-fuels has made wood residue an economical fuel to burn in large boilers for the generation of process steam.

There are several hundred steam generating boilers in the pulp and paper and allied forest product industry that use fuel which is partly or totally derived from wood residue. These boilers range in size from 6 megawatts (20 million Btu per hour) to 148 megawatts (500 million Btu per hour) and the total emissions from all boilers is estimated to be 225 tons of particulate matter per day after application of existing air pollution control devices.

Most existing wood residue-fired boilers subject to State emission standards are equipped with multitube-cyclone mechanical collectors. Manufacturers of the multitube collector have recognized that this type of control will not meet present new source standards and have been developing processes and devices to meet the new regulations. However, the use of these various systems on wood residue-fired boilers has not found widespread use to date, resulting in an information gap on expected performance of collector types other than conventional mechanical collectors.

In order to provide needed information in this area and to answer questions raised in the November 22, 1976 (41 FR 51397), amendment, a study was conducted on the most effective control systems in operation on wood residue-fired boilers. Also the amount and characteristics of the particulate emissions from wood residue-fired boilers was studied. The review that follows presents the results of that study.

PERFORMANCE REVIEW

The combustion of wood residue results in particulate emissions in the form of bark char or fly ash. Entrained with the char are varying amounts of sand and salt, the quantity depending on the method by which the original wood was logged and delivered. The fly ash particulates have a lower density and are larger in size than fly ash from coal-fired boilers. In general, the bark boiler exhaust gas will have a lower fly ash content than emissions from similar boilers burning physically cleaned coals or low-sulfur Western coals.

The bark fly ash, unlike most fly ash, is primarily unburned carbon. With collection and reinjection to the

RULES AND REGULATIONS

boiler, greater carbon burnout can increase boiler efficiency from one to four percent. The reinjection of collected ash also significantly increases the dust loading since the sand is also recirculated with the fly ash. This increased dust loading can be accommodated by the use of sand separators or decantation type dust collectors. Collectors of this type in combination with more efficient units of air pollution control equipment constitute the systems currently in operation on existing plants that were found to operate with emissions less than the 43 nanograms per joule (0.10 pounds per million Btu) standard for particulate matter.

A survey of currently operated facilities that fire wood residue alone or in combination with fossil-fuel shows that most operate with mechanical collectors; some operate with low energy wet scrubbers, and a few facilities currently use higher energy venturi scrubbers (HEVS) or electrostatic precipitators (ESP). One facility reviewed is using a high temperature baghouse control system.

Currently, the use of multitube-cyclone mechanical collectors on hogged-fuel boilers provides the sole source of particulate removal for a majority of existing plants. The most commonly used system employs two multiclones in series allowing for the first collector to remove the bulk of the dust and a second collector with special high efficiency vanes for the removal of the finer particles. Collection efficiency for this arrangement ranges from 65 to 95 percent. This efficiency range is not sufficient to provide compliance with the particulate matter standard, but does provide a widely used first stage collection to which other control systems are added.

Of special note is one facility using a Swedish designed mechanical collector in series with conventional multiclone collectors. The Swedish collector is a small diameter multitube cyclone with a movable vane ring that imparts a spinning motion to the gases while at the same time maintaining a low pressure differential. This system is reducing emissions from the largest boiler found in the review to 107 nanograms per joule.

Electrostatic precipitators have been demonstrated to allow compliance with the particulate matter standard when coal is used as an auxiliary fuel. Available information indicates that this type of control provides high collection efficiencies on combination wood residue coal-fired boilers. One ESP collects particulate matter from a 50 percent bark, 50 percent coal combination fired boiler. An emission level of 13 nanograms per joule (.03 pounds per million Btu) was obtained using test methods recommended by the

American Society of Mechanical Engineers.

The fabric filter (baghouse) particulate control system provides the highest collection efficiency available, 99.9 percent. On one facility currently using a baghouse on a wood residue-fired boiler, the sodium chloride content of the ash being filtered is high enough (70 percent) that the possibility of fire is practically eliminated. Source test data collected with EPA Method 5 showed this system reduces the particulate emissions to 5 nanograms per joule (0.01 pounds per million Btu).

The application of fabric filters to control emissions from hogged fuel boilers has recently gained acceptance from several facilities of the paper and pulp industry, mainly due to the development of improved designs and operation procedures that reduce fire hazards. Several large sized boilers, firing salt and non-salt laden wood residue, are being equipped with fabric filter control systems this year and the performance of these installations will verify the effectiveness of fabric filtration.

Practically all of the facilities currently meeting the new source particulate matter standard are using wet scrubbers of the venturi or wet-impinger type. These units are usually connected in series with a mechanical collector. Three facilities reviewed which are using the wet-impingement type wet scrubber on large boilers burning 100 percent bark are producing particulate emissions well below the 43 nanograms per joule standard at operating pressure drops of 1.5 to 2 kPa (6 to 8 inches, H₂O). Five facilities using venturi type wet scrubbers on large boilers, two burning half oil and half bark and the other three burning 100 percent bark, are producing particulate emissions consistently below the standard at pressure drops of 2.5 to 5 kPa (10 to 20 inches, H₂O).

One facility has a large boiler burning 100 percent bark emitting a maximum of 5023 nanograms per joule of particulate matter into a multi-cyclone dust collector rated at an efficiency of 87 percent. The outlet loading from this mechanical collector is directed through two wet impingement-type scrubbers in parallel. With this arrangement of scrubbers, a collection efficiency of 97.7 percent is obtained at pressure drops of 2 kPa (8 inches, H₂O). Source test data collected with EPA Method 5 showed particulate matter emissions to be 15 nanograms per joule, well below the 43 nanograms per joule standard.

Another facility with a boiler of similar size and fuel was emitting a maximum of 4650 nanograms per joule into a multi-cyclone dust collector operating at a collection efficiency of 66 per-

cent. The outlet loading from this collector is drawn into two wet-impingement scrubbers arranged in parallel. The operating pressure drop on these scrubbers was varied within the range of 1.6 to 2.0 kPa (6 to 8 inches, H₂O), resulting in a proportional decrease in discharged loadings of 25.8 to 18.5 nanograms per joule. Source test data collected on this source was obtained with the Montana Sampling Train.

Facilities using a venturi type wet scrubber were found to be able to meet the 43 nanogram per joule standard at higher pressure drops than the impingement type scrubber. One facility with a large boiler burning 100 percent bark had a multi-cyclone dust collector in series with a venturi wet scrubber operating at a pressure drop of 5 kPa (20 inches, H₂O). Source test data using EPA Method 5 showed this system consistently reduces emissions to an average outlet loading of 17.2 nanograms per joule of particulate matter. Another facility with a boiler burning 40 percent bark and 60 percent oil has a multi-cyclone and venturi scrubber system obtaining 25.8 nanograms per joule at a pressure drop of 2.5 kPa (10 inches, H₂O). The Florida Wet Train was used to obtain emission data on this source. A facility of similar design but burning 100 percent bark is obtaining the same emission control, 25.8 nanograms per joule, at a pressure drop of 3 kPa (12 inches, H₂O). Source test data collected on this source were obtained with the EPA Method 5.

This review has shown that the use of a wet scrubber, ESP, or a baghouse to control emissions from wood bark boilers will permit attainment of the particulate matter standard under 40 CFR Part 60. The control method currently used, which has the widest application is the multitube cyclone collector in series with a venturi or wet-impingement type scrubber. Source test data have shown that facilities which burn substantially more wood residue than fossil-fuel have no difficulty in complying with the 43 nanogram per joule standard for particulate matter. Also the investigated facilities have been in operation successfully for a number of years without adverse economical problems. Therefore EPA has concluded from evaluation of the available information that no revision is required of the particulate matter standard for wood residue-fired boilers.

Dated: January 3, 1979.

DOUGLAS M. COSTLE,
Administrator.

[FR Doc. 79-1421 Filed 1-16-79; 8:45 am]

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

DELEGATION OF AUTHORITY TO STATE OF TEXAS

AGENCY: Environmental Protection Agency.

ACTION: Final rule.

SUMMARY: This action amends Section 60.4, *Address*, to reflect the delegation of authority for the Standards of Performance for New Stationary Sources (NSPS) to the State of Texas.

EFFECTIVE DATE: February 7, 1979.

FOR FURTHER INFORMATION CONTACT:

James Veach, Enforcement Division, Region 6, Environmental Protection Agency, First International Building, 1201 Elm Street, Dallas, Texas 75270, telephone (214) 767-2760.

SUPPLEMENTARY INFORMATION: A notice announcing the delegation of authority is published elsewhere in the Notice Section in this issue of the *FEDERAL REGISTER*. These amendments provide that all reports and communications previously submitted to the Administrator, will now be sent to the Texas Air Control Board, 8520 Shoal Creek Boulevard, Austin, Texas 78758, instead of EPA's Region 6.

As this action is not one of substantive content, but is only an administrative change, public participation was judged unnecessary.

(Sections 111 and 301(a) of the Clean Air Act; Section 4(a) of Public Law 91-604, 84 Stat. 1683; Section 2 of Public Law 90-148, 81 Stat. 504 [42 U.S.C. 7411 and 7601(a)]).

Dated: November 15, 1978.

ADLENE HARRISON,
Regional Administrator,
Region 6.

Part 60 of Chapter 1, Title 40, Code of Federal Regulations, is amended as follows:

1. In § 60.4, paragraph (b) (SS) is amended as follows:

§ 60.4 *Address*.

(b) . . .

(SS) State of Texas, Texas Air Control Board, 8520 Shoal Creek Boulevard, Austin, Texas 78758.

FEDERAL REGISTER, VOL. 44, NO. 27—WEDNESDAY, FEBRUARY 7, 1979

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Petroleum Refineries—Clarifying Amendment

AGENCY: Environmental Protection Agency.

ACTION: Final Rule.

SUMMARY: These amendments clarify the definitions of "fuel gas" and "fuel gas combustion device" included in the existing standards of performance for petroleum refineries. These amendments will neither increase nor decrease the degree of emission control required by the existing standards. The objective of these amendments is to reduce confusion concerning the applicability of the sulfur dioxide standard to incinerator-waste heat boilers installed on fluid or Thermofor catalytic cracking unit catalyst regenerators and fluid coking unit coke burners.

EFFECTIVE DATE: March 12, 1979.

FOR FURTHER INFORMATION CONTACT:

Don R. Goodwin, Director, Emission Standards and Engineering Division (MD-13), U.S. Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone (919) 541-5271.

SUPPLEMENTARY INFORMATION: On March 8, 1974 (39 FR 9315), standards of performance were promulgated limiting sulfur dioxide emissions from fuel gas combustion devices in petroleum refineries under 40 CFR Part 60, Subpart J. Fuel gas combustion devices are defined as any equipment, such as process heaters, boilers, or flares, used to combust fuel gas. Fuel gas is defined as any gas generated by a petroleum refinery process unit which is combusted. Fluid catalytic cracking unit and fluid coking unit incinerator-waste heat boilers, and facilities in which gases are combusted to produce sulfur or sulfuric acid are

FEDERAL REGISTER, VOL. 44, NO. 49—MONDAY, MARCH 12, 1979

RULES AND REGULATIONS

exempted from consideration as fuel gas combustion devices.

Recently, the following two questions have been raised concerning the intent of exempting fluid catalytic cracking unit and fluid coking unit incinerator-waste heat boilers.

(1) Is it intended that Thermoform catalytic cracking unit incinerator waste-heat boilers be considered the same as fluid catalytic cracking unit incinerator-waste heat boilers?

(2) Is the exemption intended to apply to the incinerator-waste heat boiler as a whole including auxiliary fuel gas also combusted in this boiler?

The answer to the first question is yes. The answer to the second question is no.

The objective of the standards of performance is to reduce sulfur dioxide emissions from fuel gas combustion in petroleum refineries. The standards are based on amine treating of refinery fuel gas to remove hydrogen sulfide contained in these gases before they are combusted. The standards are not intended to apply to those gas streams generated by catalyst regeneration in fluid or Thermoform catalytic cracking units, or by coke burning in fluid coking units. These gas streams consist primarily of nitrogen, carbon monoxide, carbon dioxide, and water vapor, although small amounts of hydrogen sulfide may be present. Incinerator-waste heat boilers can be used to combust these gas streams as a means of reducing carbon monoxide emissions and/or generating steam. Any hydrogen sulfide present is converted to sulfur dioxide. It is not possible, however, to control sulfur dioxide emissions by removing whatever hydrogen sulfide may be present in these gas streams before they are combusted. The presence of carbon dioxide effectively precludes the use of amine treating, and since this technology is the basis for these standards, exemptions are included for fluid catalytic cracking units and fluid coking units.

Exemptions are not included for Thermoform catalytic cracking units because this technology is considered obsolete compared to fluid catalytic cracking. Thus, no new, modified, or reconstructed Thermoform catalytic cracking units are considered likely. The possibility that an incinerator-waste heat boiler might be added to an existing Thermoform catalytic cracking unit, however, was overlooked. To take this possibility into account, the definitions of "fuel gas" and "fuel gas combustion device" have been rewritten to exempt Thermoform catalytic cracking units from compliance in the same manner as fluid catalytic cracking units and fluid coking units.

As outlined above, the intent is to ensure that gas streams generated by catalyst regeneration or coke burning

in catalytic cracking or fluid coking units are exempt from compliance with the standard limiting sulfur dioxide emissions from fuel gas combustion. This is accomplished under the standard as promulgated March 8, 1974, by exempting incinerator-waste heat boilers installed on these units from consideration as fuel gas combustion devices.

Incinerator-waste heat boilers installed to combust these gas streams require the firing of auxiliary refinery fuel gas. This is necessary to insure complete combustion and prevent "flame-out" which could lead to an explosion. By exempting the incinerator-waste heat boiler, however, this auxiliary refinery fuel gas stream is also exempted, which is not the intent of these exemptions. This auxiliary refinery fuel gas stream is normally drawn from the same refinery fuel gas system that supplies refinery fuel gas to other process heaters or boilers within the refinery. Amine treating can be used, and in most major refineries normally is used, to remove hydrogen sulfide from this auxiliary fuel gas stream as well as from all other refinery fuel gas streams.

To ensure that this auxiliary fuel gas stream fired in waste-heat boilers is not exempt, the definition of fuel gas combustion device is revised to eliminate the exemption for incinerator-waste heat boilers. In addition, the definition of fuel gas is revised to exempt those gas streams generated by catalyst regeneration in catalytic cracking units, and by coke burning in fluid coking units from consideration as refinery fuel gas. This will accomplish the original intent of exempting only those gas streams generated by catalyst regeneration or coke burning from compliance with the standard limiting sulfur dioxide emissions from fuel gas combustion.

MISCELLANEOUS: The Administrator finds that good cause exists for omitting prior notice and public comment on these amendments and for making them immediately effective because they simply clarify the existing regulations and impose no additional substantive requirements.

Dated: February 28, 1979.

DOUGLAS M. COSTLE,
Administrator.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

1. Section 60.101 is amended by revising paragraphs (d) and (g) as follows:

§ 60.101 Definitions.

(d) "Fuel gas" means natural gas or any gas generated by a petroleum refinery process unit which is combusted separately or in any combination. Fuel gas does not include gases generated by catalytic cracking unit catalyst regenerators and fluid coking unit coke burners.

(g) "Fuel gas combustion device" means any equipment, such as process heaters, boilers, and flares used to combust fuel gas, except facilities in which gases are combusted to produce sulfur or sulfuric acid.

(Sec. 111, 301(a), Clean Air Act as amended (42 U.S.C. 7411, 7601(a)))

[FR Doc. 79-7428 Filed 3-9-79; 8:45 am]

97

40 CFR Part 60

Standards of Performance for New Stationary Sources; Delegation of Authority to Washington Local Agency**AGENCY:** Environmental Protection Agency (EPA).**ACTION:** Final Rulemaking.

SUMMARY: This rulemaking announces EPA's concurrence with the State of Washington Department of Ecology's (DOE) sub-delegation of the enforcement of the New Source Performance Standards (NSPS) program for asphalt batch plants to the Olympic Air Pollution Control Authority (OAPCA) and revises 40 CFR Part 60 accordingly. Concurrence was requested by the State on February 27, 1979.

EFFECTIVE DATE: April 19, 1979.**ADDRESS:**

Environmental Protection Agency,
Region X M/S 829, 1200 Sixth Avenue,
Seattle, WA 98101.

State of Washington, Department of
Ecology, Olympia, WA 98504.

Olympic Air Pollution Control Authority,
120 East State Avenue, Olympia, WA
98501.

Environmental Protection Agency,
Public Information Reference Unit,
Room 2922, 401 M Street SW.,
Washington, D.C. 20640.

FOR FURTHER INFORMATION CONTACT:
Clark L. Gaulding, Chief, Air Programs
Branch M/S 829, Environmental
Protection Agency, 1200 Sixth Avenue,
Seattle, WA 98101, Telephone No. (206)
442-1230 FTS 399-1230.

SUPPLEMENTARY INFORMATION: Pursuant to Section 111(c) of the Clean Air Act (42 USC 7411(c)), on February 27, 1979, the Washington State Department of Ecology requested that EPA concur with the State's sub-delegation of the NSPS program for asphalt batch plants to the Olympic Air Pollution Control Authority. After reviewing the State's request, the Regional Administrator has determined that the sub-delegation meets all requirements outlined in EPA's original February 28, 1975 delegation of authority, which was announced in the Federal Register on April 1, 1975 (40 FR 14632).

Therefore, on March 20, 1979, the Regional Administrator concurred in the sub-delegation of authority to the Olympic Air Pollution Control Authority with the understanding that all conditions placed on the original delegation to the State shall apply to the sub-delegation. By this rulemaking EPA is amending 40 CFR 60.4 (WW) to reflect the sub-delegation described above.

The amended § 60.4 provides that all reports, requests, applications and communications relating to asphalt batch plants within the jurisdiction of Olympic Air Pollution Control Authority (Clallam, Grays Harbor, Jefferson, Mason, Pacific and Thurston Counties) will now be sent to that Agency rather than the Department of Ecology. The amended section is set forth below.

The Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected.

This rulemaking is effective immediately, and is issued under the authority of Section 111(c) of the Clean Air Act, as amended. (42 U.S.C. 7411(c)).

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

1. In § 60.4, paragraph (b) is amended by revising subparagraph (WW) as follows:

§ 60.4 Address.

40 CFR Part 60

[FRL 1240-7]

New Stationary Sources Performance Standards; Electric Utility Steam Generating Units**AGENCY:** Environmental Protection Agency (EPA).**ACTION:** Final rule.

SUMMARY: These standards of performance limit emissions of sulfur dioxide (SO₂), particulate matter, and nitrogen oxides (NO_x) from new, modified, and reconstructed electric utility steam generating units capable of combusting more than 73 megawatts (MW) heat input (250 million Btu/hour) of fossil fuel. A new reference method for determining continuous compliance with SO₂ and NO_x standards is also established. The Clean Air Act Amendments of 1977 require EPA to revise the current standards of performance for fossil-fuel-fired stationary sources. The intended effect of this regulation is to require new, modified, and reconstructed electric utility steam generating units to use the best demonstrated technological system of continuous emission reduction and to satisfy the requirements of the Clean Air Act Amendments of 1977.

DATES: The effective date of this regulation is June 11, 1979.

ADDRESSES: A Background Information Document (BID; EPA 450/3-79-021) has been prepared for the final standard. Copies of the BID may be obtained from the U.S. EPA Library (MD-35), Research Triangle Park, N.C. 27711, telephone 919-541-2777. In addition, a copy is available for inspection in the Office of Public Affairs in each Regional Office, and in EPA's Central Docket Section in Washington, D.C. The BID contains (1) a summary of all the public comments made on the proposed regulation; (2) a summary of the data EPA has obtained since proposal on SO₂, particulate matter, and NO_x emissions; and (3) the final Environmental Impact Statement which summarizes the impacts of the regulation.

Docket No. OAQPS-78-1 containing all supporting information used by EPA in developing the standards is available for public inspection and copying between 8 a.m. and 4 p.m., ge a11jn0.005 Monday through Friday, at EPA's Central Docket Section, room

2903B, Waterside Mall, 401 M Street, SW., Washington, D.C. 20460.

The docket is an organized and complete file of all the information submitted to or otherwise considered by the Administrator in the development of this rulemaking. The docketing system is intended to allow members of the public and industries involved to readily identify and locate documents so that they can intelligently and effectively participate in the rulemaking process. Along with the statement of basis and purpose of the promulgated rule and EPA responses to significant comments, the contents of the docket will serve as the record in case of judicial review [section 107(d)(a)].

FOR FURTHER INFORMATION CONTACT: Don R. Goodwin, Director, Emission Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, N.C. 27711, telephone 919-541-5271.

SUPPLEMENTARY INFORMATION: This preamble contains a detailed discussion of this rulemaking under the following headings: SUMMARY OF STANDARDS, RATIONALE, BACKGROUND, APPLICABILITY, COMMENTS ON PROPOSAL, REGULATORY ANALYSIS, PERFORMANCE TESTING, MISCELLANEOUS.

Summary of Standards*Applicability*

The standards apply to electric utility steam generating units capable of firing more than 73 MW (250 million Btu/hour) heat input of fossil fuel, for which construction is commenced after September 18, 1978. Industrial cogeneration facilities that sell less than 25 MW of electricity, or less than one-third of their potential electrical output capacity, are not covered. For electric utility combined cycle gas turbines, applicability of the standards is determined on the basis of the fossil-fuel fired to the steam generator exclusive of the heat input and electrical power contribution of the gas turbine.

SO₂ Standards

The SO₂ standards are as follows:

(1) Solid and solid-derived fuels (except solid solvent refined coal): SO₂ emissions to the atmosphere are limited to 520 ng/J (1.20 lb/million Btu) heat input, and a 90 percent reduction in potential SO₂ emissions is required at all times except when emissions to the atmosphere are less than 260 ng/J (0.60 lb/million Btu) heat input. When SO₂ emissions are less than 260 ng/J (0.60 lb/million Btu) heat input, a 70 percent reduction in potential emissions is

required. Compliance with the emission limit and percent reduction requirements is determined on a continuous basis by using continuous monitors to obtain a 30-day rolling average. The percent reduction is computed on the basis of overall SO₂ removed by all types of SO₂ and sulfur removal technology, including flue gas desulfurization (FGD) systems and fuel pretreatment systems (such as coal cleaning, coal gasification, and coal liquefaction). Sulfur removed by a coal pulverizer or in bottom ash and fly ash may be included in the computation.

(2) Gaseous and liquid fuels not derived from solid fuels: SO₂ emissions into the atmosphere are limited to 340 ng/J (0.80 lb/million Btu) heat input, and a 90 percent reduction in potential SO₂ emissions is required. The percent reduction requirement does not apply if SO₂ emissions into the atmosphere are less than 86 ng/J (0.20 lb/million Btu) heat input. Compliance with the SO₂ emission limitation and percent reduction is determined on a continuous basis by using continuous monitors to obtain a 30-day rolling average.

(3) Anthracite coal: Electric utility steam generating units firing anthracite coal alone are exempt from the percentage reduction requirement of the SO₂ standard but are subject to the 520 ng/J (1.20 lb/million Btu) heat input emission limit on a 30-day rolling average, and all other provisions of the regulations including the particulate matter and NO_x standards.

(4) Noncontinental areas: Electric utility steam generating units located in noncontinental areas (State of Hawaii, the Virgin Islands, Guam, American Samoa, the Commonwealth of Puerto Rico, and the Northern Mariana Islands) are exempt from the percentage reduction requirement of the SO₂ standard but are subject to the applicable SO₂ emission limitation and all other provisions of the regulations including the particulate matter and NO_x standards.

(5) Resource recovery facilities: Resource recovery facilities that fire less than 25 percent fossil-fuel on a quarterly (90-day) heat input basis are not subject to the percentage reduction requirements but are subject to the 520 ng/J (1.20 lb/million Btu) heat input emission limit. Compliance with the emission limit is determined on a continuous basis using continuous monitoring to obtain a 30-day rolling average. In addition, such facilities must monitor and report their heat input by fuel type.

(6) Solid solvent refined coal: Electric utility steam generating units firing solid solvent refined coal (SRC I) are subject

to the 520 ng/J (1.20 lb/million Btu) heat input emission limit (30-day rolling average) and all requirements under the NO_x and particulate matter standards. Compliance with the emission limit is determined on a continuous basis using a continuous monitor to obtain a 30-day rolling average. The percentage reduction requirement for SRC I, which is to be obtained at the refining facility itself, is 85 percent reduction in potential SO₂ emissions on a 24-hour (daily) averaging basis. Compliance is to be determined by Method 19. Initial full scale demonstration facilities may be granted a commercial demonstration permit establishing a requirement of 80 percent reduction in potential emissions on a 24-hour (daily) basis.

Particulate Matter Standards

The particulate matter standard limits emissions to 13 ng/J (0.03 lb/million Btu) heat input. The opacity standard limits the opacity of emission to 20 percent (6-minute average). The standards are based on the performance of a well-designed and operated baghouse or electrostatic precipitator (ESP).

NO_x Standards

The NO_x standards are based on combustion modification and vary according to the fuel type. The standards are:

- (1) 86 ng/J (0.20 lb/million Btu) heat input from the combustion of any gaseous fuel, except gaseous fuel derived from coal;
- (2) 130 ng/J (0.30 lb/million Btu) heat input from the combustion of any liquid fuel, except shale oil and liquid fuel derived from coal;
- (3) 210 ng/J (0.50 lb/million Btu) heat input from the combustion of subbituminous coal, shale oil, or any solid, liquid, or gaseous fuel derived from coal;
- (4) 340 ng/J (0.80 lb/million Btu) heat input from the combustion in a slag tap furnace of any fuel containing more than 25 percent, by weight, lignite which has been mined in North Dakota, South Dakota, or Montana;

(5) Combustion of a fuel containing more than 25 percent, by weight, coal refuse is exempt from the NO_x standards and monitoring requirements; and

(6) 280 ng/J (0.60 lb/million Btu) heat input from the combustion of any solid fuel not specified under (3), (4), or (5).

Continuous compliance with the NO_x standards is required, based on a 30-day rolling average. Also, percent reductions in uncontrolled NO_x emission levels are required. The percent reductions are not controlling, however, and compliance with the NO_x emission limits will assure

compliance with the percent reduction requirements.

Emerging Technologies

The standards include provisions which allow the Administrator to grant commercial demonstration permits to allow less stringent requirements for the initial full-scale demonstration plants of certain technologies. The standards include the following provisions:

(1) Facilities using SRC I would be subject to an emission limitation of 520 ng/J (1.20 lb/million Btu) heat input, based on a 30-day rolling average, and an emission reduction requirement of 85 percent, based on a 24-hour average. However, the percentage reduction allowed under a commercial demonstration permit for the initial full-scale demonstration plants, using SRC I would be 80 percent (based on a 24-hour average). The plant producing the SRC I would monitor to insure that the required percentage reduction (24-hour average) is achieved and the power plant using the SRC I would monitor to insure that the 520 ng/J heat input limit (30-day rolling average) is achieved.

(2) Facilities using fluidized bed combustion (FBC) or coal liquefaction would be subject to the emission limitation and percentage reduction requirement of the SO₂ standard and to the particulate matter and NO_x standards. However, the reduction in potential SO₂ emissions allowed under a commercial demonstration permit for the initial full-scale demonstration plants using FBC would be 85 percent (based on a 30-day rolling average). The NO_x emission limitation allowed under a commercial demonstration permit for the initial full-scale demonstration plants using coal liquefaction would be 300 ng/J (0.70 lb/million Btu) heat input, based on a 30-day rolling average.

(3) No more than 15,000 MW equivalent electrical capacity would be allotted for the purpose of commercial demonstration permits. The capacity will be allocated as follows:

Technology	Pollutant	Equivalent electrical capacity MW
Solid solvent-refined coal	SO ₂	5,000-10,000
Fluidized bed combustion (atmospheric)	SO ₂	400-3,000
Fluidized bed combustion (pressurized)	SO ₂	200-1,200
Coal liquefaction	NO _x	750-10,000

Compliance Provisions

Continuous compliance with the SO₂ and NO_x standards is required and is to be determined with continuous emission monitors. Reference methods or other

approved procedures must be used to supplement the emission data when the continuous emission monitors malfunction, to provide emissions data for at least 18 hours of each day for at least 22 days out of any 30 successive days of boiler operation.

A malfunctioning FGD system may be bypassed under emergency conditions. Compliance with the particulate standard is determined through performance tests. Continuous monitors are required to measure and record the opacity of emissions. This data is to be used to identify excess emissions to insure that the particulate matter control system is being properly operated and maintained.

Rationale

SO₂ Standards

Under section 111(a) of the Act, a standard of performance for a fossil-fuel-fired stationary source must reflect the degree of emission limitation and percentage reduction achievable through the application of the best technological system of continuous emission reduction taking into consideration cost and any nonair quality health and environmental impacts and energy requirements. In addition, credit may be given for any cleaning of the fuel, or reduction in pollutant characteristics of the fuel, after mining and prior to combustion.

In the 1977 amendments to the Clean Air Act, Congress was severely critical of the current standard of performance for power plants, and especially of the fact that it could be met by the use of untreated low-sulfur coal. The House, in particular, felt that the current standard failed to meet six of the purposes of section 111. The six purposes are (H. Rept. at 184-186):

1. The standards must not give a competitive advantage to one State over another in attracting industry.
2. The standards must maximize the potential for long-term economic growth by reducing emissions as much as practicable. This would increase the amount of industrial growth possible within the limits set by the air quality standards.

3. The standards must to the extent practical force the installation of all the control technology that will ever be necessary on new plants at the time of construction when it is cheaper to install, thereby minimizing the need for retrofit in the future when air quality standards begin to set limits to growth.

4 and 5. The standards to the extent practical must force new sources to burn high-sulfur fuel thus freeing low-sulfur fuel for use in existing sources where it

is harder to control emissions and where low-sulfur fuel is needed for compliance. This will (1) allow old sources to operate longer and (2) expand environmentally acceptable energy supplies.

6. The standards should be stringent in order to force the development of improved technology.

To deal with these perceived deficiencies, the House initiated revisions to section 111 as follows:

1. New source performance standards must be based on the "best technological" control system that has been "adequately demonstrated," taking cost and other factors such as energy into account. The insertion of the word "technological" precludes a new source performance standard based solely on the use of low-sulfur fuels.

2. New source performance standards for fossil-fuel-fired sources (e.g., power plants) must require a "percentage reduction" in emissions, compared to the emissions that would result from burning untreated fuels.

The Conference Committee generally followed the House bill. As a result, the 1977 amendments substantially changed the criteria for regulating new power plants by requiring the application of technological methods of control to minimize SO₂ emissions and to maximize the use of locally available coals. Under the statute, these goals are to be achieved through revision of the standards of performance for new fossil-fuel-fired stationary sources to specify (1) an emission limitation and (2) a percentage reduction requirement. According to legislative history accompanying the amendments, the percentage reduction requirement should be applied uniformly on a nationwide basis, unless the Administrator finds that varying requirements applied to fuels of differing characteristics will not undermine the objectives of the house bill and other Act provisions.

The principal issue throughout this rulemaking has been whether a plant burning low-sulfur coal should be required to achieve the same percentage reduction in potential SO₂ emissions as those burning higher sulfur coal. The public comments on the proposed rules and subsequent analyses performed by the Office of Air, Noise and Radiation of EPA served to bring into focus several other issues as well.

These issues included performance capabilities of SO₂ control technology, the averaging period for determining compliance, and the potential adverse impact of the emission ceiling on high-sulfur coal reserves.

Prior to framing the final SO₂ standards, the EPA staff carried out extensive analyses of a range of alternative SO₂ standards using an econometric model of the utility sector. As part of this effort, a joint working group comprised of representatives from EPA, the Department of Energy, the Council of Economic Advisors, the Council on Wage and Price Stability, and others reviewed the underlying assumptions used in the model. The results of these analyses served to identify environmental, economic, and energy impacts associated with each of the alternatives considered at the national and regional levels. In addition, supplemental analyses were performed to assess impacts of alternative emission ceilings on specific coal reserves, to verify performance characteristics of alternative SO₂ scrubbing technologies, and to assess the sulfur reduction potential of coal preparation techniques.

Based on the public record and additional analyses performed, the Administrator concluded that a 90 percent reduction in potential SO₂ emissions (30-day rolling average) has been adequately demonstrated for high-sulfur coals. This level can be achieved at the individual plant level even under the most demanding conditions through the application of flue gas desulfurization (FGD) systems together with sulfur reductions achieved by currently practiced coal preparation techniques. Reductions achieved in the fly ash and bottom ash are also applicable. In reaching this finding, the Administrator considered the performance of currently operating FGD systems (scrubbers) and found that performance could be upgraded to achieve the recommended level with better design, maintenance, and operating practices. A more stringent requirement based on the levels of scrubber performance specified for lower sulfur coals in a number of prevention of significant deterioration permits was not adopted since experience with scrubbers operating with such performance levels on high-sulfur coals is limited. In selecting a 30-day rolling average as the basis for determining compliance, the Administrator took into consideration effects of coal sulfur variability on scrubber performance as well as potential adverse impacts that a shorter averaging period may have on the ability of small plants to comply.

With respect to lower sulfur coals, the EPA staff examined whether a uniform or variable application of the percent reduction requirement would best

satisfy the statutory requirements of section 111 of the Act and the supporting legislative history. The Conference Report for the Clean Air Act Amendments of 1977 says in the pertinent part:

In establishing a national percent reduction for new fossil fuel-fired sources, the conferees agreed that the Administrator may, in his discretion, set a range of pollutant reduction that reflects varying fuel characteristics. Any departure from the uniform national percentage reduction requirement, however, must be accompanied by a finding that such a departure does not undermine the basic purposes of the House provision and other provisions of the act, such as maximizing the use of locally available fuels.

In the face of such language, it is clear that Congress established a presumption in favor of a uniform application of the percentage reduction requirement and that any departure would require careful analysis of objectives set forth in the House bill and the Conference Report.

This question was made more complex by the emergence of dry SO₂ control systems. As a result of public comments on the discussion of dry SO₂ control technology in the proposal, the EPA staff examined the potential of this technology in greater detail. It was found that the development of dry SO₂ controls has progressed rapidly during the past 12 months. Three full scale systems are being installed on utility boilers with scheduled start up in the 1981-1982 period. These already contracted systems have design efficiencies ranging from 50 to 85 percent SO₂ removal, long term average. In addition, it was determined that bids are currently being sought for five more dry control systems (70 to 90 percent reduction range) for utility applications.

Activity in the dry SO₂ control field is being stimulated by several factors. First, dry control systems are less complex than wet technology. These simplified designs offer the prospect of greater reliability at substantially lower costs than their wet counterparts. Second, dry systems use less water than wet scrubbers, which is an important consideration in the Western part of the United States. Third, the amount of energy required to operate dry systems is less than that required for wet systems. Finally, the resulting waste product is more easily disposed of than wet sludge.

The applicability of dry control technology, however, appears limited to low-sulfur coals. At coal sulfur contents greater than about 1290 ng/J (3 pounds SO₂/million Btu), or about 1.5 percent sulfur coal, available data indicate that

it probably will be more economical to employ a wet scrubber than a dry control system.

Faced with these findings, the Administrator had to determine what effect the structure of the final regulation would have on the continuing development and application of this technology. A thorough engineering review of the available data indicated that a requirement of 90 percent reduction in potential SO_2 emissions would be likely to constrain the full development of this technology by limiting its potential applicability to high alkaline content, low-sulfur coals. For non-alkaline, low-sulfur coals, the certainty of economically achieving a 90 percent reduction level is markedly reduced. In the face of this finding, it would be unlikely that the technology would be vigorously pursued for these low alkaline fuels which comprise approximately one half of the Nation's low-sulfur coal reserves. In view of this, the Administrator sought a percentage reduction requirement that would provide an opportunity for dry SO_2 technology to be developed for all low-sulfur coal reserves and yet would be sufficiently stringent to assure that the technology was developed to its fullest potential. The Administrator concluded that a variable control approach with a minimum requirement of 70 percent reduction potential in SO_2 emissions (30-day rolling average) for low-sulfur coals would fulfill this objective. This will be discussed in more detail later in the preamble. Less stringent, sliding scale requirements such as those offered by the utility industry and the Department of Energy were rejected since they would have higher associated emissions, would not be significantly less costly, and would not serve to encourage development of this technology.

In addition to promoting the development of dry SO_2 systems, a variable approach offers several other advantages often cited by the utility industry. For example, if a source chose to employ wet technology, a 70 percent reduction requirement serves to substantially reduce the energy impact of operating wet scrubbers in low-sulfur coals. At this level of wet scrubber control, a portion of the untested flue gas could be used for plume reheat so as to increase plume buoyancy, thus reducing if not eliminating the need to expend energy for flue gas reheat. Further, by establishing a range of percent reductions, a variable approach would allow a source some flexibility particularly when selecting intermediate sulfur content coals. Finally, under a variable approach, a source could move

to a lower sulfur content coal to achieve compliance if its control equipment failed to meet design expectations. While these points alone would not be sufficient to warrant adoption of a variable standard, they do serve to supplement the benefits associated with permitting the use of dry technology.

Regarding the maximum emission limitation, the Administrator had to determine a level that was appropriate when a 90 percent reduction in potential emissions was applied to high-sulfur coals. Toward this end, detailed assessments of the potential impacts of a wide range of emission limitations on high-sulfur coal reserves were performed. The results revealed that a significant portion (up to 30 percent) of the high-sulfur coal reserves in the East, Midwest and portions of the Northern Appalachia coal regions would require more than a 90 percent reduction if the emission limitation were established below 520 ng/J (1.2 lb/million Btu) heat input on a 30-day rolling average basis. Although higher levels of control are technically feasible, conservatism in utility perceptions of scrubber performance could create a significant disincentive against the use of these coals and disrupt the coal markets in these regions. Accordingly, the Administrator concluded the emission limitation should be maintained at 520 ng/J (1.2 lb/million Btu) heat input on a 30-day rolling average basis. A more stringent emission limit would be counter to one of the purposes of the 1977 Amendments, that is, encouraging the use of higher sulfur coals.

Having determined an appropriate emission limitation and that a variable percent reduction requirement should be established, the Administrator directed his attention to specifying the final form of the standard. In doing so, he sought to achieve the best balance in control requirements. This was accomplished by specifying a 520 ng/J (1.2 lb/million Btu) heat input emission limitation with a 90 percent reduction in potential SO_2 emissions except when emissions to the atmosphere were reduced below 260 ng/J (0.6 lb/million Btu) heat input (30-day rolling average), when only a 70 percent reduction in potential SO_2 emissions would apply. Compliance with each of the requirements would be determined on the basis of a 30-day rolling average. Under this approach, plants firing high-sulfur coals would be required to achieve a 90 percent reduction in potential emissions in order to comply with the emission limitation. Those using intermediate- or low-sulfur content coals would be permitted to achieve between 70 and 90 percent reduction,

provided their emissions were less than 260 ng/J (0.6 lb/million Btu). The 260 ng/J (0.6 lb/million Btu) level was selected to provide for a smooth transition of the percentage reduction requirement from high- to low-sulfur coals. Other transition points were examined but not adopted since they tended to place certain types of coal at a disadvantage.

By fashioning the SO_2 standard in this manner, the Administrator believes he has satisfied both the statutory language of section 111 and the pertinent part of the Conference Report. The standard reflects a balance in environmental, economic, and energy considerations by being sufficiently stringent to bring about substantial reductions in SO_2 emissions (3 million tons in 1995) yet does so at reasonable costs without significant energy penalties. When compared to a uniform 90 percent reduction, the standard achieves the same emission reductions at the national level. More importantly, by providing an opportunity for full development of dry SO_2 technology the standard offers potential for further emission reductions (100 to 200 thousand tons per year), cost savings (over \$1 billion per year), and a reduction in oil consumption (200 thousand barrels per day) when compared to a uniform standard. The standard through its balance and recognition of varying coal characteristics, serves to expand environmentally acceptable energy supplies without conveying a competitive advantage to any one coal producing region. The maintenance of the emission limitation at 520 ng/J (1.2 lb SO_2 /million Btu) will serve to encourage the use of locally available high-sulfur coals. By providing for a range of percent reductions, the standard offers flexibility in regard to burning of intermediate sulfur content coals. By placing a minimum requirement of 70 percent on low-sulfur coals, the final rule encourages the full development and application of dry SO_2 control systems on a range of coals. At the same time, the minimum requirement is sufficiently stringent to reduce the amount of low-sulfur coal that moves eastward when compared to the current standard. Admittedly, a uniform 90 percent requirement would reduce such movements further, but in the Administrator's opinion, such gains would be of marginal value when compared to expected increases in high-sulfur coal production. By achieving a balanced coal demand within the utility sector and by promoting the development of less expensive SO_2 control technology, the final standard

will expand environmentally acceptable energy supplies to existing power plants and industrial sources.

By substantially reducing SO_2 emissions, the standard will enhance the potential for long term economic growth at both the national and regional levels. While more restrictive requirements may have resulted in marginal air quality improvements locally, their higher costs may well have served to retard rather than promote air quality improvement nationally by delaying the retirement of older, poorly controlled plants.

The standard must also be viewed within the broad context of the Clean Air Act Amendments of 1977. It serves as a minimum requirement for both prevention of significant deterioration and non-attainment considerations. When warranted by local conditions, ample authority exists to impose more restrictive requirements through the case-by-case new source review process. When exercised in conjunction with the standard, these authorities will assure that our pristine areas and national parks are adequately protected. Similarly, in those areas where the attainment and maintenance of the ambient air quality standard is threatened, more restrictive requirements will be imposed.

The standard limits SO_2 emissions from facilities firing gaseous or liquid fuels to 340 ng/J (0.80 lb/million Btu) heat input and requires 90 percent reduction in potential emissions on a 30-day rolling average basis. The percent reduction does not apply when emissions are less than 86 ng/J (0.20 lb/million Btu) heat input on a 30-day rolling average basis. This reflects a change to the proposed standards in that the time for compliance is changed from the proposed 24-hour basis to a 30-day rolling average. This change is necessary to make the compliance times consistent for all fuels. Enforcement of the standards would be complicated by different averaging times, particularly when more than one fuel is used.

Particulate Matter Standard

The standard for particulate matter limits the emissions to 13 ng/J (0.03 lb/million Btu) heat input and requires a 99 percent reduction in uncontrolled emissions for solid fuels and a 70 percent reduction for liquid fuels. No particulate matter control is necessary for units firing gaseous fuels alone, and a percent reduction is not required. The percent reduction requirements for solid and liquid fuels are not controlling, and compliance with the particulate matter

emission limit will assure compliance with the percent reduction requirements.

A 20 percent (8-minute average) opacity limit is included in this standard. The opacity limit is included to insure proper operation and maintenance of the emission control system. If an affected facility were to comply with all applicable standards except opacity, the owner or operator may request that the Administrator, under 40 CFR 60.11(e), establish a source-specific opacity limit for that affected facility.

The standard is based on the performance of a well-designed, operated and maintained electrostatic precipitator (ESP) or baghouse control system. The Administrator has determined that these control systems are the best adequately demonstrated technological systems of continuous emission reduction (taking into consideration the cost of achieving such emission reduction, and nonair quality health and environmental impacts and energy requirements).

Electrostatic Precipitators

EPA collected emission data from 21 ESP-equipped steam generating units which were firing low-sulfur coals (0.4–1.9 percent). EPA evaluated emission levels from units burning relatively low-sulfur coal because it is more difficult for an ESP to collect particulate matter emissions generated by the combustion of low-sulfur coal than high-sulfur coal. None of the ESP control systems at the 21 coal-fired steam generators tested were designed to achieve a 13 ng/J (0.03 lb/million Btu) heat input emission level, however, emission levels at 9 of the 21 units were below the standard. All of the units that were firing coal with a sulfur content between 1.0 and 1.9 percent and which had emission levels below the standard had either a hot-side ESP (an ESP located before the combustion air preheater) with a specific collection area greater than 89 square meters per actual cubic meter per second (452 ft²/1,000 ACFM), or a cold-side ESP (an ESP located after the combustion air preheater) with a specific collection area greater than 85 square meters per actual cubic meter per second (435 ft²/1,000 ACFM).

ESPs require a larger specific collection area when applied to units burning low-sulfur coal than to units burning high-sulfur coal because the electrical resistivity of the fly ash is higher with low-sulfur coal. Based on an examination of the emission data in the record, it is the Administrator's judgment that when low-sulfur coal is being fired an ESP must have a specific

collection area from about 130 (hot side) to 200 (cold side) square meters per actual cubic meter per second (650 to 1,000 ft² per 1,000 ACFM) to comply with the standard. When high-sulfur coal (greater than 3.5 percent sulfur) is being fired an ESP must have a specific collection area of about 72 (cold side) square meters per actual cubic meter per second (380 ft² per 1,000 ACFM) to comply with the standard.

Cold-side ESPs have traditionally been used to control particulate matter emissions from power plants. The problem of ESP collection of high-electrical-resistivity fly ash from low-sulfur coal can be reduced by using a hot-side ESP. Higher fly ash collection temperatures result in better ESP performance by reducing fly ash resistivity for most types of low-sulfur coal. Reducing fly ash resistivity in itself would decrease the ESP collection plate area needed to meet the standard; however, for a hot-side ESP this benefit is reduced by the increased flue gas volume resulting from the higher flue gas temperature. Although a smaller collection area is required for a hot-side ESP than for a cold side ESP, this benefit is offset by greater construction costs due to the higher quality of materials, thicker insulation, and special design provisions to accommodate the expansion and warping potential of the collection plates.

Baghouses

The Administrator has evaluated data from more than 50 emission test runs conducted at 8 baghouse-equipped coal-fired steam generating units. Although none of these baghouse-controlled units were designed to achieve a 13 ng/J (0.03 lb/million Btu) heat input emission level, 48 of the test results achieved this level and only 1 test at each of 2 units exceeded 13 ng/J (0.03 lb/million Btu) heat input. The emission levels at the two units with emission levels above 13 ng/J (0.03 lb/million Btu) heat input could conceivably be reduced below that level through an improved maintenance program. It is the Administrator's judgment that baghouses with an air-to-cloth ratio of 0.6 actual cubic meter per minute per square meter (2 ACFM/ft²) will achieve the standard at a pressure drop of less than 1.25 kilopascals (5 in. H₂O). The Administrator has concluded that this air/cloth ratio and pressure drop are reasonable when considering cost, energy, and nonair quality impacts.

When an owner or operator must choose between an ESP and a baghouse to meet the standard, it is the Administrator's judgment that

baghouses have an advantage for low-sulfur coal applications and ESP's have an advantage for high-sulfur coal applications. Available data indicate that for low-sulfur coals, ESP's (hot-side or cold-side) require a large collection area and thus ESP control system costs will be higher than baghouse control system costs. For high-sulfur coals, large collection areas are not required for ESP's, and ESP control systems offer cost savings over baghouse control systems.

Baghouses have not traditionally been used at utility power plants. At the time these regulations were proposed, the largest baghouse-controlled coal-fired steam generator for which EPA had particulate matter emission test data had an electrical output of 44 MW. Several larger baghouse installations were under construction and two larger units were initiating operation. Since the date of proposal of these standards, EPA has tested one of the new units. It has an electrical output capacity of 350 MW and is fired with pulverized, subbituminous coal containing 0.3 percent sulfur. The baghouse control system for this facility is designed to achieve a 43 Ng/j (0.01 lb/million Btu) heat input emission limit. This unit has achieved emission levels below 13 Ng/j (0.03 lb/million Btu) heat input. The baghouse control system was designed with an air-to-cloth ratio of 1.0 actual cubic meter per minute per square meter (3.32 ACFM/ft²) and a pressure drop of 1.25 kilopascals (5 in. H₂O). Although some operating problems have been encountered, the unit is being operated within its design emission limit and the level of the standard. During the testing the power plant operated in excess of 300 MW electrical output. Work is continuing on the control system to improve its performance. Regardless of type, large emission control systems generally require a period of time for the establishment of cleaning, maintenance, and operational procedures that are best suited for the particular application.

Baghouses are designed and constructed in modules rather than as one large unit. The baghouse control system for the new 350 MW power plant has 28 baghouse modules, each of which services 12.5 MW of generating capacity. As of May 1979, at least 26 baghouse-equipped coal-fired utility steam generators were operating, and an additional 28 utility units are planned to start operation by the end of 1982. About two-thirds of the 30 planned baghouse-controlled power generation systems will have an electrical output capacity greater than 150 MW, and more than one-third of these power plants will be

fired with coal containing more than 3 percent sulfur. The Administrator has concluded that baghouse control systems have been adequately demonstrated for full-sized utility application.

Scrubbers

EPA collected emission test data from seven coal-fired steam generators controlled by wet particulate matter scrubbers. Emissions from five of the seven scrubber-equipped power plants were less than 21 Ng/j (0.05 lb/million Btu) heat input. Only one of the seven units had emission test results less than 13 Ng/j (0.03 lb/million Btu) heat input. Scrubber pressure drop can be increased to improve scrubber particulate matter removal efficiencies; however, because of cost and energy considerations, the Administrator believes that wet particulate matter scrubbers will only be used in special situations and generally will not be selected to comply with the standards.

Performance Testing

When the standards were proposed, the Administrator recognized that there is a potential for both FGD sulfate carryover and sulfuric acid mist to affect particulate matter performance testing downstream of an FGD system. Data available at the time of proposal indicated that overall particulate matter emissions, including sulfate carryover, are not increased by a properly designed, constructed, maintained, and operated FGD system. No additional information has been received to alter this finding.

The data available at proposal indicated that sulfuric acid mist (H₂SO₄) interaction with Methods 5 or 17 would not be a problem when firing low-sulfur coal, but may be a problem when firing high-sulfur coals. Limited data obtained since proposal indicate that when high-sulfur coal is being fired, there is a potential for sulfuric acid mist to form after an FGD system and to introduce errors in the performance testing results when Methods 5 or 17 are used. EPA has obtained particulate matter emission test data from two power plants that were fired with coals having more than 3 percent sulfur and that were equipped with both an ESP and FGD system. The particulate matter test data collected after the FGD system were not conclusive in assessing the acid mist problem. The first facility tested appeared to experience a problem with acid mist interaction. The second facility did not appear to experience a problem with acid mist, and emissions after the ESP/FGD system were less than 13 ng/j

(0.03 lb/million Btu) heat input. The tests at both facilities were conducted using Method 5, but different methods were used for measuring the filter temperature. EPA has initiated a review of Methods 5 and 17 to determine what modifications may be necessary to avoid acid mist interaction problems. Until these studies are completed the Administrator is approving as an optional test procedure the use of Method 5 (or 17) for performance testing before FGD systems. Performance testing is discussed in more detail in the PERFORMANCE TESTING section of this preamble.

The particulate matter emission limit and opacity limit apply at all times, except during periods of startup, shutdown, or malfunction. Compliance with the particulate matter emission limit is determined through performance tests using Methods 5 or 17. Compliance with the opacity limit is determined by the use of Method 9. A continuous monitoring system to measure opacity is required to assure proper operation and maintenance of the emission control system but is not used for continuous compliance determinations. Data from the continuous monitoring system indicating opacity levels higher than the standard are reported to EPA quarterly as excess emissions and not as violations of the opacity standard.

The environmental impacts of the revised particulate matter standards were estimated by using an economic model of the coal and electric utility industries (see discussion under REGULATORY ANALYSIS). This projection took into consideration the combined effect of complying with the revised SO₂, particulate matter, and NO_x standards on the construction and operation of both new and existing capacity. Particulate matter emissions from power plants were 3.0 million tons in 1975. Under continuation of the current standards, these emissions are predicted to decrease to 1.4 million tons by 1995. The primary reason for this decrease in emissions is the assumption that existing power plants will come into compliance with current state emission regulations. Under these standards, 1995 emissions are predicted to decrease another 400 thousand tons (30 percent).

NO_x Standards

The NO_x emission standards are based on emission levels achievable with a properly designed and operated boiler that incorporates combustion modification techniques to reduce NO_x formation. The levels to which NO_x emissions can be reduced with

combustion modification depend not only upon boiler operating practice, but also upon the type of fuel burned. Consequently, the Administrator has developed fuel-specific NO_x standards. The standards are presented in this preamble under Summary of Standards.

Continuous compliance with the NO_x standards is required, based on a 30-day rolling average. Also, percent reductions in uncontrolled NO_x emission levels are required. The percent reductions are not controlling, however, and compliance with the NO_x emission limits will assure compliance with the percent reduction requirements.

One change has been made to the proposed NO_x standards. The proposed standards would have required compliance to be based on a 24-hour averaging period, whereas the final standards require compliance to be based on a 30-day rolling average. This change was made because several of the comments received, one of which included emission data, indicated that more flexibility in boiler operation on a day-to-day basis is needed to accommodate slagging and other boiler problems that may influence NO_x emissions when coal is burned. The averaging period for determining compliance with the NO_x limitations for gaseous and liquid fuels has been changed from the proposed 24-hour to a 30-day rolling average. This change is necessary to make the compliance times consistent for all fuels. Enforcement of the standards would be complicated by different averaging times, particularly where more than one fuel is used. More details on the selection of the averaging period for coal appear in this preamble under Comments on Proposal.

The proposed standards for coal combustion were based principally on the results of EPA testing performed at six electric utility boilers, all of which are considered to represent modern boiler designs. One of the boilers was manufactured by the Babcock and Wilcox Company (B&W) and was retrofitted with low-emission burners. Four of the boilers were Combustion Engineering, Inc. (CE) designs originally equipped with overfire air, and one boiler was a CE design retrofitted with overfire air. The six boilers burned a variety of bituminous and subbituminous coals. Conclusions drawn from the EPA studies of the boilers were that the most effective combustion modification techniques for reducing NO_x emitted from utility boilers are staged combustion, low excess air, and reduced heat release rate. Low-emission burners were also

effective in reducing NO_x levels during the EPA studies.

In developing the proposed standards for coal, the Administrator also considered the following: (1) data obtained from the boiler manufacturers on 11 CE, three B&W, and three Foster Wheeler Energy Corporation (FW) utility boilers; (2) the results of tests performed twice daily over 30-day periods at three well-controlled utility boilers manufactured by CE; (3) a total of six months of continuously monitored NO_x emission data from two CE boilers located at the Colstrip plant of the Montana Power Company; (4) plans underway at B&W, FW, and the Riley Stoker Corporation (RS) to develop low-emission burners and furnace designs; (5) correspondence from CE indicating that it would guarantee its new boilers to achieve, without adverse side-effects, emission limits essentially the same as those proposed; and (6) guarantees made by B&W and FW that their new boilers would achieve the State of New Mexico's NO_x emission limit of 190 ng/J (0.45 lb/million Btu) heat input.

Since proposal of the standards, the following new information has become available and has been considered by the Administrator: (1) additional data from the boiler manufacturers on four B&W and four RS utility boilers; (2) a total of 18 months of continuously monitored NO_x data from the two CE utility boilers at the Colstrip plant; (3) approximately 10 months of continuously monitored NO_x data from five other CE boilers; (4) recent performance test results for a CE and a RS utility boiler; and (5) recent guarantees offered by CE and FW to achieve an NO_x emission limit of 190 ng/J (0.45 lb/million Btu) heat input in the State of California. This and other new information is discussed in "Electric Utility Steam Generating Units, Background Information for Promulgated Emission Standards" (EPA 450/3-79-021).

The data available before and after proposal indicate that NO_x emission levels below 210 ng/J (0.50 lb/million Btu) heat input are achievable with a variety of coals burned in boilers made by all four of the major boiler manufacturers. Lower emission levels are theoretically achievable with catalytic ammonia injection, as noted by several commenters. However, these systems have not been adequately demonstrated at this time on full-size electric utility boilers that burn coal.

Continuously monitored NO_x emission data from coal-fired CE boilers indicate that emission variability during day-to-day operation is such that low NO_x

levels can be maintained if emissions are averaged over 30-day periods. Although the Administrator has not been able to obtain continuously monitored data from boilers made by the other boiler manufacturers, the Administrator believes that the emission variability exhibited by CE boilers over long periods of time is also characteristic of B&W, FW, and RS boilers. This is because the Administrator expects B&W, FW, and RS boilers to experience operational conditions which are similar to CE boilers (e.g., slagging, variations in fuel quality, and load reductions) when burning similar fuel. Thus, the Administrator believes the 30-day averaging time is appropriate for coal-fired boilers made by all four manufacturers.

Prior to proposal of the standards several electric utilities and boiler manufacturers expressed concern over the potential for accelerated boiler tube wastage (i.e., corrosion) during low- NO_x operation of a coal-fired boiler. The severity of tube wastage is believed to vary with several factors, but especially with the sulfur content of the coal burned. For example, the combustion of high-sulfur bituminous coal appears to aggravate tube wastage, particularly if it is burned in a reducing atmosphere. A reducing atmosphere is sometimes associated with low- NO_x operation.

The EPA studies of one B&W and five CE utility boilers concluded that tube wastage rates did not significantly increase during low- NO_x operation. The significance of these results is limited, however, in that the tube wastage tests were conducted over relatively short periods of time (30 days or 300 hours). Also, only CE and B&W boilers were studied, and the B&W boiler was not a recent design, but was an old-style unit retrofitted with experimental low-emission burners. Thus, some concern still exists over potentially greater tube wastage during low- NO_x operation when high-sulfur coals are burned. Since bituminous coals often have high sulfur contents, the Administrator has established a special emission limit for bituminous coals to reduce the potential for increased tube wastage during low- NO_x operation.

Based on discussions with the boiler manufacturers and on an evaluation of all available tube wastage information, the Administrator has established an NO_x emission limit of 260 ng/J (0.60 lb/million Btu) heat input for the combustion of bituminous coal. The Administrator believes this is a safe level at which tube wastage will not be accelerated by low- NO_x operation. In

support of this belief, CE has stated that it would guarantee its new boilers, when equipped with overfire air, to achieve the 260 ng/J (0.60 lb/million Btu) heat input limit without increased tube wastage rates when Eastern bituminous coals are burned. In addition, B&W has noted in several recent technical papers that its low-emission burners allow the furnace to be maintained in an oxidizing atmosphere, thereby reducing the potential for tube wastage when high-sulfur bituminous coals are burned. The other boiler manufacturers have also developed techniques that reduce the potential for tube wastage during low-NO_x operation. Although the amount of tube wastage data available to the Administrator on B&W, FW, and RS boilers is very limited, it is the Administrator's judgement that all three of these manufacturers are capable of designing boilers which would not experience increased tube wastage rates as a result of compliance with the NO_x standards.

Since the potential for increased tube wastage during low-NO_x operation appears to be small when low-sulfur subbituminous coals are burned, the Administrator has established a lower NO_x emission limit of 210 ng/J (0.50 lb/million Btu) heat input for boilers burning subbituminous coal. This limit is consistent with emission data from boilers representing all four manufacturers. Furthermore, CE has stated that it would guarantee its modern boilers to achieve an NO_x limit of 210 ng/J (0.50 lb/million Btu) heat input, without increased tube wastage rates, when subbituminous coals are burned.

The emission limits for electric utility power plants that burn liquid and gaseous fuels are at the same levels as the emission limits originally promulgated in 1971 under 40 CFR Part 60, Subpart D for large steam generators. It was decided that a new study of combustion modification or NO_x flue-gas treatment for oil- or gas-fired electric utility steam generators would not be appropriate because few, if any, of these kinds of power plants are expected to be built in the future.

Several studies indicate that NO_x emissions from the combustion of fuels derived from coal, such as liquid solvent-refined coal (SRC II) and low-Btu synthetic gas, may be higher than those from petroleum oil or natural gas. This is because coal-derived fuels have fuel-bound nitrogen contents that approach the levels found in coal rather than those found in petroleum oil and natural gas. Based on limited emission data from pilot-scale facilities and on

the known emission characteristics of coal, the Administrator believes that an achievable emission limit for solid, liquid, and gaseous fuels derived from coal is 210 ng/J (0.50 lb/million Btu) heat input. Tube wastage and other boiler problems are not expected to occur from boiler operation at levels as low as 210 ng/J when firing these fuels because of their low sulfur and ash contents.

NO_x emission limits for lignite combustion were promulgated in 1978 (48 FR 9276) as amendments to the original standards under 40 CFR Part 60, Subpart D. Since no new information on NO_x emission rates from lignite combustion has become available, the emission limits have not been changed for these standards. Also, these emission limits are the same as the proposed.

Little is known about the emission characteristics of shale oil. However, since shale oil typically has a higher fuel-bound nitrogen content than petroleum oil, it may be impossible for a well-controlled unit burning shale oil to achieve the NO_x emission limit for liquid fuels. Shale oil does have a similar nitrogen content to coal, and it is reasonable to expect that the emission control techniques used for coal could also be used to limit NO_x emissions from shale oil combustion. Consequently, the Administrator has limited NO_x emissions from units burning shale oil to 210 ng/J (0.50 lb/million Btu) heat input, the same limit applicable to subbituminous coal, which is the same as proposed. There is no evidence that tube wastage or other boiler problems would result from operation of a boiler at 210 ng/J when shale oil is burned.

The combustion of coal refuse was exempted from the original steam generator standards under 40 CFR Part 60, Subpart D because the only furnace design believed capable of burning certain kinds of coal refuse, the slag tap furnace, inherently produces NO_x emissions in excess of the NO_x standard. Unlike lignite, virtually no NO_x emission data are available for the combustion of coal refuse in slag tap furnaces. The Administrator has decided to continue the coal refuse exemption under the standards promulgated here because no new information on coal refuse combustion has become available since the exemption under Subpart D was established.

The environmental impacts of the revised NO_x standards were estimated by using an economic model of the coal and electric utility industries (see discussion under REGULATORY ANALYSIS). This projection took into

consideration the combined effect of complying with the revised SO₂, particulate matter, and NO_x standards on the construction and operation of both new and existing capacity. National NO_x emissions from power plants were 6.8 million tons in 1975 and are predicted to increase to 9.3 million tons by 1995 under the current standards. These standards are projected to reduce 1995 emissions by 600 thousand tons (6 percent).

Background

In December 1971, under section 111 of the Clean Air Act, the Administrator issued standards of performance to limit emissions of SO₂, particulate matter, and NO_x from new, modified, and reconstructed fossil-fuel-fired steam generators (40 CFR 60.40 et seq.). Since that time, the technology for controlling emissions from this source category has improved, but emissions of SO₂, particulate matter, and NO_x continue to be a national problem. In 1976, steam electric generating units contributed 24 percent of the particulate matter, 65 percent of the SO₂, and 29 percent of the NO_x emissions on a national basis.

The utility industry is expected to have continued and significant growth. The capacity is expected to increase by about 50 percent with approximate 300 new fossil-fuel-fired power plant boilers to begin operation within the next 10 years. Associated with utility growth is the continued long-term increase in utility coal consumption from some 400 million tons/year in 1975 to about 1250 million tons/year in 1995. Under the current performance standards for power plants, national SO₂ emissions are projected to increase approximately 17 percent between 1975 and 1995.

Impacts will be more dramatic on a regional basis. For example, in the absence of more stringent controls, utility SO₂ emissions are expected to increase 1300 percent by 1995 in the West South Central region of the country (Texas, Oklahoma, Arkansas, and Louisiana).

EPA was petitioned on August 6, 1976, by the Sierra Club and the Oljato and Red Mesa Chapters of the Navaho Tribe to revise the SO₂ standard so as to require a 90 percent reduction in SO₂ emissions from all new coal-fired power plants. The petition claimed that advances in technology since 1971 justified a revision of the standard. As a result of the petition, EPA agreed to investigate the matter thoroughly. On January 27, 1977 (42 FR 5121), EPA announced that it had initiated a study to review the technological, economic, and other factors needed to determine to

what extent the SO₂ standard for fossil-fuel-fired steam generators should be revised.

On August 7, 1977, President Carter signed into law the Clean Air Act Amendments of 1977. The provisions under section 111(b)(6) of the Act, as amended, required EPA to revise the standards of performance for fossil-fuel-fired electric utility steam generators within 1 year after enactment.

After the Sierra Club petition of August 1976, EPA initiated studies to review the advancement made on pollution control systems at power plants. These studies were continued following the amendment of the Clean Air Act. In order to meet the schedule established by the Act, a preliminary assessment of the ongoing studies was made in late 1977. A National Air Pollution Control Techniques Advisory Committee meeting was held on December 13 and 14, 1977, to present EPA preliminary data. The meeting was open to the public and comments were solicited.

The Clean Air Act Amendments of 1977 required the standards to be revised by August 7, 1978. When it appeared that the Administrator would not meet this schedule, the Sierra Club filed a complaint on July 14, 1978, with the U.S. District Court for the District of Columbia requesting injunctive relief to require, among other things, that the Administrator propose the revised standards by August 7, 1978 (*Sierra Club v. Costle*, No. 78-1297). The Court, approved a stipulation requiring the Administrator to (1) deliver proposed regulations to the Office of the Federal Register by September 12, 1978, and (2) promulgate the final regulations within 6 months after proposal (i.e., by March 19, 1979).

The Administrator delivered the proposal package to the Office of the Federal Register by September 12, 1978, and the proposed regulations were published September 19, 1978 (43 FR 42154). Public comments on the proposal were requested by December 15, and a public hearing was held December 12 and 13, the record of which was held open until January 15, 1979. More than 625 comment letters were received on the proposal. The comments were carefully considered, however, the issues could not be sufficiently evaluated in time to promulgate the standards by March 19, 1979. On that date the Administrator and the other parties in *Sierra Club v. Costle* filed with the Court a stipulation whereby the Administrator would sign and deliver the final standards to the Federal Register on or before June 1, 1979.

The Administrator's conclusions and responses to the major issues are presented in this preamble. These regulations represent the Administrator's response to the petition of the Navaho Tribe and Sierra Club and fulfill the rulemaking requirements under section 111(b)(6) of the Act.

Applicability

General

These standards apply to electric utility steam generating units capable of firing more than 73 MW (250 million Btu/hour) heat input of fossil fuel, for which construction is commenced after September 18, 1978. This is principally the same as the proposal. Some minor changes and clarification in the applicability requirements for cogeneration facilities and resource recovery facilities have been made.

On December 23, 1971, the Administrator promulgated, under Subpart D of 40 CFR Part 60, standards of performance for fossil-fuel-fired steam generators used in electric utility and large industrial applications. The standards adopted herein do not apply to electric utility steam generating units originally subject to those standards (Subpart D) unless the affected facilities are modified or reconstructed as defined under 40 CFR 60 Subpart A and this subpart. Similarly, units constructed prior to December 23, 1971, are not subject to either performance standard (Subpart D or Da) unless they are modified or reconstructed.

Electric Utility Steam Generating Units

An electric utility steam generating unit is defined as any steam electric generating unit that is physically connected to a utility power distribution system and is constructed for the purpose of selling more than 25 MW electrical output and more than one third of its potential electrical output capacity. Any steam that is sold and ultimately used to produce electrical power for sale through the utility power distribution system is also included under the standard. The term "potential electrical generating capacity" has been added since proposal and is defined as 33 percent of the heat input rate at the facility. The applicability requirement of selling more than 25 MW electrical output capacity has also been added since proposal.

These standards cover industrial steam electric generating units or cogeneration units (producing steam for both electrical generation and process heat) that are capable of firing more than 73 MW (250 million Btu/hr) heat

input of fossil fuel and are constructed for the purpose of selling through a utility power distribution system more than 25 MW electrical output and more than one-third of their potential electrical output capacity (or steam generating capacity ultimately used to produce electricity for sale). Facilities with a heat input rate in excess of 73 MW (250 million Btu/hour) that produce only industrial steam or that generate electricity but sell less than 25 MW electrical output through the utility power distribution system or sell less than one-third of their potential electric output capacity through the utility power distribution system are not covered by these standards, but will continue to be covered under Subpart D, if applicable.

Resource recovery units incorporating steam electric generating units that would meet the applicability requirements but that combust less than 25 percent fossil fuel on a quarterly (90-day) heat-input basis are not covered by the SO₂ percent reduction requirements under this standard. These facilities are subject to the SO₂ emission limitation and all other provisions of the regulation. They are also required to monitor their heat input by fuel type and to monitor SO₂ emissions. If more than 25 percent fossil fuel is fired on a quarterly heat input basis, the facility will be subject to the SO₂ percent reduction requirements. This represents a change from the proposal which did not include such provisions.

These standards cover steam generator emissions from electric utility combined-cycle gas turbines that are capable of being fired with more than 73 MW (250 million Btu/hr) heat input of fossil fuel and meet the other applicability requirements. Electric utility combined-cycle gas turbines that use only turbine exhaust gas to provide heat to a steam generator (waste heat boiler) or that incorporate steam generators that are not capable of being fired with more than 73 MW (250 million Btu/hr) of fossil fuel are not covered by the standards.

Modification/Reconstruction

Existing facilities are only covered by these standards if they are modified or reconstructed as defined under Subpart A of 40 CFR Part 60 and this standard (Subpart Da).

Few, if any, existing facilities that change fuels, replace burners, etc. will be covered by these standards as a result of the modification/reconstruction provisions. In particular, the standards do not apply to existing facilities that are modified to fire nonfossil fuels or to

existing facilities that were designed to fire gas or oil fuels and that are modified to fire shale oil, coal/oil mixtures, coal/oil/water mixtures, solvent refined coal, liquified coal, gasified coal, or any other coal-derived fuel. These provisions were included in the proposal but have been clarified in the final standard.

Comments on Proposal

Electric Utility Steam Generating Units

The applicability requirements are basically the same as those in the proposal; electric utility steam generating units capable of firing greater than 73 MW (250 million Btu/hour) heat input of fossil fuel for which construction is commenced after September 18, 1978, are covered. Since proposal, changes have been made to specific applicability requirements for industrial cogeneration facilities, resource recovery facilities, and anthracite coal-fired facilities. These revisions are discussed later in this preamble.

Only a limited number of comments were received on the general applicability provisions. Some commenters expressed the opinion that the standards should apply to both industrial boilers and electric utility steam generating units. Industrial boilers are not covered by these standards because there are significant differences between the economic structure of utilities and the industrial sector. EPA is currently developing standards for industrial boilers and plans to propose them in 1980.

Cogeneration Facilities

Cogeneration facilities are covered under these standards if they have the capability of firing more than 73 MW (250 million Btu/hour) heat input of fossil fuel and are constructed for the purpose of selling more than 25 MW of electricity and more than one-third of their potential electrical output capacity. This reflects a change from the proposed standards under which facilities selling less than 25 MW of electricity through the utility power-distribution system may have been covered.

A number of commenters suggested that industrial cogeneration facilities are expected to be highly efficient and that their construction could be discouraged if the proposed standards were adopted. The commenters pointed out that industrial cogeneration facilities are unusual in that a small capacity (10 MW electric output capacity, for example) steam-electric generating set may be matched with a much larger industrial

steam generator (larger than 250 million Btu/hr for example). The Administrator intended that the proposed standards cover only electric generation sets that would sell more than 25 MW electrical output on the utility power distribution system. The final standards allow the sale of up to 25 MW electrical output capacity before a facility is covered. Since most industrial cogeneration units are expected to be less than 25 MW electrical output capacity, few, if any, new industrial cogeneration units will be covered by these standards. The standards do cover large electric utility cogeneration facilities because such units are fundamentally electric utility steam generating units.

Comments suggested clarifying what was meant in the proposal by the sale of more than one-third of its "maximum electrical generating capacity". Under the final standard the term "potential electric output capacity" is used in place of "maximum electrical generating capacity" and is defined as 33 percent of the steam generator heat input capacity. Thus, a steam generator with a 500 MW (1,700 million Btu/hr) heat input capacity would have a 165 MW potential electrical output capacity and could sell up to one-third of this potential output capacity on the grid (55 MW electrical output) before being covered under the standard. Under the proposal, it was unclear if the standard allowed the sale of up to one-third of the actual electric generating capacity of a facility or one-third of the potential generating capacity before being covered under the standards. The Administrator has clarified his intentions in these standards. Without this clarification the standards may have discouraged some industrial cogeneration facilities that have low in-house electrical demand.

A number of commenters suggested that emission credits should be allowed for improvements in cycle efficiency at new electric utility power plants. The commenters suggested that the use of electrical cogeneration technology and other technologies with high cycle efficiencies could result in less overall fuel consumption, which in turn could reduce overall environmental impacts through lower air emissions and less solid waste generation. The final standards do not give credit for increases in cycle efficiency because the different technologies covered by the standards and available for commercial application at this time are based on the use of conventional steam generating units which have very similar cycle efficiencies, and credits for improved cycle efficiency would not provide

measurable benefits. Although the final standards do not address cycle efficiency, this approach will not discourage the application of more efficient technologies.

If a facility that is planned for construction will incorporate an innovative control technology (including electrical generation technologies with inherently low emissions or high electrical generation efficiencies) the owner or operator may apply to the Administrator under section 111(j) of the Act for an innovative technology waiver which will allow for (1) up to four years of operation or (2) up to seven years after issuance of a waiver prior to performance testing. The technology would have to have a substantial likelihood of achieving greater continuous emission reduction or achieve equivalent reductions at low cost in terms of energy, economics, or nonair quality impacts before a waiver would be issued.

Resource Recovery Facilities

Electric utility steam generating units incorporated into resource recovery facilities are exempt from the SO₂ percent reduction requirements when less than 25 percent of the heat input is from fossil fuel on a quarterly heat input basis. Such facilities are subject to all other requirements of this standard. This represents a change from the proposed regulation, under which any steam electric generating unit that combusts non-fossil fuels such as wood residue, sewage sludge, waste material, or municipal refuse would have been covered if the facility were capable of firing more than 75 MW (250 million Btu/hr) of fossil fuel.

A number of comments indicated that the proposed standard could discourage the construction of resource recovery facilities that generate electricity because of the SO₂ percentage reduction requirement. One commenter suggested that most new resource recovery facilities will process municipal refuse and other wastes into a dry fuel with a low-sulfur content that can be stored and subsequently fired. The commenter suggested that when firing processed refuse fuel, little if any fossil fuel will be necessary for combustion stabilization over the long term; however, fossil fuel will be necessary for startup. When a cold unit is started, 100 percent fossil fuel (oil or gas) may be fired for a few hours prior to firing 100 percent processed refuse.

Other commenters suggested that resource recovery facilities would in many cases be owned and operated by a municipality and the electricity and

steam generated would be sold by contract to offset operating costs. Under such an arrangement, commenters suggested that there may be a need to fire fossil fuel on a short-term basis when refuse is not readily available in order to generate a reliable supply of steam for the contract customer.

The Administrator accepts these suggestions and does not wish to discourage the construction of resource recovery facilities that generate electricity and/or industrial steam. For resource recovery facilities, the Administrator believes that less than 25 percent heat input from fossil fuels will be required on a long-term basis; even though 100 percent fossil fuel firing [greater than 73 MW (250 million Btu/hour)] may be necessary for startup or intermittent periods when refuse is not available. During startup such units are allowed to fire 100 percent fossil fuel because periods of startup are exempt from the standards under 40 CFR 60.8(c). If a reliable source of refuse is not available and 100 percent fossil fuel is to be fired more than 25 percent of the time, the Administrator believes it is reasonable to require such units to meet the SO₂ percent reduction requirements. This will allow resource recovery facilities to operate with fossil fuel up to 25 percent of the time without having to install and operate an FGD system.

Anthracite

These standards exempt facilities that burn anthracite alone from the percentage reduction requirements of the SO₂ standard but cover them under the 520 ng/j (1.2 lb/million Btu) heat input emission limitation and all requirements of the particulate matter and NO_x standards. The proposed regulations would have covered anthracite in the same manner as all other coals. Since the Administrator recognized that there were arguments in favor of less stringent requirements for anthracite, this issue was discussed in the preamble to the proposed regulations.

Over 30 individuals or organizations commented on the anthracite issue. Almost all of the commenters favored exempting anthracite from the SO₂ percentage reduction requirement. Some of the reasons cited to justify exemption were: (1) the sulfur content of anthracite is low; (2) anthracite is more expensive to mine and burn than bituminous and will not be used unless it is cost competitive; and (3) reopening the anthracite mines will result in improvement of acid-mine-water conditions, elimination of old mining scars on the topography, eradication of

dangerous fires in deep mines and culm banks, and creation of new jobs. One commenter pointed out that the average sulfur content of anthracite is 1.09 percent. Other commenters indicated that anthracite will be cleaned, which will reduce the sulfur content. One commenter opposed exempting anthracite, because it would result in more SO₂ emissions. Another commenter said all coal-fired power plants including anthracite-fired units should have scrubbers.

After evaluating all of the comments, the Administrator has decided to exempt facilities that burn anthracite alone from the percentage reduction requirements of the SO₂ standard. These facilities will be subject to all other requirements of this regulation, including the particulate matter and NO_x standards, and the 520 ng/j (1.2 lb/million Btu) heat input emission limitation under the SO₂ standard.

In 10 Northeastern Pennsylvania counties, where about 95 percent of the nation's anthracite coal reserves are located, approximately 40,000 acres of land have been despoiled from previous anthracite mining. The recently enacted Federal Surface Mining Control and Reclamation Act was passed to provide for the reclamation of areas like this. Under this Act, each ton of coal mined is taxed at 35 cents for strip mining and 15 cents for deep mining operations. One-half of the amount taxed is automatically returned to the State where the coal mined and one-half is to be distributed by the Department of Interior. This tax is expected to lead eventually to the reclamation of the anthracite region, but restoration will require many years. The reclamation will occur sooner if culm piles are used for fuel, the abandoned mines are reopened, and the expense of reclamation is born directly by the mine operator.

The Federal Surface Mining Control and Reclamation Act and a similar Pennsylvania law also provide for the establishment of programs to regulate anthracite mining. The State of Pennsylvania has assured EPA that total reclamation will occur if anthracite mining activity increases. They are actively pursuing with private industry the development of one area involving 12,000 to 19,000 acres of despoiled land.

In Summary, the Administrator concludes that the higher SO₂ emissions resulting from the use of anthracite without a flue gas desulfurization system is acceptable because of the other environmental improvements that will result. The impact of facilities using anthracite on ambient air quality will be

minimized, because they will have to be reviewed to assure compliance with the prevention of significant deterioration provisions under the Act.

Alaskan Coal

The final standards are the same as the proposed; facilities fired with Alaskan coal are covered in the same manner as facilities fired with other coals.

Commenters suggested that problems unique to Alaska justify special provisions for facilities located in Alaska and firing Alaskan coal. Reasons cited as justification for less stringent standards by commenters on the proposal were freezing conditions, problems with sludge disposal, adverse impact of FGD on the reliability of plant operation, low-sulfur content of the coal, and cost impact on the consumer. The Administrator has examined these factors and has concluded that technically and economically feasible means are available to overcome these problems; therefore special regulatory provisions are not justified.

In reaching this conclusion the Administrator considered whether these factors demonstrated that the standards posed a substantially greater burden unique to Alaska. In other northern States where severe freezing conditions are common, plants are enclosed in buildings and insulated vessels and piping provide protection from freezing, both for scrubber operation and for liquid sludge dewatering. For an equivalent electrical generating capacity, the disposal sites for Alaskan plants could be smaller than those for most plants in the contiguous 48 States because of the lower sulfur content of Alaskan coal. Burying pipes carrying sludge to waste ponds below the frost line is feasible, except possibly in permafrost areas. The Administrator expects that future steam generators cannot be sited in permafrost areas because fly ash as well as scrubber sludge could not be properly disposed of in accordance with requirements of the Resource Recovery and Reclamation Act. In permafrost areas, turbines or other non-waste-producing processes are used or electricity is transmitted from other locations.

One commenter pointed out that failures of the FGD system would have an adverse impact on the ability to supply customers with reliable electric service, since there are no extensive interconnections with other utility companies. The Administrator has provided relief from the standards under emergency conditions that would require a choice between meeting a

power demand or complying with the standards. These emergency provisions are discussed in a subsequent section of this preamble.

Concern was expressed by the commenters that the cost impact of the standard would be excessive and that the benefits do not justify the cost, especially since Alaskan coal is among the lowest sulfur-content coal in the country. The Administrator agrees that for comparable sulfur-content coals, scrubber operating costs are slightly higher in Alaska because of the transportation costs of required materials such as lime. However, the operating costs are lower than the typical costs of FGD units controlling emissions from higher sulfur coals in the contiguous 48 States.

The Administrator considered applying a less stringent SO₂ standard to Alaskan coal-fired units, but concluded that there is insufficient distinction between conditions in Alaska and conditions in the northern part of the contiguous 48 States to justify such action. The Administrator has concluded that Alaskan coal-fired units should be controlled in the same manner as other facilities firing low-sulfur coal.

Noncontinental Areas

Facilities in noncontinental areas (State of Hawaii, the Virgin Islands, Guam, American Samoa, the Commonwealth of Puerto Rico, and the Northern Mariana Islands) are exempt from the SO₂ percentage reduction requirements. Such facilities are required, however, to meet the SO₂ emission limitations of 520 ng/J (1.2 lb/million Btu) heat input (30-day rolling average) for coal and 340 ng/J (0.8 lb/million Btu) heat input (30-day rolling average) for oil, in addition to all requirements under the NO_x and particulate matter standards. This is the same as the proposed standards.

Although this provision was identified as an issue in the preamble to the proposed standards, very few comments were received on it. In general, the comments supported the proposal. The main question raised is whether Puerto Rico has adequate land available for sludge disposal.

After evaluating the comments and available information, the Administrator has concluded that noncontinental areas, including Puerto Rico, are unique and should be exempt from the SO₂ percentage reduction requirements.

The impact of new power plants in noncontinental areas on ambient air quality will be minimized because each will have to undergo a review to assure compliance with the prevention of

significant deterioration provisions under the Clean Air Act. The Administrator does not intend to rule out the possibility that an individual BACT or LAER determination for a power plant in a noncontinental area may require scrubbing.

Emerging Technology

The final regulations for emerging technologies are summarized earlier in this preamble under SUMMARY OF STANDARDS and are very similar to the proposed regulations.

In general, the comments received on the proposed regulations were supportive, although a few commenters suggested some changes. A few commenters indicated that section 111(j) of the Act provides EPA with authority to handle innovative technologies. Some commenters pointed out that the proposed standards did not address certain technologies such as dry scrubbers for SO₂ control. One commenter suggested that SRC I should be included under the solvent refined coal rather than coal liquefaction category for purposes of allocating the 15,000 MW equivalent electrical capacity.

On the basis of the comments and public record, the Administrator believes the need still exists to provide a regulatory mechanism to allow a less stringent standard to the initial full-scale demonstration facilities of certain emerging technologies. At the time the standards were proposed, the Administrator recognized that the innovative technology waiver provisions under section 111(j) of the Act are not adequate to encourage certain capital-intensive, front-end control technologies. Under the innovative technology provisions, the Administrator may grant waivers for a period of up to 7 years from the date of issuance of a waiver or up to 4 years from the start of operation of a facility, whichever is less. Although this amount of time may be sufficient to amortize the cost of tail-gas control devices that do not achieve their design control level, it does not appear to be sufficient for amortization of high-capital-cost, front-end control technologies. The proposed provisions were designed to mitigate the potential impact on emerging front-end technologies and insure that the standards do not preclude the development of such technologies.

Changes have been made to the proposed regulations for emerging technologies relative to averaging time in order to make them consistent with the final NO_x and SO₂ standards; however, a 24-hour averaging period has

been retained for SRC-I because it has relatively uniform emission rates, which makes a 24-hour averaging period more appropriate than a 30-day rolling average.

Commercial demonstration permits establish less stringent requirements for the SO₂ or NO_x standards, but do not exempt facilities with these permits from any other requirements of these standards.

Under the final regulations, the Administrator (in consultation with the Department of Energy) will issue commercial demonstration permits for the initial full-scale demonstration facilities of each specified technology. These technologies have been shown to have the potential to achieve the standards established for commercial facilities. If, in implementing these provisions, the Administrator finds that a given emerging technology cannot achieve the standards for commercial facilities, but it offers superior overall environmental performance (taking into consideration all areas of environmental impact, including air, water, solid waste, toxics, and land use) alternative standards can be established.

It should be noted that these permits will only apply to the application of this standard and will not supersede the new source review procedures and prevention of significant deterioration requirements under other provisions of the Act.

Modification/Reconstruction

The impact of the modification/reconstruction provisions is the same for the final standard as it was for the proposed standard; existing facilities are only covered by the final standards if the facilities are modified or reconstructed as defined under 40 CFR 60.14, 60.15, or 60.40a. Many types of fuel switches are expressly exempt from modification/reconstruction provisions under section 111 of the Act.

Few, if any, existing steam generators that change fuels, replace burners, etc., are expected to qualify under the modification/reconstruction provisions; thus, few, if any, existing electric utility steam generating units will become subject to these standards.

The preamble to the proposed regulations did not provide a detailed discussion of the modification/reconstruction provisions, and the comments received indicated that these provisions were not well understood by the commenters. The general modification/reconstruction provisions under 40 CFR 60.14 and 60.15 apply to all source categories covered under Part 60. Any source-specific modification/

reconstruction provisions are defined in more detail under the applicable subpart (60.40a for this standard).

A number of commenters expressly requested that fuel switching provisions be more clearly addressed by the standard. In response, the Administrator has clarified the fuel switching provisions by including them in the final standards. Under these provisions existing facilities that are converted to nonfossil fuels are not considered to have undergone modification. Similarly, existing facilities designed to fire gas or oil and that are converted to shale oil, coal/oil mixtures, coal/oil/water mixtures, solvent refined coal, liquified coal, gasified coal, or any other coal-derived fuel are not considered to have undergone modification. This was the Administrator's intention under the proposal and was mentioned in the Federal Register preamble for the proposal.

SO₂ Standards

SO₂ Control Technology—The final SO₂ standards are based on the performance of a properly designed, installed, operated and maintained FGD system. Although the standards are based on lime and limestone FGD systems, other commercially available FGD systems (e.g., Wellman-Lord, double alkali and magnesium oxide) are also capable of achieving the final standard. In addition, when specifying the form of the final standards, the Administrator considered the potential of dry SO₂ control systems as discussed later in this section.

Since the standards were proposed, EPA has continued to collect SO₂ data with continuous monitors at two sites and initiated data gathering at two additional sites. At the Conesville No. 5 plant of Columbus and Southern Ohio Electric company, EPA gathered continuous SO₂ data from July to December 1978. The Conesville No. 5 FGD unit is a turbulent contact absorber (TCA) scrubber using thiosorbic lime as the scrubbing medium. Two parallel modules handle the gas flow from a 411-MW boiler firing run-of-mine 4.5 percent sulfur Ohio coal. During the test period, data for only thirty-four 24-hour averaging periods were gathered because of frequent boiler and scrubber outages. The Conesville system averaged 88.8 percent SO₂ removal, and outlet SO₂ emissions averaged 0.80 lb/million Btu. Monitoring of the Wellman-Lord FGD unit at Northern Indiana Public Service Company's Mitchell station during 1978 included one 41-day continuous period of operation. Data from this period were combined with

previous data and analyzed. Results indicated 0.61 lb SO₂/million Btu and 89.2 percent SO₂ removal for fifty-six 24-hour periods.

From December 1978 to February 1979, EPA gathered SO₂ data with continuous monitors at the 10-MW prototype unit (using a TCA absorber with lime) at Tennessee Valley Authority's (TVA) Shawnee station and the Lawrence No. 4 FGD unit (using limestone) of Kansas Power and Light Company. During the Shawnee test, data were obtained for forty-two 24-hour periods in which 3.0

percent sulfur coal was fired. Sulfur dioxide removal averaged 88.6 percent. Lawrence No. 4 consists of a 125-MW boiler controlled by a spray tower limestone FGD unit. In January and February 1979, during twenty-two 24-hour periods of operation with 0.5 percent sulfur coal, the average SO₂ removal was 96.6 percent. The Shawnee and Lawrence tests also demonstrated that SO₂ monitors can function with reliabilities above 80 percent. A summary of the recent EPA-acquired SO₂ monitored data follows:

Site	Scrubber	Coal sulfur, pct	No. of 24-hour periods	Average SO ₂ removal, pct
Conesville No. 5	Thiosorbic lime/TCA	4.5	34	89.2
NIPSCO	Wellman-Lord	3.5	56	89.2
Shawnee	Lime/TCA	3.0	42	88.6
Lawrence No. 4	Limestone/spray tower	0.5	22	96.6

Since proposing the standards, EPA has prepared a report that updates information in the earlier PEDCO report on FGD systems. The report includes listings of several new closed-loop systems.

A variety of comments were received concerning SO₂ control technology. Several comments were concerned with the use of data from FGD systems operating in Japan. These comments suggested that the Japanese experience shows that technology exists to obtain greater than 90 percent SO₂ removal. The commenters pointed out that attitudes of the plant operators, the skill of the FGD system operators, the close surveillance of power plant emissions by the Japanese Government, and technical differences in the mode of scrubber operation were primary factors in the higher FGD reliabilities and efficiencies for Japanese systems. These commenters stated that the Japanese experience is directly applicable to U.S. facilities. Other comments stated that the Japanese systems cannot be used to support standards for power plants in the U.S. because of the possible differences in factors such as the degree of closed-loop versus open-loop operation, the impact of trace constituents such as chlorides, the differences in inlet SO₂ concentrations, SO₂ uptake per volume of slurry, Japanese production of gypsum instead of sludge, coal blending and the amount of maintenance.

The comments on closed-loop operation of Japanese systems inferred that larger quantities of water are purged from these systems than from their U.S. counterparts. A closed-loop

system is one where the only water leaving the system is by: (1) evaporative water losses in the scrubber, and (2) the water associated with the sludge. The administrator found by investigating the systems referred to in the comments that six of ten Japanese systems listed by one commenter and two of four coal-fired Japanese systems are operated within the above definition of closed-loop. The closed-loop operation of Japanese scrubbers was also attested to in an Interagency Task Force Report, "Sulfur Oxides Control Technology in Japan" (June 30, 1978) prepared for Honorable Henry M. Jackson, Chairman, Senate Committee on Energy and Natural Resources. It is also important to note that several of these successful Japanese systems were designed by U.S. vendors.

After evaluating all the comments, the Administrator has concluded that the experience with systems in Japan is applicable to U.S. power plants and can be used as support to show that the final standards are achievable.

A few commenters stated that closed-loop operation of an FGD system could not be accomplished, especially at utilities burning high-sulfur coal and located in areas where rainfall into the sludge disposal pond exceeds evaporation from the pond. It is important to note that neither the proposed nor final standards require

closed-loop operation of the FGD. The commenters are primarily concerned that future water pollution regulations will require closed-loop operation. Several of these commenters ignored the large amount of water that is evaporated by the hot exhaust gases in the scrubber and the water that is combined with and goes to disposal with the sludge in a typical ponding system. If necessary, the sludge can be dewatered by use of a mechanical clarifier, filter, or centrifuge and then sludge disposed of in a landfill designed to minimize rainwater collection. The sludge could also be physically or chemically stabilized.

Most U.S. systems operate open-loop (i.e., have some water discharge from their sludge pond) because they are not required to do otherwise. In a recent report "Electric Utility Steam Generating Units—Flue Gas Desulfurization Capabilities as of October 1978" (EPA-450/3-79-001), PEDCo reported that several utilities burning both low- and high-sulfur coal have reported that they are operating closed-loop FGD systems. As discussed earlier, systems in Japan are operating closed-loop if pond disposal is included in the system. Also, experiments at the Shawnee test facility have shown that highly reliable operation can be achieved with high sulfur coal (containing moderate to high levels of chloride) during closed-loop operation. The Administrator continues to believe that although not required, closed-loop operation is technically and economically feasible if the FGD and disposal system are properly designed. If a water purge is necessary to control chloride buildup, this stream can be treated prior to disposal using commercially available water treatment methods, as discussed in the report "Controlling SO₂ Emissions from Coal-Fired Steam-Electric Generators: Water Pollution Impact" (EPA-600/7-78-045b).

Two comments endorsed coal cleaning as an SO₂ emission control technique. One commenter encouraged EPA to study the potential of coal cleaning, and another endorsed coal cleaning in preference to FGD. The Administrator investigated coal cleaning and the relative economics of FGD and coal cleaning and the results are presented in the report "Physical Coal Cleaning for Utility Boiler SO₂ Emission Control" (EPA-600/7-78-034). The Administrator does not consider coal cleaning alone as representing the best demonstrated system for SO₂ emission reduction. Coal cleaning does offer the following benefits when used in conjunction with an FGD system: (1) the SO₂ concentrations entering the FGD system are lower and less variable than

would occur without coal cleaning, (2) percent removal credit is allowed toward complying with the SO₂ standard percent removal requirement, and (3) the SO₂ emission limit can be achieved when using a coal having a sulfur content above that which would be needed when coal cleaning is not practiced. The amount of sulfur that can be removed from coal by physical coal cleaning was investigated by the U.S. Department of the Interior ("Sulfur Reduction Potential of the Coals of the United States," Bureau of Mines Report of Investigations/1976, RI-8118). Coal cleaning principally removes pyritic sulfur from coal by crushing it to a maximum top size and then separating the pyrites and other rock impurities from the coal. In order to prevent coal cleaning processes from developing into undesirable sources of energy waste, the amount of crushing and the separation bath's specific gravity must be limited to reasonable levels. The Administrator has concluded that crushing to 1.5 inches topsize and separation at 1.6 specific gravity represents common practice. At this level, the sulfur reduction potential of coal cleaning for the Eastern Midwest (Illinois, Indiana, and Western Kentucky) and the Northern Appalachian Coal (Pennsylvania, Ohio, and West Virginia) regions averages approximately 30 percent. The washability of specific coal seams will be less than or more than the average.

Some comments state that FGD systems do not work on specific coals, such as high-sulfur Illinois-Indiana coal, high-chloride Illinois coal, and Southern Appalachian coals. After review of the comments and data, the Administrator concluded that FGD application is not limited by coal properties. Two reports, "Controlling SO₂ Emissions from Coal-Fired Steam-Electric Generators: Water Pollution Impact" (EPA-600/7-78-045b) and "Flue Gas Desulfurization Systems: Design and Operating Considerations" (EPA-600/7-78-030b) acknowledge that coals with high sulfur or -chloride content may present problems. Chlorides in flue gas replace active calcium, magnesium, or sodium alkalis in the FGD system solution and cause stress corrosion in susceptible materials. Prescrubbing of flue gas to absorb chlorides upstream of the FGD or the use of alloy materials and protective coatings are solutions to high-chloride coal applications. Two reports, "Flue Gas Desulfurization System Capabilities for Coal-Fired Steam Generators" (EPA-600/7-78-032b) and "Flue Gas Desulfurization Systems: Design and Operating Considerations" (EPA-600/

7-78-030b) also acknowledge that 90 percent SO₂ removal (or any given level) is more difficult when burning high-sulfur coal than when burning low-sulfur coal because the mass of SO₂ that must be removed is greater when high-sulfur coal is burned. The increased load results in larger and more complex FGD systems (requiring higher liquid-to-gas ratios, larger pumps, etc). Operation of current FGD installations such as LaCygne with over 5 percent sulfur coal, Cane Run No. 4 on high-sulfur midwestern coal, and Kentucky Utilities Green River on 4 percent sulfur coal provides evidence that complex systems can be operated successfully on high-sulfur coal. Recent experience at TVA, Widows Creek No. 8 shows that FGD systems can operate successfully at high SO₂ removal efficiencies when Southern Appalachian coals are burned.

Coal blending was the subject of two comments: (1) that blending could reduce, but not eliminate, sulfur variability; and (2) that coal blending was a relatively inexpensive way to meet more relaxed standards. The Administrator believes that coal blending, by itself, does not reduce the average sulfur content of coal but reduces the variability of the sulfur content. Coal blending is not considered representative of the best demonstrated system for SO₂ emission reduction. Coal blending, like coal cleaning, can be beneficial to the operation of an FGD system by reducing the variability of sulfur loading in the inlet flue gas. Coal blending may also be useful in reducing short-term peak SO₂ concentrations where ambient SO₂ levels are a problem.

Several comments were concerned with the dependability of FGD systems and problems encountered in operating them. The commenters suggested that FGD equipment is a high-risk investment, and there has been limited "successful" operating experience. They expressed the belief that utilities will experience increased maintenance requirements and that the possibility of forced outages due to scaling and corrosion would be greater as a result of the standards.

One commenter took issue with a statement that exhaust stack liner problems can be solved by using more expensive materials. The commenter also argued that EPA has no data supporting the assumption that scrubbers have been demonstrated at or near 90 percent reliability with one spare module. The Administrator has considered these comments and has concluded that properly designed and operated FGD systems can perform

reliably. An FGD system is a chemical process which must be designed (1) to include materials that will withstand corrosive/erosive conditions, (2) with instruments to monitor process chemistry and (3) with spare capacity to allow for planned downtime for routine maintenance. As with any chemical process, a startup or shakedown period is required before steady, reliable operation can be achieved.

The Administrator has continued to follow the progress of the FGD systems cited in the supporting documents published in conjunction with the proposed regulations in September 1978. Availability of the FGD system at Kansas City Power and Light Company's LaCygne Unit No. 1 has steadily improved. No FGD-related forced outages were reported from September 1977 to September 1978. Availability from January to September 1978 averaged 93 percent. Outages reported were a result of boiler and turbine problems but not FGD system problems. LaCygne Unit No. 1 burns high-sulfur (5 percent) coal, uses one of the earlier FGD's installed in the U.S., and reduces SO₂ emissions by 80 percent with a limestone system at greater than 90 percent availability. Northern States Power Company's Sherburne Units Numbers 1 and 2 on the other hand operate on low-sulfur coal (0.8 percent). Sherburne No. 1, which began operating early in 1976, had 93 percent availability in both 1977 and 1978. Sherburne No. 2, which began operation in late 1976 had availabilities of 93 percent in 1977 and 94 percent in 1978. Both of these systems include spare modules to maintain these high availabilities.

Several comments were received expressing concern over the increased water use necessary to operate FGD systems at utilities located in arid regions. The Administrator believes that water availability is a factor that limits power plant siting but since an FGD system uses less than 10 percent of the water consumed at a power plant, FGD will not be the controlling factor in the siting of new utility plants.

A few commenters criticized EPA for not considering amendments to the Federal Water Pollution Control Act (now the Clean Water Act), the Resource Conservation and Recovery Act, or the Toxic Substances Control Act when analyzing the water pollution and solid waste impacts of FGD systems. To the extent possible, the Administrator believes that the impacts of these Acts have been taken into consideration in this rule-making. The economic impacts were estimated on the

basis of requirements anticipated for power plants under these Acts.

Various comments were received regarding the SO₂ removal efficiency achievable with FGD technology. One comment from a major utility system stated that they agreed with the standards, as proposed. Many comments stated that technology for better than 90 percent SO₂ removal exists. One comment was received stating that 95 percent SO₂ removal should be required. The Administrator concludes that higher SO₂ removals are achievable for low-sulfur coal which was the basis of this comment. While 95 percent SO₂ removal may be obtainable on high-sulfur coals with dual alkali or regenerable FGD systems, long-term data to support this level are not available and the Administrator has concluded that the demand for dual alkali/regenerable systems would far exceed vendor capabilities. When the uncertainties of extrapolating performance from 90 to 95 percent for high-sulfur coal, or from 95 percent on low-sulfur coal to high-sulfur coal, were considered, the Administrator concluded that 95 percent SO₂ removal for lime/limestone based systems on high-sulfur coal could not be reasonably expected at this time.

Another comment stated that all FGD systems except lime and limestone were not demonstrated or not universally applicable. The proposed SO₂ standards were based upon the conclusion that they were achievable with a well designed, operated, and maintained FGD system. At the time of proposal, the Administrator believed that lime and limestone FGD systems would be the choice of most utilities in the near future but, in some instances, utilities would choose the more reactive dual alkali or regenerable systems. The use of additives such as magnesium oxides was not considered to be necessary for attainment of the standard, but could be used at the option of the utility. Available data show that greater than 90 percent SO₂ removal has been achieved at full scale U.S. facilities for short-term periods when high-sulfur coal is being combusted, and for long-term periods at facilities when low-sulfur coal is burned. In addition, greater than 90 percent SO₂ removal has been demonstrated over long-term operating periods at FGD facilities when operating on low- and medium-sulfur coals in Japan.

Other commenters questioned the exclusion of dry scrubbing techniques from consideration. Dry scrubbing was considered in EPA's background documents and was not excluded from

consideration. Five commercial dry SO₂ control systems are currently on order; three for utility boilers (400-MW, 455-MW, and 550-MW) and two for industrial applications. The utility units are designed to achieve 50 to 85 percent reduction on a long-term average basis and are scheduled to commence operation in 1981-1982. The design basis for these units is to comply with applicable State emission limitations. In addition, dry SO₂ control systems for six other utility boilers are out for bid. However, no full scale dry scrubbers are presently in operation at utility plants so information available to EPA and presented in the background document dealt with prototype units. Pilot scale data and estimated costs of full-scale dry scrubbing systems offer promise of moderately high (70-85 percent) SO₂ removal at costs of three-fourths or less of a comparable lime or limestone FGD system. Dry control system and wet control system costs are approximately equal for a 2-percent-sulfur coal. With lower-sulfur coals, dry controls are particularly attractive, not only because they would be less costly than wet systems, but also because they are expected to require less maintenance and operating staff, have greater turnaround capabilities, require less energy consumption for operation, and produce a dry solid waste material that can be more easily disposed of than wet scrubber sludge.

Tests done at the Hoot Lake Station (a 53-MW boiler) in Minnesota demonstrated the performance capability of a spray dryer-baghouse dry control system. The exhaust gas concentrations before the control systems were 800 ppm SO₂ and an average of 2 gr/acf particulate matter. With lime as the sorbent, the control system removed over 86 percent SO₂ and 99.96 percent particulate matter at a stoichiometric ratio of 2.1 moles of lime absorbent per inlet mole of SO₂. When the spent lime dust was recirculated from the bag filter to the lime slurry feed tank, SO₂ removal efficiencies up to 90 percent were obtained at stoichiometric ratios of 1.3-1.5. With the lime recirculation process, SO₂ removal efficiencies of 70-80 percent were demonstrated at a more economical stoichiometric ratio (about 0.75). Similar tests were performed at the Leland Olds Station using commercial grade lime.

Based upon the available information, the Administrator has concluded that 70 percent SO₂ removal using lime as the reactant is technically feasible and economically attractive in comparison to wet scrubbing when coals containing less than 1.5 percent sulfur are being

combusted. The coal reserves which contain 1.5 percent sulfur or less represent approximately 90 percent of the total Western U.S. reserves.

The standards specify a percentage reduction and an emission limit but do not specify technologies which must be used. The Administrator specifically took into consideration the potential of dry SO_2 scrubbing techniques when specifying the final form of the standard in order to provide an opportunity for their development on low-sulfur coals.

Averaging Time

Compliance with the final SO_2 standards is based on a 30-day rolling average. Compliance with the proposed standards was based on a 24-hour average.

Several comments state that the proposed SO_2 percent reduction requirement is attainable using currently available control equipment. One utility company commented upon their experience with operating pilot and prototype scrubbers and a full-scale limestone FGD system on a 550-MW plant. They stated that the FGD state of the art is sufficiently developed to support the proposed standards. Based on their analysis of scrubber operating variability and coal quality variability, they indicated that to achieve an 85 percent reduction in SO_2 emissions 90 percent of the time on a daily basis, the 30-day average scrubber efficiency would have to be at least 88 to 90 percent.

Other comments stated that EPA contractors did not consider SO_2 removal in context with averaging time, that vendor guarantees were not based on specific averaging times, and that quoted SO_2 removal efficiencies were based on testing modules. EPA found through a survey of vendors that many would offer 90-95 percent SO_2 removal guarantees based upon their usual acceptance test criteria. However, the averaging time was not specified. The Industrial Gas Cleaning Institute (IGCI), which represents control equipment vendors, commented that the control equipment industry has the present capability to design, manufacture, and install FGD control systems that have the capability of attaining the proposed SO_2 standards (a continuous 24-hour average basis). Concern was expressed, however, about the proposed 24-hour averaging requirement, and this commenter recommended the adoption of 30-day averaging. Since minute-to-minute variations in factors affecting FGD efficiency cannot be compensated for instantaneously, 24-hour averaging is an impracticably short period for

implementing effective correction or for creating offsetting favorable higher efficiency periods.

Numerous other comments were received recommending that the proposed 24-hour averaging period be changed to 30 days. A utility company stated that their experience with operating full scale FGD systems at 500- and 400-MW stations indicates that variations in FGD operation make it extremely difficult, if not impossible, to maintain SO_2 removal efficiencies in compliance with the proposed percent reduction on a continual daily basis. A commenter representing the industry stated that it is clear from EPA's data that the averaging time could be no shorter than 24 hours, but that neither they nor EPA have data at this time to permit a reasonable determination of what the appropriate averaging time should be.

The Administrator has thoroughly reviewed the available data on FGD performance and all of the comments received. Based on this review, he has concluded that to alleviate this concern over coal sulfur variability, particularly its effect on small plant operations, and to allow greater flexibility in operating FGD units, the final SO_2 standard should be based on a 30-day rolling average rather than a 24-hour average as proposed. A rolling average has been adopted because it allows the Administrator to enforce the standard on a daily basis. A 30-day average is used because it better describes the typical performance of an FGD system, allows adequate time for owners or operators to respond to operating problems affecting FGD efficiency, permits greater flexibility in procedures necessary to operate FGD systems in compliance with the standard, and can reduce the effects of coal sulfur variability on maintaining compliance with the final SO_2 standards without the application of coal blending systems. Coal blending systems may be required in some cases, however, to provide for the attainment and maintenance of the National Ambient Air Quality Standards for SO_2 .

Emission Limitation

In the September proposal, a 520 ng/J (1.20 lb/million Btu) heat input emission limit, except for 3 days per month, was specified for solid fuels. Compliance was to be determined on a 24-hour averaging basis.

Following the September proposal, the joint working group comprised of EPA, The Department of Energy, the Council of Economic Advisors, the Council on Wage and Price Stability, and others

investigated ceilings lower than the proposal. In looking at these alternatives, the intent was to take full advantage of the cost effectiveness benefits of a joint coal washing/scrubbing strategy on high-sulfur coal. The cost of washing is relatively inexpensive; therefore, the group anticipated that a low emission ceiling, which would require coal washing and 90 percent scrubbing, could substantially reduce emissions in the East and Midwest at a relatively low cost. Since coal washing is now a widespread practice, it was thought that Eastern coal production would not be seriously impacted by the lower emission limit. Analyses using an econometric model of the utility sector confirmed these conclusions and the results were published in the Federal Register on December 8, 1978 (43 FR 57834).

Recognizing certain inherent limitations in the model when assessing impacts at disaggregated levels, the Administrator undertook a more detailed analysis of regional coal production impacts in February using Bureau of Mines reports which provided seam-by-seam data on the sulfur content of coal reserves and the coal washing potential of those reserves. The analysis identified the amount of reserves that would require more than 90 percent scrubbing of washed coal in order to meet designated ceilings. To determine the sulfur reduction from coal washing, the Administrator assumed two levels of coal preparation technology, which were thought to represent state-of-the-art coal preparation (crushing to 1.5-inch top size with separation at 1.6 specific gravity, and $\frac{3}{8}$ -inch top size with separation at 1.6 specific gravity). The amount of sulfur reduction was determined according to chemical characteristics of coals in the reserve base. This assessment was made using a model developed by EPA's Office of Research and Development.

As a result of concerns expressed by the National Coal Association, a meeting was called for April 5, 1979, in order for EPA and the National Coal Association to present their respective findings as they pertained to potential impacts of lower emission limits on high-sulfur coal reserves in the Eastern Midwest (Illinois, Indiana, and Western Kentucky) and the Northern Appalachian (Ohio, West Virginia, and Pennsylvania) coal regions. Recognizing the importance of discussion, the Administrator invited representatives from the Sierra Club, the Natural Resources Defense Council, the Environmental Defense Fund, the Utility

Air Regulatory Group, and the United Mine Workers of America, as well as other interested parties to attend.

At the April 5 meeting, EPA presented its analysis of the Eastern Midwest and Northern Appalachian coal regions. The analysis showed that at a 240 ng/J (0.55 lb/million Btu) annual emission limit more than 90 percent scrubbing would be required on between 5 and 10 percent of Northern Appalachian reserves and on 12 to 25 percent of the Eastern Midwest reserves. At a 340 ng/J (0.80 lb/million Btu) limit, less than 5 percent of the reserves in each of these regions would require greater than 90 percent scrubbing. At that same meeting, the National Coal Association presented data on the sulfur content and washability of reserves which are currently held by member companies. While the reported National Coal Association reserves represent a very small portion of the total reserve base, they indicate reserves which are planned to be developed in the near future and provide a detailed property-by-property data base with which to compare EPA analytical results. Despite the differences in data base sizes, the National Coal Association's study served to confirm the results of the EPA analysis. Since the National Coal Association results were within 5 percentage points of EPA's estimates, the Administrator concluded that the Office of Research and Development model would provide a widely accepted basis for studying coal reserve impacts. In addition, as a result of discussions at this meeting the Administrator revised his assessment of state-of-the-art coal cleaning technology. The National Coal Association acknowledged that crushing to 1.5-inch top size with separation at 1.6 specific gravity was common practice in industry, but that crushing to smaller top sizes would create unmanageable coal handling problems and great expense.

In order to explore further the potential for dislocations in regional coal markets, the Administrator concluded that actual buying practices of utilities rather than the mere technical usability of coals should be considered. This additional analysis identified coals that might not be used because of conservative utility attitudes toward scrubbing and the degree of risk that a utility would be willing to take in buying coal to meet the emission limit. This analysis was performed in a similar manner to the analysis described above except that two additional assumptions were made: (1) utilities would purchase coal that would provide about a 10 percent margin below the emission limit in order to minimize risk, and (2) utilities

would purchase coal that would meet the emission limit (with margin) with a 90 percent reduction in potential SO₂ emissions. This assumption reflects utility preference for buying washed coal for which only 85 percent scrubbing is needed to meet both the percent reduction and the emission limit as compared to the previous assumption that utilities would do 90 percent scrubbing on washed coal (resulting in more than 90 percent reduction in potential SO₂ emissions). This analysis was performed using EPA data at 430 ng/J (1.0 lb/million Btu) and 520 ng/J (1.20 lb/million Btu) monthly emission limits. The results revealed that a significant portion (up to 22 percent) of the high-sulfur coal reserves in the Eastern Midwest and portions of Northern Appalachian coal regions would require more than a 90 percent reduction if the emission limitation was established below 520 ng/J (1.20 lb/million Btu) on a 30-day rolling average basis. Although higher levels of control are technically feasible, conservatism in utility perceptions of scrubber performance could create a significant disincentive against the use of these coals and disrupt the coal markets in these regions. Accordingly, the Administrator concluded the emission limitation should be maintained at 520 ng/J (1.20 lb/million Btu) on a 30-day rolling average basis. A more stringent emission limit would be counter to one of the basic purposes of the 1977 Amendments, that is, encouraging the use of higher sulfur coals.

Full Versus Partial Control

In September 1978, the Administrator proposed a full or uniform control alternative and set forth other partial or variable control options as well for public comment. At that time, the Administrator made it clear that a decision as to the form of the final standard would not be made until the public comments were evaluated and additional analyses were completed. The analytical results are discussed later under Regulatory Analysis.

This issue focuses on whether power plants firing lower-sulfur coals should be required to achieve the same percentage reduction in potential SO₂ emissions as those burning higher-sulfur coals. When addressing this issue, the public commenters relied heavily on the statutory language and legislative history of Section 111 of the Clean Air Act Amendments of 1977 to bolster their arguments. Particular attention was directed to the Conference Report which says in the pertinent part:

In establishing a national percent reduction for new fossil fuel-fired sources, the conferees agreed that the Administrator may, in his discretion, set a range of pollutant reduction that reflects varying fuel characteristics. Any departure from the uniform national percentage reduction requirement, however, must be accompanied by a finding that such a departure does not undermine the basic purposes of the House provision and other provisions of the act, such as maximizing the use of locally available fuels.

Comments Favoring Full or Uniform Control. Commenters in favor of full control relied heavily on the statutory presumption in favor of a uniform application of the percentage reduction requirement. They argued that the Conference Report language, "... the Administrator may, in his discretion, set a range of pollutant reduction that reflects varying fuel characteristics. . . ." merely reflects the contention of certain conferees that low-sulfur coals may be more difficult to treat than high-sulfur coals. This contention, they assert, is not borne out by EPA's technical documentation nor by utility applications for prevention of significant deterioration permits which clearly show that high removal efficiencies can be attained on low-sulfur coals. In the face of this, they maintain there is no basis for applying a lower percent reduction for such coals.

These commenters further maintain that a uniform application of the percent reduction requirement is needed to protect pristine areas and national parks, particularly in the West. In doing so, they note that emissions may be up to seven times higher at the individual plant level under a partial approach than under uniform control. In the face of this, they maintain that partial control cannot be considered to reflect best available control technology. They also contend that the adoption of a partial approach may serve to undermine the more stringent State requirements currently in place in the West.

Turning to national impacts, commenters favoring a uniform approach note that it will result in lower emissions. They maintain that these lower emissions are significant in terms of public health and that such reductions should be maximized, particularly in light of the Nation's commitment to greater coal use. They also assert that a uniform standard is clearly affordable. They point out that the incremental increase in costs associated with a uniform standard is small when compared to total utility expenditures and will have a minimal impact at the consumer level. They further maintain that EPA has inflated

the costs of scrubber technology and has failed to consider factors that should result in lower costs in future years.

With respect to the oil impacts associated with a uniform standard, these same commenters are critical of the oil prices used in the EPA analyses and add that if a higher oil price had been assumed the supposed oil impact would not have materialized.

They also maintain that the adoption of a partial approach would serve to perpetuate the advantage that areas producing low-sulfur coal enjoyed under the current standard, which would be counter to one of the basic purposes of the House bill. On the other hand, they argue, a uniform standard would not only reduce the movement of low-sulfur coals eastward but would serve to maximize the use of local high-sulfur coals.

Finally, one of the commenters specified a more stringent full control option than had been analyzed by EPA. It called for a 95 percent reduction in potential SO₂ emissions with about a 280 ng/J (0.65 lb/million Btu) emission limit on a monthly basis. In addition, this alternative reflected higher oil prices and declining scrubber costs with time. The results were presented at the December 12 and 13 public hearing on the proposed standards.

Comments Favoring Partial or Variable Control. Those commenters advocating a partial or variable approach focused their arguments on the statutory language of Section 111. They maintained that the standard must be based on the "best technological system of continuous emission reduction which (taking into consideration the cost of achieving such emission reduction, any nonair quality health and environmental impact and energy requirements) the Administrator determines has been adequately demonstrated." They also asserted that the Conference Report language clearly gives the Administrator authority to establish a variable standard based on varying fuel characteristics, i.e., coal sulfur content.

Their principal argument is that a variable approach would achieve virtually the same emission reductions at the national level as a uniform approach but at substantially lower costs and without incurring a significant oil penalty. In view of this, they maintain that a variable approach best satisfies the statutory language of Section 111.

In support of variable control they also note that the revised NSPS will serve as a minimum requirement for prevention of significant deterioration and non-attainment considerations, and

that ample authority exists to impose more stringent requirements on a case-by-case basis. They contend that these authorities should be sufficient to protect pristine areas and national parks in the West and to assure the attainment and maintenance of the health-related ambient air quality standards. Finally, they note that the NSPS is technology-based and not directly related to protection of the Nation's public health.

In addition, they argue that a variable control option would provide a better opportunity for the development of innovative technologies. Several commenters noted that, in particular, a uniform requirement would not provide an opportunity for the development of dry SO₂ control systems which they felt held considerable promise for bringing about SO₂ emission reductions at lower costs and in a more reliable manner.

Commenters favoring variable control also advanced the arguments that a standard based on a range of percent reductions would provide needed flexibility, particularly when selecting intermediate sulfur content coals. Further, if a control system failed to meet design expectations, a variable approach would allow a source to move to lower-sulfur coal to achieve compliance. In addition, for low-sulfur coal applications, a variable option would substantially reduce the energy penalty of operating wet scrubbers since a portion of the flue gas could be used for plume reheat.

To support their advocacy of a variable approach, two commenters, the Department of Energy and the Utility Air Regulatory Group (UARG, representing a number of utilities), presented detailed results of analyses that had been conducted for them. UARG analyzed a standard that required a minimum reduction of 20 percent with 520 ng/J (1.20 lb/million Btu) monthly emission limit. The Department of Energy specified a partial control option that required a 33 percent minimum requirement with a 430 ng/J (1.0 lb/million Btu) monthly emission limit.

Faced with these comments, the Administrator determined the final analyses that should be performed. He concluded that analyses should be conducted on a range of alternative emission limits and percent reduction requirements in order to determine the approach which best satisfies the statutory language and legislative history of section 111. For these analyses, the Administrator specified a uniform or full control option, a partial control option reflecting the Department of Energy's recommendation for a 33

percent minimum control requirement, and a variable control option which specified a 520 ng/J (1.20 lb/million Btu) emission limitation with a 90 percent reduction in potential SO₂ emissions except when emissions to the atmosphere were reduced below 260 ng/J (0.60 lb/million Btu), when only a 70 percent reduction in potential SO₂ emissions would apply. Under the variable approach, plants firing high-sulfur coals would be required to achieve a 90 percent reduction in potential emissions in order to comply with the emission limitation. Those using intermediate and low-sulfur content coals would be permitted to achieve between 70 and 90 percent, provided their emissions were less than 260 ng/J (0.60 lb/million BTU).

In rejecting the minimum requirement of 20 percent advocated by UARG, the Administrator found that it not only resulted in the highest emissions, but that it was also the least cost effective of the variable control options considered. The more stringent full control option presented in the comments was rejected because it required a 95 percent reduction in potential emissions which may not be within the capabilities of demonstrated technology for high-sulfur coals in all cases.

Emergency Conditions

The final standards allow an owner or operator to bypass uncontrolled flue gases around a malfunctioning FGD system provided (1) the FGD system has been constructed with a spare FGD module, (2) FGD modules are not available in sufficient numbers to treat the entire quantity of flue gas generated, and (3) all available electric generating capacity is being utilized in a power pool or network consisting of the generating capacity of the affected utility company (except for the capacity of the largest single generating unit in the company), and the amount of power that could be purchased from neighboring interconnected utility companies. The final standards are essentially the same as those proposed. The revisions involve wording changes to clarify the Administrator's intent and revisions to address potential load management and operating problems. None of the comments received by EPA disputed the need for the emergency condition provisions or objected to their intent.

The intent of the final standards is to encourage power plant owners and operators to install the best available FGD systems and to implement effective

operation and maintenance procedures but not to create power supply disruptions. FGD systems with spare FGD modules and FGD modules with spare equipment components have greater capability of reliable operation than systems without spares. Effective control and operation of FGD systems by engineering supervisory personnel experienced in chemical process operations and properly trained FGD system operators and maintenance staff are also important in attaining reliable FGD system operation. While the standards do not require these equipment and staffing features, the Administrator believes that their use will make compliance with the standards easier. Malfunctioning FGD systems are not exempt from the SO₂ standards except during infrequent power supply emergency periods. Since the exemption does not apply unless a spare module has been installed (and operated), a spare module is required for the exemption to apply. Because of the disproportionate cost of installing a spare module on steam generators having a generating capacity of 125 MW or less, the standards do not require them to have spare modules before the emergency conditions exemption applies.

The proposed standards included the requirement that the emergency condition exemption apply only to those facilities which have installed a spare FGD system module or which have 125 MW or less of output capacity. However, they did not contain procedures for demonstrating spare module capability. This capability can be easily determined once the facility commences operation. To specify how this determination is to be performed, provisions have been added to the regulations. This determination is not required unless the owner or operator of the affected facility wishes to claim spare module capability for the purpose of availing himself of the emergency condition exemption. Should the Administrator require a demonstration of spare module capability, the owner or operator would schedule a test within 60 days for any period of operation lasting from 24 hours to 30 days to demonstrate that he can attain the appropriate SO₂ emission control requirements when the facility is operated at a maximum rate without using one of its FGD system modules. The test can start at any time of day and modules may be rotated in and out of service, but at all times in the test period one module (but not necessarily the same module) must not be operated to demonstrate spare module capability.

Although it is within the Administrator's discretion to require the spare module capability demonstration test, the owner or operator of the facility has the option to schedule the specific date and duration of the test. A minimum of only 24 hours of operation are required during the test period because this period of time is adequate to demonstrate spare module capability and it may be unreasonable in all circumstances to require a longer (e.g., 30 days) period of operation at the facility's maximum heat input rate. Because the owner or operator has the flexibility to schedule the test, 24 hours of operation at maximum rate will not impose a significant burden on the facility.

The Administrator believes that the standards will not cause supply disruption because (1) well designed and operated FGD systems can attain high operating availability, (2) a spare FGD module can be used to rotate other modules out of service for periodic maintenance or to replace a malfunctioning module, (3) load shifting of electric generation to another generating unit can normally be used if a part or all of the FGD system were to malfunction, and (4) during abnormal power supply emergency periods, the bypassing exemption ensures that the regulations would not require a unit to stand idle if its operation were needed to protect the reliability of electric service. The Administrator believes that this exemption will not result in extensive bypassing because the probability of a major FGD malfunction and power supply emergency occurring simultaneously is small.

A commenter asked that the definition of system capacity be revised to ensure that the plant's capability rather than plant rated capacity be used because the full rated capacity is not always operable. The Administrator agrees with this comment because a component failure (e.g., the failure of one coal pulverizer) could prevent a boiler from being operated at its rated capacity, but would not cause the unit to be entirely shut down. The definition has been revised to allow use of the plant's capability when determining the net system capacity.

One commenter asked that the definition of system capacity be revised to include firm contractual purchases and to exclude firm contractual sales. Because power obtained through contractual purchases helps to satisfy load demand and power sold under contract affects the net electric generating capacity available in the system, the Administrator agrees with

this request and has included power purchases in the definition of net system capacity and has excluded sales by adding them to the definition of system load.

A commenter asked that the ownership basis for proration of electric capacity in several definitions be modified when there are other contractual arrangements. The Administrator agrees with this comment and has revised the definitions accordingly.

One commenter asked that definitions describing "all electric generating equipment owned by the utility company" specifically include hydroelectric plants. The proposed definitions did include these plants, but the Administrator agrees with the clarification requested, and the definitions have been revised.

A commenter asked that the word "steam" be removed from the definition of system emergency reserves to clarify that nuclear units are included. The Administrator agrees with the comment and has revised the definition.

Several commenters asked that some type of modification be made to the emergency condition provisions that would consider projected system load increases within the next calendar day. One commenter asked that emergency conditions apply based on a projection of the next day's load. The Administrator does not agree with the suggestion of using a projected load, which may or may not materialize, as a criterion to allow bypassing of SO₂ emissions, because the load on a generating unit with a malfunctioning FGD system should be reduced whenever there is other available system capacity.

A commenter recommended that a unit removed from service be allowed to return to service if such action were necessary to maintain or reestablish system emergency reserves. The Administrator agrees that it would be impractical to take a large steam generating unit entirely out of service whenever load demand is expected to later increase to the level where there would be no other unit available to meet the demand or to maintain system emergency reserves. To address the problem of reducing load and later returning the load to the unit, the Administrator has revised the proposed emergency condition provisions to give an owner or operator of a unit with a malfunctioning FGD system the option of keeping (or bringing) the unit into spinning reserve when the unit is needed to maintain (or reestablish) system emergency reserves. During this

period, emissions must be controlled to the extent that capability exists within the FGD system, but bypassing emissions would be allowed when the capability of a partially or completely failed FGD system is inadequate. This procedure will allow the unit to operate in spinning reserve rather than being entirely shut down and will ensure that a unit can be quickly restored to service. The final emergency condition provisions permit bypassing of emissions from a unit kept in spinning reserve, but only (1) when the unit is the last one available for maintaining system emergency reserves, (2) when it is operated at the minimum load consistent with keeping the unit in spinning reserve, and (3) has inadequate operational FGD capability at the minimum load to completely control SO₂ emissions. This revision will still normally require load on a malfunctioning unit to be reduced to a minimum level, even if load demand is anticipated to increase later; but it does prevent having to take the unit entirely out of operation and keep it available in spinning reserve to assume load should an emergency arise or as load increases the following day. Because emergency condition periods are a small percentage of total operating hours, this revision to allow bypassing of SO₂ emissions from a unit held in spinning reserve with reduced output is expected to have minor impact on the amount of SO₂ emitted.

One commenter stated that the proposed provisions would not reduce the necessity for additional plant capacity to compensate for lower net reliability. The Administrator does not agree with this comment because the emergency condition provisions allow operation of a unit with a failed FGD system whenever no other generating capacity is available for operation and thereby protects the reliability of electric service. When electric load is shifted from a new steam-electric generating unit to another electric generating unit, there would be no net change in reserves within the power system. Thus, the emergency condition provisions prevent a failed FGD system from impacting upon the utility company's ability to generate electric power and prevents an impact upon reserves needed by the power system to maintain reliable electric service.

A commenter asked that the definition of available system capacity be clarified because (1) some utilities have certain localized areas or zones that, because of system operating parameters, cannot be served by all of the electric generating units which constitute the utility's

system capacity, and (2) an affected facility may be the only source of supply for a zone or area. Almost all electric utility generating units in the United States are electrically interconnected through power transmission lines and switching stations. A few isolated units in the U.S. are not interconnected to at least one other electric generating unit and it is possible that a new unit could also be constructed in an isolated area where interconnections would not be practical. For a single, isolated unit where it is not practical to construct interconnections, the emergency condition provisions would apply whenever an FGD malfunction occurred because there would be no other available system capacity to which load could be shifted. It is also possible that two or three units could be interconnected, but not interconnected with a larger power network (e.g., Alaska and Hawaii). To clarify this situation, the definitions of net system capacity, system load, and system emergency reserves have been revised to include only that electric power or capacity interconnected by a network of power transmission facilities. Few units will not be interconnected into a network encompassing the principal and neighboring utility companies. Power plants, including those without FGD systems, are expected to experience electric generating malfunctions and power systems are planned with reserve generating capacity and interconnecting electric transmission lines to provide means of obtaining electricity from alternative generating facilities to meet demand when these occasions arise. Arrangements for an affected facility would typically include an interconnection to a power transmission network even when it is geographically located away from the bulk of the utility company's power system to allow purchase of power from a neighboring utility for those localized service areas when necessary to maintain service reliability. Contract arrangements can provide for trades of power in which a localized zone served by the principal company owning or operating the affected facility is supplied by a neighboring company. The power bought by the principal company can, if desired by the neighboring company, be replaced by operation of other available units in the principal company even if these units are located at a distance from the localized service zone. The proposed definition of emergency condition was contingent upon the purchase of power from another electrical generation facility. To further clarify this relationship, the

Administrator has revised the proposed definitions to define the relationship between the principal company (the utility company that owns the generating unit with the malfunctioning FGD system) and the neighboring power companies for the purpose of determining when emergency conditions exist.

A commenter requested that the proposed compliance provisions be revised so that they could not be interpreted to force a utility to operate a partially functional FGD module when extensive damage to the FGD module would occur. For example, a severely vibrating fan must be shut down to prevent damage even though the FGD system may be otherwise functional. The Administrator agrees with this comment and has revised the compliance provisions not to require FGD operation when significant damage to equipment would result.

One commenter asked that the definition of system emergency reserves account for not only the capacity of the single largest generating unit, but also for reserves needed for system load-frequency regulation. Regulation of power frequency can be a problem when the mix of capacitive and reactive loads shift. For example, at night capacitive load of industrial plants can adversely affect power factors. The Administrator disagrees that additional capacity should be kept independent of the load shifting requirements. Under the definition for system emergency reserves, capacity equivalent to the largest single unit in the system was set aside for load management. If frequency regulation has been a particular problem, extra reserve margins would have been maintained by the utility company even if an FGD system were not installed. Reserve capacity need not be maintained within a single generating unit. The utility company can regulate system load-frequency by distributing their system reserves throughout the electric power system as needed. In the Administrator's judgment, these regulations do not impact upon the reserves maintained by the utility company for the purpose of maintaining power system integrity, because the emergency condition provisions do not restrict the utility company's freedom in distributing their reserves and do not require construction of additional reserves.

A commenter asked that utility operators be given the option to ignore the loss of SO₂ removal efficiency due to FGD malfunctions by reducing the level of electric generation from an affected unit. This would control the amount of

SO₂ emitted on a pounds per hour basis, but would also allow and exemption from the percentage of SO₂ removal specified by the SO₂ standards. The Administrator believes that allowing this exemption is not necessary because load can usually be shifted to other electric generating units. This procedure provides an incentive to the owner or operator to properly maintain and operate FGD systems. Under the procedures suggested by the commenter, neglect of the FGD system would be encouraged because an exemption would allow routine operation at reduced percentages of SO₂ removal. Steam generating units are often operated at less than rated capacity and a fully operational FGD system would not be required for compliance during these periods if this exemption were allowed. The procedure suggested by the commenter is also not necessary because FGD modules can be designed and constructed with separate equipment components so that they are routinely capable of independent operation whenever another module of the steam generating unit's FGD system is not available. Thus, reducing the level of electric generation and removing the failed FGD module for servicing would not affect the remainder of the FGD system and would permit the utility to maintain compliance with the standards without having to take the generating unit entirely out of operation. Each module should have the capability of attaining the same percentage reduction of SO₂ from the flue gas it treats regardless of the operability of the other modules in the system to maintain compliance with the standards. Although the efficiency of more than one FGD module may occasionally be affected by certain equipment malfunctions, a properly designed FGD system has no routine need for an exemption from the SO₂ percentage reduction requirement when the unit is operated at reduced load. The Administrator has concluded that the final regulations provide sufficient flexibility for addressing FGD malfunctions and that an exemption from the percentage SO₂ removal requirement is not necessary to protect electric service reliability or to maintain compliance with these SO₂ standards.

Particulate Matter Standard

The final standard limits particulate matter emissions to 13 ng/J (0.03 lb/million Btu) heat input and is based on the application of ESP or baghouse control technology. The final standard is the same as the proposed. The Administrator has concluded that ESP

and baghouse control systems are the best demonstrated systems of continuous emission reduction (taking into consideration the cost of achieving such emission reduction, and nonair quality health and environmental impacts, and energy requirements) and that 13 ng/J (0.03 lb/million Btu) heat input represents the emission level achievable through the application of these control systems.

One group of commenters indicated that they did not support the proposed standard because in their opinion it would be too expensive for the benefits obtained; and they suggested that the final standard limit emissions to 43 ng/J (0.10 lb/million Btu) heat input which is the same as the current standard under 40 CFR Part 60 Subpart D. The Administrator disagrees with the commenters because the available data clearly indicate that ESP and baghouse control systems are capable of performing at the 13 ng/J (0.03 lb/million Btu) heat input emission level, and the economic impact evaluation indicates that the costs and economic impacts of installing these systems are reasonable.

The number of commenters expressed the opinion that the proposed standard was too strict, particularly for power plants firing low-sulfur coal, because baghouse control systems have not been adequately demonstrated on full-size power plants. The commenters suggested that extrapolation of test data from small scale baghouse control systems, such as those used to support the proposed standard, to full-size utility applications is not reasonable.

The Administrator believes that baghouse control systems are demonstrated for all sizes of power plants. At the time the standards were proposed, the Administrator concluded that since baghouses are designed and constructed in modules rather than as one large unit, there should be no technological barriers to designing and constructing utility-sized facilities. The largest baghouse-controlled, coal-fired power plant for which EPA had emission test data to support the proposed standard was 44 MW. Since the standards were proposed, additional information has become available which supports the Administrator's position that baghouses are demonstrated for all sizes of power plants. Two large baghouse-controlled, coal-fired power plants have recently initiated operations. EPA has obtained emission data for one of these units. This unit has achieved particulate matter emission levels below 13 ng/J (0.03 lb/million Btu) heat input. The baghouse system for this facility has 28 modules rated at 12.5 MW

capacity per module. This supports the Administrator's conclusion that baghouses are designed and constructed in modules rather than as one large unit, and there should be no technological barriers to designing and constructing utility-sized facilities.

One commenter indicated that baghouse control systems are not demonstrated for large utility application at this time and recommended that EPA gather one year of data from 1000 MW of baghouse installations to demonstrate that baghouses can operate reliably and achieve 13 ng/J (0.03 lb/million Btu) heat input. The standard would remain at 21 to 34 ng/J (0.05 to 0.08 lb/million Btu) heat input until such demonstration. The Administrator does not believe this approach is necessary because baghouse control systems have been adequately demonstrated for large utility applications.

One group of commenters supported the proposed standard of 13 ng/J (0.03 lb/million Btu) heat input. They indicated that in their opinion the proposed standard attained the proper balance of cost, energy and environmental factors and was necessary in consideration of expected growth in coal-fired power plant capacity.

Another group of commenters which included the trade association of emission control system manufacturers indicated that 13 ng/J (0.03 lb/million Btu) is technically achievable. The trade association further indicated the proposed standard is technically achievable for either high- or low-sulfur coals, through the use of baghouses, ESPs, or wet scrubbers.

A number of commenters recommended that the proposed standard be lowered to 4 ng/J (0.01 lb/million Btu) heat input. This group of commenters presented additional emission data for utility baghouse control systems to support their recommendation. The data submitted by the commenters were not available at the time of proposal and were for utility units of less than 100 MW electrical output capacity. The commenters suggested that a 4 ng/J (0.01 lb/million Btu) heat input standard is achievable based on baghouse technology, and they suggested that a standard based on baghouse technology would be consistent with the technology-forcing nature of section 111 of the Act. The Administrator believes that the available data base for baghouse performance supports a standard of 13 ng/J (0.03 lb/million Btu) heat input but

does not support a lower standard such as 4 ng/J (0.01 lb/million Btu) heat input.

One commenter suggested that the standard should be set at 26 ng/J (0.06 lb/million Btu) heat input so that particulate matter control systems would not be necessary for oil-fired utility steam generators. Although it is expected that few oil-fired utility boilers will be constructed, the ESP performance data which is contained in the "Electric Utility Steam Generating Units, Background Information for Promulgated Emission Standards" (EPA 450/3-79-021), supports the conclusion that ESPs are applicable to both oil firing and coal firing. The Administrator believes that emissions from oil-fired utility boilers should be controlled to the same level as coal-fired boilers.

NO_x Standard

The NO_x standards limit emissions to 210 ng/J (0.50 lb/million Btu) heat input from the combustion of subbituminous coal and 260 ng/J (0.60 lb/million Btu) heat input from the combustion of bituminous coal, based on a 30-day rolling average. In addition, emission limits have been established for other solid, liquid, and gaseous fuels, as discussed in the rational section of this preamble. The final standards differ from the proposed standards only in that the final averaging time for determining compliance with the standards is based on a 30-day rolling average, whereas a 24-hour average was proposed. All comments received during the public comment period were considered in developing the final NO_x standards. The major issues raised during the comment period are discussed below.

One issue concerned the possibility that the proposed 24-hour averaging period for coal might seriously restrict the flexibility boiler operators need during day-to-day operation. For example, several commenters noted that on some boilers the control of boiler tube slagging may periodically require increased excess air levels, which, in turn, would increase NO_x emissions. One commenter submitted data indicating that two modern Combustion Engineering (CE) boilers at the Colstrip, Montana plant of the Montana Power Company do not consistently achieve the proposed NO_x level of 210 ng/J (0.50 lb/million Btu) heat input on a 24-hour basis. The Colstrip boilers burn subbituminous coal and are required to comply with the NO_x standard under 40 CFR Part 60, Subpart D of 300 ng/J (0.70 lb/million Btu) heat input. Several other commenters recommended that the 24-hour averaging period be extended to 30

days to allow for greater operational flexibility.

As an aid in evaluating the operational flexibility question, the Administrator has reviewed a total of 24 months of continuously monitored NO_x data from the two Colstrip boilers. Six months of these data were available to the Administrator before proposal of these standards, and two months were submitted by a commenter. The commenter also submitted a summary of 28 months of Colstrip data indicating the number of 24-hour averages per month above 210 ng/J (0.50 lb/million Btu) heat input. The remaining Colstrip data were obtained by the Administrator from the State of Montana after proposal. In addition to the Colstrip data, the Administrator has reviewed approximately 10 months of continuously monitored NO_x data from five modern CE utility boilers. Three of the boilers burn subbituminous coal, two burn bituminous coal, and all five have monitors that have passed certification tests. These data were obtained from electric utility companies after proposal. A summary of all of the continuously monitored NO_x data that the Administrator has considered appears in "Electric Utility Steam Generating Units, Background Information for Promulgated Emission Standards" (EPA 450/3-79-021).

The usefulness of these continuously monitored data in evaluating the ability of modern utility boilers to continuously achieve the NO_x emission limits of 210 and 260 ng/J (0.50 and 0.60 lb/million Btu) heat input is somewhat limited. This is because the boilers were required to comply with a higher NO_x level of 300 ng/J (0.70 lb/million Btu) heat input. Nevertheless some conclusions can be drawn, as follows:

(1) Nearly all of the continuously monitored NO_x data are in compliance with the boiler design limit of 300 ng/J (0.70 lb/million Btu) heat input on the basis of a 24-hour average.

(2) Most of the continuously monitored NO_x data would be in compliance with limits of 260 ng/J (0.60 lb/million Btu) heat input for bituminous coal or 210 ng/J (0.50 lb/million Btu) heat input for subbituminous coal when averaged over a 30-day period. Some of the data would be out of compliance based on a 24-hour average.

(3) The volume of continuously monitored NO_x emission data evaluated by the Administrator (34 months from seven large coal-fired boilers) is sufficient to indicate the emission variability expected during day-to-day operation of a utility-size boiler. In the Administrator's judgment, this emission

variability adequately represents slagging conditions, coal variability, load changes, and other factors that may influence the level of NO_x emissions.

(4) The variability of continuously monitored NO_x data is sufficient to cause some concern over the ability of a utility boiler that burns solid fuel to consistently achieve a NO_x boiler design limit, whether 300, 260, or 210 ng/J (0.70, 0.60, or 0.50 lb/million Btu) heat input, based on 24-hour averages. In contrast, it appears that there would be no difficulty in achieving the boiler design limit based on 30-day periods.

Based on these conclusions, the Administrator has decided to require compliance with the final standards for solid fuels to be based on a 30-day rolling average. The Administrator believes that the 30-day rolling average will allow boilers made by all four major boiler manufacturers to achieve the standards while giving boiler operators the flexibility needed to handle conditions encountered during normal operation.

Although the Administrator has not evaluated continuously monitored NO_x data from boilers manufactured by companies other than CE, the data from CE boilers are considered representative of the other boiler manufacturers. This is because the boilers of all four manufacturers are capable of achieving the same NO_x design limit, and because the conditions that occur during normal operation of a boiler (e.g., slagging, variations in fuel quality, and load reductions) are similar for all four manufacturer designs. These conditions, the Administrator believes, lead to similar emission variability and require essentially the same degree of operational flexibility.

Some commenters have questioned the validity of the Colstrip data because the Colstrip continuous NO_x monitors have not passed certification tests. In April and June of 1978 EPA conducted a detailed evaluation of these monitors. The evaluation led the Administrator to conclude that the monitors were probably biased high, but by less than 21 ng/J (0.50 lb/million Btu) heat input. Since this error is so small (less than 10 percent), the Administrator considers the data appropriate to use in developing the standards.

A number of commenters expressed concern over the ability of as many as three of the four major boiler manufacturer designs to achieve the proposed standards. Although most of the available NO_x test data are from CE boilers, the Administrator believes that all four of the boiler manufacturers will be able to supply boilers capable of

achieving the standards. This conclusion is supported with (1) emission test results from 14 CE, seven Babcock and Wilcox (B&W), three Foster Wheeler (FW), and four Riley Stoker (RS) utility boilers; (2) 34 months of continuously monitored NO_x emission data from seven CE boilers; and (3) an evaluation of plans under way at B&W, FW, and RS to develop low-emission burners and furnace designs. Full-scale tests of these burners and furnace designs have proven their effectiveness in reducing NO_x emissions without apparent long-term adverse side effects.

Another issue raised by commenters concerned the effect that variations in the nitrogen content of coal may have on achieving the NO_x standards. The Administrator recognizes that NO_x levels are sensitive to the nitrogen content of the coal burned and that the combustion of high-nitrogen-content coals might be expected to result in higher NO_x emissions than those from coals with low nitrogen contents. However, the Administrator also recognizes that other factors contribute to NO_x levels, including moisture in the coal, boiler design, and boiler operating practice. In the Administrator's judgment, the emission limits for NO_x are achievable with properly designed and operated boilers burning any coal, regardless of its nitrogen content. As evidence of this, three of the six boilers tested by EPA burned coals with nitrogen contents above average, and yet exhibited NO_x emission levels well below the standards. The three boilers that burned coals with lower nitrogen contents also exhibited emission levels below the standards. The Administrator believes this is evidence that at NO_x levels near 210 and 260 ng/J (0.50 and 0.60 lb/million Btu) heat input, factors other than fuel-nitrogen-content predominate in determining final emission levels.

A number of commenters expressed concern over the potential for accelerated tube wastage (i.e., corrosion) during operation of a boiler in compliance with the proposed standards. Almost all of the 300-hour and 30-day coupon corrosion tests conducted during the EPA-sponsored low-NO_x studies indicate that corrosion rates decrease or remain stable during operation of boilers at NO_x levels as low as those required by the standards. In the few instances where corrosion rates increased during low-NO_x operation, the increases were considered minor. Also, CE has guaranteed that its new boilers will achieve the NO_x emission limits without increased tube corrosion rates. Another boiler manufacturer, B&W, has developed new low-emission burners

that minimize corrosion by surrounding the flame in an oxygen-rich atmosphere. The other boiler manufacturers have also developed techniques to reduce the potential for corrosion during low-NO_x operation. The Administrator has received no contrasting information to the effect that boiler tube corrosion rates would significantly increase as a result of compliance with the standards.

Several commenters stated that according to a survey of utility boilers subject to the 300 ng/J (0.70 lb/million Btu) heat input standard under 40 CFR Part 60, Subpart D, none of the boilers can achieve the standard promulgated here of 260 ng/J (0.60 lb/million Btu) heat input on a range of bituminous coals. Three of the six utility boilers tested by EPA burned bituminous coal. (Two of these boilers were manufactured by CE and one by B&W.) In addition, the Administrator has reviewed continuously monitored NO_x data from two CE boilers that burn bituminous coal. Finally, the Administrator has examined NO_x emission data obtained by the boiler manufacturers on seven CE, four B&W, three FW, and three RS modern boilers, all of which burn bituminous coal. Nearly all of these data are below the 260 ng/J (0.60 lb/million Btu) heat input standard. The Administrator believes that these data provide adequate evidence that the final NO_x standard for bituminous coal is achievable by all four boiler manufacturer designs.

An issue raised by several commenters concerned the use of catalytic ammonia injection and advanced low-emission burners to achieve NO_x emission levels as low as 15 ng/J (0.034 lb/million Btu) heat input. Since these controls are not yet available, the commenters recommended that new utility boilers be designed with sufficient space to allow for the installation of ammonia injection and advanced burners in the future. In the meantime the commenters recommended that NO_x emissions be limited to 190 ng/J (0.45 lb/million Btu) heat input. The Administrator believes that the technology needed to achieve NO_x levels as low as 15 ng/J (0.034 lb/million Btu) heat input has not been adequately demonstrated at this time. Although a pilot-scale catalytic-ammonia-injection system has successfully achieved 90 percent NO_x removal at a coal-fired utility power plant in Japan, operation of a full-scale ammonia-injection system has not yet been demonstrated on a large coal-fired boiler. Since the Clean Air Act requires that emission control technology for new source performance standards be

adequately demonstrated, the Administrator cannot justify establishing a low NO_x standard based on unproven technology. Similarly, the Administrator cannot justify requiring boiler designs to provide for possible future installation of unproven technology.

The recommendation that NO_x emissions be limited to 190 ng/J (0.45 lb/million Btu) heat input is based on boiler manufacturer guarantees in California. (No such utility boilers have been built as yet.) Although manufacturer guarantees are appropriate to consider when establishing emission limits, they cannot always be used as a basis for a standard. As several commenters have noted, manufacturers do not always achieve their performance guarantees. The standard is not established at this level, because emission test data are not available which demonstrate that a level of 190 ng/J (0.45 lb/million Btu) heat input can be continuously achieved without adverse side effects when a wide variety of coals are burned.

Regulatory Analysis

Executive Order 12044 (March 24, 1978), whose objective is to improve Government regulations, requires executive branch agencies to prepare regulatory analyses for regulations that may have major economic consequences. EPA has extensively analyzed the costs and other impacts of these regulations. These analyses, which meet the criteria for preparation of a regulatory analysis, are contained within the preamble to the proposed regulations (43 FR 42154), the background documentation made available to the public at the time of proposal (see STUDIES, 43 FR 42171), this preamble, and the additional background information document accompanying this action ("Electric Utility Steam Generating Units, Background Information for Promulgated Emission Standards," EPA-450/3-79-021). Due to the volume of this material and its continual development over a period of 2-3 years, it is not practical to consolidate all analyses into a single document. The following discussion gives a summary of the most significant alternatives considered. The rationale for the action taken for each pollutant being regulated is given in a previous section.

In order to determine the appropriate form and level of control for the standards, EPA has performed extensive analysis of the potential national impacts associated with the alternative standards. EPA employed economic models to forecast the structure and

operating characteristics of the utility industry in future years. These models project the environmental, economic, and energy impacts of alternative standards for the electric utility industry. The major analytical efforts took place in three phases as described below.

Phase 1. The initial effort comprised a preliminary analysis completed in April 1978 and a revised assessment completed in August 1978. These analyses were presented in the September 19, 1978 Federal Register proposal (43 FR 42154). Corrections to the September proposal package and additional information was published on November 27, 1978 (43 FR 55258). Further details of the analyses can be found in "Background Information for Proposed SO₂ Emission Standards—Supplement," EPA 450/2-78-007a-1.

Phase 2. Following the September 19 proposal, the EPA staff conducted additional analysis of the economic, environmental, and energy impacts associated with various alternative sulfur dioxide standards. As part of this effort, the EPA staff met with representatives of the Department of Energy, Council of Economic Advisors, Council on Wage and Price Stability, and others for the purpose of reexamining the assumptions used for the August analysis and to develop alternative forms of the standard for analysis. As a result, certain assumptions were changed and a number of new regulatory alternatives were defined. The EPA staff again employed the economic model that was used in August to project the national and regional impacts associated with each alternative considered.

The results of the phase 2 analysis were presented and discussed at the public hearings in December and were published in the Federal Register on December 8, 1978 (43 FR 7834).

Phase 3. Following the public hearings, the EPA staff continued to analyze the impacts of alternative sulfur dioxide standards. There were two primary reasons for the continuing analysis. First, the detailed analysis (separate from the economic modeling) of regional coal production impacts pointed to a need to investigate a range of higher emission limits.

Secondly, several comments were received from the public regarding the potential of dry sulfur dioxide scrubbing systems. The phase 1 and phase 2 analyses had assumed that utilities would use wet scrubbers only. Since dry scrubbing costs substantially less than wet scrubbing, adoption of the dry technology would substantially change

the economic, energy, and environmental impacts of alternative sulfur dioxide standards. Hence, the phase 3 analysis focused on the impacts of alternative standards under a range of emission ceilings assuming both wet technology and the adoption of dry scrubbing for applications in which it is technically and economically feasible.

Impacts Analyzed

The environmental impacts of the alternative standards were examined by projecting pollutant emissions. The emissions were estimated nationally and by geographic region for each plant type, fuel type, and age category. The EPA staff also evaluated the waste products that would be generated under alternative standards.

The economic and financial effects of the alternatives were examined. This assessment included an estimation of the utility capital expenditures for new plant and pollution control equipment as well as the fuel costs and operating and maintenance expenses associated with the plant and equipment. These costs were examined in terms of annualized costs and annual revenue requirements. The impact on consumers was determined by analyzing the effect of the alternatives on average consumer costs and residential electric bills. The alternatives were also examined in terms of cost per ton of SO₂ removal. Finally, the present value costs of the alternatives were calculated.

The effects of the alternative proposals on energy production and consumption were also analyzed. National coal use was projected and broken down in terms of production and consumption by geographic region. The amount of western coal shipped to the Midwest and East was also estimated. In addition, utility consumption of oil and natural gas was analyzed.

Major Assumptions

Two types of assumptions have an important effect on the results of the analyses. The first group involves the model structure and characteristics. The second group includes the assumptions used to specify future economic conditions.

The utility model selected for this analysis can be characterized as a cost minimizing economic model. In meeting demand, it determines the most economic mix of plant capacity and electric generation for the utility system, based on a consideration of construction and operating costs for new plants and variable costs for existing plants. It also determines the optimum operating level for new and existing plants. This

economic-based decision criteria should be kept in mind when analyzing the model results. These criteria imply, for example, that all utilities base decisions on lowest costs and that neutral risk is associated with alternative choices.

Such assumptions may not represent the utility decision making process in all cases. For example, the model assumes that a utility bases supply decisions on the cost of constructing and operating new capacity versus the cost of operating existing capacity. Environmentally, this implies a tradeoff between emissions from new and old sources. The cost minimization assumption implies that in meeting the standard a new power plant will fully scrub high-sulfur coal if this option is cheaper than fully or partially scrubbing low-sulfur coal. Often the model will have to make such a decision, especially in the Midwest where utilities can choose between burning local high-sulfur or imported western low-sulfur coal. The assumption of risk neutrality implies that a utility will always choose the low-cost option. Utilities, however, may perceive full scrubbing as involving more risks and pay a premium to be able to partially scrub the coal. On the other hand, they may perceive risks associated with long-range transportation of coal, and thus opt for full control even though partial control is less costly.

The assumptions used in the analyses to represent economic conditions in a given year have a significant impact on the final results reached. The major assumptions used in the analyses are shown in Table 1 and the significance of these parameters is summarized below.

The growth rate in demand for electric power is very important since this rate determines the amount of new capacity which will be needed and thus directly affects the emission estimates and the projections of pollution control costs. A high electric demand growth rate results in a larger emission reduction associated with the proposed standards and also results in higher costs.

The nuclear capacity assumed to be installed in a given year is also important to the analysis. Because nuclear power is less expensive, the model will predict construction of new nuclear plants rather than new coal plants. Hence, the nuclear capacity assumption affects the amount of new coal capacity which will be required to meet a given electric demand level. In practice, there are a number of constraints which limit the amount of nuclear capacity which can be constructed, but for this study, nuclear capacity was specified approximately

equal to the moderate growth projections of the Department of Energy.

The oil price assumption has a major impact on the amount of predicted new coal capacity, emissions, and oil consumption. Since the model makes generation decisions based on cost, a low oil price relative to the cost of building and operating a new coal plant will result in more oil-fired generation and less coal utilization. This results in less new coal capacity which reduces capital costs but increases oil consumption and fuel costs because oil is more expensive per Btu than coal. This shift in capacity utilization also affects emissions, since an existing oil plant generally has a higher emission rate than a new coal plant even when only partial control is allowed on the new plant.

Coal transportation and mine labor rates both affect the delivered price of coal. The assumed transportation rate is generally more important to the predicted consumption of low-sulfur coal (relative to high-sulfur coal), since that is the coal type which is most often shipped long distances. The assumed mining labor cost is more important to eastern coal costs and production estimates since this coal production is generally much more labor intensive than western coal.

Because of the uncertainty involved in predicting future economic conditions, the Administrator anticipated a large number of comments from the public regarding the modeling assumptions. While the Administrator would have liked to analyze each scenario under a range of assumptions for each critical parameter, the number of modeling inputs made such an approach impractical. To decide on the best assumptions and to limit the number of sensitivity runs, a joint working group was formed. The group was comprised of representatives from the Department of Energy, Council of Economic Advisors, Council on Wage and Price Stability, and others. The group reviewed model results to date, identified the key inputs, specified the assumptions, and identified the critical parameters for which the degree of uncertainty was such that sensitivity analyses should be performed. Three months of study resulted in a number of changes which are reflected in Table 1 and discussed below. These assumptions were used in both the phase 2 and phase 3 analyses.

After more evaluation, the joint working group concluded that the oil prices assumed in the phase 1 analysis were too high. On the other hand, no firm guidance was available as to what

oil prices should be used. In view of this, the working group decided that the best course of action was to use two sets of oil prices which reflect the best estimates of those governmental entities concerned with projecting oil prices. The oil price sensitivity analysis was part of the phase 2 analysis which was distributed at the public hearing. Further details are available in the draft report, "Still Further Analysis of Alternative New Source Performance Standards for New Coal-Fired Power Plants (docket number IV-A-5)." The analysis showed that while the variation in oil price affected the magnitude of emissions, costs, and energy impacts, price variation had little effect on the relative impacts of the various NSPS alternatives tested. Based on this conclusion, the higher oil price was selected for modeling purposes since it paralleled more closely the middle range projections by the Department of Energy.

Reassessment of the assumptions made in the phase 1 analysis also revealed that the impact of the coal washing credit had not been considered in the modeling analysis. Other credits allowed by the September proposal, such as sulfur removed by the pulverizers or in bottom ash and flyash, were determined not to be significant when viewed at the national and regional levels. The coal washing credit, on the other hand, was found to have a significant effect on predicted emissions levels and, therefore, was factored into the analysis.

As a result of this reassessment, refinements also were made in the fuel gas desulfurization (FGD) costs assumed. These refinements include changes in sludge disposal costs, energy penalties calculated for reheat, and module sizing. In addition, an error was corrected in the calculation of partial scrubbing costs. These changes have resulted in relatively higher partial scrubbing costs when compared to full scrubbing.

Changes were made in the FGD availability assumption also. The phase 1 analysis assumed 100 percent availability of FGD systems. This assumption, however, was in conflict with EPA's estimates on module availability. In view of this, several alternatives in the phase 2 analysis were modeled at lower system availabilities. The assumed availability was consistent with a 90 percent availability for individual modules when the system is equipped with one spare. The analysis also took into consideration the emergency by-pass provisions of the proposed regulation. The analysis

showed that lower reliabilities would result in somewhat higher emissions and costs for both the partial and full control cases. Total coal capacity was slightly lower under full control and slightly higher under partial control. While it was postulated that the lower reliability assumption would produce greater adverse impacts on full control than on partial control options, the relative differences in impacts were found to be insignificant. Hence, the working group discarded the reliability issue as a major consideration in the analyzing of national impacts of full and partial control options. The Administrator still believes that the newer approach better reflects the performance of well designed, operated, and maintained FGD systems. However, in order to expedite the analyses, all subsequent alternatives were analyzed with an assumed system reliability of 100 percent.

Another adjustment to the analysis was the incorporation of dry SO_2 scrubbing systems. Dry scrubbers were assumed to be available for both new and retrofit applications. The costs of these systems were estimated by EPA's Office of Research and Development based on pilot plant studies and contract prices for systems currently under construction. Based on economic analysis, the use of dry scrubbers was assumed for low-sulfur coal (less than 1290 ng/J or 3 lb SO_2 /million Btu) applications in which the control requirement was 70 percent or less. For higher sulfur content coals, wet scrubbers were assumed to be more economical. Hence, the scenarios characterized as using "dry" costs contain a mix of wet and dry technology whereas the "wet" scenarios assume wet scrubbing technology only.

Additional refinements included a change in the capital charge rate for pollution control equipment to conform to the Federal tax laws on depreciation, and the addition of 100 billion tons of coal reserves not previously accounted for in the model.

Finally, a number of less significant adjustments were made. These included adjustments in nuclear capacity to reflect a cancellation of a plant, consideration of oil consumption in transporting coal, and the adjustment of costs to 1978 dollars rather than 1975 dollars. It should be understood that all reported costs include the costs of complying with the proposed particulate matter standard and NO_x standards, as well as the sulfur dioxide alternatives. The model does not incorporate the Agency's PSD regulations nor

forthcoming requirements to protect visibility.

Public Comments

Following the September proposal, a number of comments were received on the impact analysis. A great number focused on the model inputs, which were reviewed in detail by the joint working group. Members of the joint working group represented a spectrum of expertise (energy, jobs, environment, inflation, commerce). The following paragraphs discuss only those comments addressed to parts of the analysis which were not discussed in the preceding section.

One commenter suggested that the costs of complying with State Implementation Plan (SIP) regulations and prevention of significant deterioration requirements should not be charged to the standards. These costs are not charged to the standards in the analyses. Control requirements under PSD are based on site specific, case-by-case decisions for which the standards serves as a minimum level of control. Since these judgments cannot be forecasted accurately, no additional control was assumed by the model beyond the requirements of these standards. In addition, the cost of meeting the various SIP regulations was included as a base cost in all the scenarios modeled. Thus, any forecasted cost differences among alternative standards reflect differences in utility expenditures attributable to changes in the standards only.

Another commenter believed that the time horizon for the analysis (1990/1995) was too short since most plants on line at that time will not be subject to the revised standard. Beyond 1995, our data show that many of the power plants on line today will be approaching retirement age. As utilization of older capacity declines, demand will be picked up by newer, better controlled plants. As this replacement occurs, national SO₂ emissions will begin to decline. Based on this projection, the Administrator believes that the 1990-1995 time frame will represent the peak years for SO₂ emissions and is, therefore, the relevant time frame for this analysis.

Use of a higher general inflation rate was suggested by one commenter. A distinction must be made between general inflation rates and real cost escalation. Recognizing the uncertainty of future inflation rates, the EPA staff conducted the economic analysis in a manner that minimized reliance on this assumption. All construction, operating, and fuel costs were expressed as

constant year dollars and therefore the analysis is not affected by the inflation rate. Only real cost escalation was included in the economic analysis. The inflation rates will have an impact on the present value discount rate chosen since this factor equals the inflation rate plus the real discount rate. However, this impact is constant across all scenarios and will have little impact on the conclusions of the analysis.

Another commenter opposed the presentation of economic impacts in terms of monthly residential electric bills, since this treatment neglects the impact of higher energy costs to industry. The Administrator agrees with this comment and has included indirect consumer impacts in the analysis. Based on results of previous analysis of the electric utility industry, about half of the total costs due to pollution control are felt as direct increases in residential electric bills. The increased costs also flow into the commercial and industrial sectors where they appear as increased costs of consumer goods. Since the Administrator is unaware of any evidence of a multiplier effect on these costs, straight cost pass through was assumed. Based on this analysis, the indirect consumer impacts (Table 5) were concluded to be equal to the monthly residential bills ("Economic and Financial Impacts of Federal Air and Water Pollution Controls on the Electric Utility Industry," EPA-230/3-76/013, May 1976).

One utility company commented that the model did not adequately simulate utility operation since it did not carry out hour-by-hour dispatch of generating units. The model dispatches by means of load duration curves which were developed for each of 35 demand regions across the United States. Development of these curves took into consideration representative daily load curves, traditional utility reserve margins, seasonal demand variations, and historical generation data. The Administrator believes that this approach is adequate for forecasting long-term impacts since it plans for meeting short-term peak demand requirements.

Summary of Results

The final results of the analyses are presented in Tables 2 through 5 and discussed below. For the three alternative standards presented, emission limits and percent reduction requirements are 30-day rolling averages, and each standard was analyzed with a particulate standard of 13 ng/J (0.03 lb/million Btu) and the proposed NO_x standards. The full

control option was specified as a 520 ng/J (1.2 lb/million Btu) emission limit with a 90 percent reduction in potential SO₂ emissions. The other options are the same as full control except when the emissions to the atmosphere are reduced below 280 ng/J (0.6 lb/million Btu) in which case the minimum percent reduction requirement is reduced. The variable control option requires a 70 percent minimum reduction and the partial control option has a 33 percent minimum reduction requirement. The impacts of each option were forecast first assuming the use of wet scrubbers only and then assuming introduction of dry scrubbing technology. In contrast to the September proposal which focused on 1990 impacts, the analytical results presented today are for the year 1995. The Administrator believes that 1995 better represents the differences among alternatives since more new plants subject to the standard will be on line by 1995. Results of the 1990 analyses are available in the public record.

Wet Scrubbing Results

The projected SO₂ emissions from utility boilers are shown by plant type and geographic region in Tables 2 and 3. Table 2 details the 1995 national SO₂ emissions resulting from different plant types and age groups. These standards will reduce 1995 SO₂ emissions by about 3 million tons per year (13 percent) as compared to the current standards. The emissions from new plants directly affected by the standards are reduced by up to 55 percent. The emission reduction from new plants is due in part to lower emission rates and in part to reduced coal consumption predicted by the model. The reduced coal consumption in new plants results from the increased cost of constructing and operating new coal plants due to pollution controls. With these increased costs, the model predicts delays in construction of new plants and changes in the utilization of these plants after start-up. Reduced coal consumption by new plants is accompanied by higher utilization of existing plants and combustion turbines. This shift causes increased emissions from existing coal- and oil-fired plants, which partially offsets the emission reductions achieved by new plants subject to the standard.

Projections of 1995 regional SO₂ emissions are summarized in Table 3. Emissions in the East are reduced by about 10 to 13 percent as compared to predictions under the current standards, whereas Midwestern emissions are reduced only slightly. The smaller reductions in the Midwest are due to a slow growth of new coal-fired capacity.

In general, introductions of coal-fired capacity tends to reduce emissions since new coal plants replace old coal- and oil-fired units which have higher emission rates. The greatest emission reduction occurs in the West and West South Central regions where significant growth is expected and today's emissions are relatively low. For these two regions combined, the full control option reduces emissions by 40 percent from emission levels under the current standards, while the partial and variable options produce reductions of about 30 percent.

Table 4 illustrates the effect of the proposed standards on 1995 coal production, western coal shipped east, and utility oil and gas consumption. National coal production is predicted to triple by 1995 under all the alternative standards. This increased demand raises production in all regions of the country as compared to 1975 levels. Considering these major increases in national production, the small production variations among the alternatives are not large. Compared to production under the current standards, production is down somewhat in the West, Northern Great Plains, and Appalachia, while production is up in the Midwest. These shifts occur because of the reduced economic advantage of low-sulfur coals under the revised standards. While three times higher than 1975 levels, western coal shipped east is lower under all options than under the current standards.

Oil consumption in 1975 was 1.4 million barrels per day. The 3.1 million barrels per day figure for 1975 consumption in Table 4 includes utility natural gas consumption (equivalent of 1.7 million barrels per day) which the analysis assumed would be phased out by 1990. Hence, in 1995, the 1.4 million barrel per day projection under current standards reflects retirement of existing oil capacity and offsetting increases in consumption due to gas-to-oil conversions.

Oil consumption by utilities is predicted to increase under all the options. Compared to the current standards, increased consumption is 200,000 barrels per day under the partial and variable options and 400,000 barrels per day under full control. Oil consumption differences are due to the higher costs of new coal plants under these standards, which causes a shift to more generation from existing oil plants and combustion turbines. This shift in generation mix has important implications for the decision-making process, since the only assumed constraint to utility oil use was the

price. For example, if national energy policy imposes other constraints which phase out or stabilize oil use for electric power generation, then the differences in both oil consumption and oil plant emissions (Table 2) across the various standards will be mitigated. Constraining oil consumption, however, will spread cost differences among standards.

The economic effects in 1995 are shown in Table 5. Utility capital expenditures increase under all options as compared to the \$770 billion estimated to be required through 1995 in the absence of a change in the standard. The capital estimates in Table 5 are increments over the expenditures under the current standard and include both plant capital (for new capacity) and pollution control expenditures. As shown in Table 2, the model estimates total industry coal capacity to be about 17 GW (3 percent) greater under the non-uniform control options. The cost of this extra capacity makes the total utility capital expenditures higher under the partial and variable options, than under the full control option, even though pollution control capital is lower.

Annualized cost includes leveled capital charges, fuel costs, and operation and maintenance costs associated with utility equipment. All of the options cause an increase in annualized cost over the current standards. This increase ranges from a low of \$3.2 billion for partial control to \$4.1 billion for full control, compared to the total utility annualized costs of about \$175 billion.

The average monthly bill is determined by estimating utility revenue requirements which are a function of capital expenditures, fuel costs, and operation and maintenance costs. The average bill is predicted to increase only slightly under any of the options, up to a maximum 3-percent increase shown for full control. Over half of the large total increase in the average monthly bill over 1975 levels (\$25.50 per month) is due to a significant increase in the amount of electricity used by each customer. Pollution control expenditures, including those to meet the current standards, account for about 15 percent of the increase in the cost per kilowatt-hour while the remainder of the cost increase is due to capital intensive capacity expansion and real escalations in construction and fuel cost.

Indirect consumer impacts range from \$1.10 to \$1.60 per month depending on the alternative selected. Indirect consumer impacts reflect increases in consumer prices due to the increased

energy costs in the commercial and industrial sectors.

The incremental costs per ton of SO₂ removal are also shown in Table 5. The figures are determined by dividing the change in annualized cost by the change in annual emissions, as compared to the current standards. These ratios are a measure of the cost effectiveness of the options, where lower ratios represent a more efficient resource allocation. All the options result in higher cost per ton than the current standards with the full control option being the most expensive.

Another measure of cost effectiveness is the average dollar-per-ton cost at the plant level. This figure compares total pollution control cost with total SO₂ emission reduction for a model plant. This average removal cost varies depending on the level of control and the coal sulfur content. The range for full control is from \$325 per ton on high-sulfur coal to \$1,700 per ton on low-sulfur coal. On low-sulfur coals, the partial control cost is \$2,000 per ton, and the variable cost is \$1,700 per ton.

The economic analyses also estimated the net present value cost of each option. Present value facilitates comparison of the options by reducing the streams of capital, fuel, and operation and maintenance expenses to one number. A present value estimate allows expenditures occurring at different times to be evaluated on a similar basis by discounting the expenditures back to a fixed year. The costs chosen for the present value analysis were the incremental utility revenue requirements relative to the current NSPS. These revenue requirements most closely represent the costs faced by consumers. Table 5 shows that the present value increment for 1995 capacity is \$41 billion for full control, \$37 billion for variable control, and \$32 billion for partial control.

Dry Scrubbing Results

Tables 2 through 5 also show the impacts of the options under the assumption that dry SO₂ scrubbing systems penetrate the pollution control market. These analyses assume that utilities will install dry scrubbing systems for all applications where they are technologically feasible and less costly than wet systems. (See earlier discussion of assumptions.)

The projected SO₂ emissions from utility boilers are shown by plan type and geographic region in Tables 2 and 3. National emission projections are similar to the wet scrubbing results. Under the dry control assumption, however, the variable control option is predicted to have the lowest national

emissions primarily due to lower oil plant emissions relative to the full control option. Partial control produces more emissions than variable control because of higher emissions from new plants. Compared to the current standards, regional emission impacts are also similar to the wet scrubbing projections. Full control results in the lowest emissions in the West, while variable control results in the lowest emissions in the East. Emissions in the Midwest and West South Central are relatively unaffected by the options.

Inspection of Tables 2 and 3 shows that with the dry control assumption the current standard, full control, and partial control cases produce slightly higher emissions than the corresponding wet control cases. This is due to several factors, the most important of which is a shift in the generation mix. This shift occurs because dry scrubbers have lower capital costs and higher variable costs than wet scrubbers and, therefore, the two systems have different effects on the plant utilization rates. The higher variable costs are due primarily to transportation charges on intermediate to low sulfur coal which must be used with dry scrubbers. The increased variable cost of dry controls alters the dispatch order of existing plants so that older, uncontrolled plants operate at relatively higher capacity factors than would occur under the wet scrubbing assumption, hence increasing total emissions. Another factor affecting emissions is utility coal selection which may be altered by differences in pollution control costs.

Table 4 shows the effect to the proposed standards on fuels in 1995. National coal production remains essentially the same whether dry or wet controls are assumed. However, the use of dry controls causes a slight reallocation in regional coal production, except under a full control option where dry controls cannot be applied to new plants. Under the variable and partial options Appalachian production increases somewhat due to greater demand for intermediate sulfur coals while Midwestern coal production declines slightly. The non-uniform options also result in a small shifting in the western regions with Northern Great Plains production declining and production in the rest of West increasing. The amount of western coal shipped east under the current standard is reduced from 122 million to 99 million tons (20% decrease) due to the increased use of eastern intermediate sulfur coals for dry scrubbing applications. Western coal shipped east is reduced further by the revised standards, to a low of 55

million tons under full control. Oil impacts under the dry control assumption are identical to the wet control cases, with full control resulting in increased consumption of 200 thousand barrels per day relative to the partial and variable options.

The 1995 economic effects of these standards are presented in Table 5. In general, the dry control assumption results in lower costs. However, when comparing the dry control costs to the wet control figures it must be kept in mind that the cost base for comparison, the current standards, is different under the dry control and wet control assumptions. Thus, while the incremental costs of full control are higher under the dry scrubber assumption the total costs of meeting the standard is lower than if wet controls were used.

The economic impact figures show that when dry controls are assumed the cost savings associated with the variable and partial options is significantly increased over the wet control cases. Relative to full control the partial control option nets a savings of \$1.4 billion in annualized costs which equals a \$14 billion net present value savings. Variable control results in a \$1.1 billion annualized cost savings which is a savings of \$12 billion in net present value. These changes in utility costs affect the average residential bill only slightly, with partial control resulting in a savings of \$.50 per month and variable control savings of \$.40 per month on the average bill, relative to full control.

Conclusions

One finding that has been clearly demonstrated by the two years of analysis is that lower emission standards on new plants do not necessarily result in lower national SO₂ emissions when total emissions from the entire utility system are considered. There are two reasons for this finding. First, the lowest emissions tend to result from strategies that encourage the construction of new coal capacity. This capacity, almost regardless of the alternative analyzed, will be less polluting than the existing coal- or oil-fired capacity that it replaces. Second, the higher cost of operating the new capacity (due to higher pollution costs) may cause the newer, cleaner plants to be utilized less than they would be under a less stringent alternative. These situations are demonstrated by the analyses presented here.

The variable control option produces emissions that are equal to or lower than the other options under both the

wet and dry scrubbing assumptions. Compared to full control, variable control is predicted to result in 12 GW to 17 GW more coal capacity. This additional capacity replaces dirtier existing plants and compensates for the slight increase in emissions from new plants subject to the standards, hence causing emissions to be less than or equal to full control emissions depending on scrubbing cost assumption (i.e., wet or dry). Partial control and variable control produce about the same coal capacity, but the additional 300 thousand ton emission reduction from new plants causes lower total emissions under the variable option. Regionally, all the options produce about the same emissions in the Midwest and West South Central regions. Full control produces 200 thousands tons less emissions in the West than the variable option and 300 thousand tons less than partial control. But the variable and partial options produce between 200 and 300 thousand tons less emissions in the East.

The variable and partial control options have a clear advantage over full control with respect to costs under both the wet and dry scrubbing assumptions. Under the dry assumption, which the Administrator believes represents the best prediction of utility behavior, variable control saves about \$1.1 billion per year relative to full control and partial control saves an additional \$0.3 billion.

All the options have similar impacts on coal production especially when considering the large increase predicted over 1975 production levels. With respect to oil consumption, however, the full control option causes a 200,000 barrel per day increase as compared to both the partial and variable options.

Based on these analyses, the Administrator has concluded that a non-uniform control strategy is best considering the environmental, energy, and economic impacts at both national and regional levels. Compared to other options analyzed, the variable control standard presented above achieves the lowest emissions in an efficient manner and will not disrupt local or regional coal markets. Moreover, this option avoids the 200 thousand barrel per day oil penalty which has been predicted under a number of control options. For these reasons, the Administrator believes that the variable control option provides the best balance of national environmental, energy, and economic objectives.

Performance Testing

Particulate Matter

The final regulations require that Method 5 or 17 under 40 CFR Part 60, Appendix A, be used to determine compliance with the particulate matter emission limit. Particulate matter may be collected with Method 5 at an outstack filter temperature up to 180 C (320 F); Method 17 may be used when stack temperatures are less than 180 C (320 F). Compliance with the opacity standard in the final regulation is determined by means of Method 9, under 40 CFR Part 60, Appendix A. A transmissometer that meets Performance Specification 1 under 40 CFR Part 60, Appendix B is required.

Several comments were received which questioned the accuracy of Methods 5 and 17 when used to measure particulate matter at the level of the standard. The accuracy of Methods 5 and 17 is dependent on the amount of sample collected and not the concentration in the gas stream. To maintain an accuracy comparable to the accuracy obtained when testing for mass emission rates higher than the standard, it is necessary to sample for longer times. For this reason, the regulation requires a minimum sampling time of 120 minutes and a minimum sampling volume of 1.7 dscm (60 dscf).

Three comments raised the issue of potential interference of acid mist with the measurement of particulate matter. The Administrator recognized this issue prior to proposal of the regulations. In the preamble to the proposed regulations, the Administrator indicated that investigations would continue to determine the extent of the problem. A series of tests at an FGD-equipped facility burning 3-percent-sulfur coal indicate that the amount of sample collected using Method 5 procedures is temperature sensitive over the range of filter temperatures used (250° F to 380° F), with reduced weights at higher temperatures. Presumably, the decreased weight at higher filter temperatures reflect vaporization of acid mist. Recently received particulate emission data using Method 5 at 32° F for a second coal-fired power plant equipped with an electrostatic precipitator and an FGD system apparently conflicts with the data generated by EPA. For this plant, particulate matter was measured at 0.02 lbs/million Btu. It is not known what portion of this particulate matter, if any was attributable to sulfuric acid mist.

The intent of the particulate matter standard is to insure the installation, operation, and maintenance of a good

emission control system. Since technology is not available for the control of sulfuric acid mist, which is condensed in the FGD system, the Administrator does not believe the particulate matter sample should include condensed acid mist. The final

regulation, therefore, allows particulate matter testing for compliance between the outlet of the particulate matter control device and the inlet of a wet FGD system. EPA will continue to investigate revised procedures to minimize the measurement of acid mist

by Methods 5 or 17 when used to measure particulate matter after the FGD system. Since technology is available to control particulate sulfate carryover from an FGD system, and the Administrator believes good mist eliminators should be included with all FGD systems, the regulations will be amended to require particulate matter measurement after the FGD system when revised procedures for Methods 5 or 17 are available.

SO₂ and NO_x

The final regulation requires that compliance with the sulfur dioxide and nitrogen oxides standards be determined by using continuous monitoring systems (CMS) meeting Performance Specifications 2 and 3, under 40 CFR Part 60, Appendix B. Data from the CMS are used to calculate a 30-day rolling average emission rate and percentage reduction (sulfur dioxide only) for the initial performance test required under 40 CFR 60.8. At the end of each boiler operating day after the initial performance test a new 30-day rolling average emission rate for sulfur dioxide and nitrogen oxides and an average percent reduction for sulfur dioxide are determined. The final regulations specify the minimum amount of data that must be obtained for each 30 successive boiler operating days but requires the calculation of the average emission rate and percentage reduction based on all available data. The minimum data requirements can be satisfied by using the Reference Methods or other approved alternative methods when the CMS, or components of the system, are inoperative.

The final regulation requires operation of the continuous monitors at all times, including periods of startup, shutdown, malfunction (NO_x only), and emergency conditions (SO₂ only), except for those periods when the CMS is inoperative because of malfunctions, calibration or span checks.

The proposed regulations would have required that compliance be based on the emission rate and percent reduction

(sulfur dioxide only) for each 24-hour period of operation. Continual determination of compliance with the proposed standard would have necessitated that each source owner or operator install redundant CMS or conduct manual testing in the event of CMS malfunction.

Comments on the proposed testing requirements for sulfur dioxide and nitrogen oxides indicated that CMS could not operate without malfunctions; therefore, every facility would require redundant CMS. One commenter calculated that seven CMS would be needed to provide the required data. Comments also questioned the practicality and feasibility of obtaining around-the-clock emissions data by means of manual testing in the event of CMS malfunction. The commenter stated that the need for immediate backup testing using manual methods would require a stand-by test team at all times and that extreme weather conditions or other circumstances could often make it impossible for the test team to obtain the required data. The Administrator agrees with these comments and has redefined the data requirements to reflect the performance that can be achieved with one well-maintained CMS. The final requirements are designed to eliminate the need for redundant CMS and minimize the possibility that manual testing will be necessary, while assuring acquisition of sufficient data to document compliance.

Compliance with the emission limitations for sulfur dioxide and nitrogen oxides and the percentage reduction for sulfur dioxide is determined from all available hourly averages, except for periods of startup, shutdown, malfunction or emergency conditions for each 30 successive boiler operating days. Minimum data requirements have been established for hourly averages, for 24-hour periods, and for the 30 successive boiler operating days. These minimum requirements eliminate the need for redundant CMS and minimize the need for testing using manual sampling techniques. The minimum requirements apply separately to inlet and outlet monitoring systems.

The regulation allows calculation of hourly averages for the CMS using two or more of the required four data points. This provision was added to accommodate those monitors for which span and calibration checks and minor repairs might require more than 15 minutes.

For any 24-hour period, emissions data must be obtained for a minimum of 75 percent of the hours during which the

affected facility is operated (including startup, shutdown, malfunctions or emergency conditions). This provision was added to allow additional time for CMS calibrations and to correct minor CMS problems, such as a lamp failure, a plugged probe, or a soiled lens.

Statistical analyses of data obtained by EPA show that there is no significant difference (at the 95 percent confidence interval) between 24-hour means based on 75 percent of the data and those based on the full data set.

To provide time to correct major CMS malfunctions and minimize the possibility that supplemental testing will be needed, a provision has been added which allows the source owner or operator to demonstrate compliance if the minimum data for each 24-hour period has been obtained for 22 of the 30 successive boiler operating days. This provision is based on EPA studies that have shown that a single pair of CMS pollutant and diluent monitors can be made available in excess of 75 percent of the time and several comments showing CMS availability in excess of 90 percent of the time.

In the event a CMS malfunction would prevent the source owner or operator from meeting the minimum data requirements, the regulation requires that the reference methods or other procedures approved by the Administrator be used to supplement the data. The Administrator believes, however, that a single properly designed, maintained, and operated CMS with trained personnel and an appropriate inventory of spare parts can achieve the monitoring requirements with currently available CMS equipment. In the event that an owner or operator fails to meet the minimum data requirements, a procedure is provided which may be used by the Administrator to determine compliance with the SO₂ and NO_x standards. The procedure is provided to reduce potential problems that might arise if an owner or operation is unable to meet the minimum data requirements or attempts to manipulate the acquisition of data so as to avoid the demonstration of noncompliance. The Administrator believes that an owner or operator should not be able to avoid a finding of noncompliance with the emission standards solely by noncompliance with the minimum data requirements. Penalties related only to failure to meet the minimum data requirements may be less than those for failure to meet the emission standards and may not provide as great an incentive to maintain compliance with the regulations.

The procedure involves the calculation of standard deviations for the available inlet SO₂ monitoring data and the available outlet SO₂ and NO_x monitoring data and assumes the data are normally distributed. The standard deviation of the inlet monitoring data for SO₂ is used to calculate the upper confidence limit of the inlet emission rate at the 95 percent confidence interval. The upper confidence limit of the inlet emission rate is used to determine the potential combustion concentration and the allowable emission rate. The standard deviation of the outlet monitoring data for SO₂ and NO_x are used to calculate the lower confidence limit of the outlet emission rates at the 95 percent confidence interval. The lower confidence limit of the outlet emission rate is compared with the allowable emission rate to determine compliance. If the lower confidence limit of the outlet emission rate is greater than the allowable emission rate for the reporting period, the Administrator will conclude that noncompliance has occurred.

The regulations require the source owner or operator who fails to meet the minimum data requirements to perform the calculations required by the added procedure, and to report the results of the calculations in the quarterly report. The Administrator may use this information for determining the compliance status of the affected facility.

It is emphasized that while the regulations permit a determination of the compliance status of a facility in the absence of data reflecting some periods of operation, an owner and operator is required by 40 CFR 60.11(d) to continue to operate the facility at all times so as to minimize emissions consistent with good engineering practice. Also, the added procedure which allows for a determination of compliance when less than the minimum monitoring data have been obtained does not exempt the source owner or operator from the minimum data requirements. Exemption from the minimum data requirements could allow the source owner to circumvent the standard, since the added procedure assumes random variations in emission rates.

One commenter suggested that operating data be used in place of CMS data to demonstrate compliance. The Administrator does not believe, however, that the demonstration of compliance can be based on operating data alone. Consideration was given to the reporting of operating parameters during those periods when emissions data have not been obtained. This

alternative was rejected because it would mean that the source owner or operator would need to record the operating parameters at all times, and would impose an administrative burden on source owners or operators in compliance with the emission monitoring requirements. The regulation requires the owner or operator to certify that the emission control systems have been kept in operation during periods when emissions data have not been obtained.

Several commenters indicated that CMS were not sufficiently accurate to allow for a determination of compliance. One commenter provided calculations showing that the CMS could report an FGD efficiency ranging from 77.5 to 90 percent, with the scrubber operating at an efficiency of 85 percent. The analysis submitted by the commenter is theoretically possible for any single data point generated by the CMS. For the 30-day averaging periods, however, random variations in individual data points are not significant. The criterion of importance in showing compliance for this longer averaging time is the difference between the mean values measured by the CMS and the reference methods. EPA is developing quality assurance procedures, which will require a periodic demonstration that the mean emission rates measured by the CMS demonstrates a consistent and reproducible relationship with the mean emission rates measured by the reference methods or acceptable modifications of these methods.

A specific comment received on the monitoring requirements questioned the need to respan the CMS for sulfur dioxide when the sulfur content of the fuel changed by 0.5 percent. The intent of this requirement was to assure that a change in fuel sulfur content would not result in emissions exceeding the range of the CMS. This requirement has been deleted on the premise that the source owner or operator will initiate his own procedures to protect himself against loss of data.

Several comments were also received concerning detailed technical items contained in Performance Specifications 2 and 3. One comment, for example, suggested that a single "relative accuracy" specification be used for the entire CMS, as opposed to separate values for the pollutant and diluent monitors. Another comment questioned the performance specification on instrument response time, while still other comments raised questions on calibration procedures. EPA is in the process of revising Performance Specifications 2 and 3 to respond to

these, and other questions. The current performance specifications, however, are adequate for the determination of compliance.

Fuel Pretreatment

The final regulation allows credit for fuel pretreatment to remove sulfur or increase heat content. Fuel pretreatment credits are determined in accordance with Method 19. This means that coal or oil may be treated before firing and the sulfur removed may be credited toward meeting the SO₂ percentage reduction requirement. The final fuel pretreatment provisions are the same as those proposed.

Most all commenters on this issue supported the fuel pretreatment crediting procedures proposed by EPA. Several commenters requested that credit also be given for sulfur removed in the coal bottom ash and fly ash. This is allowed under the final regulation and was also allowed under the proposal in the optional "as-fired" fuel sampling procedures under the SO₂ emission monitoring requirements. By monitoring SO₂ emissions (ng/l, lb/million Btu) with an as-fired fuel sampling system located upstream of coal pulverizers and with an in-stack continuous SO₂ monitoring system downstream of the FGD system, sulfur removal credits are combined for the coal pulverizer, bottom ash, fly ash and FGD system into one removal efficiency. Other alternative sampling procedures may also be submitted to the Administrator for approval.

Several commenters indicated that they did not understand the proposed fuel pretreatment crediting procedure for refined fuel oil. The Administrator intended to allow fuel pretreatment credits for all fuel oil desulfurization processes used in preparation of utility boiler fuels. Thus, the input and output from oil desulfurization processes (e.g., hydrotreatment units) that are used to pretreat utility boiler fuels used in determining pretreatment credits. If desulfurized oil is blended with undesulfurized oil, fuel pretreatment credits are prorated based on heat input of oils blended. The Administrator believes that the oil input to the desulfurizer should be considered the input for credit determination and not the well head crude oil or input oil to the refinery. Refining of crude oil results in the separation of the base stock into various density fractions which range from lighter products such as naphtha and distillate oils. Most of the sulfur from the crude oil is bound to the heavier residual oils which may have a sulfur content of twice the input crude oil. The residual oils can be upgraded to

a lower sulfur utility steam generator fuel through the use of desulfurization technology (such as hydrodesulfurization). The Administrator believes that it is appropriate to give full fuel pretreatment credit for hydrotreatment units and not to penalize hydrodesulfurization units which are used to process high-sulfur residual oils. Thus, the input to the hydrodesulfurization unit is used to determine oil pretreatment credits and not the lower sulfur refinery input crude. This procedure will allow full credit for residual oil hydrodesulfurization units.

In relation to fuel pretreatment credits for coal, commenters requested that sampling be allowed prior to the initial coal breaker. Under the final standards, coal sampling may be conducted at any location (either before or after the initial coal breaker). It is desirable to sample coal after the initial breaker because the smaller coal volume and coal size will reduce sampling requirements under Method 19. If sampling were conducted before the initial breaker, rock removed by the coal breaker would not result in any additional sulfur removal credit. Coal samples are analyzed to determine potential SO₂ emissions in ng/l (lb/million Btu) and any removal of rock or other similar reject material will not change the potential SO₂ emission rate (ng/l; lb/million Btu).

An owner or operator of an affected facility who elects to use fuel pretreatment credits is responsible for insuring that the EPA Method 19 procedures are followed in determining SO₂ removal credit for pretreatment equipment.

Miscellaneous

Establishment of standards of performance for electric utility steam generating units was preceded by the Administrator's determination that these sources contribute significantly to air pollution which causes or contributes to the endangerment of public health or welfare (36 FR 5931), and by proposal of regulations on September 19, 1978 (43 FR 42154). In addition, a preproposal public hearing (May 25-26, 1977) and a postproposal public hearing (December 12-13, 1978) was held after notification was given in the Federal Register. Under section 117 of the Act, publication of these regulations was preceded by consultation with appropriate advisory committees, independent experts, and Federal departments and agencies.

Standards of performance for new fossil-fuel-fired stationary sources established under section 111 of the Clean Air Act reflect:

Application of the best technological system of continuous emission reduction which (taking into consideration the cost of achieving such emission reduction, any nonair quality health and environmental impact and energy requirements) the Administrator determines has been adequately demonstrated. [section 111(a)(1)]

Although there may be emission control technology available that can reduce emissions below those levels required to comply with standards of performance, this technology might not be selected as the basis of standards of performance due to costs associated with its use. Accordingly, standards of performance should not be viewed as the ultimate in achievable emission control. In fact, the Act requires (or has potential for requiring) the imposition of a more stringent emission standard in several situations.

For example, applicable costs do not play as prominent a role in determining the "lowest achievable emission rate" for new or modified sources located in nonattainment areas, i.e., those areas where statutorily-mandated health and welfare standards are being violated. In this respect, section 173 of the Act requires that a new or modified source constructed in an area that exceeds the National Ambient Air Quality Standard (NAAQS) must reduce emissions to the level that reflects the "lowest achievable emission rate" (LAER), as defined in section 171(3), for such source category. The statute defines LAER as that rate of emission which reflects:

(A) The most stringent emission limitation which is contained in the implementation plan of any State for such class or category of source, unless the owner or operator of the proposed source demonstrates that such limitations are not achievable, or

(B) The most stringent emission limitation which is achieved in practice by such class or category of source, whichever is more stringent.

In no event can the emission rate exceed any applicable new source performance standard [section 171(3)].

A similar situation may arise under the prevention of significant deterioration of air quality provisions of the Act (Part C). These provisions require that certain sources [referred to in section 169(1)] employ "best available control technology" [as defined in section 169(3)] for all pollutants regulated under the Act. Best available control technology (BACT) must be determined on a case-by-case basis, taking energy, environmental and economic impacts, and other costs into account. In no event may the application of BACT result in emissions of any

pollutants which will exceed the emissions allowed by any applicable standard established pursuant to section 111 (or 112) of the Act.

In all events, State implementation plans (SIP's) approved or promulgated under section 110 of the Act must provide for the attainment and maintenance of National Ambient Air Quality Standards designed to protect public health and welfare. For this purpose, SIP's must in some cases require greater emission reductions than those required by standards of performance for new sources.

Finally, States are free under section 116 of the Act to establish even more stringent emission limits than those established under section 111 or those necessary to attain or maintain the NAAQS under section 110. Accordingly, new sources may in some cases be subject to limitations more stringent than EPA's standards of performance under section 111, and prospective owners and operators of new sources should be aware of this possibility in planning for such facilities.

Under EPA's sunset policy for reporting requirements in regulations, the reporting requirements in this regulation will automatically expire five years from the date of promulgation unless the Administrator takes affirmative action to extend them. Within the five year period, the Administrator will review these requirements.

Section 317 of the Clean Air Act requires the Administrator to prepare an economic impact assessment for revisions determined by the Administrator to be substantial. The Administrator has determined that these revisions are substantial and has prepared an economic impact assessment and included the required information in the background information documents.

Dated: June 1, 1979.
Douglas M. Costle,
Administrator.

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

In 40 CFR Part 60, § 60.8 of Subpart A is revised, the heading and § 60.40 of Subpart D are revised, a new Subpart Da is added, and a new reference method is added to Appendix A as follows:

1. Section 60.8(d) and § 60.8(f) are revised as follows:

§ 60.8 Performance tests.

* * * * *

(d) The owner or operator of an affected facility shall provide the Administrator at least 30 days prior notice of any performance test, except as specified under other subparts, to afford the Administrator the opportunity to have an observer present.

* * * * *

(f) Unless otherwise specified in the applicable subpart, each performance test shall consist of three separate runs using the applicable test method. Each run shall be conducted for the time and under the conditions specified in the applicable standard. For the purpose of determining compliance with an applicable standard, the arithmetic means of results of the three runs shall apply. In the event that a sample is accidentally lost or conditions occur in which one of the three runs must be discontinued because of forced shutdown, failure of an irreplaceable portion of the sample train, extreme meteorological conditions, or other circumstances, beyond the owner or operator's control, compliance may, upon the Administrator's approval, be determined using the arithmetic mean of the results of the two other runs.

2. The heading for Subpart D is revised to read as follows:

Subpart D—Standards of Performance for Fossil-Fuel-Fired Steam Generators for Which Construction Is Commenced After August 17, 1971

3. Section 60.40 is amended by adding paragraph (d) as follows:

§ 60.40 Applicability and designation of affected facility.

* * * * *

(d) Any facility covered under Subpart Da is not covered under This Subpart.

(Sec. 111, 301(a) of the Clean Air Act as amended (42 U.S.C. 7411, 7601(a)).)

4. A new Subpart Da is added as follows:

Subpart Da—Standards of Performance for Electric Utility Steam Generating Units for Which Construction Is Commenced After September 18, 1978

Sec.

60.40a Applicability and designation of affected facility.

60.41a Definitions.

60.42a Standard for particulate matter.

60.43a Standard for sulfur dioxide.

60.44a Standard for nitrogen oxides.

60.45a Commercial demonstration permit.

60.46a Compliance provisions.

60.47a Emission monitoring.

60.48a Compliance determination procedures and methods.

60.49a Reporting requirements.

Authority: Sec. 111, 301(a) of the Clean Air Act as amended (42 U.S.C. 7411, 7601(a)), and additional authority as noted below.

Subpart D—Standards of Performance for Electric Utility Steam Generating Units for Which Construction is Commenced After September 18, 1978

§ 60.40a Applicability and designation of affected facility.

(a) The affected facility to which this subpart applies is each electric utility steam generating unit:

(1) That is capable of combusting more than 73 megawatts (250 million Btu/hour) heat input of fossil fuel (either alone or in combination with any other fuel); and

(2) For which construction or modification is commenced after September 18, 1978.

(b) This subpart applies to electric utility combined cycle gas turbines that are capable of combusting more than 73 megawatts (250 million Btu/hour) heat input of fossil fuel in the steam generator. Only emissions resulting from combustion of fuels in the steam generating unit are subject to this subpart. (The gas turbine emissions are subject to Subpart GG.)

(c) Any change to an existing fossil-fuel-fired steam generating unit to accommodate the use of combustible materials, other than fossil fuels, shall not bring that unit under the applicability of this subpart.

(d) Any change to an existing steam generating unit originally designed to fire gaseous or liquid fossil fuels, to accommodate the use of any other fuel (fossil or nonfossil) shall not bring that unit under the applicability of this subpart.

§ 60.41a Definitions.

As used in this subpart, all terms not defined herein shall have the meaning given them in the Act and in subpart A of this part.

"Steam generating unit" means any furnace, boiler, or other device used for combusting fuel for the purpose of producing steam (including fossil-fuel-fired steam generators associated with combined cycle gas turbines; nuclear steam generators are not included).

"Electric utility steam generating unit" means any steam electric generating unit that is constructed for the purpose of supplying more than one-third of its potential electric output capacity and more than 25 MW electrical output to any utility power distribution system for sale. Any steam supplied to a steam distribution system for the purpose of providing steam to a steam-electric

generator that would produce electrical energy for sale is also considered in determining the electrical energy output capacity of the affected facility.

"Fossil fuel" means natural gas, petroleum, coal, and any form of solid, liquid, or gaseous fuel derived from such material for the purpose of creating useful heat.

"Subbituminous coal" means coal that is classified as subbituminous A, B, or C according to the American Society of Testing and Materials' (ASTM) Standard Specification for Classification of Coals by Rank D388-66.

"Lignite" means coal that is classified as lignite A or B according to the American Society of Testing and Materials' (ASTM) Standard Specification for Classification of Coals by Rank D388-66.

"Coal refuse" means waste products of coal mining, physical coal cleaning, and coal preparation operations (e.g., culm, gob, etc.) containing coal, matrix material, clay, and other organic and inorganic material.

"Potential combustion concentration" means the theoretical emissions (ng/l, lb/million Btu heat input) that would result from combustion of a fuel in an uncleaned state (without emission control systems) and:

(a) For particulate matter is:

(1) 3,000 ng/l (7.0 lb/million Btu) heat input for solid fuel; and

(2) 75 ng/l (0.17 lb/million Btu) heat input for liquid fuels.

(b) For sulfur dioxide is determined under § 60.48a(b).

(c) For nitrogen oxides is:

(1) 290 ng/l (0.67 lb/million Btu) heat input for gaseous fuels;

(2) 310 ng/l (0.72 lb/million Btu) heat input for liquid fuels; and

(3) 990 ng/l (2.30 lb/million Btu) heat input for solid fuels.

"Combined cycle gas turbine" means a stationary turbine combustion system where heat from the turbine exhaust gases is recovered by a steam generating unit.

"Interconnected" means that two or more electric generating units are electrically tied together by a network of power transmission lines, and other power transmission equipment.

"Electric utility company" means the largest interconnected organization, business, or governmental entity that generates electric power for sale (e.g., a holding company with operating subsidiary companies).

"Principal company" means the electric utility company or companies which own the affected facility.

"Neighboring company" means any one of those electric utility companies

with one or more electric power interconnections to the principal company and which have geographically adjoining service areas.

"Net system capacity" means the sum of the net electric generating capability (not necessarily equal to rated capacity) of all electric generating equipment owned by an electric utility company (including steam generating units, internal combustion engines, gas turbines, nuclear units, hydroelectric units, and all other electric generating equipment) plus firm contractual purchases that are interconnected to the affected facility that has the malfunctioning flue gas desulfurization system. The electric generating capability of equipment under multiple ownership is prorated based on ownership unless the proportional entitlement to electric output is—otherwise established by contractual arrangement.

"System load" means the entire electric demand of an electric utility company's service area interconnected with the affected facility that has the malfunctioning flue gas desulfurization system plus firm contractual sales to other electric utility companies. Sales to other electric utility companies (e.g., emergency power) not on a firm contractual basis may also be included in the system load when no available system capacity exists in the electric utility company to which the power is supplied for sale.

"System emergency reserves" means an amount of electric generating capacity equivalent to the rated capacity of the single largest electric generating unit in the electric utility company (including steam generating units, internal combustion engines, gas turbines, nuclear units, hydroelectric units, and all other electric generating equipment) which is interconnected with the affected facility that has the malfunctioning flue gas desulfurization system. The electric generating capability of equipment under multiple ownership is prorated based on ownership unless the proportional entitlement to electric output is otherwise established by contractual arrangement.

"Available system capacity" means the capacity determined by subtracting the system load and the system emergency reserves from the net system capacity.

"Spinning reserve" means the sum of the unutilized net generating capability of all units of the electric utility company that are synchronized to the power distribution system and that are capable of immediately accepting

additional load. The electric generating capability of equipment under multiple ownership is prorated based on ownership unless the proportional entitlement to electric output is otherwise established by contractual arrangement.

"Available purchase power" means the lesser of the following:

(a) The sum of available system capacity in all neighboring companies.

(b) The sum of the rated capacities of the power interconnection devices between the principal company and all neighboring companies, minus the sum of the electric power load on these interconnections.

(c) The rated capacity of the power transmission lines between the power interconnection devices and the electric generating units (the unit in the principal company that has the malfunctioning flue gas desulfurization system and the unit(s) in the neighboring company supplying replacement electrical power) less the electric power load on these transmission lines.

"Spare flue gas desulfurization system module" means a separate system of sulfur dioxide emission control equipment capable of treating an amount of flue gas equal to the total amount of flue gas generated by an affected facility when operated at maximum capacity divided by the total number of nonspare flue gas desulfurization modules in the system.

"Emergency condition" means that period of time when:

(a) The electric generation output of an affected facility with a malfunctioning flue gas desulfurization system cannot be reduced or electrical output must be increased because:

(1) All available system capacity in the principal company interconnected with the affected facility is being operated, and

(2) All available purchase power interconnected with the affected facility is being obtained, or

(b) The electric generation demand is being shifted as quickly as possible from an affected facility with a malfunctioning flue gas desulfurization system to one or more electrical generating units held in reserve by the principal company or by a neighboring company, or

(c) An affected facility with a malfunctioning flue gas desulfurization system becomes the only available unit to maintain a part or all of the principal company's system emergency reserves and the unit is operated in spinning reserve at the lowest practical electric generation load consistent with not causing significant physical damage to

the unit. If the unit is operated at a higher load to meet load demand, an emergency condition would not exist unless the conditions under (a) of this definition apply.

"Electric utility combined cycle gas turbine" means any combined cycle gas turbine used for electric generation that is constructed for the purpose of supplying more than one-third of its potential electric output capacity and more than 25 MW electrical output to any utility power distribution system for sale. Any steam distribution system that is constructed for the purpose of providing steam to a steam electric generator that would produce electrical power for sale is also considered in determining the electrical energy output capacity of the affected facility.

"Potential electrical output capacity" is defined as 33 percent of the maximum design heat input capacity of the steam generating unit (e.g., a steam generating unit with a 100-MW (340 million Btu/hr) fossil-fuel heat input capacity would have a 33-MW potential electrical output capacity). For electric utility combined cycle gas turbines the potential electrical output capacity is determined on the basis of the fossil-fuel firing capacity of the steam generator exclusive of the heat input and electrical power contribution by the gas turbine.

"Anthracite" means coal that is classified as anthracite according to the American Society of Testing and Materials' (ASTM) Standard Specification for Classification of Coals by Rank D388-66.

"Solid-derived fuel" means any solid, liquid, or gaseous fuel derived from solid fuel for the purpose of creating useful heat and includes, but is not limited to, solvent refined coal, liquified coal, and gasified coal.

"24-hour period" means the period of time between 12:01 a.m. and 12:00 midnight.

"Resource recovery unit" means a facility that combusts more than 75 percent non-fossil fuel on a quarterly (calendar) heat input basis.

"Noncontinental area" means the State of Hawaii, the Virgin Islands, Guam, American Samoa, the Commonwealth of Puerto Rico, or the Northern Mariana Islands.

"Boiler operating day" means a 24-hour period during which fossil fuel is combusted in a steam generating unit for the entire 24 hours.

§ 60.42a Standard for particulate matter.

(a) On and after the date on which the performance test required to be conducted under § 60.8 is completed, no owner or operator subject to the

provisions of this subpart shall cause to be discharged into the atmosphere from any affected facility any gases which contain particulate matter in excess of:

(1) 13 ng/J (0.03 lb/million Btu) heat input derived from the combustion of solid, liquid, or gaseous fuel;

(2) 1 percent of the potential combustion concentration (99 percent reduction) when combusting solid fuel; and

(3) 30 percent of potential combustion concentration (70 percent reduction) when combusting liquid fuel.

(b) On and after the date the particulate matter performance test required to be conducted under § 60.8 is completed, no owner or operator subject to the provisions of this subpart shall cause to be discharged into the atmosphere from any affected facility any gases which exhibit greater than 20 percent opacity (6-minute average), except for one 6-minute period per hour of not more than 27 percent opacity.

§ 60.43a Standard for sulfur dioxide.

(a) On and after the date on which the initial performance test required to be conducted under § 60.8 is completed, no owner or operator subject to the provisions of this subpart shall cause to be discharged into the atmosphere from any affected facility which combusts solid fuel or solid-derived fuel, except as provided under paragraphs (c), (d), (f) or (h) of this section, any gases which contain sulfur dioxide in excess of:

(1) 520 ng/J (1.20 lb/million Btu) heat input and 10 percent of the potential combustion concentration (90 percent reduction), or

(2) 30 percent of the potential combustion concentration (70 percent reduction), when emissions are less than 260 ng/J (0.60 lb/million Btu) heat input.

(b) On and after the date on which the initial performance test required to be conducted under § 60.8 is completed, no owner or operator subject to the provisions of this subpart shall cause to be discharged into the atmosphere from any affected facility which combusts liquid or gaseous fuels (except for liquid or gaseous fuels derived from solid fuels and as provided under paragraphs (e) or (h) of this section), any gases which contain sulfur dioxide in excess of:

(1) 340 ng/J (0.80 lb/million Btu) heat input and 10 percent of the potential combustion concentration (90 percent reduction), or

(2) 100 percent of the potential combustion concentration (zero percent reduction) when emissions are less than 86 ng/J (0.20 lb/million Btu) heat input.

(c) On and after the date on which the initial performance test required to be

conducted under § 60.8 is complete, no owner or operator subject to the provisions of this subpart shall cause to be discharged into the atmosphere from any affected facility which combusts solid solvent refined coal (SRC-I) any gases which contain sulfur dioxide in excess of 520 ng/J (1.20 lb/million Btu) heat input and 15 percent of the potential combustion concentration (85 percent reduction) except as provided under paragraph (f) of this section; compliance with the emission limitation is determined on a 30-day rolling average basis and compliance with the percent reduction requirement is determined on a 24-hour basis.

(d) Sulfur dioxide emissions are limited to 520 ng/J (1.20 lb/million Btu) heat input from any affected facility which:

- (1) Combusts 100 percent anthracite,
- (2) Is classified as a resource recovery facility, or
- (3) Is located in a noncontinental area and combusts solid fuel or solid-derived fuel.

(e) Sulfur dioxide emissions are limited to 340 ng/J (0.80 lb/million Btu) heat input from any affected facility which is located in a noncontinental area and combusts liquid or gaseous fuels (excluding solid-derived fuels).

(f) The emission reduction requirements under this section do not apply to any affected facility that is operated under an SO₂ commercial demonstration permit issued by the Administrator in accordance with the provisions of § 60.45a.

(g) Compliance with the emission limitation and percent reduction requirements under this section are both determined on a 30-day rolling average basis except as provided under paragraph (c) of this section.

(h) When different fuels are combusted simultaneously, the applicable standard is determined by proration using the following formula:

(1) If emissions of sulfur dioxide to the atmosphere are greater than 260 ng/J (0.60 lb/million Btu) heat input

$$E_{SO_2} = [340x + 520y]/100 \text{ and } P_{SO_2} = 10 \text{ percent}$$

(2) If emissions of sulfur dioxide to the atmosphere are equal to or less than 260 ng/J (0.60 lb/million Btu) heat input:

$$E_{SO_2} = [340x + 520y]/100 \text{ and } P_{SO_2} = [90x + 70y]/100$$

where:

E_{SO_2} is the prorated sulfur dioxide emission limit (ng/J heat input),

P_{SO_2} is the percentage of potential sulfur dioxide emission allowed (percent reduction required = $100 - P_{SO_2}$),

x is the percentage of total heat input derived from the combustion of liquid or gaseous fuels (excluding solid-derived fuels)

y is the percentage of total heat input derived from the combustion of solid fuel (including solid-derived fuels)

§ 60.44a Standard for nitrogen oxides.

(a) On and after the date on which the initial performance test required to be conducted under § 60.8 is completed, no owner or operator subject to the provisions of this subpart shall cause to be discharged into the atmosphere from any affected facility, except as provided under paragraph (b) of this section, any gases which contain nitrogen oxides in excess of the following emission limits, based on a 30-day rolling average.

(1) NO_x Emission Limits—

Fuel type	Emission limit ng/J (lb/million Btu) heat input	
Gaseous Fuels:		
Coal-derived fuels	210	(0.50)
All other fuels	86	(0.20)
Liquid Fuels:		
Coal-derived fuels	210	(0.50)
Shale oil	210	(0.50)
All other fuels	130	(0.30)
Solid Fuels:		
Coal-derived fuels	210	(0.50)
Any fuel containing more than 25%, by weight, coal refuse ..	Exempt from NO _x standards and NO _x monitoring requirements	
Any fuel containing more than 25%, by weight, lignite if the lignite is mined in North Dakota, South Dakota, or Montana, and is combusted in a slag tap furnace	340	(0.80)
Lignite not subject to the 340 ng/J heat input emission limit	260	(0.60)
Subbituminous coal	210	(0.50)
Bituminous coal	260	(0.60)
Anthracite coal	260	(0.60)
All other fuels	260	(0.60)

(2) NO_x reduction requirements—

Fuel type	Percent reduction of potential combustion concentration
Gaseous fuels	25%
Liquid fuels	30%
Solid fuels	65%

(b) The emission limitations under paragraph (a) of this section do not apply to any affected facility which is combusting coal-derived liquid fuel and is operating under a commercial demonstration permit issued by the Administrator in accordance with the provisions of § 60.45a.

(c) When two or more fuels are combusted simultaneously, the applicable standard is determined by proration using the following formula:

$$E_{NO_x} = [86w + 130x + 210y + 260z]/100$$

where:

E_{NO_x} is the applicable standard for nitrogen oxides when multiple fuels are combusted simultaneously (ng/J heat input);

w is the percentage of total heat input derived from the combustion of fuels subject to the 86 ng/J heat input standard;

x is the percentage of total heat input derived from the combustion of fuels subject to the 130 ng/J heat input standard;

y is the percentage of total heat input derived from the combustion of fuels subject to the 210 ng/J heat input standard; and

z is the percentage of total heat input derived from the combustion of fuels subject to the 260 ng/J heat input standard.

§ 60.45a Commercial demonstration permit.

(a) An owner or operator of an affected facility proposing to demonstrate an emerging technology may apply to the Administrator for a commercial demonstration permit. The Administrator will issue a commercial demonstration permit in accordance with paragraph (e) of this section. Commercial demonstration permits may be issued only by the Administrator, and this authority will not be delegated.

(b) An owner or operator of an affected facility that combusts solid solvent refined coal (SRC-I) and who is issued a commercial demonstration permit by the Administrator is not subject to the SO₂ emission reduction requirements under § 60.43a(c) but must, as a minimum, reduce SO₂ emissions to 20 percent of the potential combustion concentration (80 percent reduction) for each 24-hour period of steam generator operation and to less than 520 ng/J (1.20 lb/million Btu) heat input on a 30-day rolling average basis.

(c) An owner or operator of a fluidized bed combustion electric utility steam generator (atmospheric or pressurized) who is issued a commercial demonstration permit by the Administrator is not subject to the SO₂ emission reduction requirements under § 60.43a(a) but must, as a minimum, reduce SO₂ emissions to 15 percent of the potential combustion concentration (85 percent reduction) on a 30-day rolling average basis and to less than 520 ng/J (1.20 lb/million Btu) heat input on a 30-day rolling average basis.

(d) The owner or operator of an affected facility that combusts coal-derived liquid fuel and who is issued a commercial demonstration permit by the Administrator is not subject to the applicable NO_x emission limitation and percent reduction under § 60.44a(a) but must, as a minimum, reduce emissions to less than 300 ng/J (0.70 lb/million Btu)

heat input on a 30-day rolling average basis.

(e) Commercial demonstration permits may not exceed the following equivalent MW electrical generation capacity for any one technology category, and the total equivalent MW electrical generation capacity for all commercial demonstration plants may not exceed 15,000 MW.

Technology	Pollutant	Equivalent electrical capacity (MW electrical output)
Solid solvent refined coal (SRC I).....	SO ₂	8,000-10,000
Fluidized bed combustion (atmospheric).....	SO ₂	400-3,000
Fluidized bed combustion (pressurized).....	SO ₂	400-1,200
Coal liquefaction.....	NO _x	750-10,000
Total allowable for all technologies.....		15,000

§ 60.46a Compliance provisions.

(a) Compliance with the particulate matter emission limitation under § 60.42a(1) constitutes compliance with the percent reduction requirements for particulate matter under § 60.42a(2) and (3).

(b) Compliance with the nitrogen oxides emission limitation under § 60.44a(a) constitutes compliance with the percent reduction requirements under § 60.44a(2).

(c) The particulate matter emission standards under § 60.42a and the nitrogen oxides emission standards under § 60.44a apply at all times except during periods of startup, shutdown, or malfunction. The sulfur dioxide emission standards under § 60.43a apply at all times except during periods of startup, shutdown, or when both emergency conditions exist and the procedures under paragraph (d) of this section are implemented.

(d) During emergency conditions in the principal company, an affected facility with a malfunctioning flue gas desulfurization system may be operated if sulfur dioxide emissions are minimized by:

(1) Operating all operable flue gas desulfurization system modules, and bringing back into operation any malfunctioned module as soon as repairs are completed.

(2) Bypassing flue gases around only those flue gas desulfurization system modules that have been taken out of operation because they were incapable of any sulfur dioxide emission reduction or which would have suffered significant physical damage if they had remained in operation, and

(3) Designing, constructing, and operating a spare flue gas desulfurization system module for an affected facility larger than 365 MW (1,250 million Btu/hr) heat input (approximately 125 MW electrical output capacity). The Administrator may at his discretion require the owner or operator within 60 days of notification to demonstrate spare module capability. To demonstrate this capability, the owner or operator must demonstrate compliance with the appropriate requirements under paragraph (a), (b), (d), (e), and (i) under § 60.43a for any period of operation lasting from 24 hours to 30 days when:

(i) Any one flue gas desulfurization module is not operated,

(ii) The affected facility is operating at the maximum heat input rate,

(iii) The fuel fired during the 24-hour to 30-day period is representative of the type and average sulfur content of fuel used over a typical 30-day period, and

(iv) The owner or operator has given the Administrator at least 30 days notice of the date and period of time over which the demonstration will be performed.

(e) After the initial performance test required under § 60.8, compliance with the sulfur dioxide emission limitations and percentage reduction requirements under § 60.43a and the nitrogen oxides emission limitations under § 60.44a is based on the average emission rate for 30 successive boiler operating days. A separate performance test is completed at the end of each boiler operating day after the initial performance test, and a new 30 day average emission rate for both sulfur dioxide and nitrogen oxides and a new percent reduction for sulfur dioxide are calculated to show compliance with the standards.

(f) For the initial performance test required under § 60.8, compliance with the sulfur dioxide emission limitations and percent reduction requirements under § 60.43a and the nitrogen oxides emission limitation under § 60.44a is based on the average emission rates for sulfur dioxide, nitrogen oxides, and percent reduction for sulfur dioxide for the first 30 successive boiler operating days. The initial performance test is the only test in which at least 30 days prior notice is required unless otherwise specified by the Administrator. The initial performance test is to be scheduled so that the first boiler operating day of the 30 successive boiler operating days is completed within 60 days after achieving the maximum production rate at which the affected facility will be operated, but not later

than 180 days after initial startup of the facility.

(g) Compliance is determined by calculating the arithmetic average of all hourly emission rates for SO₂ and NO_x for the 30 successive boiler operating days, except for data obtained during startup, shutdown, malfunction (NO_x only), or emergency conditions (SO₂ only). Compliance with the percentage reduction requirement for SO₂ is determined based on the average inlet and average outlet SO₂ emission rates for the 30 successive boiler operating days.

(h) If an owner or operator has not obtained the minimum quantity of emission data as required under § 60.47a of this subpart, compliance of the affected facility with the emission requirements under §§ 60.43a and 60.44a of this subpart for the day on which the 30-day period ends may be determined by the Administrator by following the applicable procedures in sections 6.0 and 7.0 of Reference Method 19 (Appendix A).

§ 60.47a Emission monitoring.

(a) The owner or operator of an affected facility shall install, calibrate, maintain, and operate a continuous monitoring system, and record the output of the system, for measuring the opacity of emissions discharged to the atmosphere, except where gaseous fuel is the only fuel combusted. If opacity interference due to water droplets exists in the stack (for example, from the use of an FGD system), the opacity is monitored upstream of the interference (at the inlet to the FGD system). If opacity interference is experienced at all locations (both at the inlet and outlet of the sulfur dioxide control system), alternate parameters indicative of the particulate matter control system's performance are monitored (subject to the approval of the Administrator).

(b) The owner or operator of an affected facility shall install, calibrate, maintain, and operate a continuous monitoring system, and record the output of the system, for measuring sulfur dioxide emissions, except where natural gas is the only fuel combusted, as follows:

(1) Sulfur dioxide emissions are monitored at both the inlet and outlet of the sulfur dioxide control device.

(2) For a facility which qualifies under the provisions of § 60.43a(d), sulfur dioxide emissions are only monitored as discharged to the atmosphere.

(3) An "as fired" fuel monitoring system (upstream of coal pulverizers) meeting the requirements of Method 19 (Appendix A) may be used to determine

potential sulfur dioxide emissions in place of a continuous sulfur dioxide emission monitor at the inlet to the sulfur dioxide control device as required under paragraph (b)(1) of this section.

(c) The owner or operator of an affected facility shall install, calibrate, maintain, and operate a continuous monitoring system, and record the output of the system, for measuring nitrogen oxides emissions discharged to the atmosphere.

(d) The owner or operator of an affected facility shall install, calibrate, maintain, and operate a continuous monitoring system, and record the output of the system, for measuring the oxygen or carbon dioxide content of the flue gases at each location where sulfur dioxide or nitrogen oxides emissions are monitored.

(e) The continuous monitoring systems under paragraphs (b), (c), and (d) of this section are operated and data recorded during all periods of operation of the affected facility including periods of startup, shutdown, malfunction or emergency conditions, except for continuous monitoring system breakdowns, repairs, calibration checks, and zero and span adjustments.

(f) When emission data are not obtained because of continuous monitoring system breakdowns, repairs, calibration checks and zero and span adjustments, emission data will be obtained by using other monitoring systems as approved by the Administrator or the reference methods as described in paragraph (h) of this section to provide emission data for a minimum of 18 hours in at least 22 out of 30 successive boiler operating days.

(g) The 1-hour averages required under paragraph § 60.13(h) are expressed in ng/J (lbs/million Btu) heat input and used to calculate the average emission rates under § 60.46a. The 1-hour averages are calculated using the data points required under § 60.13(b). At least two data points must be used to calculate the 1-hour averages.

(h) Reference methods used to supplement continuous monitoring system data to meet the minimum data requirements in paragraph § 60.47a(f) will be used as specified below or otherwise approved by the Administrator.

(1) Reference Methods 3, 6, and 7, as applicable, are used. The sampling location(s) are the same as those used for the continuous monitoring system.

(2) For Method 6, the minimum sampling time is 20 minutes and the minimum sampling volume is 0.02 dscm (0.71 dscf) for each sample. Samples are taken at approximately 60-minute

intervals. Each sample represents a 1-hour average.

(3) For Method 7, samples are taken at approximately 30-minute intervals. The arithmetic average of these two consecutive samples represent a 1-hour average.

(4) For Method 3, the oxygen or carbon dioxide sample is to be taken for each hour when continuous SO₂ and NO_x data are taken or when Methods 6 and 7 are required. Each sample shall be taken for a minimum of 30 minutes in each hour using the integrated bag method specified in Method 3. Each sample represents a 1-hour average.

(5) For each 1-hour average, the emissions expressed in ng/J (lb/million Btu) heat input are determined and used as needed to achieve the minimum data requirements of paragraph (f) of this section.

(i) The following procedures are used to conduct monitoring system performance evaluations under § 60.13(c) and calibration checks under § 60.13(d).

(1) Reference method 6 or 7, as applicable, is used for conducting performance evaluations of sulfur dioxide and nitrogen oxides continuous monitoring systems.

(2) Sulfur dioxide or nitrogen oxides, as applicable, is used for preparing calibration gas mixtures under performance specification 2 of appendix B to this part.

(3) For affected facilities burning only fossil fuel, the span value for a continuous monitoring system for measuring opacity is between 60 and 80 percent and for a continuous monitoring system measuring nitrogen oxides is determined as follows:

Fossil fuel	Span value for nitrogen oxides (ppm)
Gas.....	500
Liquid.....	500
Solid.....	1,000
Combination.....	500 (x + y) + 1,000z

where:

x is the fraction of total heat input derived from gaseous fossil fuel,

y is the fraction of total heat input derived from liquid fossil fuel, and

z is the fraction of total heat input derived from solid fossil fuel.

(4) All span values computed under paragraph (b)(3) of this section for burning combinations of fossil fuels are rounded to the nearest 500 ppm.

(5) For affected facilities burning fossil fuel, alone or in combination with non-fossil fuel, the span value of the sulfur dioxide continuous monitoring system at the inlet to the sulfur dioxide control

device is 125 percent of the maximum estimated hourly potential emissions of the fuel fired, and the outlet of the sulfur dioxide control device is 50 percent of maximum estimated hourly potential emissions of the fuel fired.

(Sec. 114, Clean Air Act as amended (42 U.S.C. 7414).)

§ 60.48a Compliance determination procedures and methods.

(a) The following procedures and reference methods are used to determine compliance with the standards for particulate matter under § 60.42a.

(1) Method 3 is used for gas analysis when applying method 5 or method 17.

(2) Method 5 is used for determining particulate matter emissions and associated moisture content. Method 17 may be used for stack gas temperatures less than 180°C (320°F).

(3) For Methods 5 or 17, Method 1 is used to select the sampling site and the number of traverse sampling points. The sampling time for each run is at least 120 minutes and the minimum sampling volume is 1.7 dscm (60 dscf) except that smaller sampling times or volumes, when necessitated by process variables or other factors, may be approved by the Administrator.

(4) For Method 5, the probe and filter holder heating system in the sampling train is set to provide a gas temperature no greater than 180°C (32°F).

(5) For determination of particulate emissions, the oxygen or carbon-dioxide sample is obtained simultaneously with each run of Methods 5 or 17 by traversing the duct at the same sampling location. Method 1 is used for selection of the number of traverse points except that no more than 12 sample points are required.

(6) For each run using Methods 5 or 17, the emission rate expressed in ng/J heat input is determined using the oxygen or carbon-dioxide measurements and particulate matter measurements obtained under this section, the dry basis F_c-factor and the dry basis emission rate calculation procedure contained in Method 19 (Appendix A).

(7) Prior to the Administrator's issuance of a particulate matter reference method that does not experience sulfuric acid mist interference problems, particulate matter emissions may be sampled prior to a wet flue gas desulfurization system.

(b) The following procedures and methods are used to determine compliance with the sulfur dioxide standards under § 60.43a.

(1) Determine the percent of potential combustion concentration (percent PCC) emitted to the atmosphere as follows:

(i) Fuel Pretreatment (% R_f):

Determine the percent reduction achieved by any fuel pretreatment using the procedures in Method 19 (Appendix A). Calculate the average percent reduction for fuel pretreatment on a quarterly basis using fuel analysis data. The determination of percent R_f to calculate the percent of potential combustion concentration emitted to the atmosphere is optional. For purposes of determining compliance with any percent reduction requirements under § 60.43a, any reduction in potential SO_2 emissions resulting from the following processes may be credited:

- (A) Fuel pretreatment (physical coal cleaning, hydrosulfurization of fuel oil, etc.),
- (B) Coal pulverizers, and
- (C) Bottom and flyash interactions.

(ii) Sulfur Dioxide Control System (% R_s): Determine the percent sulfur dioxide reduction achieved by any sulfur dioxide control system using emission rates measured before and after the control system, following the procedures in Method 19 (Appendix A); or, a combination of an "as fired" fuel monitor and emission rates measured after the control system, following the procedures in Method 19 (Appendix A). When the "as fired" fuel monitor is used, the percent reduction is calculated using the average emission rate from the sulfur dioxide control device and the average SO_2 input rate from the "as fired" fuel analysis for 30 successive boiler operating days.

(iii) Overall percent reduction (% R_o): Determine the overall percent reduction using the results obtained in paragraphs (b)(1) (i) and (ii) of this section following the procedures in Method 19 (Appendix A). Results are calculated for each 30-day period using the quarterly average percent sulfur reduction determined for fuel pretreatment from the previous quarter and the sulfur dioxide reduction achieved by a sulfur dioxide control system for each 30-day period in the current quarter.

(iv) Percent emitted (% PCC): Calculate the percent of potential combustion concentration emitted to the atmosphere using the following equation: $\text{Percent } PCC = 100 - \text{Percent } R_o$.

(2) Determine the sulfur dioxide emission rates following the procedures in Method 19 (Appendix A).

(c) The procedures and methods outlined in Method 19 (Appendix A) are used in conjunction with the 30-day nitrogen-oxides emission data collected under § 60.47a to determine compliance with the applicable nitrogen oxides standard under § 60.44.

(d) Electric utility combined cycle gas turbines are performance tested for particulate matter, sulfur dioxide, and nitrogen oxides using the procedures of Method 19 (Appendix A). The sulfur dioxide and nitrogen oxides emission rates from the gas turbine used in Method 19 (Appendix A) calculations are determined when the gas turbine is performance tested under subpart GG. The potential uncontrolled particulate matter emission rate from a gas turbine is defined as 17 ng/j (0.04 lb/million Btu) heat input.

§ 60.49a Reporting requirements.

(a) For sulfur dioxide, nitrogen oxides, and particulate matter emissions, the performance test data from the initial performance test and from the performance evaluation of the continuous monitors (including the transmissometer) are submitted to the Administrator.

(b) For sulfur dioxide and nitrogen oxides the following information is reported to the Administrator for each 24-hour period.

(1) Calendar date.

(2) The average sulfur dioxide and nitrogen oxide emission rates (ng/j or lb/million Btu) for each 30 successive boiler operating days, ending with the last 30-day period in the quarter; reasons for non-compliance with the emission standards; and, description of corrective actions taken.

(3) Percent reduction of the potential combustion concentration of sulfur dioxide for each 30 successive boiler operating days, ending with the last 30-day period in the quarter; reasons for non-compliance with the standard; and, description of corrective actions taken.

(4) Identification of the boiler operating days for which pollutant or diluent data have not been obtained by an approved method for at least 18 hours of operation of the facility; justification for not obtaining sufficient data; and description of corrective actions taken.

(5) Identification of the times when emissions data have been excluded from the calculation of average emission rates because of startup, shutdown, malfunction (NO_x only), emergency conditions (SO_2 only), or other reasons, and justification for excluding data for reasons other than startup, shutdown, malfunction, or emergency conditions.

(6) Identification of "F" factor used for calculations, method of determination, and type of fuel combusted.

(7) Identification of times when hourly averages have been obtained based on manual sampling methods.

(8) Identification of the times when the pollutant concentration exceeded full span of the continuous monitoring system.

(9) Description of any modifications to the continuous monitoring system which could affect the ability of the continuous monitoring system to comply with Performance Specifications 2 or 3.

(c) If the minimum quantity of emission data as required by § 60.47a is not obtained for any 30 successive boiler operating days, the following information obtained under the requirements of § 60.46a(h) is reported to the Administrator for that 30-day period:

(1) The number of hourly averages available for outlet emission rates (n_o) and inlet emission rates (n_i) as applicable.

(2) The standard deviation of hourly averages for outlet emission rates (s_o) and inlet emission rates (s_i) as applicable.

(3) The lower confidence limit for the mean outlet emission rate (E_o^*) and the upper confidence limit for the mean inlet emission rate (E_i^*) as applicable.

(4) The applicable potential combustion concentration.

(5) The ratio of the upper confidence limit for the mean outlet emission rate (E_o^*) and the allowable emission rate (E_{ald}) as applicable.

(d) If any standards under § 60.43a are exceeded during emergency conditions because of control system malfunction, the owner or operator of the affected facility shall submit a signed statement:

(1) Indicating if emergency conditions existed and requirements under § 60.46a(d) were met during each period, and

(2) Listing the following information:
(i) Time periods the emergency condition existed;

(ii) Electrical output and demand on the owner or operator's electric utility system and the affected facility;

(iii) Amount of power purchased from interconnected neighboring utility companies during the emergency period;

(iv) Percent reduction in emissions achieved;

(v) Atmospheric emission rate (ng/j) of the pollutant discharged; and

(vi) Actions taken to correct control system malfunction.

(e) If fuel pretreatment credit toward the sulfur dioxide emission standard under § 60.43a is claimed, the owner or operator of the affected facility shall submit a signed statement:

(1) Indicating what percentage cleaning credit was taken for the calendar quarter, and whether the credit was determined in accordance with the

provisions of § 60.48a and Method 19 (Appendix A); and

(2) Listing the quantity, heat content, and date each pretreated fuel shipment was received during the previous quarter; the name and location of the fuel pretreatment facility; and the total quantity and total heat content of all fuels received at the affected facility during the previous quarter.

(f) For any periods for which opacity, sulfur dioxide or nitrogen oxides emissions data are not available, the owner or operator of the affected facility shall submit a signed statement indicating if any changes were made in operation of the emission control system during the period of data unavailability. Operations of the control system and affected facility during periods of data unavailability are to be compared with operation of the control system and affected facility before and following the period of data unavailability.

(g) The owner or operator of the affected facility shall submit a signed statement indicating whether:

(1) The required continuous monitoring system calibration, span, and drift checks or other periodic audits have or have not been performed as specified.

(2) The data used to show compliance was or was not obtained in accordance with approved methods and procedures of this part and is representative of plant performance.

(3) The minimum data requirements have or have not been met; or, the minimum data requirements have not been met for errors that were unavoidable.

(4) Compliance with the standards has or has not been achieved during the reporting period.

(h) For the purposes of the reports required under § 60.7, periods of excess emissions are defined as all 8-minute periods during which the average opacity exceeds the applicable opacity standards under § 60.42a(b). Opacity levels in excess of the applicable opacity standard and the date of such excesses are to be submitted to the Administrator each calendar quarter.

(i) The owner or operator of an affected facility shall submit the written reports required under this section and subpart A to the Administrator for every calendar quarter. All quarterly reports shall be postmarked by the 30th day following the end of each calendar quarter.

(Sec. 114, Clean Air Act as amended (42 U.S.C. 7414).)

4. Appendix A to part 60 is amended by adding new reference Method 19 as follows:

Appendix A—Reference Methods

Method 19. Determination of Sulfur Dioxide Removal Efficiency and Particulate, Sulfur Dioxide and Nitrogen Oxides Emission Rates From Electric Utility Steam Generators

1. Principle and Applicability

1.1 Principle.

1.1.1 Fuel samples from before and after fuel pretreatment systems are collected and analyzed for sulfur and heat content, and the percent sulfur dioxide (ng/joule, lb/million Btu) reduction is calculated on a dry basis. (Optional Procedure.)

1.1.2 Sulfur dioxide and oxygen or carbon dioxide concentration data obtained from sampling emissions upstream and downstream of sulfur dioxide control devices are used to calculate sulfur dioxide removal efficiencies. (Minimum Requirement.) As an alternative to sulfur dioxide monitoring upstream of sulfur dioxide control devices, fuel samples may be collected in an as-fired condition and analyzed for sulfur and heat content. (Optional Procedure.)

1.1.3 An overall sulfur dioxide emission reduction efficiency is calculated from the efficiency of fuel pretreatment systems and the efficiency of sulfur dioxide control devices.

1.1.4 Particulate, sulfur dioxide, nitrogen oxides, and oxygen or carbon dioxide concentration data obtained from sampling emissions downstream from sulfur dioxide control devices are used along with F factors to calculate particulate, sulfur dioxide, and nitrogen oxides emission rates. F factors are values relating combustion gas volume to the heat content of fuels.

1.2 *Applicability.* This method is applicable for determining sulfur removal efficiencies of fuel pretreatment and sulfur dioxide control devices and the overall reduction of potential sulfur dioxide emissions from electric utility steam generators. This method is also applicable for the determination of particulate, sulfur dioxide, and nitrogen oxides emission rates.

2. Determination of Sulfur Dioxide Removal Efficiency of Fuel Pretreatment Systems

2.1 Solid Fossil Fuel.

2.1.1 *Sample Increment Collection.* Use ASTM D 2234¹, Type I, conditions

¹ Use the most recent revision or designation of the ASTM procedure specified.

A, B, or C, and systematic spacing. Determine the number and weight of increments required per gross sample representing each coal lot according to Table 2 or Paragraph 7.1.5.2 of ASTM D 2234¹. Collect one gross sample for each raw coal lot and one gross sample for each product coal lot.

2.1.2 *ASTM Lot Size.* For the purpose of Section 2.1.1, the product coal lot size is defined as the weight of product coal produced from one type of raw coal. The raw coal lot size is the weight of raw coal used to produce one product coal lot. Typically, the lot size is the weight of coal processed in a 1-day (24 hours) period. If more than one type of coal is treated and produced in 1 day, then gross samples must be collected and analyzed for each type of coal. A coal lot size equaling the 90-day quarterly fuel quantity for a specific power plant may be used if representative sampling can be conducted for the raw coal and product coal.

Note.—Alternate definitions of fuel lot sizes may be specified subject to prior approval of the Administrator.

2.1.3 *Gross Sample Analysis.* Determine the percent sulfur content (%S) and gross calorific value (GCV) of the solid fuel on a dry basis for each gross sample. Use ASTM 2013¹ for sample preparation, ASTM D 3177¹ for sulfur analysis, and ASTM D 3173¹ for moisture analysis. Use ASTM D 3176¹ for gross calorific value determination.

2.2 Liquid Fossil Fuel.

2.2.1 *Sample Collection.* Use ASTM D 270¹ following the practices outlined for continuous sampling for each gross sample representing each fuel lot.

2.2.2 *Lot Size.* For the purposes of Section 2.2.1, the weight of product fuel from one pretreatment facility and intended as one shipment (ship load, barge load, etc.) is defined as one product fuel lot. The weight of each crude liquid fuel type used to produce one product fuel lot is defined as one inlet fuel lot.

Note.—Alternate definitions of fuel lot sizes may be specified subject to prior approval of the Administrator.

Note.—For the purposes of this method, raw or inlet fuel (coal or oil) is defined as the fuel delivered to the desulfurization pretreatment facility or to the steam generating plant. For pretreated oil the input oil to the oil desulfurization process (e.g. hydrotreatment emitted) is sampled.

2.2.3 *Sample Analysis.* Determine the percent sulfur content (%S) and gross calorific value (GCV). Use ASTM D 240¹ for the sample analysis. This value can be assumed to be on a dry basis.

¹ Use the most recent revision or designation of the ASTM procedure specified.

2.3 Calculation of Sulfur Dioxide Removal Efficiency Due to Fuel Pretreatment. Calculate the percent sulfur dioxide reduction due to fuel pretreatment using the following equation:

$$\%R_f = 100 \left[1 - \frac{\%S_o/GCV_o}{\%S_i/GCV_i} \right]$$

Where:

$\%R_f$ = Sulfur dioxide removal efficiency due to pretreatment; percent.

$\%S_o$ = Sulfur content of the product fuel lot on a dry basis; weight percent.

$\%S_i$ = Sulfur content of the inlet fuel lot on a dry basis; weight percent.

GCV_o = Gross calorific value for the outlet fuel lot on a dry basis; kJ/kg (Btu/lb).

GCV_i = Gross calorific value for the inlet fuel lot on a dry basis; kJ/kg (Btu/lb).

Note.—If more than one fuel type is used to produce the product fuel, use the following equation to calculate the sulfur contents per unit of heat content of the total fuel lot, $\%S/GCV$:

$$\%S/GCV = \sum_{k=1}^n Y_k (\%S_k/GCV_k)$$

Where:

Y_k = The fraction of total mass input derived from each type, k, of fuel.

$\%S_k$ = Sulfur content of each fuel type, k, on a dry basis; weight percent.

GCV_k = Gross calorific value for each fuel type, k, on a dry basis; kJ/kg (Btu/lb).

n = The number of different types of fuels.

3. Determination of Sulfur Removal Efficiency of the Sulfur Dioxide Control Device

3.1 Sampling. Determine SO_2 emission rates at the inlet and outlet of the sulfur dioxide control system according to methods specified in the applicable subpart of the regulations and the procedures specified in Section 5. The inlet sulfur dioxide emission rate may be determined through fuel analysis (Optional, see Section 3.3.)

3.2 Calculation. Calculate the percent removal efficiency using the following equation:

$$\%R_{g(m)} = 100 \times \left(1.0 - \frac{E_{SO_2o}}{E_{SO_2i}} \right)$$

Where:

$\%R_g$ = Sulfur dioxide removal efficiency of the sulfur dioxide control system using inlet and outlet monitoring data; percent.

E_{soo} = Sulfur dioxide emission rate from the outlet of the sulfur dioxide control system; ng/J (lb/million Btu).

E_{soi} = Sulfur dioxide emission rate to the outlet of the sulfur dioxide control system; ng/J (lb/million Btu).

3.3 As-fired Fuel Analysis (Optional Procedure). If the owner or operator of an electric utility steam generator chooses to determine the sulfur dioxide input rate at the inlet to the sulfur dioxide control device through an as-fired fuel analysis in lieu of data from a sulfur dioxide control system inlet gas monitor, fuel samples must be collected in accordance with applicable

paragraph in Section 2. The sampling can be conducted upstream of any fuel processing, e.g., plant coal pulverization. For the purposes of this section, a fuel lot size is defined as the weight of fuel consumed in 1 day (24 hours) and is directly related to the exhaust gas monitoring data at the outlet of the sulfur dioxide control system.

3.3.1 Fuel Analysis. Fuel samples must be analyzed for sulfur content and gross calorific value. The ASTM procedures for determining sulfur content are defined in the applicable paragraphs of Section 2.

3.3.2 Calculation of Sulfur Dioxide Input Rate. The sulfur dioxide input rate determined from fuel analysis is calculated by:

$$I_s = \frac{2.0(\%S_f)}{GCV} \times 10^7 \text{ for S. I. units.}$$

$$I_s = \frac{2.0(\%S_f)}{GCV} \times 10^4 \text{ for English units.}$$

Where:

I_s = Sulfur dioxide input rate from as-fired fuel analysis, ng/J (lb/million Btu).

$\%S_f$ = Sulfur content of as-fired fuel, on a dry basis; weight percent.

GCV = Gross calorific value for as-fired fuel, on a dry basis; kJ/kg (Btu/lb).

3.3.3 Calculation of Sulfur Dioxide Emission Reduction Using As-fired Fuel Analysis. The sulfur dioxide emission reduction efficiency is calculated using the sulfur input rate from paragraph

3.3.2 and the sulfur dioxide emission rate, E_{soi} , determined in the applicable paragraph of Section 5.3. The equation for sulfur dioxide emission reduction efficiency is:

$$\%R_{g(f)} = 100 \times \left(1.0 - \frac{E_{SO_2o}}{I_s} \right)$$

Where:

$\%R_{g(f)}$ = Sulfur dioxide removal efficiency of the sulfur dioxide control system using as-fired fuel analysis data; percent.

E_{SO_2} = Sulfur dioxide emission rate from sulfur dioxide control system; ng/J (lb/million Btu).

I_s = Sulfur dioxide input rate from as-fired fuel analysis; ng/J (lb/million Btu).

4. Calculation of Overall Reduction in Potential Sulfur Dioxide Emission

4.1 The overall percent sulfur dioxide reduction calculation uses the sulfur dioxide concentration at the inlet to the sulfur dioxide control device as

$$\%R_o = 100[1.0 - (1.0 - \frac{\%R_f}{100})(1.0 - \frac{\%R_g}{100})]$$

Where:

$\%R_o$ = Overall sulfur dioxide reduction; percent.

$\%R_f$ = Sulfur dioxide removal efficiency of fuel pretreatment from Section 2; percent. Refer to applicable subpart for definition of applicable averaging period.

$\%R_g$ = Sulfur dioxide removal efficiency of sulfur dioxide control device either O_2 or CO_2 - based calculation or calculated from fuel analysis and emission data, from Section 3; percent. Refer to applicable subpart for definition of applicable averaging period.

5. Calculation of Particulate, Sulfur Dioxide, and Nitrogen Oxides Emission Rates

5.1 *Sampling.* Use the outlet SO_2 or O_2 or CO_2 concentrations data obtained in Section 3.1. Determine the particulate, NO_x , and O_2 or CO_2 concentrations according to methods specified in an applicable subpart of the regulations.

5.2 *Determination of an F Factor.* Select an average F factor (Section 5.2.1) or calculate an applicable F factor (Section 5.2.2). If combined fuels are fired, the selected or calculated F factors are prorated using the procedures in Section 5.2.3. F factors are ratios of the gas volume released during combustion of a fuel divided by the heat content of the fuel. A dry F factor (F_d) is the ratio of the volume of dry flue gases generated to the calorific value of the fuel combusted; a wet F factor (F_w) is the ratio of the volume of wet flue gases generated to the calorific value of the fuel combusted; and the carbon F factor (F_c) is the ratio of the volume of carbon dioxide generated to the calorific value of the fuel combusted. When pollutant

the base value. Any sulfur reduction realized through fuel cleaning is introduced into the equation as an average percent reduction, $\%R_f$.

4.2 Calculate the overall percent sulfur reduction as:

and oxygen concentrations have been determined in Section 5.1, wet or dry F factors are used. (F_w) factors and associated emission calculation procedures are not applicable and may not be used after wet scrubbers; (F_c) or (F_d) factors and associated emission calculation procedures are used after wet scrubbers.) When pollutant and carbon dioxide concentrations have been determined in Section 5.1, F_c factors are used.

5.2.1 *Average F Factors.* Table 1 shows average F_d , F_w , and F_c factors (scm/l, scf/million Btu) determined for commonly used fuels. For fuels not listed in Table 1, the F factors are calculated according to the procedures outlined in Section 5.2.2 of this section.

5.2.2 *Calculating an F Factor.* If the fuel burned is not listed in Table 1 or if the owner or operator chooses to determine an F factor rather than use the tabulated data, F factors are calculated using the equations below. The sampling and analysis procedures followed in obtaining data for these calculations are subject to the approval of the Administrator and the Administrator should be consulted prior to data collection.

For SI Units:

$$F_d = \frac{227.0(\%H) + 95.7(\%C) + 35.4(\%S) + 8.6(\%N) - 28.5(\%O)}{GCV}$$

$$F_w = \frac{347.4(\%H) + 95.7(\%C) + 35.4(\%S) + 8.6(\%N) - 28.5(\%O) + 13.0(\%H_2O)^{**}}{GCV_w}$$

$$F_c = \frac{20.0(\%C)}{GCV}$$

For English Units:

$$F_d = \frac{10^6[5.57(\%H) + 1.53(\%C) + 0.57(\%S) + 0.14(\%N) - 0.46(\%O)]}{GCV}$$

$$F_w = \frac{10^6[5.57(\%H) + 1.53(\%C) + 0.57(\%S) + 0.14(\%N) - 0.46(\%O) + 0.21(\%H_2O)^{**}]}{GCV_w}$$

$$F_c = \frac{10^6[0.321(\%C)]}{GCV}$$

** The H_2O term may be omitted if $\%H$ and $\%O$ include the unavailable hydrogen and oxygen in the form of H_2O .

Where:

F_w , F_c , and F_d have the units of scfm/lb, or scf/million Btu; %H, %C, %S, %N, %O, and %H₂O are the concentrations by weight (expressed in percent) of hydrogen, carbon, sulfur, nitrogen, oxygen, and water from an ultimate analysis of the fuel; and GCV is the gross calorific value of the fuel in kJ/kg or Btu/lb and consistent with the ultimate analysis. Follow ASTM D 2015* for solid fuels, D 240* for liquid fuels, and D 1826* for gaseous fuels as applicable in determining GCV.

5.2.3 Combined Fuel Firing F Factor. For affected facilities firing combinations of fossil fuels or fossil fuels and wood residue, the F_d , F_w , or F_c factors determined by Sections 5.2.1 or 5.2.2 of this section shall be prorated in accordance with applicable formula as follows:

$$F_d = \sum_{k=1}^n x_k F_{dk} \quad \text{or}$$

$$F_w = \sum_{k=1}^n x_k F_{wk} \quad \text{or}$$

$$F_c = \sum_{k=1}^n x_k F_{ck}$$

Where:

x_k = The fraction of total heat input derived from each type of fuel, K.

n = The number of fuels being burned in combination.

5.3 Calculation of Emission Rate. Select from the following paragraphs the applicable calculation procedure and calculate the particulate, SO₂, and NO_x emission rate. The values in the equations are defined as:

E = Pollutant emission rate, ng/lb (million Btu).

C = Pollutant concentration, ng/scm (lb/scf).

Note.—It is necessary in some cases to convert measured concentration units to other units for these calculations.

Use the following table for such conversions:

Conversion Factors for Concentration

From—	To—	Multiply by—
g/scm	ng/scm	10 ⁹
mg/scm	ng/scm	10 ⁶
lb/scf	ng/scm	1.002 × 10 ¹⁰
ppm(SO ₂)	ng/scm	2.660 × 10 ⁶
ppm(NO _x)	ng/scm	1.912 × 10 ⁶
ppm/(SO ₂)	lb/scf	1.660 × 10 ⁻⁷
ppm/(NO _x)	lb/scf	1.194 × 10 ⁻⁷

5.3.1 Oxygen-Based F Factor Procedure.

5.3.1.1 Dry Basis. When both percent oxygen (%O_{2d}) and the pollutant concentration (C_d) are measured in the flue gas on a dry basis, the following equation is applicable:

$$E = C_d F_d \left[\frac{20.9}{20.9 - \%O_{2d}} \right]$$

5.3.1.2 Wet Basis. When both the percent oxygen (%O_{2w}) and the pollutant concentration (C_w) are measured in the flue gas on a wet basis, the following equations are applicable: (Note: F_w factors are not applicable after wet scrubbers.)

$$(a) \quad E = C_w F_w \left[\frac{20.9}{20.9(1 - B_{ws}) - \%O_{2w}} \right]$$

Where:

B_{ws} = Proportion by volume of water vapor in the ambient air.

In lieu of actual measurement, B_{ws} may be estimated as follows:

Note.—The following estimating factors are selected to assure that any negative error introduced in the term:

$$\left(\frac{20.9}{20.9(1 - B_{ws}) - \%O_{2ws}} \right)$$

will not be larger than -1.5 percent. However, positive errors, or over-estimation of emissions, of as much as 5 percent may be introduced depending upon the geographic location of the facility and the associated range of ambient moisture.

(i) $B_{ws} = 0.027$. This factor may be used as a constant value at any location.

(ii) B_{ws} = Highest monthly average of B_{ws} which occurred within a calendar year at the nearest Weather Service Station.

(iii) B_{ws} = Highest daily average of B_{ws} which occurred within a calendar month at the nearest Weather Service Station, calculated from the data for the past 3 years. This factor shall be calculated for each month and may be used as an estimating factor for the respective calendar month.

$$(b) \quad E = C_w F_d \left[\frac{20.9}{20.9(1 - B_{ws}) - \%O_{2w}} \right]$$

Where:

B_{ws} = Proportion by volume of water vapor in the stack gas.

5.3.1.3 Dry/Wet Basis. When the pollutant concentration (C_w) is measured on a wet basis and the oxygen concentration (%O_{2d}) or measured on a dry basis, the following equation is applicable:

$$E = \left[\frac{C_w F_d}{(1 - B_{ws})} \right] \left[\frac{20.9}{20.9 - \%O_{2d}} \right]$$

When the pollutant concentration (C_d) is measured on a dry basis and the oxygen concentration (%O_{2d}) is measured on a wet basis, the following equation is applicable:

$$E = C_d F_d \left[\frac{20.9}{20.9 - (\%O_{2w} - B_{ws})} \right]$$

5.3.2 Carbon Dioxide-Based F Factor Procedure.

5.3.2.1 Dry Basis. When both the percent carbon dioxide (%CO_{2d}) and the pollutant concentration (C_d) are measured in the flue gas on a dry basis, the following equation is applicable:

$$E = C_d F_c \left(\frac{100}{\%CO_{2d}} \right)$$

5.3.2.2 Wet Basis. When both the percent carbon dioxide (%CO_{2w}) and the pollutant concentration (C_w) are measured on a wet basis, the following equation is applicable:

$$E = C_w F_c \left(\frac{100}{\%CO_{2w}} \right)$$

5.3.2.3 Dry/Wet Basis. When the pollutant concentration (C_w) is measured on a wet basis and the percent carbon dioxide (%CO_{2d}) is measured on a dry basis, the following equation is applicable:

$$E = \left[\frac{C_w F_c}{(1 - B_{ws})} \right] \left[\frac{100}{\%CO_{2d}} \right]$$

When the pollutant concentration (C_d) is measured on a dry basis and the percent carbon dioxide (%CO_{2w}) is measured on a wet basis, the following equation is applicable:

$$E = C_d (1 - B_{ws}) F_c \left(\frac{100}{\%CO_{2w}} \right)$$

5.4 Calculation of Emission Rate from Combined Cycle-Gas Turbine Systems. For gas turbine-steam generator combined cycle systems, the emissions from supplemental fuel fired to the steam generator or the percentage reduction in potential (SO₂) emissions cannot be determined directly. Using measurements from the gas turbine exhaust (performance test, subpart GG) and the combined exhaust gases from the steam generator, calculate the emission rates for these two points following the appropriate paragraphs in Section 5.3.

Note.— F_w factors shall not be used to determine emission rates from gas turbines because of the injection of steam nor to calculate emission rates after wet scrubbers; F_d or F_c factor and associated calculation procedures are used to combine effluent emissions according to the procedure in Paragraph 5.2.3.

The emission rate from the steam generator is calculated as:

4. Calculation of Overall Reduction in Potential Sulfur Dioxide Emission

4.1 The overall percent sulfur dioxide reduction calculation uses the sulfur dioxide concentration at the inlet to the sulfur dioxide control device as

$$\%R_o = 100[1.0 - (1.0 - \frac{\%R_f}{100})(1.0 - \frac{\%R_g}{100})]$$

Where:

$\%R_o$ = Overall sulfur dioxide reduction; percent.

$\%R_f$ = Sulfur dioxide removal efficiency of fuel pretreatment from Section 2; percent. Refer to applicable subpart for definition of applicable averaging period.

$\%R_g$ = Sulfur dioxide removal efficiency of sulfur dioxide control device either O_2 or CO_2 - based calculation or calculated from fuel analysis and emission data, from Section 3; percent. Refer to applicable subpart for definition of applicable averaging period.

5. Calculation of Particulate, Sulfur Dioxide, and Nitrogen Oxides Emission Rates

5.1 *Sampling.* Use the outlet SO_2 or O_2 or CO_2 concentrations data obtained in Section 3.1. Determine the particulate, NO_x , and O_2 or CO_2 concentrations according to methods specified in an applicable subpart of the regulations.

5.2 *Determination of an F Factor.* Select an average F factor (Section 5.2.1) or calculate an applicable F factor (Section 5.2.2). If combined fuels are fired, the selected or calculated F factors are prorated using the procedures in Section 5.2.3. F factors are ratios of the gas volume released during combustion of a fuel divided by the heat content of the fuel. A dry F factor (F_d) is the ratio of the volume of dry flue gases generated to the calorific value of the fuel combusted; a wet F factor (F_w) is the ratio of the volume of wet flue gases generated to the calorific value of the fuel combusted; and the carbon F factor (F_c) is the ratio of the volume of carbon dioxide generated to the calorific value of the fuel combusted. When pollutant

the base value. Any sulfur reduction realized through fuel cleaning is introduced into the equation as an average percent reduction, $\%R_f$.

4.2 Calculate the overall percent sulfur reduction as:

and oxygen concentrations have been determined in Section 5.1, wet or dry F factors are used. (F_w) factors and associated emission calculation procedures are not applicable and may not be used after wet scrubbers; (F_d) or (F_c) factors and associated emission calculation procedures are used after wet scrubbers.) When pollutant and carbon dioxide concentrations have been determined in Section 5.1, F_c factors are used.

5.2.1 *Average F Factors.* Table 1 shows average F_d , F_w , and F_c factors (scm/l, scf/million Btu) determined for commonly used fuels. For fuels not listed in Table 1, the F factors are calculated according to the procedures outlined in Section 5.2.2 of this section.

5.2.2 *Calculating an F Factor.* If the fuel burned is not listed in Table 1 or if the owner or operator chooses to determine an F factor rather than use the tabulated data, F factors are calculated using the equations below. The sampling and analysis procedures followed in obtaining data for these calculations are subject to the approval of the Administrator and the Administrator should be consulted prior to data collection.

For SI Units:

$$F_d = \frac{227.0(\%H) + 95.7(\%C) + 35.4(\%S) + 8.6(\%N) - 28.5(\%O)}{GCV}$$

$$F_w = \frac{347.4(\%H) + 95.7(\%C) + 35.4(\%S) + 8.6(\%N) - 28.5(\%O) + 13.0(\%H_2O)^{**}}{GCV_w}$$

$$F_c = \frac{20.0(\%C)}{GCV}$$

For English Units:

$$F_d = \frac{10^6[5.57(\%H) + 1.53(\%C) + 0.57(\%S) + 0.14(\%N) - 0.46(\%O)]}{GCV}$$

$$F_w = \frac{10^6[5.57(\%H) + 1.53(\%C) + 0.57(\%S) + 0.14(\%N) - 0.46(\%O) + 0.21(\%H_2O)^{**}]}{GCV_w}$$

$$F_c = \frac{10^6[0.321(\%C)]}{GCV}$$

** The H_2O term may be omitted if $\%H$ and $\%O$ include the unavailable hydrogen and oxygen in the form of H_2O .

$$E_{sg} = \frac{E_c - X_{gt} E_{gt}}{X_{sg}}$$

Where:

E_{sg} = Pollutant emission rate from steam generator effluent, ng/J (lb/million Btu).
 E_c = Pollutant emission rate in combined cycle effluent, ng/J (lb/million Btu).
 E_{gt} = Pollutant emission rate from gas turbine effluent, ng/J (lb/million Btu).
 X_{sg} = Fraction of total heat input from supplemental fuel fired to the steam generator.
 X_{gt} = Fraction of total heat input from gas turbine exhaust gases.

Note.—The total heat input to the steam generator is the sum of the heat input from supplemental fuel fired to the steam generator and the heat input to the steam generator from the exhaust gases from the gas turbine.

5.5 Effect of Wet Scrubber Exhaust, Direct-Fired Reheat Fuel Burning. Some wet scrubber systems require that the temperature of the exhaust gas be raised above the moisture dew-point prior to the gas entering the stack. One method used to accomplish this is directfiring of an auxiliary burner into the exhaust gas. The heat required for such burners is from 1 to 2 percent of total heat input of the steam generating plant. The effect of this fuel burning on the exhaust gas components will be less than ± 1.0 percent and will have a similar effect on emission rate calculations. Because of this small effect, a determination of effluent gas constituents from direct-fired reheat burners for correction of stack gas concentrations is not necessary.

Table 19-1.—F Factors for Various fuels*

Fuel type	F_d		F_e		F_s	
	decn J	decf 10 ⁶ Btu	wdecn J	wdecf 10 ⁶ Btu	acn J	acf 10 ⁶ Btu
Coal:						
Anthracite*	2.71×10^{-7}	(10180)	2.83×10^{-7}	(10540)	0.530×10^{-7}	(1970)
Bituminous*	2.63×10^{-7}	(9780)	2.86×10^{-7}	(10640)	0.484×10^{-7}	(1800)
Lignite	2.65×10^{-7}	(9860)	3.21×10^{-7}	(11950)	0.513×10^{-7}	(1910)
Oil*	2.47×10^{-7}	(9198)	2.77×10^{-7}	(10320)	0.383×10^{-7}	(1420)

* As classified according to ASTM D 388-66.

* Crude, residual, or distillate.

* Determined at standard conditions: 20° C (68° F) and 760 mm Hg (29.92 in. Hg).

6. Calculation of Confidence Limits for Inlet and Outlet Monitoring Data

6.1 Mean Emission Rates. Calculate the mean emission rates using hourly averages in ng/J (lb/million Btu) for SO_2 and NO_x outlet data and, if applicable, SO_2 inlet data using the following equations:

$$E_o = \frac{\sum x_o}{n_o}$$

$$E_i = \frac{\sum x_i}{n_i}$$

Where:

E_o = Mean outlet emission rate; ng/J (lb/million Btu).
 E_i = Mean inlet emission rate; ng/J (lb/million Btu).
 x_o = Hourly average outlet emission rate; ng/J (lb/million Btu).
 x_i = Hourly average inlet emission rate; ng/J (lb/million Btu).
 n_o = Number of outlet hourly averages available for the reporting period.
 n_i = Number of inlet hourly averages available for reporting period.

6.2 Standard Deviation of Hourly Emission Rates. Calculate the standard deviation of the available outlet hourly average emission rates for SO_2 and NO_x and, if applicable, the available inlet hourly average emission rates for SO_2 using the following equations:

$$s_o = \sqrt{\frac{\sum \left(\frac{x_o - E_o}{n_o - 1} \right)^2}{n_o - 1}}$$

$$s_i = \sqrt{\frac{\sum \left(\frac{x_i - E_i}{n_i - 1} \right)^2}{n_i - 1}}$$

Where:

$$PCC = E_i + 2 \left(\frac{\sum S_i}{GCV_i} - \frac{\sum S_o}{GCV_o} \right) 10^7; \text{ ng/J}$$

$$PCC = E_i + 2 \left(\frac{\sum S_i}{GCV_i} - \frac{\sum S_o}{GCV_o} \right) 10^4; \text{ lb/million Btu.}$$

$\left(\frac{\sum S_i}{GCV_i} - \frac{\sum S_o}{GCV_o} \right)$ = Potential emissions removed by the pretreatment process, using the fuel parameters defined in section 2.3; ng/J (lb/million Btu).

Where:

s_o = Standard deviation of the average outlet hourly average emission rates for the reporting period; ng/J (lb/million Btu).
 s_i = Standard deviation of the average inlet hourly average emission rates for the reporting period; ng/J (lb/million Btu).

6.3 Confidence Limits. Calculate the lower confidence limit for the mean outlet emission rates for SO_2 and NO_x and, if applicable, the upper confidence limit for the mean inlet emission rate for SO_2 using the following equations:

$$E_o^* = E_o - t_{\alpha/2, n} s_o$$

$$E_i^* = E_i + t_{\alpha/2, n} s_i$$

Where:

E_o^* = The lower confidence limit for the mean outlet emission rates; ng/J (lb/million Btu).

E_i^* = The upper confidence limit for the mean inlet emission rate; ng/J (lb/million Btu).

$t_{\alpha/2, n}$ = Values shown below for the indicated number of available data points (n):

n	Values for $t_{\alpha/2, n}$
2	6.31
3	2.42
4	2.35
5	2.13
6	2.02
7	1.94
8	1.89
9	1.86
10	1.83
11	1.81
12-16	1.77
17-21	1.73
22-26	1.71
27-31	1.70
32-51	1.68
52-91	1.67
92-151	1.66
152 or more	1.65

The values of this table are corrected for n-1 degrees of freedom. Use n equal to the number of hourly average data points.

7. Calculation to Demonstrate Compliance When Available Monitoring Data Are Less Than the Required Minimum

7.1 Determine Potential Combustion Concentration (PCC) for SO_2 .

7.1.1 When the removal efficiency due to fuel pretreatment ($\% R_i$) is included in the overall reduction in potential sulfur dioxide emissions ($\% R_o$) and the "as-fired" fuel analysis is not used, the potential combustion concentration (PCC) is determined as follows:

7.1.2 When the "as-fired" fuel analysis is used and the removal efficiency due to fuel pretreatment (% R_f) is not included in the overall reduction in potential sulfur dioxide emissions (% R_o), the potential combustion concentration (PCC) is determined as follows:

$$PCC = I_s$$

$$PCC = I_s + 2 \left(\frac{\% S_1}{GCV_1} - \frac{\% S_0}{GCV_0} \right) 10^7; \text{ ng/J}$$

$$PCC = I_s + 2 \left(\frac{\% S_1}{GCV_1} - \frac{\% S_0}{GCV_0} \right) 10^4; \text{ lb/million Btu.}$$

7.1.4 When inlet monitoring data are used and the removal efficiency due to fuel pretreatment (% R_f) is not included in the overall reduction in potential sulfur dioxide emissions (% R_o), the potential combustion concentration (PCC) is determined as follows:

$$PCC = E_i^*$$

Where:

E_i^* = The upper confidence limit of the mean inlet emission rate, as determined in section 6.3.

7.2 Determine Allowable Emission Rates (E_{std}).

7.2.1 NO_x . Use the allowable emission rates for NO_x as directly defined by the applicable standard in terms of ng/J (lb/million Btu).

7.2.2 SO_2 . Use the potential combustion concentration (PCC) for SO_2 as determined in section 7.1, to determine the applicable emission standard. If the applicable standard is an allowable emission rate in ng/J (lb/million Btu), the allowable emission rate

Where:

I_s = The sulfur dioxide input rate as defined in section 3.3.

7.1.3 When the "as-fired" fuel analysis is used and the removal efficiency due to fuel pretreatment (% R_f) is included in the overall reduction (% R_o), the potential combustion concentration (PCC) is determined as follows:

is used as E_{std} . If the applicable standard is an allowable percent emission, calculate the allowable emission rate (E_{std}) using the following equation:

$$E_{std} = \% PCC / 100$$

Where:

% PCC = Allowable percent emission as defined by the applicable standard; percent.

7.3 Calculate E_o^* / E_{std} . To determine compliance for the reporting period calculate the ratio:

$$E_o^* / E_{std}$$

Where:

E_o^* = The lower confidence limit for the mean outlet emission rates, as defined in section 6.3; ng/J (lb/million Btu).

E_{std} = Allowable emission rate as defined in section 7.2; ng/J (lb/million Btu).

If E_o^* / E_{std} is equal to or less than 1.0, the facility is in compliance; if E_o^* / E_{std} is greater than 1.0, the facility is not in compliance for the reporting period.

Priority List and Additions to the List of Categories of Stationary Sources**AGENCY:** Environmental Protection Agency.**ACTION:** Final rule.

SUMMARY: This action contains EPA's promulgated list of major source categories for which standards of performance for new stationary sources are to be promulgated by August 1982. The Clean Air Act Amendments of 1977 specify that the Administrator publish a list of the categories of major stationary sources which have not been previously listed as source categories for which standards of performance will be established. The promulgated list implements the Clean Air Act and reflects the Administrator's determination that, based on preliminary assessments, emissions from the listed source categories contribute significantly to air pollution. The intended effect of this promulgation is to identify major source categories for which standards of performance are to be promulgated. The standards would apply only to new or modified stationary sources of air pollution.

EFFECTIVE DATE: August 21, 1979.

ADDRESSES: The background document for the promulgated priority list may be obtained from the U.S. EPA Library (MD-35), Research Triangle Park, North Carolina 27711, telephone number 919-541-2777. Please refer to "Revised Prioritized List of Source Categories for New Source Performance Standards," EPA-450/3-79-023. The prioritization methodology is explained in the background document for the proposed priority list. This document, "Priorities for New Source Performance Standards under the Clean Air Act Amendments of 1977," EPA-450/3-78-019, can also be obtained from the Research Triangle Park EPA Library. Copies of all comment letters received from interested persons participating in this rulemaking, a summary of these comments, and a summary of the September 29, 1978, public hearing are available for inspection and copying during normal business hours at EPA's Public Information Reference Unit, Room 2922 (EPA Library), 401 M Street, SW., Washington, DC.

FOR FURTHER INFORMATION CONTACT:

Gary D. McCutchen, Emission Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, N.C. 27711, telephone number (919) 541-5421.

SUPPLEMENTARY INFORMATION: On August 31, 1978 (43 FR 38872), EPA proposed a priority list of major source categories for which standards of performance would be promulgated by August 1982, and invited public comment on the list and the methodology used to prioritize the source categories. Promulgation of this list is required by section 111(f) of the Clean Air Act as amended August 7, 1977. The significant comments that were received during the public comment period, including those made at a September 29, 1978, public hearing, have been carefully reviewed and considered and, where determined by the Administrator to be appropriate, changes have been included in this notice of final rulemaking.

Background

The program to establish standards of performance for new stationary sources (also called New Source Performance Standards or NSPS) began on December 1970, when the Clean Air Act was signed into law. Authorized under section 111 of the Act, NSPS were to require the best control system (considering cost) for new facilities, and were intended to complement the other air quality management approaches authorized by the 1970 Act. A total of 27 source categories are regulated by NSPS, with NSPS for an additional 25 source categories under development.

During the 1977 hearings on the Clean Air Act, Congress received testimony on the need for more rapid development of NSPS. There was concern that not all sources which had the potential to endanger public health or welfare were controlled by NSPS and that the potential existed for "environmental blackmail" from source categories not subject to NSPS. These concerns were reflected in the Clean Air Act Amendments of 1977, specifically in section 111(f).

Section 111(f) requires that the Administrator publish a list of major stationary sources of air pollution not listed, as of August 7, 1977, under section 111(b)(1)(A), which in effect meant those sources for which NSPS had not yet been proposed or promulgated. Before promulgating this list, the Administrator was to provide notice of and opportunity for a public hearing and consult with Governors and State air pollution control agencies. In

developing priorities, section 111(f) specifies that the Administrator consider (1) the quantity of emissions from each source category, (2) the extent to which each pollutant endangers public health or welfare, and (3) the mobility and competitive nature of each stationary source category, e.g., the capability of a new or existing source to locate in areas with less stringent air pollution control regulations. Governors may at any time submit applications under section 111(g) to add major source categories to the list, add any source category to the list which may endanger public health or welfare, change the priority ranking, or revise promulgated NSPS.

Development of the Priority List

Development of the priority list was initiated by compiling data on a large number of source categories from literature resources. The data were first analyzed to determine major source categories, those categories for which an average size plant has the potential to emit 100 tons or more per year of any one pollutant. These major source categories were then subjected to a priority ranking procedure using the three criteria specified in section 111(f) of the Act.

The procedure used first ranks source categories on a pollutant by pollutant basis. This resulted in nine lists (one for each pollutant—volatile organic compounds (VOC), nitrogen oxides, particulate matter, sulfur dioxide, carbon monoxide, lead, fluorides, acid mist, and hydrogen sulfide) with each list ranked using the criteria in the Act. In this ranking, first priority was given to quantity of emissions, second priority to potential impact on health or welfare, and third priority to mobility. Thus, sources with the greatest growth rates and emission reduction potential were high on each list; sources with limited choice of location, low growth and small emission reduction potential were low on each list.

The nine lists were combined into one by selecting pollutant goals—a procedure which, in effect, assigned a relative priority to pollutants based upon the potential impact of NSPS. After the pollutant goals were selected, the final priority list was established through the selection of source categories which have maximum impact on attaining the selected goals. The effect of this procedure was to emphasize control of all criteria pollutants except carbon monoxide and to give carbon monoxide and non-criteria pollutants a lower priority.

In the background reports and in the preamble to the proposed priority list, the term "hydrocarbon" was used even though the emissions referred to were VOC which, unlike hydrocarbon compounds, can contain elements other than carbon and hydrogen. A VOC is defined by EPA as any organic compound that, when released to the atmosphere, can remain long enough to participate in photochemical reactions. Since VOC contribute to ambient levels of photochemical oxidants, they are considered a criteria pollutant.

The ranking of source categories on the list and the differentiation between major and minor sources was sensitive to the accuracy of the data utilized. The data base used to establish the priority list was obtained from a number of literature sources including EPA screening studies. However, screening studies were not available for all source categories. Therefore, if new information becomes available after promulgation of the list, the Administrator may delete from or add to the list in response to this new information.

Additional detail on the prioritization methodology, the input factors used, and the ranking of individual source categories is available in the two background documents (see "ADDRESSES").

Significance of Priority List

The promulgated list is essentially an advance notice of future standard development activity. It identifies major source categories and the approximate order in which NSPS development would be initiated. However, if further study indicates that an NSPS would have little or no effect on emissions, or that an NSPS would be impractical, a source category would be given a lower priority or removed from the list. Similarly, new information may increase the priority of a source category. The Administrator may also concurrently develop standards for sources which are not on the priority list, especially certain "minor" sources which, in aggregate, represent a large quantity of emissions.

The distinction between major and minor source categories is defined only for the purpose of determining NSPS priorities and should not be used to determine sources subject to New Source Review, which is conducted on a case-by-case basis. Moreover, some New Source Review programs, such as prevention of significant deterioration, have separate and distinct criteria for defining a major source (e.g., 100 tons per year potential for certain source types and 250 tons per year for others).

Identification of Source Categories

Two groups of sources in addition to minor sources are not included on the promulgated list. One group includes sources which could not be evaluated due to insufficient information. This lack of data suggests that these sources, which are identified in the background report, "Priorities for NSPS under the Clean Air Act of 1977," have not previously been regulated or studied and, therefore, are probably not major sources. Nevertheless, the Administrator will continue to investigate these sources and will consider development of NSPS for any which are identified as being significant sources of air pollution.

The second group of source categories not on the priority list consists of those listed under section 111(b)(1)(A) on or before August 7, 1977. These are:

Fossil-fuel-fired steam generators
Incinerators
Portland Cement Plants
Nitric Acid Plants
Sulfuric Acid Plants
Asphalt Concrete Plants
Petroleum Refineries
Storage Vessels for Petroleum Liquids
Secondary Lead Smelters
Secondary Brass and Bronze Ingot Production Plants
Iron and Steel Plants
Sewage Treatment Plants
Primary Copper Smelters
Primary Zinc Smelters
Primary Lead Smelters
Primary Aluminum Reduction Plants
Phosphate Fertilizer Industry: Wet Process
Phosphoric Acid Plants
Phosphate Fertilizer Industry:
Superphosphoric Acid Plants
Phosphate Fertilizer Industry: Diammonium Phosphate Plants
Phosphate Fertilizer Industry: Triple Superphosphate Plants
Phosphate Fertilizer Industry: Granular Triple Superphosphate Storage Facilities
Coal Preparation Plants
Ferroalloy Production Facilities
Steel Plants: Electric Arc Furnaces
Kraft Pulp Mills
Lime Plants
Grain Elevators

There are, however, some facilities (or subcategories) within these source categories for which NSPS have not been developed, but which may by themselves be significant sources of air pollution. A number of these facilities were evaluated as if they were separate source categories; three which rank high in priority are included on the promulgated list to indicate that the Administrator plans to develop standards for them: Petroleum refinery fugitive emissions, industrial fossil-fuel-fired steam generators, and non-municipal incinerators. In addition to these, the Administrator will continue to

evaluate affected facilities within listed source categories and may from time to time develop NSPS for such facilities. The iron and steel industry provides an example of a category which is already listed (so does not appear on the priority list), but in which an active interest remains. Although the growth rate for new sintering capacity is presently very low, the Administrator is continuing to assess emission control and measurement technology with a view toward possible development of an NSPS for sintering plants at a later date. A project is also underway to update emission factors for all steelmaking processes, including fugitive emissions, in an effort to determine the relative significance of emissions from each process. In addition, byproduct coke ovens, nearly always associated with steel mills, are included on the priority list and are undergoing standard development studies.

There are some differences between the format of the list in the background report, "Revised Prioritized List of Source Categories for NSPS Promulgation" and the format of the list which appears here. These differences are primarily a result of aggregation of subcategories which had been subdivided for size classification and priority ranking analysis. Non-metallic mineral processing, for example, had been subdivided into nine subcategories for prioritization, eight of which were analyzed separately (stone, sand and gravel, clay, gypsum lime, borax, fluorspar, and phosphate rock mining) and one of which is considered a minor source (mica mining). EPA plans to study the entire non-metallic mineral processing industry at one time, since many of the processes and control techniques are similar. For this reason, the industry is identified by a single aggregated listing. This does not necessarily imply that a single standard would apply to all sources within the listed category. Rather, as described below in the case of the synthetic organic chemical manufacturing industry, the nature and scope of standards will be determined only after a detailed study of sources within the category.

In addition to the major sources, three source categories not identified as being major source categories have been added to the list: organic solvent cleaning, industrial surface coating of metal furniture, and lead acid battery manufacture.

Organic solvent cleaning was chosen for study because this source category accounts for some 5 percent of stationary source VOC emissions

typical air quality control region. Thus, although individual facilities typically emit less than 100 tons per year, this is a significant source of VOC emissions and the Administrator considers it prudent to continue the development of a standard for this source category.

The metal furniture coating industry is also a significant source of VOC emissions, and there are over 300 existing facilities with the potential to emit more than 100 tons per year.

Lead acid battery manufacture is a significant source of lead emissions. An NSPS for this source category is expected to assist in attainment of the National Ambient Air Quality Standard for lead.

Stationary gas turbines are included on this list because this source category had not been listed by August 7, 1977, when the Clean Air Act Amendments were enacted. However, this source category has not been prioritized, since it was listed under section 111(b)(1)(A) and NSPS were proposed October 3, 1977.

One listed source category which deserves special attention is the synthetic organic chemical manufacturing industry (SOCMI). Preliminary estimates indicate that there may be over 600 different processes included in this source category, but only 27 of these processes have been evaluated. For the others, there was not enough information available. As is the case with several other aggregated source categories, generic standards will be used to cover as many of the sources as possible, so separate NSPS for each of the 600 processes are unlikely.

Based on an effort which has been underway within EPA for two years to study this complex source category, the generic standards could regulate nearly all emissions by covering four broad areas: Process facilities, storage facilities, leakage, and transport and handling losses. Also, since a number of the pollutants emitted are potentially toxic or carcinogenic, regulation under section 112, National Emission Standards for Hazardous Air Pollutants (NESHAP), rather than NSPS may be more appropriated. Therefore, SOCMI is listed as a single source category. The 27 processes considered the most likely candidates for NSPS or NESHAP coverage through generic standards are listed in the preamble to the proposed priority list and discussed in the background documents.

Additional information has resulted in the exclusion from the list of some source categories which are shown in the background reports. Mixed fuel boilers and feed and grain milling are

regulated by the NSPS for fossil-fuel steam generators and grain elevators, respectively. Beer manufacture has a much lower emission level than had been assumed in the background report, and whiskey manufacture was deleted due to a lack of any demonstrated control technology.

Public Participation

The Clean Air Act requires that the Administrator, prior to promulgating this list of source categories, consult with Governors and State air pollution control agencies. An invitation was extended on February 28, 1978, to the State and Territorial Air Pollution Program Administrators (STAPPA) and the National Governors' Association (NGA) to attend the first Working Group meeting, March 16, 1978, and review the draft background report and the methods used to apply the priority criteria. On March 24, 1978, each Governor and the director of each State air pollution control agency was notified by letter of this project, including an invitation to participate or comment:

(1) At the April 5-6, 1978, National Air Pollution Control Techniques Advisory Committee (NAPCTAC) meeting in Alexandria, Virginia;

(2) When the final background report was mailed to them;

(3) When the list was proposed in the Federal Register; or

(4) At a public hearing to be held on the proposed list. The draft background report for the proposed list was mailed to all NAPCTAC members, five of which represent State or local agencies, two of which represent environmental groups, and eight of which represent industry. Copies were mailed to six environmental groups and three consumer groups at the same time, and to a representative of the NGA. Copies of the final background report for the proposed list were sent to the Governors, State and local air pollution control agencies, NAPCTAC members, environmental groups, the NGA, and other requesters in July 1978.

The public comment period on the proposed list published in the August 31, 1978, Federal Register, extended through October 30, 1978. There were 18 comment letters received, 10 from industry and 8 from various regulatory agencies. Several comments resulted in changes to the proposed priority list.

A public hearing was held on September 29, 1978, to discuss the proposed priority list in accordance with section 111(g)(8) of the Clean Air Act. There were no written comments and only one verbal statement resulting from the public hearing.

Significant Comments and Changes to the Proposed Priority List

As a result of public comments and the availability of new screening studies and reports, 34 major and 11 minor source category data sets were reevaluated. This reexamination resulted in data changes for 29 major and 9 minor source categories.

Ten source categories have been removed from the proposed priority list. Eight of these source category deletions are a result of new data indicating that NSPS would have little or no effect. These source categories are: Varnish, carbon black, explosives, acid sulfite wood pulping, NSSC wood pulping, gasoline additives manufacturing, alfalfa dehydrating, and hydrofluoric acid manufacturing. Printing ink manufacturing was reclassified from a major to a minor source category. In addition, two source categories, gray iron and steel foundries, were combined into one source category. Finally, fuel conversion was removed from the list due to uncertainties regarding the approach and scheduled involved in developing environmental standards for the various processes. Likely candidates for NSPS include coal gasification (both low and high pressure), coal liquefaction, and oil shale and tar sand processing. These actions reduce the final priority list to 59 source categories.

The most significant comments and changes made to the proposed regulations are discussed below:

1. *Definition of "Mobility."* Several commenters felt that the treatment of source category mobility (movability) was too broad. Mobility in the prioritization analysis refers to the feasibility a stationary source has to relocate to, or locate new facilities in, areas with less stringent air pollution control regulations. Non-movable stationary source categories were identified on the basis of being firmly tied either to the market (e.g., dry cleaners) or to a supply of materials (e.g., mining operations). The Administrator recognizes that there are many other factors which would be considered in plant siting situations, but considers the approach used in determining the priority list sufficient for the purposes of this study.

2. *Source Category Aggregation.* Several commenters indicated that there were discrepancies between the source categories named in the priority list and those in the background document. The differences between the priority listing in the Federal Register and the background document list is a result of aggregation of sources which had been

subcategorized for size classification and priority ranking analysis in the background document. Aggregation indicates that all source categories under a generic industry heading, such as non-metallic mineral processing, will be evaluated at the same time, although this does not necessarily imply that a single standard would apply to all sources within the listed category.

3. Control Costs. Two commenters felt that the cost of pollution control to meet NSPS limitations should have been included in the criteria for prioritization. The Clean Air Act priority list criteria do not include the cost of pollution control, but pollution control costs were considered during the determination of control technology assumed for the priority list study. Control costs are examined in more detail during NSPS development studies for each source category, and must be considered in determining each NSPS.

4. Minor Source Categories. One commenter felt that the Administrator lacks statutory authority to make a policy decision to develop NSPS for a minor source category until after the major sources have been dealt with, since Congress indicated major sources must be given priority. The Administrator, in promulgating this list, is placing an almost exclusive emphasis on NSPS for major source categories. However, the Clean Air Act does not prohibit concurrent promulgation of NSPS for minor, but significant, source categories. For the three minor source categories listed in this regulation, NSPS development had been initiated before the priority list was available, and completion of standards development for these sources is considered justified.

5. Stationary Fuel Combustion/Waste Incineration. Two State agencies felt that stationary fuel combustion and waste incineration should have a high priority because of source activity growth in their respective States. In the promulgated list, both of these source categories are given high priority based on the most recent growth rates available. Given the concern expressed by these agencies, the Administrator has already initiated standard development studies for these source categories.

6. Chemical Products Manufacture/Fuel Conversion. One commenter felt that the growth rate and, therefore, the need for coal gasification plant NSPS is overestimated. High Btu coal gasification was reexamined; although no commercial-scale plants currently exist in this country, environmental programs need to keep pace with the emphasis on energy programs. The fuel conversion processes have been

removed from the priority list for special study.

7. Chemical Products Manufacture/Printing Ink Manufacture. One commenter indicated that neither existing conditions within the printing ink industry nor projections of future growth of the industry justify its categorization as a major source. The Administrator has examined the new data provided, and has reclassified printing ink manufacturing plants as a minor source category. As was discussed earlier, however, the Administrator may still develop standards for "minor" source categories, especially those which, in aggregate, represent a significant quantity of emissions.

8. Wood Processing/NSSC and Acid Sulfite Pulping. One commenter indicated that acid sulfite pulp production is a declining growth industry and therefore should not be included in the priority list. The Administrator agrees with this comment, based on examination of acid sulfite pulp production projections in a new screening study. In addition, the screening study indicates that NSSC pulping is, in effect, controlled by the promulgated NSPS for Kraft pulp mills, resulting in little or no further emission reduction from promulgation of an NSSC NSPS. Therefore, both acid sulfite and NSSC pulping have been removed from the list.

Development of Standards

The Administrator has undertaken a program to promulgate NSPS for the source categories on this priority list by August 7, 1982. Development of standards has already been initiated for nearly two-thirds of the source categories listed; work on the remaining source categories will be initiated within the next year.

The priority ranking is indicated by the number to the left of each source category and will be used to decide the order in which new projects are initiated, although this is not necessarily an indication of the order in which projects will be completed. In fact, higher priority source categories often present difficult technical and regulatory problems, and may be among the later source categories for which standards are promulgated.

It should be pointed out that several of the source categories listed could be subject to standards which may be adopted under section 112 of the Clean Air Act, national emission standards for hazardous air pollutants (NESHAP). Included are byproduct coke ovens and several source categories within the

petroleum transport and marketing industry. If standards are developed under section 112 for these or any other source categories on the promulgated list, then standards may not be developed for those source categories under section 111.

Promulgation of this list not only fulfills the section 111(f) requirements concerning establishment of priorities, but also constitutes notice that all source categories on the priority list are considered significant sources of air pollution and are hereby listed in accordance with section 111(b)(1)(A). It should be noted, however, that the source categories identified on this priority list, even though listed in accordance with section 111(b)(1)(A), are not subject to the provisions of section 111(b)(1)(B), which would require proposal of an NSPS for each listed source category within 120 days of adoption of the list. Rather, the promulgation of standards for sources contained on this priority list will be undertaken in accordance with the time schedule prescribed in section 111(f)(1) of the Clean Air Act Amendments. That is, NSPS for 25 percent of these source categories are to be promulgated by August 1980, 75 percent by August 1981, and all of the NSPS by August 1982.

Dated: August 15, 1979.

Douglas M. Costle,
Administrator.

Part 60 of Chapter I of Title 40 of the Code of Federal Regulations is amended by adding § 60.16 to Subpart A as follows:

§ 60.16 Priority list.

Prioritized Major Source Categories

Priority Number*

Source Category

1. Synthetic Organic Chemical Manufacturing
 - (a) Unit processes
 - (b) Storage and handling equipment
 - (c) Fugitive emission sources
 - (d) Secondary sources
2. Industrial Surface Coating: Cans
3. Petroleum Refineries: Fugitive Sources
4. Industrial Surface Coating: Paper
5. Dry Cleaning
 - (a) Perchloroethylene
 - (b) Petroleum solvent
6. Graphic Arts
7. Polymers and Resins: Acrylic Resins
8. Mineral Wool
9. Stationary Internal Combustion Engines
10. Industrial Surface Coating: Fabric
11. Fossil-Fuel-Fired Steam Generators: Industrial Boilers
12. Incineration: Non-Municipal
13. Non-Metallic Mineral Processing
14. Metallic Mineral Processing

* Low numbers have highest priority; e.g. N high priority. No. 59 is low priority.

16. Secondary Copper
16. Phosphate Rock Preparation
17. Foundries: Steel and Gray Iron
18. Polymers and Resins: Polyethylene
19. Charcoal Production
20. Synthetic Rubber
 - (a) Tire manufacture
 - (b) SBR production
21. Vegetable Oil
22. Industrial Surface Coating: Metal Coil
23. Petroleum Transportation and Marketing
24. By-Product Coke Ovens
25. Synthetic Fibers
26. Plywood Manufacture
27. Industrial Surface Coating: Automobiles
28. Industrial Surface Coating: Large Appliances
29. Crude Oil and Natural Gas Production
30. Secondary Aluminum
31. Potash
32. Sintering: Clay and Fly Ash
33. Glass
34. Gypsum
35. Sodium Carbonate
36. Secondary Zinc
37. Polymers and Resins: Phenolic
38. Polymers and Resins: Urea—Melamine
39. Ammonia
40. Polymers and Resins: Polystyrene
41. Polymers and Resins: ABS-SAN Resins
42. Fiberglass
43. Polymers and Resins: Polypropylene
44. Textile Processing
45. Asphalt Roofing Plants
46. Brick and Related Clay Products
47. Ceramic Clay Manufacturing
48. Ammonium Nitrate Fertilizer
49. Castable Refractories
50. Borax and Boric Acid
51. Polymers and Resins: Polyester Resins
52. Ammonium Sulfate
53. Starch
54. Perlite
55. Phosphoric Acid: Thermal Process
56. Uranium Refining
57. Animal Feed Defluorination
58. Urea (for fertilizer and polymers)
59. Detergent

Standards of Performance for New Stationary Sources: Asphalt Concrete; Review of Standards

AGENCY: Environmental Protection Agency (EPA)

ACTION: Review of Standards.

SUMMARY: EPA has reviewed the standard of performance for asphalt concrete plants (40 CFR 60.9, Subpart I). The review is required under the Clean Air Act, as amended August 1977. The purpose of this notice is to announce EPA's intent not to undertake revision of the standards at this time.

DATES: Comments must be received by October 29, 1979.

ADDRESS: Comments should be submitted to the Central Docket Section (A-130), U.S. Environmental Protection Agency, 401 M Street, S.W., Washington, D.C. 20460, Attention: Docket No. A-79-04.

FOR FURTHER INFORMATION CONTACT: Mr. Robert Ajax, telephone: (919) 541-5271. The document "A Review of Standards of Performance for New Stationary Sources—Asphalt Concrete" (EPA-450/3-79-014) is available upon request from Mr. Robert Ajax (MD-13), Emission Standards and Engineering Division, U.S. Environmental Protection Agency, Research Triangle Park, North Carolina 27711.

SUPPLEMENTARY INFORMATION:**Background**

In June 1973, EPA proposed a standard under Section 111 of the Clean Air Act to control particulate matter emissions from asphalt concrete plants. The standard, promulgated on March 8, 1974, limits the discharge of particulate matter into the atmosphere to a maximum of 90 mg/dscm from any affected facility. The standard also limits the opacity of emissions to 20 percent. The standard is applicable to asphalt concrete plants which commenced construction or modification after June 11, 1973.

The Clean Air Act Amendments of 1977 require that the Administrator of the EPA review and, if appropriate, revise established standards of performance for new stationary sources at least every 4 years [Section 111(b)(1)(B)]. Following adoption of the Amendments, EPA contracted with the MITRE Corporation to undertake a review of the asphalt concrete industry and the current standard. The MITRE review was completed in January 1979. Preliminary findings were presented to and reviewed by the National Air Pollution Control Techniques Advisory Committee at its meeting in Alexandria, Virginia, on January 10, 1979. This notice announces EPA's decision regarding the need for revision of the standard. Comments on the results of this review and on EPA's decision are invited.

Findings*Overview of the Asphalt Concrete Industry*

The asphalt concrete industry consists of about 4,500 plants, widely dispersed throughout the Nation. Plants are stationary (60 percent), mobile (20 percent), or transportable (20 percent), i.e., easily taken down, moved and reassembled. Types of plants include batch-mix (91 percent), continuous mix (6.5 percent), or dryer-drum mix (2.5 percent). The dryer-drum plants, which are becoming increasingly popular, differ from the others in that drying of the aggregate and mixing with the liquid asphalt both take place in the same rotary dryer. It is estimated that within the next few years, dryer-drum plants will represent up to 85 percent of all plants under construction.

Current national production is about 263 to 272 million metric tons (MG)/year, with a continued rise expected in the future. It is estimated that approximately 100 new and 50 modified plants become subject to the standard each year. Operation is seasonal, with plants reportedly averaging 666 hours/

year although many operate more extensively.

Particulate Matter Emissions and Control Technology

The largest source of particulate emissions is the rotary dryer. Both dry (fabric filters) and wet (scrubbers) collectors are used for control and are both capable of achieving compliance with the standard. However, all systems of these types have not automatically achieved control at or below the level of the standard.

Based on data from a total of 72 compliance tests, it was found that 53 or about three-fourths of the tests for particulate emissions showed compliance. Thirty-three of the 53 produced results between 45 and 90 Mg³/dscm (.02 and .04 gr/dscf). Of the 47 tests of fabric filters or venturi scrubber controlled sources over 80 percent showed compliance. The available data do not provide details on equipment design and an analysis of the cause of failures has not been performed. However, EPA is not aware of any instances in which a properly designed and installed fabric filter system or high-efficiency scrubber has failed to achieve compliance with the standard. The fact that certain facilities controlled by fabric filters and high-efficiency scrubbers have failed to comply is attributed to faulty design, installation, and/or operation. This conclusion and these data are consistent with data and findings considered in the development of the present standard.

On the basis of these findings, EPA concludes that the present standard for particulate matter is appropriate and that no revision is needed.

Much less test data are available for opacity than for particulates. Of the 26 tests for which opacity levels are reported, only 5 failed to show compliance with the opacity standard. However, none of these 5 met the standard for particulate matter. Of the 21 plants reported as meeting the current standard for opacity, 19 met the particulate standard. On the basis of these data, EPA concludes that the opacity standard is appropriate and should not be revised. While the data do indicate that a tighter standard may be possible, the rationale and basis used to establish the present standard are considered to remain valid.

Enforcement of the Standard

Because the cost of performance tests which are required to demonstrate compliance with the standard are essentially fixed and are independent of plant size, this cost is disproportionately high for small plants. Due to this, the

issue was raised as to whether formal testing could be waived and lower cost, alternative means be established for determining compliance at small plants. Support for such a waiver can be found in the fact that emission rates are generally lower at these plants and errors in compliance determinations would not be large in terms of absolute emissions. However, testing costs at all sizes of plants are small in relation to the cost of asphalt concrete production over an extended period and these costs can be viewed as a legitimate expense to be considered by an owner at the time a decision to construct is made. A number of State agencies presently require, under SIP regulations, initial and in some cases annual testing of asphalt concrete plants. Moreover, available compliance test data show that performance of control devices is variable and even with installation of accepted best available control technology the standard can be exceeded by a significant degree if the control system is not properly designed, operated, and maintained. Relaxing the requirement for formal testing thus could lead to a proliferation of low quality or marginal control equipment which would require costly repair or retrofit at a later time.

A further performance testing problem identified in the review of the standard concerns operation at less than full production capacity during a compliance test. When this occurs, EPA normally accepts the test result as a demonstration of compliance at the tested production rate, plus 23 Mg (25 tons)/hr. To operate at a higher production rate, an owner or operator must demonstrate compliance by testing at that higher rate. Industry representatives view this limitation as an unfair production penalty. It is noted in particular that reduced production is sometimes an unavoidable consequence associated with use of high moisture content aggregate. Furthermore, it is argued that facilities which show compliance at the maximum production rate associated with a given moisture level can be assumed to comply at higher production rates when moisture is lower. However, this argument assumes that the uncontrolled emission rate from the facility does not increase as production rate increases and EPA is not aware of data to support this assumption.

As a general policy it is EPA's intent to minimize administrative costs imposed on owners and operators by a standard, to the maximum extent that this can be done without sacrificing the Agency's responsibility for assuring

compliance. Specifically, in the cases cited above, EPA does not intend to impose costly testing requirements on small facilities or any facilities if compliance with the standard can be determined through less costly means. However, EPA at this time is not aware of a procedure which could be employed at a significantly lower cost to determine compliance with an acceptable degree of accuracy. Although opacity correlators with grain loading and serves as a valid means for identifying excess emissions, due to dependence on stack diameter and other factors opacity alone is not adequate to accurately assess compliance with the mass rate standard. Similarly, the purchase and installation of a baghouse or venturi scrubber does not in itself necessarily imply compliance. EPA is concerned that approval of such equipment without compliance test data or a detailed assessment of design and operating factors would provide an incentive for installation of low cost, under-designed equipment. This would place vendors of more costly systems which are well designed and properly constructed and operated at a competitive disadvantage; in the long term this would not only increase emissions but would be to the detriment of the industry.

EPA has, however, concluded that a study program to investigate alternative compliance test and administrative approaches for asphalt plants is needed. An EPA contractor working for the Office of Enforcement has initiated a study designed to assess several administrative aspects of the standard, including possible low cost alternative test methods; administrative mechanisms to deal with the problem of process variability during testing; and physical constraints affecting the ability to perform tests. If the results of this program, which is scheduled to be completed later in 1979, show that the regulations or enforcement policies can be revised to lower costs, such revisions will be adopted.

Hydrocarbon Emissions

While the principal pollutant associated with asphalt concrete production is particulate matter, the trend noted previously toward dryer-drum mix plants has raised question as to the significance of hydrocarbon emissions from these facilities. In the dryer-drum mix plant, drying of the aggregate as well as mixing with asphalt and additional fines takes place within a rotary drum. Because the drying takes place within the same container as the mixing, emissions are partly screened by the curtain of asphalt added so that the

uncontrolled particulate emissions from the dryer are lower than from conventional plants. In contrast, it has been reported that the rate of hydrocarbon emissions may be substantially higher than from conventional plants. However, data recently reported from one test in a plant equipped with fabric filters showed only traces of hydrocarbons in dust and condensate and did not support this suggestion. Thus, while these data do not indicate a need to revise the standard, more definitive data are needed on hydrocarbon emission rates and related process variables. This has been identified as an area for further research by EPA.

An additional source of hydrocarbon emissions in the asphalt industry is the use of cutback asphalts. Although not directly associated with asphalt concrete plants, this represents a significant source of hydrocarbon emissions. As such, the need for possible standards of performance pertaining to use of cutback asphalt was raised in this review. The term cutback asphalt refers to liquified asphalt products which are diluted or cutback by kerosene or other petroleum distillates for use as a surfacing material. Cutback asphalt emits significant quantities of hydrocarbons—at a high rate immediately after application and continuing at a diminishing rate over a period of years. It is estimated that over 2 percent of national hydrocarbon emissions result from use of cutback asphalt.

The substitution of emulsified asphalts, which consist of asphalt suspended in water containing an emulsifying agent, for cutback asphalt nearly eliminates the release of volatile hydrocarbons from paving operations. This substitute for petroleum distillate is approximately 98 percent water and 2 percent emulsifiers. The water in emulsified asphalt evaporates during curing while the non-volatile emulsifier is retained in the asphalt.

Because cutback asphalt emissions result from the use of a product rather than from a conventional stationary source, the feasibility of a standard of performance is unclear and the Agency has no current plans to develop such a standard. However, EPA has issued a control techniques guideline document, *Control of Volatile Organic Compounds from Use of Cutback Asphalt* (EPA-450/2-77-037) and is actively pursuing control through the State Implementation Plan process in areas where control is needed to attain oxidant standards. Because of area-to-area differences in experience with

emulsified asphalt, availability of suppliers, and ambient temperatures, the Agency believes that control can be implemented effectively by the States.

Asphalt Recycling Plants

A process for recycling asphalt paving by crushing up old road beds for reprocessing through direct-fired asphalt concrete plants has been recently implemented on an experimental basis. Plants using this process, which uses approximately 20 to 30 percent virgin material mixed with the recycled asphalt, are subject to the standard and at least two have demonstrated compliance. However, preliminary indications are that the process may have difficulty in routinely attaining the allowable level of particulate emissions and/or that the cost of control may be higher than a conventional process. The partial combustion of the recycled asphalt cement reportedly produces a blue smoke more difficult to control than the mineral dusts of plants using virgin material.

It is EPA's conclusion that there is no need at this time to revise the standard as it affects recycling, due to its limited practice and due to the data showing that compliance can be achieved at facilities which recycle asphalt. However, this matter is being studied further under the previously noted study by an EPA contractor.

Educational Program for Owners and Operators

The asphalt industry consists of a large number of facilities which in many cases are owned and operated by small businessmen who are not trained or experienced in the operation, design, or maintenance of air pollution control equipment. Because of this, the need to comply with emission regulations, and the changing technology in the industry (i.e., the introduction of dryer-drum plants, recycling, the possible move toward coal as a fuel, and the use of emulsions), the need for a training and educational program for owners and operators in the operation and maintenance of air pollution control equipment has been voiced by industry. This offers the potential for cost and energy savings along with reduced pollution.

To meet this need, EPA's Office of Enforcement, in cooperation with the National Asphalt Paving Association, conducted a series of workshops in 1978 for asphalt plant owners and operators. Only limited future workshops are currently planned. However, EPA will consider expansion of the programs if a continued need exists.

Dated: August 23, 1979.

40 CFR Part 60

[FRL 1276-2]

Standards of Performance for New Stationary Sources; Gas Turbines

AGENCY: Environmental Protection Agency.

ACTION: Final rule.

SUMMARY: This rule establishes standards of performance which limit emissions of nitrogen oxides and sulfur dioxide from new, modified and reconstructed stationary gas turbines. The standards implement the Clean Air Act and are based on the Administrator's determination that stationary gas turbines contribute significantly to air pollution. The intended effect of this regulation is to require new, modified and reconstructed stationary gas turbines to use the best demonstrated system of continuous emission reduction.

EFFECTIVE DATE: September 10, 1979.

ADDRESSES: The Standards Support and Environmental Impact Statement (SSEIS) may be obtained from the U.S. EPA Library (MD-35), Research Triangle Park, North Carolina 27711 (specify *Standards Support and Environmental Impact Statement, Volume 2: Promulgated Standards of Performance for Stationary Gas Turbines, EPA-450/2-77-017b*).

FOR FURTHER INFORMATION CONTACT: Don R. Goodwin, Director, Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone No. (919) 541-5271.

SUPPLEMENTARY INFORMATION: The Standards

The promulgated standards apply to all new, modified, and reconstructed stationary gas turbines with a heat input at peak load equal to or greater than 10.7 gigajoules per hour (about 1,000 horsepower). The standards apply to simple and regenerative cycle gas turbines and to the gas turbine portion of a combined cycle steam/electric generating system.

The promulgated standards limit the concentration of nitrogen oxides (NO_x) in the exhaust gases from stationary gas turbines with a heat input from 10.7 to and including 107.2 gigajoules per hour (about 1,000 to 10,000 horsepower), from offshore platform gas turbines, and from stationary gas turbines used for oil or gas transportation and production not located in a Metropolitan Statistical Area (MSA), to 0.0150 percent by volume (150 PPM) at 15 percent oxygen on a dry basis. The promulgated standards also limit the concentration of

NO_x in the exhaust gases from stationary gas turbines with a heat input greater than 107.2 gigajoules per hour, and from stationary gas turbines used for oil or gas transportation and production located in an MSA, to 0.0075 percent by volume (75 PPM) at 15 percent oxygen on a dry basis (see Table 1 for summary of NO_x emission limits). Both of these emission limits (75 and 150 PPM) are adjusted upward for gas turbines with thermal efficiencies greater than 25 percent using an equation included in the promulgated standards. These emission limits are also adjusted upward for gas turbines burning fuels with a nitrogen content greater than 0.015 percent by weight using a fuel-bound nitrogen allowance factor included in the promulgated standards, or a "custom" fuel-bound nitrogen allowance factor developed by the gas turbine manufacturer and approved for use by EPA. Custom fuel-bound nitrogen allowance factors must be substantiated with data and approved for use by the Administrator before they may be used for determining compliance with the standards.

The promulgated NO_x emission limits are referenced to International Standard Organization (ISO) standard day conditions of 288 degrees Kelvin, 60 percent relative humidity, and 101.3 kilopascals (1 atmosphere) pressure. Measured NO_x emission levels, therefore, are adjusted to ISO reference conditions by use of an ambient condition correction factor included in the standards, or by a custom ambient condition correction factor developed by the gas turbine manufacturer and approved for use by EPA. Custom ambient condition correction factors can only include the following variables: combustor inlet pressure, ambient air pressure, ambient air humidity, and ambient air temperature. These factors must be substantiated with data and approved for use by the Administrator before they may be used for determining compliance with the standards.

Stationary gas turbines with a heat input at peak load from 10.7 to, and including, 107.2 gigajoules per hour are to be exempt from the NO_x emission limit included in the promulgated standards for five years from the date of proposal of the standards (October 3, 1977). New gas turbines with this heat input at peak load which are constructed, or existing gas turbines with this heat input at peak load which are modified or reconstructed during this five-year period do not have to comply with the NO_x emission limit included in the promulgated standards at the end of this period. Only those new gas turbines which are constructed, or existing gas turbines which are modified or reconstructed, following this five-year period must comply with the NO_x emission limit.

Emergency-standby gas turbines, military training gas turbines, gas turbines involved in certain research and development activities, and firefighting gas turbines are exempt from compliance with the NO_x emission limits included in the promulgated standards. In addition, stationary gas turbines using wet controls are temporarily exempt from the NO_x emission limit during those periods when ice fog created by the gas turbine is deemed by the owner or operator to present a traffic hazard, and during periods of drought when water is not available.

None of the exemptions mentioned above apply to the sulfur dioxide (SO₂) emission limit. The promulgated standards limit the SO₂ concentration in the exhaust gases from stationary gas turbines with a heat input at peak load of 10.7 gigajoules per hour or more to 0.015 percent by volume (150 PPM) corrected to 15 percent oxygen on a dry basis. The standards include an alternative SO₂ emission limit on the sulfur content of the fuel of 0.8 percent sulfur by weight (see Table 1 for summary of exemptions and SO₂ emission limits).

Table 1.—Summary of Gas Turbine New Source Performance Standard

Gas turbine size and usage	NO _x emission limit ¹	Applicability date for NO _x	SO ₂ emission limit	Applicability date for SO ₂
Less than 10.7 gigajoules/hour (all uses).....	None.....	Standard does not apply.	None.....	Standard does not apply.
Between 10.7 and 107.2 gigajoules/hour (all 150 ppm uses).....	150 ppm.....	October 3, 1982.....	150 ppm SO ₂ , or fire a fuel with less than 0.8% sulfur	October 3, 1977
Greater than or equal to 107.2 gigajoules/hour:				
1. Gas and oil transportation or production not located in an MSA.....	150 ppm.....	October 3, 1977.....	Same as above.....	October 3, 1977
2. Gas and oil transportation or production located in an MSA.....	75 ppm.....	October 3, 1977.....	Same as above.....	October 3, 1977
3. All other uses.....	75 ppm.....	October 3, 1977.....	Same as above.....	October 3, 1977
Emergency standby, firefighting, military (except for garrison facility), military training, and research and development turbines.....	None.....	Standard does not apply.	Same as above.....	October 3, 1977

¹ NO_x emission limit adjusted upward for gas turbines with thermal efficiencies greater than 25 percent and for gas turbines firing fuels with a nitrogen content of more than 0.015 weight percent. Measured NO_x emissions adjusted to ISO conditions in determining compliance with the NO_x emission limit.

Environmental, Energy, and Economic Impact

The promulgated standards will reduce NO_x emissions by about 190,000 tons per year by 1982 and by 400,000 tons per year by 1987. This reduction will be realized with negligible adverse solid waste and noise impacts.

The adverse water pollution impact associated with the promulgated standards will be minimal. The quantity of water or steam required for injection into the gas turbine to reduce NO_x emissions is less than 5 percent of the water consumed by a comparable size steam/electric power plant using cooling towers. There will be no adverse water pollution impact associated with those gas turbines which employ dry NO_x control technology.

The energy impact associated with the promulgated standards will be small. Gas turbine fuel consumption could increase by as much as 5 percent in the worst cases. The actual energy impact depends on the rate of water injection necessary to comply with the promulgated standards. Assuming the "worst case," however, the standards would increase fuel consumption of large stationary gas turbines (i.e., greater than 10,000 horsepower) by about 5,500 barrels of fuel oil per day in 1982. The standards would increase fuel consumption of small stationary gas turbines (i.e., less than 10,000 horsepower) by about 7,000 barrels of fuel oil per day in 1987. This is equivalent to an increase in projected 1982 and 1987 national crude oil consumption of less than 0.03 percent. As mentioned, these estimates are based on "worst case" assumptions. The actual energy impact of the promulgated standard is expected to be much lower than these estimates because most gas turbines will not experience anywhere near a 5 percent fuel penalty due to water or steam injection. In addition, many gas turbines will comply with the standards using dry control, which in most cases has no energy penalty.

The economic impact associated with the promulgated standards is considered reasonable. The standards will increase the capital costs or purchase price of a gas turbine for most installations by about 1 to 4 percent. The annualized costs will be increased by about 1 to 4 percent, with the largest application, utilities, realizing less than a 2 percent increase.

The promulgated standards will increase the total capital investment requirements for users of large stationary gas turbines by about 36 million dollars by 1982. For the period 1982 through 1987, the standards will

increase the capital investment requirements for users of both large and small stationary gas turbines by about 67 million dollars. Total annualized costs for these users of stationary gas turbines will be increased by about 11 million dollars in 1982 and by about 30 million dollars in 1987. These impacts will result in price increases for the end products or services provided by industrial and commercial users of stationary gas turbines ranging from less than 0.01 percent in the petroleum refining industry, to about 0.1 percent in the electric utility industry.

Public Participation

Prior to proposal of the standards, interested parties were advised by public notice in the *Federal Register* of meetings of the National Air Pollution Control Techniques Advisory Committee to discuss the standards recommended for proposal. These meetings occurred on February 21, 1973; May 30, 1973; and January 9, 1974. The meetings were open to the public and each attendee was given ample opportunity to comment on the standards recommended for proposal. The standards were proposed and published in the *Federal Register* on October 3, 1977. Public comments were solicited at that time and, when requested, copies of the Standards Support and Environmental Impact Statement (SSEIS) were distributed to interested parties. The public comment period extended from October 3, 1977, to January 31, 1978.

Seventy-eight comment letters were received on the proposed standards of performance. These comments have been carefully considered and, where determined to be appropriate by the Administrator, changes have been made in the standards which were proposed.

Significant Comments and Changes to the Proposed Regulation

Comments on the proposed standards were received from electric utilities, oil and gas producers, gas turbine manufacturers, State air pollution control agencies, trade and professional associations, and several Federal agencies. Detailed discussion of these comments can be found in Volume 2 of the SSEIS. The major comments can be combined into the following areas: general, emission control technology, modification and reconstruction, economic impacts, environmental impacts, energy impacts, and test methods and monitoring.

General

Small stationary gas turbines (i.e., those with a heat input at peak load

between 10.7 and 107.2 gigajoules per hour—about 1,000 to 10,000 horsepower) are exempt from the standards for a period of five years following the date of proposal. Some commenters felt it was not clear whether small gas turbines would be required to retrofit NO_x emissions controls after the exemption period ended. These commenters felt this was not the intent of the standards and they recommended that this point be clarified.

The intent of both the proposed and the promulgated standards is to consider small gas turbines which have commenced construction on or before the end of the five year exemption period as existing facilities. These facilities will not have to retrofit at the end of the exemption period. This point has been clarified in the promulgated standards.

Several commenters requested exemptions for temporary and intermittent operation of gas turbines to permit research and development into advanced combustion techniques under full scale conditions.

This is considered a reasonable request. Therefore, gas turbines involved in research and development for the purpose of improving combustion efficiency or developing emission control technology are exempt from the NO_x emission limit in the promulgated standards. Gas turbines involved in this type of research and development generally operate intermittently and on a temporary basis. The standards have been changed, therefore, to allow exemptions in such situations on a case-by-case basis.

Emissions Control Technology

The selection of wet controls, or water injection, as the best system of emission reduction for stationary gas turbines was criticized by a number of commenters. These commenters pointed out that although dry controls will not reduce emissions as much as wet controls, dry controls will reduce NO_x emissions without the objectionable results of water injection (i.e., increased fuel consumption and difficulty in securing water of acceptable quality). These commenters, therefore, recommended postponement of standards until dry controls can be implemented on gas turbines.

As pointed out in Volume 1 of the SSEIS, a high priority has been established for control of NO_x emissions. Wet and dry controls are considered the only viable alternative control techniques for reducing NO_x emissions from gas turbines. Control of NO_x emissions by either of these two

alternatives clearly favored the development of the standards of performance based on wet controls from an environmental viewpoint. Reductions in NO_x emissions of more than 70 percent have been demonstrated using wet controls on many large gas turbines used in utility and industrial applications. Thus, wet controls can be applied immediately to large gas turbines, which account for 85-90 percent of NO_x emissions from gas turbines.

The technology of wet control is the same for both large and small gas turbines. The manufacturers of small gas turbines, however, have not experimented with or developed this technology to the same extent as the manufacturers of large gas turbines. In addition, small gas turbines tend to be produced or more of an assembly line basis than large gas turbines. Consequently, the manufacturers of small gas turbines need a lead time of five years (based on their estimates) to design, test, and incorporate wet controls on small gas turbines.

Even with a five-year delay in application of standards to small gas turbines, standards of performance based on wet controls will reduce national NO_x emissions by about 190,000 tons per year by 1982. Therefore, the reduction in NO_x emissions resulting from standards based on wet controls is significant.

Dry controls have demonstrated NO_x emissions reduction of only about 40 percent in laboratory and combustor rig tests. Because of the advanced state of research and development into dry control by the manufacturers of large gas turbines, the much longer lead time involved in ordering large gas turbines, and the greater attention that can be given to "custom" engineering designs of large gas turbines, dry controls can be implemented on large gas turbines immediately. Manufacturers of small gas turbines, however, estimate that it would take them as long to incorporate dry controls as wet controls on small gas turbines. Basing the standards only on dry controls, therefore, would significantly reduce the amount of NO_x emission reductions achieved.

The economic impact of standards based on wet controls is considered reasonable for large gas turbines. (See Economic Impact Discussion.) Thus, wet controls represent "... the best system of continuous emission reduction ... (taking into consideration the cost of achieving such emission reduction, any nonair quality health and environmental impact and energy requirements) ... for large gas turbines.

The economic impact of standards based on wet controls, however, is considered unreasonable for small gas turbines, gas turbines located on offshore platforms, and gas turbines employed in oil or gas production and transportation which are not located in a Metropolitan Statistical Area. The economic impact of standards based on dry controls, on the other hand, is considered reasonable for these gas turbines. (See Economic Impact Discussion.) Thus, dry controls represent "... the best system of continuous emission reduction ... (taking into consideration the cost of achieving such emission reduction, any nonair quality health and environmental impact and energy requirements) ... for small gas turbines, gas turbines located on offshore platforms, and gas turbines employed in oil or gas production and transportation which are not located in a Metropolitan Statistical Area.

Volume 1 of the SSEIS summarizes the data and information available from the literature and other nonconfidential sources concerning the effectiveness of dry controls in reducing NO_x emissions from stationary gas turbines. More recently, additional data and information have been published in the Proceedings of the Third Stationary Source Combustion Symposium (EPA-600/7-79-050C). Advanced Combustion Systems for Stationary Gas Turbines (interim report) prepared by the Pratt and Whitney Aircraft Group for EPA (Contract 68-02-2136), "Experimental Clean Combustor Program Phase III" (NASA CR-135253) also prepared by the Pratt and Whitney Aircraft Group for the National Aeronautics and Space Administration (NASA), and "Aircraft Engine Emissions" (NASA Conference Publication 2021). These data and information show that dry controls can reduce NO_x emissions by about 40 percent. Multiplying this reduction by a typical NO_x emission level from an uncontrolled gas turbine of about 250 ppm leads to an emission limit for dry controls of 150 ppm. This, therefore, is the numerical emission limit included in the promulgated standards for small gas turbines, gas turbines located on offshore platforms, and gas turbines employed in oil or gas production or transportation which are not located in Metropolitan Statistical Areas.

The five-year delay from the date of proposal of the standards in the applicability date of compliance with the NO_x emission limit for small gas turbines has been retained in the promulgated standards. As discussed above, manufacturers of small gas

turbines have estimated that it will take this long to incorporate either wet or dry controls on these gas turbines.

Several commenters criticized the fuel-bound nitrogen allowance included in the proposed standards. It was felt that greater flexibility in the equations used to calculate the fuel-bound nitrogen NO_x emissions contribution should be permitted, due to the limited data on conversion of fuel-bound nitrogen to NO_x. These commenters recommended that manufacturers of gas turbines be allowed to develop their own fuel-bound nitrogen allowance.

As discussed in Volume I of the SSEIS, the reaction mechanism by which fuel-bound nitrogen contributes to NO_x emissions is not fully understood. In addition, emission data are limited with respect to fuels containing significant amounts of fuel-bound nitrogen. The problem of quantifying the fuel-bound nitrogen contribution to total NO_x emissions is further complicated by the fact that the amount of nitrogen in the fuel has an effect on this contribution.

In light of this sparsity of data, the commenters' recommendations seem reasonable. Therefore, a provision has been added to the standards to allow manufacturers to develop custom fuel-bound nitrogen allowances for each gas turbine model. The use of these factors, however, must be approved by the Administrator before the initial performance test required by Section 60.8 of the General Provisions. Petitions by manufacturers for approval of the use of custom fuel-bound nitrogen allowance factors must be supported by data which clearly provide a basis for determining the contribution of fuel-bound nitrogen to total NO_x emissions. In addition, in no case will EPA approve a custom fuel-bound nitrogen allowance factor which would permit an increase in NO_x emissions of more than 50 ppm. (See Energy Impact Discussion.) Notice of approval of the use of these factors for various gas turbine models will be given in the Federal Register.

Modification and Reconstruction

Some commenters felt that existing gas turbines which now burn natural gas and are subsequently altered to burn oil should be exempt from consideration as modifications. The high cost and technical difficulties of compliance with the standards would discourage fuel switching to conserve natural gas supplies.

As outlined in the General Provisions of 40 CFR Part 60, which are applicable to all standards of performance, most changes to an existing facility which result in an increase in emission rate to

the atmosphere are considered modifications. However, according to section 60.14(e)(4) of the General Provisions, the use of an alternative fuel or raw material shall not be considered a modification if the existing facility was designed to accommodate that alternative use. Therefore, if a gas turbine is designed to fire both natural gas and oil, then switching from one fuel to the other would not be considered a modification even if emissions were increased. If a gas turbine that is not designed for firing both fuels is switched from firing natural gas to firing oil, installation of new injection nozzles which increase mixing to reduce NO_x production, or installation of new NO_x combustors currently on the market, would in most cases maintain emissions at their previous levels. Since emissions would not increase, the gas turbine would not be considered modified, and the real impact of the standards on gas turbines switching from natural gas to oil will probably be quite small. Therefore, no special provisions for fuel switching have been included in the promulgated standards.

Economic Impact

Several commenters stated that water injection could increase maintenance costs significantly. One reason cited was that chemicals and minerals in the water would likely be deposited on internal surfaces of gas turbines, such as turbine blades, leading to downtime for repair and cleaning. In addition, the commenters felt that higher maintenance requirements could be expected due to the increased complexity of a gas turbine with water injection.

As pointed out in Volume 1 of the SSEIS, to avoid deposition of chemicals and minerals on gas turbine blades, the water used for water injection must be treated. Costs for water treatment were included in the overall costs of water injection and, for large gas turbines, these costs are considered reasonable.

Actual maintenance and operating costs for gas turbines operating with water or steam injection are limited. Several major utilities, however, have accumulated significant amounts of operating time on gas turbines using water or steam injection for control of NO_x emissions. There have been some problems attributable to water or steam injection, but based on the data available, these problems have been

confined to initial periods of operation of these systems. Most of these reported problems such as turbine blade damage, flame-outs, water hammer damage, and ignition problems, were easily corrected by minor redesign of the equipment hardware. Because of the knowledge gained from these systems, such problems should not arise in the future.

As mentioned, some utilities have accumulated substantial operating experience without any significant increase in maintenance or operating costs or other adverse effects. One utility, for example, has used water injection on two gas turbines for over 55,000 hours without making any major changes to their normal maintenance and operating procedures. They followed procedures essentially identical to those required for a similar gas turbine not using water injection, and the plant experienced no outages attributable to the water injection system. Another company has accumulated over 92,000 hours of operating time with water injection on 17 gas turbines with approximately 116 hours of outage attributable to their water injection system. Increased maintenance costs which can be attributed to these water injection systems are not available, as such costs were not accounted for separately from normal maintenance. However, they were not reported as significant.

Some commenters expressed the opinion that the cost estimates for controlling NO_x emissions from large gas turbines were too low. Accordingly, these commenters felt that wet control technology should not be the basis of the standards for large stationary gas turbines.

The costs associated with wet control technology for large gas turbines were reassessed. In a few cases, it appeared the water-to-fuel ratio used in Volume 1 of the SSEIS was somewhat low. In these cases, the capital and annualized operating costs associated with wet control on large gas turbines were revised to reflect injection of more water into the gas turbine. None of these revisions, however, resulted in a significant change in the projected economic impact of wet controls on large gas turbines. Thus, depending on the size and end use of large gas turbines, wet controls are still projected to increase capital and annualized operating costs by no more than 1 to 4

percent. Increases of this order of magnitude are considered reasonable in light of the 70 percent reduction in NO_x emissions achieved by wet controls. Consequently, the basis of the promulgated standards for large gas turbines remains the same as that for the proposed standards—wet controls.

A number of commenters also expressed the opinion that the cost estimates for wet controls to reduce NO_x emissions from small gas turbines were too low. Therefore, the standards for small gas turbines should not be based on wet controls.

Information included in the comments submitted by manufacturers of small gas turbines indicated the costs of redesigning these gas turbines for water injection are much greater than those included in Volume 1 of the SSEIS. Consequently, it appears the costs of water injection would increase the capital cost of small gas turbines by about 16 percent, rather than about 4 percent as originally estimated. Despite this increase in capital costs, it does not appear water injection would increase the annualized operating costs of small gas turbines by more than 1 to 4 percent as originally estimated, due to the predominance of fuel costs in operating costs. An increase of 16 percent in the capital cost of small gas turbines, however, is considered unreasonable.

Very little information was presented in Volume 1 of the SSEIS concerning the costs of dry controls. The conclusion was drawn, however, that these costs would undoubtedly be less than those associated with wet controls.

Little information was also included in the comments submitted by the manufacturers of small gas turbines concerning the costs of dry controls. Most of the cost information dealt with the costs of wet controls. One manufacturer, however, did submit limited information which appears to indicate that the capital cost impact of dry controls on small gas turbines might be only a quarter of that of wet controls. Thus, dry controls might increase the capital costs of small gas turbines by only about 4 percent. The potential impact of dry controls on annualized operating costs would certainly be no greater than wet controls, and would probably be much less. Consequently, it appears dry controls might increase the capital costs of small gas turbines by about 4 percent and the annualized operating costs by about 1 to 4 percent.

The magnitude of these impacts is essentially the same as those originally associated with wet controls in Volume 1 of the SSEIS, and they are considered reasonable. Consequently, the basis of the promulgated standards for small gas turbines is dry controls.

A number of commenters stated that the costs associated with wet controls on gas turbines located on offshore platforms, and in arid and remote regions were unreasonable. These commenters felt that the costs of obtaining, transporting, and treating water in these areas prohibited the use of water injection.

As mentioned by the commenters, the costs associated with water injection on gas turbines in these locations are all related to lack of water of acceptable quality or quantity. Review of the costs included in Volume 1 of the SSEIS for water injection on gas turbines located on offshore platforms, indicates that the required expenditures for platform space were not incorporated into these estimates. Based on information included in the comments, platform space is very expensive, and averages approximately \$400 per square foot. When this cost is included, the use water treatment systems to provide water for NO_x emissions control would increase the capital costs of a gas turbine located on an offshore platform by approximately 33 percent. This is considered an unreasonable economic impact.

Dry controls, unlike wet controls, would not require additional space on offshore platforms. Although most gas turbines located on offshore platforms would be considered small gas turbines under the standards, it is possible that some large gas turbines might be located on offshore platforms. Therefore, all the information available concerning the costs associated with standards based on dry controls for large gas turbines was reviewed.

Unfortunately, no additional information on the costs of dry controls was included in the comments submitted by the manufacturers of large gas turbines. As mentioned above, the information presented in Volume 1 of the SSEIS is very limited concerning the costs of dry controls, although the conclusion is drawn that these costs would undoubtedly be less than the costs of wet controls. It also seems reasonable to assume that the costs of dry controls on large gas turbines would certainly be less than the costs of dry controls on small gas turbines. Consequently, standards based on dry controls should not increase the capital and annualized operating costs of large gas turbines by more than the 1 to 4

percent projected for small gas turbines. This conclusion even seems conservative in light of the projected increase in capital and annualized operating costs for wet controls on large gas turbines of no more than 1 to 4 percent. In any event, the costs of standards based on dry controls for large gas turbines are considered reasonable. Therefore, the promulgated standards for gas turbines located on offshore platforms are based on dry controls.

In many arid and remote regions, gas turbines would have to obtain water by trucking, installing pipelines to the site, or by construction of large water reservoirs. While costs included in Volume 1 of the SSEIS do not show trucking of water to gas turbine sites to be unreasonable, these costs are not based on actual remote area conditions. That is, these costs are based on paved road conditions and standard ICC freight rates. Gas turbines located in arid and remote regions, however, are not likely to have good access roads. Consequently, it is felt that the costs of trucking water, laying a water pipeline, or constructing a water reservoir would be unreasonable for most arid and remote areas.

As discussed above, the economic impact of standards based on dry controls for both large and small gas turbines is considered reasonable. Consequently, provisions have been included in the promulgated standards which essentially require gas turbines located in arid and remote areas to comply with an NO_x emission limit based on the use of dry controls. A number of options were considered before the specific provisions included in the promulgated standards were selected.

The first option considered was defining the term "arid and remote." While this is conceptually straightforward, it proved impossible to develop a satisfactory definition for regulatory purposes. The second option considered was defining all gas turbines located more than a certain distance from an adequate water supply as "arid and remote" gas turbines. Defining the distance and an adequate water supply, however, proved as impossible as defining the term "arid and remote." The third option considered was a case-by-case exemption for gas turbines where the costs of wet controls exceeded certain levels. This option, however, would provide incentive to owners and operators to develop grossly inflated costs to justify exemption and would require detailed analysis of each case on the part of the Agency to insure this did

not occur. In addition, the numerous disputes and disagreements which would undoubtedly arise under this option would lead to delays and demands on limited resources within both the Agency and industry to resolve.

Analysis of the end use of most gas turbines located in arid and remote regions gave rise to a fourth option. Generally, gas turbines located in arid or remote regions are used for either oil and gas production, or oil and gas transportation. Consequently, the promulgated standards require gas turbines employed in oil and gas production or oil and gas transportation, which are not located in a Metropolitan Statistical Area (MSA), to meet an NO_x emission limit based on the use of dry controls. The promulgated standards, however, require gas turbines employed in oil and gas production or oil and gas transportation which are located in a MSA to meet the 75 ppm NO_x emission limit. This emission limit is based on the use of wet controls and in an MSA a suitable water supply for water injection will be available.

Environmental Impact

A number of commenters felt gas turbines used as "peaking" units should be exempt. Peaking units operate relatively few hours per year. According to commenters, use of water injection would result in a very small reduction in annual NO_x emissions and negligible improvement in ground level concentrations.

As pointed out in Volume 1 of the SSEIS, about 90 percent of all new gas turbine capacity is expected to be installed by electric utility companies to generate electricity, and possibly as much as 75 percent of all NO_x emissions from stationary gas turbines are emitted from these installations. Of these electric utility gas turbines, a large majority are used to generate power during periods of peak demand. Consequently, by their very nature, peaking gas turbines tend to operate when the need for emission control is greatest, that is, when power demand is highest and air quality is usually at its worst. Therefore, it does not seem reasonable to exempt peaking gas turbines from compliance with the standards.

A number of commenters also felt that small gas turbines should be exempt from the standards because they emit only about 10 percent of the total NO_x emissions from all stationary gas turbines and therefore, the environmental impact of not regulating these turbines would be small.

A high priority has been established for NO_x emission control and dry control

techniques are considered a demonstrated and economically reasonable means for reducing NO_x emissions from small gas turbines. Therefore, the promulgated standards limit NO_x emissions from small gas turbines to 150 ppm based on the use of dry control technology.

Energy Impact

A number of writers commented on the potential impact of the standards on the use of the oil-shale, coal-derived, and other synthetic fuels. It was generally felt that these types of fuels should not be covered by the standards at this time, since this could hinder their development.

Total NO_x emissions from any combustion source, including stationary gas turbines, are comprised of thermal NO_x and organic NO_x . Thermal NO_x is formed in a well-defined high temperature reaction between oxygen and nitrogen in the combustion air. Organic NO_x is produced by the combination of fuel-bound nitrogen with oxygen during combustion in a reaction that is not yet fully understood. Shale oil, coal-derived, and other synthetic fuels generally have high nitrogen contents and, therefore, will produce relatively high organic NO_x emissions when combusted.

Neither wet nor dry control technology for gas turbines is effective in reducing organic NO_x emissions. As discussed in Volume I of the SSEIS, as fuel-bound nitrogen increases, organic NO_x emissions from a gas turbine become the predominant fraction of total NO_x emissions. Consequently, emission standards must address in some manner the contribution to NO_x emissions of fuel-bound nitrogen.

Low nitrogen fuels, such as premium distillate fuel oil and natural gas, are now being fired in nearly all stationary gas turbines. Energy supply considerations, however, may cause more gas turbines to fire heavy fuel oils and synthetic fuels in the future. A standard based on present practice of firing low nitrogen fuels, therefore, would too rigidly restrict the use of high nitrogen fuel, especially in light of the uncertainty in world energy markets.

Since control technology is not in reducing organic NO_x emissions from gas turbines, the possibility of basing standards on removal of nitrogen from the fuel prior to combustion was considered. The cost of removing nitrogen from fuel oil, however, ranges from \$2.00 to \$3.00 per barrel. Another alternative considered was exempting gas turbines using high nitrogen fuels, as some commenters requested. Exempting gas turbines based on the type of fuel

used, however, would not require the use of best control technology in all cases.

A third alternative considered was the use of a fuel-bound nitrogen allowance. Beyond some point it is simply not reasonable to allow combustion of high nitrogen fuels in gas turbines. In addition, high nitrogen fuels, including shale oil and coal-derived fuels, can be used in other combustion devices where some control of organic NO_x emissions is possible. Greater reduction of nationwide NO_x emissions could be achieved by utilizing these fuels in facilities where organic NO_x emission control is possible than in gas turbines where organic NO_x emissions are essentially uncontrolled. This approach, therefore, balances the trade-off between allowing unlimited selection of fuels for gas turbines controlling NO_x emissions.

A limited fuel-bound nitrogen allowance which would allow increased NO_x emissions above the numerical NO_x emissions limits including in the promulgated standards seems most reasonable. An upper limit on this allowance of 50 ppm NO_x was selected. Such a limit would allow approximately 50 percent of existing heavy fuel oils to be fired in stationary gas turbines. (See Volume I of the SSEIS.) This approach is considered a reasonable means of allowing flexibility in the selection of fuels while achieving reductions in NO_x emissions from stationary gas turbines. (See Control Technology for further discussion.)

A number of commenters felt the efficiency correction factor included in the standards should use the overall efficiency of a gas turbine installation rather than the thermal efficiency of the gas turbine itself. For example, many commenters recommended that the overall efficiency of a combined cycle gas turbine installation be used in this correction factor.

Section 111 of the Clean Air Act requires that standards of performance for new sources reflect the use of the best system of emission reduction. With the few exceptions noted above, water injection is considered the best system of emission control for reducing NO_x emissions from stationary gas turbines. To be consistent with the intent of section 111, the standards must reflect the use of water injection independent of any ancillary waste heat recovery equipment which might be associated with a gas turbine to increase its overall efficiency. To allow an upward adjustment in the NO_x emission limit based on the overall efficiency of a combined cycle gas turbine could mean that water injection might not have to be

applied to the gas turbine. Thus, the standards would not reflect the use of the best system of emission reduction. Therefore, the efficiency factor must be based on the gas turbine efficiency itself, not the overall efficiency of a gas turbine combined with other equipment.

Test Methods and Monitoring

A large number of commenters objected to the amount of monitoring required. The proposed standards called for daily monitoring of sulfur content, nitrogen content, and lower heating value of the fuel. The commenters were generally in favor of less frequent periodic monitoring.

These comments seem reasonable. Therefore, the standards have been changed to permit determination of sulfur content, nitrogen content, and lower heating value only when a fresh supply of fuel is added to the fuel storage facilities for a gas turbine. Where gas turbines are fueled without intermediate storage, such as along oil and gas transport pipelines, daily monitoring is still required by the standards unless the owner or operator can show that the composition of the fuel does not fluctuate significantly. In these cases, the owner or operator may develop an individual monitoring schedule for determining fuel sulfur content, nitrogen content, and lower heating value. These schedules must be substantiated by data and submitted to the Administrator for approval on a case-by-case basis.

Several commenters stated that the standards should be clarified to allow the performance test to be performed by the gas turbine manufacturer in lieu of the owner/operator. To simplify verification of compliance with the standards and to reduce costs to everyone involved, the recommendation was made that each gas turbine be performance tested at the manufacturer's site. The commenters maintained that gas turbines should not be required to undergo a performance test at the owner/operator's site if they have been shown to comply with the standard by the gas turbine manufacturer.

Section 111 of the Clean Air Act is not flexible enough to permit the use of a formal certification program such as that described by the commenter. Responsibility for complying with the standards ultimately rests with the owner/operator, not with the gas turbine manufacturers. The general provisions of 40 CFR Part 60, however, which apply to all standards of performance, allow the use of approaches other than performance tests to determine compliance on a case-by-case basis. The

alternate approach must demonstrate to the Administrator's satisfaction that the facility is in compliance with the standard. Consequently, gas turbine manufacturers' tests may be considered, on a case-by-case basis, in lieu of performance tests at the owner/operator's site to demonstrate compliance with the standards. For a gas turbine manufacturers' test to be acceptable in lieu of a performance test, as a minimum the operating conditions of the gas turbine at the installation site would have to be shown to be similar to those during the manufacturer's test. In addition, this would not preclude the Administrator from requiring a performance test at any time to demonstrate compliance with the standards.

Miscellaneous

It should be noted that standards of performance for new stationary sources established under section 111 of the Clean Air Act reflect:

"... application of the best technological system of continuous emission reduction which (taking into consideration the cost of achieving such emission reduction, any nonair quality health and environment impact and energy requirements) the Administrator determines has been adequately demonstrated. [section 111(a)(1)]

Although there may be emission control technology available that can reduce emissions below those levels required to comply with standards of performance, this technology might not be selected as the basis of standards of performance due to costs associated with its use. Accordingly, standards of performance should not be viewed as the ultimate in achievable emission control. In fact, the Act requires (or has potential for requiring) the imposition of a more stringent emission standard in several situations.

For example, applicable costs do not play as prominent a role in determining the "lowest achievable emission rate" for new or modified sources located in nonattainment areas, i.e., those areas where statutorily mandated health and welfare standards are being violated. In this respect, section 173 of the act requires that a new or modified source constructed in an area which exceeds the National Ambient Air Quality Standard (NAAQS) must reduce emissions to the level which reflects the "lowest achievable emission rate" (LAER), as defined in section 171(3), for such category of source. The statute defines LAER as that rate of emission which reflects:

(A) The most stringent emission limitation which is contained in the implementation plan of any State for

such class or category of source, unless the owner or operator of the proposed source demonstrates that such limitations are not achievable, or

(B) The most stringent emission limitation which is achieved in practice by such class or category of source, whichever is more stringent.

In no event can the emission rate exceed any applicable new source performance standard (section 171(3)).

A similar situation may arise under the prevention of significant deterioration of air quality provisions of the Act (part C). These provisions require that certain sources (referred to in section 189(1)) employ "best available control technology" (as defined in section 189(3)) for all pollutants regulated under the Act. Best available control technology (BACT) must be determined on a case-by-case basis, taking energy, environmental and economic impacts, and other costs into account. In no event may the application of BACT result in emissions of any pollutants which will exceed the emissions allowed by any applicable standard established pursuant to section 111 (or 112) of the Act.

In all events, State implementation plans (SIPs) approved or promulgated under section 110 of the Act must provide for the attainment and maintenance of National Ambient Air Quality Standards designed to protect public health and welfare. For this purpose, SIPs must in some cases require greater emission reductions than those required by standards of performance for new sources.

Finally, States are free under section 116 of the Act to establish even more stringent emission limits than those established under section 111 or those necessary to attain or maintain the NAAQS under section 110. Accordingly, new sources may in some cases be subject to limitations more stringent than EPA's standards of performance under section 111, and prospective owners and operators of new sources should be aware of this possibility in planning for such facilities.

This regulation will be reviewed 4 years from the date of promulgation. This review will include an assessment of such factors as the need for integration with other programs, the existence of alternative methods, enforceability, and improvements in emissions control technology.

No economic impact assessment under Section 317 was prepared on this standard. Section 317(a) requires such an assessment only if "the notice of proposed rulemaking in connection with such standard . . . is published in the Federal Register after the date ninety

days after August 7, 1977." This standard was proposed in the Federal Register on October 3, 1977, less than ninety days after August 7, 1977, and an assessment was therefore not required.

Dated: August 28, 1979.

Douglas M. Costle,
Administrator.

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

It is proposed to amend Part 60 of Chapter I, Title 40 of the Code of Federal Regulations as follows:

1. By adding subpart GG as follows:

Subpart GG—Standards of Performance for Stationary Gas Turbines

Sec.

60.330 Applicability and designation of affected facility.

60.331 Definitions.

60.332 Standard for nitrogen oxides.

60.333 Standard for sulfur dioxide.

60.334 Monitoring of operations.

60.335 Test methods and procedures.

Authority: Secs. 111 and 301(a) of the Clean Air Act, as amended, [42 U.S.C. 1857c-7, 1857g(a)], and additional authority as noted below.

Subpart GG—Standards of Performance for Stationary Gas Turbines

§ 60.330 Applicability and designation of affected facility.

The provisions of this subpart are applicable to the following affected facilities: all stationary gas turbines with a heat input at peak load equal to or greater than 10.7 gigajoules per hour, based on the lower heating value of the fuel fired.

§ 60.331 Definitions.

As used in this subpart, all terms not defined herein shall have the meaning given them in the Act and in subpart A of this part.

(a) "Stationary gas turbine" means any simple cycle gas turbine, regenerative cycle gas turbine or any gas turbine portion of a combined cycle steam/electric generating system that is not self propelled. It may, however, be mounted on a vehicle for portability.

(b) "Simple cycle gas turbine" means any stationary gas turbine which does not recover heat from the gas turbine exhaust gases to preheat the inlet combustion air to the gas turbine, or which does not recover heat from the gas turbine exhaust gases to heat water or generate steam.

(c) "Regenerative cycle gas turbine" means any stationary gas turbine which recovers heat from the gas turbine

exhaust gases to preheat the inlet combustion air to the gas turbine.

(d) "Combined cycle gas turbine" means any stationary gas turbine which recovers heat from the gas turbine exhaust gases to heat water or generate steam.

(e) "Emergency gas turbine" means any stationary gas turbine which operates as a mechanical or electrical power source only when the primary power source for a facility has been rendered inoperable by an emergency situation.

(f) "Ice fog" means an atmospheric suspension of highly reflective ice crystals.

(g) "ISO standard day conditions" means 288 degrees Kelvin, 60 percent relative humidity and 101.3 kilopascals pressure.

(h) "Efficiency" means the gas turbine manufacturer's rated heat rate at peak load in terms of heat input per unit of power output based on the lower heating value of the fuel.

(i) "Peak load" means 100 percent of the manufacturer's design capacity of the gas turbine at ISO standard day conditions.

(j) "Base load" means the load level at which a gas turbine is normally operated.

(k) "Fire-fighting turbine" means any stationary gas turbine that is used solely to pump water for extinguishing fires.

(l) "Turbines employed in oil/gas production or oil/gas transportation" means any stationary gas turbine used to provide power to extract crude oil/natural gas from the earth or to move crude oil/natural gas, or products refined from these substances through pipelines.

(m) A "Metropolitan Statistical Area" or "MSA" as defined by the Department of Commerce.

(n) "Offshore platform gas turbines" means any stationary gas turbine located on a platform in an ocean.

(o) "Garrison facility" means any permanent military installation.

(p) "Gas turbine model" means a group of gas turbines having the same nominal air flow, combustor inlet pressure, combustor inlet temperature, firing temperature, turbine inlet temperature and turbine inlet pressure.

§ 60.332 Standard for nitrogen oxides.

(a) On and after the date on which the performance test required by § 60.8 is completed, every owner or operator subject to the provisions of this subpart, as specified in paragraphs (b), (c), and (d) of this section, shall comply with one of the following, except as provided in paragraphs (e), (f), (g), (h), and (i) of this section.

(1) No owner or operator subject to the provisions of this subpart shall cause to be discharged into the atmosphere from any stationary gas turbine, any gases which contain nitrogen oxides in excess of:

$$STD = 0.0075 \frac{(14.4)}{Y} + F$$

32

where:

STD = allowable NO_x emissions (percent by volume at 15 percent oxygen and on a dry basis).

Y = manufacturer's rated heat rate at manufacturer's rated load (kilojoules per watt hour) or, actual measured heat rate based on lower heating value of fuel as measured at actual peak load for the facility. The value of Y shall not exceed 14.4 kilojoules per watt hour.

F = NO_x emission allowance for fuel-bound nitrogen as defined in part (3) of this paragraph.

(2) No owner or operator subject to the provisions of this subpart shall cause to be discharged into the atmosphere from any stationary gas turbine, any gases which contain nitrogen oxides in excess of:

$$STD = 0.0150 \left(\frac{14.4}{Y} \right) + F$$

where:

STD = allowable NO_x emissions (percent by volume at 15 percent oxygen and on a dry basis).

Y = manufacturer's rated heat rate at manufacturer's rated peak load (kilojoules per watt hour), or actual measured heat rate based on lower heating value of fuel as measured at actual peak load for the facility. The value of Y shall not exceed 14.4 kilojoules per watt hour.

F = NO_x emission allowance for fuel-bound nitrogen as defined in part (3) of this paragraph.

(3) F shall be defined according to the nitrogen content of the fuel as follows:

Fuel-Bound Nitrogen (percent by weight)	F (NO _x percent by volume)
N ≤ 0.015	0
0.015 < N ≤ 0.1	0.04(N)
0.1 < N ≤ 0.25	0.004 + 0.0067(N-0.1)
N > 0.25	0.005

where:

N = the nitrogen content of the fuel (percent by weight).

or:

Manufacturers may develop custom fuel-bound nitrogen allowances for each

gas turbine model they manufacture. These fuel-bound nitrogen allowances shall be substantiated with data and must be approved for use by the Administrator before the initial performance test required by § 60.8. Notices of approval of custom fuel-bound nitrogen allowances will be published in the Federal Register.

(b) Stationary gas turbines with a heat input at peak load greater than 107.2 gigajoules per hour (100 million Btu/hour) based on the lower heating value of the fuel fired except as provided in § 60.332(d) shall comply with the provisions of § 60.332(a)(1).

(c) Stationary gas turbines with a heat input at peak load equal to or greater than 10.7 gigajoules per hour (10 million Btu/hour) but less than or equal to 107.2 gigajoules per hour (100 million Btu/hour) based on the lower heating value of the fuel fired, shall comply with the provisions of § 60.332(a)(2).

(d) Stationary gas turbines employed in oil/gas production or oil/gas transportation and not located in Metropolitan Statistical Areas; and offshore platform turbines shall comply with the provisions of § 60.332(a)(2).

(e) Stationary gas turbines with a heat input at peak load equal to or greater than 10.7 gigajoules per hour (10 million Btu/hour) but less than or equal to 107.2 gigajoules per hour (100 million Btu/hour) based on the lower heating value of the fuel fired and that have commenced construction prior to October 3, 1982 are exempt from paragraph (a) of this section.

(f) Stationary gas turbines using water or steam injection for control of NO_x emissions are exempt from paragraph (a) when ice fog is deemed a traffic hazard by the owner or operator of the gas turbine.

(g) Emergency gas turbines, military gas turbines for use in other than a garrison facility, military gas turbines installed for use as military training facilities, and fire fighting gas turbines are exempt from paragraph (a) of this section.

(h) Stationary gas turbines engaged by manufacturers in research and development of equipment for both gas turbine emission control techniques and gas turbine efficiency improvements are exempt from paragraph (a) on a case-by-case basis as determined by the Administrator.

(i) Exemptions from the requirements of paragraph (a) of this section will be granted on a case-by-case basis as determined by the Administrator in specific geographical areas where mandatory water restrictions are required by governmental agencies because of drought conditions. These

exemptions will be allowed only while the mandatory water restrictions are in effect.

§ 60.333 Standard for sulfur dioxide.

On and after the date on which the performance test required to be conducted by § 60.8 is completed, every owner or operator subject to the provision of this subpart shall comply with one or the other of the following conditions:

(a) No owner or operator subject to the provisions of this subpart shall cause to be discharged into the atmosphere from any stationary gas turbine any gases which contain sulfur dioxide in excess of 0.015 percent by volume at 15 percent oxygen and on a dry basis.

(b) No owner or operator subject to the provisions of this subpart shall burn in any stationary gas turbine any fuel which contains sulfur in excess of 0.8 percent by weight.

§ 60.334 Monitoring of operations.

(a) The owner or operator of any stationary gas turbine subject to the provisions of this subpart and using water injection to control NO_x emissions shall install and operate a continuous monitoring system to monitor and record the fuel consumption and the ratio of water to fuel being fired in the turbine. This system shall be accurate to within ± 5.0 percent and shall be approved by the Administrator.

(b) The owner or operator of any stationary gas turbine subject to the provisions of this subpart shall monitor sulfur content and nitrogen content of the fuel being fired in the turbine. The frequency of determination of these values shall be as follows:

(1) If the turbine is supplied its fuel from a bulk storage tank, the values shall be determined on each occasion that fuel is transferred to the storage tank from any other source.

(2) If the turbine is supplied its fuel without intermediate bulk storage the values shall be determined and recorded daily. Owners, operators or fuel vendors may develop custom schedules for determination of the values based on the design and operation of the affected facility and the characteristics of the fuel supply. These custom schedules shall be substantiated with data and must be approved by the Administrator before they can be used to comply with paragraph (b) of this section.

(c) For the purpose of reports required under § 60.7(c), periods of excess emissions that shall be reported are defined as follows:

(1) *Nitrogen oxides.* Any one-hour period during which the average water-

to-fuel ratio, as measured by the continuous monitoring system, falls below the water-to-fuel ratio determined to demonstrate compliance with § 60.332 by the performance test required in § 60.8 or any period during which the fuel-bound nitrogen of the fuel is greater than the maximum nitrogen content allowed by the fuel-bound nitrogen allowance used during the performance test required in § 60.8. Each report shall include the average water-to-fuel ratio, average fuel consumption, ambient conditions, gas turbine load, and nitrogen content of the fuel during the period of excess emissions, and the graphs or figures developed under § 60.335(a).

(2) *Sulfur dioxide.* Any daily period during which the sulfur content of the fuel being fired in the gas turbine exceeds 0.8 percent.

(3) *Ice fog.* Each period during which an exemption provided in § 60.332(g) is in effect shall be reported in writing to the Administrator quarterly. For each period the ambient conditions existing during the period, the date and time the

$$\text{NO}_x = (\text{NO}_{x_{\text{obs}}}) \left(\frac{P_{\text{ref}}}{P_{\text{obs}}} \right)^{0.5} e^{19(H_{\text{obs}} - 0.00633)} \left(\frac{T_{\text{AMB}}}{288^\circ\text{K}} \right)^{1.53}$$

where:

NO_x = emissions of NO_x at 15 percent oxygen and ISO standard ambient conditions.

$\text{NO}_{x_{\text{obs}}}$ = measured NO_x emissions at 15 percent oxygen, ppmv.

P_{ref} = reference combustor inlet absolute pressure at 101.3 kilopascals ambient pressure.

P_{obs} = measured combustor inlet absolute pressure at test ambient pressure.

H_{obs} = specific humidity of ambient air at test.

e = transcendental constant (2.718).

T_{AMB} = temperature of ambient air at test.

The adjusted NO_x emission level shall be used to determine compliance with § 60.332.

(ii) Manufacturers may develop custom ambient condition correction factors for each gas turbine model they manufacture in terms of combustor inlet pressure, ambient air pressure, ambient air humidity and ambient air temperature to adjust the nitrogen oxides emission level measured by the performance test as provided for in § 60.8 to ISO standard day conditions. These ambient condition correction factors shall be substantiated with data and must be approved for use by the Administrator before the initial performance test required by § 60.8. Notices of approval of custom ambient condition correction factors will be published in the Federal Register.

(iii) The water-to-fuel ratio necessary to comply with § 60.332 will be determined during the initial performance test by measuring NO_x emission using Reference Method 20 and

air pollution control system was deactivated, and the date and time the air pollution control system was reactivated shall be reported. All quarterly reports shall be postmarked by the 30th day following the end of each calendar quarter.

(Sec. 114 of the Clean Air Act as amended [42 U.S.C. 1857c-9]).

§ 60.335 Test methods and procedures.

(a) The reference methods in Appendix A to this part, except as provided in § 60.8(b), shall be used to determine compliance with the standards prescribed in § 60.332 as follows:

(1) Reference Method 20 for the concentration of nitrogen oxides and oxygen. For affected facilities under this subpart, the span value shall be 300 parts per million of nitrogen oxides.

(i) The nitrogen oxides emission level measured by Reference Method 20 shall be adjusted to ISO standard day conditions by the following ambient condition correction factor:

the water-to-fuel ratio necessary to comply with § 60.332 at 30, 50, 75, and 100 percent of peak load or at four points in the normal operating range of the gas turbine, including the minimum point in the range and peak load. All loads shall be corrected to ISO conditions using the appropriate equations supplied by the manufacturer.

(2) The analytical methods and procedures employed to determine the nitrogen content of the fuel being fired shall be approved by the Administrator and shall be accurate to within ± 5 percent.

(b) The method for determining compliance with § 60.333, except as provided in § 60.8(b), shall be as follows:

(1) Reference Method 20 for the concentration of sulfur dioxide and oxygen or

(2) ASTM D2880-71 for the sulfur content of liquid fuels and ASTM D1072-70 for the sulfur content of gaseous fuels. These methods shall also be used to comply with § 60.334(b).

(c) Analysis for the purpose of determining the sulfur content and the nitrogen content of the fuel as required by § 60.334(b), this subpart, may be performed by the owner/operator, a service contractor retained by the owner/operator, the fuel vendor, or any other qualified agency provided that the analytical methods employed by these agencies comply with the applicable paragraphs of this section.

(Sec. 114 of the Clean Air Act as amended [42 U.S.C. 1857c-91]).

Appendix A—Reference Methods

2. Part 60 is amended by adding Reference Method 20 to Appendix A as follows:

Method 20—Determination of Nitrogen Oxides, Sulfur Dioxide, and Oxygen Emissions from Stationary Gas Turbines

1. Applicability and Principle

1.1 **Applicability.** This method is applicable for the determination of nitrogen oxides (NO_x), sulfur dioxide (SO₂), and oxygen (O₂) emissions from stationary gas turbines. For the NO_x and O₂ determinations, this method includes: (1) measurement system design criteria; (2) analyzer performance specifications and performance test procedures; and (3) procedures for emission testing.

1.2 **Principle.** A gas sample is continuously extracted from the exhaust stream of a stationary gas turbine; a portion of the sample stream is conveyed to instrumental analyzers for determination of NO_x and O₂ content. During each NO_x and O₂ determination, a separate measurement of SO₂ emissions is made, using Method 6, or it equivalent. The O₂ determination is used to adjust the NO_x and SO₂ concentrations to a reference condition.

2. Definitions

2.1 **Measurement System.** The total equipment required for the determination of a gas concentration or a gas emission rate. The system consists of the following major subsystems:

2.1.1 **Sample Interface.** That portion of a system that is used for one or more of the following: sample acquisition, sample transportation, sample conditioning, or protection of the analyzers from the effects of the stack effluent.

2.1.2 **NO_x Analyzer.** That portion of the system that senses NO_x and generates an output proportional to the gas concentration.

2.1.3 **O₂ Analyzer.** That portion of the system that senses O₂ and generates an output proportional to the gas concentration.

2.2 **Span Value.** The upper limit of a gas concentration measurement range that is specified for affected source categories in the applicable part of the regulations.

2.3 **Calibration Gas.** A known concentration of a gas in an appropriate diluent gas.

2.4 **Calibration Error.** The difference between the gas concentration indicated by the measurement system and the known concentration of the calibration gas.

2.5 **Zero Drift.** The difference in the measurement system output readings before and after a stated period of operation during which no unscheduled maintenance, repair, or adjustment took place and the input concentration at the time of the measurements was zero.

2.6 **Calibration Drift.** The difference in the measurement system output readings before and after a stated period of operation during which no unscheduled maintenance, repair, or adjustment took place and the input at the time of the measurements was a high-level value.

2.7 **Residence Time.** The elapsed time from the moment the gas sample enters the probe tip to the moment the same gas sample reaches the analyzer inlet.

2.8 **Response Time.** The amount of time required for the continuous monitoring system to display on the data output 95 percent of a step change in pollutant concentration.

2.9 **Interference Response.** The output response of the measurement system to a component in the sample gas, other than the gas component being measured.

3. Measurement System Performance Specifications

3.1 **NO_x to NO Converter.** Greater than 90 percent conversion efficiency of NO_x to NO.

3.2 **Interference Response.** Less than ± 2 percent of the span value.

3.3 **Residence Time.** No greater than 30 seconds.

3.4 **Response Time.** No greater than 3 minutes.

3.5 **Zero Drift.** Less than ± 2 percent of the span value.

3.6 **Calibration Drift.** Less than ± 2 percent of the span value.

4. Apparatus and Reagents

4.1 **Measurement System.** Use any measurement system for NO_x and O₂ that is expected to meet the specifications in this method. A schematic of an acceptable measurement system is shown in Figure 20-1. The essential components of the measurement system are described below:

4.1.1 **Sample Probe.** Heated stainless steel, or equivalent, open-ended, straight tube of sufficient length to traverse the sample points.

4.1.2 **Sample Line.** Heated ($> 95^{\circ}\text{C}$) stainless steel or Teflon tubing to transport the sample gas to the sample conditioners and analyzers.

4.1.3 **Calibration Valve Assembly.** A three-way valve assembly to direct the zero and calibration gases to the sample conditioners and to the analyzers. The calibration valve assembly shall be capable of blocking the sample gas flow and of introducing calibration gases to the measurement system when in the calibration mode.

4.1.4 **NO_x to NO Converter.** That portion of the system that converts the nitrogen dioxide (NO₂) in the sample gas to nitrogen oxide (NO). Some analyzers are designed to measure NO_x as NO₂ on a wet basis and can be used without an NO_x to NO converter or a moisture removal trap provided the sample line to the analyzer is heated ($> 95^{\circ}\text{C}$) to the inlet of the analyzer. In addition, an NO_x to NO converter is not necessary if the NO_x portion of the exhaust gas is less than 5 percent of the total NO_x concentration. As a guideline, an NO_x to NO converter is not necessary if the gas turbine is operated at 90 percent or more of peak load capacity. A converter is necessary under lower load conditions.

4.1.5 **Moisture Removal Trap.** A refrigerator-type condenser designed to continuously remove condensate from the sample gas. The moisture removal trap is not necessary for analyzers that can measure NO_x concentrations on a wet basis; for these analyzers, (a) heat the sample line up to the inlet of the analyzers, (b) determine the moisture content using methods subject to the approval of the Administrator, and (c) correct the NO_x and O₂ concentrations to a dry basis.

4.1.6 **Particulate Filter.** An in-stack or an out-of-stack glass fiber filter, of the type specified in EPA Reference Method 5; however, an out-of-stack filter is recommended when the stack gas temperature exceeds 250 to 300°C.

4.1.7 **Sample Pump.** A nonreactive leak-free sample pump to pull the sample gas through the system at a flow rate sufficient to minimize transport delay. The pump shall be made from stainless steel or coated with Teflon or equivalent.

4.1.8 **Sample Gas Manifold.** A sample gas manifold to divert portions of the sample gas stream to the analyzers. The manifold may be constructed of glass, Teflon, type 316 stainless steel, or equivalent.

4.1.9 **Oxygen and Analyzer.** An analyzer to determine the percent O₂ concentration of the sample gas stream.

4.1.10 **Nitrogen Oxides Analyzer.** An analyzer to determine the ppm NO_x concentration in the sample gas stream.

4.1.11 **Data Output.** A strip-chart recorder, analog computer, or digital recorder for recording measurement data.

4.2 **Sulfur Dioxide Analysis.** EPA Reference Method 6 apparatus and reagents.

4.3 **NO_x Calibration Gases.** The calibration gases for the NO_x analyzer may be NO in N₂, NO₂ in air or N₂, or NO and NO₂

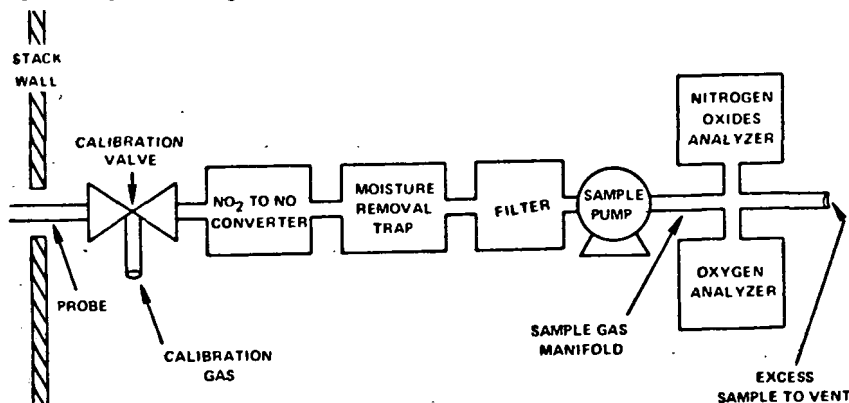

Figure 20-1. Measurement system design for stationary gas turbines.

in N_2 . For NO_x measurement analyzers that require oxidation of NO to NO_2 , the calibration gases must be in the form of NO in N_2 . Use four calibration gas mixtures as specified below:

4.3.1 High-level Gas. A gas concentration that is equivalent to 80 to 90 percent of the span value.

4.3.2 Mid-level Gas. A gas concentration that is equivalent to 45 to 55 percent of the span value.

4.3.3 Low-level Gas. A gas concentration that is equivalent to 20 to 30 percent of the span value.

4.3.4 Zero Gas. A gas concentration of less than 0.25 percent of the span value. Ambient air may be used for the NO_x zero gas.

4.4 O_2 Calibration Gases. Use ambient air at 20.9 percent as the high-level O_2 gas. Use a gas concentration that is equivalent to 11–14 percent O_2 for the mid-level gas. Use purified nitrogen for the zero gas.

4.5 NO_2/NO Gas Mixture. For determining the conversion efficiency of the NO_2 to NO converter, use a calibration gas mixture of NO_2 and NO in N_2 . The mixture will be known concentrations of 40 to 60 ppm NO_2 and 90 to 110 ppm NO and certified by the gas manufacturer. This certification of gas concentration must include a brief description of the procedure followed in determining the concentrations.

5. Measurement System Performance Test Procedures

Perform the following procedures prior to measurement of emissions (Section 6) and only once for each test program, i.e., the series of all test runs for a given gas turbine engine.

5.1 Calibration Gas Checks. There are two alternatives for checking the concentrations of the calibration gases. (a) The first is to use calibration gases that are documented traceable to National Bureau of Standards Reference Materials. Use

Traceability Protocol for Establishing True Concentrations of Gases Used for Calibrations and Audits of Continuous Source Emission Monitors (Protocol Number 1) that is available from the Environmental Monitoring and Support Laboratory, Quality Assurance Branch, Mail Drop 77, Environmental Protection Agency, Research Triangle Park, North Carolina 27711. Obtain a certification from the gas manufacturer that the protocol was followed. These calibration gases are not to be analyzed with the Reference Methods. (b) The second alternative is to use calibration gases not prepared according to the protocol. If this alternative is chosen, within 1 month prior to the emission test, analyze each of the calibration gas mixtures in triplicate using Reference Method 7 or the procedure outlined in Citation 8.1 for NO_x and use Reference Method 3 for O_2 . Record the results on a data sheet (example is shown in Figure 20-2). For the low-level, mid-level, or high-level gas mixtures, each of the individual NO_x analytical results must be within 10 percent (or 10 ppm, whichever is greater) of the triplicate set average (O_2 test results must be within 0.5 percent O_2); otherwise, discard the entire set and repeat the triplicate analyses. If the average of the triplicate reference method test results is within 5 percent for NO_x gas or 0.5 percent O_2 for the O_2 gas of the calibration gas manufacturer's tag value, use the tag value; otherwise, conduct at least three additional reference method test analyses until the results of six individual NO_x runs (the three original plus three additional) agree within 10 percent (or 10 ppm, whichever is greater) of the average (O_2 test results must be within 0.5 percent O_2). Then use this average for the cylinder value.

5.2 Measurement System Preparation. Prior to the emission test, assemble the measurement system following the manufacturer's written instructions in preparing and operating the NO_x to NO converter, the NO_x analyzer, the O_2 analyzer, and other components.

Date _____ (Must be within 1 month prior to the test period)

Reference method used _____

Sample run	Gas concentration, ppm		
	Low level ^a	Mid level ^b	High level ^c
1			
2			
3			
Average			
Maximum % deviation ^d			

^a Average must be 20 to 30% of span value.

^b Average must be 45 to 55% of span value.

^c Average must be 80 to 90% of span value.

^d Must be $\leq \pm 10\%$ of applicable average or 10 ppm, whichever is greater.

Figure 20-2. Analysis of calibration gases.

5.3 Calibration Check. Conduct the calibration checks for both the NO_x and the O₂ analyzers as follows:

5.3.1 After the measurement system has been prepared for use (Section 5.2), introduce zero gases and the mid-level calibration gases; set the analyzer output responses to the appropriate levels. Then introduce each of the remainder of the calibration gases described in Sections 4.3 or 4.4, one at a time, to the measurement system. Record the responses on a form similar to Figure 20-3.

5.3.2 If the linear curve determined from the zero and mid-level calibration gas responses does not predict the actual response of the low-level (not applicable for the O₂ analyzer) and high-level gases within ± 2 percent of the span value, the calibration shall be considered invalid. Take corrective measures on the measurement system before proceeding with the test.

5.4 Interference Response. Introduce the gaseous components listed in Table 20-1 into the measurement system separately, or as gas mixtures. Determine the total interference output response of the system to these components in concentration units; record the values on a form similar to Figure 20-4. If the sum of the interference responses of the test

gases for either the NO_x or O₂ analyzers is greater than 2 percent of the applicable span value, take corrective measure on the measurement system.

Table 20-1.—Interference Test Gas Concentration

CO	500 \pm 50 ppm.
SO ₂	200 \pm 20 ppm.
CO ₂	10 \pm 1 percent.
O ₂	20.9 \pm 1 percent.

Date of test _____			
Analyzer type _____		Serial No. _____	
Test gas type	Concentration, ppm	Analyzer output response	% of span

$$\% \text{ of span} = \frac{\text{Analyzer output response}}{\text{Instrument span}} \times 100$$

Figure 20-4 Interference response

Turbine type: _____ Identification number _____

Date: _____ Test number _____

Analyzer type: _____ Identification number _____

	Cylinder value, ppm or %	Initial analyzer response, ppm or %	Final analyzer responses, ppm or %	Difference: initial-final, ppm or %
Zero gas				
Low - level gas				
Mid - level gas				
High - level gas				

$$\text{Percent drift} = \frac{\text{Absolute difference}}{\text{Span value}} \times 100.$$

Figure 20-3. Zero and calibration data.

Conduct an interference response test of each analyzer prior to its initial use in the field. Thereafter, recheck the measurement system if changes are made in the instrumentation that could alter the interference response, e.g., changes in the type of gas detector.

In lieu of conducting the interference response test, instrument vendor data, which demonstrate that for the test gases of Table 20-1 the interference performance

specification is not exceeded, are acceptable.

5.5 Residence and Response Time.

5.5.1 Calculate the residence time of the sample interface portion of the measurement system using volume and pump flow rate information. Alternatively, if the response time determined as defined in Section 5.5.2 is less than 30 seconds, the calculations are not necessary.

5.5.2 To determine response time, first introduce zero gas into the system at the

calibration valve until all readings are stable; then, switch to monitor the stack effluent until a stable reading can be obtained. Record the upscale response time. Next, introduce high-level calibration gas into the system. Once the system has stabilized at the high-level concentration, switch to monitor the stack effluent and wait until a stable value is reached. Record the downscale response time. Repeat the procedure three times. A stable value is equivalent to a

change of less than 1 percent of span value for 30 seconds or less than 5 percent of the measured average concentration for 2 minutes. Record the response time data on a form similar to Figure 20-5, the readings of the upscale or downscale response time, and report the greater time as the "response time" for the analyzer. Conduct a response time test prior to the initial field use of the measurement system, and repeat if changes are made in the measurement system.

Date of test _____	
Analyzer type _____	S/N _____
Span gas concentration _____ ppm	
Analyzer span setting _____ ppm	
	1 _____ seconds
Upscale	2 _____ seconds
	3 _____ seconds
Average upscale response _____ seconds	
	1 _____ seconds
Downscale	2 _____ seconds
	3 _____ seconds
Average downscale response _____ seconds	
System response time = slower average time = _____ seconds.	

Figure 20-5. Response time

5.6 NO₂/NO Conversion Efficiency. Introduce to the system, at the calibration valve assembly, the NO₂/NO gas mixture (Section 4.5). Record the response of the NO_x analyzer. If the instrument response indicates less than 90 percent NO₂ to NO conversion, make corrections to the measurement system and repeat the check. Alternatively, the NO₂ to NO converter check described in Title 40 Part 86: Certification and Test Procedures for Heavy-Duty Engines for 1979 and Later Model Years may be used. Other alternate procedures may be used with approval of the Administrator.

6. Emission Measurement Test Procedure

6.1 Preliminaries.

6.1.1 Selection of a Sampling Site. Select a

sampling site as close as practical to the exhaust of the turbine. Turbine geometry, stack configuration, internal baffling, and point of introduction of dilution air will vary for different turbine designs. Thus, each of these factors must be given special consideration in order to obtain a representative sample. Whenever possible, the sampling site shall be located upstream of

the point of introduction of dilution air into the duct. Sample ports may be located before or after the upturn elbow, in order to accommodate the configuration of the turning vanes and baffles and to permit a complete, unobstructed traverse of the stack. The sample ports shall not be located within 5 feet or 2 diameters (whichever is less) of the gas discharge to atmosphere. For supplementary-fired, combined-cycle plants, the sampling site shall be located between the gas turbine and the boiler. The diameter of the sample ports shall be sufficient to allow entry of the sample probe.

6.1.2 A preliminary O₂ traverse is made for the purpose of selecting low O₂ values. Conduct this test at the turbine condition that is the lowest percentage of peak load operation included in the program. Follow the procedure below or alternative procedures subject to the approval of the Administrator may be used:

6.1.2.1 Minimum Number of Points. Select a minimum number of points as follows: (1) eight, for stacks having cross-sectional areas less than 1.5 m² (16.1 ft²); (2) one sample point for each 0.2 m² (2.2 ft²) of area, for stacks of 1.5 m² to 10.0 m² (16.1–107.6 ft²) in cross-sectional area; and (3) one sample point for each 0.4 m² (4.4 ft²) of area, for stacks greater than 10.0 m² (107.6 ft²) in cross-sectional area. Note that for circular ducts, the number of sample points must be a multiple of 4, and for rectangular ducts, the number of points must be one of those listed in Table 20-2; therefore, round off the number of points (upward), when appropriate.

6.1.2.2 Cross-sectional Layout and Location of Traverse Points. After the number of traverse points for the preliminary O₂ sampling has been determined, use Method 1 to locate the traverse points.

6.1.2.3 Preliminary O₂ Measurement. While the gas turbine is operating at the lowest percent of peak load, conduct a preliminary O₂ measurement as follows: Position the probe at the first traverse point and begin sampling. The minimum sampling time at each point shall be 1 minute plus the average system response time. Determine the average steady-state concentration of O₂ at each point and record the data on Figure 20-6.

6.1.2.4 Selection of Emission Test Sampling Points. Select the eight sampling points at which the lowest O₂ concentration were obtained. Use these same points for all the test runs at the different turbine load conditions. More than eight points may be used, if desired.

^aAverage steady-state value from recorder or instrument readout.

Figure 20-8. Stationary gas turbine sample point record.

6.2.3 After sampling the last point, conclude the test run by recording the final turbine operating parameters and by determining the zero and calibration drift, as follows:

Immediately following the test run at each load condition, or if adjustments are necessary for the measurement system during the tests, reintroduce the zero and mid-level calibration gases as described in Sections 4.3, and 4.4, one at a time, to the measurement system at the calibration valve assembly. (Make no adjustments to the measurement system until after the drift checks are made). Record the analyzers' responses on a form similar to Figure 20-3. If the drift values exceed the specified limits, the test run preceding the check is considered invalid and will be repeated following corrections to the measurement system. Alternatively, the test results may be accepted provided the measurement system is recalibrated and the calibration data that result in the highest corrected emission rate are used.

6.3 SO₂ Measurement. This test is conducted only at the 100 percent peak load condition. Determine SO₂ using Method 6, or equivalent, during the test. Select a minimum of six total points from those required for the NO_x measurements; use two points for each sample run. The sample time at each point shall be at least 10 minutes. Average the O₂ readings taken during the NO_x test runs at sample points corresponding to the SO₂ traverse points (see Section 6.2.2) and use this average O₂ concentration to correct the integrated SO₂ concentration obtained by Method 6 to 15 percent O₂ (see Equation 20-1).

If the applicable regulation allows fuel sampling and analysis for fuel sulfur content to demonstrate compliance with sulfur emission unit, emission sampling with Reference Method 6 is not required, provided

the fuel sulfur content meets the limits of the regulation.

7. Emission Calculations

7.1 Correction to 15 Percent Oxygen.

Using Equation 20-1, calculate the NO_x and SO₂ concentrations (adjusted to 15 percent O₂). The correction to 15 percent O₂ is sensitive to the accuracy of the O₂ measurement. At the level of analyzer drift specified in the method (± 2 percent of full scale), the change in the O₂ concentration correction can exceed 10 percent when the O₂ content of the exhaust is above 16 percent O₂. Therefore O₂ analyzer stability and careful calibration are necessary.

$$C_{adj} = C_{meas} \times \frac{5.9}{20.9 - \% O_2} \quad (\text{Equation 20-1})$$

Where:

C_{adj} = Pollutant concentration adjusted to 15 percent O₂ (ppm)

C_{meas} = Pollutant concentration measured, dry basis (ppm)

5.9 = 20.9 percent O₂ - 15 percent O₂, the defined O₂ correction basis

Percent O₂ = Percent O₂ measured, dry basis (%)

7.2 Calculate the average adjusted NO_x concentration by summing the point values and dividing by the number of sample points.

BILLING CODE 6560-01-M

system of adding definitions by paragraph designations at the end of the list could become administratively cumbersome and could make the list difficult to use. Therefore, paragraph designations are being eliminated and the definitions are rearranged alphabetically. New definitions will be added to § 60.2 of the General Provisions in alphabetical order automatically.

Since this rule simply reorganizes existing provisions and has no regulatory impact, it is not subject to the procedural requirements of Executive Order 12044.

Dated: September 19, 1979.

Edward F. Tuerk,

Acting Assistant Administrator for Air, Noise, and Radiation.

40 CFR 60.2 is amended by removing all paragraph designations and by rearranging the definitions in alphabetical order as follows:

§ 60.2 Definitions.

The terms used in this part are defined in the Act or in this section as follows:

"Act" means the Clean Air Act (42 U.S.C. 1857 et seq., as amended by Pub. L. 91-604, 84 Stat. 1676).

"Administrator" means the Administrator of the Environmental Protection Agency or his authorized representative.

"Affected facility" means, with reference to a stationary source, any apparatus to which a standard is applicable.

"Alternative method" means any method of sampling and analyzing for an air pollutant which is not a reference or equivalent method but which has been demonstrated to the Administrator's satisfaction to, in specific cases, produce results adequate for his determination of compliance.

"Capital expenditure" means an expenditure for a physical or operational change to an existing facility which exceeds the product of the applicable "annual asset guideline repair allowance percentage" specified in the latest edition of Internal Revenue Service Publication 534 and the existing facility's basis, as defined by section 1012 of the Internal Revenue Code.

"Commenced" means, with respect to the definition of "new source" in section 111(a)(2) of the Act, that an owner or operator has undertaken a continuous program of construction or modification or that an owner or operator has entered into a contractual obligation to undertake and complete, within a reasonable time, a continuous program of construction or modification.

"Construction" means fabrication, erection, or installation of an affected facility.

"Continuous monitoring system" means the total equipment, required under the emission monitoring sections in applicable subparts, used to sample and condition (if applicable), to analyze, and to provide a permanent record of emissions or process parameters.

"Equivalent method" means any method of sampling and analyzing for an air pollutant which has been demonstrated to the Administrator's satisfaction to have a consistent and quantitatively known relationship to the reference method, under specified conditions.

"Existing facility" means, with reference to a stationary source, any apparatus of the type for which a standard is promulgated in this part, and the construction or modification of which was commenced before the date of proposal of that standard; or any apparatus which could be altered in such a way as to be of that type.

"Isokinetic sampling" means sampling in which the linear velocity of the gas entering the sampling nozzle is equal to that of the undisturbed gas stream at the sample point.

"Malfunction" means any sudden and unavoidable failure of air pollution control equipment or process equipment or of a process to operate in a normal or usual manner. Failures that are caused entirely or in part by poor maintenance, careless operation, or any other preventable upset condition or preventable equipment breakdowns shall not be considered malfunctions.

"Modification" means any physical change in, or change in the method of operation of, an existing facility which increases the amount of any air pollutant (to which a standard applies) emitted into the atmosphere by that facility or which results in the emission of any air pollutant (to which a standard applies) into the atmosphere not previously emitted.

"Monitoring device" means the total equipment, required under the monitoring of operations sections in applicable subparts, used to measure and record (if applicable) process parameters.

"Nitrogen oxides" means all oxides of nitrogen except nitrous oxide, as measured by test methods set forth in this part.

"One-hour period" means any 60-minute period commencing on the hour.

"Opacity" means the degree to which emissions reduce the transmission of light and obscure the view of an object in the background.

102

40 CFR Part 60

(FRL 1327-8)

Standards of Performance for New Stationary Sources; General Provisions; Definitions

AGENCY: Environmental Protection Agency (EPA).

ACTION: Final Rule.

SUMMARY: This document makes some editorial changes and rearranges the definitions alphabetically in Subpart A—General Provisions of 40 CFR Part 60. An alphabetical list of definitions will be easier to update and to use.

EFFECTIVE DATE: September 25, 1979.

FOR FURTHER INFORMATION CONTACT: Mr. Don R. Goodwin, Director, Emission Standards and Engineering Division (MD-13), U.S. Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone (919) 541-5271.

SUPPLEMENTARY INFORMATION: The "Definitions" section (§ 60.2) of the General Provisions of 40 CFR Part 60 now lists 28 definitions by paragraph designations. Due to the anticipated increase in the number of definitions to be added to the General Provisions in the future, continued use of the present

"Owner or operator" means any person who owns, leases, operates, controls, or supervises an affected facility or a stationary source of which an affected facility is a part.

"Particulate matter" means any finely divided solid or liquid material, other than uncombined water, as measured by the reference methods specified under each applicable subpart, or an equivalent or alternative method.

"Proportional sampling" means sampling at a rate that produces a constant ratio of sampling rate to stack gas flow rate.

"Reference method" means any method of sampling and analyzing for an air pollutant as described in Appendix A to this part.

"Run" means the net period of time during which an emission sample is collected. Unless otherwise specified, a run may be either intermittent or continuous within the limits of good engineering practice.

"Shutdown" means the cessation of operation of an affected facility for any purpose.

"Six-minute period" means any one of the 10 equal parts of a one-hour period.

"Standard" means a standard of performance proposed or promulgated under this part.

"Standard conditions" means a temperature of 293 K (68°F) and a pressure of 101.3 kilopascals (29.92 in Hg).

"Startup" means the setting in operation of an affected facility for any purpose.

"Stationary source" means any building, structure, facility, or installation which emits or may emit any air pollutant and which contains any one or combination of the following:

(a) Affected facilities.

(b) Existing facilities.

(c) Facilities of the type for which no standards have been promulgated in this part.

(Sec. 111, 301(a), Clean Air Act as amended (42 U.S.C. 7411 and 7601(a))

[FRL 1331-5]

Standards of Performance for New Stationary Sources; Petroleum Refinery Claus Sulfur Recovery Plants; Amendment**AGENCY:** Environmental Protection Agency (EPA).**ACTION:** Final rule.

SUMMARY: This action deletes the requirement that a Claus sulfur recovery plant of 20 long tons per day (LTD) or less must be associated with a "small petroleum refinery" in order to be exempt from the new source performance standards for petroleum refinery Claus sulfur recovery plants. This action will result in only negligible changes in the environmental, energy, and economic impacts of the standards.

EFFECTIVE DATE: October 25, 1979.

ADDRESS: All comments received on the proposal are available for public inspection and copying at the EPA Central Docket Section (A-130), Room 2903B, Waterside Mall, 401 M Street, S.W., Washington, D.C. 20460. The docket number is OAQPS-79-10.

FOR FURTHER INFORMATION CONTACT: Don R. Goodwin, Director, Emission Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone (919) 541-5271.

SUPPLEMENTARY INFORMATION:**Background**

On March 15, 1978, EPA promulgated new source performance standards for petroleum refinery Claus sulfur recovery plants. These standards did not apply to Claus sulfur recovery plants of 20 LTD or less associated with a small petroleum refinery. 40 CFR 60.100 (1978). "Small petroleum refinery" was defined as a "petroleum refinery which has a crude oil processing capacity of 50,000 barrels per stream day or less, and which is owned or controlled by a refiner with a total combined crude oil processing capacity of 137,500 barrels per stream day or less," 40 CFR 60.101(m) (1978).

On May 12, 1978, two oil companies filed a Petition for Review of these new source performance standards. One issue was whether the definition of "small petroleum refinery" was unduly restrictive.

On March 20, 1979, EPA proposed to amend the definition of "small petroleum refinery" by deleting the requirement that it be "owned or controlled by a refiner with a total combined crude oil processing capacity of 137,500 barrels per stream day (BSD) or less," 44 FR 17120. This proposal would have had a negligible effect on sulfur dioxide (SO₂) emissions, costs, and energy consumption. The oil company petitioners agreed to dismiss their entire Petition for Review if the final regulation did not differ substantively from this proposal.

EPA provided a 60 day period for comment on the proposal and the opportunity for interested persons to request a hearing. The comment period closed May 21, 1979. EPA received six written comments and no requests for a hearing.

Summary of Amendment

The promulgated amendment deletes the requirement that a Claus sulfur recovery plant of 20 LTD or less must be associated with a "small petroleum refinery" in order to be exempt from the new source performance standards for such plants. Thus, the final standard will apply to any petroleum refinery Claus sulfur recovery plant of more than 20 LTD processing capacity. This amendment will apply, like the standards themselves, to affected facilities, the construction or modification of which commenced after October 4, 1976, the date the standards of performance for petroleum refinery Claus sulfur recovery plants were proposed.

Environmental, Energy, and Economic Impacts

The promulgated amendment will result in a negligible increase in nationwide sulfur dioxide emissions compared to the proposed amendment and the existing standard. The promulgated amendment will also have essentially no impact on other aspects of environmental quality, such as solid waste disposal, water pollution, or noise. Finally, the promulgated amendment will have essentially no impact on nationwide energy consumption or refinery product prices.

Summary of Comments and Rationale

All six comments received were from the petroleum refinery industry. Two commenters expressed agreement with the proposal. The other four also were not opposed to the proposal, but felt the definition of "small petroleum refinery" was still too restrictive, as explained below.

Two of the four argued for deletion of the 50,000 BSD refinery size cutoff and also that sulfur recovery plant size was not only a function of refinery size (as they felt EPA had apparently assumed in establishing the refinery size cutoff), but depended on such factors as the crude oil sulfur content and actual crude oil throughput.

The other two commenters, each planning to construct small Claus sulfur recovery plants, objected that the environmental benefits of subjecting small Claus sulfur recovery plants to the standards was not substantial even when a Claus sulfur recovery plant was associated with a petroleum refinery of more than 50,000 BSD capacity. EPA agrees. Accordingly, EPA believes it is appropriate under the circumstances to delete the refinery size requirement.

Thus, the promulgated standard would exempt from coverage by the standards any Claus sulfur recovery plant of 20 LTD or less. Alternatively, the standards of performance for petroleum refinery Claus sulfur recovery plants would apply to all plants of more than 20 LTD processing capacity.

Deletion of the refinery size requirement from the standards will not result in a significant increase in the emissions of SO₂ from petroleum refinery Claus sulfur recovery plants. This is due to the small number of small Claus sulfur recovery plants (i.e., 20 LTD or less capacity) that are likely to be built at refineries of more than 50,000 BSD and the fact that most of these exempted plants will still be required by State regulations to achieve 99.0 percent control of SO₂ (compared to the 99.9 percent control required for large Claus sulfur recovery plants). In many cases the exempted Claus sulfur recovery plants would be required to achieve greater than 99.0 percent control of SO₂ due to prevention of significant deterioration (PSD) requirements. This change will also result in a negligible decrease in costs and essentially no impact on energy and economic impacts, compared to the proposed amendment.

Docket

Docket No. OAQPS-79-10, containing all supporting information used by EPA, is available for public inspection and copying between 8:00 a.m. and 4:00 p.m., Monday through Friday, at EPA's Central Docket Section, Room 2903B (see ADDRESS Section of this preamble).

The docketing system is intended to allow members of the public and industries involved to readily identify and locate documents so that they can intelligently and effectively participate in the rulemaking process. Along with

the statement of basis and purpose of the promulgated rule and EPA responses to comments, the contents of the dockets will serve as the record in case of judicial review [Section 307(d)(a)].

Miscellaneous

The effective date of this regulation is October 25, 1979. Section 111(b)(1)(B) of the Clean Air Act provides that standards of performance become effective upon promulgation and apply to affected facilities, construction or modification of which was commenced after the date of proposal on October 4, 1976 (41 FR 43866).

EPA will review this regulation four years from the date of promulgation. This review will include an assessment of such factors as the need for integration with other programs the existence of alternative methods, enforceability, and improvements in emission control technology.

It should be noted that standards of performance for new stationary sources established under Section 111 of the Clean Air Act reflect: " * * * application of the best technological system of continuous emission reduction which (taking into consideration the cost of achieving such emission reduction, any non-air quality health and environmental impact and energy requirements) the Administrator determines has been adequately demonstrated." [Section 111(a)(1)]

Although there may be emission control technology available that can reduce emissions below those levels required to comply with standards of performance, this technology might not be selected as the basis of standards of performance due to costs associated with its use. Accordingly, standards of performance should not be viewed as the ultimate inachievable emission control. In fact, the Act requires (or has potential for requiring) the imposition of a more stringent emission standard in several situations.

For example, applicable costs do not play as prominent a role in determining the "lowest achievable emission rate" for new or modified sources locating in nonattainment areas, i.e., those areas where statutorily mandated health and welfare standards are being violated. In this respect, Section 173 of the Act requires that a new or modified source constructed in an area which exceeds the National Ambient Air Quality Standard (NAAQS) must reduce emissions to the level which reflects the "lowest achievable emission rate" (LAER), as defined in Section 171(3), for such category of source. The statute defines LAER as that rate of emissions

based on the following, whichever is more stringent:

(A) the most stringent emission limitation which is contained in the implementation plan of any State for such class or category of source, unless the owner or operator of the proposed source demonstrates that such limitations are not achievable, or

(B) the most stringent emission limitation which is achieved in practice by such class or category of source. In no event can the emission rate exceed any applicable new source performance standard [Section 171(3)].

A similar situation may arise under the prevention of significant deterioration of air quality provisions of the Act (part C). These provisions require that certain sources [referred to in Section 169(1)] employ "best available control technology" [as defined in Section 169(3)] for all pollutants regulated under the Act. Best available control technology (BACT) must be determined on a case-by-case basis, taking energy, environmental, and economic impacts and costs into account. In no event may the application of BACT result in emissions of any pollutants which will exceed the emissions allowed by any applicable standard established pursuant to Section 111 (or 112) of the Act.

In all events, State implementation plans (SIP's) approved or promulgated under Section 110 of the Act must provide for the attainment and maintenance of NAAQS designed to protect public health and welfare. For this purpose, SIP's must in some cases require greater emission reductions than those required by standards of performance for new sources.

Finally, States are free under Section 116 of the Act to establish even more stringent emission limits than those established under Section 111 or those necessary to attain or maintain the NAAQS under Section 110. Accordingly, new sources may in some cases be subject to limitations more stringent than EPA's standards of performance under Section 111; and prospective owners and operators of new sources should be aware of this possibility in planning for such facilities.

Section 317 of the Clean Air Act requires the Administrator to, among other things, prepare an economic assessment for revisions to new source performance standards determined to be substantial. Executive Order 12044 requires certain analyses of significant regulations. Since this amendment lacks the economic impact and significance to require additional analyses, it is not subject to the above requirements.

Dated: October 16, 1979.

Douglas M. Costle,
Administrator.

Part 60 of chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

1. § 60.100 is amended by revising paragraph (a), as follows:

§ 60.100 Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to the following affected facilities in petroleum refineries: fluid catalytic cracking unit catalyst regenerators, fuel gas combustion devices, and all Claus sulfur recovery plants except Claus plants of 20 long tons per day (LTD) or less. The Claus sulfur recovery plant need not be physically located within the boundaries of a petroleum refinery to be an affected facility, provided it processes gases produced within a petroleum refinery.

(b) * * *

2. § 60.101 is amended by revoking and reserving paragraph (m), as follows:

§ 60.101 Definitions

* * * * *

(m) [Reserved]

(Sec. 111, 301(a), Clean Air Act as amended [42 U.S.C. 7411, 7601(a)].)

[FRL 1342-6]

Regulations for Ambient Air Quality Monitoring and Data Reporting**AGENCY:** Environmental Protection Agency (EPA).**ACTION:** Amendment to final rule.

SUMMARY: This action amends air quality monitoring and reporting regulations which were promulgated May 10, 1979 (44 FR 27558). The amendments correct several technical errors that were made in the promulgation notice. The amendments reflect the intent of the regulations as discussed in the preambles to the proposed (August 7, 1978, 43 FR 34892) and final regulations.

DATES: These amendments are effective November 9, 1979.

FOR FURTHER INFORMATION CONTACT: Stanley Sleva, Monitoring and Data Analysis Division, (MD-14) Environmental Protection Agency, Research Triangle Park, N.C. 27711, telephone number 919-541-5351.

SUPPLEMENTARY INFORMATION: On May 10, 1979, EPA promulgated a new 40 CFR Part 58 entitled, "Ambient Air Quality Surveillance." The new regulations consist of requirements for monitoring ambient air quality and reporting data to EPA as well as other regulations such as public reporting of a daily air quality index. The requirements replace § 51.17 and portions of § 51.7 from 40 CFR Part 51 and make necessary reference changes in Parts 51, 52, and 60. Other accompanying changes were made to Part 51, such as restructuring the unchanged portion of § 51.7 into a new subpart, adding regulations concerning public notification of air quality information, and applying quality assurance requirements to such monitoring as may be required by the prevention of significant deterioration program.

These amendments to the May 10, 1979, regulations correct technical errors which were discovered after promulgation. The corrections are consistent with the intent of the rulemaking and are therefore not being proposed.

* * *

The last correction is in Part 60. The correction involves a change of references in § 60.25. The change was proposed with the other regulations on August 7, 1978, but was inadvertently left out of the final promulgation.

* * *

Part 60 of Title 40, *Code of Federal Regulations*, is amended as follows:

Section 60.25, paragraph (e), is amended by changing the reference to a semi-annual report required by § 51.7 to an annual report required by § 51.321. As amended, § 60.25 reads as follows:

§ 60.25 Emission inventories, source surveillance, reports.

(e) The State shall submit reports on progress in plan enforcement to the Administrator on an annual (calendar year) basis, commencing with the first full report period after approval of a plan or after promulgation of a plan by the Administrator. Information required under this paragraph must be included in the annual report required by § 51.321 of this chapter.

(Sec. 110, 301(a), 319 of the Clean Air Act as amended (42 U.S.C. 7410, 7601(a), 7619))

[FRL 1369-3]

New Source Performance Standards; Delegation of Authority to the State of Maryland**AGENCY:** Environmental Protection Agency.**ACTION:** Final rulemaking.

SUMMARY: Pursuant to the delegation of authority for New Source Performance Standards (NSPS) to the State of Maryland on September 15, 1978, EPA is today amending 40 CFR 60.4, *Address*, to reflect this delegation.

EFFECTIVE DATE: December 3, 1979.

FOR FURTHER INFORMATION CONTACT: Tom Shiland, 215 597-7915.

SUPPLEMENTARY INFORMATION: A Notice announcing this delegation is published today elsewhere in this *Federal Register*. The amended 60.4 which adds the address of the Maryland Bureau of Air Quality to which all reports, requests, applications, submittals, and communications to the Administrator pursuant to this part must also be addressed, is set forth below.

The Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an

administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegation which is reflected by this administrative amendment was effective on September 15, 1978, and it serves no purpose to delay the technical change of this address to the Code of Federal Regulations.

This rulemaking is effective immediately, and is issued under the authority of Section 111 of the Clean Air Act, as amended, 42 U.S.C. 7411.

Dated: November 14, 1979.

Douglas M. Costle,
Administrator.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

1. In § 60.4 paragraph (b) is amended by revising Subparagraph (V) to read as follows:

§ 60.4 Address.

(b)

(b)

(A)-(U)

(V) State of Maryland: Bureau of Air Quality and Noise Control, Maryland State Department of Health and Mental Hygiene, 201 West Preston Street, Baltimore, Maryland 21201.

40 CFR Part 60

(FRL 1353-2)

Standards of Performance for New Stationary Sources; Delegation of Authority to State of Delaware**AGENCY:** Environmental Protection Agency.**ACTION:** Final rule.

SUMMARY: This document amends 40 CFR 60.4 to reflect delegation to the State of Delaware of authority to implement and enforce certain Standards of Performance for New Stationary Sources.

EFFECTIVE DATE: December 7, 1979.

FOR FURTHER INFORMATION CONTACT: Joseph Arena, Environmental Scientist, Air Enforcement Branch, Environmental Protection Agency, Region III, 6th and Walnut Streets, Philadelphia, Pennsylvania 19106, Telephone (215) 597-4561.

SUPPLEMENTARY INFORMATION:**I. Background**

On October 5, 1978, the State of Delaware requested delegation of authority to implement and enforce certain Standards of Performance for New Stationary Sources for Sulfuric Acid Plants. The request was reviewed and on October 9, 1979 a letter was sent to John E. Wilson III, Acting Secretary, Department of Natural Resources and Environmental Control, approving the delegation and outlining its conditions. The approval letter specified that if Acting Secretary Wilson or any other representatives had any objections to the conditions of delegation they were to respond within ten (10) days after receipt of the letter. As of this date, no objections have been received.

II. Regulations Affected by this Document

Pursuant to the delegation of authority for certain Standards of Performance for New Stationary Sources to the State of Delaware, EPA is today amending 40 CFR 60.4, *Address*, to reflect this delegation. A Notice announcing this delegation is published today in the Notices Section of this Federal Register. The amended § 60.4, which adds the address of the Delaware Department of Natural Resources and Environmental Control, to which all reports, requests, applications, submittals, and communications to the Administrator pursuant to this part must also be addressed, is set forth below.

III. General

The Administrator finds good cause for foregoing prior public notice and for making this rulemaking effective immediately in that it is an administrative change and not one of substantive content. No additional substantive burdens are imposed on the parties affected. The delegation which is reflected by this administrative amendment was effective on October 9, 1979, and it serves no purpose to delay the technical change of this address to the Code of Federal Regulations.

This rulemaking is effective immediately, and is issued under the authority of Section 111 of the Clean Air Act, as amended, 42 U.S.C. 7411.

Dated: December 3, 1979.

Douglas M. Costle,
Administrator.

Part 60 of Chapter I, Title 40 of the Code of Federal Regulations is amended as follows:

1. In § 60.4, paragraph (b) is amended by revising subparagraph (I) to read as follows:

§ 60.4 Address.

• • • • •

(b) • • •

(A)-(H) • • •

(I) State of Delaware (for fossil fuel-fired steam generators; incinerators; nitric acid plants; asphalt concrete plants; storage vessels for petroleum liquids; sulfuric acid plants; and sewage treatment plants only.

Delaware Department of Natural Resources and Environmental Control, Edward Tatnall Building, Dover, Delaware 19901.

40 CFR Part 60**[FRL 1366-3]****Standards of Performance for New Stationary Sources; Adjustment of the Opacity Standard for a Fossil Fuel-Fired Steam Generator****AGENCY:** Environmental Protection Agency (EPA).**ACTION:** Final rule.

SUMMARY: This action adjusts the NSPS opacity standard (40 CFR Part 60, Subpart D) applicable to Southwestern Public Service Company's Harrington Station Unit #1 in Amarillo, Texas. The action is based upon Southwestern's demonstration of the conditions that entitle it to such an adjustment under 40 CFR 60.11(e).

EFFECTIVE DATE: December 28, 1979.

ADDRESS: Docket No. EN-79-13, containing material relevant to this rulemaking, is located in the U.S. Environmental Protection Agency, Central Docket Section, Room 2903 B, 401 M St., SW., Washington, D.C. 20460. The docket may be inspected between 8 a.m. and 4 p.m. on weekdays, and a reasonable fee may be charged for copying.

The docket is an organized and complete file of all the information submitted to or otherwise considered by the Administrator in the development of this rulemaking. The docketing system is intended to allow members of the public and industries involved to readily identify and locate documents so that they can intelligently and effectively participate in the rulemaking process.

FOR FURTHER INFORMATION CONTACT: Richard Biondi, Division of Stationary Source Enforcement (EN-341), Environmental Protection Agency, 401 M Street, SW., Washington, DC 20460, telephone No. 202-755-2564.

SUPPLEMENTARY INFORMATION:**Background**

The standards of performance for fossil fuel-fired steam generators as promulgated under Subpart D of Part 60 on December 23, 1971 (36 FR 24878) and amended on December 5, 1977 (42 FR

61537) allow emissions of up to 20% opacity (6-minute average), except that 27% opacity is allowed for one 6-minute period in any hour. This standard also requires continuous opacity monitoring and requires reporting as excess emissions all hourly periods during which there are two or more 6-minute periods when the average opacity exceeds 20%.

On December 15, 1977, Southwestern Public Service Company (SPSC) of Amarillo, Texas, petitioned the Administrator under 40 CFR 60.11(e) to adjust the 20% opacity standard applicable to its Harrington Station coal-fired Unit #1 in Amarillo, Texas. The Administrator proposed, on June 29, 1979 (44 FR 37960), to grant the petition for adjustment, concluding that SPSC had demonstrated the presence at its Harrington Station Unit #1 of the conditions that entitle it to such relief, as specified in 40 CFR 60.11(e)(3).

These final regulations are identical to the proposed ones. EPA hereby grants SPSC's petition for adjustment for Harrington Station Unit #1 from compliance with the opacity standard of 40 CFR 60.42(a)(2). As an alternative, SPSC shall not cause to be discharged into the atmosphere from the Harrington Station Unit #1 any gases which exhibit greater than 35% opacity (6-minute average), except that a maximum of 42% opacity shall be permitted for not more than one 6-minute period in any hour. This adjustment will not relieve SPSC of its obligation to comply with any other federal, state or local opacity requirements, or particulate matter, SO₂, or NO_x control requirements.

Comments

Two comment letters were received, both from industry and both supporting the proposed action. One industry representative approved of EPA efforts to adjust NSPS to account for well-known opacity difficulties found in large steam electric generating units which have hot side electrostatic precipitators and combust low-sulfur western coal.

A second industry representative suggested that the use of Best Available Control Technology on coal-fired units has not assured compliance with applicable opacity standards, and that opacity standards do not complement standards for particulate emissions. EPA disagrees with this comment. Violations of opacity standards generally reflect violations of mass emission standards, and EPA will continue to impose opacity standards as a valued tool in insuring proper operation and maintenance of air pollution control devices.

Miscellaneous

This revision is promulgated under the authority of Section 111 and 301(a) of the Clean Air Act, as amended (42 U.S.C. 7411 and 7601(a)).

Dated: December 17, 1979.

Douglas M. Costle,
Administrator.

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

40 CFR part 60 is amended as follows:

Subpart D—Standards of Performance for Fossil Fuel-Fired Steam Generators

1. Section 60.42 is amended by adding paragraph (b)(1) as follows:

§ 60.42 Standard for particulate matter.

(a) * * *

(b)(1) On and after (the date of publication of this amendment), no owner or operator shall cause to be discharged into the atmosphere from the Southwestern Public Service Company's Harrington Station Unit #1, in Amarillo, Texas, any gases which exhibit greater than 35% opacity, except that a maximum of 42% opacity shall be permitted for not more than 6 minutes in any hour.

(Sec. 111, 301(a), Clean Air Act as amended (42; U.S.C. 7411, 7601))

2. Section 60.45(g)(1) is amended by adding paragraph (i) as follows:

§ 60.45 Emission and fuel monitoring.

* * *

(g) * * *

(1) * * *

(i) For sources subject to the opacity standard of § 60.42(b)(1), excess emissions are defined as any six-minute period during which the average opacity of emissions exceeds 35 percent opacity, except that one six-minute average per hour of up to 42 percent opacity need not be reported.

[FR Doc. 79-39508 Filed 12-27-79; 8:45 am]

BILLING CODE 6560-01-M

SECTION V

STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Proposed Amendments

ENVIRONMENTAL PROTECTION AGENCY

STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

GENERAL PROVISIONS

SUBPART A

ENVIRONMENTAL PROTECTION AGENCY**[40 CFR Parts 60 and 61]****[FRL 1085-1]****Standards of Performance for New Stationary Sources and National Emission Standards for Hazardous Air Pollutants; Definition of "Commenced"****AGENCY:** Environmental Protection Agency (EPA).**ACTION:** Proposed Rule.

SUMMARY: This action proposes an amendment to the definition of "commenced" as used under 40 CFR Parts 60 and 61 (standards of performance for new stationary sources and national emission standards for hazardous air pollutants). The legislative history of the Clean Air Act Amendments of 1977 indicates that EPA should revise the definition of "commenced" to be consistent with the definition contained in the prevention of significant deterioration requirements of the Act. This proposal would effect that revision.

DATES: Comments must be received on or before July 30, 1979.

ADDRESSES: Comments should be submitted to Jack R. Farmer, Chief, Standards Development Branch (MD-13), Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, North Carolina 27711. Public comments received may be inspected and copied at the Public Information Reference Unit (EPA Library) Room 2922, 401 M Street, S.W., Washington, D.C.

FOR FURTHER INFORMATION CONTACT: Don R. Goodwin, Director, Emission Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone number 919-541-5271.

SUPPLEMENTARY INFORMATION: For many of EPA's regulations, it is important to determine whether a facility has commenced construction by a certain date. For instance, as provided under section 111 of the Clean Air Act, facilities for which construction is commenced on or after the date of proposal of standards of performance are covered by the promulgated standards. The definition of "commenced" is thus one factor determining the scope of coverage of the proposed standards. "Commenced" is currently defined under 40 CFR Part 60 as meaning:

... with respect to the definition of "new source" in section 111(a)(2) of the Act, that an owner or operator has undertaken a continuous program of construction or modification or that an owner or operator has entered into a contractual obligation to undertake and complete, within a reasonable time, a continuous program of construction or modification.

A similar definition (minus the reference to section 111(a)(2)) is used under 40 CFR Part 61. As provided under section 112 of the Act, facilities which commence construction after the date of proposal of a national emission standard for a hazardous air pollutant are subject to different compliance schedule requirements than those facilities which commence before proposal.

The Clean Air Act Amendments of 1977 include a definition of "commenced" under Part C—Prevention of Significant Deterioration (PSD) of Air Quality. The PSD definition of "commenced" requires an owner or operator to obtain all necessary preconstruction permits and either (1) to have begun physical on-site construction or (2) to have entered into a binding agreement with significant cancellation penalties before a project is considered to have "commenced."

On November 1, 1977, Congress adopted some technical and conforming amendments to the Clean Air Act Amendments of 1977. Representative Paul Rogers presented a Summary and Statement of Intent which stated:

In no event is there any intent to inhibit or prevent the Agency from revising its existing regulations to conform with the requirements of section 165. In fact, the Agency should do so as soon as possible. It is also expected that the Agency will act as soon as possible to revise its new source performance standards and the definition of 'commenced construction' for the purpose of those revised standards to conform to the definition contained in part C.

In view of this background, EPA has decided to make the definition of "commenced" as used under Part 60 consistent with the definitions used under the PSD requirement of Parts 51 and 52. Even though Congress did not specify any changes to the definition under Part 61, it is reasonable to also change that definition to be consistent with those under Parts 60, 51, and 52. The manner in which the definition would be interpreted is expressed in the preamble to the PSD regulations 43 FR 26395-26396. For complete consistency with the Clean Air Act and Parts 51 and 52, a new definition of "necessary preconstruction approvals or permits" has also been added.

EPA does not intend that sources would be brought under the standards by the revised definitions that would not have been covered by the existing definitions. The revised definitions would be effective 30 days after promulgation of the final definitions. Facilities which have commenced construction under the present definitions before the effective date of the revised definitions would be considered to have commenced construction under the revised definitions, i.e., the revised definitions would not be applied retroactively. Note, however, that under the PSD regulations, sources could be required to apply control technology capable of meeting the most recent standard of performance even though that standard is not applicable, because the applicable standard of performance requirements are only the minimum criteria for granting a PSD permit.

During the public comment period, comments are invited regarding the impact of the revised definition. In particular, comments are invited regarding actual compliance problems which may occur because of this revision.

Dated: May 23, 1979.

Douglas M. Costle,
Administrator.

It is proposed to amend 40 CFR Parts 60 and 61 by amending §§ 60.2(i) and 61.02(d) and by adding §§ 60.2(cc) and 61.02(q) as follows:

PART 60—STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES**Subpart A—General Provisions****§ 60.2 Definitions.**

* * * * *

(i) "Commenced" means, with respect to the definition of "new source" in section 111(a)(2) of the Act, either that:

(1) An owner or operator has obtained all necessary preconstruction approvals or permits and either has:

(i) Begun, or caused to begin, a continuous program of physical on-site construction of the facility to be completed within a reasonable time; or

(ii) Entered into binding agreements or contractual obligations, which cannot be cancelled or modified without substantial loss to the owner or operator, to undertake a program of construction of the facility to be completed within a reasonable time, or

(2) An owner or operator had commenced construction before (effective date of this definition) under

the definition of "commenced" in effect before (effective date of this definition).

* * * * *

(cc) "Necessary preconstruction approvals or permits" means those permits or approvals required under Federal air quality control laws and regulations and those air quality control laws and regulations which are part of the applicable State implementation plan.

(Sec. 111, 301(a) of the Clean Air Act as amended (42 U.S.C. 7411, 7601(a))).

**ENVIRONMENTAL
PROTECTION
AGENCY**

**STANDARDS OF
PERFORMANCE FOR NEW
STATIONARY SOURCES**

FOSSIL FUEL-FIRED STEAM GENERATORS

SUBPART D

**ENVIRONMENTAL PROTECTION
AGENCY****[40 CFR Part 60]****[FRL 1094-6]****Standards of Performance for New
Stationary Sources; Fossil-Fuel-Fired
Industrial Steam Generators****AGENCY:** Environmental Protection
Agency (EPA).**ACTION:** Advance Notice of Proposed
Rulemaking.**SUMMARY:** EPA seeks comments on its
plan to develop and implement new
source performance standards for air
pollutants from fossil-fuel-fired

industrial (non-utility) steam generators. The Clean Air Act, as amended, August 1977, requires the EPA to develop standards for categories of fossil-fuel-fired stationary sources. The standards will require application of the best systems of emission reduction for particulates, sulfur dioxide, and nitrogen oxides to new industrial steam generators.

DATES: Comments must be received on or before August 27, 1979.**ADDRESS:** Comments should be submitted to the Central Docket Section (A-130), United States Environmental Protection Agency, 401 M Street, S.W., Washington, D.C. 20460, ATTN: Docket No. A79-02.**FOR FURTHER INFORMATION CONTACT:** Stanley T. Cuffe, Chief, Industrial Studies Branch (MD-13), Emission Standards and Engineering Division, United States Environmental Protection Agency, Research Triangle Park, North Carolina 27711, (919) 541-5295.

SUPPLEMENTARY INFORMATION: In December 1971, pursuant to Section 111 of the Clean Air Act, the Administrator promulgated standards of performance for particulate, sulfur dioxide, and oxides of nitrogen from new or modified fossil fuel fired steam generators with greater than 250 million BTU/hour heat input (40 CFR 60.60). Since that time, the technology for controlling these emissions has been improved. In August 1977, Congress adopted amendments to the Clean Air Act which specified that the Environmental Protection Agency develop standards of performance for categories of fossil-fuel-fired stationary sources. The standards are to establish allowable emission limitations and require the achievement of a percentage reduction in the emissions. EPA is required to consider a broad range of issues in promulgating or revising a standard issued under Section 111 of the Clean Air Act.

Pursuant to the requirements of the Act, EPA developed and proposed on September 19, 1978, a revised standard applicable to fossil-fuel-fired utility boilers with heat input greater than 250 MM BTU/hour.

**Development of Industrial Boiler
Standard**

In June 1978, the Agency initiated a program to develop standards which would apply to all sizes and categories of industrial (non-utility) fossil-fuel-fired steam generators. In this program, the Agency is studying the technological, economic, and other information needed to establish a basis for standards for particulate, sulfur dioxide and oxides of

nitrogen emissions from fossil-fuel-fired steam generators. Pertinent information is being gathered on eight technologies for reducing boiler emissions: oil cleaning and existing clean oil, coal cleaning and existing clean coal; synthetic fuels; fluidized bed combustion; particulate control; flue gas desulfurization; NO_x combustion modifications; and NO_x flue gas treatment. The studies for each technology will discuss the characteristics, emission reduction methods and potential control costs, energy and environmental considerations and emission test data. A status report on the studies was presented to the National Air Pollution Control Techniques Advisory Committee (NAPCTAC), on January 11, 1979. Future presentations to the NAPCTAC will be announced in the **Federal Register**. The final technological and economic documentation necessary to support the standards is scheduled for completion by June 1980. Interested persons are invited to participate in Agency efforts by submitting written data, opinions, or arguments as they may desire. The Agency is specifically interested in information on the following subjects.

a. Should one standard be proposed for all industrial applications or should standards be set for separate industrial categories?

b. Should a single standard be proposed for all sizes of industrial boilers or should several standards be proposed for various boiler size categories?

c. Should emerging technologies such as solvent refined coal, fluidized bed combustion, and synthetic natural gas be exempt from industrial boiler standards, should they have separate standards, or should they be required to meet the same standards as conventional boilers burning natural fuels?

d. Will enforcement of standards at cogeneration facilities present special problems which should be considered?

e. How prevalent is the use of lignite and anthracite coal in industrial boilers?

f. Are there special problems which should be considered when controlling particulate, SO_x, or NO_x emissions from combustion of lignite or anthracite coals?

Dated: June 13, 1979.

Douglas M. Costle,
Administrator.

BILLING CODE 6560-01-M

ENVIRONMENTAL PROTECTION AGENCY

STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

INCINERATORS

SUBPART E

40 CFR Part 60

[FRL 1310-2]

Standards of Performance for New Stationary Sources: Incinerators; Review of Standards**AGENCY:** Environmental Protection Agency (EPA).**ACTION:** Review of standards.

SUMMARY: EPA has reviewed its standard of performance for municipal incinerators (40 CFR 60.50, Subpart E). The review is required under the Clean Air Act, as amended August 1977. The purpose of this notice is to announce EPA's intent to investigate the establishment of a revised standard which would be consistent with the performance capabilities of demonstrated best available control technology and which would include a limitation on the opacity of emissions.

DATES: Comments must be received by January 28, 1980.

ADDRESS: Send comments to: Central Docket Section (A-130), U.S. Environmental Protection Agency, 401 M Street SW., Washington, D.C. 20460, Attention: Docket A-79-18. Comments should be submitted in duplicate if possible.

FOR FURTHER INFORMATION CONTACT: Mr. Robert Ajax, Telephone: (919) 541-5271. The document "A Review of Standards of Performance for New Stationary Sources—Incinerators" (EPA-450/3-79-009) is available upon request from Mr. Robert Ajax (MD-13), Emission Standards and Engineering Division, U.S. Environmental Protection Agency, Research Triangle Park, N.C. 27711.

SUPPLEMENTARY INFORMATION:**Background**

New Source Performance Standards (NSPS) for incinerators were promulgated by the Environmental Protection Agency on December 23, 1971 (40 CFR 60.50, Subpart E). These standards regulate the emission of particulate matter to the atmosphere from municipal solid waste incinerators having charging rates greater than 45 Mg (50 tons) per day. These regulations apply to any affected facility which commenced construction or modification after August 17, 1971.

The Clean Air Act Amendments of 1977 require that the Administrator of the EPA review and, if appropriate, revise established standards of performance for new stationary sources at least every 4 years [Section 111(b)(1)(B)]. Following adoption of the

Amendments, EPA contracted with the MITRE Corporation to undertake a review of the municipal incinerator industry and the current standard. The MITRE review was completed in March 1979. This notice announces EPA's decision regarding the need for revision of the standard. Comments on the results of this review and on EPA's decision are invited.

Findings

Industry Status: In 1972 there were 193 incinerator plants operating in the U.S. By 1977 this number had decreased to 103 plants which include a total of 252 furnaces and a total solid waste disposal capacity of about 36,000 Mg/day (40,000 tons/day). The estimated national particulate emissions from municipal incineration in 1975 were between 60,000 and 100,000 tons or between 0.4 and 0.6 percent of all particulate emissions in the U.S.

Since 1971 five new incinerator facilities involving a total of eight new furnaces with a combined capacity of 2,700 Mg/day (2,970 tons/day) have become operational. In 1978, 17 cities were identified where new incinerators are planned or under construction. Both existing units and the units which are planned or under construction are concentrated primarily in the Northeast and Midwest.

Coincineration: A factor having an increasingly important impact on the use of incineration as a waste disposal process is the increasing cost of energy and the relatively new concept of resource recovery not only for recycling of material but also for utilization of the energy content of solid waste as a processed fuel source. A recent survey indicates that there are at least 28 resource recovery systems in operation, under construction, or in the final contract stage. Total capacity of these operations will be about 27,000 Mg/day (30,000 tons/day), or about three-fourths of the current installed incinerator capacity. For the most part, these systems are characterized by substantial processing of solid waste into usable recycled material and a homogenous fuel.

The processing of solid waste prior to combustion is a growing trend that has implications in the definition of incineration and the applicability of the standard. Refuse derived fuel (RDF) may be used in an industrial or utility boiler which may or may not be located at the new solid waste processing center. Similarly, RDF may be used to provide fuel for incinerating sewage sludge in a fluidized bed reactor. Such coincineration of municipal solid waste and sewage sludge has been practiced

in Europe for several years and on a limited scale in the U.S. Where energy resources are scarce and land disposal is economically or technically unfeasible, the recovery of the heat content of dewatered sludge as an energy source will become more desirable. Due to the institutional commonality of these wastes and advances in the preincineration processing of municipal refuse to a waste fuel, many communities may find joint incineration in energy recovery incinerators an economically attractive alternative to their waste disposal problems.

Coincineration of municipal solid waste and sewage sludge as described above is not explicitly covered in 40 CFR 60. The particulate standard for municipal solid waste described in Subpart E (0.18 grams/dscm or 0.08 grains/dscf at 12 percent CO₂) applies to the incineration of municipal solid waste in furnaces with a capacity of at least 45 Mg/day (50 tons/day). Subpart O, the particulate standard for sewage sludge incineration (0.65 grams/kg dry sludge input or 1.3 lb/ton dry sludge), applies to any incinerator that burns sewage sludge with the exception of small communities practicing coincineration. When coincineration is practiced, determination of the applicability of the two standards is made by EPA's Office of Enforcement according to policies which are described in the information document identified at the beginning of this notice. Such determinations are not straight forward, however, due to the differing form of the two standards and the relative stringency which, in terms of particulate matter concentration or grain loading, differs by a factor of more than two.

Particulate Matter Emissions and Control Technology

Control systems on municipal incinerators have evolved from the use of simple settling chambers which remove large particles, to the use of electrostatic precipitators (ESPs) that remove up to 99 percent of all particulate matter. Many of the incinerators constructed prior to 1971 utilized mechanical cyclone collectors with removal efficiencies in the range of 60 to 80 percent. Various scrubber techniques including the submerged entry of gases, the spray wetted-wall cyclone, and the venturi scrubber were also employed. High efficiency electrostatic precipitators were utilized in a limited number of cases.

Since the adoption in 1971 of the new source performance standard, the control device which has been most widely used and which has been most

effective is the electrostatic precipitator. A limited number of venturi scrubbers and, in one case, a fabric filter have also been employed.

In this review of the standard, a total of 19 emission tests were identified which had been performed on 14 incinerators. The control equipment on these incinerators was designed to

comply with the Federal new source performance standard for particulate matter or State or local standards which are as stringent or more stringent than the NSPS. The emission tests in each case were performed with EPA Method 5. A summary of the test results is provided in Table 1.

Table 1.—Municipal Incinerator Test Results

State	City/name	(Tons/day)	Control	Test results	
				(Gr/dscf at 12 pct CO ₂)	Year
Massachusetts	E. Bridgewater	150	F.F.	0.024	1975
Massachusetts	Saugus	600	ESP	0.049	1976
Tennessee	Nashville	360	ESP	0.018	1976
Virginia	Norfolk (Navy)	280	ESP	0.05	1976
Utah	Ogden-3	150	ESP	0.045	1974
District of Columbia	Washington	200	ESP	0.040/0.06	1973
Illinois	Chicago NW	400	ESP	0.030/0.050	1971/75
Maryland	Baltimore No. 4	300	ESP	0.025	1976
Pennsylvania	EC Philadelphia	300	ESP	0.047	1977
Pennsylvania	NW Philadelphia	300	ESP	0.048	1976
Illinois	Calumet	200	VS (15)	0.046/0.049	1974
Kentucky	Louisville	200	VS (15-18)	0.05/0.06	1976
Wisconsin	Sheboygan Falls	30-90	S (7-8)	0.11	1977
Rhode Island	Pawtucket	200	VS (35-40)	0.416	1976
				0.0775	1978

The results shown in Table 1 indicate that ESP control technology is capable of limiting emissions to the values well below the 0.18 g/dscf (0.08 gr/dscf) level at 12 percent CO₂. Specifically, the results from 11 tests performed at 9 facilities employing electrostatic precipitators showed results ranging from .041 to 0.14 g/dscf (0.018 to 0.06 gr/dscf) at 12 percent CO₂; 10 of the 11 were below 0.114 g/dscf (0.05 gr/dscf). The Baltimore Number 4 incinerator emission control system meets the strict Maryland standard for incinerators of 0.07 g/dscf (0.03 gr/dscf) at 12 percent CO₂. Similarly, the Saugus, Massachusetts, facility was designed for the State standard of 0.11 g/dscf (0.05 gr/dscf) at 12 percent CO₂ and was successfully tested at this level of compliance.

The use of scrubbers on municipal incinerators has met with mixed results and an overall difficulty in complying with the particulate emission standard. Although the data obtained from five tests at three venturi scrubber-controlled sources ranged from 0.015 to 0.166 g/dscf (0.046 to 0.0775 gr/dscf), the scrubber performance results, which are discussed in more detail in the information document, indicate that venturi scrubbers for control of municipal waste particulate emissions may involve considerable risk of nonattainment of the current NSPS. The

Pawtucket facility venturi scrubber, for example, operates at pressure drops higher than the original design to barely meet the standard of 0.18 g/dscf (0.08 gr/dscf) at 12 percent CO₂.

The Sheboygan Falls, Wisconsin, incinerator utilizes a spray chamber with baffles. Although reportedly designed to meet a 0.08 gr/dscf standard, this type of control technology would not normally be expected to exhibit the control efficiency necessary to obtain the standard.

Since 1971, only the East Bridgewater, Massachusetts, facility has been tested with a fabric filter control device. In 1975, that facility tested at 0.054 g/dscf (0.024 gr/dscf) at 12 percent CO₂, well below the Massachusetts standard of 0.11 g/dscf (0.05 gr/dscf) at 12 percent CO₂. However, problems of bag and baghouse corrosion and periodic high opacity observations have persisted.

Currently, Framingham, Massachusetts, is the only other municipal incinerator facility with a fabric filter control system. The specially coated bags are designed to prevent deterioration and to achieve 0.07 g/dscf (0.03 gr/dscf) at 12 percent CO₂.

Gaseous and Trace Metal Emissions

Gaseous and trace metal emissions are not specifically controlled under the present NSPS although the incinerator

and the particulate matter control equipment do limit such emissions. Among possible gaseous emissions, the potential for high levels of hydrochloric acid (HCL) from the increased incineration of polyvinyl chlorides has received particular attention. Similarly, lead and cadmium have been subject to several studies. Cadmium emissions are reported to represent approximately 0.2 percent of all particulate emissions and about 0.4 percent of emissions less than 2 microns. Lead concentrations are reported to represent about 4 percent of all particulate matter and 11 percent of respirable particulates emitted from the scrubber. Emission factors are 9×10^{-1} kg/Mg (18×10^{-1} lb/ton) refuse for cadmium and 1.9×10^{-1} kg/Mg (3.8×10^{-1} lb/ton) refuse for lead.

In this review of the current NSPS no new findings were identified which indicate the need for a specific, nationally applicable limitation on the gaseous or trace metal emissions. There is, however, currently a program underway within EPA to independently look at the need to regulate cadmium from incinerators and other sources. Separate documents have been prepared which examine emissions, resulting atmospheric concentrations, and population exposure. These documents are part of an overall EPA program to satisfy requirements of the 1977 Clean Air Act to evaluate the need to regulate emissions of cadmium to the air.

Opacity

The current NSPS does not contain a standard for opacity because testing of a limited number of incinerators prior to promulgation of the standard in 1971 did not indicate a consistent relationship between emission opacity and particulate mass concentrations. However, a survey of current State regulations shows that every State has an opacity standard for new incinerators of 20 percent or stricter except Illinois (30 percent), Indiana (40 percent), and Delaware (no standard). Maryland has a "no visible emissions" standard and the District of Columbia has a new source ban on the incineration of municipal waste. However, data were not found in this review of the NSPS to determine whether sources are consistently in compliance with these limits.

Conclusions

Based upon a review of the current NSPS and other available information as summarized above, EPA concludes that there is a need to undertake a program to revise the standard. This program, which is expected to begin in FY 1980, will be directed toward:

(1) Investigation of a more restrictive particulate matter limitation consistent with the capabilities of the best available technology. This is based upon the available data which indicate that the capability of electrostatic precipitators applied to incinerators has improved measurably since the standard was developed in 1971. This investigation will include analysis of the costs associated with a more restrictive standard.

(2) Establishment of an opacity standard. Such a standard is considered important by EPA as a means for assessing proper operation and maintenance of particulate matter control equipment and is included in most of the Agency's particulate matter NSPS. Although a relationship between particulate mass and opacity was not established when the standard was adopted in 1971, the additional number of well controlled plants which are now in operation and the widespread existence of State opacity limits are expected to provide a basis for establishment of an opacity standard. Consistent with EPA policy, such a standard would not be more restrictive than the particulate mass standard.

(3) Establishment of a consistent basis for the limitation of particulate emissions from differing combustion devices independent of the fuel or waste material being fired. While a single standard is probably not possible, there is a need to investigate the possibility of expressing standards for sludge incinerators, and municipal incinerators on a common basis, and of making the standards more uniform. To do so, EPA plans to closely coordinate the development of the industrial and waste-fired boiler standards which are now underway, and the planned revision of the sewage sludge incinerator standard and the municipal incinerator standard.

(4) In addition, if the need to reduce cadmium emissions is indicated as a result of the EPA program noted above, appropriate action will be taken to limit cadmium emissions.

Public Participation

All interested persons are invited to comment on this review, the conclusions and EPA's planned action.

Dated: November 16, 1979.

Barbara Blum,
Acting Administrator.

ENVIRONMENTAL PROTECTION AGENCY

STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

PORTLAND CEMENT PLANTS

SUBPART F

40 CFR Part 60

Standards of Performance for New Stationary Sources: Portland Cement Plants; Review of Standards

AGENCY: Environmental Protection Agency (EPA).

ACTION: Review of Standards.

SUMMARY: EPA has reviewed the standards of performance for portland cement plants (40 CFR 60.60). The review is required under the Clean Air Act, as amended August 1977. The purpose of this notice is to announce that, based on an assessment of the industry, applicable control technology, and results of performance tests conducted pursuant to the standard, EPA has determined that no revision to the particulate emission limitation is needed but that the standard should be revised to require continuous opacity monitoring.

DATES: Comments must be received by December 21, 1979.

ADDRESS: Comments should be submitted to the Central Docket Section (A-130), U.S. Environmental Protection Agency, 401 M Street, S.W., Washington, D.C. 20460, Attention: Docket No. A-79-19.

The document, "A Review of Standards of Performance for New Stationary Sources—Portland Cement Industry" (EPA-450/3-79-012), is available upon request from Mr. Robert Ajax (MD-13), Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, North Carolina 27711.

FOR FURTHER INFORMATION CONTACT: Mr. Robert Ajax, telephone: (919) 541-5271.

SUPPLEMENTARY INFORMATION:**Background**

On August 17, 1971, the Environmental Protection Agency proposed a standard under Section 111 of the Clean Air Act to control particulate matter emissions from portland cement plants. The standard, promulgated on December 23, 1971, applies to any facility constructed or modified after August 17, 1971, which manufactures portland cement by either the wet or dry process. Specific affected facilities are the: kiln, clinker cooler, raw mill system, finish mill system, raw mill dryer, raw material storage, clinker storage, finished product storage, conveyor transfer points, bagging, and bulk loading and unloading and unloading systems.

The standard prohibits the discharge into the atmosphere from any kiln any gases which:

1. Contain particulate matter in excess of 0.15 kg/Mg (0.30 lb/ton) feed to the kiln, or

2. Exhibit greater than 20 percent opacity.

The standard prohibits the discharge into the atmosphere from any clinker cooler any gases which:

1. Contain particulate matter in excess of 0.050 kg/Mg (0.10 lb/ton) feed (dry basis) to the kiln, or

2. Exhibit 10 percent opacity or greater.

The standard prohibits the discharge into the atmosphere from any affected facility other than the kiln and clinker cooler any gases which exhibit 10 percent opacity, or greater.

The Clean Air Act Amendments of 1977 require that the Administrator of the EPA review and, if appropriate, revise established standards of performance for new stationary sources at least every 4 years [Section 111(b)(1)(B)]. This notice announces that EPA has undertaken a review of the standard of performance for portland cement plants. As a result of this review, EPA has concluded that the present particulate emission limit is appropriate, and does not need revision. However, a provision to require opacity monitoring should be added. In addition, EPA is, however, planning to undertake a program, in its Office of Research and Development, to investigate and demonstrate methods such as combustion modifications which could reduce NO_x emissions from combustion used in process sources such as cement plants. Positive results from this program would form the basis for a possible revision to the standard in 1982 or 1983. Comments on these findings and plans are invited.

Findings**Industry Status**

Capacity. There are currently 53 cement companies producing portland cement in the U.S. The 53 companies operate 158 cement plants throughout the U.S. with single plant capacity ranging from 50,000 Mg to 2,161,000 Mg per year. The industry also includes 8 plants with only clinker grinding facilities which use either an imported or domestic clinker as feed material. Cement plants are found in nearly every State because of the high cost of transportation. The actual clinker capacity of these plants is also distributed throughout the U.S., although some regions have little capacity due to a lack of demand; and although many areas of the Country are presently experiencing cement shortages and

delays, announced capacity increases in these areas are still small.

Energy Considerations. The portland cement industry is very energy intensive with energy costs accounting for approximately 40 percent of the cost of cement. Accordingly, significant emphasis in the industry is on increasing energy efficiency. For this reason, almost all new and planned construction will use the dry process which can be twice as energy efficient as the wet process. Additional savings can be realized by using preheaters, especially suspension preheaters.

These process changes have both positive and negative effects on particulate emissions. The replacement of wet process units with dry process units increases potential emissions, particularly in the grinding, mixing, blending, storage, and feeding of raw materials to the kiln. The suspension preheater, on the other hand, tends to decrease particulate emissions due to its multicyclone construction. It also ensures more thorough contact of the kiln exhaust gases with the feed material which may increase sorption of sulfur oxide from the exhaust on the feed.

Economic Considerations. Almost all cement produced is utilized by the construction industry. As a result, the production of cement follows the cyclical pattern of the construction industry. Relatively high cement production has occurred during periods of growth in new home and other construction markets, and production has decreased in such periods of recession as occurred in 1973-1975.

In contrast, over the short term, production capacity has not closely paralleled actual production. This is due apparently to the lead time required to add capacity, to the difficulty in accurately predicting future demand, and to economic and other factors including the effect of pollution control requirements on the closure of old, marginal plants.

An examination of production and capacity over the past 10 years suggests the difficulty which the industry has experienced in attempting to meet demand while avoiding excess capacity. In the early 1970's, utilization of production capacity was greater than 90 percent. However, wage and price controls were in effect from 1971 to 1973 during which time the industry experienced its lowest profit margin since the 1930's. New plant construction was postponed while some older plants were being closed. As a result, regional cement shortages occurred in 1972-1973. When price controls were removed in

1973, the price of cement jumped 14 percent and some new capacity construction was begun. Shortly thereafter, the Country entered a recession and cement production fell to 70 percent of capacity.

The cyclic occurrence of high demand exceeding capacity has been evidenced again in the past several years. The rapid growth in the construction industry since 1975 has increased the demand for cement and parts of the U.S. have seen shortages, particularly in the West. At the same time, the industry has not rapidly added new capacity, although the Bureau of Mines projects high demand in the early 1980's.

In considering whether pollution control costs influenced the recent lag in capacity, the Council on Wage and Price Stability concluded that:

... the added pollution control costs do change the way a firm would consider a new investment decision by making larger price increases necessary for the expenditures to be committed. This does not mean that the imposition of these controls has necessarily cause any reduction in new capacity expenditures in the cement industry. However, this analysis does leave open the possibility that an investment decision could be changed for a marginal plant because of pollution control costs (particularly a plant selling cement for \$40 per ton and using a 12 percent rate of return). (*Prices and Capacity Expansion in the Cement Industry*, Council on Wage and Price Stability, Washington, D.C., 1977.)

Since cement is already selling for as high as \$53 per ton on the West Coast, it is very likely that capital investment will not be stifled by pollution control expenditures.

Emission Control Status

Fifty-one cement kilns and clinker coolers have been identified which are operating and are subject to the new source performance standard. Of these, 49 are in compliance with 0.15 kg/Mg kiln feed (kiln) and 0.05 kg/Mg kiln feed, (cooler) emission limits. One completed kiln has only recently been tested and data are not available; and one facility has notified its State authority that it cannot meet the standards. Also, five cement kilns potentially subject to the standard were identified for which data were not available. The number of sources with other NSPS-affected facilities was not determined, although there are none reported that are not in compliance with the applicable 10 percent opacity standard.

For the 29 kilns and 20 clinker coolers which were in compliance, the kiln test results averaged 0.073 kg/Mg and ranged from a high of 0.142 kg/Mg feed to a low of 0.013 kg/Mg feed. The range for kilns with emissions controlled by

ESP is 0.142 to 0.020 kg/Mg, and for kilns with fabric filter baghouses the range is 0.132 to 0.013 kg/Mg dry kiln feed. The data indicate that neither the ESP nor the baghouse is significantly better at controlling cement kiln particulate matter emissions.

Cement plant clinker coolers have been tested at emission levels ranging from a high of 0.061 kg/Mg to a low of 0.005 kg/Mg dry kiln feed with a mean of 0.024 kg/Mg. Compliance test data on a single wet scrubber show emissions near the mean emission level for fabric filter baghouse controls (0.022 kg/Mg). Data for affected facilities using gravel bed filters indicate a mean emission level of 0.034 kg/Mg dry feed (0.023-0.045 kg/Mg).

The compliance test data were analyzed to determine if the type of control technology, the process type (i.e., wet or dry), or interaction of process type and control technology affected the ability to control the emission of particulate matter from portland cement kilns or clinker coolers. This analysis indicates that no control technology in use today is more effective for controlling particulate matter emissions. Although comparison of mean values indicates that the possibility that emissions from dry process kilns are controlled slightly more effectively than wet process kilns, the difference is not statistically significant.

Nitrogen Oxide Emissions

Cement kilns are a very large and presently unregulated source of nitrogen oxides (NO_x) emissions. Based upon estimated NO_x emissions of 1.3 kg/Mg of cement produced and 71.4 million Mg of portland cement produced in 1977, an estimated 93,000 Mg of NO_x were emitted by portland cement plants that year. The main factors that result in the production of NO_x are the flame and kiln temperature, the residence time that combustion gases remain at this temperature, the rate of cooling of these gases, and the quantity of excess air in the flame. Control of these factors may permit the operator to sharply reduce the emission of NO_x, but such practices have not been demonstrated in cement plants for NO_x emissions.

Opacity Monitoring

When the NSPS for portland cement plants was established in 1971 no provisions were included to require continuous monitoring of opacity. This was, in part, because the presence of water vapor in the exhaust gases from wet-process facilities would affect monitor accuracy. In addition, monitoring systems had not been demonstrated at baghouse controlled

facilities where stack gases are emitted from roof monitors or multiple stub stacks. However, since the standard was adopted, a monitoring system has been demonstrated at a steel plant utilizing baghouse controls and stub stacks.

Conclusions

On the basis of the findings which are summarized above, EPA has concluded that the current particulate matter standards are appropriate and effective and that no revision is needed. While the compliance test data do show that the mean results are well below the standards, the range of data suggest that the standard is set at a level which reflects the performance of the best systems of emission reduction.

However, it is concluded that the standard should be revised to include provisions requiring the continuous monitoring of opacity. This conclusion is based upon the demonstration of opacity monitors on baghouse stub stacks and on the shift in the portland cement industry toward the dry process, as well as EPA's belief that continuous monitoring represents an important and effective means for assuring proper operation and maintenance of particulate matter control equipment. Adoption of any opacity monitoring requirement will be preceded by a proposal and the opportunity for public comment. The Agency expects to undertake development and to propose this revision during 1980.

It is also concluded that the lack of demonstrated control technology and an emission limitation for NO_x is an important deficiency. The Agency is therefore planning to evaluate, develop, and demonstrate means for limiting NO_x emissions. This program, which will include other industrial process fuel users, will be aimed at transferring technology being employed to control NO_x emissions from steam generators. If this proves successful, the results will be used as a basis for development of NO_x standards.

Public Participation

All interested persons are invited to comment on this review, the conclusions, and EPA's planned action.

STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

NITRIC ACID PLANTS

SUBPART G

[40 CFR Part 60]

[FRL 1095-1]

**Review of Standards of Performance
for New Stationary Sources: Nitric
Acid Plants**

AGENCY: Environmental Protection
Agency (EPA).

ACTION: Review of standards.

SUMMARY: EPA has reviewed the standard of performance for nitric acid plants. The review is required under the Clean Air Act, as amended August 1977. The purpose of this notice is to announce EPA's intent not to undertake revision of the standards at this time.

DATES: Comments must be received on or before August 20, 1979.

ADDRESSES: Send comments to the Central Docket Section (A-130), U.S. Environmental Protection Agency, 401 M Street, S.W., Washington, D.C. 20460, Attention: Docket No. A-79-08. The document "A Review of Standards of Performance for New Stationary Sources—Nitric Acid Plants" (EPA report number EPA-450/3-79-013) is available upon request from Mr. Robert Ajax (MD-13), Emission Standards and Engineering Division, U.S. Environmental Protection Agency, Research Triangle Park, North Carolina 27711.

FOR FURTHER INFORMATION CONTACT:
Mr. Robert Ajax, (919) 541-5271.

SUPPLEMENTARY INFORMATION:

Background

Prior to the promulgation of the NSPS in 1971, only 10 of the existing 194 weak nitric acid (50 to 60 percent acid) production facilities were specifically designed to accomplish NO_x abatement.

Without control equipment, total NO_x emissions are approximately 3,000 ppm in the stack gas, equivalent to a release of 21.5 kg/Mg (43 lb/ton) of 100 percent acid produced.

At the time of the NO_x New Source Performance Standard (NSPS) promulgation there were no State or local NO_x emission abatement regulations in effect in the U.S. which applied specifically to nitric acid production plants. Ventura County, California, had enacted a limitation of 250 ppm NO_x to govern nitric acid plants as well as steam generators and other sources.

In August of 1971, the EPA proposed a regulation under Section 111 of the Clean Air Act to control nitrogen oxides emissions from nitric acid plants. The regulation, promulgated in December 1971, requires that no owner or operator of any nitric acid production unit (or "train") producing "weak nitric acid" shall discharge to the atmosphere from any affected facility any gases which contain nitrogen oxides, expressed as NO_x, in excess of 1.5 kg per metric ton of acid produced (3.0 lb per ton), the production being expressed as 100 percent nitric acid; and any gases which exhibit 10 percent opacity or greater.

The Clean Air Act Amendments of 1977 require that the Administrator of the EPA review and, if appropriate, revise established standards of performance for new stationary sources at least every 4 years [Section 111(b)(1)(B)]. This notice announces that EPA has completed a review of the standard of performance for nitric acid plants and invites comment on the results of this review.

Findings

Industry Growth Rate

The average rate of production increase for nitric acid fell from 9 percent/year in the 1960-1970 period to 0.7 percent from 1971 to 1977. The decline in demand for nitric acid parallels that for nitrogen-based fertilizers during the same period.

Nitric acid production shows an increasing trend toward plant/unit location and growth in the southern tier of States. In 1971, 48 percent of the national production was in the south. This figure increased to 54 percent in 1976.

About 50 percent of plant capacity in 1972 consisted of small to moderately sized units (50 to 300-ton/day capacity). Because of the economies of scale some producers are electing to replace their

existing units with new, larger units. New nitric acid production units have been built as large as 910 Mg/day (1000 tons/day). The average size of new units is approximately 430 Mg/day (500 tons/day).

Control Technology

A mixture of nitrogen oxides (NO_x) is present in the tail gas from the ammonia oxidation process for the production of nitric acid. In modern U.S. single pressure process plants producing 50 to 60 percent acid, uncontrolled NO_x emissions are generated at the rate of about 21 kg/Mg of 100 percent acid (42 lb/ton) corresponding to approximately 3000 ppm NO_x (by volume) in the exit gas stream. The catalytic reduction process which was considered the best demonstrated control technology at the time the present standard was established has been largely supplanted by the extended absorption process as the preferred control technology for NO_x emissions from new nitric acid plants. The latter control system appears to have become the technology of choice for the nitric acid industry due to the increasing cost and danger of shortages of natural gas used in the catalytic reduction process. Since the energy crisis of the mid-1970's, over 50 percent of the nitric acid plants that had come on stream through mid-1978 and almost 90 percent of the plants scheduled to come on stream through 1979 use the extended absorption process for NO_x control.

Levels Achievable with Demonstrated Control Technology

All 14 of the new or modified operational nitric acid production units subject to NSPS and tested showed compliance with the current standard of 1.50 kg/Mg (3 lb/ton). The average of seven sets of test data from catalytic reduction-controlled plants is 0.22 kg/Mg (0.44 lb/ton), and the average of six sets of test data from extended absorption-controlled plants is 0.91 kg/Mg (1.82 lb/ton). All of the plants tested were in compliance with the opacity standard. It appears that the extended absorption process, while it has become the preferred control technology for NO_x control, cannot control these emissions as efficiently as the catalytic reduction process. In fact, over half of the test results for extended absorption were within 20 percent of the NO_x standard. The extended absorption process thus appears to have limitations with respect

to NO_x control, and compares unfavorably with catalytic reduction in its ability to reduce NO_x emissions much below the present NSPS level.

Economic Considerations Affecting the NO_x NSPS

The annualized costs of the extended absorption process and the catalytic reduction NO_x control methods appear to be quite comparable. Capital cost for the extended absorption process is appreciably higher than that for catalytic reduction. However, this is offset by the higher operating cost of the latter system which requires increasingly costly natural gas.

Conclusions

Based on the above findings, EPA concludes that the existing standard of performance is appropriate at this time. While lower emission levels are attainable, the energy penalty and shortages of natural gas are concluded to be a basis for retaining the current standard of performance under Section 111 of the Clean Air Act. However, the recent deregulation will alter the price and availability of natural gas, and provides a basis for optimism about its future availability for process and pollution control purposes. The Agency, therefore, plans to continue to assess the standard as the effect of deregulation materializes. Moreover, it should be noted that for the purpose of attaining and maintaining national ambient air quality standards and prevention of significant deterioration requirements, State Implementation Plan new source reviews may in some cases require greater emission reductions than those required by the standards of performance for new sources.

Public participation

All interested persons are invited to comment on this review, the conclusions, and EPA's planned action. Comments should be submitted to: Mr. Don Goodwin (MD-13), Emission Standards and Engineering Division, U.S. Environmental Protection Agency, Research Triangle Park, North Carolina 27711.

ENVIRONMENTAL PROTECTION AGENCY

STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

SULFURIC ACID PLANTS

SUBPART H

PROPOSED RULES

541-5271. The document "A Review of Standards of Performance for New Stationary Sources—Sulfuric Acid Plants" (EPA report number EPA-450/3-79-003) is available upon request from Mr. Robert Ajax (MD-13), Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, North Carolina 27711.

SUPPLEMENTARY INFORMATION:

BACKGROUND

Prior to the proposal of the standard of performance in 1971, almost all existing contact process sulfuric acid plants were of the single-absorption design and had no SO₂ emission controls. Emissions from these plants ranged from 1500 to 6000 ppm SO₂ by volume, or from 10.8 kg of SO₂/Mg of 100 percent acid produced (21.5 lb/ton) to 42.5 kg of SO₂/Mg of 100 percent acid produced (85 lb/ton). Several State and local agencies limited SO₂ emissions to 500 ppm from new sulfuric acid plants, but few such facilities had been put into operation (EPA, 1971).

In August of 1971, the Environmental Protection Agency (EPA) proposed a regulation under Section 111 of the Clean Air Act to control SO₂ and sulfuric acid mist emissions from sulfuric acid plants. The regulation, promulgated in December 1971, requires that no owner or operator of any new sulfuric acid production unit producing sulfuric acid by the contact process by burning elemental sulfur, alkylation acid, hydrogen sulfide, organic sulfides, mercaptans, or acid sludge shall discharge into the atmosphere any gases which contain sulfur dioxide in excess of 2 kg/Mg (4 lb/ton); any gases which contain acid mist, expressed as H₂SO₄, in excess of 0.075 kg/Mg of acid produced (0.15 lb/ton), expressed as 100 percent H₂SO₄; or any gases which exhibit 10 percent opacity or greater. Facilities which produce sulfuric acid as a means of controlling SO₂ emissions are not included under this regulation.

The Clean Air Act Amendments of 1977 require that the Administrator of the EPA review and, if appropriate, revise established standards of performance for new stationary sources at least every 4 years [Section 111(b)(1)(B)]. This notice announces that EPA has completed a review of the standard of performance for sulfuric acid plants and invites comment on the results of this review.

FINDINGS

INDUSTRY GROWTH

Since the proposal, 32 contact process sulfuric acid units have been constructed. Of these, at least 24 units result from growth in the phosphate

fertilizer industry and are dedicated to the acidulation of phosphate rock, mainly in the Southern U.S.

In 1976, over 70 percent of the total national production of new sulfuric acid was in the South. It is projected that three of the four units predicted to be coming on line each year will most probably be located in the South.

BEST DEMONSTRATED CONTROL TECHNOLOGY

Sulfur dioxide and acid mist are present in the tail gas from the contact process sulfuric acid production unit. In modern four-stage converter contact process plants burning sulfur with approximately 8 percent SO₂ in the converter feed, and producing 98 percent acid, SO₂ and acid mist emissions are generated at the rate of 13 to 28 kg/Mg of 100 percent acid (26 to 56 lb/ton) and 0.2 to 2 kg/Mg of 100 percent acid (0.4 to 4 lb/ton), respectively. The dual absorption process is the best demonstrated control technology for SO₂ emissions from sulfuric acid plants, while the high efficiency acid mist eliminator is the best demonstrated control technology for acid mist emissions. These two emission control systems have become the systems of choice for sulfuric acid plants built or modified since the promulgation of the NSPS. Twenty-eight of the 32 sulfuric acid production plants subject to the standard incorporate the dual absorption process; all 32 plants use the high efficiency acid mist eliminator.

COMPLIANCE TEST RESULTS

All 32 sulfuric acid production units subject to the standard showed compliance with the current SO₂ standard of 2 kg/Mg (4 lb/ton). The 29 compliance test results for dual absorption plants ranged from a low of 0.16 kg/Mg (0.32 lb/ton) to a high of 1.9 kg/Mg (3.7 lb/ton) with an average of 0.9 kg/Mg (1.8 lb/ton). Information received on the performance of several sulfuric acid plants indicates that low SO₂ emission results achieved in NSPS compliance tests apparently do not reflect day-to-day SO₂ emission levels. These levels appear to rise toward the standard as the conversion catalyst ages and its activity drops. Additionally, there may be some question about the validity of low SO₂ NSPS values, i.e., less than 1 kg/Mg (2 lb/ton), due to errors in the application of the original EPA Method 8. This method was revised on August 18, 1977, to include more detailed procedures to prevent such errors.

All 32 affected sulfuric acid production units also showed compliance with the current acid mist standard of 0.075 kg/Mg of 100 percent acid (0.15 lb/ton). The compliance test data are all from plants with acid mist emission control provided by the high efficiency

NEW STATIONARY SOURCES: SULFURIC ACID PLANTS

Review of Performance Standards

AGENCY: Environmental Protection Agency (EPA).

ACTION: Review of Standards.

SUMMARY: EPA has reviewed the standards of performance for sulfuric acid plants (40 CFR 60.80). The review is required under the Clean Air Act, as amended August 1977. The purpose of this notice is to announce EPA's decision to not revise the standards at this time and to solicit comments on this decision.

DATES: Comments must be received by May 14, 1979.

ADDRESS: Send comments to: Mr. Don Goodwin (MD-13), Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, North Carolina 27711.

FOR FURTHER INFORMATION CONTACT:

Mr. Robert Ajax, telephone: (919)

PROPOSED RULES

cy acid mist eliminator. The data showed a range with a low of 0.008 kg/Mg (0.016 lb/ton) to a high of 0.071 kg/Mg (0.141 lb/ton), and an overall average value of 0.04 kg/Mg (0.081 lb/ton). Acid mist emission (and related opacity) levels are unaffected by factors affecting SO₂ emissions, i.e., conversion efficiency and catalyst aging. Rather, acid mist emissions are primarily a function of moisture levels in the sulfur feedstock and air fed to the sulfur burner, and the efficiency of the final absorber operation. The order-of-magnitude spread observed in compliance test values is probably a result of variation in these factors. Additionally, the potential for imprecision in the application of the original EPA Method 8 may have contributed to this spread.

POSSIBLE REVISION TO STANDARD

The compliance test data indicate that the available control technology could possibly meet both lower sulfur dioxide and sulfuric acid mist emission standards. However, the available test data indicate that variability in indicated emission rates occurs—possibly as a result of process variables, and test method precision. Therefore, to meet a tighter standard designers and operators would need to design for attainment of a lower average emission rate in order to retain a margin of safety needed to accommodate emission variability. The available compliance data do not provide a basis for concluding that this is possible.

In contrast, the effect of catalyst aging is controllable by more frequent replacement. As an outside limit, complete replacement of catalyst in the first 3 beds of a four-bed converter 3 times as frequently as is normally practiced could potentially maintain emissions in the range of 1 to 1.5 kg/Mg and would result in a net emission reduction of approximately 0.3 kg/Mg (0.6 lb/ton).

Based on an estimated sulfuric acid plant growth rate of four new production lines per year between 1981 and 1984, a 50 percent reduction of the present SO₂ NSPS level—from 2 kg/Mg (4 lb/ton) to 1 kg/Mg (2 lb/ton)—would result in a drop in the estimated SO₂ contribution to these new sulfuric acid plants to the total national SO₂ emissions, from 0.04 percent to 0.02 percent (8,000 tons to 4,000 tons).

CONCLUSIONS

Based upon the above findings, EPA concludes that the current best demonstrated control technology, the dual absorption process and the acid mist eliminator are identical in basic design to that used as the rationale for the original SO₂ standard. Therefore, from the standpoint of control technology, and considering costs, and the small

quantity of emissions in question, it does not appear necessary or appropriate to revise the present standard of performance adopted under Section 111 of the Clean Air Act. It should be noted that for the purpose of attaining national ambient air quality standards and prevention of significant deterioration, State Implementation Plan new source reviews may in some cases require greater emission reductions than those required by standards of performance for new sources.

PUBLIC PARTICIPATION

All interested persons are invited to comment on this review, the conclusions, and EPA's planned action. Comments should be submitted to: Mr. Don Goodwin (MD-13), Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, N.C. 27711.

(Section 111(6)(1)(B) of the Clean Air Act, as amended (42 U.S.C. 7411(6)(1)(B)).

Dated: March 9, 1979.

DOUGLAS M. COSTLE,
Administrator.

PETROLEUM REFINERY

SUBPART J

40 CFR Part 60**[FRL 1295-1]****Standards of Performance for New Stationary Sources: Petroleum Refineries Review of Standards****AGENCY:** Environmental Protection Agency (EPA).**ACTION:** Review of Standards.

SUMMARY: EPA has reviewed its standard of performance for petroleum refineries (40 CFR 60.100, Subpart J). The review is required under the Clean Air Act, as amended August 1977. The purpose of this notice is to announce EPA's intent to undertake the development of a revised standard which would limit SO₂ emissions from catalyst regenerators.

DATE: Comments must be received by December 21, 1979.

ADDRESS: Send comments to: Central Docket Section (A-130), U.S. Environmental Protection Agency, 401 M Street, S.W., Washington, D.C. 20460, Attention: Docket A-79-09.

The document "A Review of Standards of Performance for New Stationary Sources—Petroleum Refineries" (EPA-450/3-79-008) is available upon request from Mr. Robert Ajax (MD-13), Emission Standards and Engineering Division, U.S. Environmental Protection Agency, Research Triangle Park, North Carolina 27711.

FOR FURTHER INFORMATION CONTACT: Mr. Robert Ajax, Telephone: (919) 541-5271.

SUPPLEMENTARY INFORMATION:**Background**

New Source Performance Standards (NSPS) for petroleum refineries were promulgated by the Environmental Protection Agency on March 8, 1974. (40 CFR 60.100, Subpart J). These standards regulate the emission of particulate matter and carbon monoxide, and the opacity of flue gases from fluid catalytic cracking unit (FCCU) catalyst regenerators and FCCU regenerator incinerator-waste heat boilers. They also regulate the emission of sulfur dioxide from fuel gas combustion devices. These regulations apply to any affected facility which commenced construction or modification after June 11, 1973.

The Clean Air Act Amendments of 1977 require that the Administrator of the EPA review and, if appropriate, revise established standards of performance for new stationary sources at least every 4 years [Section 111(b)(1)(B)]. This notice announces that

EPA has completed a review of the standard of performance for petroleum refineries and invites comment on the results of this review.

Findings

On the basis of a review of compliance data available in EPA's Regional Offices and a review of literature describing recent control technology applicable to catalyst regenerators and fuel gas combustion devices, EPA has made the following conclusions regarding the need to revise the existing standard.

Particulate Matter

The available data indicate that the current limitation on particulate matter emissions accurately reflects the performance capability of best available control systems. It is, therefore, concluded that no revision should be made to the particulate standard. New technologies such as high efficiency separators, high temperature regenerators, and new catalysts have reduced the total quantity of uncontrolled particulate matter emitted. However, the method established in the standard for calculating the allowable emissions effectively corrects for the reduction due to changes in catalysts and operating procedures.

While it is concluded that the particulate matter standard should not be revised, a question has been raised as to the validity of Reference Method 5 when high concentrations of condensible sulfur compounds are present. This test method, which is used to measure compliance with the particulate standard, operates at a nominal temperature of 120°C and, as such, is capable of collecting condensible matter which exists in gaseous form at stack temperature. If significant quantities of such condensible material exist which are not controllable by the best systems of emission reduction, then a facility employing such systems could be found to be in non-compliance with the standard. An analysis of data available when the standard was established indicated this was not a problem at that time. However, with high sulfur content feed, there is evidence that condensible sulfur oxides may exist at concentrations sufficient to affect compliance.

EPA is currently studying this question. Depending on the results of this study, EPA may revise the standard or the test method.

Carbon Monoxide

The present standard for carbon monoxide emissions was established at

a level which would permit regenerator in situ combustion. This method of controlling carbon monoxide emissions offers production and energy efficiencies but is recognized to be less effective than a carbon monoxide boiler. No new data were obtained during this review to alter the original finding that it is not practical to control CO emissions to less than 500 ppm by in situ regeneration and, therefore, no revision in the standard is planned at this time. However, it should be noted that the recent advent and increased use of CO oxidation catalysts and additives may provide data showing that concentrations lower than 500 ppm are achievable. If such data become available, the Agency will consider revision of the standard. It should be further noted that for the purpose of attaining and maintaining the national ambient air quality standards, State Implementation Plan new source reviews may, in some cases, require greater CO emission reductions than those required by the standards of performance for new sources.

At the time the standard was established, EPA concluded that CO emissions should be continuously monitored. A requirement for such monitoring was, therefore, included in the standard. This requirement is applicable to all catalyst regenerators subject to the standard. However, the effective date of the monitoring requirement was deferred until EPA develops performance specifications for CO monitoring systems. EPA has found no basis for revising this monitoring requirement and performance specifications are currently under development and evaluation. It is planned to issue an advanced notice of proposed rulemaking in 1979 setting forth the specifications which have been developed and which will be assessed in field studies.

Sulfur Dioxide

The present standard currently limits SO₂ emissions resulting from the combustion of fuel gas. The catalyst regenerator is also a significant source of SO₂ emissions but is not subject to the standard. The review considered both the need to revise the current limitation and the need to include limitations on SO₂ emissions from the catalyst regenerator.

Available compliance test data indicate that the current standard limiting sulfur to 230 mg H₂S/dscm from combustion of fuel gas is being met and, in some cases, exceeded by a wide margin. Six tests showed an average of 107 mg H₂S/dscm and a range of 7 to 229 mg H₂S/dscm. While these data indicate that a reduction in the present limitation

is possible, the range exhibited is consistent with the control device performance documented at the time the standard was established. On the basis of this, along with the increased sulfur content of feedstock expected with increased imports and the variable crude oil supply conditions now existing, it is concluded that the fuel gas sulfur limitation is appropriate and that no revision is needed.

A deficiency in the current standard limiting sulfur in fuel gas relates to the lack of a continuous monitoring method. EPA recognized the need for continuous monitoring at the time the standard was adopted. However, at that time, no monitoring systems had been demonstrated to be adequate for this purpose and EPA had not established performance specifications for such systems. Consequently, application of the monitoring requirement was deferred until performance specifications could be adopted. Since the adoption of the standard, EPA has pursued a program to develop and assess the performance of an H₂S monitoring system. On this basis, performance specifications are now being developed. It is planned to issue an advanced notice of proposed rulemaking in 1979 setting forth the specifications which have been developed and which will be assessed in field studies.

During the review of the standard, an ambiguity was identified in the current limitation on sulfur in fuel gas concerning the applicability of this limitation to fuel gas burned in waste-heat boilers. To clarify this, an amendment was prepared which was published in the *Federal Register* on March 12, 1979. This amendment makes clear that fuel gas fired in waste-heat boilers is not exempt from the standard.

Sulfur dioxide emissions from fluid catalytic cracking unit (FCCU) catalyst regenerators are not regulated by the standard. However, sulfur dioxide scrubber technology is available and being used to control steam generator emissions and a limited number of FCCU regenerators. Also, Amoco Oil Company has developed a new cracking process which reduces sulfur oxide emissions from FCCU regenerators. The process uses a new catalyst that retains sulfur oxides and returns them to the reactor where they are removed with the product stream. If a low sulfur product is required, the sulfur will be removed by amine stripping or hydrotreating and eventually recovered in a sulfur recovery unit. Pilot tests indicate that the new catalyst is capable of reducing sulfur oxide emissions 80 to 90 percent

and commercial tests are planned to confirm these data.

The potential uncontrolled emissions from new, modified, or reconstructed catalyst regenerators are significant. Uncontrolled emission rates from catalyst regenerators are typically 5 to 10 Mg/day and range up to 100 Mg/day from the largest units. The growth rate in terms of new catalyst regenerators is uncertain due to the present uncertainty of petroleum supplies and demand. However, for perspective a growth rate of 0.5 percent in capacity from 1979 through 1985 would result in additional emissions from uncontrolled new sources of 23 Mg per day in 1985; a growth rate of 0.75 percent would result in additional uncontrolled emissions of 58 Mg SO₂/day. Emissions from modified or reconstructed sources would add to this total.

Based on the existence of these SO₂ control technologies, EPA plans to initiate a program later this year to assess the applicability, cost, performance, and non-air environmental impacts of these technologies. If supported by the findings of this program EPA will propose a limit on FCCU SO₂ emissions.

Volatile Organic Compounds

The emission of volatile organic compounds (VOC) from FCC unit regenerators is not limited in the present NSPS. These are, however, of concern, both because of their role as oxidant precursors and as potentially hazardous compounds. Of particular concern are the polynuclear aromatic compounds (PNA) because of their potential carcinogenic effects. The most abundant PNA measured in regenerator flue gas is benzo-a-pyrene (BAP) with a concentration of 0.218 kg BAP/1,000 barrels of feed. The concentration of BAP can effectively be reduced in a carbon monoxide boiler to 1.41×10^{-8} kg BAP/1,000 barrels of feed. However, there are no data indicating the concentration of BAP in the flue gas from high temperature (in situ) regeneration nor from regenerators using CO oxidation promoting catalyst. This, therefore, has been identified as an area for future study by EPA's Office of Research and Development.

Public Participation

All interested persons are invited to comment on this review, the conclusions, and EPA's planned action.

ENVIRONMENTAL PROTECTION AGENCY

PETROLEUM LIQUID STORAGE VESSELS

**Proposed Standards and
Notice of Hearing**

SUBPART K and Ka

PROPOSED RULES

ENVIRONMENTAL PROTECTION AGENCY

[40 CFR Part 60]

[FRL 870-5]

STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Storage Vessels for Petroleum Liquids

AGENCY: Environmental Protection Agency (EPA).

ACTION: Proposed rule.

SUMMARY: The proposed standards would limit emissions of hydrocarbons from new, modified, and reconstructed petroleum liquid storage vessels with a capacity greater than 151,416 liters (40,000 gallons). The standards implement the Clean Air Act and are based on a review of the current standards of performance which indicated that the technology for storage vessels has improved and it is appropriate to revise the standards. The current standards for storage vessels require a single seal to close the space between the roof edge and tank wall on external and internal floating roof tanks. The intended effect of the proposed standard is to require double seals on external floating roof tanks for which construction is commenced after (date of proposal of the standards).

DATES: Comments must be received on or before June 19, 1978. A public hearing will be held on June 7, 1978; a notice is published elsewhere in this *FEDERAL REGISTER* regarding the time and place the hearing will be held.

ADDRESSES: Comments should be submitted to the Emission Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, N.C. 27711, Attention: Mr. Jack R. Farmer. Public comments received and other documents used in the development of the proposed standards comprise the docket required by section 307(d) of the Clean Air Act. Included in the docket is the economic impact assessment of the proposed standards entitled "Financial and Economic Impacts of Proposed Standards of Performance for New Sources—Storage Vessels for Petroleum Liquids." The docket, numbered OAQPS-78-2, is available for public inspection and copying at the Public Information Reference Unit, Room 2922, 401 M Street SW., Washington, D.C. 20460.

FOR FURTHER INFORMATION CONTACT:

Mr. Don R. Goodwin, Director, Emission Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, N.C. 27711, telephone number 919-541-5271.

SUPPLEMENTARY INFORMATION:

SUMMARY OF PROPOSED STANDARDS AND IMPACTS

The proposed standards of performance would apply to storage vessels which have a capacity greater than 151,416 liters (40,000 gallons) and which are constructed after (proposal date of these standards). The proposed standards differ from the current standards in that they contain more stringent requirements for storage vessels which have external floating roofs or internal-floating-type covers. The current standards require that storage vessels containing a petroleum liquid with a true vapor pressure equal to or greater than 78 mm Hg (1.5 psia) but not greater than 570 mm Hg (11.1 psia) be equipped with a floating roof, a vapor recovery system, or equivalent. Storage vessels containing petroleum liquids with a true vapor pressure greater than 570 mm Hg (11.1 psia) are to be equipped with a vapor recovery system or its equivalent. The current standards remain in effect for those affected facilities which began construction, modification, or reconstruction after the applicable date of the current standards (March 8, 1974, for vessels with capacities between 40,000 and 65,000 gallons and June 11, 1973, for vessels with greater than 65,000 gallon capacity) and before (date of proposal of these standards). Retrofit of such facilities would not be required by the proposed standards.

The proposed standards would require the use of double seals on external floating roof storage vessels. The primary seal would have to be a metallic shoe seal or equivalent with a seal fabric having no holes, tears, or other openings. Gaps between the tank wall and the primary seal could not exceed 0.32 cm ($\frac{1}{8}$ in.) in width for a cumulative length of 60 percent of the circumference of the tank, 1.3 cm ($\frac{1}{2}$ in.) in width for a cumulative length of 30 percent of the circumference of the tank, and 3.8 cm ($1\frac{1}{2}$ in.) in width for a cumulative length of 10 percent of the circumference of the tank. The secondary seal would be required to completely cover the space between the roof edge and the tank wall. Gaps between the tank wall and the secondary seal could not exceed 0.32 cm ($\frac{1}{8}$ in.) in width for a cumulative length of 95 percent of the circumference of the tank, and 1.3 cm ($\frac{1}{2}$ in.) in width for a cumulative length of 5 percent of the circumference of the tank.

The proposal also specifies that the Administrator approves as equivalent technology the use of a nonmetallic resilient seal as the primary seal provided that the gaps between the tank wall and the primary seal do not exceed 0.32 cm ($\frac{1}{8}$ in.) in width for a cumulative length of 95 percent of the circumference of the tank and do not

exceed 1.3 cm ($\frac{1}{2}$ in.) in width for a cumulative length of the remaining 5 percent of the circumference of the tank, and the gaps between the tank wall and the secondary seal used above the nonmetallic resilient seal do not exceed 0.32 cm ($\frac{1}{8}$ in.) in width over the entire circumference of the tank.

Since the current standards already require at least single seals on floating roof tanks, the maximum cost of the proposed standards would be the incremental cost of using a shoe seal instead of a nonmetallic resilient seal as the primary seal and of installing a second seal. These two costs are estimated to increase the cost of a new 61-meter (200-foot) diameter storage vessel by about 0.9 to 1.9 percent.

The proposed standards would have a positive impact on environmental quality. The estimated emission reduction attributed to the current standards is 80 percent. The proposed standards would further reduce emissions from a new storage vessel containing a petroleum liquid by about 75 percent. The total emission reduction, therefore, would be about 95 percent. The proposed standards would have no adverse environmental or energy impacts.

BACKGROUND

On March 8, 1974, under the authority of section 111 of the Clean Air Act, EPA promulgated standards of performance in Subpart K of 40 CFR Part 60 for hydrocarbon emissions from petroleum liquid storage vessels with a capacity greater than 151,416 liters (40,000 gallons). These standards require that new storage vessels containing petroleum liquids with a true vapor pressure greater than 570 mm Hg (11.1 psia) be equipped with a vapor recovery system or its equivalent. For petroleum liquids with a true vapor pressure equal to or greater than 78 mm Hg (1.5 psia) but not greater than 570 mm Hg (11.1 psia), new storage vessels are required to be equipped with a floating roof (internal or external), a vapor recovery system, or equivalent. The primary intent of Subpart K was to prohibit the use of fixed roofs on new storage vessels. A floating roof or vapor recovery system has the potential for reducing emissions by 70 to 90 percent more than the reduction achieved with a fixed roof only.

An external floating roof tank consists of a welded or riveted cylindrical vessel equipped with a deck or roof which floats on the liquid surface and rises and falls with the liquid level in the tank. The liquid surface is completely covered by the roof except for the space between the roof and the wall. The current standards require that a sliding seal be attached to the roof to close the space between the roof edge and the tank wall. The seals

PROPOSED RULES

in current use are metallic shoe seals or nonmetallic resilient seals (see Figures 1 and 2). For a storage vessel equipped to meet the current standards, emissions are primarily due to wind-induced hydrocarbon losses through the seal system. Seal losses increase if there is an improper fit between the seal and the tank wall or leakage through the fabric cover that is used to bridge the space between a shoe seal and the floating roof.

Although good maintenance and inspection programs may be effective in reducing emissions through a single seal, recent industry tests have indicated that reductions can be achieved

by installing a second seal over the primary seal (see Figure 3). As improved technology is developed, section 111(b)(1)(B) of the Clean Air Act provides for revision of standards of performance. Since the promulgation of the current standards, the use of double seals on external floating roof tanks has been demonstrated and has been shown to significantly reduce emissions. The intent of the proposed standards is to require the use of double seals instead of single seals on external floating roof petroleum liquid storage vessels for which construction is commenced on or after (date of proposal of these standards).

PROPOSED RULES

Figure 1. Primary metallic shoe seal

Figure 2. Primary nonmetallic resilient seal

Figure 3. Metallic-shoe-type seal with secondary seal

PROPOSED RULES

The proposed standards are in terms of equipment specifications and maintenance requirements rather than mass emission rates. It is extremely difficult to quantify mass emission rates for petroleum liquid storage vessels because of the varying loss mechanisms and the number of variables affecting loss rate. Section 111(h)(1) of the Act provides that equipment standards may be established for a source category if it is not feasible to prescribe or enforce a standard which specifies an emission limitation. It also requires that an equipment standard include requirements to insure the proper operation and maintenance of the equipment. Therefore, the proposed standards contain certain monitoring requirements.

RATIONALE FOR PROPOSED STANDARDS

SELECTION OF THE SOURCE CATEGORY AND AFFECTED FACILITY

Section 111 of the Act directs the Administrator to establish standards of performance for new and modified stationary sources that may contribute significantly to air pollution which causes or contributes to the endangerment of public health or welfare. EPA considers petroleum liquid storage vessels to be significant contributors to air pollution. Based on emission factors (1, 2) derived from equations in American Petroleum Institute Bulletins, current nationwide hydrocarbon emissions from petroleum liquid storage tanks are estimated to be about 750 Gg (or about 850,000 tons) per year. This represents about 4.5 percent of the estimated 1975 national hydrocarbon emissions from stationary sources. (3)

In a 1976 study of the petroleum refining industry, (4) EPA estimated that the growth rate of domestic petroleum demand would be about 2½ percent annually for the period 1974 to 1985. It is assumed that the growth rate of petroleum liquid storage tanks would be the same. Although this estimated growth rate is subject to change depending on the world energy situation and the nation's energy policy, growth in the construction of new petroleum liquid storage tanks is likely to contin-

ue at about this rate at least into the near future. All new petroleum storage tanks will be required by EPA's current standards of performance to have floating roofs, vapor recovery systems, or equivalent. Because petroleum liquid storage vessels are significant contributors to air pollution and it has been demonstrated that emissions from these vessels which are equipped with external floating roofs in compliance with the current standards can be reduced further by installation of double seals, petroleum liquid storage vessels have been selected for additional regulation. Petroleum liquid storage vessels for which construction was commenced before (date of proposal of these standards) are still subject to the existing standards of performance and those storage vessels equipped with external floating roofs are required to have single seals only.

SELECTION OF BEST TECHNOLOGY CONSIDERING COSTS

Measurement of emissions to the atmosphere from commercial size petroleum liquid storage vessels with external floating roofs using conventional measurement techniques is virtually impossible because the emissions are not confined. The proposed standards, therefore, are based primarily on studies conducted recently by Chicago Bridge and Iron (CBI) for Standard Oil of Ohio and Western Oil and Gas Association (5), (6), (7), (10), (11) on a 6-meter (20-foot) diameter test tank which was enclosed for the purpose of emission measurement. During the CBI studies, pressure drop measurements were made around the circumference of the tank on the windward and leeward sides. Emissions were measured under a variety of conditions to determine the impact of such factors as wind speed, the use of double seals, gap size between the seals and tank wall, shoe seal tightness, rim temperatures, and product vapor pressure on emission levels.

It was found that most hydrocarbon emission from storage vessels are due to wind-induced pressure losses. Relative to reference atmospheric pressure, pressure variations occur around the edges of the roof of a tank as a func-

tion of wind velocity and position of the roof. With respect to wind direction, the pressure is higher on the leeward side than on the windward side of the tank. The pressure differences on a tank roof are such that fresh air flows downward through the space between the tank wall and the seal on the leeward side, across the liquid surface along the circumference of the tank, and out the other side. The spaces are saturated with hydrocarbon vapors, which are carried out in the flow of air. The true vapor pressure of the liquid being stored, which determines the hydrocarbon concentration in the spaces between the seal and tank wall and the roof and liquid surface, and the type and condition of seals are other factors which were found to significantly influence emissions.

Figure 4 shows the effect of various types of seals and seal conditions on emission levels. The other two factors which were found to have the most impact on emissions—wind velocity and vapor pressure of the stored liquid—are held constant. Emission levels would deviate from those shown in the figure if one of these conditions were changed. As indicated in Figure 4, for both nonmetallic resilient seals and shoe seals, using a secondary seal above the primary seal and reducing the gaps between both the primary and the secondary seals and the tank wall significantly reduce the emissions resulting from wind-induced pressure losses. Using double seals reduces the impact of the size of the gap between the primary seal and the tank wall on emission levels, but reducing these gaps still has a positive effect.

The CBI test data in Figure 4 also indicate that when a nonmetallic resilient seal is used as the primary seal and the secondary seal has a 1.3 cm (½ in.) gap for 5 percent of the circumference of the vessel, emissions are 5 times higher than when a shoe seal is used as the primary seal and the secondary seal has the same gaps. Based on these data, it is concluded that the use of a shoe seal achieves a greater reduction in emissions than the use of a nonmetallic resilient seal.

PROPOSED RULES

Figure 4. Emissions from CBI test tank with various seals.

PROPOSED RULES

It can also be seen in Figure 4 that a primary metallic shoe seal with no gap used in conjunction with a secondary seal with no gap achieves the lowest emission level. However, it is difficult to comply with a no gap requirement because in most cases the storage vessels are not perfectly round. A more viable regulatory approach would be to allow some small gaps between the seals and tank wall. From Figure 4 it can be seen that even with small gaps, the hydrocarbon emission level remains low. Consequently, the proposed standards contain certain gap requirements for both the primary and secondary seals.

For a shoe seal used as the primary seal, the permeability of the seal fabric used to bridge the space between the shoe seal and the floating roof can be an important factor affecting emission levels. The use of fabric with holes, tears, or openings increases leakage due to gas penetration through the fabric. Therefore, it is concluded that requiring the use of a metallic shoe seal with no holes, tears, or openings would result in reduced hydrocarbon emissions.

Costs must be considered in setting standards of performance under section 111. Since the current standards already require single seals on floating roof storage vessels the costs associated with the proposed standards are only the incremental costs of using a metallic shoe seal instead of a nonmetallic resilient seal as the primary seal and the costs of adding a secondary seal. For a new 61-meter (200-foot) diameter storage vessel, the total installed cost of a nonmetallic resilient seal is estimated to be approximately \$20,000 to \$33,000, and the total installed cost of a shoe seal is estimated to range from \$28,000 to \$41,000, or approximately \$8,000 more than a nonmetallic resilient seal. The total annualized cost for a shoe seal is estimated to be about \$2,400 more than that for a nonmetallic resilient seal. EPA is not aware of any situations where technological or economic considerations would preclude the installation of shoe seals in lieu of nonmetallic resilient seals during the construction of new petroleum storage vessels.

Adding a secondary seal is estimated to cost \$12,600 to \$19,000, and to increase total annualized costs by \$4,000 to \$5,800 if it is assumed that there are no savings due to retention of petroleum product. Total annualized costs would be reduced to between \$1,700 and \$5,400, however, if a savings in petroleum product is assumed. A range is estimated because the amount of petroleum product saved would depend on the true vapor pressure of the petroleum liquid and wind velocity.

The cost of a new 61-meter diameter storage vessel is estimated to be about

\$1,400,000 to \$2,200,000. This cost includes the tank foundation, firewalls, connections to refinery pumps, lines, etc. Thus, using a shoe seal instead of a nonmetallic resilient seal as the primary seal and installing a secondary seal would increase the cost of a new storage vessel by only about 0.9 to 1.9 percent. By comparison, the increased cost for a new storage vessel to comply with the current standards is 12 to 25 percent. Therefore, the increased cost of complying with the proposed standards is considered to be reasonable and would not adversely affect the demand for new vessels. Since the additional cost would not reduce the demand for new vessels, the economic impact of the proposed standard on the manufacturers of storage vessels is small.

EPA also attempted to determine the impact of the proposed standards on nonmetallic resilient seal manufacturers; however, it was discovered that the materials for the seals are purchased by the storage vessel manufacturers who then fabricate and install the seals. Nearly all the storage vessel manufacturers have the expertise to install either metallic shoe seals or nonmetallic resilient seals with most manufacturers being indifferent to customer preference toward a certain type of seal. One manufacturer does stress its expertise with nonmetallic resilient seals; however, this emphasis has not caused disproportional sales of nonmetallic resilient seals over metallic shoe seals. Also, since the seals are fabricated on site, little or no extra capital would be needed to convert plant and equipment to produce a greater quantity of metallic shoe seals. In addition, storage vessel manufacturers generally do not maintain an inventory of nonmetallic resilient seal materials that would need to be liquidated.⁽¹²⁾ Consequently, any shift towards more installation of metallic shoe seals caused by the proposed standards would have little impact on the storage vessel manufacturers.

Three companies in the United States currently supply the rubber casings and urethane foam necessary for the fabrication of the nonmetallic resilient seals. All three of these companies are highly diversified and the sale of nonmetallic resilient seal materials makes up only a small portion of their total sales. The average losses in sales of the three companies due to the proposed standard would range from about 0.5 to 1.4 percent of total sales.⁽¹²⁾ Consequently, the economic impact on the nonmetallic resilient seal materials suppliers would be small.

Any difference in maintenance requirements for metallic shoe seals as compared with maintenance requirements for nonmetallic resilient seals could also impact the storage vessel purchasers. Generally, however, me-

tallic shoe seals last longer and require less maintenance than nonmetallic resilient seals.⁽¹²⁾ Therefore, this aspect of the proposed standards would have no adverse impact on the storage vessel purchasers.

The longer life of the average metallic shoe seal would also impact the vessel service companies. However, since replacing seals is only a small part of a vessel service company's business, the economic impact of the proposed standard would be small.

There is expected to be little, if any, economic impact on existing storage vessels as a result of modifications of existing vessels. The only change EPA is presently aware of which could potentially be considered a modification is a change in the petroleum liquid being stored. However, 40 CFR 60.14(e)(4) states that a change in fuel or raw material is not considered to be a modification if the existing facility was designed to accommodate that alternative use prior to the promulgation of standards of performance for that source type. There are likely to be few, if any, changes in the product being stored which a storage vessel was not originally designed to accommodate.

Using the emission control technology described in the preceding paragraphs—double seals; shoe seals as the primary seals; seal fabric with no holes, tears, or openings and narrow gap widths—would have a beneficial impact on environmental quality. Compared with the current standards, this technology would reduce hydrocarbon emissions from petroleum liquid storage vessels equipped with external floating roofs by 60 percent assuming a metallic shoe seal was used to meet the current standard, and up to 98 percent assuming a nonmetallic resilient seal was used to meet the current standard. These figures are based on Figure 4 and the assumption that the storage vessel is exposed to a wind velocity of 3.58 m/s (8 mph) and contains a petroleum liquid with a true vapor pressure of 258 mm Hg (5 psia). The percentage reduction would be expected to vary for different storage vessels depending on the wind speed and the true vapor pressure of the petroleum liquid being stored. There would be no adverse impacts on other environmental media. National energy requirements would actually be decreased very slightly since this technology would result in retention of petroleum products that would otherwise be lost as hydrocarbon emissions.

Consequently, the use of double seals employing a shoe seal with a seal fabric with no holes, tears, or openings as the primary seal, and having narrow gaps between both the primary and secondary seals and the storage vessel wall, has been selected as the best demonstrated technology, consid-

PROPOSED RULES

ering costs, for reducing emissions from petroleum liquid storage vessels. Thus, the proposed standards require either the use of this technology or technology demonstrated to be equivalent.

As can be observed in Figure 4, if a nonmetallic resilient seal is used as the primary seal and there are no gaps (i.e., gap widths of 0.32 cm or less) between the secondary seal and the storage vessel wall, emissions are approximately the same as when a shoe seal is used as the primary seal and the gaps on the secondary seal are as much as 1.3 cm ($\frac{1}{2}$ in.) for 5 percent of the circumference of the tank. The proposed regulation, therefore, states that the Administrator approves the use of a nonmetallic resilient seal as equivalent to a shoe seal for the primary seal if the secondary seal above the nonmetallic resilient seal has gaps no greater than 0.32 cm.

Instead of approving as equivalent technology the use of nonmetallic resilient seals in conjunction with secondary seals with no gaps greater than 0.32 cm, the standards of performance could require either the use of shoe seals or the use of nonmetallic resilient seals with the more stringent gap requirement for nonmetallic resilient seals. If the standard were written in this way, nonmetallic resilient seals would always be required to meet the more stringent gap requirement. It is possible, however, that improvements can be made to nonmetallic resilient seals to make them equivalent to metallic shoe seals without meeting a more stringent gap requirement. It is also possible that other seals can be developed that would be equivalent to metallic shoe seals. The proposed standards, therefore, provide maximum flexibility for manufacturers to make improvements in nonmetallic resilient seals or other types of seals and demonstrate their equivalency to metallic shoe seals.

SELECTION OF MISCELLANEOUS REQUIREMENTS

The current standards of performance do not apply to storage vessels for petroleum or condensate stored, processed, and/or treated at a drilling and production facility prior to custody transfer. These vessels were exempted because many of them are normally bolted for purposes of mobility. The proposed standards of performance, however, would apply to storage vessels at drilling and production facilities if the vessels are larger than 151,416 liters (40,000 gallons). Bolted vessels larger than the cut-off size would not be exempt because they are no different from other large storage vessels being covered with regard to emissions, control technology, or costs.

The definition of "petroleum refinery" has been expanded in both Sub-

parts K and Ka to include extracting. This change is being made to ensure that the definition covers all activities at a petroleum refinery. "Extracting" was not purposely excluded in Subpart K and its addition should not change the impact of the standard.

SELECTION OF TESTING, MONITORING, AND RECORDKEEPING REQUIREMENTS

The proposed standards include a section on testing (section 60.114a) for determining compliance with the gap requirements. The current standards of performance do not have a comparable testing section because they do not contain gap requirements. Performance tests for most sources subject to Part 60 are required within 60 days after achieving the maximum production rate. The maximum production rate for a storage vessel would be the filling of the vessel with petroleum liquid. The proposed standards for storage vessels provide the option of doing the performance test before a tank is filled with petroleum liquid. This is based on the reasoning that the gaps between a primary seal and the tank wall have to be measured when the secondary seal is not in place when doing a performance test. This means that the tank could not contain petroleum liquid, since the secondary seal is required by the standard to cover the primary seal when the tank is in operation. The gaps for the primary seal would be most easily measured during the construction of the tank before the secondary seal is installed. If the owner or operator chose to do the measurements on the primary seal after the tank has been filled with petroleum liquid, it would be necessary to empty the tank and remove the secondary seal. The secondary seal gaps, on the other hand, could be measured when the tank is filled with petroleum liquid. The proposed standards would require that this performance test be repeated every five years.

The proposed standards would require that the distance between the seals and the tank wall be measured while the floating roof is placed at different levels. This could be done by putting different quantities of water into the tank before the tank is filled with petroleum liquid. Measuring the gaps at different levels is required because the floating roof would be located at different levels while the tank is in normal operation. The proposed standards would also require that the gaps be measured around the circumference of the tank. For each gap size, the distances around the tank which have that gap size would need to be accumulated. Gaps would be measured with a probe having a diameter equivalent to one of the gap widths specified in the standard. In the process of measuring gaps, those gap widths which are between two sizes specified

in the standards would be considered equivalent to the larger of the two sizes. For example, a gap between 0.32 cm ($\frac{1}{8}$ in.) and 1.3 cm ($\frac{1}{2}$ in.) in width would be considered as 1.3 cm ($\frac{1}{2}$ in.).

Most of the monitoring and recordkeeping requirements in the proposed standards (sections 60.115a (a), (b), (c), and (d)) are the same as the ones in the current standards. An additional requirement is proposed to allow for routine inspection of the primary seal between performance tests. Under this requirement the secondary seal would allow easy insertion of probes in at least four locations for measuring gaps in the primary seal. This would allow for inspection of the primary seal without removing the secondary seal which would make emptying the tank unnecessary. The tank, therefore, would have to be emptied only during performance tests and routine maintenance of the secondary seal.

MISCELLANEOUS

In accordance with section 117 of the Act, publication of these proposed standards was preceded by consultation with independent experts and Federal departments and agencies. The Administrator will welcome comments on all aspects of the proposed regulation, including economic and technological issues and record keeping requirements.

It should be noted that standards of performance for new sources established under section 111 of the Clean Air Act reflect the degree of emission limitation achievable through application of the best adequately demonstrated technological system of continuous emission reduction (taking into consideration the cost of achieving such emission reduction, any nonair quality health and environmental impact and energy requirements). State implementation plans (SIPs) approved or promulgated under section 110 of the Act, on the other hand, must provide for the attainment and maintenance of national ambient air quality standards (NAAQS) designed to protect public health and welfare. For that purpose, SIPs must in some cases require greater emission reductions than those required by standards of performance for new sources. Section 173 of the Act requires, among other things, that a new or modified source constructed in an area which exceeds the NAAQS must reduce emissions to the level which reflects the "lowest achievable emission rate" for such category of source, as defined in section 171(3). In no event can the emission rate exceed any applicable standard of performance.

A similar situation may arise when a major emitting facility is to be constructed in a geographic area which falls under the prevention of significant deterioration of air quality provi-

PROPOSED RULES

sions of the Act (Part C). These provisions require, among other things, that major emitting facilities to be constructed in such areas are to be subject to best available control technology for all pollutants regulated under the Act. The term "best available control technology" (BACT), as defined in section 169(3), means "an emission limitation based on the maximum degree of reduction of each pollutant subject to regulation under this Act emitted from or which results from any major emitting facility, which the permitting authority, on a case-by-case basis, taking into account energy, environmental, and economic impacts and other costs, determines is achievable for such facility through application of production processes and available methods, systems, and techniques, including fuel cleaning or treatment or innovative fuel combustion techniques for control of each such pollutant. In no event shall application of 'best available control technology' result in emissions of any pollutants which will exceed the emissions allowed by any applicable standard established pursuant to section 111 or 112 of this Act."

Standards of performance should not be viewed as the ultimate in achievable emission control and should not preclude the imposition of a more stringent emission standard, where appropriate. For example, while cost of achievement may be an important factor in determining standards of performance applicable to all areas of the country (clean as well as dirty), costs must be accorded far less weight in determining the "lowest achievable emission rate" for new or modified sources locating in areas violating statutorily-mandated health and welfare standards. Although there may be emission control technology available that can reduce emissions below those levels required to comply with standards of performance, this technology might not be selected as the basis of standards of performance due to costs associated with its use. This in no way should preclude its use in situations where cost is a lesser consideration, such as determination of the "lowest achievable emission rate."

In addition, States are free under section 116 of the Act to establish even more stringent emission limits than those established under section 111 or those necessary to attain or maintain the NAAQS under section 110. Thus, new sources may in some cases be subject to limitations more stringent than standards of performance under section 111, and prospective owners and operators of new sources should be aware of this possibility in planning for such facilities.

Economic impact assessment: An economic impact assessment has been prepared as required under section 317

of the Act and is included in the docket.

Dated: May 2, 1978.

DOUGLAS M. COSTLE,
Administrator.

It is proposed that 40 CFR Part 60 be amended by revising § 60.11(a) of Subpart A, by revising the heading and amending §§ 60.110 and 60.111 of Subpart K, and by adding a new Subpart Ka as follows:

1. § 60.11(a) is revised to read as follows:

§ 60.11 Compliance with standards and maintenance requirements.

(a) Compliance with standards in this part, other than opacity standards, shall be determined only by performance tests established by § 60.8, unless otherwise specified in the applicable standard.

2. The heading for Subpart K is revised to read as follows:

Subpart K—Standards of Performance for Storage Vessels for Petroleum Liquids Constructed Prior to (Date of Proposal of These Standards)

3. Paragraphs (c)(1) and (c)(2) of § 60.110 are revised to read as follows:

§ 60.110 Applicability and designation of affected facility.

(c) ***

(1) Has a capacity greater than 151,416 liters (40,000 gallons), but not exceeding 246,052 liters (65,000 gallons), and commences construction or modification after March 8, 1974, and prior to (date of proposal of these standards).

(2) Has a capacity greater than 246,052 liters (65,000 gallons) and commences construction or modification after June 11, 1973, and prior to (date of proposal of these standards).

4. Paragraph (c) of § 60.111 is revised to read as follows:

§ 60.111 Definitions.

(c) "Petroleum refinery" means any facility engaged in producing gasoline, kerosene, distillate fuel oils, residual fuel oils, lubricant, or other products through distillation of petroleum or through redistillation, cracking, extracting, or reforming of unfinished petroleum derivatives.

5. A new Subpart Ka is added to read as follows:

Subpart Ka—Standards of Performance for Storage Vessels for Petroleum Liquids Constructed on or After (Date of Proposal of These Standards)

Sec.

60.110a Applicability and designation of affected facility.

60.111a Definitions.

60.112a Standard for hydrocarbons.

60.113a Equivalent equipment.

60.114a Testing and procedures.

60.115a Monitoring of operations.

AUTHORITY: Sec. 111, 301(a) of the Clean Air Act as amended (42 U.S.C. 7411, 7601(a)), and additional authority as noted below.

§ 60.110a Applicability and designation of affected facility.

(a) The affected facility to which this subpart applies is each storage vessel for petroleum liquids which has a storage capacity greater than 151,416 liters (40,000 gallons) and for which construction is commenced after (date of proposal of these standards).

§ 60.111a Definitions.

As used in this subpart, all terms not defined herein shall have the meaning given them in the Act and in Subpart A of this part.

(a) "Storage vessel" means any tank, reservoir, or container used for the storage of petroleum liquids, but does not include:

(1) Pressure vessels which are designed to operate in excess of

PROPOSED RULES

0.0044kg/m³ (15 lb/in.³ gauge) without emissions to the atmosphere except under emergency conditions.

(2) Subsurface caverns or porous rock reservoirs, or

(3) Underground tanks if the total volume of petroleum liquids added to and taken from a tank annually does not exceed twice the volume of the tank.

(b) "Petroleum liquids" means petroleum, condensate, and any finished or intermediate products manufactured in a petroleum refinery but does not mean Nos. 2 through 6 fuel oils as specified in A.S.T.M. D396-69, gas turbine fuel oils Nos. 2-GT through 4-GT as specified in A.S.T.M. D2880-71, or diesel fuel oils Nos. 2-D and 4-D as specified in A.S.T.M. D975-68.

(c) "Petroleum refinery" means any facility engaged in producing gasoline, kerosene, distillate fuel oils, residual fuel oils, lubricants, or other products through distillation of petroleum or through redistillation, cracking, extracting, or reforming of unfinished petroleum derivatives.

(d) "Petroleum" means the crude oil removed from the earth and the oils derived from tar sands, shale, and coal.

(e) "Hydrocarbon" means any organic compound consisting predominantly of carbon and hydrogen.

(f) "Condensate" means hydrocarbon liquid separated from natural gas which condenses due to changes in the temperature and/or pressure and remains liquid at standard conditions.

(g) "True vapor pressure" means the equilibrium partial pressure exerted by a petroleum liquid as determined in accordance with methods described in American Petroleum Institute Bulletin 2517, Evaporation Loss from Floating Roof Tanks, 1962.

(h) "Reid vapor pressure" is the absolute vapor pressure of volatile crude oil and volatile non-viscous petroleum liquids, except liquified petroleum gases, as determined by ASTM-D-323-58 (reapproved 1968).

§ 60.112a Standard for hydrocarbons.

(a) The owner or operator of any storage vessel which contains a petroleum liquid which, as stored, has a true vapor pressure equal to or greater than 78 mm Hg (1.5 psia) but not greater than 570 mm Hg (11.1 psia), shall equip the storage vessel with one of the following:

(1) An external floating roof, consisting of a pontoon-type or double-deck-type cover that rests on the surface of the liquid contents and is equipped with a closure device between the tank wall and roof edge. Except during initial tank fill, performance tests, or when the tank is completely emptied, the roof is to be floating on the liquid, i.e. off the roof leg supports, at all times. The closure device is to consist of two seals, one

above the other. The lower seal is referred to as the primary seal and the upper seal is referred to as the secondary seal.

(i) The primary seal is to be a metallic shoe seal or equivalent as provided in § 60.113a(b), and is to meet the following requirements:

(A) Gaps between the tank wall and the primary seal are not to exceed 0.32 cm ($\frac{1}{8}$ in.) in width for a cumulative length of 60 percent of the circumference of the tank, are not to exceed 1.3 cm ($\frac{1}{2}$ in.) in width for a cumulative length of the next 30 percent of the circumference of the tank, and are not to exceed 3.8 cm ($1\frac{1}{2}$ in.) in width for a cumulative length of the remaining 10 percent of the circumference of the tank. No gap between the tank wall and the primary seal shall exceed 3.8 cm ($1\frac{1}{2}$ in.). No continuous gap greater than 0.32 cm ($\frac{1}{8}$ in.) shall exceed 10 percent of the circumference of the tank.

(B) One end of the shoe seal is to extend into the stored liquid and the other end is to extend a minimum vertical distance of 61 cm (24 in.) above the stored liquid surface.

(C) There are to be no holes, tears, or other openings in the shoe or seal fabric.

(ii) The secondary seal is to meet the following requirements:

(A) Gaps between the tank wall and the secondary seal are not to exceed 0.32 cm ($\frac{1}{8}$ in.) in width for a cumulative length of 95 percent of the circumference of the tank, and are not to exceed 1.3 cm ($\frac{1}{2}$ in.) in width for a cumulative length of the remaining 5 percent of the circumference of the tank. No gap between the tank wall and the secondary seal shall exceed 1.3 cm ($\frac{1}{2}$ in.).

(B) The secondary seal is to be installed above the primary seal so that the space between the roof edge and tank wall is completely covered, except as provided in paragraph (a)(1)(ii)(A) of this section.

(C) There are to be no holes, tears, or other openings in the seal or in any seal fabric.

(iii) All openings in the roof except for automatic bleeder vents and rim space vents are to provide a projection below the liquid surface and are to be equipped with a cover, seal, or lid. The cover, seal, or lid is to be in a closed (i.e. no visible gap) position at all times except when the device is in actual use. Automatic bleeder vents are to be closed at all times except when the roof is floated off or landed on the roof leg supports and rim vents are to be set to open only when the roof is being floated off the roof leg supports.

(iv) Any emergency roof drain is to be provided with a slotted membrane fabric cover that covers at least 90 percent of the area of the opening, or equivalent as provided in § 61.113a.

(2) A fixed roof container with an internal-floating-type cover which is equipped with a closure seal between the tank wall and roof edge. All openings, except stub drains, are to be equipped with a cover, seal, or lid. The cover, seal, or lid is to be in a closed position at all times except when the device is in actual use. Automatic bleeder vents are to be closed at all times except when the roof is floated off or landed on the roof leg supports. Rim vents, if provided, are to be set to open when the roof is being floated off the roof leg supports or at the manufacturer's recommended setting.

(3) A vapor recovery system, capable of collecting all hydrocarbon vapors and gases discharged from the storage vessel, and a vapor disposal system capable of processing such hydrocarbon vapors and gases so as to prevent their emission to the atmosphere.

(4) A system equivalent to those described in paragraphs (a)(1), (a)(2), or (a)(3), as provided in § 61.113a.

(b) The owner or operator of any storage vessel which contains a petroleum liquid which, as stored, has a true vapor pressure greater than 570 mm Hg (11.1 psia), shall equip the storage vessel with:

(1) A vapor recovery system, capable of collecting all organic vapors and gases discharged, and a vapor return or disposal system capable of processing such hydrocarbon vapors and gases so as to prevent their emission to the atmosphere; or

(2) Equivalent as provided in § 60.113a.

§ 61.113a Equivalent equipment.

(a) Upon written application from an owner or operator, the Administrator may approve use of equipment which has been demonstrated to his satisfaction to be equivalent in terms of reducing hydrocarbon emissions to the atmosphere to that prescribed for compliance with a specific paragraph of this subpart.

(b) A nonmetallic resilient seal is approved as equivalent to the shoe seal required by § 61.112a(a)(1)(i) if the gaps between the tank wall and the primary seal do not exceed 0.32 cm ($\frac{1}{8}$ in.) in width for a cumulative length of 95 percent of the circumference of the tank and do not exceed 1.3 cm ($\frac{1}{2}$ in.) in width for a cumulative length of the remaining 5 percent of the circumference of the tank and the gaps between the tank wall and the secondary seal used above the nonmetallic resilient seal do not exceed 0.32 cm ($\frac{1}{8}$ in.) over the entire circumference of the tank.

(Sec. 114 of the Clean Air Act as amended (42 U.S.C. 7414).)

§ 60.114a Testing and procedures.

(a) Except as provided in § 60.8(b), compliance with the standard pre-

PROPOSED RULES

scribed in § 60.112(a) shall be determined as follows:

(1) The owner or operator of any storage vessel subject to this Subpart which has an external floating roof shall meet the following requirements:

(i) Determine the gap widths between the primary seal and the tank wall and the secondary seal and the tank wall, and furnish the Administrator with a written report of the results. This shall be done either before, or within 60 days after, the storage vessel is initially filled with petroleum liquid, at least once every five years thereafter, and at other times as may be required by the Administrator under section 114 of the Act. The gap widths shall be determined according to the following procedures:

(A) Measure the gaps at various roof levels, including the lowest level of the roof legs, the maximum roof height, and six approximately equidistant points between these two levels.

(B) Measure the gaps continuously around the circumference of the tank and determine the accumulated distance for each gap width.

(C) Measure the gaps with probes of diameter equal to each gap width specified in §§ 60.112a(a)(1) (i)(A) and (ii)(A). A gap is deemed to exist under the following conditions:

(1) For a primary seal, the probe is to touch the liquid surface without forcing, and

(2) For a secondary seal, the probe is to touch the primary seal without forcing.

(D) Tabulate the gap widths: gaps less than or equal to 0.32 cm (1/8 in.) are to be considered equivalent to 0.32 cm (1/8 in.), gaps greater than 0.32 cm (1/8 in.) but less than or equal to 1.3 cm (1/2 in.) are to be considered to be equivalent to 1.3 cm (1/2 in.), and gaps greater than 1.3 cm (1/2 in.) but less than or equal to 3.8 cm (1 1/2 in.) are to be considered equivalent to 3.8 cm (1 1/2 in.).

(ii) Provide the Administrator 30 days prior notice of the gap measurement to afford the Administrator the opportunity to have an observer present.

[Sec. 114 of the Clean Air Act as amended (42 U.S.C. 7414)].

§ 60.115a. Monitoring of operations.

(a) The owner or operator of any storage vessel to which this subpart applies shall for each storage vessel maintain a file of each type of petroleum liquid stored, of the typical Reid vapor pressure of each type of petroleum liquid stored, and of the dates of storage. Dates on which the storage vessel is empty shall be shown.

(b) The owner or operator of any storage vessel to which this subpart applies shall for each storage vessel determine and record the average

monthly storage temperature and true vapor pressure of the petroleum liquid stored at such temperature if:

(1) The petroleum liquid has a true vapor pressure, as stored, greater than 26 mm Hg (0.5 psia) but less than 78 mm Hg (1.5 psia) and is stored in a storage vessel other than one equipped with an external floating roof, an interval-floating-type cover, a vapor recovery system or their equivalents; or

(2) The petroleum liquid has a true vapor pressure, as stored, greater than 470 mm Hg (9.1 psia) and is stored in a storage vessel other than one equipped with a vapor recovery system or its equivalent.

(c) The average monthly storage temperature is an arithmetic average calculated for each calendar month, or portion thereof if storage is for less than a month, from bulk liquid storage temperatures determined at least once every 7 days.

(d) The true vapor pressure is to be determined by the procedure in API Bulletin 2517. This procedure is dependent upon determination of the storage temperature and the Reid vapor pressure, which requires sampling of the petroleum liquids in the storage vessels. Unless the Administrator requires in specific cases that the stored petroleum liquid be sampled, the true vapor pressure may be determined by using the average monthly storage temperature and the typical Reid vapor pressure. For those liquids for which certified specifications limiting the Reid vapor pressure exist, that Reid vapor pressure may be used. For other liquids, supporting analytical data must be made available on request to the Administrator when typical Reid vapor pressure is used.

(e) In order that the primary seal may be routinely inspected, the secondary seal is to allow easy insertion of probes up to 3.8 cm (1 1/2 in.) in diameter in at least four locations to measure gaps in the primary seal on storage vessels equipped with external floating roofs.

[Sec. 114 of the Clean Air Act as amended (42 U.S.C. 7414)].

STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Public Hearing on Proposed Standards for Petroleum Liquid Storage Vessels

AGENCY: Environmental Protection Agency.

ACTION: Hearing on proposed rule.

SUMMARY: This document announces a public hearing on the stand-

ards of performance for petroleum liquid storage vessels which are proposed in this issue of the FEDERAL REGISTER.

DATES: Hearing Date: Wednesday, June 7, 1978. See *Supplementary Information* for additional information.

ADDRESSES: Hearing held: Room 3906, Waterside Mall, 401 M Street SW., Washington, D.C. See *Supplementary Information* for additional information.

FOR FURTHER INFORMATION CONTACT:

Mr. Don R. Goodwin, Director, Emission Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, N.C. 27711, telephone 919-541-5271.

SUPPLEMENTARY INFORMATION: In accordance with section 307(d)(5) of the Clean Air Act, a public hearing on the standards of performance for petroleum liquid storage vessels which are proposed in this issue of the FEDERAL REGISTER will be held as follows:

DATE: Wednesday, June 7, 1978.

PLACE: Room 3906, Waterside Mall, 401 M Street SW., Washington, D.C.

TIME: 9:00 a.m.

PURPOSE: Interested persons will be provided the opportunity for oral presentation of data, views, or arguments concerning the proposed standards of performance for petroleum liquid storage vessels. The hearing is open to the public.

Persons wishing to make oral presentations, which will be limited to 15 minutes each, or to attend the hearing should notify EPA by May 31 by contacting Ms. Mary Jane Clark, Emission Standards and Engineering Division (MD-13), U.S. Environmental Protection Agency, Research Triangle Park, N.C. 27711, telephone 919-541-5271. Any member of the public may file a written statement with EPA before, during, or within 30 days after the hearing. Written statements should be addressed to Mr. Jack R. Farmer at the address above.

A verbatim transcript of the hearing and written statements will be available for public inspection and copying during normal working hours at the U.S. Environmental Protection Agency's Public Information Reference Unit, Room 2922, Waterside Mall, 401 M Street SW., Washington, D.C. 20460 (Docket Number OAQPS-78-2).

Dated: May 9, 1978.

EDWARD F. TUERK,
Acting Assistant Administrator
for Air and Waste Management

ENVIRONMENTAL PROTECTION AGENCY

STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

SECONDARY BRASS OR BRONZE INGOT PRODUCTION PLANTS

SUBPART M

**ENVIRONMENTAL PROTECTION
AGENCY****(40 CFR Part 60)****(FRL-1231-1)****Review of Standards of Performance
for New Stationary Sources:
Secondary Brass and Bronze Ingot
Production****AGENCY:** Environmental Protection
Agency (EPA).**ACTION:** Review of Standards.

SUMMARY: EPA has reviewed the standard of performance for secondary brass and bronze ingot production plants (40 CFR 60.130, Subpart M). The review is required under the Clean Air Act, as amended August 1977. The purpose of this notice is to announce EPA's intent not to undertake revision of the standards at this time.

DATES: Comments must be received on or before August 20, 1979.

ADDRESSES: Comments should be sent to the Central Docket Section (A-130). U.S. Environmental Protection Agency, 401 M Street, SW., Washington, D.C. 20460, Attention: Docket No. A-79-10. The Document "A Review of Standards of Performance for New Stationary Sources—Secondary Brass and Bronze Plant Plants" (EPA-450/3-79-011) is available upon request from Mr. Robert Ajax (MD-13), Emission Standards and Engineering Division, U.S. Environmental Protection Agency, Research Triangle Park, North Carolina 27711.

FOR FURTHER INFORMATION CONTACT: Mr. Robert Ajax, telephone: (919) 541-5271.

SUPPLEMENTARY INFORMATION:**Background**

In June of 1973, the EPA proposed a standard under Section 111 of the Clean Air Act to control particulate matter emissions from secondary brass and bronze ingot production plants (40 CFR 60.230, Subpart M). The standard, promulgated in March 1974, limits the discharge of any gases into the atmosphere from a reverberatory furnace which:

1. Contain particulate matter in excess of 50 mg/dscm (0.022 gr/dscf).
2. Exhibit 20 percent opacity or greater.

In addition, any blast (cupola) or electric furnace may not emit any gases which exhibit 10 percent opacity or greater.

The Clean Air Act Amendments of 1977 require that the Administrator of the EPA review and, if appropriate, revise established standards of performance for new stationary sources at least every 4 years [Section 111(b)(1)(B)]. This notice announces that EPA has completed a review of the standard of performance for secondary brass and bronze ingot production plants and invites comment on the results of this review.

Findings**Industry Statistics**

In 1969, there were approximately 60 brass and bronze ingot production facilities in the United States. Currently, only 35 facilities are operational, and only one facility has become operational since the promulgation of the NSPS in 1974. No new facilities or modifications are known to be currently planned or under construction.

Ingot production has shown a steady decline from the 1966 peak year production of 315,000 Mg (347,000 tons) to a low of 160,000 Mg (186,000 tons) in 1975, the last year for which nationwide statistics were published. The decline has been caused by a decline in the demand for products made with brass or bronze and large scale substitution of other materials or technologies for the previously used brass or bronze. No information has been reported which would indicate a reversal of the decline in brass and bronze ingot production or in the number of operating plants.

Emissions and Control Technology

The current best demonstrated control technology, the fabric filter, is the same as when the standards were originally promulgated. No major improvements in this technology have occurred during the intervening period.

High-pressure drop venturi scrubbers are used, to some extent, in the brass and bronze industry, but their overall control efficiency is lower than that of fabric filters. Electrostatic precipitators have not been used in the industry due to both the low gas flow rates and high resistivity of metallic fumes.

Only one facility has become subject to the standard since its original promulgation. This facility was tested in February 1978. The average test result of 16.9 milligrams/dry standard cubic meters (mg/dscm), or 0.0074 grains/dry standard cubic feet (gr/dscf), is lower than most of the test data used for justification of the current standard of 50 mg/dscm (0.022 gr/dscf), but this single test is not considered sufficient to

draw any overall conclusion about improved control technology.

Fugitive emissions continue to be a problem in the brass and bronze industry. In most cases, these emissions are very difficult to capture and equally difficult to measure during testing. It was primarily for the former reason that the current particulate standard does not apply during pouring of the ingots. This overall situation has not changed in that only complete enclosure of the furnace can result in full control of fugitive emissions. However, information is available indicating that there may be additives capable of reducing fugitive emissions during pouring. Also, improved control of fugitive emissions may be possible through improved hood design.

Conclusions

Based on the above findings, EPA concludes that the existing standard of performance is appropriate and no revision is needed. While extension of the standard to include fugitive emissions would be possible, the lack of anticipated growth in the industry does not justify such action.

PUBLIC PARTICIPATION: All interested persons are invited to comment on this review and the conclusions.

Dated: June 12, 1979.

Douglas M. Costle,
Administrator.

STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES: IRON AND STEEL PLANTS, BASIC OXYGEN FURNACES

Review of Standards

AGENCY: Environmental Protection Agency (EPA).

ACTION: Review of standards.

SUMMARY: EPA has reviewed the standards of performance for basic oxygen process furnaces (BOPFs) used at iron and steel plants. The review is required under the Clean Air Act, as amended in August 1977. The purpose of this notice is to announce EPA's intent to propose amendments to the standards at a later date.

DATES: Comments must be received by May 21, 1979.

ADDRESS: Send comments to: Mr. Don Goodwin (MD-13), Emission Standards and Engineering Division, U.S. Environmental Protection Agency, Research Triangle Park, N.C. 27711.

FOR FURTHER INFORMATION
CONTACT:

Mr. Robert Ajax, telephone: (919) 541-5271.

The document "A Review of Standards of Performance of New Stationary Sources—Iron and Steel Plants/Basic Oxygen Furnaces" (report number EPA-450/3-78-116) is available upon request from Mr. Robert Ajax (MD-13), Emission Standards and Engineering Division, U.S. Environmental Protection Agency, Research Triangle Park, N.C. 27711.

SUPPLEMENTARY INFORMATION:

BACKGROUND

Particulate matter emissions from BOPFs fall in two categories, primary and secondary. Emissions associated with the oxygen blow portion of the BOPF are termed "primary" emissions. These emissions are generated at the rate of 25 to 28 kg/Mg (50 to 55 lb/ton) of raw steel. Emissions generated during ancillary operations, such as charging and tapping, are termed "secondary" or fugitive emissions. These emissions are generated at a lower rate in the range of 0.5 to 1 kg/Mg (1 to 2 lb/ton) of raw steel.

In June of 1973, EPA proposed a regulation under Section 111 of the Clean Air Act to control primary particulate emissions from basic oxygen process furnaces at iron and steel plants. The

regulation, promulgated in March 1974, requires that no owner or operator of any furnace producing steel by charging scrap steel, hot metal, and flux materials into a vessel and introducing a high volume of an oxygen-rich gas shall discharge into the atmosphere any gases which contain particulate matter in excess of 50 mg/dscm (0.022 gr/dscf).

The Clean Air Act Amendments of 1977 require that the Administrator of the EPA review and, if appropriate, revise established standards of performance for new stationary sources at least every 4 years (Section 111(b)(1)(B)). This notice announces that EPA has completed a review of the standard of performance for basic oxygen process furnaces at iron and steel plants and invites comment on the results of this review.

FINDINGS

INDUSTRY GROWTH RATE

The present economic conditions in the United States and worldwide steel industry have created a significant excess U.S. BOPF capacity and a tightening of the availability of capital for future expansion. Since the promulgation of the BOPF standard, new BOPF construction has declined significantly. For example, three of the four units scheduled for startup in 1978 were originally scheduled to begin production in 1974. This coupled with the lack of any additional industry announcements of new U.S. BOPF construction, indicates that construction of new BOPFs which would be subject to a revised new source performance standard (NSPS) is not likely to commence before 1980, if then. Construction of new plants beyond 1980 will be dictated by domestic economic conditions and international competition, and is, therefore, uncertain.

PRIMARY EMISSION CONTROL

Review of the literature and performance test data indicates that the use of a closed hood in conjunction with a scrubber or an open hood in conjunction with either a scrubber or electrostatic precipitator currently represents the best demonstrated control technologies for controlling BOPF primary emissions. All BOPFs that have been installed since 1973 incorporate closed hood systems for particulate emission control. The closed hood control system in combination with a venturi scrubber has become the system of choice of the U.S. steel industry because this system saves energy and has generally lower maintenance requirements compared with the older open-hood electrostatic precipitator system. Use of the closed hood system requires that approxi-

mately 80 percent less air be cleaned than with the open hood system. The potential also exists with the closed hood system for using the carbon monoxide off-gas as a fuel source.

As of early 1978, no NSPS compliance tests had been carried out since the promulgation of the standard. Pertinent data are available, however, from emission tests on a limited number of new BOPFs. These tests, carried out using EPA Method 5, indicate that primary particulate emission levels of between 32 and 50 mg/dscf (0.014 and 0.022 gr/dscf) are being achieved using the same control technology as that existing at the time the standard for primary emissions was established for BOPFs. The rationale for the current NSPS level of 50 mg/dscm (0.022 gr/dscf) for primary stack emissions, as described in 1973, is therefore, still considered to be valid.

SECONDARY EMISSION CONTROL TECHNOLOGY

Secondary or fugitive emissions not captured by the BOPF primary emissions control system during various BOPF ancillary operations currently amount to more than 100 tons annually. One of the principal sources of these emissions, the hot metal charging cycle, can generate amounts of fugitive emissions on the order of 0.25 kg/Mg (0.5 lb/ton) of charge. These emissions are presently uncontrolled in most of the older BOPFs and only partially controlled in most BOPFs that have come on stream during the past 5 years.

Control of secondary emissions involves a developing technology that requires in-depth study to determine the most effective methods of fume capture. Although potentially expensive to construct, the complete furnace enclosure equipped with several auxiliary hoods is currently the only demonstrated technology exhibiting the potential for effectively minimizing fugitive emissions from a new BOPF.

Seven new BOPFs installed in the U.S. in the past 7 years have incorporated partial or full furnace enclosures as part of the original particulate emission control system. Since these designs had deficiencies, these systems are operating with varying degrees of success. Six new furnace enclosure installations due to commence operations in 1978, including four on new BOPFs and two retrofit installations, will incorporate a secondary hood inside the furnace enclosure with sufficient volume for fugitive emission control.

CLARIFICATION OF WORDING OF NSPS STANDARD

Review of the existing standard revealed possible ambiguity in the wording of the NSPS with regard to the

PROPOSED RULES

definitions of a BOPF. Also, the definition of the operating cycle during which sampling is performed requires clarification. Specifically, the stack emissions averaged over the oxygen blow part of the cycle could be significantly different from the emissions averaged over a period or periods that includes scrap preheating and turn-down for vessel sampling. The current standard is unclear as to which averaging time should be used. Since no tests to date have come under the NSPS, averaging time has not been an issue; however, interpreting the standard will be a problem until this matter is resolved.

CONCLUSIONS

Based upon the above findings, the following conclusions have been reached by EPA:

(1) The best demonstrated systems of emissions control at the time the standard for primary emissions was established for BOPF have not changed in the past 5 years. (See APTD-1352c (EPA/2-74-003), Background Information for New Source Performance Standards, Volume 3, Promulgated Standards.) These technologies control emissions to a level consistent with the current standard; therefore, revision to the existing standard is not required, if only primary emissions are to be controlled.

(2) Secondary or fugitive emissions from BOPFs represent a major air pol-

lution emission source. EPA, therefore, intends to initiate a project to revise the existing standard of performance to include fugitive emissions. This development project is planned to begin during 1979 and lead to a proposal 20 months after initiation. In addition, an assessment of foreign technology, which has been initiated by the Agency, will be included in the basis for the revised standard. The assessment may lead to further conclusions about the allowable emissions from the primary gas cleaning stack due to the interdependence of primary and secondary control technologies.

(3) The ambiguities in the present standard concerning definition of a BOPF and the operating cycle to be measured should be clarified, and a project to do so has been initiated.

PUBLIC PARTICIPATION

All interested persons are invited to comment on this review, the conclusions, and EPA's planned action. Comments should be submitted to: Mr. Don Goodwin (MD-13), Emission Standards and Engineering Division, U.S. Environmental Protection Agency, Research Triangle Park, N.C. 27711.

Dated: March 9, 1979.

BARBARA BLUM,
Acting Administrator.

STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

SEWAGE TREATMENT PLANTS

SUBPART 0

40 CFR Part 60

(FRL 1310-3)

Standards of Performance for New Stationary Sources: Sewage Treatment Plants; Review of Standards**AGENCY:** Environmental Protection Agency (EPA).**ACTION:** Review of standards.

SUMMARY: EPA has reviewed the standards of performance for sewage treatment plant sludge incinerators (40 CFR 60.150). The review is required under the Clean Air Act, as amended August 1977. The purpose of this notice is to announce EPA's plan to defer decision on the need to revise the standards and to undertake a program to further assess emission rates, control technology, and the current standard.

DATES: Comments must be received by January 28, 1980.

ADDRESS: Comments should be submitted to the Central Docket Section (A-130), U.S. Environmental Protection Agency, 401 M Street, S.W., Washington, D.C. 20460, Attention: Docket No. A-79-17.

FOR FURTHER INFORMATION CONTACT: Mr. Robert Ajax, telephone: (919) 541-5271. The document "A Review of Standards of Performance for New Stationary Sources—Sewage Sludge Incinerators" (EPA-450/3-79-010) is available upon request from Mr. Robert Ajax (MD-13), Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, North Carolina 27711.

SUPPLEMENTARY INFORMATION:**Background**

Prior to the promulgation of the NSPS in 1974, most sewage sludge incinerators utilized low pressure scrubbers (2 to 8 in. WG) to reduce emissions to the atmosphere. These scrubbers were designed to meet State and local standards that were on the order of 0.2 to 0.9 grams/dry standard cubic meter (dscm) or 0.1 to 0.4 grains/dry standard cubic foot (dscf) at 50 percent excess air. Incineration standards, for the most part, reflected general incineration of all types with emphasis on municipal solid waste. A separate standard for sewage sludge incineration emissions was unusual. Control efficiencies, based on an uncontrolled rate of 0.9 grains/dscf, were between 50 and 90 percent.

In June of 1973, the Environmental Protection Agency proposed a standard

under Section 111 of the Clean Air Act to control particulate matter emissions from sewage sludge incinerators. The standard, promulgated in March 1974 and amended in November 1977, applies to any incinerator constructed or modified after June 11, 1973, that burns wastes containing more than 10 percent sewage sludge (dry basis) produced by municipal sewage treatment plants, or charges more than 1000 kg (2205 lb/day) municipal sewage sludge (dry basis). The standard prohibits the discharge of particulate matter at a rate greater than 0.65 grams/kg of dry sludge input (1.30 lb/ton) and prohibits the discharge of any gases exhibiting 20 percent opacity or greater.

The Clean Air Act Amendments of 1977 require that the Administrator of the EPA review and, if appropriate, revise established standards of performance for new stationary sources at least every 4 years [Section 111(b)(1)(B)]. This notice announces that EPA has undertaken a review of the standard of performance for sewage sludge incinerators and sets forth initial findings based on this review. EPA is however, deferring a final decision on the need to revise the standard until further data can be obtained and analyzed pertaining to the form of the standard, parameters affecting emission rates, and coincineration. Comments on these findings and this action are invited.

Findings*Status of Sewage Sludge Incinerators*

It is estimated that approximately 240 municipal sludge incinerator units are presently in operation. A large number of incinerators were built in the 1967-1972 period and this growth has continued, although at a somewhat slower rate since 1972. A compilation of incinerator units subject to the construction grants program indicated that 92 new units were either in the construction or planning stages in mid-1977. A total of 23 sludge incinerators have been identified which are subject to the standard and which have been tested for compliance.

Emission Rates and Control Technology

Particulate matter from the inert material in sludge is present in the flue gas of sewage sludge incinerators. Uncontrolled emissions may vary from as low as 4 g/kg (8 lb/ton) dry sludge input to as high as 110 g/kg (220 lb/ton) dry sludge input depending upon the incinerator type and the sludge composition (e.g., percent volatile solids, percent moisture, and source treatment). Since adoption of the standard, wet

scrubbers operating with pressure drops in the range of 7 to 32 in. WG and a mean of 20 in. WG have been employed exclusively and have been successful for controlling emissions to the level required by the standard. The average emission from tests of 26 facilities since 1974 was 0.55 g/kg with a standard deviation of 0.35 g/kg (1.1 ± 0.7 lb/ton) dry sludge input. When tests from one obviously underdesigned facility and three facilities not subject to the standard were deleted, the average emission was 0.45 g/kg with a standard deviation of 0.17 g/kg (0.91 ± 0.33 lb/ton) dry sludge input or about 30 percent below the standard. The scrubber configurations which were employed included three-stage perforated plate impingement scrubbers operating at 7 to 9 in WG and venturi scrubbers, or venturi scrubbers in series with various impingement plate scrubbers operating in the 9 to 32 in. WG range.

While these test results are consistent with the standard, an analysis of the test results shows an inconsistent relationship between scrubber pressure drop and emissions as expressed in units of the standard. This appears to be due to both the facility type and input sludge composition, particularly solids content. Moreover, experimental data from some of the tested units suggest that incinerators burning sludge below 20 percent solids may have difficulty complying with the NSPS. Because combustion air requirements per unit of dry sludge increase with increasing sludge moisture, actual stack volume concentrations of 0.01 grains/dry standard cubic meter or less are needed to meet the standard when high moisture sludges are incinerated. For example, two incinerators burning sludges of 16 percent solids achieved only marginal compliance and low volume concentrations of 0.009 and 0.010 grains/acf.

An additional finding based on an analysis of the test data which are now available concerns the relationship between emissions expressed in terms of grain loading on a dry basis and emissions per weight of dry sludge burned. As initially proposed, the standard was expressed as a volume concentration standard equal to 0.031 grains/dscf. Due to comments received relative to the use of dilution air and the difficulties involved in measuring and correcting to dry volume, the promulgated standard was established at 1.3 lb/dry ton sludge input. This was based on data available at the time of promulgation showing that the promulgated and proposed standards were equivalent. However, an analysis

of the data which are now available indicate a nominal equivalence between 1.8 lb/ton dry sludge and 0.031 grains/dscf for typical sludges.

One factor at least partially responsible for the difference in equivalent emission factors, in addition to affecting the relationship between pressure drop and mass emissions, is the moisture content in the input sludge. The average solids content of the sludge associated with the data cited above is 24 percent. However, tests of two other facilities with input sludge having a relatively high solids content of between 27 and 33 percent showed an equivalence similar to that found by EPA in 1973 (e.g., 0.03 grains/dscf equivalent to 1.3 lb/ton dry sludge input).

Opacity levels from successful emissions tests never exceeded 15 percent and were most often either 0 or 5 percent. These results are similar to those found when the standard was first proposed as a 10 percent value with exceptions allowed during 2 minutes of a 60 minute test cycle. This standard was changed to 20 percent with no exemptions except during startup, shut down, or malfunctions. The current data indicate that the rationale used to arrive at the 20 percent opacity level still applies. This rationale, in addition to field observations obtained with Method 9, involved instrumental data and theoretical projections of the opacity which could, under extreme conditions, occur at a facility complying with the particulate matter standard. A reevaluation of this standard was undertaken and reaffirmation was announced in the Federal Register on February 18, 1976.

Application of the Standard to Coincineration

The coincineration of municipal solid waste and sewage sludge has been practiced in Europe for several years, and on a limited scale in the U.S. However, as energy resources become scarce and more costly, and where land disposal is economically or technically unfeasible, the recovery of the heat content of dewatered sludge as an energy source will become more desirable. Due to this and the institutional commonality of these wastes and advances in the preincineration processing of municipal refuse to a waste fuel, many communities may find joint incineration in energy recovery incinerators an economically attractive alternative to their waste disposal problems.

Coincineration of municipal solid waste and sewage sludge, as described above, is not explicitly covered in 40

CFR 60. The particulate standard for municipal solid waste described in Subpart E (0.18 g/dscm or 0.08 g/dscf at 12 percent CO₂) applies to the incineration of municipal solid waste in furnaces with a capacity of at least 45 Mg/day (50 tons/day). Subpart O, the particulate standard for sewage sludge incineration (0.65 g/kg dry sludge input or 1.3 lb/ton dry sludge), applies to any incinerator that burns sewage sludge, with the exception of small communities practicing coincineration.

To clarify the situation when coincineration is involved, EPA adopted the policy that when an incinerator with a capacity of at least 45 Mg/day (50 tons/day) burns at least 50 percent municipal solid waste, then the Subpart E applies regardless of the amount of sewage sludge burned. When more than 50 percent sewage sludge and more than 45 Mg/day (50 tons) is incinerated, the standard is based upon Subpart O or, alternatively, a proration between Subparts O and E. The proration scheme, however, has a discontinuity when a municipal incinerator burns 50 percent solid waste.

The alternative of prorating the Subparts E and O is not straightforward, since the two standards are stated in different units. The proration scheme requires a transformation of the municipal incineration standard (Subpart E) from grams per dry standard cubic meter (grains per dry standard cubic foot) at 12 percent CO₂ to grams per kilograms (pounds per dry ton) refuse input, or a transformation of the sewage sludge standard (Subpart O) from grams per dry kilograms (pounds per dry ton) input to grams per dry standard cubic meter at 12 percent CO₂. Such transformations are dependent on the percent CO₂ in the flue gas stream, the stoichiometric air requirements, excess air, the volume of combustion products to require air, and percent moisture in refuse or sludge, and the heat content of the sludge and solid waste.

Other Pollutants

Incineration of sewage sludge results in the emission to the atmosphere of trace elements and compounds, some of which are hazardous or potentially hazardous. Substances of concern include mercury, lead, cadmium, pesticides, and organic matter. Among these, mercury emissions from sewage sludge incinerators are specifically limited under the National Emission Standards for Hazardous Air Pollutants (40 CFR 61.50 et seq.).

The emission of other trace compounds and elements, while not subject to specific limitations is

controlled by particulate matter control equipment or directly by the high temperatures in the combustion process and with the exception of cadmium, no data were obtained during this review to indicate a need for specific limitations on emissions of these materials resulting from incineration of typical sludges. Tests have shown high destruction efficiencies for pesticides, and organics in sewage sludge incinerators. Similarly, test data suggest that high pressure scrubbers of the type normally employed to meet the particulate standards also reduce lead emissions to below the level required to meet ambient standards. In contrast, data suggest that cadmium emissions may not be adequately controlled. A separate program is underway in EPA to independently assess the need to regulate cadmium. Final decisions on this will be announced in a separate action. In the event that the need to limit cadmium emissions from sewage sludge incinerators is indicated, appropriate action will be taken.

Conclusions

The available test data support the validity of the standard. However, the marginal compliance of several facilities operating with high pressure drops, the apparent relationship between sludge moisture content and emission rates, and the inconsistent relationship between pressure drop and scrubber performance as measured in terms of the standard are matters which require further study. Such a study will be undertaken later and will include further analysis of data regarding sludge dewatering, incinerator types, control technology, and the relationship between control device operating parameters, sludge solids content, emission rates, and alternative forms for expression of emission rates. This will also include an analysis of alternative means for establishment of standards applicable to coincineration. A final conclusion on the need for revision of the standard will not be made until this study is complete.

Dated: November 16, 1979.

Barbara Blum,
Acting Administrator.

ENVIRONMENTAL PROTECTION AGENCY

PRIMARY ALUMINUM INDUSTRY

**Standards of Performance for
New Stationary Sources; Public
Hearing**

SUBPART S

PROPOSED RULES

ENVIRONMENTAL PROTECTION AGENCY

[40 CFR Part 60]

[FRL 915-5]

STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

Primary Aluminum Industry

AGENCY: Environmental Protection Agency (EPA).

ACTION: Proposed rule and notice of public hearing.

SUMMARY: The proposed amendments would require primary aluminum plant performance tests to be conducted at least once each month, allow potroom emissions to be above the level of the current standard (but not above a higher limit of 1.25 kg/Mg (2.5 lb/ton)) if an owner or operator can establish that the emission control system was properly operated at the time the excursion above the current standard occurred, revise the reference method for determining fluoride emissions from potroom roof monitors, and clarify some provisions in the existing standard. These amendments are being proposed in response to arguments raised by four aluminum companies who filed petitions for review of the standard of performance. The intended effect of the proposed amendments is to account for the inherent variability of fluoride emissions from the aluminum reduction process and to require monitoring of fluoride emissions to insure proper operation and maintenance of the pollution control systems.

A public hearing will be held to provide interested persons an opportunity for oral presentation of data, views, or arguments concerning the proposed standards.

DATES: *Comments.* Comments must be received on or before November 20, 1978. *Public hearing.* The public hearing will be held on October 16, 1978, beginning at 9:30 a.m. and ending at 4:30 p.m. *Request to speak at hearing.* Persons wishing to attend the hearing or present oral testimony should contact EPA by October 11, 1978.

ADDRESSES: *Comments.* Comments should be submitted to Jack R. Farmer, Chief, Standards Development Branch (MD-13), Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, N.C. 27711.

Public hearing. The public hearing will be held at Waterside Mall, Room 3906, 401 M Street SW., Washington, D.C. 20460. Persons wishing to present oral testimony should notify Mary Jane Clark, Emission Standards and Engineering Division (MD-13), Envi-

ronmental Protection Agency, Research Triangle Park, N.C. 27711, telephone 919-541-5271.

Standard support document. The support document for the proposed amendments may be obtained from the U.S. EPA Library (MD-35), Research Triangle Park, N.C. 27711, telephone 919-541-2777. Please refer to Primary Aluminum Background Information: Proposed Amendments (EPA-450/2-78-025a).

Docket. The docket, number OAQPS-78-10, is available for public inspection and copying at the EPA Central Docket Section (A-130), Room 2903B, Waterside Mall, 401 M Street SW., Washington, D.C. 20460.

FOR FURTHER INFORMATION CONTACT:

Don R. Goodwin, Director, Emission Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, N.C. 27711, telephone 919-541-5271.

SUPPLEMENTARY INFORMATION:

PROPOSED AMENDMENTS

It is proposed to amend Subpart S—Standards of Performance for Primary Aluminum Plants by requiring that performance tests be performed at least once each month during the life of an affected facility. Previously, performance tests were required only as provided in 40 CFR 60.8(a) (i.e., within 60 days after achieving the maximum production rate, but not later than 180 days after initial start-up and at other times as may be required by the Administrator under section 114 of the Clean Air Act). The proposed amendments would also allow potroom emissions to be above the level of the current standard (0.95 kg/Mg (1.9 lb/ton) for prebake plants and 1.0 kg/Mg (2.0 lb/ton) for Soderberg plants), but not above 1.25 kg/Mg (2.5 lb/ton), if an owner or operator can establish that the emission control system was properly operated and maintained at the time the excursion above the current standard occurred. Emissions may not be above 1.25 kg/Mg under any condition. Other amendments would (1) clarify Reference Method 14 procedures; (2) clarify the definition of "potroom group;" (3) replace English and metric units of measure with the International System of Units (SI); (4) allow the owner or operator of a new facility to apply to the Administrator for an exemption from the monthly testing requirement for primary and anode bake plant emissions; and (5) clarify the procedure for determining the rate of aluminum production for fluoride emission calculations.

BACKGROUND

A standard of performance for new primary aluminum plants was promul-

gated on January 26, 1976 (41 FR 3826), and shortly thereafter petitions for review were filed by four U.S. aluminum companies. The principal argument raised by the petitioners was that the standard was too stringent and could not be consistently complied with by modern, well-controlled facilities. (Facilities which commenced construction prior to October 23, 1974, are not affected by the standard.) Following discussions with the petitioning aluminum companies, EPA conducted an emission test program at the Anacosta Aluminum Co. plant in Sebree, Ky. The Sebree plant is the newest primary aluminum plant in the United States, and its emission control system conforms with what EPA has defined as the best technological system of continuous emission reduction for new facilities. The purpose of the test program was to aid EPA in its reevaluation of the standard by expanding the emission data base. The test results were available in August of 1977 and indicated that there is some probability that the result of a performance test conducted at a modern, well-controlled plant would be above the existing standard. EPA has concluded that this justifies revising the standard.

RATIONALE

EPA's decision to amend the existing standard is based primarily on the results of the Sebree test program. The test results may be summarized as follows: (1) The measured emissions were variable, ranging from 0.43 to 1.37 kg/Mg (0.85 to 2.74 lb/ton) for single test runs; and (2) emission variability appeared to be inherent in the production process and beyond the control of plant personnel. Since the Sebree plant represents the latest technology for the aluminum industry, EPA expects that new plants covered by the standard may also exhibit emission variability.

An analysis performed by EPA on the results of the nine Sebree test runs indicates that there is about an 8-percent probability that a performance test would violate the current standard. (A performance test is defined in 40 CFR 60.8(f) as the arithmetic mean of three separate test runs, except in situations where a run must be discounted or canceled and the Administrator approves using the arithmetic mean of two runs.) The petitioners have estimated chances of violation ranging from about 2.5 to 10 percent. Although the Sebree data base is not large enough to permit a thorough statistical analysis, EPA believes it is adequate to demonstrate a need for revising the current standard.

EPA considered a number of possible solutions to the emission variability problem including raising the level of

PROPOSED RULES

the current standard, allowing a certain number of monthly tests to exceed the current standard based on an expected failure rate, and specifying an equipment standard in place of the current emission standard. These and other possible solutions were rejected because they did not satisfy the following criteria: The revised standard (1) must be enforceable, (2) must provide for the variability of emissions, and (3) must not allow emission levels to be higher than indicated by the Sebree plant, which employs the best system of emission reduction.

The solution EPA proposes is to amend Subpart S to allow a performance test to be above the current standard provided the owner or operator submits to EPA a report clearly demonstrating that the emission control system was properly operated and maintained during the excursion above the standard. The report would be used as evidence that the high emission level resulted from random and uncontrollable emission variability, and that the emission variability was entirely beyond the control of the owner or operator of the affected facility. Under no circumstances, however, would performance test results be allowed above 1.25 kg/Mg (2.5 lb/ton). EPA believes that emissions from a plant equipped with the proper control system which is properly operated and maintained would be below 1.25 kg/Mg at all times.

Within 15 days of receipt of the results of a performance test which fall between the current standard and 1.25 kg/Mg, the owner or operator of the affected facility would be required to submit a report to the Enforcement Division of the appropriate EPA Regional Office indicating that all necessary control devices were on-line and operating properly during the performance test, describing the operation and maintenance procedures followed, and setting forth any explanation for the excess emissions. EPA requests comments on additional criteria to be used by the Regional Offices to determine whether the control devices were properly operated and maintained during the performance test.

The proposed amendments would also require, following the initial performance test required under 40 CFR 60.8(a), additional performance testing at least once each month during the life of the affected facility. During visits to existing plants, EPA personnel have observed that the emission control systems are not always operated and maintained as well as possible. EPA believes that good operation and maintenance of control systems is essential and expects the monthly testing requirement to help achieve this goal. The Administrator has the authority under section 114 of the Clean

Air Act to require additional testing if necessary.

It is important to emphasize that the following operating and maintenance procedures are exemplary of good control of emissions and should be implemented at all times: (1) Hood covers should fit properly and be in good repair; (2) if equipped with an adjustable air damper system, the hood exhaust rate for individual pots should be increased whenever hood covers are removed from a pot (the exhaust system should not be overloaded by placing too many pots on high exhaust); (3) hood covers should be replaced as soon as possible after each potroom operation; (4) dust entrainment should be minimized during materials handling operations and sweeping of the working aisles; (5) only tapping crucibles with functional aspirator air return systems (for returning gases under the collection hooding) should be used; and (6) the primary control system should be regularly inspected and properly maintained. EPA believes that the proposed amendments are clearly achievable provided the control system is properly designed and installed and, as a minimum, the six procedures noted above are implemented.

The proposed amendments affect not only prebake designs, such as the Sebree plant, but also Soderberg plants. Available data for existing plants indicate that Soderberg and prebake plants have similar emission variability. Thus, EPA feels justified in extrapolating its conclusions about the Sebree prebake plant to cover Soderberg designs. It is unlikely that any new Soderberg plant will be built due to the high cost of emission control for these designs. However, existing Soderberg plants may be modified to such an extent that they would be subject to these regulations.

Under the proposed amendments anode bake plants would be subject to the monthly testing requirement, but emissions would not be allowed under any circumstances to be above the level of the current bake plant standard. Since there is no evidence that bake plant emissions are as variable as potroom emissions, there is no need to excuse excursions above the bake plant standard.

The proposed amendments would allow the owner or operator of a new plant to apply to the Administrator for an exemption from the monthly testing requirement for the primary control system and the anode bake plant. EPA believes that the testing of these systems as often as once each month may be unreasonable given that (1) The contribution of primary and bake plant emissions to the total emission rate is minor, averaging about 2.5 and 5 percent, respectively;

(2) primary and bake plant emissions are much less variable than secondary emissions; and (3) the cost of primary and bake plant emissions sampling is high. An application to the Administrator for an exemption from monthly testing would be required to include (1) evidence that the primary and bake plant emissions have low variability; (2) an alternative testing schedule; and (3) a representative value for primary emissions to be used in total fluoride emission calculations.

EPA estimates the costs associated with monthly performance testing to average about \$4,000 for primary tests, \$5,000 for secondary tests, and \$4,000 for bake plant tests. These estimates assume that (1) Testing would be performed by plant personnel; (2) each monthly performance test would consist of the average of 3 24-hour runs; (3) sampling would be performed by two crews working 13-hour shifts; (4) primary control system sampling would be performed at a single point in the stack; and (5) Sebree inhouse testing costs would be representative of average costs for other new plants. Although these assumptions may not hold for all situations, EPA believes they provide a representative estimate of what testing costs would be for new plants.

Also amended is the procedure for determining the rate of aluminum production. Previously, the rate was based on the weight of metal tapped during the test period. However, since the weight of metal tapped does not always equal the weight of metal produced, undertapping or overtapping during a test period would result in erroneous production rates. EPA believes it would be more reasonable to judge the weight of metal produced according to the average weight of metal tapped during a 30-day period (720 hours) prior to and including the test date. The 3-day period would allow for overtapping and undertapping to average out, and this would give a more accurate estimate of the true production rate.

Other amendments would (1) clarify the definition of potroom group to cover situations where two potroom segments are ducted to a common control system; (2) incorporate use of the International System of Units (SI); and (3) make minor editorial changes in the regulations.

METHOD 14

The proposed amendments to Reference Method 14 would update the test method to reflect EPA's experiences at the Sebree test program. Also, the amendments would make Method 14 consistent with recent revisions of Methods 1 through 8 (42 FR 41754). The intended effect of the proposed amendments is to clarify testing proce-

PROPOSED RULES

dures and to improve the reliability of the test method.

The principal amendments would be as follows: (1) More detailed anemometer specifications and calibration procedures would be delineated; (2) a performance check of each anemometer and each recorder (or counter) would be required following each test series (i.e., following each series of test runs as required for a performance test under 40 CFR 60.8(f)); (3) data adjustment procedures would be included for anemometers and recorders (or counters) that fail the performance check; (4) to be consistent with the new definition of "potroom group" more specific guidelines would be included for both the location of the sampling manifold and the number and location of the propeller anemometers; (5) for convenience, each Method 14 test run could be divided into "sub-runs"; (6) the use of a separate Method 13 train for each sub-run would be allowed, provided that the sampling nozzle size for all trains is the same; (7) a procedure would be included for calculating the fluoride concentration when more than one sampling train is used; (8) the tester would be allowed greater freedom as to the method by which velocity estimates are made for setting isokinetic flow; (9) the limits of acceptable isokinetic results would be more clearly defined, and a data adjustment procedure would be included for cases where the results are outside these limits; (10) the number and location of points for the Method 13 sampling runs would be determined according to the revised Method 1; (11) the use of a Type S pitot tube for making manifold intake nozzle adjustments would be disallowed; (12) the use of a differential pressure gauge conforming to the specifications of the revised Method 2 would be required for manifold intake nozzle velocity measurements; and (13) calibration of the thermocouple would be required after each test series, using the procedure outlined in the revised Method 2.

Due to the complexity of the amendments, the entire test method has been rewritten and is presented in revised form.

PUBLIC HEARING

A public hearing will be held to discuss the proposed standards in accordance with section 307(d)(5) of the Clean Air Act. Persons wishing to make oral presentations should contact EPA at the address above. Any member of the public may file a written statement with EPA before, during, or within 30 days after the hearing. Written statements should be addressed to Mr. Jack R. Farmer at the address above.

A verbatim transcript of the hearing and written statements will be available for public inspection and copying during normal working hours at EPA's Central Docket Section in Washington, D.C. (address same as above).

MISCELLANEOUS

The docket is an organized and complete file of all the information submitted to or otherwise considered by EPA in the development of this rulemaking. The principal purposes of the docket are (1) to allow members of the public and industries involved to identify and participate in the rulemaking process, and (2) to serve as the record for judicial review. The docket is required under section 307(d) of the Clean Air Act, as amended, and is available for public inspection and copying at the address above.

The proposed amendments would not alter the applicability date of Subpart S. Subpart S applies to all new primary aluminum plants for which construction or modification began after the original proposal date (October 23, 1974).

As prescribed by section 111 of the Clean Air Act, promulgation of the original standard of performance (41 FR 3826) was preceded by the Administrator's determination that primary aluminum plants contribute significantly to air pollution which causes or contributes to the endangerment of public health or welfare. In accordance with section 117 of the act, publication of the original proposed standard (39 FR 37739) was preceded by consultation with appropriate advisory committees, independent experts, and Federal departments and agencies. The Administrator will welcome comments on all aspects of the proposed regulation, including economic and technological issues, and on the revised test method.

It should be noted that standards of performance for new sources established under section 111 of the Clean Air Act reflect:

(T)he degree of emission limitation and the percentage reduction achievable through application of the best technological system of continuous emission reduction which (taking into consideration the cost of achieving such emission reduction, any nonair quality health and environmental impact and energy requirements) the Administrator determines has been adequately demonstrated (section 111(a)(1)).

Although there may be emission control technology available that can reduce emissions below those levels required to comply with standards of performance, this technology might not be selected as the basis of standards of performance due to costs associated with its use. Accordingly, standards of performance should not be viewed as the ultimate in achievable

emission control. In fact, the act requires (or has potential for requiring) the imposition of a more stringent emission standard in several situations.

For example, applicable costs do not necessarily play as prominent a role in determining the "lowest achievable emission rate" for new or modified sources located in nonattainment areas, i.e., those areas where statutorily-mandated health and welfare standards are being violated. In this respect, section 173 of the act requires that a new or modified source constructed in an area which exceeds the National Ambient Air Quality Standard (NAAQS) must reduce emissions to the level which reflects the "lowest achievable emission rate" (LAER), as defined in section 171(3), for such category of source. The statute defines LAER as that rate of emissions which reflects:

(A) The most stringent emission limitation which is contained in the implementation plan of any State for such class or category of source, unless the owner or operator of the proposed source demonstrates that such limitations are not achievable or

(B) The most stringent emission limitation which is achieved in practice by such class or category of source, whichever is more stringent.

In no event can the emission rate exceed any applicable new source performance standard (section 171(3).)

A similar situation may arise under the prevention of significant deterioration of air quality provisions of the act (Part C). These provisions require that certain sources (referred to in section 169(1)) employ "best available control technology" (as defined in section 169(3)) for all pollutants regulated under the act. Best available control technology (BACT) must be determined on a case-by-case basis, taking energy, environmental and economic impacts, and other costs into account. In no event may the application of BACT result in emissions of any pollutants which will exceed the emissions allowed by any applicable standard established pursuant to section 111 (or 112) of the act.

In all events, State implementation plans (SIP's) approved or promulgated under section 110 of the act must provide for the attainment and maintenance of National Ambient Air Quality Standards, designed to protect public health and welfare. For this purpose, SIP's must in some cases require greater emission reductions than those required by standards of performance for new sources.

Finally, States are free under section 116 of the act to establish even more stringent emission limits than those established under section 111 or those necessary to attain or maintain the NAAQS under section 110. According-

PROPOSED RULES

ly, new sources may in some cases be subject to limitations more stringent than EPA's standards of performance under section 111, and prospective owners and operators of new sources should be aware of this possibility in planning for such facilities.

The major costs incurred by the proposed amendments are associated with the periodic emission testing requirement. EPA believes that these costs are reasonable and would have a negligible impact on: (1) Potential inflationary or recessionary effects; (2) competition with respect to small business; (3) consumer costs; and (4) energy use. The Administrator has determined that the proposed amendments are not "substantial" and do not require preparation of an Economic Impact Assessment.

Dated: September 8, 1978.

DOUGLAS M. COSTLE,
Administrator.

It is proposed to amend Part 60 of Chapter I, Title 40 of the Code of Federal Regulations as follows:

Subpart A—General Provisions

1. Section 60.8 is amended by revising paragraph (d) to read as follows:

§ 60.8 Performance tests.

(d) The owner or operator of an affected facility shall provide the Administrator 30 days prior notice of any performance test, except as specified under other subparts, to afford the Administrator the opportunity to have observers present.

Subpart S—Standards of Performance for Primary Aluminum Plants

2. Section 60.191 is amended by deleting paragraph (i) and by revising paragraphs (d) and (f) as follows:

§ 60.191 Definitions.

(d) "Potroom group" means an uncontrolled potroom, a potroom which is controlled individually, or a group of potrooms or potroom segments ducted to a common control system.

(f) "Aluminum equivalent" means an amount of aluminum which can be produced from a Mg of anodes produced by an anode bake plant as determined by § 60.195(g).

3. Section 60.192 is amended by revising paragraph (a) and adding paragraph (b) to read as follows:

§ 60.192 Standards for fluorides.

(a) On and after the date on which the initial performance test required to be conducted by § 60.8 is completed, no owner or operator subject to the provisions of this subpart shall cause to be discharged into the atmosphere from any affected facility any gases containing total fluorides, as measured according to § 60.8, above:

(1) 1.0 kg/Mg (2.0 lb/ton) of aluminum produced for potroom groups at Soderberg plants; except that emissions between 1.0 kg/Mg and 1.25 kg/Mg (2.5 lb/ton) will be considered in compliance if the owner or operator demonstrates that exemplary operation and maintenance procedures were used with respect to the emission control system and that proper control equipment was operating at the affected facility during the performance test;

(2) 0.95 kg/Mg (1.9 lb/ton) of aluminum produced for potroom groups at prebake plants; except that emissions between 0.95 kg/Mg and 1.25 kg/Mg (2.5 lb/ton) will be considered in compliance if the owner or operator demonstrates that exemplary operation and maintenance procedures were used with respect to the emission control system and that proper control equipment was operating at the affected facility during the performance test; and

(3) 0.05 kg/Mg (0.1 lb/ton) of aluminum equivalent for anode bake plants.

(b) Within 15 days of receipt of the results of a performance test which fall between the 1.0 kg/Mg and 1.25 kg/Mg levels in paragraph (a)(1) of this section or between the 0.95 kg/Mg and 1.25 kg/Mg levels in paragraph (a)(2) of this section, the owner or operator shall submit a report indicating whether all necessary control devices were on-line and operating properly during the performance test, describing the operation and maintenance procedures followed, and setting forth any explanation for the excess emissions, to the Director of the Enforcement Division of the appropriate EPA Regional Office.

4. Section 60.195 is amended as follows:

(a) By redesignating paragraphs (a) through (g) as (c) through (i) respectively;

(b) By deleting in redesignated paragraphs (g)(1), (h), and (i) the words "metric ton" wherever they appear and inserting in their place "Mg;"

(c) By deleting "(a)" in redesignated paragraph (e) and inserting in its place "(c);"

(d) By deleting the word "tons" in redesignated paragraph (g)(3) and inserting in its place "Mg;"

(e) By deleting "§ 60.195(d)" in redesignated paragraph (h) and inserting in its place "§ 60.195(f);"

(f) By deleting "§ 60.195(e)" in redesignated paragraph (i) and inserting in its place "§ 60.195(g);"

(g) By adding new paragraphs (a) and (b), and by revising redesignated paragraph (f) as follows:

§ 60.195 Test methods and procedures.

(a) Following the initial performance test as required under § 60.8(a), an owner or operator shall conduct a performance test at least once each month during the life of the affected facility, except when malfunction prevent representative sampling, as provided under § 60.8(c). The owner or operator shall give the Administrator at least 7 days advance notice of each test. The Administrator may require additional testing under section 114 of the Clean Air Act.

(b) An owner or operator may petition the Administrator to establish an alternative testing requirement that requires testing less frequently than once each month for a primary control system or an anode bake plant. If the owner or operator shows that emissions from the primary control system or the anode bake plant have low variability during day-to-day operations, the Administrator may establish such an alternative testing requirement. The alternative testing requirement shall include a testing schedule and, in the case of a primary control system, the method to be used to determine primary control system emissions for the purpose of performance tests. The Administrator shall publish the alternative testing requirement in the FEDERAL REGISTER.

(f) The rate of aluminum production is determined by dividing 720 hours into the weight of aluminum tapped from the affected facility during a period of 30 days prior to and including the final run of a performance test.

(Sec. 111, 114, 301(a) of the Clean Air Act as amended (42 U.S.C. 7411, 7414, 7601(a)).)

APPENDIX A—REFERENCE METHODS

5. Method 14 is revised to read as follows:

14—DETERMINATION OF FLUORIDE EMISSIONS FROM POTROOM ROOF MONITORS OF PRIMARY ALUMINUM PLANTS

1. Principle and applicability.

1.1 Principle—Gaseous and particulate fluoride roof monitor emissions are drawn into a permanent sampling manifold

PROPOSED RULES

through several large nozzles. The sample is transported from the sampling manifold to ground level through a duct. The gas in the duct is sampled using Method 13A or 13B—Determination of Total Fluoride Emissions from Stationary Sources. Effluent velocity and volumetric flow rate are determined with anemometers permanently located in the roof monitor.

1.2 *Applicability*—This method is applicable for the determination of fluoride emissions from stationary sources only when specified by the test procedures for determining compliance with new source performance standards.

2. Apparatus.

2.1 Velocity measurement apparatus.

2.1.1 *Anemometers*—Propeller anemometers, or equivalent. Each anemometer shall meet the following specifications: (1) Its propeller shall be made of polystyrene, or similar material of uniform density. To insure uniformity of performance among propellers, it is desirable that all propellers be made from the same mold; (2) the propeller shall be properly balanced, to optimize performance; (3) when the anemometer is mounted horizontally, its threshold velocity shall not exceed 15 m/min (50 fpm); (4) the measurement range of the anemometer shall extend to at least 600 m/min (2,000 fpm); (5) the anemometer shall be able to withstand prolonged exposure to dusty and corrosive environments; one way of achieving this is to continuously purge the bearings of the anemometer with filtered air during operation; (6) all anemometer components shall be properly shielded or encased, such that the performance of the anemometer is uninfluenced by potroom magnetic field effects; (7) a known relationship shall exist between the electrical output signal from the anemometer generator and the propeller shaft rpm, at minimum of three rpm settings between 60 and 1800 rpm; note that one of the three rpm settings shall be within 25 percent of 60 rpm. Anemometers having other types of output signals (e.g., optical) may be used, subject to the approval of the Administrator. If other types of anemometers are used, there must still be a known relationship (as described

above) between output signal and shaft rpm; also, each anemometer must be equipped with a suitable readout system.

2.1.2 *Installation of anemometers*—2.1.2.1 If the affected facility consists of a single, isolated potroom (or potroom segment), install at least one anemometer for every 85 meters of roof monitor length. If the length of the roof monitor divided by 85 meters is not a whole number, round the fraction to the nearest whole number to determine the number of anemometers needed. For monitors that are less than 130 m in length, use at least two anemometers. Divide the monitor cross-section into as many equal areas as anemometers and locate an anemometer at the centroid of each equal area.

2.1.2.2 If the affected facility consists of two or more potrooms (or potroom segments) ducted to a common control device, install anemometers in each potroom (or segment) that contains a sampling manifold. Install at least one anemometer for every 85 meters of roof monitor length of the potroom (or segment). If the potroom (or segment) length divided by 85 is not a whole number, round the fraction to the nearest whole number to determine the number of anemometers needed. If the potroom (or segment) length is less than 130 m, use at least two anemometers. Divide the potroom (or segment) monitor cross-section into as many equal areas as anemometers and locate an anemometer at the centroid of each equal area.

2.1.2.3 At least one anemometer shall be installed in the immediate vicinity (i.e., within 10 m) of the center of the manifold (see § 2.2.1). Make a velocity traverse of the width of the roof monitor where an anemometer is to be placed. This traverse may be made with any suitable low velocity measuring device, and shall be made during normal process operating conditions. Install the anemometer at a point of average velocity along this traverse.

2.1.3 *Recorders*—Recorders, equipped with suitable auxiliary equipment (e.g. transducers) for converting the output signal from each anemometer to a continuous recording of air flow velocity, or to an integrated measure of volumetric flowrate.

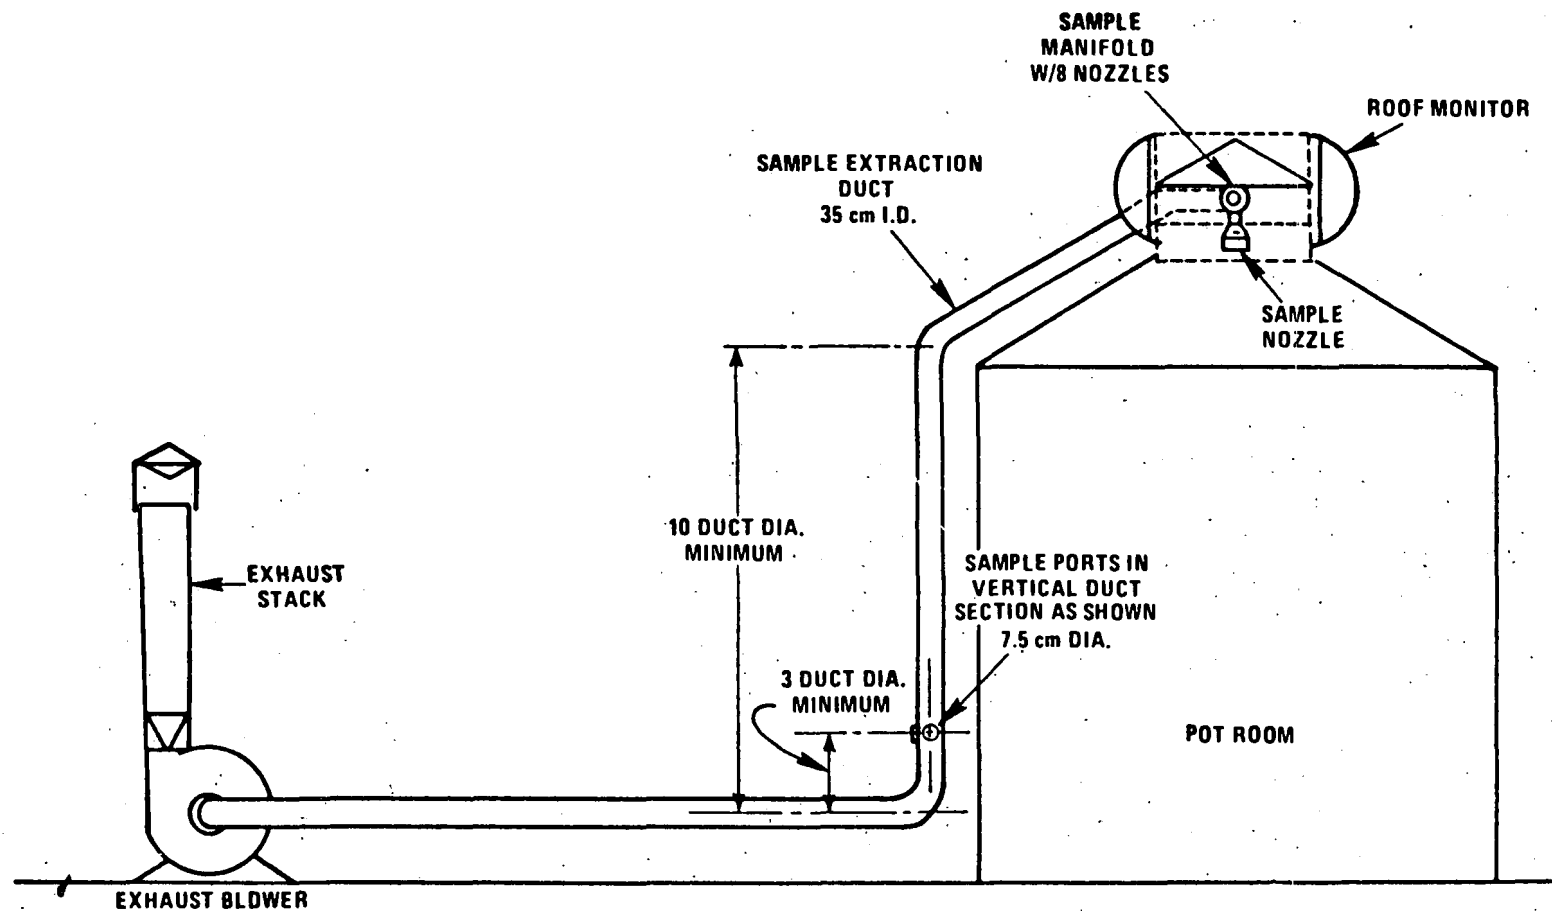

For the purpose of recording velocity, "continuous" shall mean one readout per 15-minute or shorter time interval. A constant amount of time shall elapse between readings. Volumetric flow rate may be determined by an electrical count of anemometer revolutions. The recorders or counters shall permit identification of the velocities or flowrate measured by each individual anemometer.

2.1.4 *Pitot tube*—Standard-type pitot tube, as described in § 2.7 of Method 2, and having a coefficient of 0.99 ± 0.01 .

2.1.5 *Pitot tube (optional)*—Isolated, Type S pitot tube, as described in § 2.1 of Method 2. The pitot tube shall have a known coefficient, determined as outlined in § 4.1 of Method 2.

2.1.6 *Differential pressure gauge*—Inclined manometer or equivalent, as described in § 2.2 of Method 2.

2.2 *Roof monitor air sampling system.*
2.2.1 *Sampling ductwork*—A minimum of one manifold system shall be installed for each 'potroom group' (as defined in Subpart S, § 60.191). The manifold system and connecting duct shall be permanently installed to draw an air sample from the roof monitor to ground level. A typical installation of duct for drawing a sample from a roof monitor to ground level is shown in figure 14-1. A plan of a manifold system that is located in a roof monitor is shown in figure 14-2. These drawings represent a typical installation for a generalized roof monitor. The dimensions on these figures may be altered slightly to make the manifold system fit into a particular roof monitor, but the general configuration shall be followed. There shall be eight nozzles each having a diameter of 0.40 to 0.50 meters. Unless otherwise specified by the Administrator, the length of the manifold system from the first nozzle to the eighth shall be 35 meters or eight percent of the length of the potroom (or potroom segment) roof monitor, whichever is greater. The duct leading from the roof monitor manifold shall be round with a diameter of 0.30 to 0.40 meters. As shown in figure 14-2, each of the sample legs of the manifold shall have a device, such as a blast gate or valve, to enable adjustment of flow into each sample nozzle.

PROPOSED RULES

Figure 14-1. Roof monitor sampling system.

Figure 14-2. Sampling manifold and nozzles.

PROPOSED RULES

The manifold shall be located in the immediate vicinity of one of the propeller anemometers (see § 2.1.2.3) and as close as possible to the midsection of the potroom (or potroom segment). Avoid locating the manifold near the end of a potroom or in a section where the aluminum reduction pot arrangement is not typical of the rest of the potroom (or potroom segment). Center the sample nozzles in the throat of the roof monitor (see fig. 14-1). Construct all sample-exposed surfaces within the nozzles, manifold and sample duct of 316 stainless steel. Aluminum may be used if a new ductwork system is conditioned with fluoride-laden roof monitor air for a period of six weeks prior to initial testing. Other materials of construction may be used if it is demonstrated through comparative testing that there is no loss of fluorides in the system. All connections in the ductwork shall be leak free.

Locate two sample ports in a vertical section of the duct between the roof monitor and exhaust fan. The sample ports shall be at least 10 duct diameters downstream and three diameters upstream from any flow disturbance such as a bend or contraction. The two sample ports shall be situated 90° apart. One of the sample ports shall be situated so that the duct can be traversed in the plane of the nearest upstream duct bend.

2.2.2 Exhaust fan—An industrial fan or blower shall be attached to the sample duct at ground level (see fig. 14-1). This exhaust fan shall have a capacity such that a large enough volume of air can be pulled through the ductwork to maintain an isokinetic sampling rate in all the sample nozzles for all flow rates normally encountered in the roof monitor.

The exhaust fan volumetric flow rate shall be adjustable so that the roof monitor air can be drawn isokinetically into the sample nozzles. This control of flow may be achieved by a damper on the inlet to the exhaust or by any other workable method.

2.3 Temperature measurement apparatus. **2.3.1 Thermocouple**—Install a thermocouple in the roof monitor near the sample duct. The thermocouple shall conform to

the specifications outlined in § 2.3 of Method 2.

2.3.2 Signal Transducer—Transducer, to change the thermocouple voltage output to a temperature readout.

2.3.3 Thermocouple Wire—To reach from roof monitor to signal transducer and recorder.

2.3.4 Recorder—Suitable recorder to monitor the output from the thermocouple signal transducer.

2.4 Sampling train—Use the train described in Methods 13A and 13B.

3. Reagents.

3.1 Sampling and analysis. Use reagents described in Method 13A or 13B.

4. Calibration.

4.1 Propeller anemometers. **4.1.1 Initial calibration**—Anemometers which meet the specifications outlined in § 2.1.1 need not be calibrated, provided that a reliable performance curve relating anemometer signal output to air velocity (covering the velocity range of interest) is available from the manufacturer. For the purposes of this method, a "reliable" performance curve is defined as one that has been derived from primary standard calibration data, with the anemometer mounted vertically. "Primary standard" data are obtainable by: (1) Direct calibration of one or more of the anemometers by the National Bureau of Standards (NBS); (2) NBS-traceable calibration; or (3) Calibration by direct measurement of fundamental parameters such as length and time (e.g., by moving the anemometers through still air at measured rates of speed, and recording the output signals). If a reliable performance curve is not available from the manufacturer, such a curve shall be generated, using one of the three methods described immediately above.

4.1.2 Recalibration—Extended field use of propeller anemometers can cause deterioration of some of the anemometer components, thus affecting performance. Therefore, a performance-check of each anemometer shall be made before (optional) and after (mandatory) each test series. The performance-check shall be done as outlined in § 4.1.2.1 through 4.1.2.3, below. Alternatively, the tester may use any other suitable

method, subject to the approval of the Administrator, that takes into account the signal output, propeller condition and threshold velocity of the anemometer.

4.1.2.1 Check the signal output of the anemometer by using an accurate rpm generator (see fig. 14-3) or synchronous motors to spin the propeller shaft at each of the three rpm settings described in § 2.1.1 above (specification No. 7), and measuring the output signal at each setting. If, at each setting, the output signal is within ± 5 percent of its original value, the anemometer can continue to be used. If the anemometer performance is unsatisfactory, the anemometer shall either be replaced or repaired.

4.1.2.2 Check the propeller condition, by visually inspecting the propeller, making note of any significant damage or warpage; damaged or deformed propellers shall be replaced.

4.1.2.3 Check the anemometer threshold velocity as follows: With the anemometer mounted as shown in figure 14-4(A), fasten a known weight (a straight-pin will suffice) to the anemometer propeller, at a fixed distance from the center of the propeller shaft. This will generate a known torque; for example, a 0.1 g weight, placed 10 cm from the center of the shaft, will generate a torque of 1.0 g-cm. If the known torque causes the propeller to rotate downward, approximately 90° (see fig. 14-4(B)), then the known torque is greater than or equal to the starting torque; if the propeller fails to rotate approximately 90°, the known torque is less than the starting torque. By trying different combinations of weight and distance, the starting torque of a particular anemometer can be satisfactorily estimated. Once an estimate of the starting torque has been obtained, the threshold velocity of the anemometer (for horizontal mounting) can be estimated from a graph such as figure 14-5. If the horizontal threshold velocity is acceptable (< 16.7 m/min (55 fpm), when this technique is used), the anemometer can continue to be used. If the threshold velocity of an anemometer is found to be unacceptably high, the anemometer shall either be replaced or repaired.

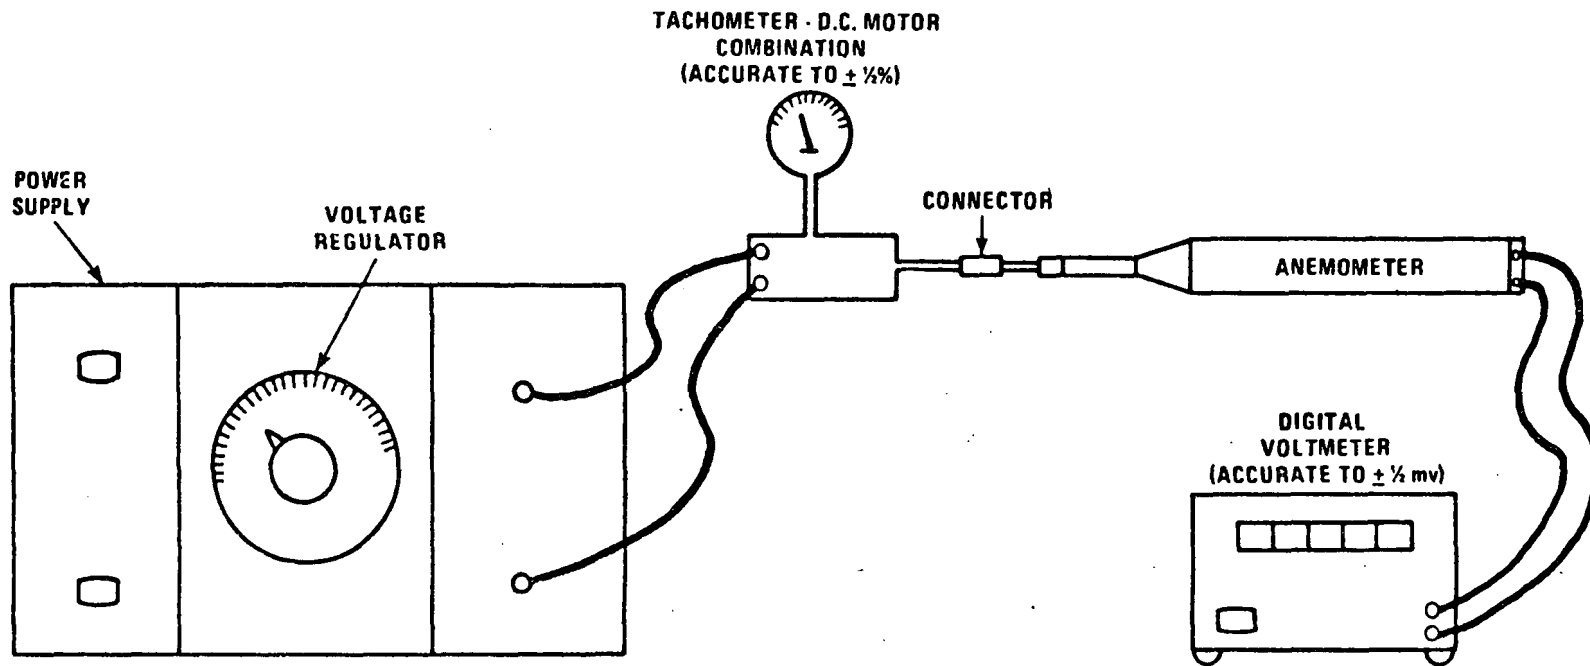

Figure 14-3. Typical RPM generator.

PROPOSED RULES

(A)

(B)

Figure 14-4. Check of anemometer starting torque. A "y" gram weight placed "x" centimeters from center of propeller shaft produces a torque of "xy" g-cm. The minimum torque which produces a 90° (approximately) rotation of the propeller is the "starting torque."

PROPOSED RULES

Figure 14-5. Typical curve of starting torque vs horizontal threshold velocity for propeller anemometers. Based on data obtained by R.M. Young Company, May, 1977.

PROPOSED RULES

4.1.2.4 If an anemometer fails the post-test performance-check (i.e., if repair or replacement of any anemometer components is necessary), proceed as follows: (1) Calibrate the anemometer (before repairing it), using one of the three methods described in section 4.1.1, above. Alternatively, the anemometer may be calibrated against another propeller anemometer that meets the specifications of section 2.1.1 (a detailed procedure is described in Citation 1 of section 7); (2) referring to the calibration curve obtained in step (1), recalculate (for each run) the average velocity (v) for the anemometer, using the data print-out obtained during the test series; (3) Compare each recalculated value of v against the reported value. If the recalculated value of v is less than the reported value, no adjustment in the reported overall average velocity for the run shall be made. If, however, the recalculated value of v exceeds the reported value, replace the reported value of v with the recalculated value, and then recompute the overall average velocity (and total flowrate).

NOTE.—If the anemometer located in the section of the roof monitor containing the sampling manifold fails the performance check, additional emission rate adjustments may be necessary (see section 6.1).

4.2 **Manifold Intake Nozzles.**—Adjust the exhaust fan to draw a volumetric flow rate (refer to equation 14-1) such that the entrance velocity into each manifold nozzle approximates the average effluent velocity in the roof monitor. Measure the velocity of the air entering each nozzle by inserting a standard pitot tube into a 2.5 cm or less diameter hole (see fig. 14-2) located in the manifold between each blast gate (or valve) and nozzle. Note that a standard pitot tube is used, rather than a type S, to eliminate possible velocity measurement errors due to cross-section blockage in the small (0.13 m diameter) manifold leg ducts. The pitot tube tip shall be positioned at the center of each manifold leg duct. Take care to insure that there is no leakage around the pitot tube, which could affect the indicated velocity in the manifold leg. If the velocity of air being drawn into each nozzle is not the same, open or close each blast gate (or valve) until the velocity in each nozzle is the same. Fasten each blast gate (or valve) so that it will remain in this position and close the pitot port holes. This calibration shall be performed when the manifold system is installed.

NOTE.—It is recommended that this calibration be repeated at least once a year.

4.3 **Thermocouple.**—After each test series, the thermocouple shall be calibrated, using the procedures outlined in section 4.3 of method 2.

4.4 **Recorders and/or Counters.**—After each test series, check the calibration of each recorder and/or counter that was used (see section 2.1.3). Check the recorder or counter calibration at a minimum of three points, approximately spanning the range of velocities observed during the test series. Use the calibration procedures recommended by the manufacturer, or other suitable procedures (subject to the approval of the Administrator). If a recorder or counter is

found to be out of calibration, by an average amount greater than 5 percent for the three calibration points, proceed as follows: (1) Based on the results of the post-test calibration check, recalculate (for each run) the average velocity (v) for the anemometer that was connected to the recorder during the test series. If a particular recalculated value of v is less than the reported value, no adjustment in the reported overall average velocity for the run shall be made. If, however, the recalculated value of v is greater than the reported value, replace the reported value of v with the recalculated value, and recompute the overall average velocity (and total flowrate).

NOTE.—If the malfunctioning recorder or counter was connected to the anemometer in the section of the roof monitor containing the sampling manifold, additional emission rate adjustments may be necessary (see § 6.1).

5. Procedure

5.1 Roof Monitor Velocity Determination.

5.1.1 **Velocity estimate(s) for setting isokinetic flow.**—To assist in setting the flow in the manifold sample nozzles to isokinetic, the anticipated average velocity in the section of the roof monitor containing the sampling manifold shall be estimated prior to each test run. The tester may use any convenient means to make this estimate (e.g., the velocity indicated by the anemometer in the section of the roof monitor containing the sampling manifold may be continuously monitored during the 24-hour period prior to the test run).

If there is question as to whether a single estimate of average velocity is adequate for an entire test run (e.g., if velocities are anticipated to be significantly different during different potroom operations), the tester may opt to divide the test run into two or more "sub-runs," and to use a different estimated average velocity for each sub-run (see § 5.3.2.2).

5.1.2 **Velocity determination during a test run.**—During the actual test run, record the velocity or volumetric flowrate readings of each propeller anemometer in the roof monitor. Readings shall be taken for each anemometer every 15 minutes or at shorter equal time intervals (or continuously).

5.2 **Temperature recording.** Record the temperature of the roof monitor every 2 hours during the test run.

5.3 **Sampling.** 5.3.1 **Preliminary air flow in duct.**—During the 24 hours preceding the test, turn on the exhaust fan and draw roof monitor air through the manifold duct to condition the ductwork. Adjust the fan to draw a volumetric flow through the duct such that the velocity of gas entering the manifold nozzles approximates the average velocity of the air exiting the roof monitor in the vicinity of the sampling manifold.

5.3.2 **Isokinetic sample rate adjustment(s).** 5.3.2.1 **Initial adjustment.**—Prior to the test run (or first sub-run, if applicable; see §§ 5.1.1 and 5.3.2.2), adjust the fan to provide the necessary volumetric flowrate in the sampling duct, so that air enters the manifold sample nozzles at a velocity equal to the appropriate estimated average velocity determined under § 5.1.1. Equation 14-1 gives the correct stream velocity needed in the duct at the sampling location, in order for sample gas to be drawn

isokinetically into the manifold nozzles. Next, verify that the correct average stream velocity has been achieved, by performing a pitot tube traverse of the sample duct (using either a standard or type S pitot tube); use the procedure outlined in method 2.

$$V_d = \frac{E (C_n)^2}{(C_d)^2} (V_m) \frac{1 \text{ m}^3/\text{min}}{60 \text{ sec}} \quad \text{Equation 14-1}$$

Where:

V_d = Desired velocity in duct at sampling location, meters/sec.

D_n = Diameter of a roof monitor manifold nozzle, meters.

D_d = Diameter of duct at sampling location, meters.

V_m = Average velocity of the air stream in the roof monitor, meters/minute, as determined under § 5.1.1.

5.3.2.2 **Adjustments during run.**—If the test run is divided into two or more "sub-runs" (see § 5.1.1), additional isokinetic rate adjustment(s) may become necessary during the run. Any such adjustment shall be made just before the start of a sub-run, using the procedure outlined in § 5.3.2.1 above.

NOTE.—Isokinetic rate adjustments are not permissible during a sub-run.

5.3.3 **Sample train operation.**—Sample the duct using the standard fluoride train and methods described in methods 13A and 13B. Determine the number and location of the sampling points in accordance with method 1. A single train shall be used for the entire sampling run. Alternatively, if two or more sub-runs are performed, a separate train may be used for each sub-run; note, however, that if this option is chosen, the area of the sampling nozzle shall be the same (± 2 percent) for each train. If the test run is divided into sub-runs, a complete traverse of the duct shall be performed during each sub-run.

5.3.4 **Time per run.**—Each test run shall last 8 hours or more; if more than one run is to be performed, all runs shall be of approximately the same (± 10 percent) length. If question exists as to the representativeness of an 8-hour test, a longer period may be selected. Conduct each run during a period when all normal operations are performed underneath the sampling manifold. During the test period, all pots in the potroom group shall be operated such that emissions are representative of normal operating conditions in the potroom group.

5.3.5 **Sample recovery.**—Use the sample recovery procedures described in method 13A or 13B.

5.4 **Analysis.**—Use the analysis procedures described in method 13A or 13B.

6. Calculations

6.1 **Isokinetic sampling check.** 6.1.1 Calculate the mean velocity (V_m) for the sampling run, as measured by the anemometer in the section of the roof monitor containing the sampling manifold. If two or more sub-runs have been performed, the tester may opt to calculate the mean velocity for each sub-run.

6.1.2 Using equation 14-1, calculate the expected average velocity (V_d) in the sam-

PROPOSED RULES

pling duct, corresponding to each value of V_m obtained under § 6.1.1.

6.1.3 Calculate the actual average velocity (v_a) in the sampling duct for each run or sub-run, according to equation 2-9 of method 2, and using data obtained from method 13.

6.1.4 Express each value of v_a from § 6.1.3 as a percentage of the corresponding V_m value from § 6.1.2.

6.1.4.1 If v_a is less than or equal to 120 percent of V_m , the results are acceptable (note that in cases where the above calculations have been performed for each sub-run, the results are acceptable if the average percentage for all sub-runs is less than or equal to 120 percent).

6.1.4.2 If v_a is more than 120 percent of V_m , multiply the reported emission rate by the following factor:

$$1 + \frac{\frac{100 - v_a}{V_m} - 100}{200}$$

6.2 Average velocity of roof monitor gases. Calculate the average roof monitor velocity using all the velocity or volumetric flow readings from § 5.1.2.

6.3 Roof monitor temperature. Calculate the mean value of the temperatures recorded in § 5.2.

6.4 Concentration of fluorides in roof monitor air (in mg F/m³). 6.4.1 If a single

sampling train was used throughout the run, calculate the average fluoride concentration for the roof monitor using equation 13A-5 of method 13A.

6.4.2 If two or more sampling trains were used (i.e., one per sub-run), calculate the average fluoride concentration for the run, as follows:

$$\bar{C}_s = \frac{\sum_{i=1}^n (F_i)}{\sum_{i=1}^n (V_{m(i)} \text{ dscm})} \quad \text{(Equation 13A-5)}$$

where:

C_s = Average fluoride concentration in roof monitor air, mg F/dscm.

$(F_i)_t$ = Total fluoride mass collected during a particular sub-run, mg F (from equation 13A-4 of method 13A or equation 13B-1 of method 13B).

$(V_{m(i)})_t$ = Total volume of sample gas passing through the dry gas meter during a particular sub-run, dscm (see equation 13A-1 of method 13A).

n = Total number of sub-runs.

6.5 Average volumetric flow from the roof monitor of the potroom(s) (or potroom segment(s)) containing the anemometers is given by equation 14-3.

$$Q_m = \frac{V_{mt} (A) (H_d) P_m (293^\circ K)}{(T_m + 273^\circ) (1.760 \text{ mm Hg})} \quad \text{(Equation 14-3)}$$

where:

Q_m = Average volumetric flow from roof monitor at standard conditions on a dry basis, m³/min.

A = Roof monitor open area, m².

V_m = Average velocity of air in the roof monitor, meters/minute, from § 6.2.

P_m = Pressure in the roof monitor; equal to barometric pressure for this application, mm Hg.

T_m = Roof monitor temperature, °C, from § 6.3.

M_d = Mole fraction of dry gas, which is given by:

$$M_d = \frac{100 - 100(B_w)}{100}$$

NOTE.— B_w is the proportion by volume of water vapor in the gas stream, from equation 13A-3, method 13A.

ENVIRONMENTAL PROTECTION AGENCY

STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

GLASS MANUFACTURING PLANTS

SUBPART CC

ENVIRONMENTAL PROTECTION AGENCY**[40 CFR Part 60]****[FRL 1203-7]****Standards of Performance for New Stationary Sources; Glass Manufacturing Plants****AGENCY:** Environmental Protection Agency (EPA).**ACTION:** Proposed rule and notice of public hearing.

SUMMARY: The proposed standards would limit emissions of particulate matter from new, modified, and reconstructed glass manufacturing plants. The standards implement the Clean Air Act and are based on the Administrator's determination that glass manufacturing plants contribute significantly to air pollution. The intended effect is to require new, modified, and reconstructed glass manufacturing plants to use the best demonstrated system of continuous emission reduction, considering costs, nonair quality health and environmental impact, and energy impacts.

A public hearing will be held to provide interested persons an opportunity for oral presentation of data, views, or arguments concerning the proposed standards.

DATES: *Comments.* Comments must be received on or before August 14, 1979.

Public Hearing. The public hearing will be held on July 9, 1979 beginning at 9:30 a.m. and ending at 4:30 p.m.

Request to Speak at Hearing. Persons wishing to present oral testimony at the hearing should contact EPA by June 29, 1979.

ADDRESSES: *Comments.* Comments should be submitted to Central Docket Section (A-130), United States Environmental Protection Agency, 401 M Street, S.W., Washington, D.C. 20460, Attention: Docket No. OAQPS 79-2.

Public Hearing. The public will be held at Office of Administration Auditorium, Research Triangle Park, North Carolina 27711. Persons wishing to present oral testimony should notify Mary Jane Clark, Emission Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone (919) 541-5271.

Standards Support Document. The support document for the proposed standards may be obtained from the U.S. EPA Library (MD-35), Research Triangle Park, North Carolina 27711, telephone number (919) 541-2777. Please refer to

"Glass Manufacturing Plants, Background Information: Proposed Standards of Performance," EPA-450/3-79-005a.

Docket. A docket, number OAQPS 79-2, containing information used by EPA in development of the proposed standard, is available for public inspection between 8:00 a.m. and 4:00 p.m. Monday through Friday, at EPA's Central Docket Section (A-130), Room 2903 B, Waterside Mall, 401 M Street, S.W., Washington, D.C. 20460.

FOR FURTHER INFORMATION CONTACT: Mr. Don R. Goodwin, Director, Emission Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone number (919) 541-5271.

SUPPLEMENTARY INFORMATION:**Proposed Standards**

The standards would apply to glass melting furnaces with glass manufacturing plants with two exceptions: day pot furnaces (which melt two tons or less of glass per day) and all-electric melting furnaces. No existing plants would be covered unless they were to undergo modification or reconstruction. Change of fuel from gas to fuel oil would be exempt from consideration as a modification and rebricking of furnaces would be exempt from consideration as reconstruction.

Specifically, the proposed standards would limit exhaust emissions from gas-fired glass melting furnaces to 0.15 grams of particulate matter per kilogram of glass produced for flat glass production; 0.1 g/kg (0.2 lb/ton) for container glass production; 0.2 g/kg (0.4 lb/ton) for wool fiberglass production; 0.1 g/kg (0.2 lb/ton) for pressed and blown glass production of soda-lime formulation; and 0.25 g/kg (0.5 lb/ton) for pressed and blown glass production of borosilicate, opal, and other formulations. A 15 percent allowance above the emission limits for gas-fired furnaces is proposed for fuel oil-fired glass melting furnaces and an additional proportionate allowance is proposed for furnaces simultaneously firing gas and fuel oil.

Summary of Environmental and Economic Impacts**Environmental Impacts**

The proposed standards would reduce projected 1983 emissions from new uncontrolled glass melting furnaces from about 5,200 megagrams (Mg)/year (5,732 ton/year) to about 400 Mg/year (441 ton/year). This is a reduction of about 92 percent of uncontrolled emissions.

Meeting a typical State Implementation Plan (SIP), however, would reduce emissions from new uncontrolled furnaces by about 3,700 Mg/year (4,079 ton/year), or by about 70 percent. The proposed standard would exceed the reduction achieved under a typical SIP by about 1,100 Mg/year (1,213 ton/year). This reduction in emissions would result in a reduction of ambient air concentrations of particulate matter in the vicinity of new glass manufacturing plants.

The proposed standards are based on the use of electrostatic precipitators (ESP's) and fabric filters, which are dry control techniques; therefore, no water discharge would be generated and there would be no adverse water pollution impact.

The solid waste impact of the proposed standards would be minimal. Less than 2 Mg (2.2 ton) of particulate would be collected for every 1,000 Mg (1,102 ton) of glass produced. These dusts can generally be recycled, or they can be landfilled if recycling proves to be unattractive. The current solid waste disposal practice among most controlled plants surveyed is landfilling. Since landfill operations are subject to State regulation, this disposal method would not be expected to have an adverse environmental impact. The additional solid material collected under the proposed standard would not differ chemically from the material collected under a typical SIP regulation; therefore, adverse impact from landfilling should be minimal. Also, recycling of the solids has no adverse environmental impact.

For typical plants in the glass manufacturing industry, the increased energy consumption that would result from the proposed standards ranges from about 0.1 to 2 percent of the energy consumed to produce glass. The energy required in excess of that required by a typical SIP regulation to control all new glass melting furnaces constructed by 1983 to the level of the proposed standards would be about 2,500 kilowatt-hours per day in the fifth year and is considered negligible. Thus, the proposed standards would have a minimal impact on national energy consumption.

Economic Impacts

The economic impact of the proposed standards is reasonable. Compliance with the standards would result in annualized costs in the glass manufacturing industry of about \$8.5 million by 1983. For typical plants constructed between 1978-1983 capital costs associated with the proposed

standards would range from about \$235,000 for a small furnace in the pressed and blown glass sector which melts formulations other than soda-lime to about \$770,000 for a large pressed and blown glass furnace which melts soda-lime formulations. Annualized costs associated with the proposed standards would range from about \$70,000/year to about \$235,000/year for the furnaces mentioned above. Cumulative capital costs of complying with the proposed standards for the glass manufacturing industry as a whole would amount to about \$28 million between 1978-1983. The percent price increase necessary to offset costs of compliance with the proposed standards would range from about 0.3 percent in the wool fiberglass sector to about 1.8 percent in the container glass sector. Industry-wide, the price increase would amount to about 0.7 percent.

The economic impact of the proposed standards may vary depending on the size of the glass melting furnace being considered. EPA is requesting comments specifically on the economic impact of the proposed standards with regard to a possible lower cut-off size for glass melting furnaces.

Rationale

Selection of Source and Pollutants

The proposed Priority List, 40 CFR 60.16, identifies various sources of emissions on a nationwide basis in terms of the quantities of emissions from source categories, the mobility and competitive nature of each source category, and the extent to which each pollutant endangers health or welfare. The sources on this proposed list are ranked in decreasing order. Glass manufacturing ranks 38th on the proposed list, and is therefore of considerable importance nationwide.

The production of glass is projected to increase at compounded annual growth rates of up to 7 percent through the year 1983. In 1975, over 17 million megagrams (18.8 million ton) of glass were produced; by 1983 this production rate is expected to increase by nearly 2.9 million Mg/year (3.2 million ton/year). Geographically, the glass manufacturing industry is relatively concentrated with plants currently located in 17 states. Total particulate emissions in the United States in 1975 were estimated to be about 12.4 million Mg/year (13.7 million ton/year); by the year 1983 new glass manufacturing plants would cause annual nationwide particulate matter emissions to increase by about 1,500 Mg/year (1.620 ton/year) with emissions

controlled to the level of a typical SIP regulation.

On March 18, 1977, the Governor of New Jersey petitioned EPA to establish standards of performance for glass manufacturing plants. The petition was primarily motivated by the Governor's concern that the glass manufacturing industry might locate plants in other States rather than comply with New Jersey's air pollution regulations limiting emissions of particulate matter. The glass manufacturing industry is not geographically tied to either markets or resources. Only a few States have specialized air pollution standards for glass manufacturing plants in their SIP's, and these standards vary in the level of control required. Therefore, new glass manufacturing operations could be located in States which do not have stringent SIP regulations.

Glass manufacturing plants are significant contributors to nationwide emissions of particulate matter, especially when viewed as contributors to emissions in the limited number of States in which they are located. They rank high with regard to potential reduction of emissions. Since they are free to relocate in terms of both markets and required resources, the possibility exists that operations could be moved or relocated to avoid stringent SIP regulations, thereby generating economic dislocations. For these reasons, emissions of particulate matter from new glass manufacturing plants have been selected for control by NSPS.

Glass manufacturing plants also emit other criteria pollutants: sulfur oxides (SO_x), nitrogen oxides (NO_x), carbon monoxide, and hydrocarbons. Carbon monoxide and hydrocarbon emissions from efficiently operated glass manufacturing plants, however, are negligible.

Nationwide, the largest aggregate emissions from glass manufacturing plants are NO_x . The techniques generally applicable to control NO_x produced by combustion are staged combustion, off-stoichiometric combustion, or reduced-temperature combustion. To date none of these techniques has been applied to the control of NO_x emissions from glass melting furnaces. Accordingly, there is no way of determining how effective they might be in such applications. Consequently, NO_x was not selected for control by standards of performance.

SO_x emissions result from combustion of sulfur-containing fuels and from chemical reactions of raw materials. In general there are two alternatives for control of SO_x emissions: (1) scrubbing of exhaust gases containing SO_x , and (2)

reducing the sulfur content of fuel and raw materials. SO_x emissions from glass melting furnaces are in most cases already less than the emission limits of applicable SIP's for fuel burning sources. Flue-gas scrubbing for control of SO_x emissions from glass melting furnaces is not considered economically reasonable.

There are difficulties as well with the use of low-sulfur fuels or reduction of sulfur content of raw materials. Using low-sulfur fuel would not adequately address the problem of SO_x control for two reasons. Natural gas is the preferred fuel for glass melting furnaces. The only alternative fuel currently in use or projected for future use by the glass manufacturing industry is distillate fuel oil, which normally contains more sulfur than natural gas. The elimination of sulfur-containing fuel oil is not considered reasonable. Alternatively, standards of performance based solely on combustion of low-sulfur fuels could distort existing fuel distribution patterns, since low-sulfur fuels could be diverted to new facilities to meet NSPS in areas that have no difficulty attaining or maintaining the National Ambient Air Quality Standards (NAAQS) for SO_x . This would reduce the supply of low-sulfur fuels for existing facilities in areas that have great difficulty attaining or maintaining the NAAQS for SO_x . Consequently, standards of performance for SO_x emissions based on use of low-sulfur fuels do not seem reasonable.

Use of reduced-sulfur raw materials has not been demonstrated as a means of reducing SO_x emissions from glass melting furnaces. There is a wide variety of formulations, most of which are considered by the industry to be trade secrets. The present state of glass making is such that formula alterations of the type envisioned here would lead to glass of unpredictable quality. For these reasons, standards of performance for SO_x emissions from glass melting furnaces based on reduced-sulfur raw materials, or any other approach, do not seem reasonable and have not been proposed.

Selection of Affected Facility

Ninety-eight percent of the particulate matter emitted from glass manufacturing plants is emitted in gaseous exhaust streams from glass melting furnaces. Only two percent of the particulate matter emitted from glass manufacturing plants is emitted from raw material handling and glass forming and finishing. Therefore, the glass melting furnace has been selected as the affected facility.

The proposed standards would apply to all glass melting furnaces within glass manufacturing plants with two exceptions: day pot furnaces and all-electric melters. A day pot furnace is a glass melting furnace which is capable of producing no more than two tons of glass per day. These small glass melting furnaces constitute an extremely small percentage of total glass production and their control is not considered economically reasonable. Therefore, the regulation exempts day pot furnaces from the proposed standards.

Well operated and maintained all-electric furnaces have particulate emissions only slightly higher than fossil-fuel fired furnaces controlled to meet the proposed standards. Most of these furnaces are open to the atmosphere and do not have stacks. Thus, control and measurement of emissions from all-electric furnaces does not appear to be economically reasonable. Therefore, all-electric melting furnaces are not regulated by the proposed standards.

Selection of Format

Two alternative formats were considered for the proposed standards: mass standards, which limit emissions per unit of feed to the glass furnace or per unit of glass produced by the glass furnace; and concentration standards, which limit emissions per unit volume of exhaust gases discharged to the atmosphere.

Enforcement of concentration standards requires a minimum of data and information, decreasing the costs of enforcement and reducing chances of error. Furthermore, vendors of emission control equipment usually guarantee equipment performance in terms of the pollutant concentration in the discharge gas stream.

There is a potential for circumventing concentration standards by diluting the exhaust gases discharged to the atmosphere with excess air, thus lowering the concentration of pollutants emitted but not the total mass emitted. This problem can be overcome, however, by correcting the concentration measured in the gas stream to a reference condition such as a specified oxygen percentage in the gas stream.

Concentration standards would penalize energy-efficient furnaces, since a decrease in the amount of fuel required to melt glass decreases the volume of gases released but not the quantity of particulate matter emitted. As a result, the concentration of particulate matter in the exhaust gas stream would be increased even though

the total mass emitted remained the same. Even if a concentration standard were corrected to a specified oxygen content in the gas stream, this penalizing effect of the concentration would not be overcome.

Primary disadvantages of mass standards, as compared to concentration standards, are that their enforcement is more costly and that the more numerous calculations required increase the opportunities for error. Determining mass emissions requires the development of a material balance on process data concerning the operation of the plant, whether it be input flow rates or production flow rates. Development of this balance depends on the availability and reliability of production figures supplied by the plant. Gathering of these data increases the testing or monitoring necessary, the time involved, and, consequently, the costs. Manipulation of these data increases the number of calculations necessary; e.g., the conversion of volumetric flow rates to mass flow rates, thus compounding error inherent in the data and increasing the chance for error.

Although concentration standards involve lower resource requirements than mass standards, mass standards are more suitable for regulation of particulate emissions from glass melting furnaces because of their flexibility to accommodate process improvements and their direct relationship to quantity of particulate emitted to the atmosphere. These advantages outweigh the drawbacks associated with creating and manipulating a data base. Consequently, mass standards are selected as the format for expressing standards of performance for glass melting furnaces.

The proposed standards express allowable particulate emissions in grams of particulates per kilogram of glass pulled. While emissions data referring to raw material input as well as data referring to glass pulled were used in the development of the standards, an examination of the several sectors of the glass manufacturing industry indicated that an emission rate based on quantity of glass pulled would be more representative of industry practice. Further, emissions are more dependent on pull rate than on rate of raw material input. Accordingly, the mass of glass pulled is used as the denominator in the proposed standards. Raw material input data could be employed to estimate glass pulled from a furnace if a quantitative relationship between raw material input and glass pulled were developed following good engineering methods.

Selection of the Best System of Emission Reduction and Emission Limits

Introduction

Particulate emissions from glass melting furnaces can be reduced significantly by the use of the following emission control techniques: electrostatic precipitators, fabric filters, and venturi scrubbers. Since these emission control techniques do not achieve the same level of control for glass melting furnace emissions within all sectors of the glass manufacturing industry, they are discussed separately for each sector.

Process modifications such as batch formulation alteration and electric boosting also may be capable of reducing particulate emissions from glass melting furnaces. The test data available for furnaces where process modifications are used as emissions reduction techniques indicate that emission reduction by process modification is indefinite with respect to the effectiveness of the techniques. Accordingly, the selection of the best system of emission reduction is based on the use of add-on emission reduction techniques of known effectiveness. However, there is nothing in this proposal nor is it the intent of this proposal to preclude the use of process modifications to comply with the proposed standards.

The glass manufacturing industry is divided into four principal sectors designated by Standard Industrial Classifications (SIC's). The container glass sector (SIC 3221) manufactures containers for commercial packing and bottling and for home canning by pressing (stamping) and/or blowing (air-forming) molten glass usually of soda-lime recipe. The pressed and blown glass, not elsewhere classified, sector (SIC 3229) includes such diverse products as: table, kitchen, art and novelty glassware; lighting and electronic glassware; scientific, technical, and other glassware; and textile glass fibers. Based on the differing rates of particulate matter emissions, it is necessary to subdivide the pressed and blown glass sector into plants producing glass from soda-lime formulations and plants producing glass from other formulation (primarily borosilicate, opal and lead). Glass manufacturing plants in the wool fiberglass sector are classified under mineral wool (SIC 3296); fiberglass insulation is a major product. The flat glass sector (SIC 3211) uses continuous glass forming processes, and materials almost exclusively of soda lime

formulation, to manufacture sheet, plate, float, rolled, and wire glass.

Each of the glass manufacturing sectors is unique both from a technical and an economic standpoint. Thus, uncontrolled particulate emission rate, furnace size, and the applicability of emission control techniques vary from one sector to another. Since the products manufactured by the different sectors of the glass manufacturing industry serve different markets, each sector is working in a different economic environment. For these reasons it was apparent that no single model furnace could adequately characterize the glass manufacturing industry. Accordingly, several model furnaces were specified in terms of the following parameters: production rate, stack height, stack diameter, exhaust gas exit velocity, exhaust gas flow rate, and exhaust gas temperature. The evaluation of these parameters may be found in the Background Information document. The model furnace production rate specified for the container glass sector was 225 Mg/day (250 ton/day). For pressed and blown glass furnaces melting soda-lime and other formulations two model furnace production rates were specified: 45 Mg/day (50 ton/day) and 90 Mg/day (100 ton/day). Model furnace production rates for the wool fiberglass and flat glass sector were 180 Mg/day (200 ton/day) and 635 Mg/day (700 ton/day), respectively.

Review of the performance of the emission control techniques led to the identification of two regulatory options for each sector. These options specify numerical emission limits for glass melting furnaces in each sector of the glass manufacturing industry. The environmental impacts, energy impacts, and cost and economic impacts of each regulatory option were compared with those associated with a typical SIP regulation and those associated with no control.

Container Glass

Uncontrolled particulate emissions from container glass furnaces are generally about 1.25 g/kg (2.5 lb/ton) of glass pulled. Emission tests (using EPA Method 5) on three container glass furnaces equipped with ESP's indicate an average particulate emission of 0.06 g/kg (0.12 lb/ton) of glass pulled.

Emission test data for container glass furnaces equipped with fabric filters are not available. However, emission test results for a pressed and blown glass furnace melting a soda-lime formulation essentially identical to that used for container glass indicate that emissions can be reduced to 0.12 g/kg (0.24 lb/ton)

of glass pulled with a fabric filter. This fabric filter installation was tested with the Los Angeles Air Pollution Control District particulate matter test method (LAAPCD Method), which considers the combined weight of the particulate matter collected in water-filled impingers and of that collected on a filter. EPA Method 5 also uses impingers and a filter, but considers only the weight of the particulate matter collected on the filter. The LAAPCD Method collects a larger amount of particulate matter than does EPA Method 5, and, consequently, greater mass emissions would be reported for comparable tests. An emission level of 0.1 g/kg (0.2 lb/ton) as determined by EPA Method 5, could be achieved by a container glass furnace equipped with a properly designed and operated fabric filter.

EPA Method 5 tests of four furnaces equipped with venturi scrubbers indicated an average particulate emission of 0.21 g/kg (0.42 lb/ton) of glass pulled.

Based on the data cited above, an emission level of 0.1 g/kg (0.2 lb/ton) of glass pulled from container glass furnaces can be achieved with ESP's or fabric filters. An emission level of 0.2 g/kg (0.4 lb/ton) of glass pulled can reasonably be achieved with a venturi scrubber when operated at a pressure drop somewhat higher than the average of those scrubbers tested. ESP's and fabric filters could also be designed to achieve an emission level of 0.2 g/kg (0.4 lb/ton) of glass pulled.

On the basis of these conclusions, two regulatory options for reducing particulate emissions from container glass furnaces were formulated. Option I would set an emission limit of 0.1 g/kg (0.2 lb/ton), requiring a particulate emission reduction of somewhat over 90 percent as compared with an uncontrolled furnace. Option II would set an emission limit of 0.2 g/kg (0.4 lb/ton), requiring a particulate emission reduction of about 85 percent.

By 1983 approximately 1900 gigagrams (Gg)/year (2.1 million ton/year) of additional production is anticipated in the container glass sector. About 25 new container glass furnaces of about 225 Mg/day (250 ton/day) production capacity (the size of the model furnace) would be built in order to provide this additional production. If uncontrolled, these new container glass furnaces would add about 2,400 Mg/year (2,646 ton/year) to national particulate emissions by 1983. Compliance with a typical SIP regulation would reduce this impact to about 1,000 Mg/year (1,102 ton/year). Under Option I, emissions

would be reduced to about 19 percent of those emitted under a typical SIP regulation. Under Option II, emissions would be reduced to about 38 percent of those emitted under a typical SIP regulation.

Ambient dispersion modeling indicates that under worst case conditions the annual maximum ground-level particulate concentration near an uncontrolled container glass furnace producing 225 Mg/day of glass would be less than 1 $\mu\text{g}/\text{m}^3$. The annual maximum ground-level concentration resulting from compliance with a typical SIP regulation, Option I, or Option II would also be less than 1 $\mu\text{g}/\text{m}^3$. The calculated maximum 24-hour ground-level particulate concentration near an uncontrolled container glass furnace producing 225 Mg/day of glass would be approximately 10 $\mu\text{g}/\text{m}^3$. The corresponding concentration for complying with a typical SIP regulation would be 5 $\mu\text{g}/\text{m}^3$. Under Option I, with an ESP or a fabric filter being employed for control, the maximum 24-hour ground-level concentration would be reduced to 1 $\mu\text{g}/\text{m}^3$. Under Option II, with the same techniques being employed, the concentration would be reduced to 2 $\mu\text{g}/\text{m}^3$. Use of a venturi scrubber to meet the Option II emissions limit would only reduce the concentration to 6 $\mu\text{g}/\text{m}^3$ due to the decreased stack height of a scrubber-controlled plant and the resulting increased building wake effects.

With one exception, standards of performance for container glass furnaces would have no water pollution impact. The exception would be the use of a venturi scrubber to comply with a standard based on Option II. Such a system, applied to a furnace producing 225 Mg/day of glass, would discharge about 0.5 m³/hr of waste water containing about 5 percent solids. The waste water would probably be discharged directly to an available waste water treatment system. To date, however, only a few container glass furnaces have been controlled with venturi scrubbers; dry collection techniques have been preferred. Consequently, few container glass manufacturers would be expected to install venturi scrubbers on their furnaces to comply with a standard based on Option II. The overall water pollution impact would then be negligible.

The potential solid waste impacts of the regulatory options would result from collected particulate matter. Solid waste from container glass furnaces, other than collected particulate matter, is minimal since cullet is normally

recycled back into the glass melting process. Under a typical SIP regulation, about 1,400 Mg/year (1,543 ton/year) of particulate matter would be collected from the 25 new 225 Mg/day container glass furnaces projected to come on-stream during the 1978-1983 period. Compliance with standards based on Option I and Option II would add about 800 Mg/year (882 ton/year) and about 600 Mg/year (661 ton/year), respectively, to the solid waste collected under a typical SIP regulation. Option I would increase the mass of solids for disposal by about 60 percent over that resulting from compliance with a typical SIP regulation, and Option II would increase it by about 45 percent. The additional solid material collected under Option I or Option II would not differ chemically from the material collected under a typical SIP regulation. Collected solids either are recycled back into the glass melting process or are disposed of in a landfill. Recycling of the solids has no adverse environmental impact, and, since landfill operations are subject to State regulation, this disposal method also would not be expected to have an adverse environmental impact.

The potential energy impacts of the regulatory options would be due to the energy used to drive the fans in emission control systems and the energy used to charge the electrodes in ESP's. Since ESP's have been the predominant control system used in the industry, the energy requirements estimated for a typical SIP regulation, Option I, and Option II were based on the use of ESP's. The energy required to control particulate emissions from the 25 new container glass furnaces would be about 40 million kWh (22 thousand barrels of oil/year) for a typical SIP regulation for the new furnaces equipped with ESP's. This required energy would be about 0.2 percent of the total energy use in the container glass sector. There would be no energy impact associated with either Option I or Option II because the energy required to operate an ESP for Option I or Option II is essentially the same as the energy required to operate an ESP for a typical SIP regulation.

Incremental installed cost (cost in excess of a typical SIP regulation cost) in January 1978 dollars associated with Option I for controlling particulate emissions from a 225 Mg/day container

glass furnace would be about \$700 thousand for an ESP and about \$1.2 million for a fabric filter. Incremental installed cost associated with Option II would be about \$450 thousand for an ESP, and about \$1 million for a fabric filter. The incremental installed cost of control equipment associated with Option I level of control would be about 1.6 times the incremental installed cost associated with Option II if ESP's were selected. If fabric filters were selected, the incremental installed cost associated with the Option I level of control would be about 1.2 times the incremental installed cost associated with Option II.

Incremental annualized costs associated with Option I for a 225 Mg/day furnace would be about \$200 thousand/year and about \$350 thousand/year for an ESP and a fabric filter, respectively. Incremental annualized costs associated with Option II would be about \$130 thousand/year for an ESP, and about \$300 thousand/year for a fabric filter. The incremental annualized cost associated with Option I would be about 1.5 times the incremental annualized cost associated with Option II if ESP's were used. If fabric filters were used the incremental annualized cost associated with Option I would be about 1.2 times the incremental annualized cost associated with Option II.

Based on the use of control equipment with the highest annualized cost (worst case conditions), a price increase of about 1.8 percent would be necessary to offset the cost of installing control equipment on a 225 Mg/day container glass furnace to meet the emissions limit of Option I. A price increase of about 1.5 percent would be necessary to comply with the emission limit of Option II.

Incremental cumulative capital costs for the 25 new 225 Mg/day container glass furnaces during the 1978-1983 period associated with Option I would be about \$17 million if ESP's were used. Use of ESP's to comply with a standard based on Option II would require incremental cumulative capital costs of about \$11 million for the same period. Fifth-year annualized costs for controlling container glass melting furnaces to comply with Option I would be about \$5 million/year. To comply with Option II, fifth-year annualized costs would be about \$3 million/year.

A summary of incremental impacts (in

excess of impacts of a typical SIP regulation) associated with Option I and Option II is shown in Table 1. Air impacts, expressed in Mg/year of particulate matter emissions reduced, would approximate the quantity of particulate matter collected and disposed of as solid waste.

Table 1.—Summary of Incremental Impacts Associated With Regulatory Options

	Impacts			
	Air ¹	Water	Energy ²	Economic ³
Regulatory option:				
I.....	800	None.....	Negligible	~1.8
II.....	600	Negligible	Negligible	~1.5

¹ Mg/Yr. reduced.

² Barrels of oil/day.

³ Percent price increase.

Consideration of the beneficial impact on national particulate emissions, the degree of water pollution impact, the small potential for adverse solid waste impact, the lack of energy impact, the reasonableness of cost impact, and the general availability of demonstrated emission control technology leads to the selection of Option I as the basis for standards for glass melting furnaces in the container glass sector.

Pressed and Blown Glass—Soda-Lime Formulation

Because the glass production rates, the furnace configurations, and the glass formulations melted in furnaces in this sector are very similar to those in container glass sector, the quantity and chemical composition of particulate emissions approximate those of container glass furnaces. On the basis of this similarity of process and emissions, the emission reduction techniques which have been shown to be effective for container glass furnaces would also be effective in reducing particulate emissions from furnaces in this sector.

Uncontrolled particulate emissions from pressed and blown glass furnaces melting soda-lime formulations are generally about 1.25 g/kg (2.5 lb/ton) of glass pulled from the furnace. Test data for a pressed and blown glass furnace melting a soda-lime formulation and equipped with a fabric filter indicate particulate emissions of 0.12 g/kg (0.24 lb/ton) of glass pulled using the

LAAPCD Method. No emissions data for pressed and blown glass furnaces equipped with ESP's are available. However, emission tests using EPA Method 5 on three container-glass furnaces equipped with ESP's indicate an average particulate emission rate of 0.06 g/kg (0.12 lb/ton) of glass pulled. Because of the similarities between this sector and the container glass sector, both ESP's and fabric filters would be expected to be capable of reducing emissions to about 0.1 g/kg (0.2 lb/ton) of glass pulled.

Based on the similarity of pressed and blown glass production methods in this sector to those of the container glass sector, as well as on test data available on container glass furnace emissions, two regulatory options were formulated. The regulatory options are identical to those formulated for container glass furnaces. Option I would set an emission limit of 0.1 g/kg (0.2 lb/ton) of glass pulled, which would require a particulate emission reduction of about 90 percent. Option II would set an emission limit of 0.2 g/kg (0.4 lb/ton) of glass pulled, which would require about 85 percent particulate emission reduction.

By 1983 approximately 310 Mg/year (342 ton/year) of additional production is anticipated in this glass manufacturing sector. About four new 45 Mg/day (50 ton/day) (small) and six new 90 Mg/day (100 ton/day) (large) furnaces would be built in order to provide this production. Emissions from the large furnaces would have to be reduced in order to comply with a typical SIP regulation, while small furnaces would meet a typical SIP regulation without reducing emissions. If uncontrolled, the four new small furnaces would add about 80 Mg/year (88 ton/year) to national particulate emissions by 1983, while the six new large furnaces would add about 230 Mg/year (254 ton/year). Compliance with a typical SIP regulation would reduce the impact of the new large furnaces to about 70 Mg/year (77 ton/year). Under Option I, these furnace emissions would be reduced to about 26 percent of those emitted under a typical SIP regulation. Under Option II, large furnace emissions would be reduced to about 53 percent of those emitted under a typical SIP regulation.

The small furnaces would be in compliance with a typical SIP regulation without control. Under Option I, emissions would be reduced to about 8 percent of uncontrolled emissions. Under Option II, emissions would be reduced to about 16 percent of uncontrolled emissions.

The effect of a typical SIP regulation for both 90 Mg/day (100 ton/day) and 45 Mg/day (50 ton/day) furnaces would be a reduction of about 48 percent of uncontrolled emissions. Under Option I, emissions would be reduced to about 16 percent of those emitted under a typical SIP regulation. Under Option II, emissions would be reduced to about 33 percent of those emitted under a typical SIP regulation.

Ambient dispersion modeling indicates that under worst case conditions the annual maximum ground-level particulate concentration near an uncontrolled pressed and blown glass furnace producing 45 Mg/day of glass would be less than $1 \mu\text{g}/\text{m}^3$, as would the concentrations resulting from compliance with Option I or Option II. Corresponding annual maximum ground-level concentrations near an uncontrolled pressed and blown glass furnace producing 90 Mg/day of glass would also be less than $1 \mu\text{g}/\text{m}^3$. Emissions from uncontrolled furnaces of either size in this sector would result in calculated maximum 24-hour ground-level concentrations of $3 \mu\text{g}/\text{m}^3$. Under Option I this concentration would be reduced to below $1 \mu\text{g}/\text{m}^3$. Under Option II it would be reduced to about $1 \mu\text{g}/\text{m}^3$.

Since fabric filters and electrostatic precipitators are likely to be the control systems installed on furnaces in this sector to comply with standards, there would be no water pollution impact associated with standards based on either Option I or Option II.

Under a typical SIP regulation, no particulate matter would be collected from the four new 45 Mg/day pressed and blown glass furnaces projected to come on-stream during the 1978-1983 period. The six new 90 Mg/day furnaces would collect about 160 Mg/year (176 ton/year) under a typical SIP regulation. For the six 90 Mg/day furnaces the amounts collected in addition to those collected through compliance with a typical SIP regulation would be about 50 Mg/year (55 ton/year) for Option I and about 33 Mg/year (36 ton/year) for Option II. Compliance with standards based on Option I and Option II would result in the collection of about 72 Mg/year (79 ton/year) and about 68 Mg/year (75 ton/year), respectively, of solid waste from the four 45 Mg/day furnaces. Option I would increase the mass of solids for disposal by 100 percent and by about 31 percent over that required by a typical SIP regulation for 45 Mg/day and 90 Mg/day furnaces, respectively. Option II would increase the mass of solids for disposal by 100 percent and 21 percent over that required by a typical SIP regulation for 45 Mg/day and 90 Mg/day

day furnaces, respectively. The total masses of solids for disposal collected from all new furnaces would be about 122 Mg/year (135 ton/year) and 101 Mg/year (111 ton/year) for Option I and Option II, respectively.

The additional solid material collected under Option I and Option II would not differ chemically from the material collected under a typical SIP regulation. Collected solids either are recycled back into the glass melting process or are disposed of in a landfill. Recycling of the solids has no adverse environmental impact, and, since landfill operations are subject to State regulation, this disposal method also would not be expected to have an adverse environmental impact.

Since the four new 45 Mg/day furnaces would be in compliance with a typical SIP regulation without add-on controls, there would be no associated energy requirement. The estimated energy required to control particulates emissions from the four new 45 Mg/day furnaces projected to come on-stream in the 1978-1983 period to the levels required by both Option I and Option II would be about 1.5 million kWh (900 barrels of oil/year). The energy required to control particulate emissions from the six new 90 Mg/day furnaces would be 4.4 million kWh (2,500 barrels of oil/year) for a typical SIP regulation. Option I, or Option II if ESP's were installed.

The energy required to comply with the emission limits of the regulatory options would be about 0.5 percent of the total energy use in this glass manufacturing sector. The energy impacts of both Option I and Option II are negligible (~ 3 barrels of oil/day) for the new 45 Mg/day furnaces. There would be no energy impact associated with either Option I or Option II for the new 90 Mg/day furnaces beyond the impact associated with the requirements to meet a typical SIP regulation.

Incremental installed costs in January 1978 dollars associated with Option I for controlling particulate emissions from a 45 Mg/day pressed and blown glass furnace melting soda-lime formulations would be about \$740 thousand for an ESP and about \$710 thousand for a fabric filter. Incremental installed costs associated with Option II would be about \$645 thousand for an ESP, and about \$675 thousand for a fabric filter. The incremental installed costs of control equipment associated with the Option I level of control would be about 1.1 times the incremental installed costs associated with Option II if ESP's were selected. If fabric filters were selected the incremental installed costs associated with the Option I level of

control would be about 1.1 times the incremental installed costs associated with Option II.

Incremental annualized costs for a 45 Mg/day furnace associated with Option I would be about \$230 thousand/year for both ESP's and fabric filters. Incremental annualized costs associated with Option II would be about \$205 thousand/year for an ESP, and about \$215 thousand/year for a fabric filter. The incremental annualized costs associated with Option I would be about 1.1 times the incremental annualized costs associated with Option II if ESP's were used. If fabric filters were used, the incremental annualized costs associated with Option I would be about 1.1 times the incremental annualized costs associated with Option II.

Based on the use of control equipment with the highest annualized costs (worse case conditions), a price increase of about 0.6 percent would be necessary to offset the costs of installing control equipment on a 45 Mg/day pressed and blown glass furnace melting soda-lime formulations to meet the emission limits of Option I. A price increase of about 0.5 percent would be necessary to comply with the emission limits of Option II.

Incremental cumulative capital costs for the 1978-1983 period associated with Option I for the four new 45 Mg/day furnaces would be about \$2.8 million if a fabric filter were used. Use of an ESP to comply with Option II would require incremental cumulative capital costs of about \$2.6 million for the same period. Fifth-year annualized costs for controlling the furnace to comply with Option I would be about \$910 thousand. To comply with Option II, fifth-year annualized costs would be about \$815 thousand.

Incremental installed costs in January 1978 dollars associated with Option I for controlling particulate emissions from a 90 Mg/day pressed and blown glass furnace melting soda-lime formulations would be about \$615 thousand for an ESP and about \$770 thousand for a fabric filter. Incremental installed costs associated with Option II would be about \$450 thousand for an ESP, and about \$680 thousand for a fabric filter. The incremental installed costs of control equipment associated with the Option I level of control would be about 1.4 times the incremental installed costs associated with Option II, if ESP's were selected. If fabric filters were selected, the incremental installed costs associated with the Option I level of control would be about 1.1 times the incremental installed costs associated with Option II.

Incremental annualized costs for a 90 Mg/day furnace associated with Option I would be about \$175 thousand/year and about \$235 thousand/year for an ESP and a fabric filter, respectively. Incremental annualized costs associated with Option II would be about \$130 thousand/year for an ESP, and about \$205 thousand/year for a fabric filter. The incremental annualized costs associated with Option I would be about 1.3 times the incremental annualized costs associated with Option II if ESP's were used. If fabric filters were used the incremental annualized costs associated with Option I would be about 1.1 times the incremental annualized costs associated with Option II.

Based on the use of control equipment with the highest annualized cost, a price increase of about 0.6 percent would be necessary to offset the costs of installing control equipment on the large pressed and blown glass furnace melting soda-lime formulations to meet the emission limits of Option I. A price increase of about 0.5 percent would be necessary to comply with the emission limits of Option II.

Incremental cumulative capital costs for the 1978-1983 period associated with Option I for the six new 90 Mg/day furnaces would be about \$3.7 million if ESP's were used. Use of ESP's to comply with Option II would require incremental cumulative capital costs of about \$2.7 million for the same period. Fifth-year annualized costs for controlling these glass melting furnaces to comply with Option I would be about \$1.1 million. To comply with Option II, fifth-year annualized costs would be about \$790 thousand.

A summary of incremental impacts (in excess of impacts of the typical SIP regulation) associated with Option I and Option II is shown in Table II for both small and large furnaces. Air impacts, expressed in Mg/year of particulate matter emissions reduced, would approximate the quantity of particulate matter collected and disposed of as solid waste.

Table II.—Summary of Incremental Impacts Associated With Regulatory Options

	Impacts			
	Air ¹	Water	Energy ²	Economic ³
I.....	122	None	~3.0	~0.6
II.....	101	None	~3.0	~0.5

¹ Mg/Yr. reduced.

² Barrels of oil/day.

³ Percent price increase.

Consideration of the beneficial impact on national particulate emissions, the lack of water pollution impact, the small potential for adverse solid waste impact, the reasonableness of energy and costs impacts, and the general availability of demonstrated emission control technology leads to the selection of Option I as the basis for standards for pressed and blown glass furnaces melting soda-lime formulations.

Pressed and Blown Glass—Other Than Soda-Lime Formulations

Uncontrolled particulate emissions from furnaces in this sector are about 5 g/kg (10 lb/ton) of glass pulled. Emission tests using EPA Method 5 on four furnaces melting borosilicate formulations and equipped with ESP's yielded a representative emission rate of about 0.50 g/kg (1.0 lb/ton) of glass pulled. A single emission test using EPA Method 5 on an ESP-controlled furnace melting fluoride/opal formulations yielded an emission rate of 0.17 g/kg (0.34 lb/ton) of glass pulled. EPA Method 5 tests of six ESP-controlled furnaces melting lead glass yielded a representative emission rate of 0.12 g/kg (0.24 lb/ton) of glass pulled. A single EPA method 5 emission test of an ESP-controlled furnace melting potash-soda-lead glass yielded an emission rate of 0.03 g/kg (0.06 lb/ton) of glass pulled. An EPA method 5 emission test on a furnace equipped with a fabric filter and melting soda-lead-borosilicate glass produced an emission rate of 0.17 g/kg (0.34 lb/ton) of glass pulled.

Upon consideration of the data cited above, an emission limit of 0.25 g/kg (0.5 lb/ton) of glass pulled was identified as a reasonable limit for control for pressed and blown glass furnaces melting other than soda-lime formulations. This limit was selected for Option I; it provides for about 95 percent particulate removal. Option II would set an emission limit of 0.5 g/kg (1.0 lb/ton) of glass pulled, which provides for a particulate removal of about 90 percent. Fabric filters and ESP's could be designed to achieve the levels of emission reduction required by either regulatory option.

By 1983 approximately 70 Gg/year (77,200 ton/year) of additional production is anticipated in this sector. One 45 Mg/day (50 ton/day) (small) furnace and two 90 Mg/day (100 ton/day) (large) furnaces would be built in order to provide this production. If uncontrolled, emissions from the one new small pressed and blown glass furnace melting formulations other than soda-lime would add about 90 Mg/year (100 ton/year) to national particulate

emissions by 1983, while the emissions from the two new large furnaces would add about 260 Mg/year (287 ton/year) during the same period.

Compliance with a typical SIP regulation would reduce the impact from the small furnace to about 27 Mg/year (30 ton/year). Control to the Option I emissions limit would reduce the emissions to about 17 percent of those emitted under a typical SIP regulation. With Option II emissions would be reduced to about 33 percent of those emitted under a typical SIP regulation.

Compliance with a typical SIP regulation would reduce the impact of the large furnaces to about 47 Mg/year (52 ton/year). Under Option I, these emissions would be reduced to about 28 percent of those emitted under a typical SIP regulation. Under Option II, the large furnace emissions would be reduced to about 56 percent of those emitted under a typical SIP regulation.

The effect of a typical SIP regulation for both large and small furnaces would be a reduction of about 79 percent. Under Option I, emissions would be reduced to about 25 percent of those emitted under a typical SIP regulation. Under Option II, emissions would be reduced to about 50 percent of those emitted under a typical SIP regulation.

Ambient dispersion modeling indicates that under worst case conditions the annual maximum ground-level particulate concentration near an uncontrolled 45 Mg/day pressed and blown glass furnace melting formulations other than soda-lime would be less than $1 \mu\text{g}/\text{m}^3$, as would be the concentrations resulting from compliance with a typical SIP regulation, Option I, or Option II. Corresponding annual maximum ground-level concentrations near a 90 Mg/day furnace also would be less than $1 \mu\text{g}/\text{m}^3$.

The calculated maximum 24-hour ground-level concentration near an uncontrolled 45 Mg/day furnace in this sector would be $11 \mu\text{g}/\text{m}^3$. This concentration would be reduced to $3 \mu\text{g}/\text{m}^3$ with a typical SIP regulation. With Options I and II, the concentrations would be reduced to $1 \mu\text{g}/\text{m}^3$ or less. The calculated maximum 24-hour ground-level concentration near an uncontrolled 90 Mg/day furnace would be $14 \mu\text{g}/\text{m}^3$. This concentration would be reduced to $3 \mu\text{g}/\text{m}^3$ with a typical SIP regulation and to below $1 \mu\text{g}/\text{m}^3$ with Option I; with Option II it would reach $2 \mu\text{g}/\text{m}^3$.

Since fabric filters and ESP's are likely to be the control systems installed on furnaces in this sector to comply with standards, there would be no water

pollution impact associated with standards based on either Option I or Option II.

Under a typical SIP regulation, about 64 Mg/year (71 ton/year) of particulate matter would be collected from the one new 45 Mg/day furnace projected to come on-stream in the 1978-1983 period. Compliance with standards based on Option I and Option II would add about 23 Mg/year (25 ton/year) and 18 Mg/year (20 ton/year), respectively, to the solid waste collected under a typical SIP regulation. Option I would increase the mass of solids by about 36 percent over that resulting from compliance with a typical SIP regulation, and Option II would increase it by about 28 percent.

Under a typical SIP regulation, about 210 Mg/year (232 ton/year) of particulate matter would be collected from the two new 90 Mg/day furnaces projected to come on-stream in the 1978-1983 period. Compliance with standards based on Option I and Option II would add about 34 Mg/year (38 ton/year) and 21 Mg/year (23 ton/year), respectively, to the solid waste collected under a typical SIP regulation. Option I would increase the mass of solids by about 16 percent over that resulting from compliance with a typical SIP regulation, and Option II would increase it by about 10 percent. The total mass of solids for disposal collected from all three new furnaces in this sector, associated with Option I and Option II, would be about 57 Mg/year (63 ton/year) and about 39 Mg/year (43 ton/year), respectively.

The additional solid material collected under Option I or Option II would not differ chemically from the material collected under the typical SIP regulation. Collected solids either are recycled back into the glass melting process or are disposed of in a landfill. Recycling of the solids has no adverse environmental impact, and, since landfill operations are subject to State regulation, this disposal method also is not expected to have an adverse environmental impact.

Since ESP's have been the predominant control system used in the industry and are anticipated as the predominant system to be used for new plants coming on-stream between 1978-1983 regardless of which regulatory option is selected, energy requirements estimated for the typical SIP regulation, Option I, and Option II are based on the use of ESP's.

The energy required to control particulate emissions from the new 45 Mg/day pressed and blown glass furnace melting formulations other than soda-lime to the level required by the

typical SIP regulation would be about 2.7 million kWh (1,500 barrels of oil/year). The energy required to comply with the Option I and Option II emissions limits would be essentially the same as that required for meeting a typical SIP regulation.

Control to the level required by a typical SIP regulation of the two new 90 Mg/day pressed and blown glass furnaces melting formulations other than soda-lime and projected to come on-stream during the 1978-1983 period would require about 6.6 million kWh (3,700 barrels of oil/year) if an ESP were used. The energy requirements to achieve the Option I and Option II emission limits would be essentially the same as the requirements for meeting a typical SIP regulation.

The energy required to comply with the emission limits of the regulatory options would be about 0.1 percent of total energy use for all new furnaces in this glass manufacturing sector. Considering the small amounts of additional oil and electricity required and the slight increase in total energy use in this sector, the energy impacts of either Option I or Option II would be negligible.

Incremental installed costs in January 1978 dollars associated with Option I for controlling particulate emissions from a 45 Mg/day pressed and blown glass furnace melting formulations other than soda-lime would be about \$760 thousand for an ESP and about \$235 thousand for a fabric filter. Incremental installed costs associated with Option II would be about \$320 thousand for an ESP, and about \$190 thousand for a fabric filter. The incremental installed costs of control equipment associated with the Option I level of control would be about 2.4 times the incremental installed costs associated with Option II if ESP's were selected. If fabric filters were selected the incremental installed costs associated with the Option I level of control would be about 1.2 times the incremental installed costs associated with Option II level of control.

Incremental annualized costs for a 45 Mg/day furnace associated with Option I would be about \$230 thousand/year and about \$70 thousand/year for an ESP and a fabric filter, respectively. Incremental annualized costs associated with Option II would be about \$95 thousand/year for an ESP, and about \$60 thousand/year for a fabric filter. The incremental annualized costs associated with Option I would be about 2.4 times the incremental annualized costs associated with Option II if ESP's were used. If fabric filters were used the incremental annualized costs associated

with Option I would be about 1.2 times the incremental annualized costs associated with Option II.

Based on the use of control equipment with the highest annualized costs (worse case conditions), a price increase of about 0.4 percent would be necessary to offset the costs of installing control equipment on a 45 Mg/day pressed and blown glass furnace melting other than soda-lime formulations to meet the emission limits of Option I. A price increase of about 0.3 percent would be necessary to comply with the emission limits of Option II.

Incremental cumulative capital costs for the 1978-1983 period associated with Option I for the 45 Mg/day furnace would be about \$235 thousand if an ESP were used. Use of an ESP to comply with Option II would require incremental cumulative capital costs of about \$190 thousand for the same period. Fifth-year annualized costs for controlling this furnace in this sector to comply with Option I would be about \$70 thousand. To comply with Option II, fifth-year annualized costs would be about \$60 thousand.

Incremental installed costs in January 1978 dollars associated with Option I for controlling particulate emissions from a 90 Mg/day pressed and blown glass furnace melting other than soda-lime formulations would be about \$800 thousand for an ESP and about \$260 thousand for a fabric filter. Incremental installed costs associated with Option II would be about \$140 thousand for an ESP, and about \$180 thousand for a fabric filter. The incremental installed costs of control equipment associated with the Option I level of control would be about 5.7 times the incremental installed costs associated with Option II if ESP's were selected. If fabric filters were selected the incremental installed costs associated with the Option I level of control would be about 1.4 times the incremental installed costs associated with Option II.

Incremental annualized costs for a 90 Mg/day furnace associated with Option I would be about \$245 thousand per year and about \$85 thousand per year for an ESP and a fabric filter, respectively. Incremental annualized costs associated with Option II would be about \$45 thousand per year for an ESP, and about \$55 thousand per year for a fabric filter. The incremental annualized costs associated with Option I would be about 5.4 times the incremental annualized costs associated with Option II if ESP's were used. If fabric filters were used the incremental annualized costs associated with Option I would be about 1.5 times

the incremental annualized costs associated with Option II.

Based on the use of control equipment with the highest annualized costs, a price increase of about 0.8 percent would be necessary to offset the costs of installing control equipment on the 90 Mg/day pressed and blown glass furnace melting formulations other than soda-lime to meet the emission limits of Option I. A price increase of about 0.5 percent would be necessary to comply with the emission limits of Option II.

Incremental cumulative capital costs for the 1978-1983 period associated with Option I for the two new 90 Mg/day furnaces would be about \$500 thousand if fabric filters were used. Use of ESP's to comply with Option II would require incremental cumulative capital costs of about \$300 thousand for the same period. Fifth-year annualized costs for controlling these glass melting furnaces to comply with Option I would be about \$160 thousand. To comply with Option II, fifth-year annualized costs would be about \$85 thousand.

A summary of incremental impacts (in excess of impacts of the typical SIP regulation) associated with Option I and Option II is shown in Table III for both small and large furnaces. Air impacts, expressed in Mg/year of particulate matter emissions reduced, would approximate the quantity of particulate matter collected and disposed of as solid waste.

Table III.—Summary of Incremental Impacts Associated With Regulatory Options

Regulatory option:	Impacts			
	Air ¹	Water	Energy ²	Economic ³
I.....	57 None	Negligible
II.....	38 None	Negligible
				~0.7 ~0.4

¹ Mg/Yr. reduced.

² Barrels of oil/day.

³ Percent price increase.

Consideration of the beneficial impact on national particulate emissions, lack of water pollution impact, the small potential for adverse solid waste impact, the lack of energy impact, the reasonableness of cost impacts, and the general availability of demonstrated emission control technology leads to the selection of Option I as the basis for standards for pressed and blown glass furnaces melting formulations other than soda-lime.

Wool Fiberglass

Uncontrolled particulate emissions from wool fiberglass furnaces are generally about 5 g/kg (10 lb/ton) of

glass pulled. The average emission from three furnaces in the wool fiberglass sector equipped with ESP's was 0.18 g/kg (0.36 lb/ton) of glass pulled. EPA Method 5 tests of three furnaces equipped with fabric filters indicated emissions of 0.2 g/kg (0.4 lb/ton), 0.26 g/kg (0.52 lb/ton), and 0.55 g/kg (1.1 lb/ton) of glass pulled. The test data cited indicate that an emission limit of 0.2 g/kg (0.4 lb/ton) of glass pulled could be met through the use of an ESP and that a limit of 0.4 g/kg (0.8 lb/ton) of glass pulled could be met through the use of either an ESP or a fabric filter.

On the basis of these conclusions, two regulatory options for reducing particulate emissions from wool fiberglass furnaces were formulated. Option I would set an emission limit of 0.2 g/kg (0.4 lb/ton) of glass pulled, which would provide for about 95 percent particulate removal. Option II would set an emission limit of 0.4 g/kg (0.8 lb/ton) of glass pulled, which would provide for about 90 percent removal of particulates.

By 1983 approximately 360 Gg/year (397,000 ton/year) of additional production is anticipated in the wool fiberglass sector. About six new wool fiberglass furnaces of about 180 Mg/day (200 ton/day production capacity (the size of the model furnace) would be built in order to provide this additional production. If uncontrolled, these new wool fiberglass furnaces would add about 1,800 Mg/year (1,984 ton/year) to national particulate emissions by 1983. Compliance with a typical SIP regulation would reduce this impact to about 210 Mg/year (232 ton/year). Under Option I, emissions would be reduced to about 33 percent of those emitted under a typical SIP regulation. Under Option II, emissions would be reduced to about 66 percent of those emitted under a typical SIP regulation.

Ambient dispersion modeling indicates that under worst case conditions the annual maximum ground-level particulate concentration near an uncontrolled wool fiberglass furnace producing 180 Mg/day of glass would be about 2 $\mu\text{g}/\text{m}^3$. The annual maximum ground-level concentrations resulting from compliance with a typical SIP regulation, Option I, or Option II would be less than 1 $\mu\text{g}/\text{m}^3$. The calculated maximum 24-hour ground-level particulate concentration near an uncontrolled wool fiberglass furnace producing 180 Mg/day of glass would be about 29 $\mu\text{g}/\text{m}^3$. The corresponding concentration for complying with a typical SIP regulation would be about 3 $\mu\text{g}/\text{m}^3$. Under Option I, with an ESP employed for control, the maximum 24-

hour ground-level concentration would be reduced to 2 $\mu\text{g}/\text{m}^3$. Under Option II it would be reduced to 3 and 4 $\mu\text{g}/\text{m}^3$ with the fabric filter and ESP, respectively.

Since fabric filters and ESP's are likely to be the control systems installed on wool fiberglass furnaces to comply with standards, there would be no water pollution impact associated with standards based on either Option I or Option II.

Under a typical SIP regulation, about 1800 Mg/year (1,764 ton/year) of particulate matter would be collected from the six new 180 Mg/day wool fiberglass furnaces projected to come on-stream during the 1978-1983 period. Compliance with standards based on Option I and Option II would add about 140 Mg/year (154 ton/year) and about 70 Mg/year (77-ton/year), respectively, to the solid waste collected under a typical SIP regulation. Option I would increase the mass of solids for disposal by about 9 percent over that resulting from compliance with a typical SIP regulation, and Option II would increase it by about 4 percent. The additional solid material collected under Option I or Option II would not differ chemically from the material collected under a typical SIP regulation. Collected solids either are recycled back into the glass melting process or are disposed of in a landfill. Recycling of the solids has no adverse environmental impact, and, since landfill operations are subject to State regulation, this disposal method also is not expected to have an adverse environmental impact.

The estimated energy required to control particulate emissions from the six new wool fiberglass furnaces expected to come on-stream in the 1978-83 period to comply with a typical SIP regulation would be about 6.8 million kWh (3,850 barrels of oil/year) if electrostatic precipitators were used. Complying with the emission limits of Option I and Option II with electrostatic precipitators would require about 6.9 million kWh (3,900 barrels of oil/year). The energy required would be about 0.3 percent of the total energy use in the wool fiberglass sector. The energy impacts of either Option I or Option II would be negligible—only about 50 barrels of oil/year.

Incremental installed costs in January 1978 dollars associated with Option I for controlling particulate emissions from a 180 Mg/day wool fiberglass furnace would be about \$500 thousand for an ESP and about \$70 thousand for a fabric filter. Incremental installed costs associated with Option II would be about \$110 thousand and about \$30

thousand for an ESP and a fabric filter, respectively. The incremental installed costs of control equipment associated with the Option I level of control would be nearly 5 times the incremental installed costs associated with Option II if ESP's were selected. If fabric filters were selected, the incremental installed costs associated with the Option I level of control would be about twice the incremental installed costs associated with Option II.

Incremental annualized costs associated with Option I for a 180 Mg/day wool fiberglass furnace would be about \$155 thousand/year and about \$20 thousand/year for an ESP and a fabric filter, respectively. Incremental annualized costs associated with Option II would be about \$35 thousand/year for an ESP and about \$10 thousand/year for a fabric filter. The incremental annualized costs associated with Option I would be about five times the incremental annualized costs associated with Option II if ESP's were used. If fabric filters were used, the incremental annualized costs associated with Option I would be about two times the incremental annualized costs associated with Option II.

Based on the use of control equipment with the highest annualized costs (worst case conditions), a price increase of about 0.3 percent would be necessary to offset the costs of installing control equipment on a 180 Mg/day wool fiberglass furnace to meet the emission limits of Option I. A price increase of about 0.1 percent would be necessary to complying with the emission limits of Option II.

Incremental cumulative capital costs for the six new 180 Mg/day wool fiberglass furnaces during the 1978-1983 period associated with Option I would be about \$3 million if ESP's were used. Use of fabric filters to comply with Option II would require incremental cumulative capital costs of about \$185 thousand for the same period. Fifth-year annualized costs for controlling wool fiberglass furnaces complying with Option I would be about \$930 thousand. To comply with Option II, fifth-year annualized costs would be about \$60 thousand.

A summary of incremental impacts associated with Option I and Option II is shown in Table IV. Air impacts, expressed in Mg/year of particulate matter emissions reduced, would approximate the quantity of particulate matter collected and disposed of as solid waste.

Table IV.—Summary of Incremental Impacts Associated With Regulatory Options

	Impacts			
	Air ¹	Water	Energy ²	Economic ³
Regulatory option:				
I	140 None	Negligible		0.3
II	70 None	Negligible		0.1

¹ Mg/Yr. reduced.

² Barrels of oil/day.

³ Percent price increase.

Consideration of the beneficial impact on national particulate emissions, the lack of water pollution impact, the small potential for adverse solid waste impact, the reasonableness of energy and cost impacts, and the general availability of demonstrated emission control technology leads to the selection of Option I as the basis for standards for glass melting furnaces in the wool fiberglass sector.

Flat Glass

Uncontrolled particulate emissions from flat glass furnaces are about 1.5 g/kg (3.0 lb/ton) of glass pulled. There are no emissions test data for flat glass furnaces equipped with control devices available for evaluation. However, the soda-lime formulations melted in these furnaces are quite similar to those melted in container glass furnaces, as are the chemical composition and physical characteristics of the particulate emissions. The primary difference between container glass and flat glass furnaces is that the uncontrolled emission rates of flat glass furnaces are greater. Given the similarity of processes, glass formulations, and emissions it is expected that the percentage reduction in particulate emissions achieved by control of container glass furnaces also could be achieved with flat glass furnaces. This conclusion is supported by the performance guarantee underwritten by an ESP manufacturer for a flat glass facility which indicates at least 90 percent control efficiency. Thus, uncontrolled emissions from flat glass furnaces can be reduced with an ESP by at least 90 percent or to about 0.15 g/kg (0.3 lb/ton) of glass pulled.

The similarity of container glass and flat glass furnace formulations and emissions and the vendor guarantee noted above provide the basis for Option I. Option I would set an emission limit of 0.15 g/kg (0.3 lb/ton) of glass pulled, which would provide about 90 percent control. The Option II emission limit for furnaces in the other glass manufacturing sectors has been found to be twice the Option I limit. For

consistency, therefore, Option II would set an emission limit of 0.3 g/kg (0.6 lb/ton) of glass pulled, which would provide about 80 percent control.

By 1983 approximately 240 Gg/year (264,555 ton/year) of additional production is expected in the flat glass sector. One new flat glass furnace of about 635 Mg/day (700 ton/day) capacity (the size of the model furnace) would be built in order to provide this additional production.

If uncontrolled, this new flat glass furnace would add about 360 Mg/year (397 ton/year) to national particulate emissions by 1983. Compliance with a typical SIP regulation would reduce this impact to about 90 Mg/year (100 ton/year). Under Option I, emissions would be reduced to about 40 percent of those emitted under a typical SIP regulation. Under Option II, emissions would be reduced to about 80 percent of those emitted under a typical SIP regulation.

Ambient dispersion modeling indicates that under worst case conditions the annual maximum ground-level particulate concentration near an uncontrolled flat glass furnace producing 635 Mg/day of glass would be about $1 \mu\text{g}/\text{m}^3$. The annual maximum ground-level concentrations resulting from compliance with a typical SIP regulation, Option I, or Option II, would be less than $1 \mu\text{g}/\text{m}^3$. The calculated maximum 24-hour ground-level particulate concentration near an uncontrolled flat glass furnace producing 635 Mg/day of glass would be about $21 \mu\text{g}/\text{m}^3$. The corresponding concentration for complying with a typical SIP regulation would be about $5 \mu\text{g}/\text{m}^3$. Under Option I, this concentration would be reduced to about $2 \mu\text{g}/\text{m}^3$. Under Option II it would be reduced to about $5 \mu\text{g}/\text{m}^3$.

Since the ESP is likely to be the emission control system installed on flat glass furnaces to comply with standards, there would be no water pollution impact associated with standards based on either Option I or Option II.

Under a typical SIP regulation, about 270 Mg/year (298 ton/year) of particulate matter would be collected from the one new 635 Mg/day flat glass furnace projected to come on-stream in the 1978-1983 period. Compliance with standards based on Option I and II would add about 50 Mg/year (55 ton/year) and about 20 Mg/year (22 ton/year), respectively, to the solid waste collected under a typical SIP regulation. Option I would increase the mass of solids for disposal by about 20 percent over that resulting from compliance with a typical SIP regulation, and Option II would increase it by about 7 percent.

The additional solid material collected under Option I or Option II would not differ chemically from the material collected under a typical SIP regulation. Collected solids either are recycled back into the glass melting process or are disposed of in a landfill. Recycling of the solids has no adverse environmental impact, and, since landfill operations are subject to State regulations, this disposal method also is not expected to have an adverse environmental impact.

Since the energy requirements for an electrostatic precipitator do not vary significantly over the range of emission reductions considered here, the estimate of energy required to control particulate emissions from the one new flat glass furnace would be about the same for compliance with a typical SIP regulation, Option I, or Option II—about 7.6 million kWh (4,300 barrels of oil/year). The energy required to comply with the emission limits of the regulatory options would be about 0.2 percent of the total energy use in the flat glass sector. There would be no incremental energy impact associated with either Option I or Option II as compared with a typical SIP regulation.

The incremental installed cost in January 1978 dollars associated with Option I for controlling particulate emissions from a 635 Mg/day flat glass furnace would be about \$605 thousand. Incremental installed cost associated with Option II would be about \$140 thousand. The incremental installed cost of control equipment associated with the Option I level of control would be somewhat more than four times the incremental installed cost associated with the Option II level of control.

Incremental annualized cost associated with Option I for a 635 Mg/day flat glass furnace would be about \$190 thousand/year; the corresponding incremental annualized cost for Option II would be about \$45 thousand/year. The incremental annualized cost associated with Option I would be more than four times the incremental annualized cost associated with Option II.

A price increase of about 0.4 percent would be necessary to offset the cost of installing an ESP on a 635 Mg/day flat glass furnace to meet the emission limit of Option I. A price increase of about 0.1 percent would be necessary to comply with the emission limit of Option II.

Incremental cumulative capital cost for the one new 635 Mg/day flat glass furnace during the 1978-1983 period associated with Option I would be about \$605 thousand. Compliance with Option II would require an incremental cumulative capital cost of about \$145

thousand for the same period. Fifth-year annualized costs for controlling the one new flat glass furnace to comply with Option I would be about \$190 thousand. To meet the Option II emissions limit, fifth-year annualized costs would be about \$45 thousand.

A summary of incremental impacts associated with Option I and Option II is shown in Table V. Air impacts, expressed in Mg/year of particulate matter emissions reduced, would approximate the quantity of particulate matter collected and disposed of as solid waste.

Table V.—Summary of Incremental Impacts Associated With Regulatory Options

	Impacts			
	Air ¹	Water	Energy ²	Economic ³
Regulatory option:				
I.....	320 None	Negligible
II.....	290 None	Negligible
				—0.4
				—0.1

¹ Mg/Yr. reduced.

² Barrels of oil/day.

³ Percent price increase.

Consideration of the beneficial impact on national particulate emissions, the lack of water pollution impact, the small potential for adverse solid waste impact, the lack of energy impact, the reasonableness of cost impacts, and the general availability of demonstrated emission control technology leads to the selection of the Option I as the basis for standards for glass melting furnaces in the flat glass sector.

Summary

If uncontrolled, total particulate emissions from the 45 new glass melting furnaces projected to come on-stream between 1978 and 1983 would be about 5,200 Mg/year (5,732 ton/year). Compared to a typical SIP regulation, Option I would reduce particulate emissions by an additional 1,100 Mg/year (1,213 ton/year).

Ambient dispersion modeling indicates that the annual maximum ground-level particulate concentrations near uncontrolled glass melting furnaces would be $2 \mu\text{g}/\text{m}^3$ or less. Both a typical SIP regulation and the Option I emission limits would reduce the annual maximum ground-level particulate concentrations to under $1 \mu\text{g}/\text{m}^3$. The 24-maximum ground-level particulate concentrations near uncontrolled glass melting furnaces would be less than $30 \mu\text{g}/\text{m}^3$, with a median concentration of about $11 \mu\text{g}/\text{m}^3$. Under a typical SIP regulation these concentrations would be reduced to $5 \mu\text{g}/\text{m}^3$ or less. Control to the Option I emission limits would

reduce the 24-hour maximum ground-level concentrations near glass melting furnaces to about $2 \mu\text{g}/\text{m}^3$ or less.

The glass manufacturing process has minimal water pollution potential. Complying with a standard based on Option I would have a negligible water pollution impact, because control systems installed to meet Option I would not discharge waste water streams.

The amounts of solid waste generated in the control of particulates from glass melting furnaces would approximate the amount of particulate removed from exhaust gases. Compliance with a typical SIP regulation would produce 3,700 Mg (4,080 tons) of solid waste per year. Meeting the Option I emission limits would generate an additional 1,100 Mg/year (1,213 ton/year). Either recycling or landfilling would present minimal adverse environmental impact. Totally recycling the collected solids would have no adverse impact. Landfilling operations must meet State regulations, and therefore this disposal method would have limited potential for adverse environmental impact.

Implementing Option I would require about 1.6 million kWh of electricity to power the emission control equipment installed above the requirements for implementing a typical SIP regulation. To meet this power requirement electric utilities would require about 950 barrels of oil/year, or about 3 barrels/day. The energy that would be required to operate emission reduction systems to meet a standard based on the Option I limits would be 2 percent or less of the total energy used in glass production.

Incremental cumulative capital costs to the glass manufacturing industry for controlling emissions from new glass melting furnaces projected to come on-stream during the 1978-1983 period to comply with a standard based on the Option I emission limits would be about \$27.9 million. The fifth-year annualized costs to the glass manufacturing industry associated with compliance with the Option I emission limits would be about \$8.4 million. An industry-wide price increase of about 0.7 percent would be necessary to offset the costs of installing control equipment to meet the emission limits of Option I.

Modification, Reconstruction, and Other Considerations

An exemption from provisions of the modification section (40 CFR § 60.14) is proposed for those plants which convert to fuel-oil firing, even though particulate emissions would more than likely be increased. The primary objective of the proposed standards is to control

emissions of particulates from glass melting furnaces. The data and information supporting the standards consider essentially only those emissions arising from the basic melting process, not those arising from fuel combustion. It is not the prime purpose of these standards, therefore, to control emissions from fuel combustion per se. Consequently, since emissions from fuel combustion are small in comparison with those from the basic melting process, and a conversion of glass melting furnaces to firing oil rather than natural gas will aid in efforts to conserve natural gas resources, the standards proposed herein include a provision exempting fuel switching in glass melting furnaces from consideration as a modification. The proposed increment in emissions allowed fuel oil-fired glass melting furnaces is 15 percent, a small allowance; however, without this exemption there would be a large economic impact on the industry.

An exemption from reconstruction provisions (40 CFR § 60.15) is proposed for the cold refining (rebricking) of the melter of an existing furnace. Under 40 CFR § 60.15 the Administrator must be notified of intent to conduct such a procedure 60 days in advance of commencement, and will determine whether or not the rebricking constitutes a reconstruction. This rebricking procedure has been a routine operation in the glass manufacturing industry and would not generally be considered an opportunity to evade the provisions of the standard by unduly extending the useful life of an existing glass melting furnace. Therefore, the exemption of rebricking from reconstruction provision has been proposed.

Glass melting furnaces fired with number 2 fuel oil would be expected to exhibit a 10 percent increase in particulate emissions over those produced in gas-fired furnaces since particulates are formed by the combustion of oil. Similarly, furnaces fired with number 4, 5, or 6 fuel oil would show a 15 percent increase in particulate emissions over those produced in gas-fired furnaces. This effect of fuel oil on furnace emissions being recognized, it is proposed that the emission limits for furnaces fired with fuel oil be the limits for gas-fired furnaces multiplied by 1.15. It is additionally proposed that simultaneously liquid and gas-fired furnaces have emission limits based on an equation, taking into consideration the relative proportions of the fuels being fired.

Selection of Performance Test Methods

The use of EPA Reference Method 5—"Determination of Particulate Emissions from Stationary Sources" (Appendix A, 40 CFR § 60, Federal Register, December 23, 1971) is required to determine compliance with the mass standards for particular matter emissions. Emission test data used in the development of the proposed standard were obtained either by the LAAPCD sampling method or by EPA Method 5. However, results of performance tests using Method 5 conducted by EPA on existing glass melting furnaces comprise a major portion of the data base used in the development of the proposed standard. EPA Reference Method 5 has been shown to provide a representative measurement of particulate matter emissions. Therefore, it has been included for determining compliance with the proposed standards.

Calculations applicable under Method 5 necessitate the use of data obtained from three other EPA test methods conducted previous to the performance of Method 5. Method 1—"Sample and Velocity Traverse for Stationary Sources" must be conducted in order to obtain representative measurements of pollutant emissions. The average gas velocity in the exhaust stack is measured by conducting Method 2—"Determination of Stack Gas Velocity and Volumetric Flow Rate (Type S Pitot Tube)." The analysis of gas composition is measured by conducting Method 3—"Gas Analysis for Carbon Dioxide, Oxygen, Excess Air and Dry Molecular Weight." These three tests provide data necessary in Method 5 for converting volumetric flow rate to mass flow rate. In addition, Method 4—"Determination of Moisture Content in Stack Gases" is suggested as an accurate mode of predetermination of moisture content.

Since the proposed standards are expressed as mass of emissions per unit mass of glass pulled, it will be necessary to quantify glass pulled in addition to measuring particulate emissions. Glass production in Mg shall be determined by direct measurement or computed from materials balance data using good engineering practices. The materials balance computation may consist of a process relationship between feed material input rate and the glass pull rate. In all materials balance computations, glass pulled from the furnace shall include product, cullet, and any waste glass. The hourly glass pull rate for a furnace shall be determined by averaging the glass pull rate over the time of the performance test.

Selection of Monitoring Requirements

To provide a convenient means for enforcement personnel to ensure that installed emission control systems comply with standards of performance through proper operation and maintenance, monitoring requirements are generally included in standards of performance. For glass melting furnaces the most straightforward means of ensuring proper operation and maintenance is to monitor emissions released to the atmosphere. EPA has established opacity monitoring performance specifications in Appendix B of 40 CFR § 60 for industrial sources with well-developed velocity and temperature profiles.

The best indirect method of monitoring proper operation and maintenance of compliance control equipment is the determination of exhaust gas opacity limits. Determining an acceptable exhaust gas opacity limit is not presently possible because the relationship between particulate emissions and corresponding opacity levels was not evaluated for glass melting furnaces. The data base for the particulate standards does not include information on opacity. Also, currently there are no continuous particulate monitors operating on glass melting furnaces; consequently, the data base necessary for developing an opacity-emission rate relationship is not available. Resolution of the sampling problems, development of performance standards for continuous particulate monitors, and obtaining a data base for developing an opacity-emission rate relationship would entail a major development program. For these reasons, continuous monitoring of particulate emissions from glass melting furnaces would not be required by the proposed standards.

Public Hearing

A public hearing will be held to discuss these proposed standards in accordance with Section 307(d)(5) of the Clean Air Act. Persons wishing to make oral presentations should contact EPA at the address given in the ADDRESSES section of this preamble. Oral presentations will be limited to 15 minutes each. Any member of the public may file a written statement with EPA before, during, or within 30 days after the hearing. Written statements should be addressed to the Docket address given in the ADDRESSES section of this preamble.

A verbatim transcript of the hearing and written statements will be available for public inspection and copying during

normal working hours at EPA's Central Docket Section in Washington, D.C. (See ADDRESSES section of this preamble).

Miscellaneous

The docket is an organized and complete file of all the information considered by EPA in the development of this rulemaking. The principal purposes of the docket are: (1) to allow interested persons to identify and locate documents so that they can intelligently and effectively participate in the rulemaking process, and (2) to serve as the record for judicial review. The docket requirement is discussed in Section 307(d) of the Clean Air Act.

As prescribed by Section 111 of the Act, this proposal of standards has been preceded by the Administrator's determination that emissions from glass manufacturing plants contribute to the endangerment of public health or welfare, and by publication of this determination in this issue of the Federal Register. In accordance with Section 117 of the Act, publication of these proposed standards was preceded by consultation with appropriate advisory committees, independent experts, and Federal departments and agencies. The Administrator will welcome comments on all aspects of the proposed regulation, including the designation of glass manufacturing plants as a significant contributor to air pollution which causes or contributes to the endangerment of public health or welfare, economic and technological issues, and on the proposed test method.

It should be noted that standards of performance for new sources established under Section 111 of the Clean Air Act reflect:

"Application of the best technological system of continuous emission reduction which (taking into consideration the cost of achieving such emission reduction, any nonair quality health and environmental impact and energy requirements) the Administrator determines has been adequately demonstrated." [Section 111(a)(1)]

Although there may be emission control technology available that is capable of reducing emissions below those levels required to comply with the standards of performance, this technology might not be selected as the basis of standards of performance because of costs associated with its use. Accordingly, these standards of performance should not be viewed as the ultimate in achievable emissions control. In fact, the Act requires (or has the potential for requiring) the imposition of a more stringent emission standard in several situations. For example, applicable costs do not

necessarily play as prominent a role in determining the "lowest achievable emission rate" for new or modified sources locating in nonattainment areas; i.e., those areas where statutorily-mandated health and welfare standards are being violated. In this respect, Section 173 of the Act requires that new or modified sources constructed in an area which is in violation of the NAAQS must reduce emissions to the level which reflects the "lowest achievable emission rate" (LAER), as defined in Section 171(3), for such category of source. The statute defines LAER as that rate of emissions which reflects:

"(A) the most stringent emission limitation which is contained in the Implementation plan of any State for such class or category of source, unless the owner or operator of the proposed source demonstrates that such limitations are not achievable; or (B) the most stringent emission limitation which is achieved in practice by such class or category of source, whichever is more stringent."

In no event can the emission rate exceed any applicable new source performance standard [Section 171(3)].

A similar situation may arise under the prevention of significant deterioration of air quality provisions of the Act (Part C). These provisions require that certain sources (referred to in Section 169(1)) employ "best available control technology" (as defined in Section 169(3)) for all pollutants regulated under the Act. Best available control technology (BACT) must be determined on a case-by-case basis, taking energy, environmental, and economic impacts and other costs into account. In no event may the application of BACT result in emissions of any pollutants which will exceed the emissions allowed by an applicable standard established pursuant to Section 111 (or 112) of the Act.

In all events, State Implementation Plans approved or promulgated under Section 110 of the Act must provide for the attainment and maintenance of national ambient air quality standards (NAAQS) designed to protect public health and welfare. For this purpose, SIP's must in some cases require greater emission reductions than those required by standards of performance for new sources.

Finally, States are free under Section 116 of the Act to establish even more stringent limits than those established under Section 111 of those necessary to attain or maintain the NAAQS under Section 110. Accordingly, new sources may in some cases be subject to limitations more stringent than EPA's standards of performance under Section

111, and prospective owners and operators of new sources should be aware of this possibility in planning for such facilities.

EPA will review this regulation four years from the date of promulgation. This review will include an assessment of such factors as the need for integration with other programs, the existence of alternative methods, enforceability, and improvements in emission control technology.

An economic impact assignment has been prepared as required under Section 317 of the Act and is included in the Background Information Document.

Dated: May 22, 1979.

Douglas M. Costle,
Administrator.

It is proposed to amend Part 60 of Chapter I, Title 40 of the Code of Federal Regulations as follows:

Subpart CC—Standards of Performance for Glass Manufacturing Plants

Sec.

60.290 Applicability and designation of affected facility.

60.291 Definitions.

60.292 Standards for particulate matter.

60.293 Test methods and procedures.

Authority: Sections 111 and 301(a) of the Clean Air Act, as amended [42 U.S.C. 7411, 7601(a)], and additional authority as noted below.

§ 60.290 Applicability and designation of affected facility.

The affected facility to which the provisions of this subpart apply is each glass melting furnace within a glass manufacturing plant.

§ 60.291 Definitions.

As used in this subpart, all terms not defined herein shall have the meaning given them in the Act and in Subpart A.

(a) "Glass manufacturing plant" means any plant which produces glass or glass products.

(b) "Glass melting furnace" means a unit comprising a refractory vessel in which raw materials are charged, melted at high temperature, refined, and conditioned to produce molten glass. The unit includes foundations, superstructure and retaining walls, raw material charger systems, heat exchangers, melter cooling system, exhaust system, refractory brick work, fuel supply and electrical boosting equipment, integral control systems and instrumentation, and appendages for conditioning and distributing molten glass to forming apparatuses.

(c) "Day pot" means any glass melting furnace designed to produce less than 1800 kilograms of glass per day.

(d) "All-electric melter" means a glass melting furnace in which all the heat required for melting is provided by electric current from electrodes submerged in the molten glass, although some fossil fuel may be charged to the furnace as raw material.

(e) "Glass" means flat glass; container glass; pressed and blown glass; and wool fiberglass.

(f) "Flat glass" means glass made of soda-lime recipe and produced into continuous flat sheets and other products listed in Standard Industrial Classification 3211 (SIC 3211).

(g) "Container glass" means glass made of soda-lime recipe, clear or colored, which is pressed and/or blown into bottles, jars, ampoules, and other products listed in SIC 3211.

(h) "Pressed and blown glass" means glass which is pressed and/or blown, including textile fiberglass, noncontinuous process flat glass, noncontainer glass, and other products listed in SIC 3229. It is separated into:

(1) Glass of soda-lime recipe; and

(2) Glass of borosilicate, opal, lead and other recipes.

(i) "Wool fiberglass" means fibrous glass of random texture, including fiberglass insulation, and other products listed in SIC 3296.

(j) "Recipe" means formulation of raw materials.

(k) "Glass production" means the weight of glass pulled from a glass melting furnace.

(l) "Rebrick" means cold replacement of damaged or worn refractory parts of the glass melting furnace. Rebrick includes replacement of the refractories comprising the bottom, sidewalls, or roof of the melting vessel; replacement of refractory work in the heat exchanger; replacement of refractory portions of the glass conditioning and distribution system.

(m) "Soda-lime recipe" means raw material formulation of the following approximate proportions: 72 percent silica; 15 percent soda; 10 percent lime and magnesia; 2 percent alumina; and 1 percent miscellaneous materials.

§ 60.292 Standards for particulate matter.

(a) On or after the date on which the performance test required to be conducted by § 60.8 is completed, no owner or operator of a glass melting furnace subject to the provisions of this subpart shall cause to be discharged into the atmosphere, except as provided in paragraph (d) of this section:

(1) From any glass melting furnace, fired with a gaseous fuel, particulate matter at emission rates exceeding those specified in Table CC-1.

(2) From any glass melting furnace, fired with a liquid fuel, particulate matter at emission rates exceeding 1.15 times those specified in Table CC-1.

(3) From any glass melting furnace, simultaneously fired with gaseous and liquid fuel, particulate matter at emission rates exceeding those specified by the following equation:

$$STD = X[1.15(Y) + (Z)]$$

where:

STD = Particulate matter emission limit

X = Emission rate specified in Table CC-1

Y = Decimal percent of liquid fuel heating value to total (gaseous and liquid) fuel heating value

kilojoules

kilojoules

$$Z = (1 - Y)$$

(b) Conversion of a glass melting furnace to use of liquid fuel shall not be considered a modification for purposes of 40 CFR 60.14.

(c) Rebrick and the cost of rebrick shall not be considered reconstruction for the purposes of 40 CFR 60.15.

(d) This subpart shall not apply to day pots and all-electric melters.

Table CC-1—Emission Rates

Glass category	g of particulate/kg of glass produced
(1) Flat Glass.....	0.18
(2) Container Glass.....	.10
(3) Pressed and Blown Glass:	
(a) Other than soda-lime recipes (i.e., borosilicate, opal, lead, and other recipes, including textile fiberglass).....	.25
(b) Soda-lime recipes.....	.10
(4) Wool Fiberglass.....	.20

§ 60.293 Test methods and procedures.

(a) Reference methods in Appendix A of this part, except as provided under § 60.8(b), shall be used to determine compliance with § 60.292 as follows:

(1) Method 5 shall be used to determine the concentration of particulate matter and the associated moisture content.

(2) Method 1 shall be used for sample and velocity traverses, and

(3) Method 2 shall be used to determine velocity and volumetric flow rate.

(4) Method 3 shall be used for gas analysis.

(b) For Method 5, the sample probe and filter holder shall be heated to 121°C (250°F). The sampling time for each run

shall be at least 60 minutes and the volume shall be at least 4.25 dscm.

(c) The particulate emission rate, E, shall be computed as follows:

$$E = V \times C$$

where:

(1) E is the particulate emission rate (g/hr).

(2) V is the average volumetric flow rate (dscm/hr) as found from Method 2; and

(3) C is the average concentration (g/dscm) of particulate matter as found from Method 5.

(d) the rate of glass production, P (kg/hr) shall be determined by dividing the weight of glass pulled in kilograms (kg) from the affected facility during the performance test by the number of hours (hr) taken to perform the performance test. The glass pulled in kilograms shall be determined by direct measurement or computed from materials balance by good engineering practice.

(e) The furnace emission rate shall be computed as follows:

$$R = E/P$$

where:

(1) R is the furnace emission rate (g/kg);

(2) E is the particulate emission rate (g/hr) from (c) above; and

(3) P is the rate of glass production (kg/hr) from (d) above.

[Sec. 114 of Clean Air Act as amended (42 U.S.C. 7414).]

[40 CFR Part 60]

[FRL 1297-3]

Standards of Performance for New Stationary Sources; Glass Manufacturing Plants

AGENCY: Environmental Protection Agency (EPA).

ACTION: Extension of Comment Period.

SUMMARY: The deadline for submittal of comments on the proposed standards of performance for glass manufacturing plants, which were proposed on June 15, 1979 (44 FR 34840), is being extended from August 14, 1979, to September 14, 1979.

DATES: Comments must be received on or before September 14, 1979.

ADDRESSES: Comments should be submitted to Central Docket Section (A-130), United States Environmental Protection Agency, 401 M Street, S.W., Washington, D.C. 20460, Attention: Docket No. OAQPS 79-2.

FOR FURTHER INFORMATION CONTACT: Mr. Don R. Goodwin, Director, Emission Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone number (919) 541-5271.

SUPPLEMENTARY INFORMATION: On June 15, 1979 (44 FR 34840), the Environmental Protection Agency proposed standards of performance for the control of emissions from glass manufacturing plants. The notice of proposal requested public comments on

the standards by August 14, 1979. Due to delay in the shipping of the Background Information Document, sufficient copies of the document have not been available to all interested parties in time to allow their meaningful review and comment by August 14, 1979. EPA has received a request from the industry to extend the comment period by 30 days through September 14, 1979. An extension of this length is justified since the shipping delay has resulted in approximately a three-week delay in processing requests for the document.

Dated: August 8, 1979.

David G. Hawkins,
Assistant Administrator for Air, Noise, and Radiation.

PERFORMANCE FOR NEW
STATIONARY SOURCES**

**STATIONARY INTERNAL
COMBUSTION ENGINES**

SUBPART FF

[FRL 1099-5]

[40 CFR Part 60]

Stationary Internal Combustion Engines; Standards of Performance for New Stationary Sources**AGENCY:** Environmental Protection Agency (EPA).**ACTION:** Proposed rule.

SUMMARY: The proposed standards, which would apply to facilities that commence construction 30 months after today's date, would limit emissions of nitrogen oxides (NO_x) from new, modified, and reconstructed stationary gas, diesel, and dual-fuel internal combustion (IC) engines to 700 parts per million (ppm), 600 ppm, 600 ppm, respectively at 15 percent oxygen (O₂) on a dry basis. A revision to Reference Method 20 for determining the concentration of nitrogen oxides and oxygen in the exhaust gases from large stationary IC engines is also proposed.

The standards implement the Clean Air Act and are based on the Administrator's determination that stationary IC engines contribute significantly to air pollution. The intent is to require new, modified, and reconstructed stationary IC engines to use the best demonstrated system of continuous emission reduction, considering costs, non-air quality health, and environmental and energy impacts.

A public hearing will be held to provide interested persons an opportunity for oral presentation of data, views, or arguments concerning the proposed standards.

DATES: *Comments.* Comments must be received on or before September 21, 1979.

Public Hearing. The public hearing will be held on August 22, 1979 beginning at 9:30 a.m. and ending at 4:30 p.m.

Request to Speak at Hearing. Persons wishing to attend the hearing or present oral testimony should contact EPA by August 15, 1979.

ADDRESSES: *Comments.* Comments should be submitted to Mr. Jack R. Farmer, Chief, Standards Development Branch (MD-13), Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, North Carolina 27711.

Public Hearing. The public hearing will be held at the Environmental Research Center Auditorium, Room

B101, Research Triangle Park, N.C. 27711. Persons wishing to attend or present oral testimony should notify Mary Jane Clark, Emission Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone number (919) 541-5271.

Standards Support Document. The support document for the proposed standards may be obtained from the EPA Library (MD-35), Research Triangle Park, North Carolina 27711, telephone number (919) 541-2777. Please refer to "Standards Support and Environmental Impact Statement: Proposed Standards of Performance for Stationary Internal Combustion Engines," EPA-450/3-78-125a.

Docket. The Docket, number OAQPS-79-5, is available for public inspection and copying at the EPA's Central Docket Section, Room 2903 B, Waterside Mall, Washington, D.C. 20460.

FOR FURTHER INFORMATION CONTACT: Mr. Don R. Goodwin, Director, Emission Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone (919) 541-5271.

**SUPPLEMENTARY INFORMATION:
Proposed Standards**

The proposed standards, which are summarized in Table A, would apply to all new, modified, and reconstructed stationary internal combustion engines as follows:

1. Diesel and dual-fuel engines greater than 560 cubic inch displacement per cylinder (CID/cyl).
2. Gas engines greater than 350 cubic inch displacement per cylinder (CID/cyl) or equal to or greater than eight cylinders and greater than 240 cubic inch displacement per cylinder (CID/cyl).
3. Rotary engines greater than 1500 cubic inch displacement per rotor.

The proposed standards, which would go into effect 30 months after the date of proposal (i.e., today's date), would limit the concentration of NO_x in the exhaust gases from stationary gas, diesel and dual-fuel IC engines to 0.0700 percent by volume (700 ppm), 0.600 percent by volume (600 ppm), and 0.0600 percent by volume (600 ppm), respectively, at 15 percent oxygen (O₂) on a dry basis. These emission limits are adjusted upward linearly for IC engines with thermal efficiencies greater than 35 percent.

Table A.—Summary of Internal Combustion Engine New Source Performance Standard

Internal combustion engine size and fuel type	NO _x emission limit* (ppm)	Applicability date
Diesel Engines > 560 CID/cyl or > 1500 CID/rotor	600	30 months from date of proposal (i.e., today's date)
Dual-Fuel Engines > 560 CID/cyl or > 1500 CID/rotor	600	30 months from date of proposal (i.e., today's date)
Gas Engines > 350 CID/cyl or ≥ 8 cylinders and > 240 CID/cyl or 1500 > CID/rotor.	700	30 months from date of proposal (i.e., today's date)

*NO_x emission limit adjusted upward for internal combustion engines with thermal efficiencies greater than 35 percent. Measured NO_x emissions adjusted to standard atmospheric conditions of 101.3 kilopascals (29.92 inches mercury), 29.4 degrees Centigrade (85 degrees Fahrenheit), and 17 grams moisture per kilogram dry air (75 grains moisture per pound of dry air) in determining compliance with the NO_x emission limit.

The proposed standards would be referenced to standard atmospheric conditions of 101.3 kilopascals (29.92 inches mercury), 29.4 degrees centigrade (85 degrees Fahrenheit), and 17 grams moisture per kilogram dry air (75 grains moisture per pound of dry air). Measured NO_x emission levels, therefore, would be adjusted to standard atmospheric conditions by use of ambient correction factors included in the standard. Manufacturers, owners, or operators may also elect to develop custom ambient condition correction factors, in terms of ambient temperature, and/or humidity, and/or ambient pressure. All correction factors would have to be substantiated with data and

approved for use by EPA before they could be used for determining compliance with the proposed standards.

Emergency-standby IC engines and all one- and two-cylinder reciprocating gas engines would be exempt from the NO_x emission standard.

Summary of Environmental and Economic Impacts

The proposed standards would reduce uncontrolled NO_x emissions levels from stationary IC engines by about 40 percent. Based on industry growth projections, a reduction in national NO_x emissions of about 145,000 megagrams per year (160,000 tons per year) would

be realized in the fifth year after the standards go into effect. Except for a few local areas (e.g., Los Angeles), there are currently no state standards limiting NO_x emissions from IC engines.

The proposed standards, however, would increase uncontrolled CO and HC emissions levels from stationary IC engines. Based on industry growth projections, an increase in national CO emissions of about 218,000 megagrams (238,000 tons) annually would be realized in the fifth year after the standards go into effect. Similarly, an increase in national total HC emissions of about 4600 megagrams (5000 tons) annually would be realized in the fifth year after the standards go into effect.

The large increase in CO emissions is due primarily to carbureted or naturally aspirated gas engines. These engines operate closer to stoichiometric conditions under which a small change in the air-to-fuel ratio results in a large increase in CO emissions.

Though total national CO emissions would increase significantly, ambient air CO concentrations in the immediate vicinity of these carbureted or naturally aspirated gas engines would not be adversely affected. As a result of the proposed standards of performance, the CO emissions from a naturally aspirated engine would increase about 180 percent. NO_x emissions from the same engine, however, would decrease concurrently about 40 percent.

Thus, there exists a trade-off between NO_x emissions reduction and CO emissions increase, particularly for carbureted or naturally aspirated gas engines. It should be noted though that CO emissions are considered to be a local problem since CO readily reacts to form CO₂. Additionally, most naturally aspirated gas engines are operated in remote locations where CO is not a problem. NO_x emissions, however, are linked to the formation of photochemical oxidants and are subject to long range transport. Also, NO_x emission control techniques are essentially design modifications, not add-on equipment, therefore, NO_x emissions reductions are much harder to achieve than CO or HC emissions reductions which may be achieved more easily from other sources.

One alternative is to propose a CO emissions limit based on the use of oxidizing catalysts. These catalysts can provide CO and HC emissions reductions on the order of 90 percent. Initial capital costs are high, however, averaging about \$7500 for a typical 1000 horsepower naturally aspirated gas engine, or about 15 percent of the

purchase price of this engine. EPA feels these costs for control of CO emissions are unreasonable.

The trade-off between NO_x and CO emissions appears reasonable. However, EPA invites comments from state and local air pollution control agencies, environmental groups, the industry, and other interested individuals concerning all aspects of the attractiveness of these standards which reduce NO_x emissions at the expense of CO emissions.

Industry has requested a waiver from the national mobile source standards for diesel engines used in light duty vehicles. Based on their tests, industry believes that the application of NO_x control techniques to these mobile diesel engines causes increased particulate (smoke) emissions. The plumes from most well maintained large-bore stationary IC engines, however, are virtually invisible when the engine is operating at steady state. Though excessive retard will cause diesel and dual fuel units to emit smoke, the NO_x control results used in the development of this standard were only considered if the plume did not exceed ten percent visibility. Therefore, EPA feels the NO_x control techniques used to meet the proposed standards for large stationary IC engines will not cause excessive visible and/or particulate emissions. However, EPA invites comments on the aspects of the proposed standards which reduce NO_x emissions at the expense of visible and/or particulate emissions.

There would be essentially no adverse water pollution, solid waste, or noise impact resulting from the proposed standards.

The energy impact of the proposed standards would be small. Turbocharged gas IC engine fuel consumption would be increased about two percent. Dual-fuel IC engine fuel consumption would be increased about three percent. Diesel IC engine fuel consumption would be increased about seven percent. Naturally aspirated gas IC engine fuel consumption would be increased by about eight percent. The fifth year energy impact of the proposed standards would be equivalent to an increase in fuel oil consumption of about 1.5 million barrels of oil per year (4,300 barrels of oil per day). This represents an increase of only 0.03 percent of the oil projected to be imported in the United States five years after the standards go into effect. In addition, these estimates are based on "worst-case" assumptions which yield the greatest energy impacts, and actual impacts are expected to be lower.

The economic impacts of the proposed standards are considered reasonable. The proposed standards would increase IC engine manufacturers' total capital investment requirements for developmental testing of engine models by about \$5 million. These expenditures would be made over a two year period. Analysis of financial reports and other public financial information indicates that the manufacturers' overhead budgets are sufficient to support these requirements without adverse impact on their financial positions. The proposed standards would not give rise to a significant sales advantage for one or two manufacturers over competing manufacturers. The maximum intra-industry sales losses, based on "worst-case" assumptions, would be about six percent.

The proposed standards would increase the total annualized costs to users of a large stationary IC engines of all fuel types by about two to seven percent. The capital cost or purchase price of a large stationary IC engine would increase by about two percent.

The proposed standards would increase the total annualized costs for all engine users by about \$32 million in the fifth year after standards go into effect. The total capital investment requirements for all users would equal about \$6 million on a cumulative basis over the first five years the standards are in effect.

These impacts would result in price increases for the end products or services provided by the industrial and commercial users of large stationary IC engines. The electric utility industry would pass on a price increase after five years of 0.02 percent. After five years, delivered natural gas prices would increase 0.04 percent. Even after a full phase-in period of 30 years, during which new controlled engines would replace all existing uncontrolled engines, the electric utility industry would pass on a price increase of only 0.1 percent. Delivered natural gas prices would increase only 0.3 percent.

Rationale—Selection of Source for Control

Stationary IC engines are sources of NO_x, hydrocarbons (HC), particulates, sulfur dioxide (SO₂), and carbon monoxide (CO) emissions. NO_x emissions from IC engines, however, are of more concern than emissions of these other pollutants for two reasons. First, compared to total U.S. emissions for each pollutant, NO_x is the primary pollutant emitted by stationary engines. Second, EPA has assigned a high priority to development of standards of

performance limiting NO_x emissions. A study by Argonne National Laboratory, "Priorities and Procedures for Development of Standards of Performance for New Stationary Sources of Atmospheric Emissions" (EPA-450/3-76-020), concluded that national NO_x emissions from stationary sources would increase by more than 40 percent between 1975 and 1990 in the absence of additional emission controls. Applying best technology to all sources would reduce this increase but would not prevent it from occurring. This unavoidable increase in NO_x emissions is attributable largely to the fact that current NO_x emission control techniques are based on combustion redesign. In addition, few NO_x emission control techniques can achieve large (i.e., in the range of 90 percent) reductions in NO_x emissions. Consequently, EPA has assigned a high priority to the development of standards of performance for major NO_x emission sources wherever significant reductions in NO_x can be achieved. Studies have shown that IC engines are significant contributors to total U.S. NO_x emissions from stationary sources. Internal combustion engines account for 16.4 percent of all stationary source NO_x emissions, exceeded only by utility and packaged boilers.

Studies have investigated the effect that standards of performance would have on nationwide emissions of particulates, NO_x, SO_x, HC, and CO from stationary sources. The "Priority List for New Source Performance Standards under the Clean Air Act Amendments of 1977," which was proposed in the August 31, 1978, Federal Register, ranked sources according to the impact, in tons per year, that standards promulgated in 1980 would have on emissions in 1990. This ranking placed spark ignition IC engines second and compression ignition IC engines third on a list of 32 stationary NO_x emission sources. Consequently, stationary IC engines have been selected for development of standards of performance.

Selection of Pollutants

Nitrogen oxides, hydrocarbons, and carbon monoxide.—Stationary IC engines emit the following pollutants: NO_x, CO, HC, particulates, and SO_x. The primary pollutant emitted by stationary IC engines is NO_x, accounting for over six percent (or 16 percent of all stationary sources) of the total U.S. inventory of NO_x emissions.

Stationary IC engines also emit substantial quantities of CO and HC. Numerous small (1-100 hp) spark

ignition engines, which are similar to automotive engines, account for about 20 percent of the uncontrolled HC emissions and about 80 percent of the uncontrolled CO emissions. The large annual production of these small spark ignition engines (approximately 12.7 million), however, makes enforcement of a new source performance standard for this group difficult.

Large-bore engines, which account for three-quarters of NO_x emissions from stationary IC engines, contribute relatively small amounts to nationwide HC and CO emissions, especially if one considers that 80 percent of the HC emissions from large-bore IC engines are methane. An additional factor in considering CO and HC control is that inherent engine characteristics result in a trade-off between NO_x control and control of CO and HC.

As mentioned before, in some cases, particularly naturally aspirated gas engines, the application of NO_x emission control techniques could cause increases in CO and HC emissions. This increase in CO and HC emissions is strictly a function of the engine operating position relative to stoichiometric conditions, not the NO_x control technique. These engines operate closer to stoichiometric conditions under which a small change in the air-to-fuel ratio results in a large increase in CO emissions. Any increase in CO and HC emissions, however, represents an increase in unburned fuel and hence a loss in efficiency. Since IC engines manufacturers compete with one another on the basis of engine operating costs, which is primarily a function of engine operating efficiency, the marketplace will effectively ensure that CO and HC emissions are as low as possible following application of NO_x control techniques.

Though total national CO emissions would increase significantly, ambient air CO concentrations in the immediate vicinity of these carbureted or naturally aspirated gas engines would not be adversely affected. As a result of the proposed standards of performance, the CO emissions from a naturally aspirated engine would increase about 160 percent. NO_x emissions from the same engine, however, would decrease concurrently about 40 percent.

Thus, there exists a trade-off between NO_x emissions reduction and CO emissions increase, particularly for carbureted or naturally aspirated gas engines. It should be noted though that CO emissions are considered to be a local problem as CO readily reacts to form CO₂. Additionally, most naturally aspirated gas engines are operated in

remote locations where CO is not a problem. NO_x emissions, however, are linked to the formation of photochemical oxidants and are subject to long range transport. NO_x emissions reductions are also much harder to achieve than CO or HC emissions reductions which may be achieved more easily from other sources.

In addition, promulgation of CO standard of performance could, in effect, preclude significant NO_x control. NO_x emissions are primarily a function of combustion flame temperature. Decreasing the air-to-fuel ratio of a gas engine lowers the flame temperature and consequently reduces NO_x formation. As will be discussed later, this technique is the most effective means of reducing NO_x emissions from gas engines. CO emissions, however, are primarily a function of oxygen availability. Decreasing the air-to-fuel ratio reduces oxygen availability and consequently increases CO emissions. Hence naturally aspirated gas engines show a pronounced rise in CO emissions as the air-to-fuel mixture becomes richer (i.e., decreasing air-to-fuel ratio). Thus, placing a limit on CO emissions from internal combustion engines could effectively limit the decrease in the air-to-fuel ratio which would be applied to reduce NO_x emissions from naturally aspirated gas engines and, consequently, could limit the amount of NO_x emissions reduction achievable.

One alternative is to propose a CO emissions limit based on the use of oxidizing catalysts. These catalysts can provide CO and HC emissions reductions on the order of 90 percent. Initial capital costs are high, however, averaging about \$7500 for a typical 1000 horsepower naturally aspirated gas engine, or about 15 percent of the purchase price of this engine. EPA feels these costs for control of CO emissions are unreasonable.

The trade-off between NO_x and CO emissions appears reasonable, and consequently, only NO_x emissions from large stationary IC engines were selected for control by standards of performance.

EPA, however, invites comments from state and local air pollution control agencies, environmental groups, the industry, and interested individuals concerning all aspects of the attractiveness of these standards which reduce NO_x emissions at the expense of CO emissions.

Particulate.—Virtually no data are available on particulate emission rates from stationary IC engines. It is believed, however, that particulate emissions from stationary IC engines are

very low because the plumes from most of these engines are not visible. Therefore, neither particulate emissions nor visible emissions (plume opacity) were selected for control by standards of performance.

Sulfur oxides.—Sulfur oxides (SO_x) emissions from an IC engine depend on the sulfur content of the fuel and the fuel consumption of the engine. Scrubbing of IC engine exhausts to control SO_x emissions does not appear to be reasonable from an economic viewpoint. Therefore, the only viable means of controlling SO_x emissions would be combustion of low sulfur fuels. IC engines, however, currently burn low-sulfur fuels and will likely continue to do so because of the lower operating and maintenance costs associated with combustion of these fuels. Therefore, SO_x emissions were not selected for control by standards of performance.

Selection of Affected Facilities

A relatively small number of large-bore IC engines account for over 75 percent of all NO_x emissions from stationary engines. The remaining smaller bore IC engines, which make up the majority of all engine sales, are, from a NO_x emission standpoint, a considerably less significant segment of the industry. These engines have different emission characteristics due to their size, design, and operating parameters. The NO_x reduction technology developed for use on the large-bore IC engines may not be directly applicable to these smaller engines. Therefore, at this time, only large-bore engines have been selected for control by standards of performance.

Diesel engines.—The primary high usage (large emissions impact) domestic application of large-bore diesel engines during the past five years has been for oil and gas exploration and production. The market for prime (continuous) electric generation and other industrial applications all but disappeared after the 1973 oil embargo, but was quickly replaced by sales of standby electric units for building services, utilities, and nuclear power stations. The rapid growth in the oil and gas production market occurred because diesel units are being used on oil drilling rigs of various sizes. Sales of engines to export applications have also grown steadily since 1972, and are now a major segment of the entire sales market.

Medium-bore as well as large-bore engines are sold for oil and gas exploration, standby service, and other industrial applications. Applying standards of performance to medium-bore engines serving the same

applications as large-bore designs would increase the number of affected facilities from about 200 to about 2,000 units per year (based on 1976 sales information) but consequently further reduce national NO_x emissions. Medium-bore sales accounted for significant NO_x emissions in 1976 (approximately 12,500 megagrams). It is estimated that approximately 25 percent, or about 500 of these units in high usage applications, accounted for most of the medium-bore NO_x emissions, since most of the remainder of these units were sold as standby generator sets. Though the potential achievable NO_x reduction is significant, this alternative causes the standard to apply to lower power engine models with fewer numbers of cylinders competing with other unregulated engines in different stationary markets. Additionally, considering this large number, and the remoteness and mobility of petroleum applications, this alternative would create serious enforcement difficulties. Consequently, a definition is required that distinguishes large-bore engines competing with medium-bore high power engines used for baseload electrical generation from large-bore engines competing solely with other large-bore engines.

One approach would be to define diesel engines covered by standards of performance as those exceeding 560 cubic inch displacement per cylinder (i.e., CID/cyl). IC engines below this size are generally used for different applications than those above it. Considering the sizes and displacements offered by each diesel manufacturer and the applications served by diesel engines, this definition was selected as a reasonable approach for separating large-bore engines that compete with medium-bore engines from large-bore engines that compete solely with each other.

Dual-fuel engines.—The concept of dual-fuel operation was developed to take advantage of both compression ignition performance and inexpensive natural gas. These engines have been used almost exclusively for prime electric power generation. Shortages of natural gas and the 1973 oil embargo have combined to significantly reduce the sales of these engines in recent years. The few large-bore units that were sold (11 in 1976) were all greater than 350 CID/cyl.

Although a greater-than-350-CID/cyl limit would subject nearly all new dual-fuel sources to standards of performance, the criterion chosen to define affected diesel engines (i.e.,

greater than 560 CID/cyl) has also been selected for dual-fuel engines. The primary reason is that supplies of natural gas are likely to become even more scarce; thus dual-fuel engines will likely operate as diesel engines.

Gas engines.—The primary application of large-bore gas engines during the past five years has been for oil and gas production. The primary uses are to power gas compressors for recovery, gathering, and distribution. About 75 to 80 percent of all gas engine horsepower sold during the past five years was used for these applications. During this time, sales to pipeline transmission applications declined. Pipeline applications combined with standby power, electric generation, and other services (industrial and sewage pumping) accounted for the remaining 20 to 25 percent of horsepower sales. The growth of oil and gas production applications during this period corresponds to the increasing efforts to find new, or to recover marginal, gas reserves and distribute them to the existing pipeline transmission network.

It is estimated that the 400,000 horsepower of large-bore gas engine capacity sold for oil and gas production applications in 1976 emitted 35,000 megagrams of NO_x emissions, or nearly three times more NO_x than was emitted by the 200,000 horsepower of large-bore diesel engine capacity sold for the same application in that year. Thus, large-bore gas engines are primary contributors of NO_x emissions from new stationary IC engines, and standards of performance should be directed particularly at these sources.

If affected engines were defined as those greater than 350 CID/cyl, then all competing manufacturers of large-bore gas engines except one would be affected by the proposed standards of performance. This one manufacturer produces primarily medium-bore engines. Therefore, a 350 CID/cyl limit would give this one manufacturer an unfair competitive advantage over other large-bore engine manufacturers. Consequently, this definition should be lowered, or another definition adopted, to include the manufacturer in question. Either of the following two definitions would subject this manufacturer's gas engine to standards of performance:

- Greater than 240 CID/cyl
- Greater than 350 CID/cyl or greater than or equal to 8-cylinder and greater than 240 CID/cyl

Both measures would essentially include only this manufacturer's gas engines which compete with other manufacturer's large-bore gas engines. The second definition has a slight

advantage over the first since it includes only gas engines produced by all manufacturers that have competitor counterparts of about the same power. Therefore, this second definition of affected gas engines was selected.

Rotary engines.—Rotary or wankel type engines have only recently been introduced as power sources in package stationary applications. These internal combustion engines convert energy in the fuel directly to rotary motion rather than through reciprocating pistons and a crankshaft. These engines consist of a triangular rotor rotating eccentrically inside an epitrochoidal housing.

Until recently the largest rotary engine in production was 90 cubic inches per rotor. Now, however, one manufacturer is producing a rotary engine with a displacement of 2,500 cubic inches per rotor. This engine is being offered as a one rotor model rated at 550 horsepower and a two rotor unit rated at 1,100 horsepower.

The displacement of the rotary engine is defined as the volume contained in the chamber, bordered by one flank of the rotor and the housing, at the instant the inlet port closes. These engines are presently sold as naturally aspirated gaseous fueled units primarily for fuel gathering compressors and power generation on offshore platforms.

NO_x emissions from these large rotary engines are similar to NO_x emissions from naturally aspirated four stroke, gaseous fuel reciprocating engines. Further sales of these engines are estimated to be 50,000 horsepower per year over the next five years. Since these large rotary engines contribute to NO_x emissions, standards of performance for new stationary IC engines should include these sources.

Due to design differences, rotary engines develop more power per cubic inch displacement than reciprocating engines. If the lower cutoff limit for affected rotary engines were 350 CID/rotor—in an attempt to equate displacement per cylinder and also use the same limit as for gaseous fueled engines—then rotary engines of approximately 100 horsepower would be regulated by standards of performance. Thus rotary engine manufacturers would be at a competitive disadvantage with unregulated reciprocating engine manufacturers in this power range. To ensure that the standards of performance do not alter the competitive position of the two types of engines, the lower size limit for affected rotary engines should correspond to an engine whose power output is the same as the smallest affected reciprocating unit.

Based on this criterion of equivalent horsepower, it is estimated that rotary engines greater than 1,500 CID/rotor would compete with reciprocating engines greater than 350 CID/cyc. Therefore, a greater than 1,500 CID/rotor definition of affected rotary engines is selected to subject these engines to standards of performance. The definition applies to rotary engines of all fuel types.

Exemptions.—One and two cylinder reciprocating engines could be covered by the above definitions. These engines, however, account for less than 10 percent of all engine horsepower and therefore are less significant NO_x emitters. Additionally, the engines operate at a small fraction of their power output and probably have lower NO_x emissions than the larger, high rated engines. Therefore, all one and two cylinder reciprocating engines were exempted from standards of performance.

Emergency standby engines also require special consideration. These engines operate less than 200 hours per year under all but very unusual circumstances. Consequently, they add relatively little to regional or national total NO_x emissions. The largest category of emergency standby units is for nuclear power plants, where these engines provide power for the pumps used for cooling the reactors. These engines must attain a set speed in ten seconds and must assume full rated load in 30 seconds. In some cases, application of the demonstrated NO_x control technique limits the responsiveness of these engines in emergency situations. Therefore, all emergency standby engines are exempted from standards of performance.

Selection of Best System of Emission Reduction

Four emission control techniques, or combinations of these techniques, have been identified as demonstrated NO_x emission reduction systems for stationary large-bore IC engines. These techniques are: (1) Retarded ignition or fuel injection, (2) air-to-fuel ratio changes, (3) manifold air cooling, and (4) derating power output (at constant speed). In general, all four techniques are applied by changing an engine operating adjustment.

Fuel injection retard is the most effective NO_x control technique for diesel engines. Similarly, air-to-fuel ratio change is the most effective NO_x control technique for gas engines. Both retard and air-to-fuel ratio changes are

effective in reducing NO_x emissions from dual-fuel engines.

Other NO_x emission control techniques exist but are not considered feasible alternatives. Of these other techniques, catalytic reduction of NO_x emissions through the use of systems similar to automobile catalyst systems is probably the first to come to mind. Most large stationary IC engines operate at air-to-fuel ratios that are typically much greater than stoichiometric, and consequently the engine exhaust is characterized by high oxygen (O₂) concentrations. Existing automobile catalytic converters, however, operate near stoichiometric conditions (i.e., low exhaust O₂ concentrations). These automobile catalysts are not effective in reducing NO_x in the presence of high O₂ concentrations.

Consequently, entirely different catalyst systems would be needed to reduce NO_x emissions from large stationary IC engines. Although such catalyst systems are currently under development and have been demonstrated for one very narrow application (i.e., fuel-rich naturally aspirated gas engines), they have not been demonstrated for the broad range of IC engines manufactured, such as turbocharged engines, fuel-lean gas engines, or diesel engines. For these engines the reduction of NO_x by ammonia injection over a precious metal (e.g., platinum) catalyst appears promising with NO_x reductions of approximately 90 percent having been reported; however, the cost of such a system is high.

For a typical 1000 horsepower engine approximately two cubic feet of honeycomb catalyst (platinum based) would be required to ensure proper operation of the system. The cost of the catalyst was estimated at \$1,500/cubic foot (in 1973). Assuming that the engine costs \$150/hp and that the cost of the catalyst accounts for about one-half the cost of the whole system (container, substrate, and catalyst), the capital investment for this control system represents approximately four percent of the engine purchase price.

The amount of ammonia required for an ammonia/catalyst NO_x reduction system will depend on the NO_x emission rate (g/hp-hr). Based on uncontrolled NO_x emission rates of 9 to 22 g/hp-hr, and the cost of \$150/ton for the ammonia, the cost impact of injecting ammonia is approximately 5 to 15 percent of the total annual operating costs (\$/hp-hr) for natural gas engines. When this operating cost is combined with the capital cost of the catalytic system discussed above, the total cost

increase is about 25 percent. Therefore, in continuous service applications this system is expensive compared to control techniques such as retard or air-to-fuel changes.

It is also important to note that the consumption of ammonia can be expressed as a quantity of fuel since natural gas is generally used to produce ammonia. Assuming a conservative NO_x emission rate of 20 g/hp-hr, and engine heat rate of 7500 Btu/hp-hr, a heating value of 21,800 Btu/lb for natural gas, and a requirement for approximately 900 lbs of gas per ton of ammonia produced, then the ammonia necessary for the catalytic reduction has the same effect on the supply of natural gas as a two percent increase in fuel consumption. Additional fuel is required to operate the plant which produces the ammonia.

Catalytic reduction, therefore, is currently not a demonstrated NO_x emission control technique which could be used by all IC engines. Consequently, although catalytic reduction of NO_x emissions could be used in a few isolated cases to comply with standards of performance, it could not be used as the basis for developing standards of performance which are applicable to all IC engines.

The data and information presented in the Standards Support and Environmental Impact Statement clearly indicate that the four demonstrated control techniques mentioned above will reduce NO_x emissions from IC engines. Due to inherent differences in the uncontrolled emission characteristics of various engines, it is difficult to draw conclusions from this data and information concerning the ability of these emission control techniques to reduce NO_x emissions from all IC engines to a specific level. In general, engines with high uncontrolled NO_x emissions levels have relatively high controlled NO_x emissions levels and engines with low uncontrolled NO_x emissions levels have relatively low controlled NO_x emissions levels. To eliminate these inherent differences in NO_x emission characteristics among various engines, the data were analyzed in terms of the degree of reduction in NO_x emissions as a function of the degree of application of each emission control technique.

Ignition retard in excess of eight degrees in diesel engines frequently leads to unacceptably high exhaust temperatures, resulting in exhaust valve and/or turbocharger turbine damage. Similarly, changes in the air-to-fuel ratio in excess of five percent in gas engines frequently lead to excessive misfiring or detonation which could lead to a serious

explosion in the exhaust manifold. Eight degrees of ignition retard in diesel engines and five percent change in air-to-fuel ratios in gas engines yield about a 40 percent reduction in NO_x emissions. Consequently, in light of these limitations to the application of these emission control techniques, it is apparent that a 40 percent reduction in NO_x emissions is the most stringent regulatory option which could be selected as the basis for standards of performance. An alternative of 20 percent NO_x emission reduction was also considered a viable regulatory option which could serve as the basis for standards of performance.

Environmental impacts.—Standards of performance based on alternative I (20 percent reduction) would reduce national NO_x emissions by 72,500 megagrams annually in the fifth year after the standards went into effect. In contrast, standards of performance based on alternative II (40 percent reduction) would reduce national NO_x emissions by about 145,000 megagrams annually in the fifth year after the standards went into effect. Thus, standards of performance based on alternative II would have a much greater impact on national NO_x emissions than standards based on alternative I.

Standards of performance based on either alternative would, with the exception of naturally aspirated gas engines, result in a small increase in carbon monoxide (CO) and hydrocarbon emissions (HC) from most engines. A typical diesel engine with a sales-weighted average uncontrolled CO emission level of approximately 2.9 g/hp-hr would experience an increase in CO emissions of about 0.75 g/hp-hr to comply with standards of performance based on alternative I, and an increase of about 1.5 g/hp-hr to comply with standards of performance based on alternative II. Total hydrocarbon emissions would increase a sales-weighted average uncontrolled emission level of 0.3 g/hp-hr by about 0.06 g/hp-hr to comply with standards based on alternative I, and would increase by about 0.1 g/hp-hr to comply with standards of performance based on alternative II.

Similarly, a typical dual-fuel engine with a sales-weighted average uncontrolled CO emission level of approximately 2.7 g/hp-hr would experience an increase in CO emissions of about 1.2 g/hp-hr and about 2.7 g/hp-hr to comply with standards of performance based on alternatives I and II, respectively. Total HC emissions, however, would increase by about 0.3 g/hp-hr from a sales-weighted average

uncontrolled level of approximately 2.8 g/hp-hr to comply with standards of performance based on alternative I. To comply with standards of performance based on alternative II total hydrocarbon emissions would decrease by 0.6 g/hp-hr.

A typical turbocharged or blower scavenged gas engine with a sales-weighted average uncontrolled CO emission level of approximately 7.7 g/hp-hr would experience an increase in CO emissions of about 1.9 g/hp-hr to comply with standards of performance based on alternative I and about 3.8 g/hp-hr to comply with standards of performance based on alternative II. Total hydrocarbon emissions would increase a sales-weighted average uncontrolled level of approximately 1.9 g/hp-hr by about 0.2 g/hp-hr to comply with standards of performance based on alternative I. To comply with standards of performance based on alternative II total hydrocarbon emissions would increase by about 0.4 g/hp-hr.

A typical naturally aspirated gas engine with a sales-weighted average uncontrolled CO emission level of approximately 7.7 g/hp-hr would experience an increase in CO emissions of about 3.9 g/hp-hr to comply with standards of performance based on alternative I and about 17 g/hp-hr to comply with standards of performance based on alternative II. Total hydrocarbon emissions would increase a sales-weighted average uncontrolled level of approximately 1.8 g/hp-hr by about 0.04 g/hp-hr to comply with standards of performance based on alternative I. To comply with standards of performance based on alternative II total hydrocarbon emissions would increase by about 0.08 g/hp-hr.

As noted earlier, the increase in ambient air CO levels resulting from compliance with NO_x standards of performance based on either alternative would be insignificant compared to the NAAQS of 10 mg/m³ for CO. Additionally, CO emissions are a local problem as CO readily reacts to form CO_2 . Additionally, most naturally aspirated engines are operated in remote or sparsely populated areas, CO emissions will not present a problem.

Currently, national stationary CO emissions are approximately 33 million megagrams per year. Standards of performance based on alternative I would increase these emissions by approximately 63,000 megagrams annually in the fifth year after the standards went into effect. In contrast, standards of performance based on alternative II would increase national CO emissions by about 216,000

megagrams annually in the fifth year after the standards went into effect.

Standards of performance based on alternative I would increase national total HC emissions by about 2,200 megagrams annually in the fifth year after the standards went into effect compared to an increase of about 4,800 megagrams annually associated with alternative II. It is estimated that more than 90 percent of total HC emissions from large-bore gas-fuel engines and 75 percent of total HC emissions from large-bore dual-fuel engines are methane, which is nonreactive and does not lead to oxidant formation. Standards of performance based on alternative I would increase national reactive HC emissions by approximately 108 megagrams annually in the fifth year after the standards went into effect, compared to an increase of approximately 216 megagrams annually associated with alternative II.

Stationary IC engines are sources of NO_x, HC, and CO emissions, with both NO_x and HC contributing to oxidant formation. With regard to regulation of emissions from IC engines, NO_x emissions are of more concern than emissions of HC for two reasons. First, NO_x is emitted in greater quantities from stationary IC engines than HC. Second, as mentioned earlier, a high priority has been assigned to development of standards of performance limiting NO_x emissions. A study by Argonne National Laboratory, "Priorities and Procedures for development of Standards of Performance for New Stationary Sources of Atmospheric Emissions," concluded that national NO_x emissions from stationary sources would increase by more than 40 percent between 1975 and 1990 in the absence of additional emission controls. The slight increase in HC emissions from IC engines associated with control of NO_x can be offset in most cases from other sources more easily than NO_x emissions can be reduced from other sources. Therefore, the adverse environmental impact of increased HC emissions because of the reduction in NO_x emissions is considered small.

There would be essentially no water pollution, solid waste, or noise impact of standards of performance based on either alternative I or alternative II.

Thus, as reflected in Table I, the environmental impacts of standards of performance based on either alternative are small and reasonable

TABLE I
ENVIRONMENTAL IMPACTS OF ALTERNATIVES

Pollutant	Base Level ^a	Alternative I	Alternative II
National NO _x Emissions	14.6 x 10 ⁶ megagrams	Reduced by 72,500 megagrams annually in the fifth year after standard goes into effect	Reduced by 145,000 megagrams annually in the fifth year after standard goes into effect
National CO Emissions	33.0 x 10 ⁶ megagrams	Increased by 63,000 megagrams annually in the fifth year after standard goes into effect	Increased by 216,000 megagrams annually in the fifth year after standard goes into effect
National Total HC Emissions	10.2 x 10 ⁶ megagrams	<p><u>Total Hydrocarbons</u> Increased by 2,300 megagrams annually in the fifth year after standard goes into effect</p> <p><u>Reactive Hydrocarbons</u> Increased by 108 megagrams annually in the fifth year after standard goes into effect</p>	<p><u>Total Hydrocarbons</u> Increased by 4,600 megagrams annually in the fifth year after standard goes into effect</p> <p><u>Reactive Hydrocarbons</u> Increased by 216 megagrams annually in the fifth year after standard goes into effect</p>
Water Pollution	--	No increase	No increase
Solid Waste	--	No increase	No increase
Noise	--	No adverse impact	No adverse impact

^aTotal U.S. emission from stationary sources as per EPA Nationwide Air Pollutant Inventory for 1975

Energy impacts. The potential energy impact of standards of performance based on either alternative is small. Standards of performance based on alternative I would increase the fuel consumption of a typical blower-scavenged or turbocharged gas engine by approximately one percent, whereas standards of performance based on alternative II would increase the fuel consumption by approximately two percent.

Standards of performance based on alternative I would increase the fuel consumption of a typical dual-fuel engine by about one percent. Standards of performance based on alternative II, however, would increase the fuel consumption by three percent. Standards of performance based on alternative I would increase the fuel consumption of a typical naturally aspirated gas engine by approximately six percent. Standards of performance based on alternative II, however, would increase the fuel consumption by approximately eight percent.

Standards of performance based on alternative I would increase the fuel consumption of a typical diesel engine by approximately three percent. Standards of performance based on alternative II, however, would increase the fuel consumption by approximately seven percent.

The potential energy impact in the fifth year after the standards go into effect, based on alternative I, would be equivalent to an increase in fuel consumption of approximately 1.03 million barrels of oil per year compared to the uncontrolled fuel consumption of IC engines affected by the standards of 31 million barrels per year. The potential energy impact in the fifth year after the standard goes into effect, based on alternative II, would be equivalent to approximately 1.5 million barrels of oil per year.

It should be noted that the largest increase represents only 0.02 percent of the 1977 domestic consumption of crude oil and natural gas. The largest increase also represents only 0.03 percent of the projected total oil imported to the U.S. five years after the standards go into effect.

Thus, the energy impacts of standard of performance based on either alternative are small and reasonable.

Economic impact of alternatives. Manufacturers of stationary IC engines would incur additional costs due to standards of performance. These costs, however, would be small. It is estimated that the total cost to the manufacturers for each engine model family, including development, durability tests, and

retooling, would be approximately: (1) \$125,000 for retard and air-to-fuel change; (2) \$150,000 for manifold air temperature reduction; and (3) \$25,000 for derate. For each manufacturer therefore, total costs would vary depending on (1) the number of engine model families produced; (2) their degree of advancement in emission testing; (3) the uncontrolled emission levels of their engines; (4) the development and durability testing required to produce engines that can meet proposed standards of performance; and (5) the emission control technique selected for NO_x emission reduction.

The manufacturer's total capital investment requirements for developmental testing of engine models is estimated to be about \$4.5 million to comply with standards of performance based on alternative I and about \$5 million to comply with standards of performance based on alternative II. These expenditures would be made over a two year period. Analyses of the financial statements and other public financial information of engine manufacturers or their parent companies indicate that the manufacturer's overhead budgets are sufficient to support the development of these controls without adverse impact on their financial position.

Manufacturers would not experience significant differential cost impacts among competing engine model families. Consequently, no significant sales advantages or disadvantages would develop among competing manufacturers as a result of standards of performance based on either alternative. Based on "worst-case" assumptions, the maximum intra-industry sales losses would be about six percent as a result of standards of performance based on either alternative. Thus, the intra-industry impacts would be moderate and not cause any major dislocations within the industry.

The total annualized cost penalties imposed on IC engines by standards of performance would also have very little impact with regard to increasing sales of gas turbines. Standards of performance based on alternative I would result in no loss of sales to gas turbines whereas standards of performance based on alternative II could result in the possible loss of sales for one diesel manufacturer.

It should be noted that this conclusion is based on limited data. It is quite likely, however, that this manufacturer's line of diesel engines, through minor combustion modifications, could reduce its NO_x emissions as discussed in the

SSEIS to levels comparable to those of other manufacturers. Further, due to technical limitations, economic considerations, and customer preference, it is unlikely that IC engine users would switch to gas turbines. Thus, the impact on sales would be minimal.

Therefore, the economic impacts on the manufacturers of standards of performance based on either alternative are considered small and reasonable.

The application of NO_x controls will also increase costs to the engine user. The magnitude of this increase will depend upon the amount and type of emission control applied. Fuel penalties are the major factor affecting this increase.

The following four end uses represent the major applications of diesel, dual-fuel, and natural gas engines: (1) Diesel engine, electrical generation; (2) dual-fuel engine, electrical generation; (3) gas engine, oil and gas transmission and (4) gas engine, oil and gas production.

The manufacturers' capital budget requirements to develop and test engine NO_x control techniques would be regarded as an added expense and most likely passed on to the engine users in the form of higher prices. Therefore, users of IC engines would have to expend additional capital to purchase more expensive engines. This capital cost penalty, however, is small. A two percent increase in engine price would be expected on the average as the result of standards of performance based on either alternative. Typical initial costs for uncontrolled diesel and dual-fuel, electrical generation engines, and natural gas oil and gas transmission engines are about \$150/hp. Initial costs for gas, gas production engines are about \$50/hp.

The total additional capital cost for all users would equal about \$9.6 million on a cumulative basis over the first five years to comply with standards of performance based on either alternative.

As mentioned earlier, fuel penalties are the major factor affecting the total annualized cost of high usage engines. The total annualized cost of a typical uncontrolled diesel, electrical generation engine is about 2.5¢/hp-hr. As a result of standards of performance based on alternative I this total annualized cost would increase by about 0.04¢/hp-hr (1.5 percent). As a result of standards of performance based on alternative II this total annualized cost would increase by about 0.11¢/hp-hr (4.5 percent).

The total annualized cost of a typical uncontrolled dual-fuel electrical generation engine is about 2.8¢/hp-hr. As a result of standards of performance

base on alternative II this total annualized cost would increase by about 0.07¢/hp-hr (2.5 percent). As a result of standards of performance based on alternative II this total annualized cost would increase by about 0.09¢/hp-hr (3.2 percent).

The total annualized cost of a typical uncontrolled gas, oil and gas transmission engine is about 2.2¢/hp-hr. As a result of standards of performance based on alternative I this total annualized cost would increase by about 0.02¢/hp-hr (1 percent). As a result of standards of performance based on alternative II this total annualized cost would increase by about 0.04¢/hp-hr (2 percent).

The total annualized cost of a typical uncontrolled gas, oil and gas production engine is about 2.2¢/hp-hr. As a result of standards of performance based on alternative I this total annualized cost would increase by about 0.14¢/hp-hr (6.5 percent). As a result of standards of performance based on alternative II this total annualized cost would increase by about 0.16¢/hp-hr (7.5 percent).

Thus, the total annualized cost penalties to the user associated with either alternative are small. Total uncontrolled annualized costs of about \$580 million by all large stationary IC engine users would increase by about \$25 million to comply with standards of performance based on alternative I and would increase by about \$32 million to comply with standards of performance based on alternative II in the fifth year after the standards go into effect.

The economic impacts on users arising from the cost penalties outlined above would be small. In general, these impacts translate into price increases for the end products or services provided by the industrial and commercial users of large stationary IC engines. The electric utility industry would pass on a price increase after five years of 0.02 percent to comply with standards of performance based on either alternative. After five years, delivered natural gas prices would increase 0.02 percent if standards of performance based on alternative I were applied and 0.04 percent if standards of performance based on alternative II were applied.

Even after a full phase-in period of 30 years, during which new controlled engines would replace all existing uncontrolled engines, the electric utility industry would realize a price increase of only 0.1 percent to comply with standards of performance based on either alternative. Similarly, delivered natural gas prices would increase only 0.1 percent if standards of performance based on alternative I were applied and

0.3 percent if standards of performance based on alternative II were applied. Thus, as summarized in Table II, the economic impacts of standards of performance based on either alternative are considered small and reasonable.

TABLE II
ECONOMIC IMPACTS OF ALTERNATIVES

Impact	Uncontrolled Level of Cost	Alternative I	Alternative II
<u>Impact on Manufacturer</u>			
Capital budget requirements	--	\$4.5 million over two years; able to generate internally from profits.	\$5 million over two years; able to generate internally from profits.
Intra-industry competition	--	Maximum sales loss unlikely to exceed 6% of internal combustion engine sales for any firm.	6% maximum loss for any firm
Competition from gas turbines	--	No losses.	Possible sales loss for one diesel manufacturer.
<u>Impact on End-Use Applications</u>			
Total annualized cost ^a			
Diesel fuel, electrical generation	2.5¢/hp-hr	Base increased by 0.04¢/hp-hr	Increased by 0.11¢/hp-hr
Dual-fuel, electrical generation	2.8¢/hp-hr	Increased by 0.07¢/hp-hr	Increased by 0.09¢/hp-hr
Natural gas fuel, oil and gas transmission	2.2¢/hp-hr	Increased by 0.02¢/hp-hr	Increased by 0.04¢/hp-hr
Natural gas fuel, oil and gas production	2.2¢/hp-hr	Increased by 0.14¢/hp-hr	Increased by 0.16¢/hp-hr
Totals of all new engines after 5 years	\$580 million	Increased by \$25 million	Increased by \$32 million
Capital Cost Penalty ^a			
Diesel fuel, electrical generation or dual fuel, electrical generation or natural gas fuel, oil and gas transmission	\$150/hp	Increased by \$3.00/hp	Increased by \$3.00/hp
Natural gas fuel, oil and gas production	\$ 50/hp	Increased by \$1.00/hp	Increased by \$1.00/hp
Totals etc.	\$450 million	\$9.6 million on a cumulative basis over first 5 years after standards go into effect.	\$9.6 million on a cumulative basis over first 5 years after standards go into effect.
<u>Impact on Product Prices and Users</u>			
Electricity prices	--	U.S. electric bill up 0.02% after 5 years. U.S. electric bill up 0.1% after full phase-in.	U.S. electric bill up 0.02% after 5 years. U.S. electric bill up 0.1% after full phase-in.
Gas prices	--	Delivered natural gas prices up 0.02% after 5 years. Delivered natural gas prices up 0.1% after full phase-in.	Delivered natural gas prices up 0.04% after 5 years. Delivered natural gas prices up 0.1% full phase-in.

Assumed typical 2000 horsepower engine operating 8000 hours per year in all cases
Full phase-in implies replacement of all existing engines

Based on the assessment of the impacts of each alternative, and since alternative II achieves a greater degree of NO_x reduction, it is selected as the best technological system of continuous emission reduction of NO_x from stationary large-bore IC engines, considering the cost of achieving such emission reduction, any nonair quality health and environmental impact, and energy requirements.

Selection of Format for the Proposed Standards

A number of different formats could be used to limit NO_x emissions from large stationary IC engines. Standards could be developed to limit emissions in terms of: (1) Percent reduction; (2) mass emissions per unit of energy (power) output; or (3) concentration of emissions in the exhaust gases discharged to the atmosphere.

Analysis of the effectiveness of the various NO_x emission control techniques clearly shows that the ability to achieve a percent reduction in NO_x emissions is what has been demonstrated. However, a percent reduction format is highly impractical for two reasons. First, a reference uncontrolled NO_x emission level would have to be established for each manufacturer's engine, a difficult task since some manufacturers produce as many as 25 models which are sold with several ratings. Second, a reference uncontrolled NO_x emission level would have to be established for any new engines developed after promulgation of the standard. This would be quite simple for engines that employed NO_x control techniques such as ignition retard or air-to-fuel ratio change to comply with standards of performance. Emissions could be measured without the use of these techniques. For engines designed to comply with the standards through the use of combustion chamber modifications, however, this would not be possible. Thus, new engines would receive no credit for the NO_x emission reduction achieved by combustion chamber redesign and this would effectively preclude the use of this approach to comply with the standards.

A mass-per-unit-of-energy-output format, typically referred to as brake-specific emissions (g/hp-hr), relates the total mass of NO_x emissions to the engine's productivity. Although brake-specific mass standards (g/hp-hr) appear meaningful because they relate directly to the quantity of emissions discharged into the atmosphere, there are disadvantages in that enforcement of mass standards would be costly and complicated in practice. Exhaust flow and power output would have to be

determined in addition to NO_x concentration. Power output can be determined from an engine dynamometer in the laboratory, but dynamometers cannot be used in the field. Power output could be determined by: (1) Inferring the power from engine operating parameters (fuel flow, rpm, manifold pressure, etc.); or (2) inferring engine power from the output of the generator or compressor attached to the engine. In practice, however, these approaches are time consuming and are less accurate than dynamometer measurements.

Another possible format would be to limit the concentration of NO_x emissions in the exhaust gases discharged to the atmosphere. Concentrations would be specified in terms of parts-per-million volume (ppm) of NO_x. The major advantage of this format is its simplicity of enforcement. As compared to the formats discussed previously, only a minimum of data and calculations are required, which decreases testing costs and minimizes errors in determining compliance with an emission standard since measurements are direct.

The primary disadvantages associated with concentration standards are: (1) A standard could be circumvented by dilution of exhaust gases discharged into the atmosphere, which lowers the concentration of pollutant emissions but does not reduce the total pollutant mass emitted; and (2) a concentration standard could penalize high efficiency engines. Both these problems, however, can be overcome through the use of appropriate "correction" factors.

Since the percent reduction format is impractical, and the problems associated with the enforcement of mass standards (mass-per-unit energy output) appear to outweigh the benefits, the concentration format was selected for standards of performance for large stationary IC engines.

As mentioned above, because a concentration standard can be circumvented by dilution of the exhaust gases, measured concentrations must be expressed relative to some fixed dilution level. For combustion processes, this can be accomplished by correcting measured concentrations to a reference concentration of O₂. The O₂ concentration in the exhaust gases is related to the excess (or dilution) air. Typical O₂ concentrations in large-bore IC engines can range from 8 to 16 percent but are normally about 15 percent. Thus, referencing the standard to a typical level of 15 percent O₂ would prevent circumvention by dilution.

As also mentioned above, selection of a concentration format could penalize

high efficiency IC engines. These highly efficient engines generally operate at higher temperature and pressures and, as a result, discharge gases with higher NO_x concentrations than less efficient engines, although the brake-specific mass emissions from both engines could be the same. Thus, a concentration standard based on low efficiency engines could effectively require more stringent controls for high efficiency engines. Conversely, a concentration standard based on high efficiency engines could allow such high NO_x concentrations that less efficient engines would require no controls. Consequently, selecting a concentration format for standards of performance requires an efficiency adjustment factor to permit higher NO_x emissions from more efficient engines.

The incentive for manufacturers to increase engine efficiency is to lower engine fuel consumption. Therefore, the objective of an efficiency adjustment factor should be to give an emissions credit for the lower fuel consumption of more efficient IC engines. Since the fuel consumption of IC engines varies linearly with efficiency, a linear adjustment factor is selected to permit increased NO_x emissions from highly efficient IC engines.

The efficiency adjustment factor needs to be referenced to a baseline efficiency. Most large existing stationary IC engines fall in the range of 30 to 40 percent efficiency. Therefore, 35 percent is selected as the baseline efficiency.

The efficiency adjustment factor included in the proposed standards permits a linear increase in NO_x emissions for engine efficiencies above 35 percent. This adjustment would not be used to adjust the emission limit downward for IC engines with efficiencies of less than 35 percent. This efficiency adjustment factor also applies only to the IC engine itself and not the entire system of which the engine may be a part. Since Section 111 of the Clean Air Act requires the use of the best system of emission reduction in all cases, this precludes the application of the efficiency adjustment factor to an entire system. For example, IC engines with waste heat recovery may have a higher overall efficiency than the IC engine alone. Thus, the application of the efficiency adjustment factor to the entire system would permit greater NO_x emissions because of the system's higher overall efficiency, and would not necessarily require the use of the best demonstrated system emission reduction on the IC engine.

Selection of Numerical Emission Limits

Overall approach.—As mentioned earlier it is difficult to select a specific NO_x emission limit which all IC engines could meet primarily through the use of ignition retard or air-to-fuel ratio change. Because of inherent differences among various IC engines with regard to uncontrolled NO_x emission levels, there exists a rather large variation within the data and information included in the Standards Support and Environmental Impact Statement concerning controlled NO_x emission levels. Generally speaking, engines with relatively low uncontrolled NO_x emissions levels achieved low controlled NO_x emissions levels and engines with high uncontrolled NO_x emissions levels achieved relatively high controlled NO_x emissions levels. Consequently, the following alternatives were considered for selecting the numerical concentration emission limits based on a 40 percent reduction in NO_x emissions:

1. Apply the 40 percent reduction to the highest observed uncontrolled NO_x emission level.
2. Apply the 40 percent reduction to a sales-weighted average uncontrolled NO_x emission level.
3. Apply the 40 percent reduction to this sales-weighted average uncontrolled NO_x emission level plus one standard deviation.

The highest observed uncontrolled NO_x emission levels for gas, dual-fuel and diesel engines are as follows: (1) Gas, 29 g/hp-hr. (2) dual-fuel, 15 g/hp-hr. and (3) diesel, 19 g/hp-hr.

Sales-weighted uncontrolled NO_x emission levels were determined by applying a sales-weighting to each manufacturer's average uncontrolled NO_x emissions for engines of each fuel type. The sales-weighting, based on horsepower sold, gives more weight to those engine models which have the highest sales. The sales-weighted average uncontrolled NO_x emission level for each engine fuel type are as follows: (1) Gas, 15 g/hp-hr. (2) dual-fuel, 8 g/hp-hr. and (3) diesel, 11 g/hp-hr.

The third alternative incorporates a "margin for engine variability" by adding one standard deviation to the sales-weighted average uncontrolled NO_x emission level and then applying the 40 percent reduction. Standard deviations were calculated from the uncontrolled NO_x emission data included in the Standards Support and Environmental Impact Statement, assuming the data had normal distribution. A subsequent statistical evaluation of the data indicated that this assumption was valid: The standard

deviations for each engine fuel type are as follows: (1) Gas, 4 g/hp-hr. (2) dual-fuel, 3.2 g/hp-hr. and (3) diesel, 3.7 g/hp-hr.

The standard deviation of the uncontrolled NO_x emission data base is relatively large compared to the sales-weighted average uncontrolled NO_x emission level for each engine type. This indicates that the distribution of uncontrolled NO_x emissions levels is quite broad. In addition, the standard deviation is of the same magnitude as the 40 percent reduction in NO_x emissions that can be achieved. Thus, regardless of which alternative approach is followed to select the numerical NO_x concentration emission limit, a significant portion of the IC engine population may have to achieve more or less than a 40 percent reduction in NO_x emissions to comply with the standards.

It is important to note that the 40 percent reduction in NO_x emissions is based on the application of a single control technique, such as ignition retard, or air-to-fuel ratio change. Other emission control techniques, however, such as manifold air cooling and engine derate, exist, although they are generally not as effective in reducing NO_x emissions. Since emission control techniques are additive to some extent, it is possible in a number of cases to reduce NO_x emissions by greater than 40 percent.

The following factors were examined for each engine type to choose the alternative for selecting the numerical NO_x concentration emission limit: (1) The percentage of engines that would have to reduce NO_x emissions by 40 percent or less to meet the standards; (2) the percentage of engines that would be required to do nothing to meet the standards; and (3) the percentage of engines that would be required to reduce NO_x emissions by more than 40 percent to meet the standards. The normal distribution curve presented in Figure 1 illustrates the trade-offs among the three alternatives for selecting the numerical NO_x concentration emission limit.

The first alternative is to apply the 40 percent reduction to the highest uncontrolled NO_x emission level within a fuel category. For example, 29 g/hp-hr is the highest uncontrolled NO_x emission level for gas engines. The application of a 40 percent reduction would lead to an emission level of about 17 g/hp-hr. As illustrated in Figure 1, if this level were selected as a standard of performance, 99 percent of production gas engines could easily meet the emission limit by reducing emissions by 40 percent or less.

However, 69 percent of production engines would not have to reduce NO_x emissions at all. Only one percent of production engines would have to reduce NO_x emissions by more than 40 percent.

FIGURE 1. Statistical effects of alternative emission limits on gas engines.

The second alternative is to apply 40 percent reduction to the sales-weighted average uncontrolled NO_x emission level. For example, the sales-weighted average uncontrolled NO_x level for gas engines is 15 g/hp-hr. The application of a 40 percent reduction would lead to a NO_x emission level of 9 g/hp-hr. As illustrated in Figure I, if this level were selected as a standard of performance, 50 percent of production gas engines could meet the standard with 40 percent or less reduction in NO_x emissions. However, 50 percent of production gas engines would be required to reduce NO_x emissions by greater than 40 percent. Only seven percent of production gas engines would not have to reduce NO_x emissions at all.

The third alternative is to base the standards on a 40 percent reduction in NO_x emissions from the sales-weighted average uncontrolled NO_x emission level plus one standard deviation. For example, the sales-weighted average uncontrolled NO_x emission level for gas production gas engines is 15 g/hp-hr and the standard deviation of the production gas engine data base is 4 g/hp-hr. Thus, the application of a 40 percent reduction to the sum of these two values would lead to an emission level of 11 g/hp-hr. As illustrated in Figure I, if this level were selected as a standard of performance, 84 percent of the production gas engines could easily meet the emission limit by reducing emissions by 40 percent or less. However, 18 percent of the production gas engines would not have to reduce NO_x emission at all. Only 16 percent of the production gas engines would have to reduce NO_x emissions by more than 40 percent.

This same analysis applied to dual-fuel and diesel engines leads to the results summarized in Table III. If standards of performance were based on Alternative I, essentially all engines could achieve the emission limit by reducing NO_x emissions 40 percent or less. A significant reduction in NO_x emissions would not be achieved, however, since 50 to 70 percent of the IC engines would not have to reduce NO_x emissions at all. If the standards of performance were based on Alternative II, about 50 percent of the IC engines (in all categories) would have to reduce NO_x emissions by greater than 40 percent. Less than 10 percent would not have to reduce NO_x emissions at all. Thus this alternative would achieve a significant reduction in NO_x emissions from new sources. If standards of performance were based on Alternative III, the results would be similar to those achieved with Alternative I. About 85

percent of engines could easily meet the standards by reducing NO_x emissions by less than 40 percent. About 20 to 30 percent of IC engines would not have to reduce NO_x emissions at all, and about 15 percent of IC engines would have to reduce NO_x emissions by more than 40 percent.

In light of the high priority which has been given to standards directed toward reducing NO_x emissions and the significance of IC engines in terms of their contribution to NO_x emissions from stationary sources, the second alternative was chosen for selecting the NO_x emission concentration limit. This approach will achieve the greatest reduction in NO_x emissions from new IC engines.

TABLE III
SUMMARY OF STATISTICAL ANALYSES OF ALTERNATE EMISSION LIMITS

GAS ENGINES

Alternative	I	II	III
Standard	17	9	11
Percent required to apply less than or equal to 40 percent control	99	50	84
Percent required to do nothing	69	7	18
Percent required to apply more than 40 percent control	1	50	16

DUAL-FUEL ENGINES

Alternative	I	II	III
Standard	9	5	7
Percent required to apply less than or equal to 40 percent control	98	54	87
Percent required to do nothing	62	18	48
Percent required to apply more than 40 percent control	2	46	13

DIESEL ENGINES

Alternative	I	II	III
Standard	11	7	9
Percent required to apply less than or equal to 40 percent control	98	56	86
Percent required to do nothing	50	4	29
Percent required to apply more than 40 percent control	2	44	14

Selection of limits.—A concentration (ppm) format was selected for the standards. Consequently, the brake-specific NO_x emission limits corresponding to the second alternative for selecting numerical emission limits (i.e., gas – 9 g/hp-hr; dual-fuel – 5 g/hp-hr; diesel – 7 g/hp-hr) must be converted to concentration limits (corrected to 15 percent O₂ on a dry basis). This may be done by dividing the brake-specific volume of NO_x emissions by the brake-specific total exhaust gas volume. Determining the brake-specific volume of NO_x emissions is straight-forward. Determining the brake-specific total exhaust gas volume is more complex, in that the brake-specific exhaust flow and the exhaust gas molecular weight are unknown. Knowing the fuel heating value and composition, the brake-specific fuel consumption, and assuming 15 percent excess air, however, defines these unknowns. (The complete derivation is explained in detail in the Standards Support and Environmental Impact Statement.) Combining these factors leads to the following conversion factor:

$$NO_x = \frac{\left(\frac{10^6}{46}\right) \times (BSNO_x)}{\left(\frac{16.6 + 3.29Z}{12.0 + Z}\right) \times (BSFC)}$$

where:

NO_x = NO_x concentration (ppm) corrected to 15 percent O₂.

BSNO_x = Brake-specific NO_x emissions, g/hp-hr.

BSFC = Brake-specific fuel consumption, g/hp-hr.

Z = Hydrogen/Carbon ratio of the fuel.

For natural gas, a hydrogen-to-carbon (H/C) ratio of 3.5 and a lower heat value (LHV) of 20,000 Btu/lb was assumed. Diesel ASTM-2 has a H/C ratio of 1.8 and a LHV of 18,320 Btu/lb.

Applying this conversion factor to the brake-specific emission limits associated with the second alternative for selecting NO_x emissions limits leads to the NO_x concentration emission limits included in the proposed standards:

Engine:	NO _x emission limit
Gas.....	700 ppm.
Dual-fuel/Diesel.....	600 ppm.

These emission limits have been rounded upward to the nearest 100 ppm to include a "margin" to allow for source variability. The standard for diesel engines has also been applied to dual-fuel engines. If a separate emission limit has been selected for dual-fuel engines, the corresponding numerical NO_x

concentration emission limit would be 400 ppm. Sales of dual-fuel engines, however, have ranged from 17 to 95 units annually over the past five years, with a general trend of decreasing sales. Dual-fuel engines serve the same applications as diesel engines, and new dual-fuel engines will likely operate primarily as diesel engines because of increasingly limited natural gas supplies. Thus, the combining of dual-fuel engines with diesel engines for standards of performance will have little adverse impact and will simplify enforcement of the standards of performance.

The effect of ambient atmospheric conditions on NO_x emissions from large stationary IC engines can be significant. Therefore, to enforce the standards uniformly, NO_x emissions must be determined relative to a reference set of ambient conditions. All existing ambient correction factors were reviewed that could potentially be applied to large stationary IC engines to correct NO_x emissions to standard conditions.

The correction factors that were selected for both spark ignition (SI) and compression ignition (CI) engines are included in the proposed standards. For the compression ignition engines (i.e., diesel and dual-fuel), a single correction factor for both temperature and humidity was selected. For spark ignition engines (i.e., gas), separate correction factors were selected for humidity and temperature, and measured NO_x emissions are corrected to reference ambient conditions by multiplying these two factors together. No correction factor was selected for changes in ambient pressure because no generalized relationship could be determined from the very limited data that are available. These correction factors represent the general effects of ambient temperature and relative humidity on NO_x emissions, and will be used to adjust measured NO_x emissions during any performance test to determine compliance with the numerical emission limit.

Since the recommended factors may not be applicable to certain engine models, as an alternative to the use of these correction factors, engine manufacturers, owners, or operators may elect to develop their own ambient correction factors. All such correction factors, however, must be substantiated with data and then approved by EPA for use in determining compliance with NO_x emission limits. The ambient correction factor will be applied to all performance tests, not only those in which the use of such factors would reduce measured emission levels.

As discussed in "Standards Support and Environmental Impact Statement: Proposed Standards of Performance for Stationary Gas Turbines," EPA-450/2-77-017a, the contribution to NO_x emissions by the conversion of fuel-bound nitrogen in heavy fuel to NO_x can be significant for stationary gas turbines. The organic NO_x contribution to total gas turbine NO_x emissions is complicated by the fact that the percentage of fuel-bound nitrogen converted to NO_x decreases as the fuel-bound nitrogen level increases. Below a fuel-bound nitrogen level of about 0.05 percent, essentially 100 percent of the fuel-bound nitrogen is converted to NO_x. Above a fuel-bound nitrogen level of about 0.4 percent, only about 40 percent is converted to NO_x.

As discussed in the Standards Support and Environmental Impact Statement, Volume I for Stationary Gas Turbines, assuming a fuel with 0.25 percent weight fuel-bound nitrogen (which allows approximately 50 percent availability of domestic heavy fuel oil), controlled NO_x emissions would increase by about 50 ppm due to the contribution to NO_x emissions of fuel-bound nitrogen. In gas turbines, this contribution was significant when compared to the proposed emission limit of 75 ppm. However, for large IC engines, the contribution of fuel-bound nitrogen to NO_x emissions is likely to be small (approximately 10 percent). Sales of IC engines firing heavy fuels is insignificant and not expected to increase in the near future. Given that the emission limits have been rounded upward to the nearest 100 ppm and the potential contribution of fuel-bound nitrogen to NO_x emissions is very small, no allowance has been included for the fuel-bound nitrogen content of the fuel in determining compliance with the standards of performance.

Selection of Compliance Time Frame

Manufacturers of large-bore IC engines are generally committed to a particular design approach and, therefore, conduct extensive research, development, and prototype testing before releasing a new engine model for sale. Consequently, these manufacturers will require some period of time to alter or reoptimize and test IC engines to meet standards of performance. The estimated time span between the decision by a manufacturer to control NO_x emissions from an engine model and start of production of the first controlled engine is about 15 months for any of the four demonstrated emission control techniques. With their present facilities, however, testing can typically

be conducted on only two to three engine models at a time. Since most manufacturers produce a number of engine models, additional time is required before standards of performance become effective. In addition, a number of manufacturers produce their most popular engine models at a fairly steady rate of production and satisfy fluctuating demands from inventory. Consequently, additional time is necessary to allow manufacturers to sell their current inventory of uncontrolled IC engines before they must comply with standards of performance.

It is estimated that about 30 months delay in the applicability date of the standard is appropriate to allow manufacturers time to comply with the proposed standards of performance. In addition, in light of the stringency of the standards (i.e., many engine models will have to reduce NO_x emissions by more than 40 percent) this time period provides the flexibility for manufacturers to develop and use combinations of the control techniques upon which the standards are based or other control techniques. Consequently, 30 months from today's date is selected as the delay period for implementation of these standards on large stationary IC engines.

Selection of Monitoring Requirements

To provide a means for enforcement personnel to ensure that an emission control system installed to comply with standards of performance is properly operated and maintained, monitoring requirements are generally included in standards of performance. For stationary IC engines, the most straightforward means of ensuring proper operation and maintenance would be to monitor NO_x emissions released to the atmosphere.

Installed costs, however, for continuous monitors are approximately \$25,000. Thus the cost of continuous NO_x emission monitoring is considered unreasonable for IC engines since most large stationary IC engines cost from \$50,000 to \$3,000,000 (i.e., 1000 hp gas production engine and 20,000 hp electrical generation engine).

A more simple and less costly method of monitoring is measuring various engine operating parameters related to NO_x emissions. Consequently, monitoring of exhaust gas temperature was considered since this parameter could be measured just after the combustion process during which NO_x is formed. However, a thorough investigation of this approach showed

no simple correlation between NO_x emission and exhaust gas temperature.

A qualitative estimate of NO_x emissions, however, can be developed by measuring several engine operating parameters simultaneously, such as spark ignition or fuel injector timing, engine speed, and a number of other parameters. These parameters are typically measured at most installations and thus should not impose an additional cost impact. For these reasons, the emission monitoring requirements included in the proposed standards of performance require monitoring various engine operating parameters.

For diesel and dual-fuel engines, the engine parameters to be monitored are: (1) Intake manifold temperature; (2) intake manifold pressure; (3) rack position; (4) fuel injector timing; and (5) engine speed. Gas engines would require monitoring of (1) intake manifold temperature; (2) intake manifold pressure; (3) fuel header pressure; (4) spark timing; and (5) engine speed.

Another parameter that could be monitored for gas engines is the fuel heat value, since it can affect NO_x emissions significantly. Because of the high costs of a fuel heating value monitor, and the fact that many facilities can obtain the lower heating value directly from the gas supplier, monitoring of this parameter would not be required.

The operating ranges for each parameter over which the engine could operate and in which the engine could comply with the NO_x emission limit would be determined during the performance test. Once established, these parameters would be monitored to ensure proper operation and maintenance of the emission control techniques employed to comply with the standards of performance.

For facilities having an operator present every day these operating parameters would be recorded daily. For remote facilities, where an operator is not present every day, these operating parameters would be recorded weekly. The owner/operator would record the parameters and, if these parameters include values outside the operating ranges determined during the performance test, a report would be submitted to the Administrator on a quarterly basis identifying these periods as excess emissions. Each excess emission report would include the operating ranges for each parameter as determined during the performance test, the monitored values for each parameter, and the ambient air conditions.

Selection of Performance Test Method

A performance test method is required to determine whether an engine complies with the standards of performance. Reference Method 20, "Determination of Nitrogen Oxides, Sulfur Dioxide, and Oxygen emissions from Stationary Gas Turbines," which was proposed in the October 3, 1977 Federal Register, is proposed as the performance test method for IC engines. Reference Method 20 has been shown to provide valid results. Consequently, rather than developing a totally new reference test method, Reference Method 20 would be modified for use on IC engines.

The changes and additions to Reference Method 20 required to make it applicable for testing of internal combustion engines include (by section):

1. *Principle and Applicability.* Sulfur dioxide measurements are not applicable for internal combustion engine testing.

6.1 Selection of a sampling site and the minimum number of traverse points.

6.1.1 Select a sampling site located at least five stack diameters downstream of any turbocharger exhaust, crossover junction, or recirculation take-offs and upstream of an dilution air inlet. Locate the sample site no closer than one meter or three stack diameters (whichever is less) upstream of the gas discharge to the atmosphere.

6.1.2 A preliminary O₂ traverse is not necessary.

6.1.2.2 Cross-sectional layout and location of traverse points use a minimum of three sample points located at positions of 16.7, 50 and 83.3 percent of the stack diameter.

6.2.1 Record the data required on the engine operation record on Figure 20.7 of Reference Method 20. In addition, record (a) the intake manifold pressure; (b) the intake manifold temperature; (c) rack position; (d) engine speed; and (e) injector or spark timing. (The water or steam injection rate is not applicable to internal combustion engines.)

NO_x emissions measured by Reference Method 20 will be affected by ambient atmospheric conditions. Consequently, measured NO_x emissions would be adjusted during any performance test by the ambient condition correction factors discussed earlier, or by custom correction factors approved for use by EPA.

The performance test may be performed either by the manufacturer or at the actual user operating site. If the test is performed at the manufacturer's facility, compliance with that performance test will be sufficient proof

of compliance by the user as long as the engine operating parameters are not varied during user operation from the settings under which testing was done.

Public Hearing

A public hearing will be held to discuss these proposed standards in accordance with section 307(d)(5) of the Clean Air Act. Persons wishing to make oral presentations should contact EPA at the address given in the ADDRESSES Section of this preamble. Oral presentations will be limited to 15 minutes each. Any member of the public may file a written statement with EPA before, during, or within 30 days after the hearing. Written statement should be addressed to Mr. Jack R. Farmer (see ADDRESSES Section).

The docket is an organized and complete file of all the information considered by EPA in the development of this rulemaking. The principal purposes of the docket are (1) to allow interested parties to identify and locate documents so that they can intelligently and effectively participate in the rulemaking process, and (2) to serve as the record for judicial review. The docket requirement is discussed in section 307(d) of the Clean Air Act.

Miscellaneous

As prescribed by Section 111 of the Act, this proposal is accompanied by the Administrator's determination that emissions from stationary IC engines contribute to air pollution which causes or contributes to the endangerment of public health or welfare, and by publication of this determination in this issue of the Federal Register. In accordance with section 117 of the Act, publication of these standards was preceded by consultation with appropriate advisory committees, independent experts, and federal department and agencies. The Administrator welcomes comments on all aspects of the proposed regulations, including the designation of stationary IC engines as a significant contributor to air pollution which causes or contributes to the endangerment of public health or welfare, economic and technological issues, monitoring requirements and the proposed test method.

Comments are specifically invited on the severity of the economic and environmental impact of the proposed standards on stationary naturally aspirated carbureted-gas IC engines since some parties have expressed objection to applying the proposed standards to these engines. Comments are also invited on the selection of rotary engines for control by standards

of performance. These engines were included because they are expected to be contributors to NO_x emissions from stationary sources and can be controlled by demonstrated NO_x emission control techniques. Any comments submitted to the Administrator on these issues, however, should contain specific information and data pertinent to an evaluation of the magnitude of this impact, its severity, and its consequences.

It should be noted that standards of performance for new sources established under section 111 of the Clean Air Act reflect:

The degree of emission limitation and the percentage reduction achievable through application of the best technological system of continuous emission reduction which (taking into consideration the cost of achieving such emission reduction, any nonair quality health and environmental impact and energy requirements) the Administrator determines has been adequately demonstrated [section 111(a)(1)].

Although there may be emission control technology available that can reduce emissions below those levels required to comply with standards of performance, this technology might not be selected as the basis of standards of performance because of costs associated with its use. Accordingly, standards of performance should not be viewed as the ultimate in achievable emission control. In fact, the Act may require the imposition of a more stringent emission standard emission in several situations.

For example, applicable costs do not necessarily play as prominent a role in determining the "lowest achievable emission rate" for new or modified sources located in nonattainment areas (i.e., those areas where statutorily mandated health and welfare standards are being violated). In this respect, section 173 of the Act requires that new or modified sources constructed in an area which exceeds the National Ambient Air Quality Standard (NAAQS) must reduce emissions to the level which reflects the "lowest achievable emission rate" (LAER), as defined in section 171(3). The statute defines LAER as that rate of emissions which reflects:

(A) The most stringent emission limitation which is contained in the implementation plan of any state for such class or category of source, unless the owner or operator of the proposed source demonstrates that such limitations are not achievable or

(B) The most stringent emission limitation which is achieved in practice by such class or category of source, whichever is more stringent.

In no event can the emission rate exceed any applicable new source performance standard.

A similar situation may arise under the prevention-of-significant-deterioration-of-air-quality provisions of the Act. These provisions require that certain sources employ "best available control technology" (BACT) as defined in section 169(3) for all pollutants regulated under the Act. Best available control technology must be determined on a case-by-case basis, taking energy, environmental and economic impacts, and other costs into account. In no event may the application of BACT result in emissions of any pollutants which will exceed the emissions allowed by any applicable standard established pursuant to section 111 (or 112) of the Act.

In all cases, State Implementation Plans (SIP's) approved or promulgated under section 110 of the Act must provide for the attainment and maintenance of NAAQS designed to protect public health and welfare. For this purpose, SIP's must in some cases require greater emission reduction than those required by standards of performance for new sources.

Finally, states are free under section 116 of the Act to establish even more stringent emission limits than those established under section 111 or those necessary to attain or maintain the NAAQS under section 110. Accordingly, new sources may in some cases be subject to limitations more stringent than standards of performance under section 111, and prospective owners and operators of new sources should be aware of this possibility in planning for such facilities.

Under EPA's "new" sunset policy for reporting requirements in regulations, the reporting requirements in this regulation will automatically expire five years from the date of promulgation unless EPA takes affirmative action to extend them.

EPA will review this regulation four years from the date of promulgation. This review will include an assessment of such factors as the need for integration with other programs, the existence of alternative methods, enforceability, and improvements in emissions control technology.

An economic impact assessment has been prepared as required under section 317 of the Act and is included in the Standards Support and Environmental Impact Statement.

Dated: July 11, 1979.

Douglas M. Costle,
Administrator.

It is proposed to amend Part 60 of Chapter I, Title 40 of the Code of Federal Regulations as follows:

1. By adding Subpart FF as follows:

Subpart FF—Standards of Performance for Stationary Internal Combustion Engines

Sec.

60.320 Applicability and designation of affected facility.

60.321 Definitions.

60.322 Standards for nitrogen oxides.

60.323 Monitoring of operations.

60.324 Test methods and procedures.

Authority: Secs. 111 and 301(a) of the Clean Air Act, as amended, (42 U.S.C. 1857c-7, 1857g(a)), and additional authority as noted below.

Subpart FF—Standards of Performance for Stationary Internal Combustion Engines

§ 60.320 Applicability and designation of affected facility.

The provisions of this subpart are applicable to the following affected facilities which commence construction beginning 30 months from today's date:

(a) All gas engines that are either greater than 350 cubic inch displacement per cylinder or equal to or greater than 8 cylinders and greater than 240 cubic inch displacement per cylinder.

(b) All diesel or dual-fuel engines that are greater than 500 cubic inch displacement per cylinder.

(c) All rotary engines that are greater than 1500 cubic inch displacement per rotor.

§ 60.321 Definitions.

As used in this subpart, all terms not defined herein shall have the meaning given them in the Act or in subpart A of this part.

(a) "Stationary internal combustion engine" means any internal combustion engine, except gas turbines, that is not self propelled. It may, however, be mounted on a vehicle for portability.

(b) "Emergency standby engine" means any stationary internal combustion engine which operates as a mechanical or electrical power source only when the primary power source for a facility has been rendered inoperable during an emergency situation.

(c) "Reference ambient conditions" means standard air temperature (29.4°C, or 85°F), humidity (17 grams H₂O/kg dry air, or 75 grains H₂O/lb dry air), and pressure (101.3 kilopascals, or 29.92 in. Hg.).

(d) "Peak load" means operation at 100 percent of the manufacturer's design capacity.

(e) "Diesel engine" means any stationary internal combustion engine burning a liquid fuel.

(f) "Gas engine" means any stationary internal combustion engine burning a gaseous fuel.

(g) "Dual-fuel engine" means any stationary internal combustion engine that is burning liquid and gaseous fuel simultaneously.

(h) "Unmanned engine" means any stationary internal combustion engine installed and operating at a location which does not have an operator regularly present at the site for some portion of a 24-hour day.

(i) "Non-remote operation" means any engine installed and operating at a location which has an operator regularly present at the site for some portion of a 24-hour day.

(j) "Brake-specific fuel consumption" means fuel input heat rate, based on the lower heating value of the fuel, expressed on the basis of power output (i.e., (kJ/w-hr).

(k) "Weekly basis" means at seven day intervals.

(l) "Daily basis" means at 24 hours intervals.

(m) "Rotary engine" means any Wankel type engine where energy from the combustion of fuel is converted directly to rotary motions instead of reciprocating motion.

(n) "Displacement per rotor" means the volume contained in the chamber of a rotary engine between one flank of the rotor and the housing at the instant the inlet port is closed.

§ 60.322 Standards for nitrogen oxides.

(a) On and after the date on which the performance test required to be conducted by § 60.8 is completed, no owner or operator subject to the provisions of this subpart shall cause to be discharged into the atmosphere, except as provided in paragraphs (b) and (c) of this section—

(1) From any gas engine, with a brake-specific fuel consumption at peak load more than or equal to 10.2 kilojoules/watt-hour any gases which contain nitrogen oxides in excess of 700 parts per million volume, corrected to 15 percent oxygen on a dry basis.

(2) From any diesel or dual-fuel engine with a brake-specific fuel consumption at peak load more than or equal to 10.2 kilojoules/watt-hour any gases which contain nitrogen oxides in excess of 600 parts per million volume, corrected to 15 percent oxygen on a dry basis.

(3) From any stationary internal combustion engine with a brake-specific fuel consumption at peak load of less than or equal to 10.2 kilojoules/watt-hour any gases which contain nitrogen oxides in excess of:

$$(i) \text{ STD} = 700 \frac{10.2}{Y} \text{ for any gas engine,}$$

$$(ii) \text{ STD} = 600 \frac{10.2}{Y} \text{ for any diesel or dual-fuel engine}$$

where:

STD = allowable NO_x emissions (parts-per-million volume corrected to 15 percent oxygen on a dry basis).

Y = manufacturer's rated brake-specific fuel consumption at peak load (kilojoules per watt-hour) or owner/operator's brake-specific fuel consumption at peak load as determined in the field.

(b) All one and two cylinder reciprocating gas engines are exempt from paragraph (a) of this section.

(c) Emergency standby engines are exempt from paragraph (a) of this section.

§ 60.323 Monitoring of operations.

(a) The owner or operator of any stationary internal combustion engine, subject to the provisions of this subpart must, on a weekly basis for unmanned engines and on a daily basis for manned engines, monitor and record the following parameters. All monitoring systems shall be accurate to within five percent and shall be approved by the Administrator.

(1) For diesel and dual-fuel engines:

- (i) Intake manifold temperature
- (ii) Intake manifold pressure
- (iii) Engine speed
- (iv) Diesel rack position (fuel flow)
- (v) Injector timing

(2) For gas engines:

- (i) Intake manifold temperature
- (ii) Intake manifold pressure
- (iii) Fuel header pressure
- (iv) Engine speed
- (v) Spark ignition timing

(b) For the purpose of reports required under § 60.7(c), periods of excess emissions that shall be reported are defined as any daily (for manned engines) or weekly (for unmanned engines) period during which any one of the parameters specified under paragraph (a) of this section falls outside the range identified for that parameter under § 60.324(a)(3). Each excess emission report shall include the range identified for each operating parameter under § 60.324(a)(4), the monitored value for each operating parameter specified under § 60.323(a).

the ambient air conditions during the period of excess emissions, and any graphs and/or figures developed under § 60.324(a)(4)

(Sec. 114 of the Clean Air Act, as amended (42 U.S.C. 1857c-9))

§ 60.324 Test methods and procedures.

The reference methods in Appendix A to this part, except as provided in § 60.8(b), shall be used to determine compliance with the standards prescribed in § 60.322 as follows:

(a) Reference Method 20 for the concentration of nitrogen oxides and oxygen. The span for the nitrogen oxides analyzer used in this method shall be 1500 ppm.

(1) The following changes and additions (by section) to Reference Method procedures should be followed when determining compliance with § 60.322:

1. *Principle and Applicability.* Sulfur dioxide measurements are not applicable for internal combustion engine testing.

6.1 Selection of a sampling site and the minimum number of traverse points.

6.1.1 Select a sampling site located at least five stack diameters downstream of any turbocharger exhaust, crossover junction, or recirculation take-offs and upstream of any dilution air inlet. Locate the sample site no closer than one meter or three stack diameters (whichever is less) upstream of the gas discharge to the atmosphere.

6.1.2 a preliminary O₂ traverse is not necessary.

6.2 Cross-sectional layout and location of traverse points. Use a minimum of three sample points located at positions of 18.7, 50 and 83.3 percent of the stack diameter.

6.2.1 Record the data required on the engine operation record on Figure 20.7 of Reference Method 20. In addition, record (a) the intake manifold pressure; (b) the intake manifold temperature; (c) rack position, fuel header pressure or carburetor position; (d) engine speed; and (e) injector or spark timing. (The water or steam injection rate is not applicable to internal combustion engines.)

(2) The nitrogen oxides emission level measured by Reference Method 20 shall be adjusted to reference ambient conditions by the following ambient condition correction factors:

$NO_x \text{ corrected} = (K) NO_x \text{ observed}$

where K is determined as follows:

where:

H = observed humidity, grains H₂O/lb dry air

T = observed inlet air temperature, °F

The adjusted NO_x emission level shall be used to determine compliance with § 60.322.

(3) Manufacturers, owners, or operators may develop custom ambient correction factors in terms of ambient air temperature and/or pressure, and/or humidity to adjust the nitrogen oxide emission level measured by the performance test to reference ambient conditions. These correction factors must be substantiated with data and must be approved by the Administrator before they can be used to determine compliance with § 60.322. Notices of approval of custom ambient condition correction factors will be published in the Federal Register.

(4) Testing shall be conducted and ranges identified for each parameter specified under § 60.323(a) over which the numerical emission limits included under § 60.322 are not exceeded. This will be accomplished by measuring NO_x emissions, using Reference Method 20, and these parameters at four points over the normal load range of the internal combustion engine, including the minimum and maximum points in the range if the stationary internal combustion engine will be operated over a range of load conditions.

(b) ASTM D-2382 shall be used to determine the lower heating value of liquid fuels and ASTM D-1826 shall be used to determine the lower heating value of gaseous fuels.

(Sec. 114 of the Clean Air Act, as amended (42 U.S.C. 1857c-9))

**Air Pollution Prevention and Control;
Addition to the List of Categories of
Stationary Sources**

Section 111 of the Clean Air Act (42 U.S.C. 1857c-6) directs the Administrator of the Environmental Protection Agency to publish, and from time to time revise, a list of categories of stationary sources which he determines may contribute significantly to air pollution which causes or contributes to the endangerment of public health or welfare. Within 120 days after the inclusion of a category of stationary sources in such list, the Administrator is required to propose regulations establishing standards of performance for new and modified sources within such category. At present standards of performance for 27 categories of sources have been promulgated.

The Administrator, after evaluating available information, has determined that stationary internal combustion engines are an additional category of stationary sources which meets the above requirements. The basis for this determination is discussed in the preamble to the proposed regulation that is published elsewhere in this issue of the Federal Register. Evaluation of other stationary source categories is in progress, and the list will be revised from time to time as the Administrator deems appropriate. Stationary internal combustion engines are included on the proposed NSPS priority list (published August 31, 1978) required by section 111(f)(1), but since the priority list is not final, stationary internal combustion engines are also being listed as indicated below at this time. Once the priority list is promulgated, all source categories on the promulgated list are considered listed under section 111(b)(1)(A), and separate listings such as this will not be made for those source categories.

Accordingly, notice is given that the Administrator, pursuant to section 111(b)(1)(A) of the Act, and after consultation with appropriate advisory committees, experts and Federal departments and agencies in accordance with section 117(f) of the Act, effective July 23, 1979 amends the list of categories of stationary sources to read as follows:

**List of Categories of Stationary Sources
and Corresponding Affected Facilities**

* * * * *

Source Category

* * * * *

Affected Facilities**Internal combustion engines**

Proposed standards of performance applicable to the above source category appear elsewhere in this issue of the Federal Register.

Dated: July 11, 1979.

Douglas M. Costle,
Administrator./

Federal Register / Vol. 44, No. 182 / Tuesday, September 18, 1979**[40 CFR Part 60]**

[FRL 1321-5]

**Standards of Performance for New
Stationary Sources; Stationary Internal
Combustion Engines**

AGENCY: Environmental Protection
Agency (EPA).

ACTION: Extension of Comment Period.

SUMMARY: The deadline for submittal of comments on the proposed standards of performance for stationary internal combustion engines, which were proposed on July 23, 1979 (44 FR 43152), is being extended from September 21, 1979, to October 22, 1979.

DATES: Comments must be received on or before October 22, 1979.

ADDRESSES: Comments should be submitted to Mr. David R. Patrick, Chief, Standards Development Branch (MD-13), Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, North Carolina 27711.

FOR FURTHER INFORMATION CONTACT: Mr. Don R. Goodwin, Director, Emission Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone number (919) 541-5271.

SUPPLEMENTARY INFORMATION: On July 23, 1979 (44 FR 43152), the Environmental Protection Agency proposed standards of performance for the control of emissions from stationary internal combustion engines. The notice of proposal requested public comments on the standards by September 21, 1979. Due to a delay in the shipping of the Standards Support Document, sufficient copies of the document have not been available to all interested parties in time to allow their meaningful review and comment by September 21, 1979. EPA has received a request from the industry to extend the comment period by 30 days through October 22, 1979. An extension of this length is justified since the shipping delay has resulted in approximately a three-week delay in processing requests for the document.

Additionally, page 9-75 of the Standards Support Document was inadvertently omitted. Persons wishing to obtain copies of this page should contact Mr. Doug Bell, Emission Standards and Engineering Division, Research Triangle Park, North Carolina 27711, telephone number (919) 541-5477.

Dated: September 12, 1979.

David G. Hawkins,
Assistant Administrator for Air, Noise, and
Radiation.

**STANDARDS OF
PERFORMANCE FOR NEW
STATIONARY SOURCES**

**AUTOMOBILE AND LIGHT-DUTY TRUCK
SURFACE COATING OPERATIONS**

SUBPART MM

40 CFR Part 60

(FRL-1285-4)

Automobile and Light-Duty Truck Surface Coating Operations; Standards of Performance**AGENCY:** Environmental Protection Agency (EPA).**ACTION:** Proposed rule.

SUMMARY: Standards of performance are proposed to limit emissions of volatile organic compounds (VOC) from new, modified, and reconstructed automobile and light-duty truck surface coating operations within assembly plants. Three new test methods are also proposed. Reference Method 24 (Candidate 1 or Candidate 2) would be used to determine the VOC content of coating materials, and Reference Method 25 would be used to determine the percentage reduction of VOC emissions achieved by add-on emission control devices.

The standards implement the Clean Air Act and are based on the Administrator's determination that automobile and light-duty truck surface coating operations within assembly plants contribute significantly to air pollution. The intent is to require new, modified, and reconstructed automobile and light-duty truck surface coating operations to use the best demonstrated system of continuous emission reduction, considering costs, nonair quality health, and environmental and energy impacts.

A public hearing will be held to provide interested persons an opportunity for oral presentation of data, views, or arguments concerning the proposed standards.

DATES: *Comments.* Comments must be received on or before December 14, 1979.

Public Hearing. The public hearing will be held on November 9, 1979, at 9 a.m.

Request to Speak at Hearing. Persons wishing to present oral testimony should contact EPA by November 2, 1979.

ADDRESSES: *Comments.* Comments should be submitted to: Central Docket Section (A-130), Attention: Docket Number A-79-05, U.S. Environmental Protection Agency, 401 M Street SW., Washington, D.C. 20460.

Public Hearing. The public hearing will be held at National Environmental Resource Center (NERC), Rm. B-102, R.T.P., N.C. Persons wishing to present

oral testimony should notify Ms. Shirley Tabler, Emission Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone number (919) 541-5421.

Background Information Document. The Background Information Document (BID) for the proposed standards may be obtained from the U.S. EPA Library (MD-35), Research Triangle Park, North Carolina 27711, telephone number (919) 541-2777. Please refer to "Automobile and Light-Duty Truck Surface Coating Operations—Background Information for Proposed Standards." EPA-450/3-79-030.

Docket. The Docket, number A-79-05, is available for public inspection and copying at the EPA's Central Docket Section, Room 2903 B, Waterside Mall, Washington, D.C. 20460.

FOR FURTHER INFORMATION CONTACT: Mr. Don R. Goodwin, Director, Emission Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone number (919) 541-5271.

SUPPLEMENTARY INFORMATION:**Proposed Standards**

The proposed standards would apply to new automobile and light-duty truck surface coating operations. Existing plants would not be covered unless they undergo modifications resulting in increased emissions or reconstructions. The proposed standards would apply to each prime coat operation, each guide coat operation, and each topcoat operation within an assembly plant. Emissions of VOC from each of these operations would be limited as follows: 0.10 kilogram of VOC (measured as mass of carbon) per liter of applied coating solids from prime coat operations, 0.84 kilogram of VOC (measured as mass of carbon) per liter applied coating solids from guide coat operations, 0.84 kilogram of VOC (measured as mass of carbon) per liter of applied coating solids from topcoat operations.

These proposed emission limits are based on Method 24 (Candidate 1) which determines VOC content of coatings expressed as the mass of carbon. At the time the standards were developed, it was believed that VOC emissions should be determined from carbon measurements. Method 24 (Candidate 1) was developed to measure carbon directly and thus improve the accuracy of the previously used ASTM procedure D 2369-73, which measures the mass of volatile organics indirectly. However, questions have been raised

concerning the validity of using the carbon method since the ratio of mass of carbon to mass of VOC in solvents used in automotive coatings varies over a wide range. The effect which this variation might have on the standards is still being investigated. Method 24 (Candidate 2) was developed as a test method for determining VOC emissions from coating materials in terms of mass of volatile organics and is also derived from ASTM procedure D 2369-73. The proposed emission limits, based on Method 24 (Candidate 2) which measures volatile organics, are: 0.16 kilogram of VOC per liter of applied coating solids from prime coat operations, and 1.36 kilogram of VOC per liter of applied coating solids for guide coat operations, and 1.36 kilogram of VOC per liter of applied coating solids from top coat operations. In order to provide an opportunity for public comment on both test methods, both are being proposed, and the final selection of a test method will be made before promulgation, based on the comments received.

Although the emission limits are based on the use of water-based coating materials in each coating operation, they can also be met with solvent-based coating materials through the use of other control techniques, such as incineration. Exemptions are included in the proposed standards which specifically exclude annual model changeovers from consideration as modifications.

Summary of Environmental, Energy, and Economic Impacts

Environmental, energy, and economic impacts of standards of performance are normally expressed as incremental differences between the impacts from a facility complying with the proposed standard and those for one complying with a typical State Implementation Plan (SIP) emission standard. In the case of automobile and light-duty truck surface coating operations, the incremental differences will depend on the control levels that will be required by revised SIP's. Revisions to most SIP's are currently in progress.

Most existing automobile and light-duty truck surface coating operations are located in areas which are considered nonattainment areas for purposes of achieving the National Ambient Air Quality Standard (NAAQS) for ozone. New facilities are expected to locate in similar areas. States are in the process of revising their SIP's for these areas and are expected to include revised emission limitations for automobile and light-duty truck surface coating operations in their new SIP's. In

revising their SIPs the States are relying on the control techniques guideline document, "Control of Volatile Organic Emissions from Existing Stationary Sources—Volume II: Surface Coating of Cans, Coil, Paper, Fabrics, Automobiles and Light-Duty Trucks" (EPA-450/2-77-088 [CTG]).

Since control technique guidelines are not binding, States may establish emission limits which differ from the guidelines. To the extent States adopt the emission limits recommended in the control techniques guideline document as the basis for their revised SIPs, the proposed standards of performance would have little environmental, energy, or economic impacts. The actual incremental impacts of the proposed standards of performance, therefore, will be determined by the final emission limitations adopted by the States in their revised SIPs. For the purpose of this rulemaking, however, the environmental, energy, and economic impacts of the proposed standards have been estimated based on emission limits contained in existing SIPs.

In addition to achieving further reductions in emissions beyond those required by a typical SIP, standards of performance have other benefits. They establish a degree of national uniformity to avoid situations in which some States may attract industries by relaxing air pollution standards relative to other States. Further, standards of performance improve the efficiency of case-by-case determinations of best available control technology (BACT) for facilities located in attainment areas, and lowest achievable emission rates (LAER) for facilities located in nonattainment areas, by providing a starting point for the basis of these determinations. This results from the process for developing a standard of performance, which involves a comprehensive analysis of alternative emission control technologies and an evaluation and verification of emission test methods. Detailed cost and economic analyses of various regulatory alternatives are presented in the supporting documents for standards of performance.

Based on emission control levels contained in existing SIPs, the proposed standards of performance would reduce emissions of VOC from new, modified, or reconstructed automobile and light-duty truck surface coating operations by about 80 percent. National emissions of VOC would be reduced by about 4,800 metric tons per year by 1983.

Water pollution impacts of the proposed standards would be relatively small compared to the volume and quality of the wastewater discharged

from plants meeting existing SIP levels. The proposed standards are based on the use of water-based coating materials. These materials would lead to a slight increase in the chemical oxygen demand (COD) of the wastewater discharged from the surface coating operations within assembly plants. This increase in COD, however, is not great enough to require additional wastewater treatment capacity beyond that required in existing assembly plants using solvent-based surface coating materials.

The solid waste impact of the proposed standards would be negligible compared to the amount of solid waste generated by existing assembly plants. The solid waste generated by water-based coatings, however, is very sticky, and equipment cleanup is more time consuming than for solvent-based coatings. Solid wastes from water-based coatings do not present any special disposal problems since they can be disposed of by conventional landfill procedures.

National energy consumption would be increased by the use of water-based coatings to comply with the proposed standards. The equivalent of an additional 18,000 barrels of fuel oil would be consumed per year at a typical assembly plant. This is equivalent to an increase of about 25 percent in the energy consumption of a typical surface coating operation. National energy consumption would be increased by the equivalent of about 72,000 barrels of fuel oil per year in 1983. This increase is based on the projection that four new assembly plants will be built by 1983.

The proposed standards would increase the capital and annualized costs of new automobile and light-duty truck surface coating operations within assembly plants. Capital costs for the four new facilities planned by 1983 would be increased by approximately \$19 million as a result of the proposed standards. The incremental capital costs for control represent about 0.2 percent of the \$10 billion planned for capital expenditures. The corresponding annualized costs would be increased by approximately \$9 million in 1983. The price of an automobile or light-duty truck manufactured at a new plant which complies with the proposed standards of performance would be increased by less than 1 percent. This is considered to be a reasonable control cost.

Modifications and Reconstructions

During the development of the proposed standards, the automobile industry expressed concern that changes to assembly plants made only for the purpose of annual model changeovers

would be considered a modification or reconstruction as defined in the Code of Federal Regulations, Title 40, Parts 60.14 and 60.15 (40 CFR 60.14 and 60.15). A modification is any physical or operational change in an existing facility which increases air pollution from that facility. A reconstruction is any replacement of components of an existing facility which is so extensive that the capital cost of the new components exceeds 50 percent of the capital cost of a new facility. In general, modified and reconstructed facilities must comply with standards of performance. According to the available information, changes to coating lines for annual model changeovers do not cause emissions to increase significantly. Further, these changes would normally not require a capital expenditure that exceeds the 50 percent criterion for reconstruction. Hence, it is very unlikely that these annual facility changes would be considered either modifications or reconstructions. Therefore, the proposed standards state that changes to surface coating operations made only to accommodate annual model changeovers are not modifications or reconstructions. In addition, by exempting annual model changeovers, enforcement efforts are greatly reduced with little or no adverse environmental impact.

Selection of Source and Pollutants

VOC are organic compounds which participate in atmospheric photochemical reactions or are measured by Reference Methods 24 (Candidate 1 or Candidate 2) and 25. There has been some confusion in the past with the use of the term "hydrocarbons." In addition to being used in the most literal sense, the term "hydrocarbons" has been used to refer collectively to all organic chemicals. Some organics which are photochemical oxidant precursors are not hydrocarbons (in the strictest definition) and are not always used as solvents. For purposes of this discussion, organic compounds include all compounds of carbon except carbonates, metallic carbides, carbon monoxide, carbon dioxide and carbonic acid.

Ozone and other photochemical oxidants result in a variety of adverse impacts on health and welfare, inducing impaired respiratory function, eye irritation, deterioration of materials such as rubber, and necrosis of plant tissue. Further information on these effects can be found in the April 1978 EPA document "Air Quality Criteria for Ozone and Other Photochemical Oxidants," EPA-600/8-78-004. This

document can be obtained from the EPA library (see Addresses Section).

Industrial coating operations are a major source of air pollution emissions of VOC. Most coatings contain organic solvents which evaporate upon drying of the coating, resulting in the emission of, VOC. Among the largest individual operations producing VOC emissions in the industrial coating category are automobile and light-duty truck surface coating operations. Since the surface coating operations for automobiles and light-duty trucks are very similar in nature, with line speed being the primary difference, they are being considered together in this study. Automobile and light-duty truck manufacturers employ a variety of surface coatings, most often enamels and lacquers, to produce the protective and decorative finishes of their product. These coatings normally use an organic solvent base, which is released upon drying.

The "Priority List for New Source Performance Standards under the Clean Air Act Amendments of 1977," which was promulgated in 40 CFR 60.16, 44 FR 49222, dated August 21, 1979, ranked sources according to the impact that standards promulgated in 1980 would have on emissions in 1990. Automobile and light-duty truck surface coating operations rank 27 out of 59 on this list of sources to be controlled.

The surface coating operation is an integral part of an automobile or light-duty truck assembly plant, accounting for about one-quarter to one-third of the total space occupied by a typical assembly plant. Surface coatings are applied in two main steps, prime coat and topcoat. Prime coats may be water-based or organic solvent-based. Water-based coatings use water as the main carrier for the coating solids, although these coatings normally contain a small amount of organic solvent. Solvent-based coatings use organic solvent as the coating solids carrier. Currently about half of the domestic automobile and light-duty truck assembly plants use water-based prime coats.

Where water-based prime coating is used, it is usually applied by EDP. The EDP coat is normally followed by a "guide coat," which provides a suitable surface for application of the topcoat. The guide coat may be water-based or solvent-based.

Automobile and light-duty truck topcoats presently being used are almost entirely solvent-based. One or more applications of topcoats are applied to ensure sufficient coating thickness. An oven bake may follow each topcoat application, or the coating may be applied wet on wet.

In 1976, nationwide emissions of VOC from automobile and light-duty truck surface coating operations totaled about 135,000 metric tons. Prime and guide coat operations accounted for about 50,000 metric tons with the remaining 85,000 metric tons being emitted from topcoat operations. This represents almost 15 percent of the volatile organic emissions from all industrial coating operations.

VOC comprise the major air pollutant emitted by automobile and light-duty truck assembly plants. Technology is available to reduce VOC emissions and thereby reduce the formation of ozone and other photochemical oxidants. Consequently, automobile and light-duty truck surface coating operations have been selected for the development of standards of performance.

Selection of Affected Facilities

The prime coat, guide coat, and topcoat operations usually account for more than 80 percent of the VOC emissions from automobile and light-duty truck assembly plants. The remaining VOC emissions result from final topcoat repair, cleanup, and coating of various small component parts. These VOC emission sources are much more difficult to control than the main surface coating operations for several reasons. First, water-based coatings cannot be used for final topcoat repair, since the high temperatures required to cure water-based coatings may damage heat sensitive components which have been attached to the vehicle by this stage of production. Second, the use of solvents is required for equipment cleanup procedures. Third, add-on controls, such as incineration, cannot be used effectively on these cleanup operations because they are composed of numerous small operations located throughout the plant. Since prime coat, guide coat, and topcoat operations account for the bulk of VOC emissions from automobile and light-duty truck assembly plants, and control techniques for reducing VOC emissions from these operations are demonstrated, they have been selected for control by standards of performance.

The "affected facility" to which the proposed standards would apply could be designated as the entire surface coating line or each individual surface coating operation. A major consideration in selecting the affected facility was the potential effect that the modification and reconstruction provisions under 40 CFR 60.14 and 60.15, which apply to all standards of performance, could have on existing assembly plants. A modification is any physical or operational change in an existing facility which increases air

pollution from that facility. A reconstruction is any replacement of components of an existing facility which is so extensive that the capital cost of the new components exceeds 50 percent of the capital cost of a new facility. For standards of performance to apply, EPA must conclude that it is technically and economically feasible for the reconstructed facility to meet the standards.

Many automobile and light-duty truck assembly plants that have a spray prime coat system will be switching to EDP prime coat systems in the future to reduce VOC emissions to comply with revised SIP's. The capital cost of this change could be greater than 50 percent of the capital cost of a new surface coating line. If the surface coating line were chosen as the affected facility, and if this switch to an EDP prime coat system were considered a reconstruction of the surface coating line, all surface coating operations on the line would be required to comply with the proposed standards. Most plants would be reluctant to install an EDP prime coat system to reduce VOC emissions if, by doing so, the entire surface coating line might then be required to comply with standards of performance. By designating the prime coat, guide coat, and topcoat operations as separate affected facilities, this potential problem is avoided. Thus, each surface coating operation (i.e., prime coat, guide coat, and topcoat) has been selected as an affected facility in the proposed standards.

Selection of Best System of Emission Reduction

VOC emissions from automobile and light-duty truck surface coating operations can be controlled by the use of coatings having a low organic solvent content, add-on emissions control devices, or a combination of the two. Low organic solvent coatings consist of water-based enamels, high solids enamels, and powder coatings. Add-on emission control devices consist of such techniques as incineration and carbon adsorption.

Control Technologies

Water-based coating materials are applied either by conventional spraying or by EDP. Application of coatings by EDP involves dipping the automobile or truck to be coated into a bath containing a dilute water solution of the coating material. When charges of opposite polarity are applied to the dip tank and vehicle, the coating material deposits on the vehicle. Most EDP systems presently in use are anodic systems in which the vehicle is given a positive charge.

Cathodic EDP, in which the vehicle is negatively charged, is a new technology which is expanding rapidly in the automotive industry. Cathodic EDP provides better corrosion resistance and requires lower cure temperatures than anodic systems. Cathodic EDP systems are also capable of applying better coverage on deep recesses of parts.

The prime coat is usually followed by a spray application of an intermediate coat, or guide coat, before topcoat application. The guide coat provides the added film thickness necessary for sanding and a suitable surface for topcoat application. EDP can only be used if the total film thickness on the metal surface does not exceed a limiting value. Since this limiting thickness is about the same as the thickness of the prime coat, spraying has to be used for guide coat and topcoat application of water-based coatings.

Currently, nearly half of domestic automobile and light-duty truck assembly plants use EDP for prime coat application, but only two domestic plants use water-based coating for guide coat and topcoat applications.

Coatings whose solids content is about 45 to 60 percent are being developed by a number of companies. When these coatings are applied at high transfer efficiency rates, VOC emissions are significantly less than emissions from existing solvent-based systems. While these high solids coatings could be used in the automotive industry, certain problems must be overcome. The high working viscosity of these coatings makes them unsuitable for use in many existing application devices. In addition, this high viscosity can produce an "orange peel," or uneven, surface. It also makes these coatings unsuitable for use with metallic finishes. Metallic finishes, which account for about 50 percent of domestic demand, are produced by adding small metal flakes to the paint. As the paint dries, these flakes become oriented parallel to the surface. With high solids coatings, the viscosity of the paint prevents movement of the flakes, and they remain randomly oriented, producing a rough surface. However, techniques such as heated application are being investigated to reduce these problems, and it is expected that by 1982 high solids coatings will be considered technically demonstrated for use in the automotive industry.

Powder coatings are a special class of high solids coatings that consist of solids only. They are applied by electrostatic spray and are being used on a limited basis for topcoating automobiles, both foreign and domestic. The use of powder coatings is severely limited, however, because metallic

finishes cannot be applied using powder. As with other high solids coatings, research is continuing in the use of powder coatings for the automotive industry.

Thermal incineration has been used to control VOC emissions from bake ovens in automobile and light-duty truck surface coating operations because of the fairly low volume and high VOC concentration in the exhaust stream. Incineration normally achieves a VOC emission reduction of over 90 percent. Thermal incinerators have not, however, been used for control of spray booth VOC emissions. Typically, the spray booth exhaust stream is a high volume stream (95,000 to 200,000 liters per second) which is very low in concentration of VOC (about 50 ppm). Thermal incineration of this exhaust stream would require a large amount of supplemental fuel, which is its main drawback for control of spray booth VOC emissions. There are no technical problems with the use of thermal incineration.

Catalytic incineration permits lower incinerator operating temperatures and, therefore, requires about 50 percent less energy than thermal incineration. Nevertheless, the energy consumption would still be high if catalytic incineration were used to control VOC emissions from a spray booth. In addition, catalytic incineration allows the owner or operator less choice in selecting a fuel; it requires the use of natural gas to preheat the exhaust gases, since oil firing tends to foul the catalyst. While catalytic incineration is not currently being employed in automobile and light-duty truck surface coating operations for control of VOC emissions, there are no technical problems which would preclude its use on either bake oven or spray booth exhaust gases. The primary limiting factor is the high energy consumption of natural gas, if catalytic incineration is used to control emissions from spray booths.

Carbon adsorption has been used successfully to control VOC emissions in a number of industrial applications. The ability of carbon adsorption to control VOC emissions from spray booths and bake ovens in automobile and light-duty truck surface coating operations, however, is uncertain. The presence of a high volume, low VOC exhaust stream from spray booths would require carbon adsorption units much larger than any that have ever been built. For bake ovens in automobile and light-duty truck surface coating operations, a major impediment to the use of carbon adsorption is heat. The

high temperature of the bake oven exhaust stream would require the use of refrigeration to cool the gas stream before it passes through the carbon bed. Carbon adsorption, therefore, is not considered a demonstrated technology at this time for controlling VOC emissions from automobile and light-duty truck surface coating operations. Work is continuing within the automotive industry on efforts to apply carbon adsorption to the control of VOC emissions, however, and it may become a demonstrated technology in the near future.

Regulatory Options

Water-based coatings and incineration are two well-demonstrated and feasible techniques for controlling emissions of VOC from automobile and light-duty truck surface coating operations. Based upon the use of these two VOC emission control techniques, the following two regulatory options were evaluated.

Regulatory Option I includes two alternatives which achieve essentially equivalent control of VOC emissions. Alternative A is based on the use of water-based prime coats, guide coats, and topcoats. The prime coat would be applied by EDP. Since the guide coat is essentially a topcoat material, guide coat emission levels as low as those achieved by water-based topcoats should be possible through a transfer of technology from topcoat operations to guide coat operations. Alternative B is based on the use of a water-based prime coat applied by EDP and solvent-based guide coats and topcoats. Incineration of the exhaust gas stream from the topcoat spray booth and bake oven would be used to control VOC emissions under this alternative.

Regulatory Option II is based on the use of a water-based prime coat applied by EDP and solvent-based guide coats and topcoats. In this option, the exhaust gas streams from both the guide coat and topcoat spray booths and bake ovens would be incinerated to control VOC emissions.

Environmental, Energy, and Economic Impacts

Standards based on Regulatory Option I would lead to a reduction in VOC emissions of about 80 percent, and standards based on Regulatory Option II would lead to a reduction in emissions of about 90 percent, compared to VOC emissions from automobile and light-duty truck surface coating operations controlled to meet current SIP requirements. Growth projections indicate there will be four new automobile and light-duty truck

assembly lines constructed by 1983. Very few, if any, modifications or reconstructions are expected during this period. Based on these projections, national VOC emissions in 1983 would be reduced by about 4,800 metric tons with standards based on Regulatory Option I and about 5,400 metric tons with standards based on Regulatory Option II. Thus, both regulatory options would result in a significant reduction in VOC emissions from automobile and light-duty truck surface coating operations.

With regard to water pollution, standards based on Regulatory Option II would have essentially no impact. Similarly, standards based on Regulatory Option I(B) would have no water pollution impact. Standards based on Regulatory Option I(A), however, would result in a slight increase in the chemical oxygen demand (COD) of the wastewater discharged from automobile and light-duty truck surface coating operations within assembly plants. This increase is due to water-miscible solvents in the water-based guide coats and topcoats which become dissolved in the wastewater. The increase in COD of the wastewater, however, would be small relative to current COD levels at plants using solvent-based surface coatings and meeting existing SIP's. In addition, this increase would not require the installation of a larger wastewater treatment facility than would be built for an assembly plant which used solvent-based surface coatings.

The solid waste impact of the proposed standards would be negligible. The volume of sludge generated from water-based surface coating operations is approximately the same as that generated from solvent-based surface coating operations. The solid waste generated by water-based coatings, however, is very sticky, and equipment cleanup is more time consuming than for solvent-based coatings. Sludge from either type of system can be disposed of by conventional landfill procedures without leachate problems.

With regard to energy impact, standards based on Regulatory Option I(A) would increase the energy consumption of surface coating operations at a new automobile or light-duty truck assembly plant by about 25 percent. Regulatory Option I(B) would cause an increase of about 150 to 425 percent in energy consumption. Standards based on Regulatory Option II would result in an increase of 300 to 700 percent in the energy consumption of surface coating operations at a new automobile or light-duty truck assembly plant. The range in energy consumption

for those options which are based on use of incineration reflects the difference between catalytic and thermal incineration.

The relatively high energy impact of standards based on Regulatory Option I(B) and Regulatory Option II is due to the large amount of incineration fuel needed. Standards based on Regulatory Option II would increase energy consumption at a new automobile and light-duty truck assembly plant by the equivalent of about 200,000 to 500,000 barrels of fuel oil per year, depending upon whether catalytic or thermal incineration was used. Standards based on Regulatory Option I(B) would increase energy consumption by the equivalent of about 100,000 to 300,000 barrels of fuel oil per year.

Standards based on Regulatory Option I(A) would increase the energy consumption of a typical new automobile and light-duty truck assembly plant by the equivalent of about 18,000 barrels of fuel oil per year. Approximately one-third of this increase in energy consumption is due to the use of air conditioning, which is necessary with the use of water-based coatings, and the remaining two-thirds are due to the increased fuel required in the bake ovens for curing water-based coatings.

Growth projections indicate that four new automobile and light-duty truck assembly lines (two automobile and two truck lines) will be built by 1983. Based on these projections, standards based on Regulatory Option I(A) would increase national energy consumption in 1983 by the equivalent of about 72,000 barrels of fuel oil. Standards based on Regulatory Option I(B) would increase national energy consumption in 1983 by the equivalent of 400,000 to 1,200,000 barrels of fuel oil, depending on whether catalytic or thermal incineration were used. Standards based on Regulatory Option II would increase national energy consumption in 1983 by the equivalent of 800,000 to 2,000,000 barrels of fuel oil, again depending on whether catalytic or thermal incineration were used.

The economic impacts of standards based on each regulatory option were estimated using the growth projection of four new assembly lines by 1983. Incremental control costs were determined by calculating the difference between the capital and annualized costs of new assembly plants controlled to meet Regulatory Options I(A), I(B), and II, respectively, with the corresponding costs for new plants designed to comply with existing SIP's. Of the four assembly plants projected by 1983, two were assumed to be lacquer lines and the other two enamel lines.

There are basic design differences between these two types of surface coatings which have a substantial impact on the magnitude of the costs estimated to comply with standards of performance. Lacquer surface coating operations, for example, require much larger spray booths and bake ovens than enamel surface coating operations. Water-based systems also require large spray booths and bake ovens; thus, the incremental capital cost of installing a water-based system in a plant which would otherwise have used a lacquer system is relatively low. The incremental capital costs differential, however, would be much larger if the plant would have been designed for an enamel system.

Tables 1 and 2 summarize the economic impacts of the proposed standards on plants of typical sizes. Table 1 presents the incremental costs of the various control options for a plant which would have used solvent-based lacquers. Table 2 presents similar costs for plants which would have been designed to use solvent-based enamels. Though these tables present incremental costs for passenger car plants, light-duty truck plants would have similar cost differentials. In all cases, it is assumed the plants would install a water-based EDP prime system in the absence of standards of performance. Therefore, no incremental costs associated with EDP prime coat operations are included in the costs presented in Tables 1 and 2. A nominal production rate of 55 passenger cars per hour was assumed for both plants. Tables 1 and 2 show incremental capitalized and annualized costs per vehicle produced at each new facility. The manufacturers would probably distribute these incremental costs over their entire annual production to arrive at purchase prices for the automobiles and light-duty trucks.

Table 1. INCREMENTAL CONTROL COSTS^a
(Compared to the Costs of a Lacquer Plant)

	<u>Regulatory Options</u>				
	<u>I(A)</u>	<u>I(B)</u>		<u>II</u>	
	Water-Based Coatings	Thermal	Catalytic	Thermal	Catalytic
Capital Cost of Control Alternative	\$ 720,000	\$11,800,000	\$15,000,000	\$12,800,000	\$16,200,000
Annualized Cost of Control Alternative	\$1,550,000	\$14,500,000	\$10,700,000	\$15,500,000	\$11,500,000
Incremental Cost/Vehicle Produced at this Facility	\$7.34	\$68.66	\$50.66	\$73.39	\$54.45

^a Assumes a line speed of 55 vehicles per hour and an annual production of 211,200 vehicles.

Table 2. INCREMENTAL CONTROL COSTS^a
(Compared to the Costs of an Enamel Plant)

	<u>Regulatory Options</u>				
	<u>I(A)</u>	<u>I(B)</u>		<u>II</u>	
	Water-Based Coatings	Thermal	Catalytic	Thermal	Catalytic
Capital Cost of Control Alternative	\$10,300,000	\$ 4,630,000	\$ 5,850,000	\$ 5,640,000	\$ 7,000,000
Annualized Cost of Control Alternative	\$ 3,640,000	\$ 5,620,000	\$ 4,150,000	\$ 6,610,000	\$ 4,890,000
Incremental Cost/Vehicle Produced at this Facility	\$17.23	\$26.61	\$19.65	\$31.30	\$23.15

^a Assumes a line speed of 55 vehicles per hour and an annual production of 211,200 vehicles.

Incremental capital costs for suing incineration to reduce VOC emissions from solvent-based lacquer plants to levels comparable to water-based plants are much larger than they are for using incineration on a solvent-based enamel plant. This large difference in costs occurs because lacquer plants have larger spray booth and bake oven areas than enamel plants and, therefore, a larger volume of exhaust gases. Since larger incineration units are required, the incremental capital costs of using incineration to control VOC emissions from a solvent-based lacquer plant are about 15 to 25 times greater than they are for using water-based coatings. Similarly, energy consumption is much greater; hence, the annualized costs of using incineration are about 10 times greater than they are for using water-based coatings.

On the other hand, the incremental capital costs of controlling VOC emissions from new solvent-based enamel plants by the use of incineration are only about one-half the incremental capital costs between a new solvent-based enamel plant and a new water-based plant. Due to the energy consumption associated with incinerators, however, the incremental annualized costs of using incineration with solvent-based enamel coatings could vary from as little as 15 percent more to as much as 90 percent more than the annualized costs of using water-based coatings.

While the incremental capital costs of building a plant to use water-based coatings can be larger or smaller than the costs of using incineration, depending upon whether a solvent-based lacquer plant or a solvent-based enamel plant is used as the starting point, the annualized costs of using water-based coatings are always less than they are for using incineration. This is due to the large energy consumption of incineration units compared to the energy consumption of water-based coatings.

Since the incremental annualized costs are less with Regulatory Option I(A) than with Regulatory Option I(B), it is assumed in this analysis that Regulatory Option I(A) would be incorporated at any new, modified, or reconstructed facility to comply with standards based on Regulatory Option I. As noted, four new assembly plants are expected to be built by 1983. The incremental capital cost to the industry for these plants to comply with standards based on Regulatory Option I would be approximately \$19 million. The corresponding incremental annualized costs would be about \$9 million in 1983.

If standards are based on Regulatory Option II, it is expected that the industry would choose catalytic incineration because its annualized costs are lower than those for thermal incineration. Based this assumption, the incremental capital costs for the industry under Regulatory Option II would be approximately \$42 million, and the incremental annualized costs by 1983 would be about \$30 million. For standards based on either Regulatory Option I or Regulatory Option II, the increase in the price of an automobile or light-duty truck that is manufactured at one of the new plants would be less than 1 percent of the base price of the vehicle.

Best System of Emission Reduction

Both Regulatory Options I and II achieve a significant reduction in VOC emissions compared to automobile and light-duty truck assembly plants controlled to comply with existing SIP's, and neither option creates a significant adverse impact on other environmental media. In terms of energy consumption, standards based on Regulatory Option II would have as much as 10 to 25 times the adverse impact on energy consumption as standards based on Regulatory Option I, while only achieving 10 to 15 percent more reductions in VOC emissions. The costs of standards based on Regulatory Option II range from two to three times the costs of standards based on Regulatory Option I. Thus, Regulatory Option I(A), water-based coatings, was selected as the best system of continuous emission reduction, considering costs and nonair quality health, and environmental and energy impacts.

Although water-based coatings are considered to be the best system of emission reduction at the present time, it is very likely that plants built in the future will use other systems to control VOC emissions, such as high solids coatings and powder coatings. High solids coatings applied at high transfer efficiencies are capable of achieving equivalent emission reductions and are expected to be less costly and require less total energy than water-based systems. These high solids coatings are expected to be available by 1982 and will probably be used by most new sources to comply with the VOC emission limitations. Powder coatings are also expected to be available in the future but are not demonstrated at this time.

Selection of Format for the Proposed Standards

A number of different formats could be selected to limit VOC emissions from automobile and light-duty truck surface coating operations. The format ultimately selected must be compatible with any of the three different control systems that could be used to comply with the proposed standards. One control system is the use of water-based coating materials in the prime coat, guide coat, and topcoat operations. Another control system is the use of solvent-based coating materials and add-on VOC emission control devices such as incineration. The third control system consists of the use of high solids coatings. Although the coatings to be used in this system are not demonstrated at this time, research is continuing toward their development; hence, they may be used in the future.

The formats considered were emission limits expressed in terms of (1) concentration of emissions in the exhaust gases discharged to the atmosphere; (2) mass emissions per unit of production; or (3) mass emissions per volume of coating solids applied.

The major advantage of the concentration format is its simplicity of enforcement. Direct emission measurements could be made using Reference Method 25. There are, however, two significant drawbacks to the use of this format. Regardless of the control approach chosen, emission testing would be required for each stack exhausting gases from the surface coating operations (unless the owner or operator could demonstrate to the Administrator's satisfaction that testing of representative stacks would give the same results as testing all the stacks). This testing would be time consuming and costly because of the large number of stacks associated with automobile and light-duty truck surface coating operations. Another potential problem with this format is the ease of circumventing the standards by the addition of dilution air. It would be extremely difficult to determine whether diluted air was being added intentionally to reduce the concentration of VOC emissions in the gases discharged to the atmosphere, or whether the air was being added to the application or drying operation to optimize performance and maintain a safe working space.

A format of mass VOC emissions per unit of production relates emissions to individual plant production on a direct basis. Where water-based coatings are used, the average VOC content of the coating materials could be determined

by using Reference Method 24 (Candidate 1 or Candidate 2). The volume of coating materials used and the percent solids could be determined from purchase records. VOC emissions could then be calculated by multiplying the VOC content of the coating materials by the volume of coating materials used in a given time period and by the percentage of solids, and dividing the result by the number of vehicles produced in that time period. This would provide a VOC emission rate per unit of production. Consequently, procedures to determine compliance would be direct and straightforward, although very time consuming. This procedure would also require data collection over an excessively long period of time.

Where solvent-based coatings were used with add-on emission control devices, stack emission tests could be performed to determine VOC emissions. Dividing VOC emissions by the number of vehicles produced would again yield VOC emissions per unit of production. This format, however, would not account for differences in surface coating requirements for different vehicles caused by size and configuration. In addition, manufacturers of larger vehicles would be required to reduce VOC emissions more than manufacturers of smaller vehicles.

A format of mass of VOC emissions per volume of coating solids applied also has the advantage of not requiring stack emission testing unless add-on emission control devices rather than water-based coatings are used to comply with the standards. The introduction of dilution air into the exhaust stream would not present a problem with this format. The problem of varying vehicle sizes and configurations would be eliminated since the format is in terms of volume of applied solids regardless of the surface area or number of vehicles coated. This format would also allow flexibility in selection of control systems, for it is usable with any of the control methods. Since this format overcomes the varying dilution air and vehicle size problems inherent with the other formats, it has been selected as the format for the proposed standards. In order to use a format which is in terms of applied solids, the transfer efficiency of the application devices must be considered. Transfer efficiency is defined as the fraction of the total sprayed solids which remain on the vehicle. Transfer efficiency is an important factor because as efficiency decreases, more coating material is used and VOC emissions

increase. Equations have been developed to use this format with water-based coating materials as well as with solvent-based coating materials in combination with high transfer efficiencies and/or add-on emission controls devices. These equations are included in the proposed standards.

Selection of Numerical Emission Limits

Numerical Emission Limits

The numerical emission limits selected for the proposed standard are:

- 0.10 kilogram of VOC per liter of applied coating solids from prime coat operations
- 0.84 kilogram of VOC per liter of applied coating solids from guide coat operations
- 0.84 kilogram of VOC per liter of applied coating solids from topcoat operations

In all three limits, the mass of VOC is measured as carbon in accordance with Reference Methods 24 (Candidate 1) and 25. These emission limits are based on the use of water-based coating materials in the prime coat, guide coat, and topcoat operations. Water-based coating data were obtained from plants which were using these materials as well as from the vendors who supply them. These data were used to calculate VOC emission limits using a procedure similar to proposed Method 24 (Candidate 1). A transfer efficiency of 40 percent was then applied to the values obtained for guide coat and topcoat emissions. This efficiency was determined to be representative of a well-operated air-atomized spray system. The CTG-recommended limits are based on the use of the same coating materials as the proposed standards. The limits in the CTG are expressed in pounds of VOC per gallon of coating (minus water) used in the EDP system or the spray device. The limits in these proposed standards, however, are referenced to the amount of coating solids which adhere to the vehicle body. Therefore, to compare the limits in the CTG to those proposed here, it is necessary to account for the solids content of the coating and the efficiency of applying the guide coat and topcoat to the vehicle body. Consideration of transfer efficiency is significant because the proposed standards can be met by using high solids content coating materials if the amount of overspray is kept to a minimum. Since this format provides equivalency determinations for systems using solvent-based coating materials in combination with high transfer efficiencies and/or add-on control devices, it allows flexibility in selection of control systems.

As discussed in previous sections, there are two types of EDP systems. Anodic EDP was the first type developed for use in automobile surface coating operations. Cathodic EDP is the second type and is a recent technology improvement which results in greater corrosion resistance. Consequently, nearly 50 percent of the existing EDP operations use cathodic systems, and continued changeovers from anodic to cathodic EDP are expected. Since cathodic EDP produces a coating with better corrosion resistance, the proposed standards are based on the best available cathodic EDP systems.

The coating material on which the EDP emission limit is based is presently in production use. Although this low solvent content material is currently available only in limited quantities, it is expected to be available in sufficient quantities for use in all new or modified sources before promulgation of the standard. The final promulgated standards will be based on this low solvent content material, rather than the EDP material commonly used now, if it is determined to be widely available at that time.

The emission limit for guide coat operations is based on a transfer of technology from topcoat operations. The guide coat is essentially a topcoat material, without pigmentation, and water-based topcoats are available which can comply with the proposed limits. Hence, the same emission limit is proposed for the guide coat operation as for the topcoat operation.

Because of the elevated temperatures present in the prime coat, guide coat, and topcoat bake ovens, additional amounts of "cure volatile" VOC may be emitted. These "cure volatile" emissions are present only at high temperatures and are not measured in the analysis which is used to determine the VOC content of coating materials. Cure volatile emissions, however, are believed to constitute only a small percentage of total VOC emissions. Consequently, because of the complexity of measuring and controlling cure volatile emissions, they will not be considered in determining compliance with the proposed standards.

A large number of coating materials are used in topcoat operations, and each may have a different VOC content. Hence, an average VOC content of all the coatings used in this operation would be computed to determine compliance with the proposed standards. Either of two averaging techniques could be used for computing this average. Weighted averages provide very accurate results but would require keeping records of the total volume and

percent solids of each different coating used. Arithmetic averages are not always as accurate; however, they are much simpler to calculate. In the case of topcoat operations, normally 15 to 20 different coatings are used, and the VOC content for most of these coatings is in the same general range. Therefore, an arithmetic average would closely approximate the values obtained from a weighted average. An arithmetic average would be calculated by summing the VOC content of each surface coating material used in a surface coating operation (i.e., guide coat or topcoat), and dividing the sum by the number of different coating materials used. Arithmetic averages are also consistent with the approach being incorporated into some revised SIP's.

For the EDP process, however, an arithmetic average VOC content is not appropriate to determine compliance with the proposed standards. In an EDP system, the coating material applied to an automobile or light-duty truck body is replaced by adding fresh coating materials to maintain a relatively constant concentration of solids, solvent, and fluid level in the EDP coating tank. Three different types of materials are usually added in separate streams—clear resin, pigment paste, and solvent.

The clear resin and pigment paste are very low in VOC content (i.e., 10 percent or less), while the solvent is very high in VOC content (i.e., 90 percent or more). The solvent additive stream is only about 2 percent of the total volume added. Consequently, an arithmetic average of the three streams seriously misrepresents the actual amount of VOC added to the EDP coating tank. Weighted averages, therefore, were selected for determining the average VOC content of coating materials applied by EDP.

If an automobile or light-duty truck manufacturer chooses to use a control technique other than water-based coatings, the transfer efficiency of the application devices used becomes very important. As transfer efficiency decreases, more coating material is used and VOC emissions increase. Therefore transfer efficiency must be taken into account to determine equivalency to water-based coatings.

Electrostatic spraying, which applies surface coatings at high transfer efficiencies, can in many industries be used with water-based coatings if the entire paint handling system feeding the atomizers is insulated electrically from ground. Otherwise, the high conductivity of the water involved would ground out and make ineffective the electrostatic effect. In the case of the coating of

automobiles, however, because of the larger number of colors involved, the high frequency and speed of color changes required, the large volume of coatings consumed per shift, and the large number of both automatic and manual atomizers involved, it is not technically feasible to combine water-based coatings and electrostatic methods for reasons of complexity, cost, and personnel comfort. Consequently, water-based surface coatings are applied by air-atomized spray systems at a transfer efficiency of about 40 percent. The numerical emission limits included in the proposed standards were developed based on the use of water-based surface coatings applied at a 40 percent transfer efficiency. Therefore, if surface coatings are applied to a greater than 40 percent transfer efficiency, surface coatings with higher VOC contents may be used with no increase in VOC emissions to the atmosphere. Transfer efficiencies for various means of applying surface coatings have been estimated, based on information obtained from industries and vendors, as follows:

Application method:	Transfer efficiency (percent)
Air Atomized Spray	40
Manual Electrostatic Spray	75
Automatic Electrostatic Spray	95
Electrodeposition (EDP)	100

These values are estimates which reflect the high side of expected transfer efficiency ranges, and therefore, are intended to be used only for the purpose of determining compliance with the proposed standards.

Frequently, more than one application method is used within a single surface coating operation. In these cases, a weighted average transfer efficiency, based on the relative volume of coating sprayed by each method, will be estimated. These situations are likely to vary among the different manufacturers and the estimates, therefore, will be subject to approval by the Administrator on a case-by-case basis.

Method of Determining Compliance

The procedure for determining compliance with the proposed standards is complicated due to the number of different control systems which may be used. The following multistep procedure would be used.

1. Determine the average VOC content per liter of coating solids of the prime coat, guide coat, and topcoat materials being used. This would require analyzing all coating materials used in each coating operation using the proposed Reference Method 24 (Candidate 1 or Candidate 2) and

calculating an average VOC content for each coating operation.

2. Select the appropriate transfer efficiency for each surface coating operation from the table included in the proposed standards.

3. Calculate the mass of VOC emissions per volume of applied solids for each surface coating operation by dividing the appropriate average VOC content of the coatings (Step 1) by the transfer efficiency of the surface coating operation (Step 2). If the value obtained is lower than the emission limit included in the proposed standards, the surface coating operation would be in compliance. If the value obtained is higher than the emission limit, add-on VOC emission control would be required to comply with the proposed standards.

4. If add-on emission control is required, calculate the emission reduction efficiency in VOC emissions which is required using the equations included in the proposed standards.

5. In cases where all exhaust gases are not vented to an emission control device, determine the percentage of total VOC emissions which enter the add-on emission control device by sampling all the stacks and using the equations included in the proposed standards. Representative sampling, however, could be approved by the Administrator, on a case-by-case basis, rather than requiring sampling of all stacks for this determination.

6. Calculate the actual efficiency of the control device by determining VOC emissions before and after the device using the proposed Reference Method 25.

7. Calculate the VOC emission reduction efficiency achieved by multiplying the percentage of VOC emissions which enter the add-on VOC emission control device (Step 5) by the add-on control device efficiency (Step 6). If the resulting value of the emission reduction efficiency achieved were greater than that required (Step 4), then the surface coating operation would be in compliance.

Detailed instructions, as well as the equations to be used for these calculations, are contained in the proposed standards.

Selection of Monitoring Requirements

Monitoring requirements are generally included in standards of performance to provide a means for enforcement personnel to ensure that emission control measures adopted by a facility to comply with standards of performance are properly operated and maintained. Surface coating operations which have achieved compliance with

the proposed standards without the use of add-on VOC emission control devices would be required to monitor the average VOC content (weighted averages for EDP and arithmetic averages for guide coat and topcoat) of the coating materials used in each surface coating operation. Generally, increases in the VOC content of the coating materials would cause VOC emissions to increase. These increases could be caused by the use of new coatings or by changes in the composition of existing coatings. Therefore, following the initial performance test, increases in the average VOC content of the coating materials used in each surface coating operation would have to be reported on a quarterly basis.

Where add-on control devices, such as incinerators, were used to comply with the proposed standards, combustion temperatures would be monitored. Following the initial performance test, decreases in the incinerator combustion temperature would be reported on a quarterly basis.

Performance Test Methods

Reference Method 24, "Determination of Volatile Organic Compound Content of Paint, Varnish, Lacquer, or Related Products," is proposed in two forms—Candidate 1 and Candidate 2. Candidate 1 leads to a determination of VOC content expressed as the mass of carbon. Candidate 2 yields a determination of VOC content measured as mass of volatile organics. The decision as to which Candidate will be used depends on the final format selected for the proposed standards. Reference Method 25, "Determination of Total Gaseous Nonmethane Volatile Organic Compound Emissions," is proposed as the test method to determine the percentage reduction of VOC emissions achieved by add-on emission control devices.

Public Hearing

A public hearing will be held to discuss the proposed standards in accordance with Section 307(d)(5) of the Clean Air Act. Persons wishing to make oral presentations should contact EPA at the address given above (see Addresses Section). Oral presentations will be limited to 15 minutes each. Any member of the public may file a written statement before, during, or within 30 days after the hearing. Written statements should be addressed to "Docket" (see Addresses Section).

A verbatim transcript of the hearing and written statements will be available for public inspection and copying during normal working hours at EPA's Central

Docket Section, Room 2903B, Waterside Mall, 401 M Street, S.W., Washington, D.C. 20460.

Docket

The docket, containing all supporting information used by EPA to date, is available for public inspection and copying between 8:00 a.m. and 4:00 p.m., Monday through Friday, at EPA's Central Docket Section, Room 2903B, Waterside Mall, 401 M Street, S.W., Washington, D.C. 20460.

The docket is an organized and complete file of all the information submitted to or otherwise considered by EPA in the development of the rulemaking. The docket is a dynamic file, since material is added throughout the rulemaking development. The docketing system is intended to allow members of the public and industries involved to readily identify and locate documents so that they can intelligently and effectively participate in the rulemaking process. Along with the statement of basis and purpose of the promulgated rule and EPA responses to significant comments, the contents of the Docket will serve as the record in case of judicial review [Section 307(d)(a)].

Miscellaneous

As prescribed by Section 111, establishment of standards of performance for automobile and light-duty truck surface coating operations was preceded by the Administrator's determination (40 CFR 60.16, 44 FR 49222, dated August 21, 1979) that these sources contribute significantly to air pollution which may reasonably be anticipated to endanger public health or welfare. In accordance with Section 117 of the Act, publication of these standards was preceded by consultation with appropriate advisory committees, independent experts, and Federal departments and agencies. The Administrator welcomes comments on all aspects of the proposed regulations, including the technological issues, monitoring requirements, and the proposed test methods. Comments are requested specifically on Method 24 (Candidate 1 and Candidate 2) and the coating material used as the basis for the prime coat emission limit.

It should be noted that standards of performance for new sources established under Section 111 of the Clean Air Act reflect:

... application of the best technological system of continuous emission reduction which (taking into consideration the cost of achieving such emission reduction, and any nonair quality health and environmental impact and energy requirements) the

Administrator determines has been adequately demonstrated [Section 111(a)(1)].

Although emission control technology may be available that can reduce emissions below those levels required to comply with standards of performance, this technology might not be selected as the basis of standards of performance because of costs associated with its use. Accordingly, standards of performance should not be viewed as the ultimate in achievable emission control. In fact, the Act may require the imposition of a more stringent emission standard in several situations.

For example, applicable costs do not necessarily play as prominent a role in determining the "lowest achievable emission rate" for new or modified sources locating in nonattainment areas (i.e., those areas where statutorily mandated health and welfare standards are being violated). In this respect, section 173 of the Act requires that new or modified sources constructed in an area which exceeds the NAAQS must reduce emissions to the level which reflects the LAER, as defined in section 171(3). The statute defines LAER as the rate of emissions based on the following, whichever is more stringent:

(A) the most stringent emission limitation which is contained in the implementation plan of any State for such class or category of source, unless the owner or operator of the proposed source demonstrates that such limitations are not achievable; or

(B) the most stringent emission limitation which is achieved in practice by such class or category of source.

In no event can the emission rate exceed any applicable new source performance standard.

A similar situation may arise under the prevention-of-significant-deterioration-of-air-quality provisions of the Act. These provisions require that certain sources employ BACT as defined in section 169(3) for all pollutants regulated under the Act. BACT must be determined on a case-by-case basis, taking energy, environmental and economic impacts, and other costs into account. In no event may the application of BACT result in emissions of any pollutants which will exceed the emissions allowed by any applicable standard established pursuant to section 111 (or 112) of the Act.

In all cases, SIP's approved or promulgated under section 110 of the Act must provide for the attainment and maintenance of NAAQS designed to protect public health and welfare. For this purpose, SIP's must, in some cases, require greater emission reduction than those required by standards of performance for new sources.

Finally, States are free under section 116 of the Act to establish even more stringent emission limits than those established under section 111 or those necessary to attain or maintain the NAAQS under section 110. Accordingly, new sources may in some cases be subject to limitations more stringent than standards of performance under section 111, and prospective owners and operators of new sources should be aware of this possibility in planning for such facilities.

Under EPA's sunset policy for reporting requirements in regulations, the reporting requirements in this regulation will automatically expire 5 years from the date of promulgation unless EPA takes affirmative action to extend them.

Section 317 of the Clean Air Act requires the Administrator to prepare an economic impact assessment for any new source standard of performance under section 111(b) of the Act. An economic impact assessment was prepared for the proposed regulations and for other regulatory alternatives. All aspects of the assessment were considered in the formulation of the proposed standards to ensure that the proposed standards would represent the best system of emission reduction considering costs. The economic impact assessment is included in the Background Information Document.

Dated: September 27, 1979.

Douglas M. Costle,
Administrator.

This proposed amendment to Part 60 of Chapter I, Title 40 of the Code of Federal Regulations would—

1. Add a definition of the term "volatile organic compound" to § 60.2 of Subpart A—General Provisions as follows:

§ 60.2 Definitions.

(dd) "Volatile Organic Compound" means any organic compound which participates in atmospheric photochemical reaction or is measured by the applicable reference methods specified under any subpart.

2. Add Subpart MM as follows:

Subpart MM—Standards of Performance for Automobile and Light-Duty Truck Surface Coating Operations

Sec.

60.390 Applicability and designation of affected facility.

60.391 Definitions.

60.392 Standards for volatile organic compounds.

60.393 Monitoring of operations.

60.394 Test methods and procedures.

60.395 Modifications.

Authority: Secs. 111 and 301(a) of the Clean Air Act, as amended. [42 U.S.C. 7411, 7601(a)], and additional authority as noted below.

Subpart MM—Standards of Performance for Automobile and Light-Duty Truck Surface Coating Operations

§ 60.390 Applicability and designation of affected facility.

(a) The provisions of this subpart apply to the following affected facilities in an automobile or light-duty truck surface coating line: each prime coat operation, each guide coat operation, and each topcoat operation.

(b) The provisions of this subpart apply to any affected facility identified in paragraph (a) of this section that begins construction or modification after _____ (date of publication in the Federal Register).

§ 60.391 Definitions.

All terms used in this subpart that are not defined below have the meaning given to them in the Act and in Subpart A of this part.

(a) "Automobile" means a motor vehicle capable of carrying no more than 12 passengers.

(b) "Automobile and light-duty truck body" means the body section rearward of the windshield and the front-end sheet metal or plastic exterior panel material forward of the windshield of an automobile or light-duty truck.

(c) "Bake oven" means a device which uses heat to dry or cure coatings.

(d) "Electrodeposition (EDP)" means a method of applying prime coat. The automobile or light-duty truck body is submerged in a tank filled with coating material, and an electrical field is used to deposit the material on the body.

(e) "Electrostatic spray application" means a spray application method that uses an electrical potential to increase the transfer efficiency of the coating solids. Electrostatic spray application can be used for prime coat, guide coat, or topcoat operations.

(f) "Flash-off area" means the structure on automobile and light-duty truck assembly lines between the coating application system (EDP tank or spray booth) and the bake oven.

(g) "Guide coat operation" means the guide coat spray booth, flash-off area and bake oven(s) which are used to apply and dry or cure a surface coating on automobile and light-duty truck bodies between the prime coat and topcoat operation.

(h) "Light-duty truck" means any motor vehicle rated at 3,850 kilograms (ca. 8,500 pounds) gross vehicle weight or less designed mainly to transport property.

(i) "Prime coat operation" means the prime coat application system (spray booth or dip tank), flash-off area, and bake oven(s) which are used to apply and dry or cure the initial coat on the surface of automobile or light-duty truck bodies.

(j) "Spray application" means a method of applying coatings by atomizing the coating material and directing this atomized spray toward the part to be coated. Spray applications can be used for prime coat, guide coat, and topcoat operations.

(k) "Spray booth" means a structure housing or manual spray application equipment where prime coat, guide coat, or topcoat is applied to automobile or light-duty truck bodies.

(l) "Surface coating operation" means any prime coat, guide coat, or topcoat operation on an automobile or light-duty truck surface coating line.

(m) "Topcoat operation" means the topcoat spray booth(s), flash-off area(s), and bake oven(s) which are used to apply and dry or cure the final coating(s) on automobile and light-duty truck bodies (i.e., those which give an automobile or light-duty truck body its color and surface appearance).

(n) "Transfer efficiency" means the fraction of the total applied coating solids which remains on the part.

(o) "Volatile organic compound" (VOC) means any organic compound which is measured by Method 24 (Candidate 1 or Candidate 2) and Method 25.

(p) "VOC emissions" means the mass of volatile organic compounds, expressed as kilograms of carbon per liter of applied coating solids, emitted from a surface coating operation.

(q) "VOC content" means the volatile organic compound content, in kilograms of carbon per liter of coating solids, of a coating material used in spray applications or coating make-up stream to an EDP tank.

§ 60.392 Standards for volatile organic compounds.

After the performance test required by § 60.8 has been completed, no owner or operator subject to the provisions of this subpart shall discharge or cause of the discharge into the atmosphere of VOC emissions which exceed the following limits:

(a) 0.10 kilogram of VOC (measured as mass of carbon) per liter of applied coating solids from each prime coat operation.

(b) 0.84 kilogram of VOC (measured as mass of carbon) per liter of applied coating solids from each guide coat operation.

(c) 0.84 kilogram of VOC (measured as mass of carbon) per liter of applied coating solids from each topcoat operation.

§ 60.393 Monitoring of operations.

(a) Any owner or operator subject to the provisions of this subpart shall—(1) Install, calibrate, operate, and maintain a monitoring device which records the combustion temperature of any effluent gases which are emitted from any surface coating operation and which are incinerated to comply with § 60.392. The manufacturer must certify that the monitoring device is accurate to within $\pm 2^\circ\text{C}$ ($\pm 3.6^\circ\text{F}$).

(2) Determine the weighted average VOC content of the coating materials used in any EDP prime coat operation whenever a change occurs in the composition of any of these coating materials. The owner or operator shall compute the weighted average by the following equation:

$$C = \frac{\sum_{i=1}^n CS_i \times VOLS_i \times SC_i}{\sum_{i=1}^n VOLS_i \times SC_i}$$

where:

C = the weighted averaged VOC content of all the coating materials used in an EDP system.

CS_i = the VOC content of the material in each coating makeup stream.

$VOLS_i$ = the volume (cubic meters) of each makeup stream added to the EDP tank during the previous month.

SC_i = the solid content of the material in each coating makeup stream expressed as a volume fraction.

n = the number of makeup streams.

(3) Determine the average VOC content of the coating materials in any surface coating operation which uses spray application whenever a change occurs in the composition of any of these coating materials. The owner or operator shall determine and record the arithmetic average of the VOC content of all coating materials in a coating operation which uses more than one coating material.

(b) Any owner or operator subject to the provisions of this subpart shall report for each calendar quarter all measurement results as follows:

(1) Where compliance with § 60.392 is achieved without the use of add-on control devices, any month during which—

(i) The weighted average VOC content of the makeup materials used in any prime coat operation employing EDP exceeds the most recent value which demonstrated compliance with § 60.392(a) by the performance test required in § 60.8.

(ii) The arithmetic average VOC content of the coating materials used in any surface coating operation employing spray application exceeds the most recent value which demonstrated compliance with § 60.392 by the performance test required in § 60.8.

(2) Where compliance with § 60.392 is achieved by the use of incineration, all periods in excess of 5 minutes during which the temperature in any incinerator used to control the emission from a surface coating operation remains below the most recent level which demonstrated compliance with § 60.392 by the performance tests required in § 60.8. The report required under § 60.7(c) shall identify each such occurrence and its duration.

(3) The reporting requirements in this regulation will automatically expire five years from the date of promulgation unless EPA takes affirmative action to extend them.

§ 60.394 Test methods and procedures.

(a) The reference methods in Appendix A to this part, except as provided for in § 60.8(b), shall be used to determine compliance with § 60.392 as follows:

(1) The owner or operator shall use Reference Method 24 (Candidate 1 or Candidate 2) to measure the VOC content of every coating or makeup material used in each surface coating operation of an automobile or light-duty truck surface coating line. The coating sample shall be a 1 liter sample taken at a point where the sample will be representative of the coating material as applied to the vehicle surface. The 1 liter sample shall be divided into three aliquots for triplicate determinations by Method 24 (Candidate 1 or Candidate 2).

(2) The owner or operator shall compute the arithmetic average VOC content of all coating materials used in each surface coating operation that uses spray application.

(3) The owner or operator shall use the calculation procedures given in § 60.393(a)(2) to compute the weighted average VOC content of all makeup materials added to an EDP tank during a selected one month period for each prime coat operation that uses EDP.

(4) The owner or operator shall determine the VOC emissions by the equation:

$$E = \frac{C}{TE}$$

where:

E = the VOC emissions.

C = the average VOC content of all the coating or makeup materials used in that operation. The owner or operator shall

use an arithmetic average for systems using spray application and a weighted average for systems using EDP.

TE = the appropriate transfer efficiency as determined in paragraph (a)(5) of this section.

(5) The owner or operator shall select the appropriate transfer efficiency from the following table for each surface coating operation.

Application method	Transfer efficiency (TE)
Air Atomized Spray	0.40
Manual Electrostatic Spray	0.75
Automatic Electrostatic Spray	0.95
Electrodeposition	1.00

If the owner or operator can justify to the Administrator's satisfaction that other values for transfer efficiencies are appropriate, the Administrator will approve their use on a case-by-case basis. Where more than one application method is used on an individual surface coating operation, the owner or operator shall perform an analysis to determine the relative volume of solids coating materials applied by each method. The owner or operator shall use these relative volumes of solids to compute a weighted average transfer efficiency for the operation. The Administrator will review and approve this analysis on a case-by-case basis.

(b) For each surface coating operation which cannot achieve compliance with § 60.392 without the use of add-on control devices, the owner or operator shall use the following procedures to determine that the emission reduction efficiency of the control device(s) is sufficient to achieve compliance with § 60.392:

(1) The owner or operator shall compute the emission reduction efficiency required for each surface coating operation by the following equation:

$$ER = \frac{E - EL}{E} \times 100$$

where:

ER = the required emission reduction efficiency (in percent) for the applicable surface coating operation to achieve compliance with § 60.392.

E = the VOC emissions from the applicable surface coating operation.

EL = the numerical VOC emission limit in § 60.392 for the applicable surface coating operation.

(2) The owner or operator shall determine the emission reduction efficiency achieved by the control device(s) on each applicable surface coating operation as follows:

(i) The owner or operator shall use Reference Method 25 to determine the

VOC concentration in the effluent gas before and after the emission control device for each stack that is equipped with an emission control device. The owner or operator shall use Reference Method 2 to determine the volumetric flowrate of the effluent gas before and after the emission control device on each stack. The Administrator will approve testing of representative stacks, on a case-by-case basis, if the owner or operator can show to the Administrator's satisfaction that testing of representative stacks yields results comparable to those that would be obtained by testing all stacks.

(ii) For Method 25, the sampling time for each run shall be at least 60 minutes and the minimum sample volume shall be at least 0.003 dscm (0.106 dscf) except that shorter sampling times or smaller volumes, when necessitated by process variables or other factors, may be approved by the Administrator.

(iii) The owner or operator shall determine the efficiency of each emission control device by the following equation:

$$EFF = \frac{(CB \times VOLB) - (CA \times VOLA)}{(CB \times VOLB)} \times 100$$

where:

EFF = the emission control device efficiency, in percent.

CB = the concentration of VOC in the effluent gas before the emission control device, in parts per million by volume.

CA = the concentration of VOC in the effluent gas after the emission control device, in parts per million by volume.

VOLA = the volumetric flow rate of the effluent gas after the emission control device, in dry standard cubic meters per second.

VOLB = the volumetric flow rate of the effluent gas before the emission control device, in dry standard cubic meters per second.

If an emission control device controls the emissions from more than one stack, the owner or operator shall measure CB and VOLB at a location between the manifold that receives all the exhausts from the applicable surface coating operation and the control device. If a manifold is not used, the product $CB \times VOLB$ shall be replaced by the sum of the individual products for each stack on the applicable surface coating operation controlled by this device.

(iv) The owner or operator shall determine the fraction of the total VOC discharged from an applicable surface coating operation which enters each emission control device on that operation by the following equation:

$$F_i = \frac{CB_i \times VOLB_i}{\sum_{k=1}^n (CB_k \times VOLB_k)}$$

where:

F_i = the fraction of the total VOC discharged from the applicable surface coating operation which enters the emission control device.

CB_i = the value of CB for stack (i) on the applicable surface coating operation.

CB_k = the value of CB for each stack (k) on the applicable surface coating operation.

$VOLB_i$ = the value of VOLB for each emission control device (i).

$VOLB_k$ = the value of VOLB for each stack (k) on the applicable surface coating operation.

n = the number of stacks on the applicable surface coating operation.

The owner or operator shall use the procedures contained in clause (ii) of this subparagraph for any emission control device (i) that controls the emissions from more than one stack.

(v) The owner or operator shall determine the emission reduction efficiency achieved by the control device(s) on the applicable surface coating operation using the equation:

$$EA = \sum_{i=1}^m (F_i \times EFF_i)$$

where:

EA = the emission reduction efficiency achieved, in percent.

EFF_i = the emission reduction efficiency (in percent) of each control device on the applicable surface coating operation.

m = the number of control devices on the applicable surface coating operation.

(3) If EA is greater than or equal to ER, the applicable surface coating operation will be in compliance with § 60.392.

§ 60.395 Modifications.

(a) The following physical or operational changes are not, by themselves, considered modifications of existing facilities:

(1) Changes as a result of model year changeovers or switches to larger cars.

(2) Changes in the application of the coatings to increase paint film thickness.

Appendix A—Reference Methods

3. Method 24 (Candidate 1), Method 24 (Candidate 2), and Method 25 are added to Appendix A as follows:

Method 24 (Candidate 1)—Determination of Volatile Content (as Carbon) of Paint, Varnish, Lacquer, or Related Products

1. Applicability and Principle

1.1 *Applicability.* This method is applicable for the determination of volatile

content (as carbon) of paint, varnish, lacquer, and related products listed in Section 2.

1.2 *Principle.* The weight of volatile carbon per unit volume of solids is calculated for paint, varnish, lacquer, or related surface coating after using standard methods to determine the volatile matter content, density of the coating, density of the solvent, and using the oxidation-nondispersive infrared (NDIR) analysis for the carbon content.

2. Classification of Surface Coating

For the purpose of this method, the applicable surface coatings are divided into two classes. They are:

2.1 *Class I: General Solvent-Type Paints and Water Thinned Paints.* This class includes white linseed oil outside paint, white soya and phthalic alkyd enamel, white linseed o-phthalic alkyd enamel, red lead primer, zinc chromate primer, flat white inside enamel, white epoxy enamel, white vinyl toluene, modified alkyd, white amino modified baking enamel, and other solvent-type paints not included in class II. It also includes emulsion or latex paints and colored enamels.

2.2 *Class II: Varnishes and Lacquers.* This class includes clear and pigmented lacquers and varnishes.

3. Applicable Standard Methods

Use the apparatus, reagents, and procedures specified in the standard methods below:

3.1 *ASTM D 1644-59 Method A:* Standard Methods of test for Non-volatile Contents of Varnishes. Do not use Method B.

3.2 *ASTM D 1475-60.* Standard Method of Test for Density of Paint, Lacquer, and Related Products.

3.3 *ASTM D 2369-73:* Standard Method of Test for Volatile Content of Paints.

3.4 *ASTM D 3272-76:* Standard Recommended Practice for Vacuum Distillation of Solvents from Solvent-Base Paints for Analysis.

4. Apparatus (Oxidation/NDIR Procedure)

4.1 *Electric Furnace.* Capable of maintaining a temperature of $800 \pm 50^\circ \text{C}$.

4.2 *Combustion Chamber.* Stainless steel tubing, 13 mm ($\frac{1}{2}$ in.) internal diameter and 46 cm (18 in.) in length. Pack the tube loosely with 3 mm ($\frac{1}{8}$ in.) alumina pellets coated with 5 percent palladium. Place plugs of stainless steel wool at either end. Other catalytic systems which can demonstrate 95 percent efficiency as described in Section 6.5.4 are considered equivalent.

4.3 *Septum.* Teflon¹-coated rubber septum.

4.4 *Condenser.* Ice bath condenser.

4.5 *Analyzer.* Nondispersive infrared analyzer (NDIR) to measure CO_2 TO WITHIN 0.5 PERCENT OF THE CALIBRATION GAS CONCENTRATION.

4.6 *Recorder.* Capable of matching the output of the NDIR.

4.7 *Collection Tank.* A collection tank of at least 8 liters in volume. See procedure in Section 6.5.1 for calibrating the volume of the tank. The tank should be capable of

¹ Mention of trade names or specific products does not constitute endorsement by the Environmental Protection Agency.

withstanding a pressure of 2000 mm (80 in.) Hg (gauge).

4.8 *Pressure Gauge for Collection Tank.* Capable of measuring positive pressure to 1100 mm (42 in.) Hg and vacuum pressure to 700 ± 5 mm (28 ± 0.25 in.) Hg.

4.9 *Vacuum Pump.* Capable of evacuating the collection tank to an absolute pressure of 51 mm (2 in.) Hg.

4.10 *Analytical Balance.* To measure to within ± 0.5 mg.

4.11 *Syringes.* 100 ± 1.0 μ l, 500 ± 1.0 μ l, and 1000 ± 5 μ l syringe, with needles long enough to inject sample directly into the carrier gas stream.

4.12 *Mixer.* Vortex-mixer to ensure homogeneous mixing of solvent.

4.13 *Flow Regulators.* Rotameters, or equivalent, to measure to 500 cc/min in flow-rate.

4.14 *Temperature Gauge.* A thermometer graduated in 0.1° C, with range from 0° C to 100° C.

4.15 *Tank Calibration Equipment.* A balance to weigh collection tank to ± 30 g or a graduated glass cylinder to measure tank volume within ± 30 ml.

5. Reagents (Oxidation/NDIR Procedure)

5.1 Calibration Gases.

5.1.1 *Zero Gas.* Nitrogen.

5.1.2 *CO₂ Gas.* A range of concentration to allow at least a 3-point calibration of each measuring range of the instrument.

5.1.3 *Carrier Gas.* Air containing less than 1 ppm hydrocarbon as carbon, as certified by the manufacturer.

5.2 *Catalyst.* Alumina (3 mm pellets) coated with 5 percent palladium, or equivalent (commercially available).

5.3 *Acetone.* Reagent grade.

5.4 *Nitric Acid Solution.* Dilute 70 percent nitric acid 1:1 by volume with distilled water.

5.5 *1-Butanol.* Ninety-nine molecular percent pure.

5.6 *Methane Gas.* 0.5 percent methane in air.

6. Procedure

6.1 *Classification of Samples.* Assign the coating to one of the two classes discussed in Section 2 above. Assign any coating not clearly belonging to Class II to Class I.

6.2 *Volatile Content.* Use one of the following methods to determine the volatile content according to the class of coating.

6.2.1 *Class I.* Use the Procedure in ASTM D 2369-73. Record the following information: W_1 = Weight of dish and sample, g.
 W_2 = Weight of dish and sample after heating.

g.

S = Sample weight, g.

Repeat the procedure for a total of three determinations for each coating. Calculate the weight fraction of volatile matter W for each analysis as follows:

$$W = \frac{W_1 - W_2}{S}$$

Report the arithmetic average weight fraction \bar{W} of the three determinations.

6.2.2 *Class II.* Use the procedure in ASTM D 1644-59 Method A; record the following information:

A = Weight of dish, g.

B = Weight of sample used, g.

C = Weight of dish and sample after heating, g.

Repeat the procedure for a total of three determinations for each coating. Calculate the weight fraction W of volatile content for each analysis as follows:

$$W = \frac{(A + B - C)}{B}$$

Report the arithmetic average weight fraction \bar{W} of three determinations.

6.3 *Coating Density.* Determine the density D_m (in g/cm³) of the paint, varnish, lacquer, or related product of either class according to the procedure outlined in ASTM D 1475-60. Make a total of three determinations for each coating. Report the density \bar{D}_m as the arithmetic average of the three determinations.

6.4 Solvent Density.

6.4.1 Perform the solvent extraction according to the procedure outlined in ASTM D 3272-76. For aqueous paint, use a collection-tube in an ice-bath prior to the collection-tube in the acetone and dry-ice mixture to prevent water from freezing in the collection-tube. Combine the contents of both tubes before analysis. If excessive foaming occurs during distillation, discard the sample, and repeat with a new sample treated with an anti-foam spray (e.g. Dow Corning's "Anti-foam A Spray") before distillation. Anti-foam spray must be nonorganic and nonflammable. Use spray sparingly.

6.4.2 Determine the density D_s (in g/cm³) of the solvent according to the procedure outlined in ASTM D 1475-60. Make a total of three determinations for the solvent, and report the average density \bar{D}_s as the arithmetic average of the three determinations.

6.5 Carbon Content of the Solvent.

Analyze the solvent within 24 hours after distillation; keep it under refrigeration when not in use. To determine the carbon content, follow the procedure below:

6.5.1 Clean and calibrate the collection tank as follows: Rinse the inside of the tank once with acetone, twice with tap water, thrice with the nitric acid solution, and twice with tap water. Weigh the tank when empty and when full of water. Measure the temperature of the water, and calculate the volume as follows:

$$V = \frac{W_f - W_e}{D_t}$$

Where:

t = Temperature of the water, $^\circ$ C ($^\circ$ F).

V = Volume of the tank, ml.

W_e = Weight of the empty tank, g.

W_f = Weight of the full tank, g.

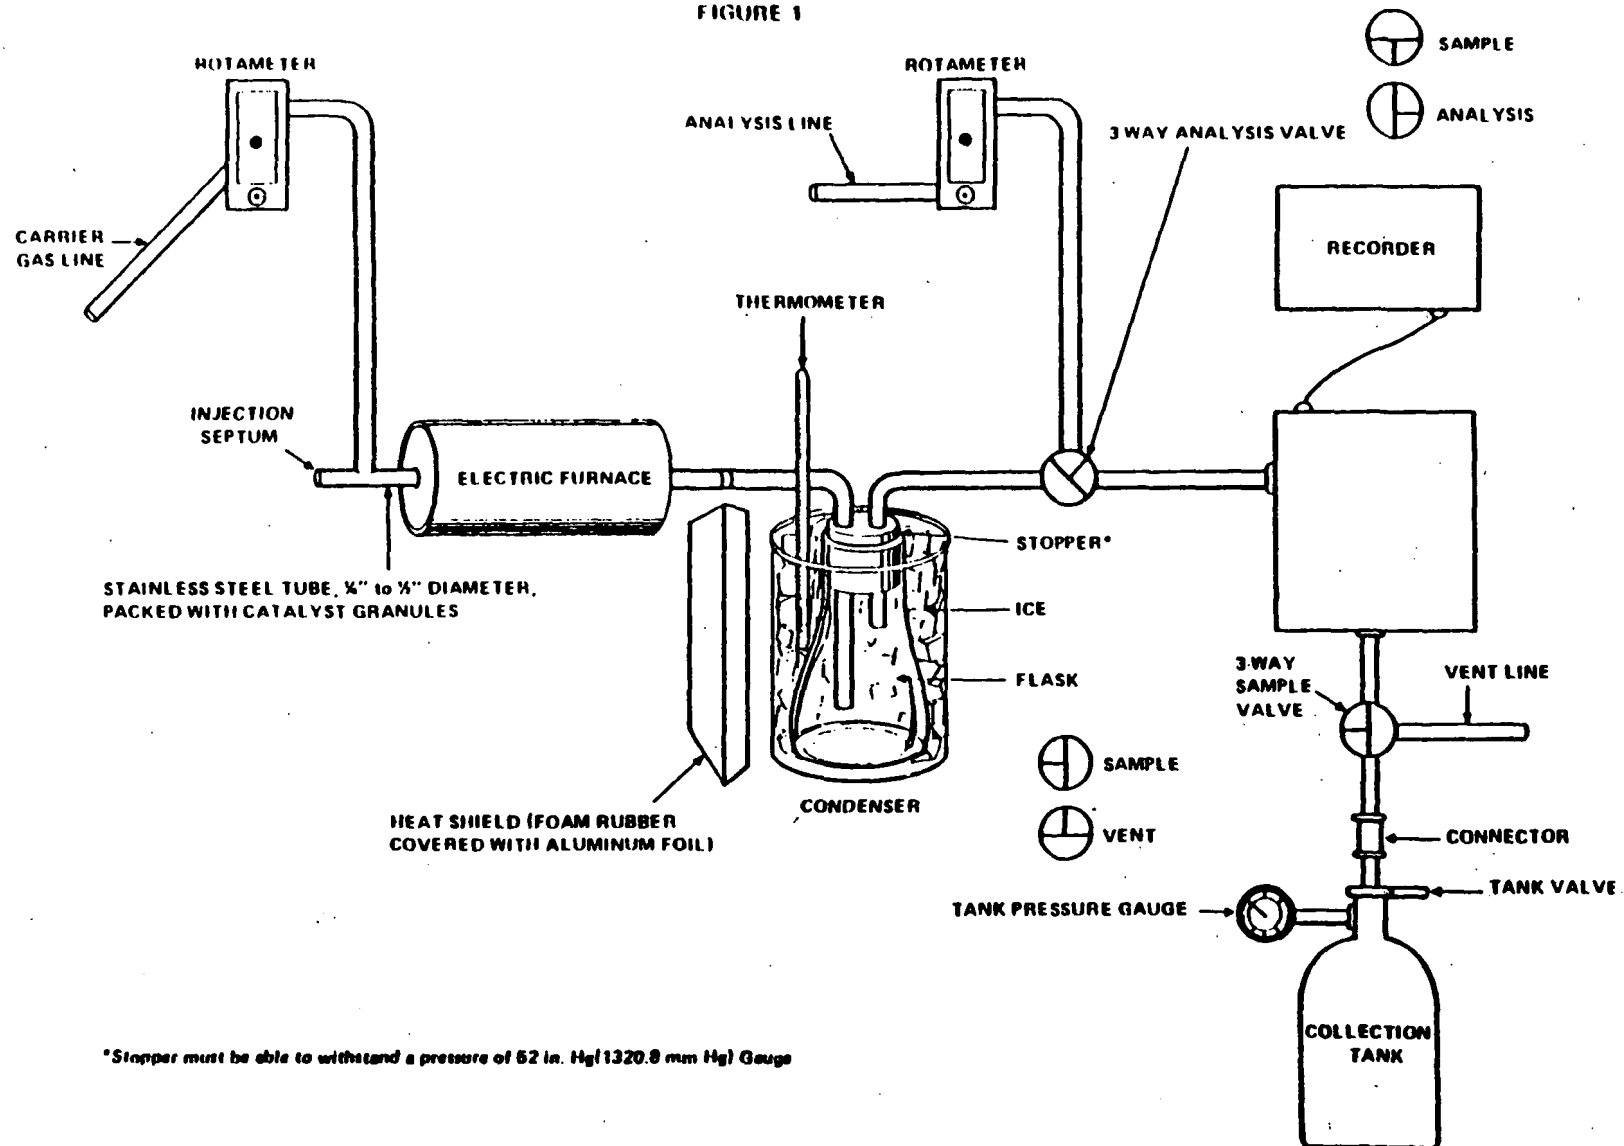

D_t = Density of water at temperature t, g/ml.

Alternatively, measure the volume of water necessary to fill the tank. The volume of the tank connections and pressure gauge are negligible for a tank volume of at least 6 liters.

6.5.2 Calibrate the NDIR according to the manufacturer's instruction. Use at least a 3-point calibration. Introduce the CO₂ calibration gas through the analysis line.

6.5.3 Assemble the oxidation system as shown in Figure 1. Heat the catalyst until the temperature reaches equilibrium at $800 \pm 50^\circ$ C. Add ice to the condenser and remove excess water to maintain the temperature at 0° C.

FIGURE 1

*Stopper must be able to withstand a pressure of 52 in. Hg (1320.8 mm Hg) Gauge

6.5.4 Determination of Conversion Efficiency. Pass 0.5 percent methane gas in air through carrier gas line; 0.5 percent CO₂ should be generated within ± 5 percent error. Using a 100 μ l sample of l-butanol, follow the procedure in 6.5.5 to 6.5.13. Calculate the theoretical CO₂ volume percent as in Section 7.3. This value should equal the value as measured by the NDIR, within ± 5 percent error. If conversion efficiency is 100 ± 5 percent, analyze the solvent extracted from the paint according to procedure in Sections 6.5.5 to 6.5.14.

6.5.5 Purge the collection tank twice with N₂, then evacuate the tank to at least 50.8 mm (2 in.) Hg absolute pressure. Connect the cylinder to the collection line.

6.5.6 Mix the solvent sample thoroughly on a vortex-mixer. Then, draw a sample (0.100 to 0.300 ml) into the syringe. Record the volume of sample used.

6.5.7 Turn analysis valve to "sample" position, and turn the sample valve to "vent" position. Then turn on the carrier gas at a rate of 500 cc/min to flush the system for 2 minutes.

6.5.8 With gas flowing at 500 cc/min (maintain this rate throughout the test procedure), turn sample valve to "sample" position. Open the tank valve and inject the sample into the gas stream through the injection septum. Continue to draw the sample into the tank until the NDIR reads zero. (Note.—On replicate samples, a decrease in peak value indicates that the catalyst or sample has deteriorated, assuming that other factors, such as leaks, cell contamination, mechanical defects of the instruments, etc., have not occurred.)

6.5.9 At completion of collection, close the tank valve, and turn sample valve to "vent" position. Let the carrier gas flush the system for 2 minutes, then turn off the carrier gas.

6.5.10 Disconnect the tank and pressurize it with N₂ to about 1016 mm (40 in.) Hg gauge pressure. Record the final tank pressure after pressurization, the atmospheric pressure, and the room temperature.

6.5.11 Connect the tank to the analysis line and turn the analysis valve to "analysis" position.

6.5.12 Pass the CO₂ sample gas at the same rate as the calibration gas. Keep the rate constant by adjusting the rotameter as tank pressure falls.

6.5.13 Record the CO₂ concentration when the peak value is reached. This peak value will remain constant as long as the sample gas continues to flow at a constant rate.

6.5.14 Repeat steps 6.5.5 through 6.5.13 until three consecutive results are obtained which differ from one another in value by no more than ± 5 percent. At the end of the third test, check the catalyst function by passing the collected sample gas through the catalyst and into the NDIR. No increase in concentration value should occur. If the concentration is higher, invalidate the test series, replace the catalyst and repeat the test.

6.5.15 Report the results as an arithmetic average of the three determinations.

7. Calculations. Carry out the calculations, retaining at least one extra decimal figure beyond that of the acquired data. Round off figures after decimal calculation.

7.1 Nomenclature.

C₂ = Volatile matter content as carbon per unit volume of paint solids, g/l (lb/gal).
D₂ = Density of l-Butanol, g/cm³.
D₂ = Average coating density, g/cm³ (See Section 6.3).
D₂ = Average solvent density, g/cm³ (See Section 6.4).
L₂ = Volume of l-Butanol used in the test, cm³.
L₂ = Volume of paint solvent used in the test, cm³.
74.12 = Molecular weight of l-Butanol.
M₂ = Mass of carbon, g.
4 = Number of carbon atoms in l-Butanol.
P_{std} = Absolute standard pressure, 760 mm Hg (29.92 in. Hg).
P₁ = Absolute final tank pressure after pressurization, mm Hg (in. Hg).
T_{std} = Absolute standard temperature, 293° K (528° R).
T₁ = Absolute tank temperature, °K (°R).
%Solv. = Volume percent of solvent in paint coating.
V_{CO2} = Volume of CO₂ in liters, at standard temperature and pressure.
V_{tot} = Total gas volume, corrected to standard conditions, in liters.
V_{pc} = Volume percent of CO₂.
V₁ = Volume of tank, liters.
W = Weight fraction of volatile matter content.

7.2 Total Gas Volume, Corrected to Standard Conditions.

$$V_{gs} = \frac{T_{std}}{T_1} \frac{P_1}{P_{std}} V_1 = K_1 \frac{P_1}{T_1} V_1 \quad \text{Equation 1}$$

Where:

K₁ = 17.65 for English units.

K₁ = 0.3855 for Metric units.

Method 24 (Candidate 2)—

Determination of Volatile Organic Compound Content (as Mass) of Paint, Varnish, Lacquer, or Related Products

1. Applicability and Principle.

1.1 Applicability. This method applies to the determination of volatile organic compound content (as mass) of paint, varnish, lacquer, and related products listed in Section 2.

1.2 Principle. Standard methods are used to determine the volatile matter content, density of the coating, volume of solid, and water content of the paint, varnish, lacquer, and related surface coating. From this information, the mass of volatile organic compounds per unit volume of solids is calculated.

2. Classification of Surface Coating. For the purpose of this method, the applicable surface coatings are divided into three classes. They are:

2.1 Class I: General Solvent Reducible Paints. This class includes white linseed oil outside paint, white soya and phthalic alkyd enamel, white linseed o-phthalic alkyd enamel, red lead primer, zinc chromate primer, flat white inside enamel, white epoxy enamel, white vinyl toluene, modified alkyd, white amino modified baking enamel, and other solvent-type paints not included in Class II.

2.2 Class II: Varnishes and Lacquers. This class includes clear and pigmented lacquers and varnishes.

2.3 Class III. This class includes all water reducible paints.

3. Applicable Standard Methods. Use the apparatus, reagents, and procedures specified in the standard method below:

3.1 ASTM D 1644-75 Method A: Standard Method of Test for Non-volatile Contents of Varnishes. Do not use Method B.

3.2 ASTM D 1475-60. Standard Method of Test for Density of Paint, Lacquer, and Related Products.

3.3 ASTM D 2369-73. Standard Method of Test for Volatile Content of Paints.

3.4 ASTM D 2697-73. Standard Method of Test for Volume Non-volatile Matter in Clear or Pigmented Coatings.

3.5 ASTM D 3792. Standard Method of Test for Water in Water Reducible Paint by Direct Injection into a Gas Chromatograph.

3.6 - ASTM Draft Method of Test for Water in Paint or Related Coatings by the Karl Fischer Titration Method.

4. Procedure.

4.1 Classification of Samples. Assign the coating to one of the three classes discussed in Section 2 above. Assign any coating not clearly belonging to Class II or III to Class I.

4.2 Non-Aqueous Volatile Content. Use one of the following methods to determine the non-aqueous volatile content according to the class of coating.

4.2.1 Class I. Use the procedure in ASTM D 2369-73; record the following information:

W₁ = Weight of dish and sample, g.
W₂ = Weight of dish and sample after heating g.

S = Sample of weight, g.

Repeat the procedure for a total of three determinations for each coating. Calculate the weight fraction of non-aqueous volatile matter W_v for each analysis as follows:

$$W_v = \frac{W_1 - W_2}{S}$$

Report the arithmetic average weight fraction W_v of the three determinations.

4.2.2 Class II. Use the procedure in ASTM D 1644-75 Method A; record the following information:

A = Weight of dish, g.

B = Weight of sample used, g.

C = Weight of dish and sample after heating, g.

Repeat the procedure for a total of three determinations for each coating. Calculate the weight fraction W_v of non-aqueous volatile content for each analysis as follows:

$$W_v = \frac{(A + B - C)}{B}$$

Report the arithmetic average weight fraction W_v of the three determinations.

4.2.3 Class III.

4.2.3.1 Water Content. Determine the water content (in % H₂O) of the coating according to either "Provisional Method of Test for Water in Water Reducible Paint by Direct Injection into a Gas Chromatograph" or "Provisional Method of Test for Water in Paint or Related Coatings by the Karl Fischer Titration Method." Repeat the procedure for a total of three determinations for each coating. Report the arithmetic average weight percent % H₂O of the three determinations.

4.2.3.2 Volatile Content (Including Water). Use the procedure in ASTM D 2369-73; record the following information:

W₁ = Weight of dish and sample, g.

W₂ = Weight of dish and sample after heating, g.

S = Sample weight, g.

Repeat the procedure for a total of three determinations for each coating. Calculate the weight fraction of volatile matter as follows:

$$V = \frac{W_1 - W_2}{S}$$

Report the arithmetic average weight fraction V of the three determinations.

4.2.3.3 Non-Aqueous Volatile Matter. Calculate the average non-aqueous volatile matter W_v as follows:

$$\bar{W}_v = \bar{V} - \frac{\% H_2O}{100}$$

4.3 Coating Density. Determine the density D_m (in g/cm³) of the paint, varnish, lacquer, or related product of any class according to the procedure outlined in ASTM D 1475-60. Make a total of three determinations for each coating. Report the density D_m as the arithmetic average of the three determinations.

4.4 Non-Volatile Content. Determine the volume fraction of the non-volatile matter of the coating of any class according to the procedure outlined in ASTM D 2697-73. Calculate the volume fraction P_n of non-volatile matter as follows:

$$P_n = \frac{\% \text{ Volume Nonvolatile Matter}}{100}$$

Make a total of three determinations for each coating. Report the arithmetic average volume fraction P_n of the three determinations.

5. Volatile Organic Compounds Content. Calculate the volatile organic compound content C_m in terms of mass per volume of solids (g/liter) as follows:

$$C_m = \frac{W_v D_m}{P_n}$$

To convert g/liter to lb/gal. multiply C_m by 8.3455 × 10⁻³.

Method 25—Determination of Total Gaseous Nonmethane Organic Emissions as Carbon: Manual Sampling and Analysis Procedure

1. Principle and Applicability.

1.1 Principle. An emission sample is anisokinetically drawn from the stack through a chilled condensate trap by means

of an evacuated gas collection tank. Total gaseous nonmethane organics (TGNMO) are determined by combining the analytical results obtained from independent analyses of the condensate trap and evacuated tank fractions. After sampling is completed, the organic contents of the condensate trap are oxidized to carbon dioxide which is quantitatively collected in an evacuated vessel; a portion of the carbon dioxide is reduced to methane and measured by a flame ionization detector (FID). A portion of the sample collected in the gas sampling tank is injected into a gas chromatographic (GC) column to achieve separation of the nonmethane organics from carbon monoxide, carbon dioxide and methane; the nonmethane organics are oxidized to carbon dioxide, reduced to methane, and measured by a FID.

1.2 Applicability. This method is applicable to the measurement of total gaseous nonmethane organics in source emissions.

2. Apparatus.

2.1 General. TGNMO sampling equipment can be constructed by a laboratory from commercially available components and components fabricated in a machine shop. The primary components of the sampling system are a condensate trap, flow control system, and gas sampling tank (Figure 1). The analytical system consists of two major subsystems: an oxidation system for recovery of the sample from the condensate trap and a TGNMO analyzer. The TGNMO analyzer is a FID preceded by a reduction catalyst, oxidation catalyst, and GC column with backflush capability (Figures 2 and 3). The system for the removal and conditioning of the organics captured in the condensate trap consists of a heat source, oxidation catalyst, nondispersive infrared (NDIR) analyzer and an intermediate gas collection tank (Figure 4).

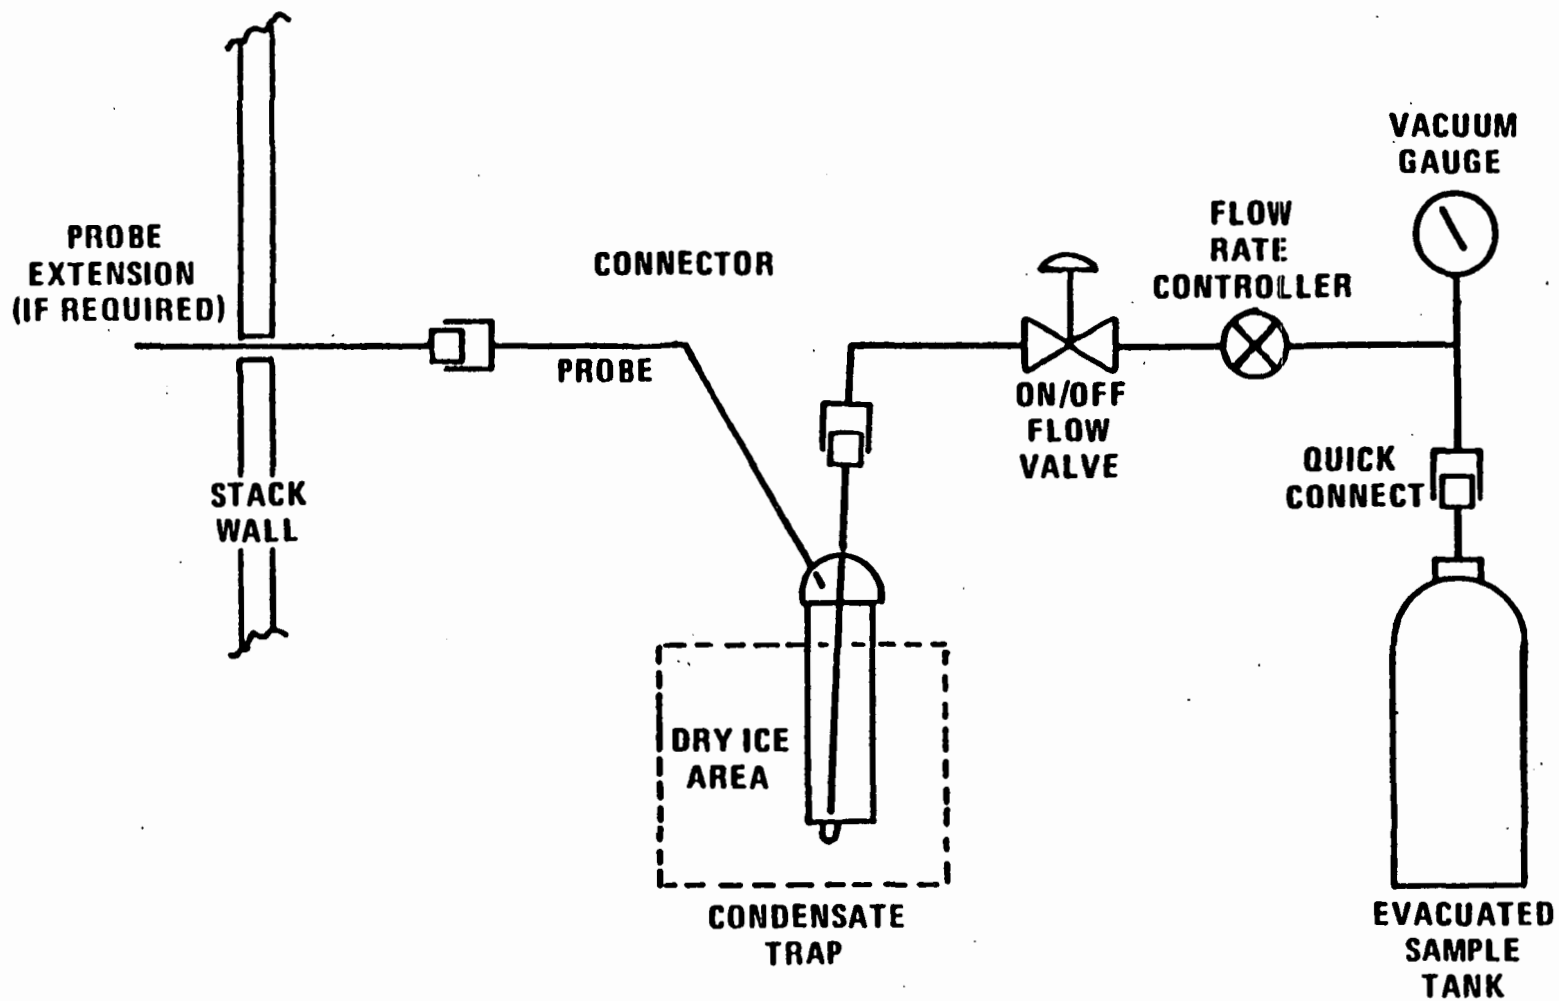

Figure 1. Sampling apparatus.

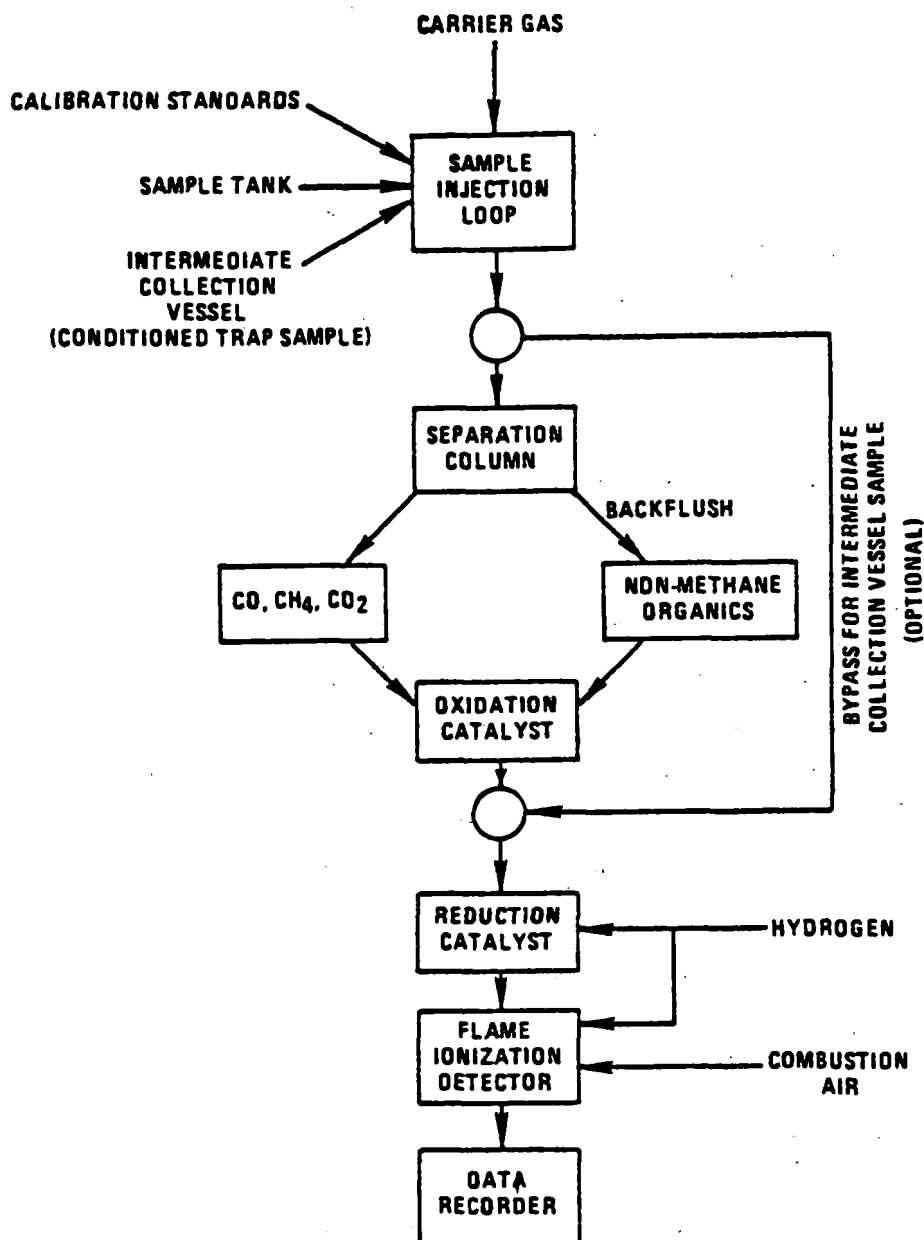

Figure 2. Simplified schematic of total gaseous non-methane organic (TGNMO) analyzer.

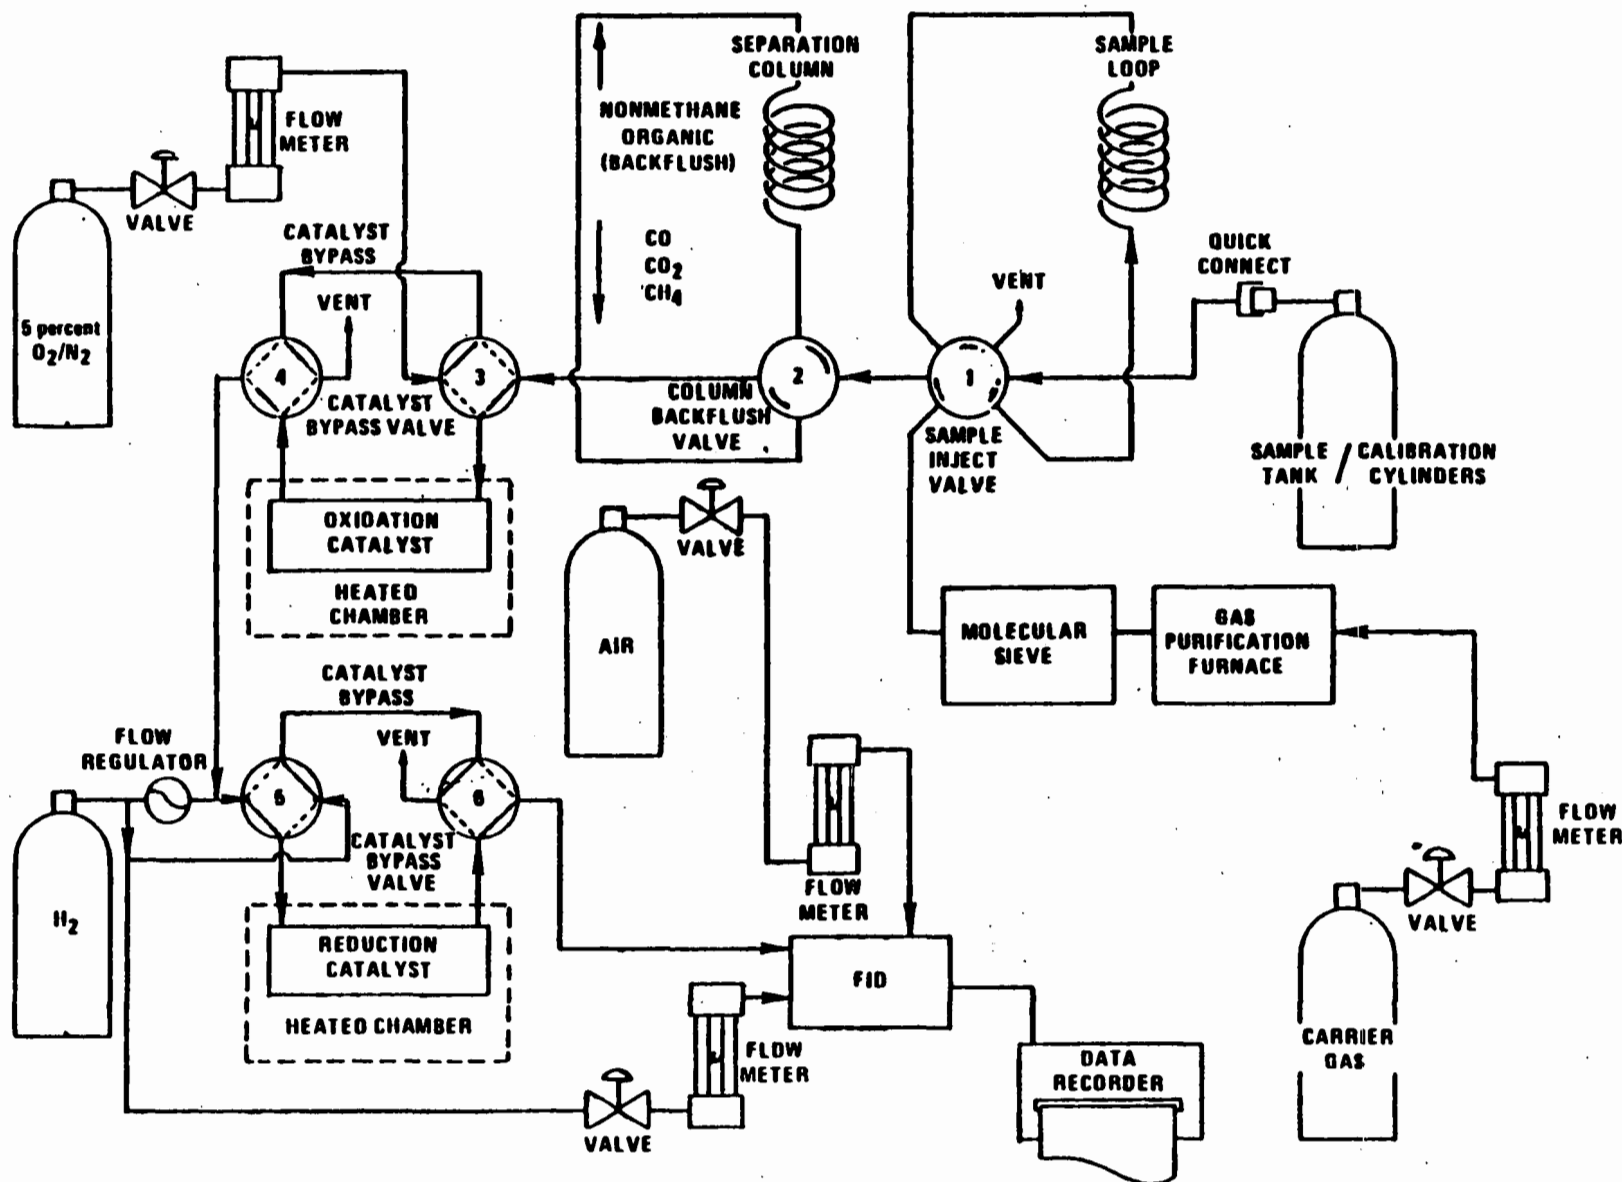

Figure 3. Total gaseous nonmethane organic (TGNMO) analyzer.

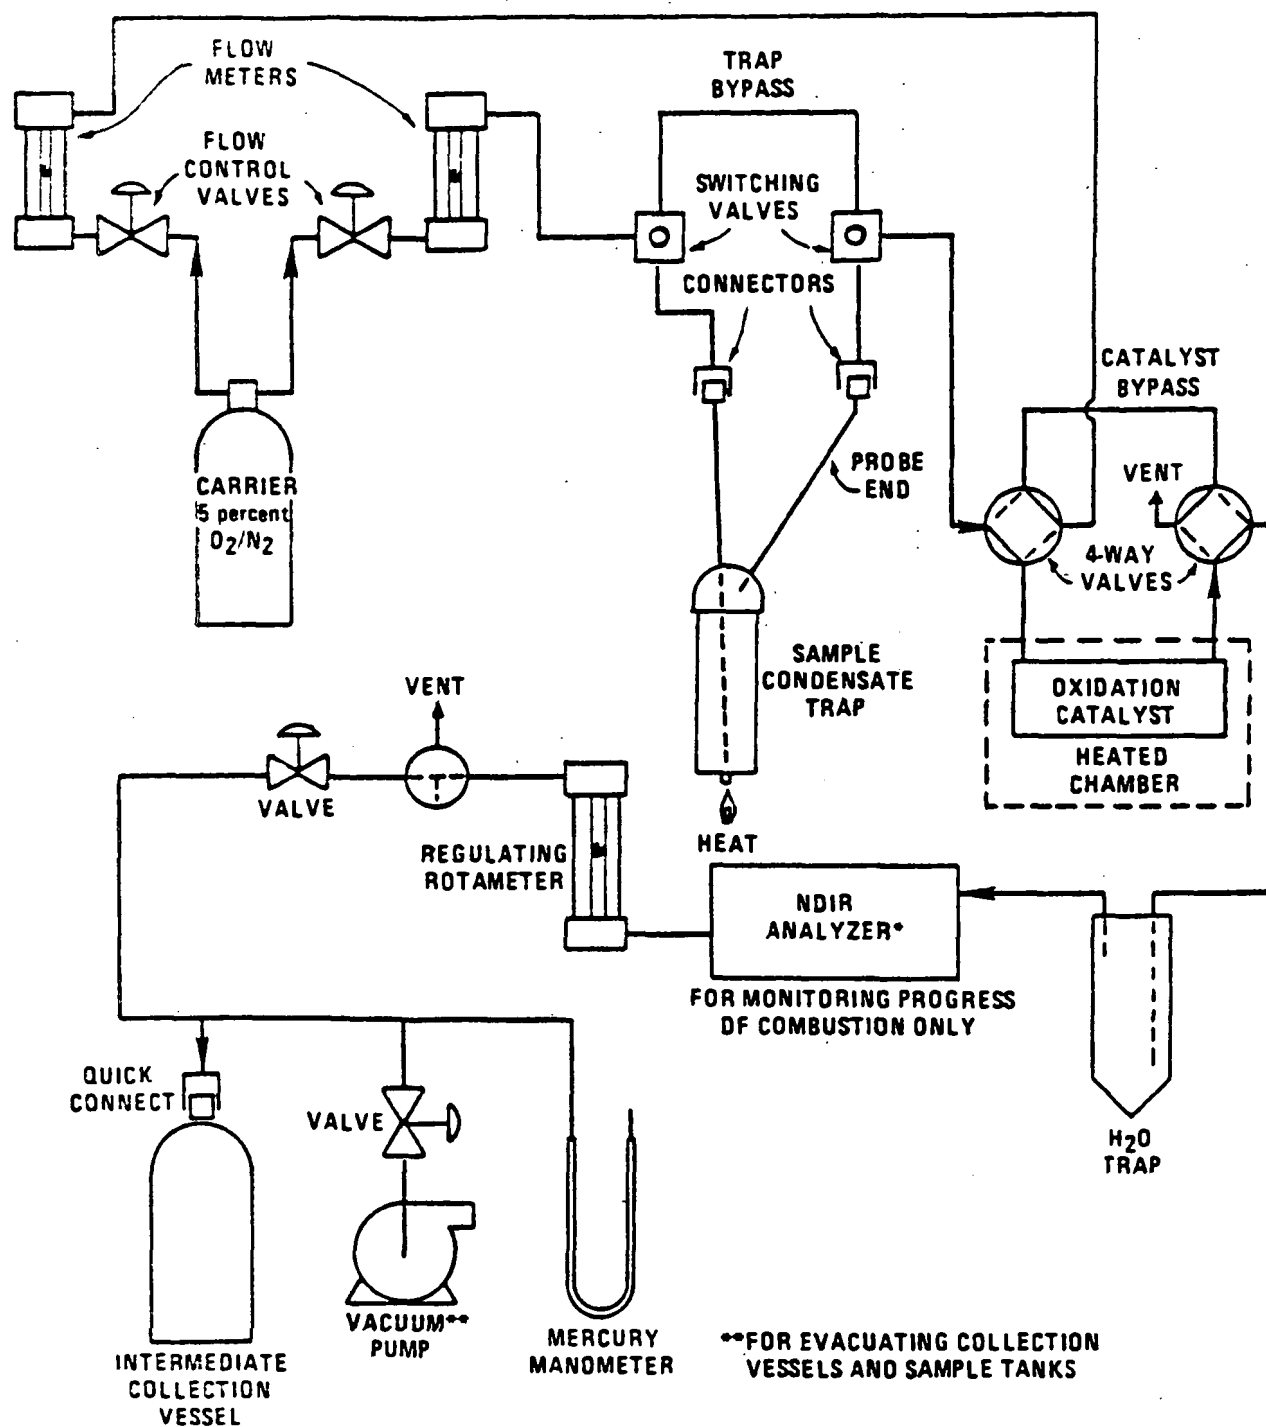

Figure 4. Condensate recovery and conditioning apparatus.

2.2 Sampling.

2.2.1 Probe. $\frac{1}{8}$ " stainless steel tubing.

2.2.2 Condensate Trap. The condensate trap shall be constructed of 316 stainless steel; construction details of a suitable trap are shown in Figure 5.

2.2.3 Flow Shut-off Valve. Stainless steel control valve for starting and stopping sample flow.

2.2.4 Flow Control System. Any system capable of maintaining the sampling rate to within ± 10 percent of the selected flow rate (50–100 cc/min. range).

2.2.5 Vacuum Gauge. Vacuum gauge calibrated in mm Hg. for monitoring the vacuum of the evacuated sampling tank during leak checks and sampling.

2.2.6 Gas Collection Tank. Stainless steel or aluminum tank with a volume of 4 to 8 liters. The tank is fitted with a stainless steel female quick connect for assembly to the sampling train and analytical system.

2.2.7 Mercury manometer. U-tube mercury manometer capable of measuring pressure to within 1.0 mm Hg in the 0/900 mm range.

2.2.8 Vacuum Pump. Capable of pulling a vacuum of 700 mm Hg.

2.3 Analysis. For analysis, the following equipment is needed.

2.3.1 Condensate Recovery and Conditioning Apparatus (Figure 4).

2.3.1.1 Heat Source. A heat source sufficient to heat the condensate trap to a temperature just below the point where the trap turns a "cherry red" color is required. An electric muffle-type furnace heated to 600° C is recommended.

2.3.1.2 Oxidizing Catalyst. Inconel tubing packed with an oxidizing catalyst capable of meeting the catalyst efficiency criteria of this method (Section 4.4.2).

2.3.1.3 Water Trap. Any leak proof moisture trap capable of removing moisture from the gas stream may be used.

2.3.1.4 NDIR Detector. A detector capable of indicating CO₂ concentration in the zero to 5 percent range. This detector is required for monitoring the progress of combustion of the organic compounds from the condensate trap.

2.3.1.5 Pressure Regulator. Stainless steel needle valve required to maintain the NDIR detector cell at a constant pressure.

2.3.1.6 Intermediate Collection Tank. Stainless steel or aluminum collection vessel. Tanks with nominal volumes in the 1 to 4 liter range are recommended. The end of the tank is fitted with a female quick connect.

2.3.2 Total Gaseous Nonmethane Organic (TGNMO) Analyzer. Semi-continuous GC/FID analyzer capable of: (1) separating CO, CO₂, and CH₄ from nonmethane organic compounds, and (2) oxidizing the non-methane organic compounds to CO₂, reducing the CO₂ to methane, and quantifying the methane.

The analyzer shall be demonstrated prior to initial use to be capable of proper separation, oxidation, reduction, and measurement. As a minimum, this demonstration shall include measurement of a known TGNMO concentration present in a mixture that also contains CH₄, CO, and CO₂ (see paragraph 4.4.1).

2.3.2.1 The TGNMO analyzer consists of the following major components.

2.3.2.1.1 Oxidation Catalyst. Inconel tubing packed with an oxidation catalyst capable of meeting the catalyst efficiency criteria of paragraph 4.4.1.2.

2.3.2.1.2 Reduction Catalyst. Inconel tubing packed with a reduction catalyst capable of meeting the catalyst efficiency criteria of paragraph 4.4.1.3.

2.3.2.1.3 Separation Column. A gas chromatographic column capable of separating CO, CO₂, and CH₄ from nonmethane organic compounds. The specified column is as follows: $\frac{1}{8}$ inch O.D. stainless steel packed with 3 feet of 10 percent methyl silicone, Sp 2100* (or equivalent) on Supelcoport* (or equivalent), 80/100 mesh, followed by 1.5 feet porapak Q* (or equivalent) 60/80 mesh. The inlet side is to the silicone.

Other columns may be used subject to the approval of the Administrator. In any event, proper separation shall be demonstrated according to the procedures of paragraph 4.4.1.4.

2.3.2.1.4 Sample Injection System. A gas chromatographic sample injection valve with sample loop sized to properly interface with the TGNMO system.

2.3.2.1.5 Flame Ionization Detector (FID). A flame ionization detector meeting the following specifications is required:

2.3.2.1.5.1 Linearity. A linearity of ± 5 percent of the expected value for each full scale setting up to the maximum percent absolute (methane or carbon equivalent) calibration point is required. The FID shall be demonstrated prior to initial use to meet this specification through a 5-point (minimum) calibration. There shall be at least one calibration point in each of the following ranges: 5–10, 50–100, 500–1,000, 5,000–10,000, and 40,000–100,000 ppm (methane or carbon equivalent). Certification of such demonstration by the manufacturer is acceptable. An additional linearity performance check (see Section 4.4.1.1) must be made before each use (i.e., before each set of samples is analyzed or daily whichever occurs first).

2.3.2.1.5.2 Range. Signal attenuators shall be available so that a minimum

signal response of 10 percent of full scale can be produced when analyzing calibration gas or sample.

2.3.2.1.5.3 Sensitivity. The detector sensitivity shall be equal to or better than 2.0 percent of the full scale setting, with a minimum full scale setting of 10 ppm (methane or carbon equivalent).

2.3.2.1.6 Data Recording System. Analog strip chart recorder or digital integration system for permanently recording the analytical results.

2.3.3 Mercury Manometer. U-tube mercury manometer capable of measuring pressure to within 1.0 mm Hg in the 0–900 mm range.

2.3.4 Barometer. Mercury, aneroid, or other barometer capable of measuring atmospheric pressure to within 1 mm.

2.3.5 Vacuum Pump. Laboratory vacuum pump capable of evacuating the sample tanks to an absolute pressure of 5 mm Hg.

3. Reagents.**3.1 Sampling.**

3.1.1 Crushed Dry Ice.

3.2 Analysis.

3.2.1 TGNMO Analyzer.

3.2.1.1 Carrier Gas. Pure helium, containing less than 1 ppm organics.

3.2.1.2 Fuel Gas. Pure Hydrogen, containing less than 1 ppm organics.

3.2.2 Condensate Recovery and Conditioning Apparatus.

3.2.2.1 Carrier Gas. Five percent O₂ in N₂, containing less than 1 ppm organics.

3.3 Calibration. For all calibration gases, the manufacturer must recommend a maximum shelf life for each cylinder so that the gas concentration does not change more than ± 5 percent from its certified value. The date of gas cylinder preparation, certified organic concentration and recommended maximum shelf life must be affixed to each cylinder before shipment from the gas manufacturer to the buyer.

3.3.1 TGNMO Analyzer.

3.3.1.1 Oxidation Catalyst Efficiency Check. Gas mixture standard with nominal concentration of 5 percent methane and 5 percent oxygen in nitrogen.

3.3.1.2 Reduction Catalyst Efficiency Check. Gas mixture standard with nominal concentration of 5 percent CO₂ in air.

3.3.1.3 Flame Ionization Detector Linearity Calibration Gases (3). Gas mixture standards with known methane (CH₄) concentrations in the 5–10 ppm, 500–1,000 ppm, and 5–10 percent range, in air. These gas standards are to be used to check the FID linearity as described in Section 4.4.1.1.

3.3.1.4 System Operation Standards (2). These calibration gases are required

*Mention of trade name does not constitute endorsement.

to check the total system operation as specified in Section 4.4.1.4. Two gas mixtures are required:

3.3.1.4.1 Gas mixture standard containing (nominal) 50 ppm CO, 50 ppm CH₄, 2 percent CO₂, and 15 ppm C₃H₈, prepared in air.

3.3.1.4.2 Gas mixture standard containing (nominal) 50 ppm CO, 50 ppm CH₄, 2 percent CO₂, and 1,000 ppm C₃H₈, prepared in air.

3.3.2 Condensate Recovery and Conditioning Apparatus. The calibration gas specified in paragraph 3.3.1.1 is required for performing an oxidation catalyst check according to the procedure of paragraph 4.4.2.

4. Procedure.

4.1 Sampling.

4.1.1 Sample Tank Evacuation.

Either in the laboratory or in the field, evacuate the sample tank to 5 mm Hg absolute pressure or less (measured by a mercury U-tube manometer). Record the temperature, barometric pressure, and tank vacuum as measured by the manometer.

4.1.2 Sample Tank Leak Check. Leak check the gas sample tank immediately after the tank is evacuated. Once the tank is evacuated, allow the tank to sit for 30 minutes. The tank is acceptable if no change in tank vacuum (measured by the mercury manometer) is noted.

4.1.3 Assembly. Just prior to assembly, use a mercury U-tube manometer to measure the tank vacuum. Record this vacuum (P_{ti}), the ambient temperature (T_{ti}), and the barometric pressure (P_{bi}) at this time. Assuring that the flow control valve is in the closed position, assemble the sampling system as shown in Figure 1. Immerse the condensate trap body in dry ice to within 1 or 2 inches of the point where the inlet tube joins the trap body.

4.1.4 Leak Check Procedures.

Figure 5. Condensate trap².

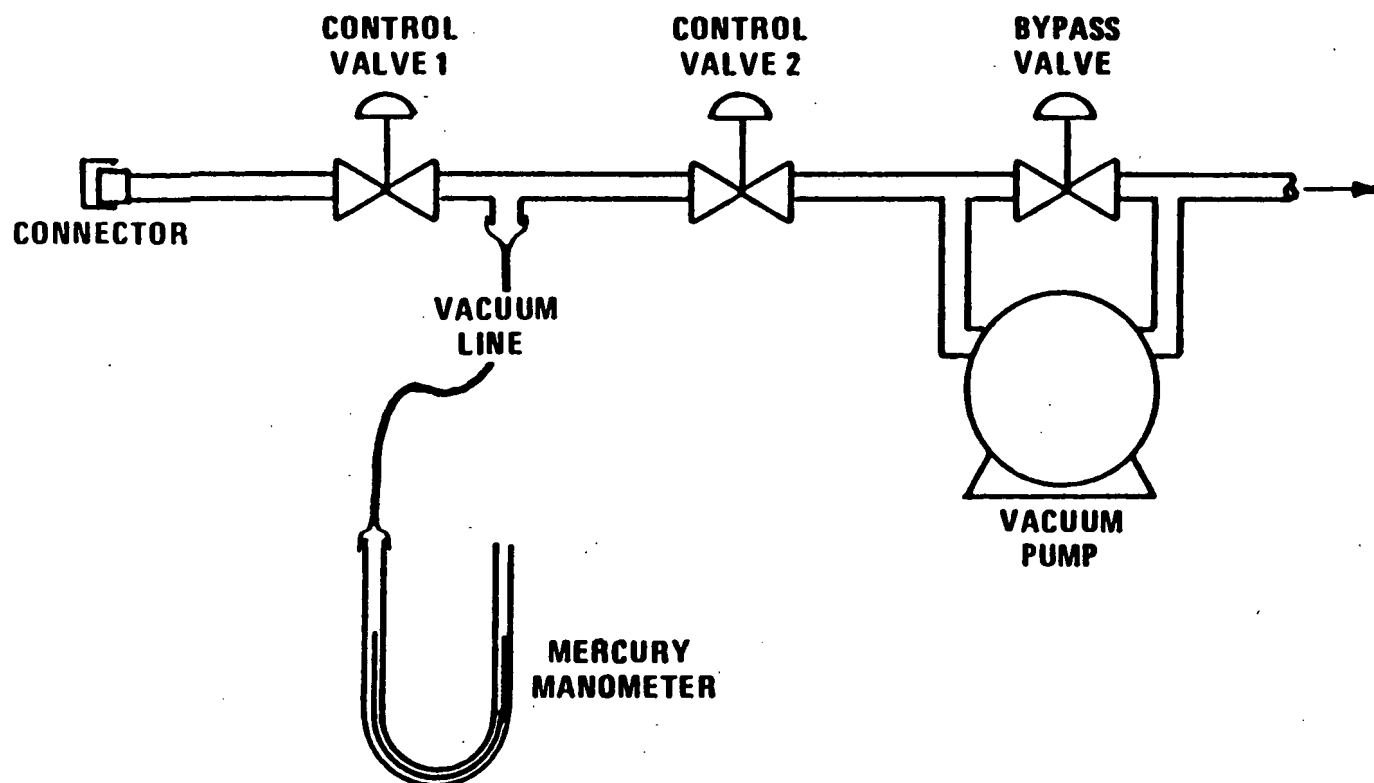

Figure 6. Leak check apparatus.

4.1.4.1 Pretest Leak Check. A pretest leak check is required. After the sampling train is assembled, record the tank vacuum as indicated by the vacuum gauge. Wait a minimum period of 15 minutes and recheck the indicated vacuum. If the vacuum has not changed, the portion of the sampling train behind the shut-off valve does not leak and is considered acceptable. To check the front portion of the sampling train, attach the leak check apparatus (Figure 6) to the probe tip. Evacuate the front half of the train (i.e., do not open the sampling train flow control valve) to a vacuum of at least 500 mm Hg. Close the shut-off valve on the leak check apparatus and record the vacuum indicated by the manometer on the data sheet (Figure 7). Allow the system to sit for 5 minutes and then recheck the vacuum. A change of less than 2 mm Hg for the 5-minute leak check period is acceptable. Record the front half leak rate (mm Hg/5-minute period) on the data form. When an acceptable leak rate has been obtained disconnect the leak check apparatus from the probe tip.

4.1.4.2 Post Test Leak Check. A leak check is mandatory at the conclusion of each test run. After sampling is completed, attach the U-tube manometer to the probe tip; minimize the amount of flexible line used. Open the sample train flow control valve for a period of 2 minutes or until the vacuum indicated on the manometer stabilizes, whichever occurs first; shut off the sample train flow control valve. Record the vacuums indicated on the manometer (front half) and on the tank vacuum gauge (back-half). After 5 minutes, recheck these vacuum readings. A leak rate of less than 2 mm Hg per 5-minute period is acceptable for the front half; the back half portion is acceptable if no visible change in the tank vacuum gauge occurs. Record the post test leak rate (mm Hg per 5 minutes), and then disconnect the manometer from the probe tip and seal the probe. If the sampling train does not pass the post test leak check, invalidate the run.

4.1.5 Sample Train Operation. Place the probe into the stack such that the probe is perpendicular to the direction of stack gas flow; locate the probe tip at a single preselected point. For stacks having a negative static pressure, assure that the sample port is sufficiently sealed to prevent air in-leakage around the probe. Check the dry ice level and add ice if necessary. Record the clock time and sample tank gauge vacuum. To begin sampling, open and adjust (if applicable) the flow control valve(s) of the flow control system utilized in the sampling train; maintain a constant flow

rate (± 10 percent) throughout the duration of the sampling period. Record the gauge vacuum and flowmeter setting (if applicable) at 5-minute intervals. Select a total sample time greater than or equal to the minimum sampling time specified in the applicable subpart of the regulation; end the sampling when this time period is reached or when a constant flow rate can no longer be maintained. When the sampling is completed, close the gas sampling tank control valve. Record the final readings. Note: If the sampling had to be stopped before obtaining the minimum sampling time (specified in the applicable subpart) because a constant flow rate could not be maintained, proceed as follows: After removing the probe from the stack, remove the evacuated tank from the sampling train (without disconnecting other portions of the sampling train) and connect another evacuated tank to the sampling train. Prior to attaching the new tank to the sampling train, assure that the tank vacuum (measured on-site by the U-tube manometer) has been recorded on the data form and that the tank has been leak-checked (on-site). After the new tank is attached to the sample train, proceed with the sampling; after the required minimum sampling time has been exceeded, end the test.

4.2 Sample Recovery. After sampling is completed, remove the probe from the stack and seal the probe end. Conduct the post test leak check according to the procedures of paragraph 4.1.4.2. After the post test leak check has been conducted, disconnect the condensate trap at the flow metering system. Tightly seal the ends of the condensate trap; keep the trap packed in dry ice until analysis. Remove the flow metering system from the sample tank. Attach the U-tube manometer to the tank (keep length of flexible connecting line to a minimum) and record the final tank vacuum (P_t); record the tank temperature (T_t) and barometric pressure at this time. Disconnect the manometer from the tank. Assure that the test run number is properly identified on the condensate trap and evacuated tank(s).

4.3 Analysis.

4.3.1 Preparation.

4.3.1.1 TGNMO Analyzer. Set the carrier gas, air, and fuel flow rates and then begin heating the catalysts to their operating temperatures. Conduct the calibration linearity check required in paragraph 4.4.1.1 and the system operation check required in paragraph 4.4.1.4. Optional: Conduct the catalyst performance checks required in paragraphs 4.4.1.2 and 4.4.1.3 prior to analyzing the test samples.

4.3.1.2 Condensate Recovery and Conditioning Apparatus. Set the carrier gas flow rate and begin heating the catalyst to its operating temperature. Conduct the catalyst performance check required in paragraph 4.4.2 prior to oxidizing any samples.

4.3.2 Condensate Trap Carbon Dioxide Purge and Evacuated Sample Tank Pressurization. The first step in analysis is to purge the condensate trap of any CO_2 which it may contain and to simultaneously pressurize the gas sample tank. This is accomplished as follows: Obtain both the sample tank and condensate trap from the test run to be analyzed. Set up the condensate recovery and conditioning apparatus so that the carrier flow bypasses the condensate trap hook-up terminals, bypasses the oxidation catalyst, and is vented to the atmosphere. Next, attach the condensate trap to the apparatus and pack the trap in dry ice. Assure that the valve isolating the collection vessel connection from the atmospheric vent is closed and then attach the gas sample tank to the system as if it were the intermediate collection vessel. Record the tank vacuum on the laboratory data form. Assure that the NDIR analyzer indicates a zero output level and then switch the carrier flow through the condensate trap; immediately switch the carrier flow from vent to collect and open the valve to the tank. The condensate trap recovery and conditioning apparatus should now be set up as indicated in Figure 8. Monitor the NDIR; when CO_2 is no longer being passed through the system, switch the carrier flow so that it once again bypasses the condensate trap. Continue in this manner until the gas sample tank is pressurized to a nominal gauge pressure of 800 mm mercury. At this time, isolate the tank, vent the carrier flow, and record the sample tank pressure (P_t), barometric pressure (P_w), and ambient temperature (T_w). Remove the gas sample tank from the system.

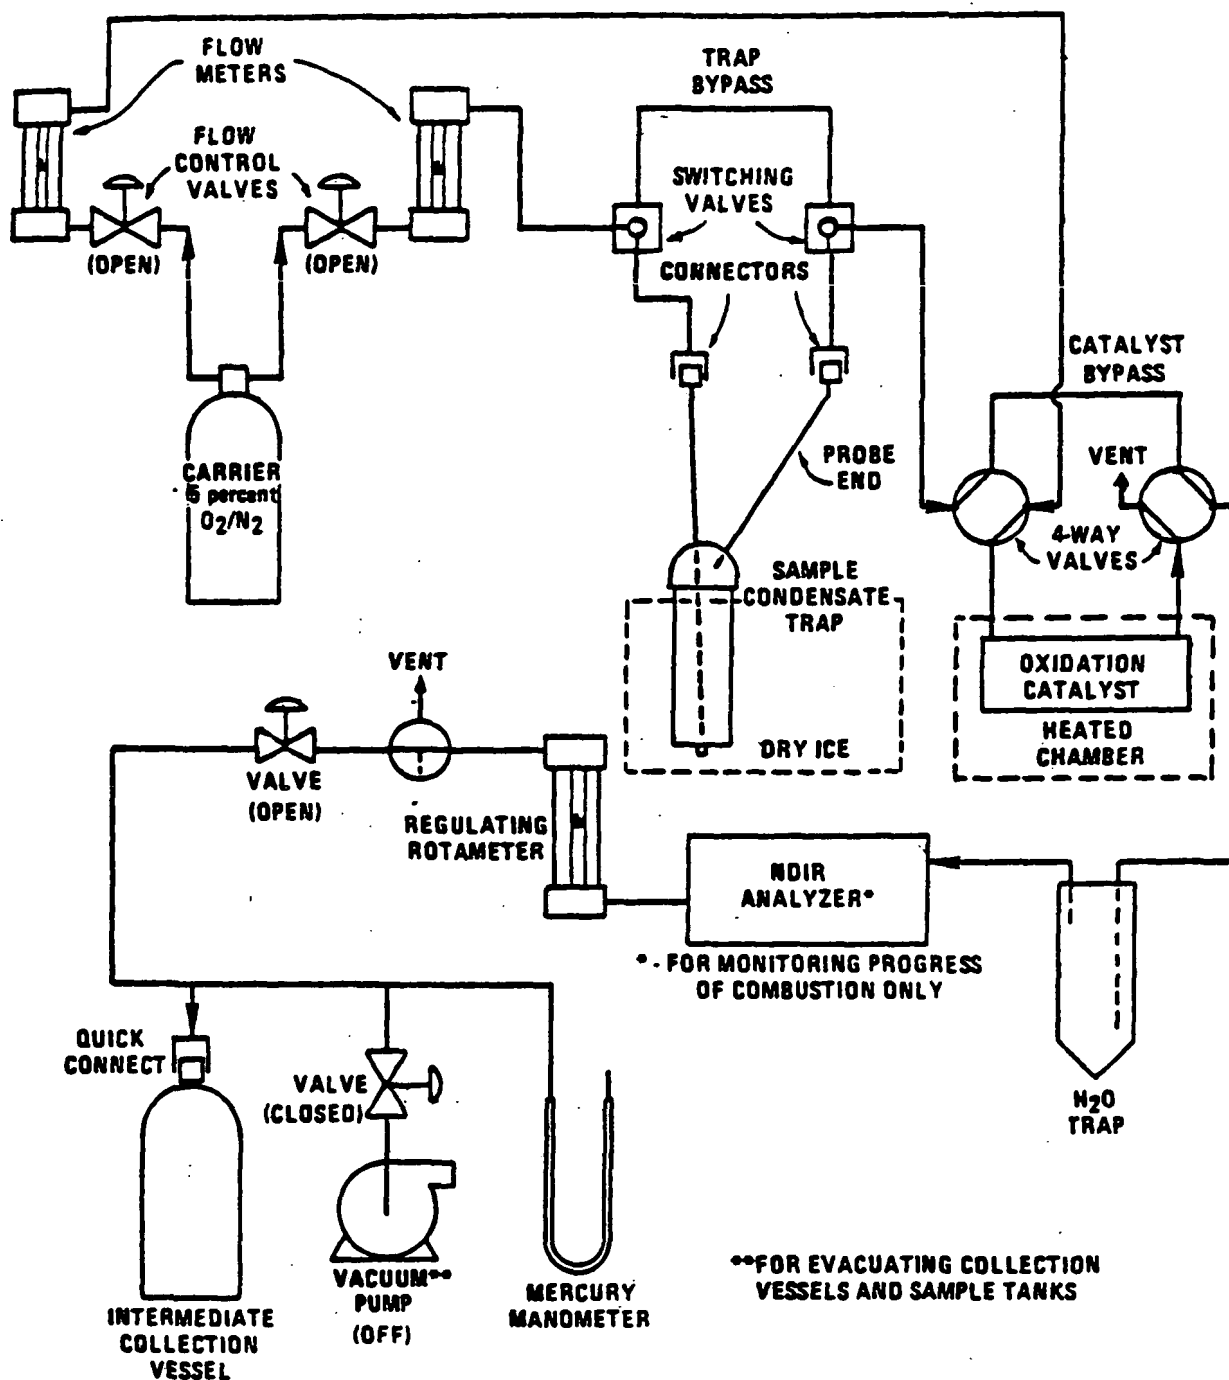

Figure 8. Condensate recovery and conditioning apparatus, carbon dioxide purge.

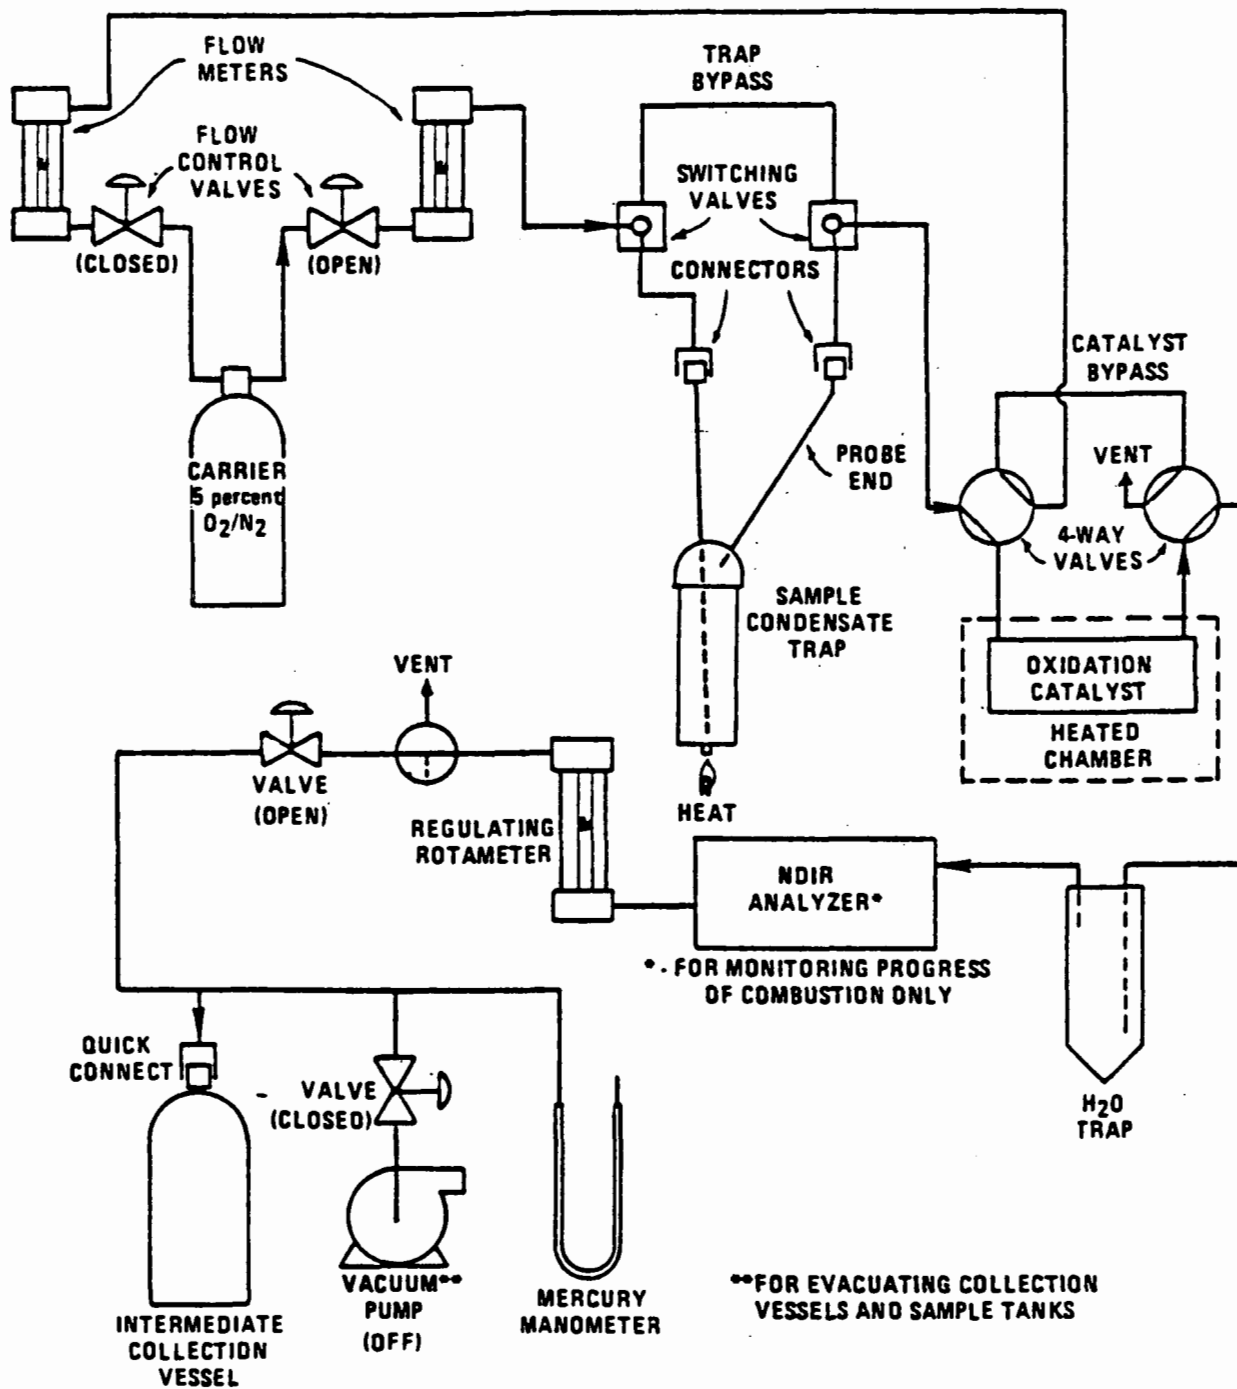

Figure 9. Condensate recovery and conditioning apparatus, collection of trap organics.

4.3.3 Recovery of Condensate Trap Sample. Oxidation and collection of the sample in the condensate trap is now ready to begin. From the step just completed in paragraph 4.3.2 above, the system should be set up so that the carrier flow bypasses the condensate trap, bypasses the oxidation catalyst, and is vented to the atmosphere. Attach an evacuated intermediate collection vessel to the system and then, switch the carrier so that it flows through the oxidation catalyst. Monitor the NDIR and assure that the analyzer indicates a zero output level. Switch the carrier from vent to collect and open the collection tank valve; remove the dry ice from the trap and then switch the carrier flow through the trap. The system should now be set up to operate as indicated in Figure 9.

Begin heating the condensate trap. The trap should be heated to a temperature at which the trap glows a "dull red" (approximately 600° C) and should be maintained at this temperature for at least 5 minutes. During oxidation of the condensate trap sample, monitor the NDIR to determine when all the sample has been removed and oxidized (indicated by return to baseline of NDIR analyzer output). When complete recovery has been indicated, remove the heat from the trap. However, continue the carrier flow until the intermediate collection vessel is pressurized to a gauge pressure of 800 mm Hg (nominal). When the vessel is pressurized, vent the carrier; measure and record the final intermediate collection vessel pressure (P_i) as well as the barometric pressure (P_b), ambient temperature (T_a), and collection vessel volume (V_c).

4.3.4 Analysis of Recovered Condensate Sample. After the preparation steps in paragraph 4.3.1 have been completed, the analyzer is ready for conducting analyses. Assure that the analyzer system is set so that the carrier gas is routed through the reduction catalyst to the FID (flow through the separation column and oxidation catalyst is optional). Attach the intermediate collection vessel to the tank inlet fitting of the TGNMO analyzer. Purge the sample loop with sample and then inject a preliminary sample in order to determine the appropriate FID attenuation. Inject triplicate samples from the intermediate collection vessel and record the values (C_m). When appropriate, check the instrument calibration according to the procedures of paragraph 4.4.1.4.

4.3.5 Analysis of Gas Sample Tank. Assure that the analyzer is set up so that the carrier flow is routed through the

separation column as well as both the oxidation and reduction catalysts. During analysis for the nonmethane organics the separation column is operated as follows: First, operate the column at -78° C (dry ice temperature) to elute the CO and CH₄. After the CH₄ peak, operate the column at 0° C to elute the CO₂. When the CO₂ is completely eluted, switch the carrier flow to backflush the column and simultaneously raise the column temperature to 100° C in order to elute all nonmethane organics. (Exact timings for column operation are determined from the calibration standard). Attach the gas sample tank to the tank inlet fitting of the TGNMO analyzer. Purge the sample loop with sample and inject a preliminary sample in order to determine the appropriate FID attenuation for monitoring the backflushed non-methane organics. Inject triplicate samples from the gas sample tank and record the values obtained for the nonmethane organics (C_m). When appropriate, check the instrument calibration according to the procedures of paragraph 4.4.1.4.

4.4 Calibration. Maintain a record of performance of each item.

4.4.1 TGNMO Analyzer.

4.4.1.1 FID Calibration and linearity check. Set up the TGNMO system so that the carrier gas bypasses the oxidation and reduction catalysts. Zero and span the FID by injecting samples of the high value (5-10 percent) calibration gas (paragraph 3.3.1.3) and adjusting the instrument output to the correct level. Then check the instrument linearity by injecting triplicate samples of the low (5-10 ppm) and mid-range (500-1,000 ppm) calibration gases (paragraph 3.3.1.3). The system linearity is acceptable if the results (average for triplicate samples of each gas) are within ± 5 percent of the expected values. This calibration and linearity check shall be conducted prior to analyzing each set of samples (i.e., samples from a given source test).

4.4.1.2 Oxidation Catalyst Efficiency Check. This check should be performed on a frequency established by the amount of use of the analyzer and the nature of the organic emissions to which the catalyst is exposed. As a minimum, perform this check prior to putting the analyzer into service.

To confirm that the oxidation catalyst is functioning in a correct manner, the operator must turn off or bypass the reduction catalyst while operating the analyzer in an otherwise normal fashion. Inject triplicate samples of the methane standard gas (paragraph 3.3.1.1) into the system. If oxidation is adequate, the only gas that will then

reach the detector will be CO₂, to which the FID has no response. If a response is noted, the oxidation catalyst must be replaced.

4.4.1.3 Reduction Catalyst Efficiency Check. This check should be performed on a frequency established by the amount of use of the analyzer. As a minimum, perform this check prior to putting the analyzer into service. To confirm proper operation of the reduction catalyst, the operator must bypass the oxidation catalyst while operating the analyzer in an otherwise normal manner. After setting the carrier flow to bypass the oxidation catalyst, inject triplicate samples of the carbon dioxide standard gas (Section 3.3.1.2). The catalyst operation is acceptable if the average response of the triplicate CO₂ sample injections is within ± 2 percent of the expected value and no one CO₂ sample injection varies by more than ± 5 percent from the expected value.

4.4.1.4 System Operation Check. This system check should be conducted at a frequency consistent with the amount of use and the reliability of the particular analyzer. As a minimum, this system check shall be conducted before and after each set of emission samples is analyzed. If this system check is not successfully completed at the conclusion of the analyses, the results shall be invalidated. Operate the TGNMO analyzer in a normal fashion, passing the carrier flow through the separation column and both the oxidation and reduction catalysts. Inject triplicate samples of the two mixed gas standards specified in Section 3.3.1.4. The system operation is acceptable if, for each gas mixture, the average non-methane organic value for the triplicate samples is within ± 3 percent of the expected value and no one sample analysis varies by more than ± 5 percent from the average value for the triplicate samples.

4.4.2 Condensate Trap Recovery and Conditioning Apparatus Oxidation Catalyst Check. This catalyst check should be conducted at a frequency consistent with the amount of use of the catalyst, as well as, the nature and concentration level of the organics being recovered by the system. As a minimum, perform this check prior to and immediately after conditioning each set of emission sample traps.

Set up the condensate trap recovery system so that the carrier flow bypasses the trap inlet and is vented to the atmosphere at the system outlet. Assure that the tank collection valve is closed and then attach an evacuated intermediate collection vessel to the system. Connect the methane standard gas cylinder (Section 3.3.1.1) to the

system's condensate trap connector (probe end, figure 4). Adjust the system valving so that the standard gas cylinder acts as the carrier gas; switch off the carrier and use the cylinder of standard gas to supply a gas flow rate equal to the carrier flow normally used during trap sample recovery. Now switch from vent to collect in order to begin collecting a sample. Continue collecting a sample in the normal manner until the intermediate vessel is filled to a nominal pressure of 300 mm Hg. Remove the intermediate vessel from the system and vent the carrier flow to the atmosphere. Switch the valving to return the system to its normal carrier gas and normal operating conditions. Set up the TGNMO analyzer to operate with the oxidation and reduction catalysts bypassed. Inject a sample from the intermediate collection vessel into the analyzer. The operation of the condensate trap recovery system oxidation catalyst is acceptable if oxidation of the standard methane gas was 99.5 percent complete, as indicated by the response of the TGNMO analyzer FID.

4.4.3 Gas Sampling Tank. The volume of the gas sampling tanks used must be determined. Prior to putting each tank in service, determine the tank volume by weighting the tanks empty and then filled with water; weight to the nearest 0.5 gm and record the results.

4.4.4 Intermediate Collection Vessel. The volume of the intermediate collection vessels used to collect CO₂ during the analysis of the condensate traps must be determined. Prior to putting each vessel into service, determine the volume by weighting the vessel empty and then filled with water; weigh to the nearest 0.5 gm and record the results.

5. Calculations.

Note. All equations are written using absolute pressure; absolute pressures are determined by adding the measured barometric pressure to the measured gauge pressure.

5.1 Sample Volume. For each test run, calculate the gas volume sampled:

$$V_s = 0.386 V \left(\frac{P_t}{P_{t1}} \right) - \left(\frac{P_{t1}}{P_t} \right)$$

5.2 Noncondensable Organics. For each collection tank, determine the concentration of nonmethane organics (ppm C):

$$C_t = \frac{\frac{P_{t1}}{P_t} - \frac{P_{t1}}{P_{t1}}}{\frac{P_{t1}}{P_t} - \frac{P_{t1}}{P_{t1}}} \times \frac{1}{r} \times \sum_{j=1}^r C_{tmj}$$

5.3 Condensible Organics. For each condensate trap determine the concentration of organics (ppm C):

$$C_c = 0.386 \frac{V_v \times P_f}{V_s \times P_t} \times \frac{1}{N} \times \sum_{k=1}^n C_{cmk}$$

5.4 Total Gaseous Nonmethane Organics (TGNMO). To determine the TGNMO concentration for each test run, use the following equation:

$$C = C_t + C_c$$

Where:

C = Total gaseous nonmethane organic (TGNMO) concentration of the effluent, ppm carbon equivalent.

C_c = Calculated condensable organic (condensate trap) concentration of the effluent, ppm carbon equivalent.

C_{cm} = Measured concentration (TGNMO analyzer) for the condensate trap (intermediate collection vessel), ppm methane.

C_t = Calculated noncondensable organic concentration of the effluent, ppm carbon equivalent.

C_{tm} = Measured concentration (TGNMO analyzer) for gas collection tank sample, ppm methane.

P_t = Final pressure of intermediate collection vessel, mm Hg., absolute.

P_u = Gas sample tank pressure prior to sampling, mm Hg., absolute.

P_t = Gas sample tank pressure after sampling, but prior to pressurizing, mm Hg., absolute.

P_u = Final gas sample tank pressure after pressurizing, mm Hg., absolute.

T_t = Final temperature of intermediate collection vessel, °K.

T_u = Gas sample tank temperature prior to sampling, °K.

T_t = Gas sample tank temperature at completion of sampling, °K.

T_u = Gas sample tank temperature after pressurizing, °K.

V = Gas collection tank volume, dscm.

V_s = Intermediate collection tank volume, dscm.

V_s = Gas volume sampled, dscm.

r = Total number of analyzer injections of tank sample during analysis (where j = injection number, 1 . . . r).

n = Total number of analyzer injections of condensable intermediate collection vessel during analysis (where k = injection number, 1 . . . n).

Standard Conditions = Dry, 750 mm Hg, 293°K.

ENVIRONMENTAL PROTECTION AGENCY

STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

PHOSPHATE ROCK PLANTS

SUBPART NN

[40 CFR Part 60]**[FRL-1282-2]****Standards of Performance for New Stationary Sources; Phosphate Rock Plants****AGENCY:** Environmental Protection Agency.**ACTION:** Proposed Rule and Announcement of Public Hearing.

SUMMARY: This action is being proposed to limit emissions of particulate matter from new, modified, and reconstructed phosphate rock plants. Reference Method 5 would be used for determining compliance with these standards. The standards implement the Clean Air Act and result from the Administrator's determination on August 21, 1979 (44 FR 49222) that phosphate rock plant emissions contribute significantly to air pollution. The intended effect is to require new, modified, and reconstructed phosphate rock plants to use the best demonstrated system of emission reduction, considering costs, nonair quality health and environmental impact and energy impacts.

DATES: *Comments.* Deadline for comments is November 26, 1979.

Public hearing. A public hearing will be held on October 25, 1979.

Requests to speak at hearing. Persons wishing to speak at the hearing must contact Shirley Tabler, Emission Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone number (919) 541-5421 by October 18, 1979.

ADDRESSES: *Comments.* Comments should be submitted to the Central Docket Section (A-130), U.S. Environmental Protection Agency, 401 M Street, SW., Washington, D.C. 20460. Attention: Docket No. OAQPS-79-6.

Background Information. The Background Information Document for the proposed standards may be obtained from the U.S. EPA Library (MD-35), Research Triangle Park, North Carolina 27711, telephone number: (919) 541-2777. Please refer to "Phosphate Rock Plants, Background Information: Proposed Standards of Performance" (EPA-450/3-79-017).

Docket. A docket (number OAQPS-79-6) containing information used by EPA in development of the proposed standard is available for public inspection between 8:00 a.m. and 4:00 p.m., Monday through Friday, at EPA's

Central Docket Section, Room 2903B, Waterside Mall, 401 M Street, SW., Washington, D.C. 20460.

FOR FURTHER INFORMATION CONTACT: Don Goodwin, Director, Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone number: (919) 541-5271.

SUPPLEMENTARY INFORMATION:**Summary of Proposed Standards**

The proposed standards would apply to new, modified, or reconstructed phosphate rock dryers, calciners, grinders, and ground rock handling and storage facilities. The proposed standards would limit emissions of particulate matter to 0.02 kilogram (kg) per megagram (Mg) of rock feed (0.04 lb/ton) from phosphate rock dryers, 0.055 kg/Mg (0.11 lb/ton) from phosphate rock calciners, and 0.006 kg/Mg (0.012 lb/ton) from phosphate rock grinders. An opacity standard of zero percent opacity is proposed for ground rock handling system, dryers, calciners, and grinders.

The use of continuous opacity monitoring systems would be required for each affected facility. However, when scrubbers are used for emission control, continuous opacity monitoring would not be required. Instead, the pressure drop of the scrubber and the liquid supply pressure would be monitored as indicators of the scrubber performance.

Summary of Environmental and Economic Impacts

The proposed standards would impact an estimated 110 teragrams (122 million tons) of annual phosphate rock production by 1995. About one half of that would be due to construction of new phosphate rock processing plants and the remainder due to expansion of industry capacity at existing plants.

The proposed standards would reduce the particulate emissions from new phosphate rock plants by about 99 percent below the levels that would occur with no control and by about 85 to 98 percent below the levels allowed by typical State standards, depending on the type of facility. These emission reductions would reduce nationwide particulate emissions by about 19 gigagrams (21,000 tons) per year in 1985. The maximum 24-hour average ambient air concentration of particulate matter due to emissions from a typical dryer controlled to the level required by the proposed standard would be about 88 $\mu\text{g}/\text{m}^3$. Similarly, for a typical calciner, imposition of the proposed emission standard would result in a maximum ambient level of 14 $\mu\text{g}/\text{m}^3$, and for a

typical grinder the ambient level could reach a maximum of 1 $\mu\text{g}/\text{m}^3$.

The annualized costs of operating control equipment that would be needed to attain the proposed standards were estimated using model plants. Because typical Florida phosphate rock plants are larger than Western plants, the control costs per ton of production are lower.

The annualized cost of installing and operating prevailing controls used to meet existing State standards at typical Florida phosphate rock plants is estimated at \$0.35 per metric ton. The additional cost of employing control technology to meet the proposed standards at a new Florida plant is estimated at \$0.02/metric ton when using baghouses and \$0.07/metric ton for scrubbers.

The annualized cost of using prevailing controls to meet existing State standards in a typical new Western plant is \$0.87/metric ton. The additional cost of using control technology to meet the proposed standards at new Western plants is estimated at \$0.06/metric ton for baghouse control and \$0.21/metric ton for scrubbers.

The additional costs of meeting the proposed standards are relatively minor when scrubbers or baghouses are used. Electrostatic precipitators (ESP) could also be used to meet the proposed standards, but their use is not anticipated because of their higher annualized costs of operation. The difference in cost between using the best system of emission reduction to meet the proposed standards level and using prevailing controls to meet the State Implementation Plan (SIP) levels would have negligible impact on the profitability of the plant and the future growth of the phosphate rock industry if the proposed standards were implemented. By the year 1985, compliance with the proposed standards would increase the industry cost of production of phosphate rock by 0.1 percent (baghouse controls) to 0.2 percent (scrubber controls) above the cost to meet existing State Implementation Plan regulations. A more detailed discussion of the economic analysis is discussed in the Background Information Document.

Assuming baghouses are used to meet the proposed standards, the total industry capital cost for the first five years after imposition of the proposed standards would be about \$8.5 million greater than the capital costs incurred meeting typical State standards. The total industry annualized cost increase to meet the proposed standards by the fifth year would be about \$0.8 million.

The incremental energy required to meet the proposed standards depends on the control utilized. If baghouses are employed, total industry energy consumption in the fifth year after imposition of the proposed standards will increase by about 1.7 percent over the levels projected to occur under State regulations. Total industry consumption in the fifth year will increase by 2.6 percent when scrubbers are employed, and about 0.1 percent should electrostatic precipitators be used. This corresponds to a fifth year total increase in industry energy consumption of 39×10^6 kWh/yr when baghouses are used, 60×10^6 kWh/yr when high energy scrubbers are used, and $.009 \times 10^6$ kWh/yr when electrostatic precipitators are used.

Utilization of any of the alternative control technologies (baghouse, scrubber, or ESP) would result in minimal adverse environmental impacts. If high energy scrubbers or wet ESPs are used to achieve the standards, this would result in adverse impacts on solid waste disposal, water pollution, and energy consumption. However, the incremental increase (over the prevailing controls) of solid materials and wastewaters produced during control of emissions from phosphate rock facilities is minor in comparison with (1) the large volumes of process wastewaters and solid wastes, and (2) the total amounts of wastewaters and solid waste already collected by prevailing controls to meet existing State standards. Utilization of baghouse technology is marginally more environmentally acceptable than other control alternatives because no water pollution and less solid waste is produced.

Rationale for the Proposed Standards

Selection of Source for Control

Section 111 of the Act requires establishment of standards of performance for new, modified, or reconstructed stationary sources that cause or contribute significantly to air pollution which may reasonably be anticipated to endanger public health or welfare. The EPA has determined that sources which cause ambient suspended particulate matter may cause adverse health and welfare effects. Accordingly, under the authority of Section 109 of the Act, the Administrator has designated particulate matter as a criteria pollutant and has established national ambient air quality standards for this pollutant.

Phosphate rock processing plants have been shown to be a significant source of particulate matter emissions. The Priority List of sources for New

Source Performance Standards (40 CFR 60.16, 44 FR 49222, dated August 21, 1979) identified various sources of emissions on a nationwide basis in terms of the potential improvement in emission reduction that could result from their imposition. The sources on this list are ranked based on decreasing order of potential emission reduction. Phosphate rock plants currently rank 16th of 59 sources on the list, and are, therefore, of considerable importance nationwide. In addition, a study performed for EPA in 1975 by the Argonne National Laboratory showed phosphate rock dryers ranked 4th of the nation's highest 18 particulate source categories which require control systems with moderate energy consumption. The same study showed phosphate rock grinders as ranking fifteenth of the nation's 56 largest particulate source categories. Finally, results of dispersion modeling analysis indicate that particulate emission sources at phosphate rock plants contribute significantly to the deterioration of air quality.

Additional factors leading to the selection of the phosphate rock industry for the development of standards of performance include the expected growth rate of the industry and the significant reductions in particulate matter emissions achievable with application of available emissions control technology. The United States is the largest producer and consumer of phosphate rock in the world. From 1959 to 1973, the production of phosphate rock increased at an annual rate of about six percent and production is expected to increase at an annual rate of about three percent per year through the year 2000. By the year 1985 new and modified phosphate rock plants would cause an increase in nationwide emissions of particulate matter of about 19 gigagrams per year (21,000 tons/year) above the level expected with implementation of the proposed standards. At most plants, the degree of emissions control (imposed by State Implementation plans) is considerably less than that achievable with application of the best technology for emission control.

Selection of Affected Facility and Pollutants

At phosphate rock installations, the normal sequence of operation is: Mining, beneficiation, conveying of wet rock to and from storage, drying or calcining or nodulizing, conveying and storage of dry rock, grinding, and conveying and storage of ground rock. Mining and beneficiation are a minor source of particulate emissions. Nodulizing, and

elemental phosphorous production are not selected as affected facilities as these sources are not expected to exhibit growth potential. Dryers, calciners, grinders and ground rock handling systems account for nearly all of the particulate matter emissions from phosphate rock plants. Accordingly, the proposed standards have been developed for these sources.

Phosphate rock processing plants are sources of emissions of particulates, fluorides, sulfur dioxide (SO_2) and certain radioactive substances. Standards are being proposed only for the control of particulate matter emissions at this time. Based on Tennessee Valley Authority research, and emission measurements of fluorides in calciner exhaust gases, it is unlikely that significant quantities of fluorine will be volatilized at temperatures experienced in dryers or calciners. Emission of sulfur oxides generated by oil-firing in dryers and calciners is minimized by reaction with alkaline materials naturally occurring in the phosphate rock ore. Additional studies of the radioactive materials in the emissions are planned and EPA could, if warranted, take additional action under Section 112 of the Clean Air Act at a future date.

Potential particulate emissions from typical uncontrolled phosphate rock facilities would amount to about 2.9 kg/Mg (5.8 lb/ton) of rock feed from the dryer, 7.7 kg/Mg (15.4 lb/ton) of rock feed from the calciner, and about 0.8 kg/Mg (1.6 lb/ton) of rock feed from the grinder. The typical State emission limit for dryers is 0.13 kg/Mg (0.26 lb/ton), and the limit for calciners and grinders is about 0.44 kg/Mg (0.88 lb/ton). Through application of alternative control technology (e.g., the baghouse, or high energy scrubber), the emissions from these facilities could be further reduced to 0.02 kg/Mg (0.04 lb/ton) for dryers, 0.055 kg/Mg (0.11 lb/ton) for calciners, and 0.006 kg/Mg (0.012 lb/ton) for grinders. Control limits for ground rock handling and storage operations are difficult to define owing to wide variations in system equipment and the numerous fugitive emission sources contained in these systems. At most installations, particulate emissions are collected by an evacuation system and vented through a baghouse. Greater assurance that such control system are installed, operated and maintained in accordance with good practice can be achieved by enforcing stringent opacity standards.

Selection of Best System of Emission Reduction Considering Costs.

Based on potential environmental, economic and energy impacts, EPA has concluded that either a fabric filtration system or a high energy venturi scrubber system is the best technological system of continuous particulate emissions reduction from each of the affected facilities. The fabric filtration system, high energy scrubber and high efficiency electrostatic precipitator are judged to be equally effective in terms of emissions reduction capability. The proposed standards are, therefore, based on the use of any of the three alternative control methods, although cost considerations would favor the use of the baghouse or high energy scrubber over the ESP.

The economic and environmental adverse impacts associated with the alternative controls would favor the use of the baghouse controls. The economic and environmental advantages of the baghouse are most apparent at grinding and material handling/storage facilities, where baghouses are already the prevailing control employed. In contrast to the baghouse, wet collection systems produce water pollution and more solid waste, although the incremental adverse environmental impact produced by these systems is small in comparison with adverse effects presently produced by phosphate rock plant processes, and would not preclude the use of these systems as environmentally acceptable control alternatives.

Selection of Format for Standard

The format of the proposed standard could be either a concentration standard or a mass-per-unit-of-feed standard. A control efficiency format could not be selected because of limited scope in the data base and practical considerations involving the complexity of performance test requirements. An equipment standard was not considered because Section 111 of the Act requires application of emission limits when feasible. The mass-emission-per-unit-feed standard was selected over the concentration standard format because this format: (1) is related directly to the total quantity of emissions discharged to the atmosphere, (2) is more equitable in that the degree of emissions permitted is related to the amount of product processed, (3) is consistent with the format of existing applicable State standards, (4) does not discourage use of more efficient process systems which reduce exhaust gas volumes, and (5) provides that the standard is not circumvented by dilution or high volume flows in the exhaust system. The mass

emissions format is appropriate for the dryers, calciners, and grinder facilities. However, because of wide variations in the designs of ground rock handling systems, and because a substantial portion of the potential emissions are fugitive and difficult to measure, a visible emission standard is the only format appropriate for ground rock handling systems.

Emission Standards for Dryers

Source tests were conducted on dryers at two phosphate rock plants processing pebble rock. The pebble rock is considered to present the most adverse conditions for control of emissions from dryers because it receives relatively little washing and enters the dryer containing a substantial percentage of clay. Hence, any control level limit for dryers processing pebble rock should also be capable of meeting the limit for all other dryers as well.

Particulate emissions from the dryer controlled by a venturi scrubber operating at about 4.4 kilopascals pressure drop (18 inches of water) averaged 0.020 and 0.019 kg/Mg (0.039 and 0.038 lb/ton) for separate EPA tests. Particulate emissions from the dryer controlled by an ESP averaged 0.012 and 0.027 kg/Mg (0.024 and 0.054 lb/ton) for EPA and operator tests, respectively. The test results show that the venturi scrubber was capable of achieving emission levels of 0.02 kg/Mg or better from phosphate rock dryers emitting high levels of particulates. The tests also revealed that the venturi scrubber was achieving a control efficiency of 99.2 percent. This is nearly equivalent to that estimated to be attainable by the best system of emission reduction (99.4 percent by a baghouse) when treating the same emission loading and particle size distribution. Based on analysis using a programmable EPA scrubber model (the model is described in EPA report No. EPA-600/7-78-026), it was estimated that increasing the scrubber energy to a pressure drop of 6.2 kilopascals (25 inches of water) would achieve the degree of control equivalent to the best system of emission reduction, reducing emission levels only marginally (about 20 percent) below that measured. It is concluded, therefore, that an emission limit of 0.02 kg/Mg (0.04 lb/ton) represents the emission level attainable by the best system of emission reduction.

Opacity data were gathered during particulate tests at the two dryers. Approximately fourteen hours of measurements on four separate dates were obtained as specified in EPA Reference Method 9. At one facility where emissions were controlled by a

medium-energy venturi scrubber, the observations revealed zero percent opacity throughout the test periods. At the other facility, where emissions were controlled by an ESP, opacity observations ranged from zero percent to 7.7 percent. The difference between the opacity levels observed for the two types of control systems primarily reflected differences in diameters of discharge stacks rather than significant differences in control performance. ESPs typically require larger stacks due to higher volumes of flow required during operation. Setting separate opacity standards for the two control systems was rejected because ESPs are not expected to be used in meeting the proposed standards. Thus the proposed opacity standard is based on the performance of the scrubber-controlled facility and is set at zero percent opacity. Control systems reflecting best emissions control capability (the high energy scrubber or baghouse) which meets the proposed emissions limit should experience no difficulty meeting the proposed opacity standard. Should any affected dryer facility be controlled with an ESP and comply with the particulate limit of 0.02 kg/Mg but not the opacity limits, a separate opacity limit may be established for the facility under 40 CFR 60.11(e). The provisions of 40 CFR 60.11(e) allow owners or operators of sources which exceed the opacity standard while concurrently achieving the performance emissions limit to request establishment of a specific opacity standard for that facility.

Emission Standards for Calciners

Source tests were conducted on calciners at two phosphate rock plants processing western phosphate rock. The western rock is considered to present the most adverse conditions for emissions control from calciners because it receives less cleaning during beneficiation than other ore types. In addition one of the calciners selected for test also processes a mix of both beneficiated and unbeneficiated rock, leading to a still more adverse control problem. Presumably, any control system demonstrating an emissions level for these facilities should also be capable of meeting this level for all other calciners as well.

Particulate emissions from a calciner controlled by a high-energy scrubber operating in the range of 4.9 to 7.4 kilopascals pressure drop (twenty to thirty inches of water) averaged 0.04 and 0.05 kg/Mg (0.08 and 0.10 lb/ton) for two different tests by the operator.

Particulate emissions from a calciner controlled by a venturi scrubber

operating at 3.0 kilopascals pressure drop (12 inches of water) averaged 0.07 kg/Mg (0.14 lb/ton) for EPA tests and 0.12 and 0.068 kg/Mg (0.24 and 0.136 lb/ton) for different operator tests. The emission level which would have been attained had best technology been used by this facility is estimated by adjusting the test results to reflect the venturi scrubber performance at 6.8 kilopascals (27 inches water) pressure drop using the EPA programmable scrubber model. Section 8.5 of the Background Information Document for Phosphate Rock Plants summarizes the expected emission levels when the scrubber energy is increased from medium to high level. The adjusted level of control is equivalent to that which would be expected if baghouses were employed to control calciner emissions, or 0.055 kg/Mg (0.11 lb/ton). Accordingly, this control level is proposed as the emission limit for calciners.

Opacity data were obtained during the performance testing of the two calciners. Zero percent opacity was recorded at both facilities throughout the 13.75 hours of observations. Based on these test data, plus the fact that better control technology must be installed to comply with the performance limits, it is proposed that the opacity limit for calciner facilities be set at zero percent opacity.

Emission Standards for Grinders

Source tests were conducted on four separate grinders representing a wide variation of exhaust air rates, grinder designs, capacities, and product feeds. Emissions from each of the facilities are controlled with baghouses. Emissions averaged 0.0044, 0.002, 0.0005, and 0.0005 kg/Mg for EPA tests and 0.0022 kg/Mg for operator tests. The emission tests demonstrate that an emission level of 0.005 kg/Mg (0.01 lb/ton) can be achieved by fabric filters for a variety of grinder applications. Installation of baghouse controls for grinders is motivated by the recovery value of the product collected as much as by existing emission standards. Hence, it is expected that baghouses will remain the predominant means of compliances with emission standards for grinder facilities.

Nearly 17 hours of opacity observations were gathered during particulate tests at two of the grinder facilities. The average opacity level recorded throughout the measurement periods was zero percent. The use of baghouses as control devices on these two facilities represents demonstrated best technology, therefore, the Administrator believes that the opacity standard for phosphate rock grinding

processes should be zero percent opacity.

Emission Standards for Ground Rock Handling and Storage Systems

Particulate emissions from handling and storage of ground rock are very difficult to characterize due to the fact that these systems vary greatly from plant to plant. A substantial portion of the potential emissions from handling and storage operations is fugitive emissions. Normal industrial practice is to control dust from the various sources by utilizing enclosures and air evacuation or pressure systems ducted to baghouses. Baghouses provide recovery of the rock dust which is subsequently returned to the rock inventory. Emissions from the enclosures have zero percent opacity when the process equipment is properly maintained. Consequently, emissions from the ground rock transfer system are manifested and monitored at the overall collection device (e.g., the baghouse). Because of wide variations in handling and storage facilities, an opacity standard is the only standard appropriate for these facilities.

Source tests were conducted on three pneumatic systems employed in the transfer of ground phosphate rock. The exhaust from the baghouses of each of the transfer systems was witnessed to determine the opacity of emissions during normal transfer operations for two hours at one system, and one hour at the others. The opacity level of the baghouse emissions was observed to be zero percent throughout the test period. Based on these results, an opacity limit of zero percent opacity is proposed for ground phosphate rock handling systems.

Testing, Monitoring, and Recordkeeping

Performance tests to determine compliance with the proposed standards would be required. Reference Method 5 (40 CFR Part 60, Appendix A) would be used to measure the amount of particulate emissions.

The proposed standards would require continuous monitoring of the opacity of emissions discharged from phosphate rock dryers, calciners, grinders and ground rock handling systems. When a scrubber is used to control the emissions, entrained water droplets prevent the accurate measurement of opacity; therefore, in this case the proposed standard would require monitoring the pressure drop across the scrubber and the scrubbing fluid supply pressure to the scrubber rather than opacity. If other controls are employed which would also preclude the use of a continuous monitoring

system for measuring opacity as specified by the standard, the operator may request establishment of alternative monitoring requirements under the provisions of 40 CFR 60.13(i).

Excess emissions for affected facilities using opacity monitoring equipment are defined as all six-minute periods in which the average opacity of the stack plume exceeds zero percent. Reporting of any excess emissions is required under 40 CFR 60 on a quarterly basis. For those facilities which use a wet scrubber as the particulate control device, the owner or operator is instead required to submit reports each calendar quarter for all measurements of scrubber pressure drops and liquid supply pressures less than 90 percent of the average levels maintained during the most recent performance test in which compliance with the proposed standards was demonstrated.

Public Hearing

A public hearing will be held to discuss these proposed standards in accordance with Section 307(d)(5) of the Clean Air Act. Persons wishing to make oral presentations should contact EPA at the address given in the ADDRESSES Section of this preamble. Oral presentations will be limited to 15 minutes each. Any member of the public may file a written statement with EPA before, during, or within 30 days after the hearing.

A verbatim transcript of the hearing and written statements will be available for public inspection and copying during normal working hours at the address of the Docket (see ADDRESSES Section).

Docket

The docket is an organized and complete file of all the information considered by EPA in the development of this rulemaking. The principal purposes of the docket are (1) to allow interested persons to identify and locate documents so that they can intelligently and effectively participate in the rulemaking process, and (2) to serve as the record for judicial review.

Miscellaneous

As prescribed by Section 111 of the Act, this proposal of standards was preceded by the Administrator's determination that emissions from phosphate rock plants contribute significantly to air pollution which causes or contributes to the endangerment of public health or welfare. In accordance with Section 117 of the Act, publication of this proposal was preceded by consultation with appropriate advisory committees, independent experts, and Federal

departments and agencies. The Administrator will welcome comments on all aspects of the proposed regulation.

Under EPA's sunset policy for reporting requirements in regulations, the reporting requirements in this regulation will automatically expire 5 years from the date of promulgation unless EPA takes affirmative action to extend them. To accomplish this, a provision automatically terminating the reporting requirements at that time will be included in the text of the final regulations.

It should be noted that standards of performance for new sources established under Section 111 of the Clean Air Act reflect the degree of emission limitation achievable through application of the best technological system of continuous emission reduction which (taking into consideration the cost of achieving such emission reduction, any nonair quality health and environmental impact and energy requirements) the Administrator determines has been adequately demonstrated.

Although there may be emission control technology available that can reduce emissions below those levels required to comply with the standards of performance, this technology might not be selected as the basis of standards of performance because of costs associated with its use. Accordingly, standards of performance should not be viewed as the ultimate in achievable emission control. In fact, the Act requires (or has the potential for requiring) the imposition of a more stringent emission standard in several situations. For example, applicable costs do not play as prominent a role in determining the "lowest achievable emission rate" for new or modified sources locating in nonattainment areas; i.e., those areas where statutorily-mandated health and welfare standards are being violated. In this respect, Section 173 of the Act requires that new or modified sources constructed in an area which violates the National Ambient Air Quality Standards (NAAQS) must reduce emissions to the level which reflects the "lowest achievable emission rate" (LAER), as defined in Section 171(3), for such category of source. The statute defines LAER as that rate of emissions based on the following, whichever is more stringent:

(A) The most stringent emission limitation which is contained in the implementation plan of any State for such class or category of source, unless the owner or operator of the proposed

source demonstrates that such limitations are not achievable; or,

(B) The most stringent emission limitation which is achieved in practice by such class or category of source.

In no event can the emission rate exceed any applicable new source performance standard (Section 171(3)).

A similar situation may arise under the prevention of significant deterioration of air quality provisions of the Act (Part C). These provisions require that certain sources (referred to in Section 169(1)) employ "best available control technology" (as defined in Section 169(3)) for all pollutants regulated under the Act. Best available control technology (BACT) must be determined on a case-by-case basis, taking energy, environmental and economic impacts and other costs into account. In no event may the application of BACT result in emissions of any pollutants which will exceed the emissions allowed by any applicable standard established pursuant to Section 111 (or 112) of the Act.

In all events, State Implementation Plans approved or promulgated under Section 110 of the Act must provide for the attainment and maintenance of National Ambient Air Quality Standards (NAAQS) designed to protect public health and welfare. For this purpose, SIPs must in some cases require greater emission reductions than those required by standards of performance for new sources.

Finally, States are free under Section 116 of the Act to establish even more stringent emission limits than those established under Section 111 or those necessary to attain or maintain the NAAQS under Section 110. Accordingly, new sources may in some cases be subject to limitations more stringent than EPA's standards of performance under Section 111, and prospective owners and operators of new sources should be aware of this possibility in planning for such facilities.

EPA will review this regulation 4 years from the date of promulgation. This review will include an assessment of such factors as the need for integration with other programs, the existence of alternative methods, enforceability, and improvements in emission control technology.

Executive Order 12044, dated March 24, 1978, whose objective is to improve government regulations, requires executive branch agencies to prepare regulatory analyses for regulations that may have major economic consequences. The screening criteria used by EPA to determine if a proposal requires a regulatory analysis under Executive Order 12044 are: (1)

Additional national annualized compliance costs, including capital charges, which total \$100 million within any calendar year by the attainment date, if applicable, or within five years, (2) a major increase in prices or production costs.

The impacts associated with the proposal of performance standards for phosphate rock plants do not exceed the EPA screening criteria. Therefore, promulgation of the proposed standard does not constitute a major action requiring preparation of a regulatory analysis under Executive Order 12044. However, an economic impact assessment of alternative control technologies capable of meeting the proposed NSPS has been prepared as required under Section 317 of the Clean Air Act and is included in the Background Information Document for Phosphate Rock Plants. EPA considered all the information in the economic impact assessment in determining the cost of the proposed standard.

Dated: September 14, 1979.

Douglas M. Costle,
Administrator.

It is proposed to amend Part 60 of Chapter I of Title 40 of the Code of Federal Regulations as follows:

1. By adding Subpart NN to the Table of Sections as follows:

Subpart NN—Standards of Performance for Phosphate Rock Plants

- Sec.
- 60.400 Applicability and designation of affected facility.
 - 60.401 Definitions.
 - 60.402 Standard for particulate matter.
 - 60.403 Monitoring of emissions and operations.
 - 60.404 Test methods and procedures.

Authority. Sec. 111 and 301(a), Clean Air Act, as amended, (42 U.S.C. 7411, 7601(a)), and additional authority as noted below:

2. By adding subpart NN as follows:

Subpart NN—Standards of Performance for Phosphate Rock Plants

§ 60.400 Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to the following affected facilities used in phosphate rock plants: dryers, calciners, grinders, and ground rock handling and storage facilities.

(b) Any facility under paragraph (a) of this section which commences construction, modification, or reconstruction after September 21, 1979, is subject to the requirements of this part.

§ 60.401 Definitions.

(a) "Phosphate rock plant" means any plant which produces or prepares phosphate rock product by any or all of the following processes: mining, beneficiation, crushing, screening, cleaning, drying, calcining, and grinding.

(b) "Phosphate rock feed" means the ore which is fed to phosphate rock facilities, including, but not limited to the following minerals: Fluorapatite, hydroxylapatite, chlorapatite and carbonate-apatite.

(c) "Dryer" means a unit in which the moisture content of phosphate rock is reduced by contact with a heated gas stream.

(d) "Calciner" means a unit in which the moisture and organic matter of phosphate rock is reduced within a combustion chamber.

(e) "Grinder" means a unit which is used to reduce the size of dry phosphate rock.

(f) "Ground phosphate rock handling and storage system" means a system which is used for the conveyance and storage of ground phosphate rock.

§ 60.402 Standard for particulate matter.

(a) On and after the date on which the performance test required to be conducted by § 60.8 is completed, no owner or operator subject to the provisions of this subpart shall cause to be discharged into the atmosphere:

(1) From any phosphate rock dryer any gases which:

(i) Contain particulate matter in excess of 0.020 kilogram per megagram of phosphate rock feed (0.04 lb/ton), or
(ii) Exhibit greater than 0 percent opacity.

(2) From any phosphate rock calciner any gases which:

(i) Contain particulate matter in excess of 0.055 kilogram per megagram of phosphate rock feed (0.11 lb/ton), or
(ii) Exhibit greater than 0 percent opacity.

(3) From any phosphate rock grinder any gases which:

(i) Contain particulate matter in excess of 0.006 kilogram per megagram of phosphate rock feed (0.012 lb/ton), or
(ii) Exhibit greater than 0 percent opacity.

(4) From any phosphate rock handling and storage system any gases which exhibit greater than 0 percent opacity.

§ 60.403 Monitoring of emissions and operations

(a) Any owner or operator subject to the provisions of this subpart shall install, calibrate, maintain, and operate a continuous monitoring system, except as provided in paragraph (b) of this section, to monitor and record the

opacity of the gases discharged into the atmosphere from any phosphate rock dryer, calciner, grinder or ground rock handling system. The span of this system shall be set at 40 percent opacity.

(b) The owner or operator of any affected phosphate rock facility using a wet scrubbing emission control device shall not be subject to the requirements in paragraph (a) of this section, but shall install, calibrate, maintain, and operate the following continuous monitoring devices:

(1) A monitoring device for the continuous measurement of the pressure loss of the gas stream through the scrubber. The monitoring device must be certified by the manufacturer to be accurate within ± 250 pascals (± 1 inch water) gauge pressure.

(2) A monitoring device for the continuous measurement of the scrubbing liquid supply pressure to the control device. The monitoring device must be accurate within ± 5 percent of design scrubbing liquid supply pressure.

(c) For the purpose of conducting a performance test under § 60.8, the owner or operator of any phosphate rock plant subject to the provisions of this subpart shall install, calibrate, maintain, and operate a device for measuring the phosphate rock feed to any affected dryer, calciner, grinder, or ground rock handling system. The measuring device used must be accurate to within ± 5 percent of the mass rate over its operating range.

(d) For the purpose of reports required under § 60.7(c), periods of excess emissions that shall be reported are defined as all six-minute periods during which the average opacity of the plume from any phosphate rock dryer, calciner, grinder or ground rock handling system subject to paragraph (a) of this section exceeds 0 percent.

(e) Any owner or operator subject to requirements under paragraph (b) of this section shall report for each calendar quarter all measurement results that are less than 90 percent of the average levels maintained during the most recent performance test conducted under § 60.8 in which the affected facility demonstrated compliance with the standard under § 60.402.

(Sec. 114, Clean Air Act as amended (42 U.S.C. 7414))

§ 60.404 Test methods and procedures

(a) Reference methods in Appendix A of this part, except as provided under § 60.8(b) shall be used to determine compliance with § 60.402 as follows:

(1) Method 5 for the measurement of particulate matter and associated moisture content,

(2) Method 1 for sample and velocity traverses,

(3) Method 2 for velocity and volumetric flow rates,

(4) Method 3 for gas analysis, and

(5) Method 9 for the measurement of the opacity of emissions.

(b) For Method 5, the sampling time for each run shall be at least 60 minutes and the minimum sampled volume of 0.84 dscm (30 dscf) except that shorter sampling times and smaller sample volumes, when necessitated by process variables or other factors, may be approved by the Administrator.

(c) For each run, average phosphate rock feed rate in megagrams per hour shall be determined using a device meeting the requirements of § 60.403(c).

(d) For each run, emissions expressed in kilograms per megagram of phosphate rock feed shall be determined using the following equation:

$$E = \frac{(C_p Q_p) 10^{-6}}{M}$$

Where:

E = Emissions of particulates in kilograms per megagrams of phosphate rock feed.

C_p = Concentration of particulates in mg/dscm as measured by Method 5.

Q_p = Volumetric flow rate in dscm/hr as determined by Method 2.

10^{-6} = Conversion factor for milligrams to kilograms.

M = Average phosphate rock feed rate in megagrams per hour.

(Sec. 114, Clean Air Act, as amended, (42 U.S.C. 7414))

[FR Doc. 79-29399 Filed 9-20-79; 8:45 am]

40 CFR Part 60

[FRL 1349-8]

**Standards of Performance for New
Stationary Sources; Phosphate Rock
Plants; Extension of Comment Period**

AGENCY: Environmental Protection
Agency (EPA).

ACTION: Extension of Comment Period.

SUMMARY: The deadline for submittal of comments on the proposed standards of performance for phosphate rock plants, which were proposed on September 21, 1979 (44 FR 54970), is being extended from November 26, 1979 to December 26, 1979.

DATES: Comments must be received on or before December 26, 1979.

ADDRESSES: Comments should be submitted to Mr. David R. Patrick, Chief, Standards Development Branch (MD-13), Emission Standards and Engineering Division, Environmental Protection Agency, Research Triangle Park, North Carolina 27711.

FOR FURTHER INFORMATION CONTACT: Mr. Don R. Goodwin, Director, Emission Standards and Engineering Division (MD-13), Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone number (919) 541-5271.

SUPPLEMENTARY INFORMATION: On September 21, 1979 (44 FR 54970), the Environmental Protection Agency proposed standards of performance for the control of particulate emissions from phosphate rock plants. The notice of proposal requested public comments on the standards by November 26, 1979. Due to a delay in the shipping of the Support Document, sufficient copies of the document have not been available to all interested parties in time to allow their meaningful review and comment by November 26, 1979. EPA has received a request from the industry to extend the comment period by 30 days through December 26, 1979. An extension of this length is justified since the shipping delay has resulted in approximately a three-week delay in processing requests for the document.

Dated: October 26, 1979.

David G. Hawkins,

*Assistant Administrator for Air, Noise, and
Radiation.*

ENVIRONMENTAL PROTECTION AGENCY

STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

CONTINUOUS MONITORING PERFORMANCE SPECIFICATIONS

APPENDIX B

40 CFR Part 60

[FRL 1276-4]

Standards of Performance for New Stationary Sources; Continuous Monitoring Performance Specifications

AGENCY: Environmental Protection Agency (EPA).

ACTION: Proposed Revisions.

SUMMARY: On October 6, 1975 (40 FR 46250), the EPA promulgated revisions to 40 CFR Part 60, Standards of Performance for New Stationary Sources, to establish specific requirements pertaining to continuous emission monitoring. An appendix to the regulation contained Performance Specifications 1 through 3, which detailed the continuous monitoring instrument performance and equipment specifications, installation requirements, and test and data computation procedures for evaluating the acceptability of continuous monitoring systems. Since the promulgation of these performance specifications, the need for a number of changes which would clarify the specification test procedures, equipment specifications, and monitoring system installation requirements has become apparent. The purpose of the revisions is to incorporate these changes into Performance Specifications 1 through 3.

The proposed revisions would apply to all monitoring systems currently subject to performance specifications 1, 2, or 3, including sources subject to Appendix P to 40 CFR Part 51.

DATES: Comments must be received on or before December 10, 1979.

ADDRESSES: *Comments.* Comments should be submitted (in duplicate if possible) to the Central Docket Section (A-130), Attn: Docket No. OAQPS-79-4, U.S. Environmental Protection Agency, 401 M Street, S.W., Washington, D.C. 20460.

Docket. Docket No. OAQPS-79-4, containing material relevant to this rulemaking, is located in the U.S. Environmental Protection Agency, Central Docket Section, Room 2903B, 401 M Street, S.W., Washington, D.C. The docket may be inspected between 8 A.M. and 4 P.M. on weekdays, and a reasonable fee may be charged for copying.

FOR FURTHER INFORMATION CONTACT: Don R. Goodwin, Director, Emission Standards and Engineering Division

(MD-13), Environmental Protection Agency, Research Triangle Park, North Carolina 27711, telephone number (919) 541-5271.

SUPPLEMENTARY INFORMATION: Changes common to all three of the performance specifications are the clarification of the procedures and equipment specifications, especially the requirement for installing the continuous monitoring sample interface and of the calculation procedure for relative accuracy. Specific changes to the specifications are as follows:

Performance Specification

1. The optical design specification for mean and peak spectral responses and for the angle of view and projection have been changed from "500 to 600 nm" range to "515 to 585 nm" range and from "5°" to "3°", respectively.

2. The following equipment specifications have been added:

a. Optical alignment sight indicator for readily checking alignment.

b. For instruments having automatic compensation for dirt accumulation on exposed optical surfaces, a compensation indicator at the control panel so that the permissible maximum 4 percent compensation can be determined.

c. Easy access to exposed optical surfaces for cleaning and maintenance.

d. A system for checking zero and upscale calibration (previously required in paragraph 60.13).

e. For systems with slotted tubes, a slotted portion greater than 90 percent of effluent pathlength (shorter slots are permitted if shown to be equivalent).

f. An equipment specification for the monitoring system data recorder resolution of <5 percent of full scale.

3. A procedure for determining the acceptability of the optical alignment sight has been specified; the optical alignment sight must be capable of indicating that the instrument is misaligned when an error of ± 2 percent opacity is caused by misalignment of the instrument at a pathlength of 8 meters.

4. Procedures for calibrating the attenuators used during instrument calibrations have been added; these procedures require the use of a laboratory spectrophotometer operating in the 400-700 nm range with a detector angle view of <10 degrees and an accuracy of 1 percent.

5. The following changes have been made to the procedures for the operational test period:

a. The requirement for an analog strip chart recorder during the performance tests has been deleted; all data are collected on the monitoring system data recorder.

b. Adjustment of the zero and span at 24-hour intervals during the drift tests is optional; adjustments are required only when the accumulated drift exceeds the 24-hour drift specification.

c. The amount of automatic zero compensation for dirt accumulation must be determined during the 24-hour zero check so that the actual zero drift can be quantified. The automatic zero compensation system must be operated during the performance test.

d. The requirement for offsetting the data recorder zero during the operational test period has been deleted.

e. Off the stack "zero alignment" of the instrument prior to installation is permitted.

Performance Specification 2

1. "Continuous monitoring system" has been redefined to include the diluent monitor, if applicable. The change requires that the relative accuracy of the system be determined in terms of the emission standard, e.g., mass per unit calorific value for fossil-fuel fired steam generators.

2. The applicability of the test procedures excludes single-pass, in-situ continuous monitoring systems. The procedures for determining the acceptability of these systems are evaluated on a case-by-case basis.

3. For extractive systems with diluent monitors, the pollutant and diluent monitors are required to use the same sample interface.

4. The procedure for determining the acceptability of the calibration gases has been revised, and the 20 percent (with 95 percent confidence interval) criterion has been changed to 5 percent of mean value with no single value being over 10 percent from the mean.

5. For low concentrations, a 10 percent of the applicable standard limitation for the relative accuracy has been added.

6. An equipment specification for the system data recorder requiring that the chart scale be readable to within <0.50 percent of full-scale has been added.

7. Instead of spanning the instrument at 90 percent of full-scale, a mid-level span is required.

8. The response time test procedure has been revised and the difference limitation between the up-scale and down-scale time has been deleted.

9. The relative accuracy test procedure has been revised to allow different tests (e.g., pollutant, diluent, moisture) during a 1-hour period to be correlated.

10. A low-level drift may be substituted for the zero drift test.

Performance Specification 3

1. The applicability of the test procedures has been limited to those monitors that introduce calibration gases directly into the analyzer and are used as diluent monitors. Alternative procedures for other types of monitors are evaluated on a case-by-case basis.

2. Other changes were made to be consistent with the revisions under Performance Specification 2.

The proposed revised performance specifications would apply to all sources subject to Performance Specifications 1, 2, or 3. These include sources subject to standards of performance that have already been promulgated and sources subject to Appendix P to 40 CFR Part 51. Since the purpose of these revisions is to clarify the performance specifications which were promulgated on October 6, 1975, not to establish more stringent requirements, it is reasonable to conclude that most continuous monitoring instruments which met and can continue to meet the October 6, 1975, specifications can also meet the revised specifications.

Under Executive Order 12044, the Environmental Protection Agency is required to judge whether a regulation is "significant" and therefore subject to the procedural requirements of the Order or whether it may follow other specialized development procedures. EPA labels these other regulations "specialized". I have reviewed this regulation and determined that it is a specialized regulation not subject to the procedural requirements of Executive Order 12044.

Dated: October 1, 1979.

Douglas M. Costle,
Administrator.

It is proposed to revise Appendix B, Part 60 of Chapter I, Title 40 of the Code of Federal Regulations as follows:

Appendix B—Performance Specifications**Performance Specification 1—
Specifications and Test Procedures For
Opacity Continuous Monitoring Systems
in Stationary Sources****1. Applicability and Principle**

1.1 **Applicability.** This Specification contains instrument design, performance, and installation requirements, and test and data computation procedures for evaluating the acceptability of continuous monitoring systems for opacity. Certain design requirements and test procedures established in the Specification may not be applicable to all instrument designs; equivalent systems and test procedures may be used with prior approval by the Administrator.

1.2 **Principle.** The opacity of particulate matter in stack emissions is continuously monitored by a measurement system based upon the principle of transmissometry. Light having specific spectral characteristics is projected from a lamp through the effluent in the stack or duct and the intensity of the projected light is measured by a sensor. The projected light is attenuated due to absorption and scatter by the particulate matter in the effluent; the percentage of visible light attenuated is defined as the opacity of the emission. Transparent stack emissions that do not attenuate light will have a transmittance of 100 percent or an opacity of zero percent. Opaque stack emissions that attenuate all of the visible light will have a transmittance of zero percent or an opacity of 100 percent.

This specification establishes specific design criteria for the transmissometer system. Any opacity continuous monitoring system that is expected to meet this specification is first checked to verify that the design specifications are met. Then, the opacity continuous monitoring system is calibrated, installed, an operated for a specified length of time. During this specified time period, the system is evaluated to determine conformance with the established performance specifications.

2. Definitions

2.1 **Continuous Monitoring System.** The total equipment required for the determination of opacity. The system consists of the following major subsystems:

2.1.1 **Sample Interface.** That portion of the system that protects the analyzer from the effects of the stack effluent and aids in keeping the optical surfaces clean.

2.1.2 **Analyzer.** That portion of the system that senses the pollutant and generates a signal output that is a function of the opacity.

2.1.3 **Data Recorder.** That portion of the system that processes the analyzer output and provides a permanent record of the output signal in terms of opacity. The data recorder may include automatic data reduction capabilities.

2.2 **Transmissometer.** That portion of the system that includes the sample interface and the analyzer.

2.3 **Transmittance.** The fraction of incident light that is transmitted through an optical medium.

2.4 **Opacity.** The fraction of incident light that is attenuated by an optical medium. Opacity (Op) and transmittance (Tr) are related by:
$$Op = 1 - Tr.$$

2.5 **Optical Density.** A logarithmic measure of the amount of incident light attenuated. Optical density (D) is related to the transmittance and opacity as follows:

$$D = -\log_{10} Tr = -\log_{10} (1 - Op).$$

2.6 **Peak Spectral Response.** The wavelength of maximum sensitivity of the transmissometer.

2.7 **Mean Spectral Response.** The wavelength which bisects the total area under the effective spectral response curve of the transmissometer.

2.8 **Angle of View.** The angle that contains all of the radiation detected by the photodetector assembly of the analyzer at a level greater than 2.5 percent of the peak detector response.

2.9 **Angle of Projection.** The angle that contains all of the radiation projected from the lamp assembly of the analyzer at a level of greater than 2.5 percent of the peak illuminance.

2.10 **Span Value.** The opacity value at which the continuous monitoring system is set to produce the maximum data display output as specified in the applicable subpart.

2.11 **Upscale Calibration Value.** The opacity value at which a calibration check of the monitoring system is performed by simulating an upscale opacity condition as viewed by the receiver.

2.12 **Calibration Error.** The difference between the opacity values indicated by the continuous monitoring system and the known values of a series of calibration attenuators (filters or screens).

2.13 **Zero Drift.** The difference in continuous monitoring system output readings before and after a stated period of normal continuous operation during which no unscheduled maintenance, repair, or adjustment took place and when the opacity (simulated) at the time of the measurements was zero.

2.14 **Calibration Drift.** The difference in the continuous monitoring system output readings before and after a stated period of normal continuous operation during which no unscheduled maintenance, repair, or adjustment took place and when the opacity (simulated) at the time of the measurements was the same known upscale calibration value.

2.15 **Response Time.** The amount of time it takes the continuous monitoring system to display on the data recorder 95 percent of a step change in opacity.

2.16 **Conditioning Period.** A period of time (168 hours minimum) during which the continuous monitoring system is operated without unscheduled maintenance, repair, or adjustment prior to initiation of the operational test period.

2.17 Operational Test Period. A period of time (168 hours) during which the continuous monitoring system is expected to operate within the established performance specifications without any unscheduled maintenance, repair, or adjustment.

2.18 Pathlength. The depth of effluent in the light beam between the receiver and the transmitter of a single-pass transmissometer, or the depth of effluent between the transceiver and reflector of a double-pass transmissometer. Two pathlengths are referenced by this Specification as follows:

2.18.1 Monitor Pathlength. The pathlength at the installed location of the continuous monitoring system.

2.18.2 Emission Outlet Pathlength. The pathlength at the location where emissions are released to the atmosphere.

3. Apparatus

3.1 Continuous Monitoring System. Use any continuous monitoring system for opacity which is expected to meet the design specifications in Section 5 and the performance specifications in Section 7. The data recorder may be an analog strip chart recorder type or other suitable device with an input signal range compatible with the analyzer output.

3.2 Calibration Attenuators. Use optical filters with neutral spectral characteristics or screens known to produce specified optical densities to visible light. The attenuators must be of sufficient size to attenuate the entire light beam of the transmissometer. Select and calibrate a minimum of three attenuators according to the procedures in Sections 8.1.2. and 8.1.3.

3.3 Upscale Calibration Value Attenuator. Use an optical filter with neutral spectral characteristics, a screen, or other device that produces an opacity value (corrected for pathlength, if necessary) that is greater than the sum of the applicable opacity standard and one-fourth of the difference between the opacity standard and the instrument span value, but less than the sum of the opacity standard and one-half of the difference between the opacity standard and the instrument span value.

3.4 Calibration Spectrophotometer. To calibrate the calibration attenuators use a laboratory spectrophotometer meeting the following minimum design specification:

Parameter	Specification
Wavelength range.....	400-700 nm
Detector angle of view.....	$\leq 10^\circ$
Accuracy.....	≤ 0.5 pct. transmittance

4. Installation Specifications

Install the continuous monitoring system where the opacity measurements are representative of the total emissions from the affected facility. Use a measurement path that represents the average opacity over the cross section. Those requirements can be met as follows:

4.1 Measurement Location. Select a measurement location that is (a) downstream from all particulate control equipment; (b) where condensed water vapor is not present; (c) accessible in order to permit routine maintenance; and (d) free of interference from ambient light (applicable only if transmissometer is responsive to ambient light).

4.2 Measurement Path. Select a measurement path that passes through the centroid of the cross section. Additional requirements or modifications must be met for certain locations as follows:

4.2.1 If the location is in a straight vertical section of stack or duct and is less than 4 equivalent diameters downstream or 1 equivalent diameter upstream from a bend, use a path that is in the plane defined by the bend.

4.2.2 If the location is in a vertical section of stack or duct and is less than 4 diameters downstream and 1 diameter upstream from a bend, use a path in the plane defined by the bend upstream of the transmissometer.

4.2.3 If the location is in a horizontal section of duct and is at least 4 diameters downstream from a vertical bend, use a path in the horizontal plane that is one-third the distance up the vertical axis from the bottom of the duct.

4.2.4 If the location is in a horizontal section of duct and is less than 4 diameters downstream from a vertical bend, use a path in the horizontal plane that is two-thirds the distance up the vertical axis from the bottom of the duct for upward flow in the vertical section, and one-third the distance up the vertical axis from the bottom of the duct for downward flow.

4.3 Alternate Locations and Measurement Paths. Other locations and measurement paths may be selected by demonstrating to the Administrator that the average opacity measured at the alternate location or path is equivalent (± 10 percent) to the opacity as measured at a location meeting the criteria of Sections 4.1 and 4.2. To conduct this demonstration, measure the opacities at the two locations or paths for a minimum period of two hours. The opacities of the two locations or paths may be measured at different times, but

must be measured at the same process operating conditions.

5. Design Specifications

Continuous monitoring systems for opacity must comply with the following design specifications:

5.1 Optics.

5.1.1 Spectral Response. The peak and mean spectral responses will occur between 515 nm and 585 nm. The response at any wavelength below 400 nm or above 700 nm will be less than 10 percent of the peak spectral response.

5.1.2 Angle of View. The total angle of view will be no greater than 4 degrees.

5.1.3 Angle of Projection. The total angle of projection will be no greater than 4 degrees.

5.2 Optical Alignment sight. Each analyzer will provide some method for visually determining that the instrument is optically aligned. The system provided will be capable of indicating that the unit is misaligned when an error of ± 2 percent opacity occurs due to misalignment at a monitor pathlength of eight (8) meters.

5.3 Simulated Zero and Upscale Calibration System. Each analyzer will include a system for simulating a zero opacity and an upscale opacity value for the purpose of performing periodic checks of the transmissometer calibration while on an operating stack or duct. This calibration system will provide, as a minimum, a system check of the analyzer internal optics and all electronic circuitry including the lamp and photodetector assembly.

5.4 Access to External Optics. Each analyzer will provide a means of access to the optical surfaces exposed to the effluent stream in order to permit the surfaces to be cleaned without requiring removal of the unit from the source mounting or without requiring optical realignment of the unit.

5.5 Automatic Zero Compensation Indicator. If the monitoring system has a feature which provides automatic zero compensation for dirt accumulation on exposed optical surfaces, the system will also provide some means of indicating that a compensation of 4 ± 0.5 percent opacity has been exceeded; this indicator shall be at a location accessible to the operator (e.g., the data output terminal). During the operational test period, the system must provide some means for determining the actual amount of zero compensation at the specified 24-hour intervals so that the actual 24-hour zero drift can be determined (see Section 8.4.1).

5.6 Slotted Tube. For transmissometers that use slotted tubes, the length of the slotted portion(s) must

be equal to or greater than 90 percent of the monitor pathlength, and the slotted tube must be of sufficient size and orientation so as not to interfere with the free flow of effluent through the entire optical volume of the transmissometer photodetector. The manufacturer must also show that the transmissometer uses appropriate methods to minimize light reflections; as a minimum, this demonstration shall consist of laboratory operation of the transmissometer both with and without the slotted tube in position. Should the operator desire to use a slotted tube design with a slotted portion equal to less than 90 percent of the monitor pathlength, the operator must demonstrate to the Administrator that acceptable results can be obtained. As a minimum demonstration, the effluent opacity shall be measured using both the slotted tube instrument and another instrument meeting the requirement of this specification but not of the slotted tube design. The measurements must be made at the same location and at the same process operating conditions for a minimum period of two hours with each instrument. The shorter slotted tube may be used if the average opacity measured is equivalent (± 10 percent) to the opacity measured by the non-slotted tube design.

6. Optical Design Specifications Verification Procedure.

These procedures will not be applicable to all designs and will require modification in some cases; all modifications are subject to the approval of the Administrator.

Test each analyzer for conformance with the design specifications of Sections 5.1 and 5.2 or obtain a certificate of conformance from the analyzer manufacturer as follows:

6.1 Spectral Response. Obtain detector response, lamp emissivity and filter transmittance data for the components used in the measurement system from their respective manufacturers.

6.2 Angle of View. Set up the receiver as specified by the manufacturer's written instructions. Draw an arc with radius of 3 meters in the horizontal direction. Using a small (less than 3 centimeters) non-directional light source, measure the receiver response at 4-centimeter intervals on the arc for 24 centimeters on either side of the detector centerline. Repeat the test in the vertical direction.

6.3 Angle of Projection. Set up the projector as specified by the manufacturer's written instructions. Draw an arc with radius of 3 meters in the horizontal direction. Using a small

(less than 3 centimeters) photoelectric light detector, measure the light intensity at 4-centimeter intervals on the arc for 24 centimeters on either side of the light source centerline of projection. Repeat the test in the vertical direction.

6.4 Optical Alignment Sight. In the laboratory set up the instrument as specified by the manufacturer's written instructions for a monitor pathlength of 8 meters. Assure that the instrument has been properly aligned and that a proper zero and span have been obtained. Insert an attenuator of 10 percent (nominal) opacity into the instrument pathlength. Slowly misalign the projector unit until a positive or negative shift of two percent opacity is obtained by the data recorder. Then, following the manufacturer's written instructions, check the alignment and assure that the alignment procedure does in fact indicate that the instrument is misaligned. Realign the instrument and follow the same procedure for checking misalignment of the receiver or retroreflector unit.

6.5 Manufacturer's Certificate of Conformance (Alternative to above). Obtain from the manufacturer a certificate of conformance which certifies that the first analyzer randomly sampled from each month's production was tested according to Sections 6.1 through 6.3 and satisfactorily met all requirements of Section 5 of this Specification. If any of the requirements were not met, the certificate must state that the entire month's analyzer production was resampled according to the military standard 105D sampling procedure (MIL-STD-105D) inspection level II; was retested for each of the applicable requirements under Section 5 of this Specification; and was determined to be acceptable under MIL-STD-105D procedures, acceptable quality level 1.0. The certificate of conformance must include the results of each test performed for the analyzer(s) sampled during the month the analyzer being installed was produced.

7. Performance Specifications

The opacity continuous monitoring system performance specifications are listed in Table 1-1.

Table 1-1.—Performance specifications

Parameter	Specifications
1. Calibration error *	≤ 3 pct opacity.
2. Response time	≤ 10 seconds.
3. Conditioning period *	≥ 168 hours.
4. Operational test period *	≥ 168 hours.
5. Zero drift (24-hour) *	≤ 2 pct opacity.

Table 1-1.—Performance specifications—Continued

Parameter	Specifications
6. Calibration drift (24-hour) *	≤ 2 pct opacity.
7. Data recorder resolution	≤ 0.50 pct of full scale span value.

* Expressed as sum of absolute mean and the 95 percent confidence interval.

* During the conditioning and operational test periods, the continuous monitoring system shall not require any corrective maintenance, repair, replacement, or adjustment other than that clearly specified as routine and required in the operation and maintenance manuals.

8. Performance Specification Verification Procedure

Test each continuous monitoring system that conforms to the design specifications (Section 5) using the following procedures to determine conformance with the performance specifications of Section 7.

8.1 Preliminary Adjustments and Tests. Prior to installation of the system on the stack, perform these steps or tests at the affected facility or in the manufacturer's laboratory.

8.1.1 Equipment Preparation. Set up and calibrate the monitoring system for the monitor pathlength to be used in the installation as specified by the manufacturer's written instructions. If the monitoring system has automatic pathlength adjustment, follow the manufacturer's instructions to adjust the signal output from the analyzer to equivalent values based on the emission outlet pathlength. Set the span at the value specified in the applicable subpart. At this time perform the zero alignment by balancing the response of the continuous monitoring system so that the simulated zero check coincides with the actual zero check performed across the simulated monitor pathlength. Then, assure that the upscale calibration value is within the required opacity range (Section 3.3).

8.1.2 Calibrated Attenuator Selection. Based on the span value specified in the applicable subpart, select a minimum of three calibrated attenuators (low, mid, and high range) using Table 1-2. If the system is operating with automatic pathlength compensation, calculates the attenuator values required to obtain a system response equivalent to the applicable values shown in Table 1-2; use equation 1-1 for the conversion. A series of filters with nominal optical density (opacity) values of 0.1(20), 0.2(37), 0.3(50), 0.4(60), 0.5(68), 0.6(75), 0.7(80), 0.8(84), 0.9(88), and 1.0(90) are commercially available. Within this limitation of filter availability, select the calibrated

attenuators having the values given in Table 1-2 or having values closest to those calculated by Equation 1-1.

Table 1-2.—Required Calibrated Attenuator Values (Nominal)

Span value (percent opacity)	Calibrated attenuator optical density (equivalent opacity in parenthesis)		
	Low-range D ₁	Mid-range	High-range
50	0.1 (20)	0.2 (37)	0.3 (50)
60	.1 (20)	.2 (37)	.3 (50)
70	.1 (20)	.3 (50)	.4 (60)
80	.1 (20)	.3 (50)	.6 (75)
90	.1 (20)	.4 (60)	.7 (80)
100	.1 (20)	.4 (60)	.9 (87½)

$$D_1 = D_2 (L_1/L_2) \quad \text{Equation 1-1}$$

Where:

D_1 = Nominal optical density value of required mid, low, or high range calibration attenuators.

D_2 = Desired attenuator optical density output value from Table 1-2 at the span required by the applicable subpart.

L_1 = Monitor pathlength.

L_2 = Emission outlet pathlength.

8.1.3 Attenuator Calibration.

Calibrate the required filters or screens using a laboratory spectrophotometer meeting the specifications of Section 3.4 to measure the transmittance in the 400 to 700 nm wavelength range; make measurements at wavelength intervals of 20 nm or less. As an alternate procedure use an instrument meeting the specifications of Section 3.4 to measure the C.I.E. Daylight Luminous Transmittance of the attenuators. During the calibration procedure assure that a minimum of 75 percent of the total area of the attenuator is checked. The attenuator manufacturer must specify the period of time over which the attenuator values can be considered stable, as well as any special handling and storing procedures required to enhance attenuator stability. To assure stability, attenuator values must be rechecked at intervals less than or equal to the period of stability guaranteed by the manufacturer. However, values must be rechecked at least every 3 months. If desired, the stability checks may be performed on an instrument other than that initially used for the attenuator calibration (Section 3.4). However, if a different instrument is used, the instrument shall be a high quality laboratory transmissometer or spectrophotometer and the same instrument shall always be used for the stability checks. If a secondary instrument is to be used for stability checks, the value of the calibrated attenuator shall be measured on this secondary instrument immediately following calibration and prior to being used. If over a period time an attenuator

value changes by more than ± 2 percent opacity, it shall be recalibrated or replaced by a new attenuator.

If this procedure is conducted by the filter or screen manufacturer or independent laboratory, obtain a statement certifying the values and that the specified procedure, or equivalent, was used.

8.1.4 Calibration Error Test. Insert the calibrated attenuators (low, mid, and high range) in the transmissometer path at or as near to the midpoint as feasible. The attenuator must be placed in the measurement path at a point where the effluent will be measured; i.e., do not place the calibrated attenuator in the instrument housing. While inserting the attenuator, assure that the entire projected beam will pass through the attenuator and that the attenuator is inserted in a manner which minimizes interference from reflected light. Make a total of five nonconsecutive readings for each filter. Record the monitoring system output readings in percent opacity (see example Figure 1-1).

8.1.5 System Response Test. Insert the high-range calibrated attenuator in the transmissometer path five times and record the time required for the system to respond to 95 percent of final zero and high-range filter values (see example Figure 1-2).

8.2 Preliminary Field Adjustments. Install the continuous monitoring system on the affected facility according to the manufacturer's written instructions and perform the following preliminary adjustments:

8.2.1 Optical and Zero Alignment. When the facility is not in operation, conduct the optical alignment by aligning the light beam from the transmissometer upon the optical surface located across the duct or stack (i.e., the retroreflector or photodetector, as applicable) in accordance with the manufacturer's instructions. Under clear stack conditions, verify the zero alignment (performed in Section 8.1.1) by assuring that the monitoring system response for the simulated zero check coincides with the actual zero measured by the transmissometer across the clear stack. Adjust the zero alignment, if necessary. Then, after the affected facility has been started up and the effluent stream reaches normal operating temperature, recheck the optical alignment. If the optical alignment has shifted realign the optics.

8.2.2 Optical and Zero Alignment (Alternative Procedure). If the facility is already on line and a zero stack condition cannot practicably be obtained, use the zero alignment obtained during the preliminary adjustments (Section 8.1.1) prior to

installation of the transmissometer on the stack. After completing all the preliminary adjustments and tests required in Section 8.1, install the system at the source and align the optics, i.e., align the light beam from the transmissometer upon the optical surface located across the duct or stack in accordance with the manufacturer's instruction. The zero alignment conducted in this manner shall be verified and adjusted, if necessary, the first time the facility is not in operation after the operational test period has been completed.

8.3 Conditioning Period. After completing the preliminary field adjustments (Section 8.2), operate the system according to the manufacturer's instructions for an initial conditioning period of not less than 168 hours while the source is operating. Except during times of instrument zero and upscale calibration checks, the continuous monitoring system will analyze the effluent gas for opacity and produce a permanent record of the continuous monitoring system output. During this conditioning period there shall be no unscheduled maintenance, repair, or adjustment. Conduct daily zero calibration and upscale calibration checks, and, when accumulated drift exceeds the daily operating limits, make adjustments and/or clean the exposed optical surfaces. The data recorder shall reflect these checks and adjustments. At the end of the operational test period, verify that the instrument optical alignment is correct. If the conditioning period is interrupted because of source breakdown (record the dates and times of process shutdown), continue the 168-hour period following resumption of source operation. If the conditioning period is interrupted because of monitor failure, restart the 168-hour conditioning period when the monitor becomes operational.

8.4 Operational Test Period. After completing the conditioning period operate the system for an additional 168-hour period. It is not necessary that the 168-hour operational test period immediately follow the 168-hour conditioning period. Except during times of instrument zero and upscale calibration checks, the continuous monitoring system will analyze the effluent gas for opacity and will produce a permanent record of the continuous monitoring system output. During this period, there will be no unscheduled maintenance, repair, or adjustment. Zero and calibration adjustments, optical surface cleaning, and optical realignment may be performed (optional) only at 24-hour intervals or at

such shorter intervals as the manufacturer's written instructions specify. Automatic zero and calibration adjustments made by the monitoring system without operator intervention or initiation are allowable at any time. If the operational test period is interrupted because of source breakdown, continue the 168-hour period following resumption of source operation. If the test period is interrupted because of monitor failure, restart the 168-hour period when the monitor becomes operational. During the operational test period, perform the following test procedures:

8.4.1 Zero Drift Test. At the outset of the 168-hour operational test period, record the initial simulated zero and upscale opacity readings (see example Figure 1-3). After each 24-hour interval check and record the final zero reading before any optional or required cleaning and adjustment. Zero and upscale calibration adjustments, optical surface cleaning, and optical realignment may be performed only at 24-hour intervals (or at such shorter intervals as the manufacturer's written instructions specify) but are optional. However, adjustments and/or cleaning must be performed when the accumulated zero calibration or upscale calibration drift exceeds the 24-hour drift specifications (± 2 percent opacity). If no adjustments are made after the zero check the final zero reading is recorded as the initial reading for the next 24-hour period. If adjustments are made, the zero value after adjustment is recorded as the initial zero value for the next 24-hour period. If the instrument has an automatic zero compensation feature for dirt accumulation on exposed lens, and the zero value cannot be measured before compensation is entered then record the amount of automatic zero compensation for the final zero reading of each 24-hour period. (List the indicated zero values of the monitoring system in parenthesis.)

8.4.2 Upscale Drift Test. At each 24-hour interval, after the zero calibration value has been checked and any optional or required adjustments have been made, check and record the simulated upscale calibration value. If no further adjustments are made to the calibration system at this time, the final upscale calibration value is recorded as the initial upscale value for the next 24-hour period. If an instrument span adjustment is made, the upscale value after adjustment is recorded as the initial upscale for the next 24-hour period.

During the operational test period record all adjustments, realignments and lens cleanings.

9. Calculation, Data Analysis, and Reporting

9.1 Arithmetic Mean. Calculate the mean of a set of data as follows:

$$\bar{x} = \frac{1}{n} \sum_{i=1}^n x_i \quad \text{Equation 2-1}$$

Where:

\bar{x} = mean value.
 n = number of data points.
 $\sum x_i$ = algebraic sum of the individual measurements, x_i

9.2 Confidence Interval. Calculate the 95 percent confidence interval (two-sided) as follows:

$$C.I._{95} = \frac{t_{.975}}{n-1} \sqrt{n (\sum x_i^2) - (\sum x_i)^2} \quad \text{Equation 2-2}$$

Where:

$C.I._{95}$ = 95 percent confidence interval estimate of the average mean value.
 $t_{.975} = t_{(1-\alpha/2)}$.

Table 1-3—.975 Values

n	.975	n	.975	n	.975
2	12.706	7	2.447	12	2.201
3	4.303	8	2.385	13	2.179
4	3.182	9	2.308	14	2.160
5	2.776	10	2.262	15	2.145
6	2.571	11	2.228	16	2.131

The values in this table are already corrected for $n-1$ degrees of Freedom. Use n equal to the number of data points.

9.3 Conversion of Opacity Values from Monitor Pathlength to Emission Outlet Pathlength. When the monitor pathlength is different than the emission outlet pathlength, use either of the following equations to convert from one basis to the other (this conversion may be automatically calculated by the monitoring system):

$$\log(1-Op_2) = (L_2/L_1) \log(1-Op_1) \quad \text{Equation 1-4}$$

$$D_2 = (L_2/L_1) \quad \text{Equation 1-5}$$

Where:

Op_1 = opacity of the effluent based upon L_1
 Op_2 = opacity of the effluent based upon L_2
 L_1 = monitor pathlength
 L_2 = emission outlet pathlength
 D_1 = optical density of the effluent based upon L_1
 D_2 = optical density of the effluent based upon L_2

9.4 Spectral Response. Using the spectral data obtained in Section 6.1, develop the effective spectral response curve of the transmissometer. Then determine and report the peak spectral response wavelength, the mean spectral

response wavelength, and the maximum response at any wavelength below 400 nm and above 700 nm expressed as a percentage of the peak response.

9.5 Angle of View. For the horizontal and vertical directions, using the data obtained in Section 6.2, calculate the response of the receiver as a function of viewing angle (21 centimeters of arc with a radius of 3 meters equal 4 degrees), report relative angle of view curves, and determine and report the angle of view.

9.6 Angle of Projection. For the horizontal and vertical directions, using the data obtained in Section 6.3, calculate the response of the photoelectric detector as a function of projection angle, report relative angle of projection curves, and determine and report the angle of projection.

9.7 Calibration Error. See Figure 1-1. If the pathlength is not adjusted by the measurement system, subtract the actual calibrated attenuator value from the value indicated by the measurement system recorder for each of the 15 readings obtained pursuant to Section 8.1.4. If the pathlength is adjusted by the measurement system subtract the "path adjusted" calibrated attenuator values from the values indicated by the measurement system recorder the "path adjusted" calibrated attenuator values are calculated using equation 1-4 or 1-5). Calculate the arithmetic mean difference and the 95 percent confidence interval of the five tests at each attenuator value using Equations 1-2 and 1-3. Calculate the sum of the absolute value of the mean difference and the 95 percent confidence interval for each of the three test attenuators; report these three values as the calibration error.

9.8 Zero and Upscale Calibration Drifts. Using the data obtained in Sections 8.4.1 and 8.4.2 calculate the zero and upscale calibration drifts. Then calculate the arithmetic means and the 95 percent confidence intervals using Equations 1-2 and 1-3. Calculate the sum of the absolute value of the mean and the 95 percent confidence interval and report these values as the 24-hour zero drift and the 24-hour calibration drift.

9.9 Response Time. Using the data collected in Section 8.1.5, calculate the mean time of the 10 upscale and downscale tests and report this value as the system response time.

9.10 Reporting. Report the following (summarize in tabular form where appropriate).

- 9.10.1 General Information.
 - a. Instrument Manufacturer.
 - b. Instrument Model Number.
 - c. Instrument Serial Number.

- d. Person(s) responsible for operational and conditioning test periods and affiliation.
 - e. Facility being monitored.
 - f. Schematic of monitoring system measurement path location.
 - g. Monitor pathlength, meters.
 - h. Emission outlet pathlength, meters.
 - i. System span value, percent opacity.
 - j. Upscale calibration value, percent opacity.
 - k. Calibrated Attenuator values (low, mid, and high range), percent opacity.
- 9.10.2 Design Specification Test Results
- a. Peak spectral response, nm.
 - b. Mean spectral response, nm.
 - c. Response above 700 nm, percent of peak.
 - d. Response below 400 nm, percent of peak.
 - e. Total angle of view, degrees.
 - f. Total angle of projection, degrees.
- 9.10.3 Operational Test Period Results.
- a. Calibration error, high-range, percent opacity.
 - b. Calibration error, mid-range, percent opacity.
 - c. Calibration error, low-range, percent opacity.
 - d. Response time, seconds.
 - e. 24-hour zero drift, percent opacity.
 - f. 24-hour calibration drift, percent opacity.
 - g. Lens cleaning, clock time.
 - h. Optical alignment adjustment, clock time.
- 9.10.4 Statements. Provide a statement that the conditioning and operational test periods were completed according to the requirements of Sections 8.3 and 8.4. In this statement, include the time periods during which the conditioning and operational test periods were conducted.
- 9.10.5 Appendix. Provide the data tabulations and calculations for the above tabulated results.
- 9.11 Retest. If the continuous monitoring system operates within the specified performance parameters of Table 1-1, the operational test period will be successfully concluded. If the continuous monitoring system fails to meet any of the specified performance parameters, repeat the operational test period with a system that meets the design specifications and is expected to meet the performance specifications.

Figure 1-2. Response Time Determination

**Performance Specification 2—
Specifications and Test Procedures for
SO₂ and NO_x Continuous Monitoring
Systems in Stationary Sources**

1. Applicability and Principle

1.1 Applicability. This Specification contains (a) installation requirements, (b) instrument performance and equipment specifications, and (c) test procedures and data reduction procedures for evaluating the acceptability of SO₂ and NO_x continuous monitoring systems, which may include, for certain stationary sources, diluent monitors. The test procedures in item (c), above, are not applicable to single-pass, in-situ continuous monitoring systems; these systems will be evaluated on a case-by-case basis upon written request to the Administrator and alternative test procedures will be issued separately.

1.2 Principle. Any SO₂ or NO_x continuous monitoring system that is expected to meet this Specification is installed, calibrated, and operated for a specified length of time. During this specified time period, the continuous monitoring system is evaluated to determine conformance with the Specification.

2. Definitions

2.1 Continuous Monitoring System. The total equipment required for the determination of a gas concentration or a gas emission rate. The system consists of the following major sub-systems:

2.1.1 Sample Interface. That portion of a system that is used for one or more of the following: sample acquisition, sample transportation, sample conditioning, or protection of the monitor from the effects of the stack effluent.

2.1.2. Pollutant Analyzer. That portion of the system that senses the pollutant gas and generates an output that is proportional to the gas concentration.

2.1.3. Diluent Analyzer (if applicable). That portion of the system that senses the diluent gas (e.g., CO₂ or O₂) and generates an output that is proportional to the gas concentration.

2.1.4 Data Recorder. That portion of the monitoring system that provides a permanent record of the analyzer output. The data recorder may include automatic data reduction capabilities.

2.2 Types of Monitors. Continuous monitors are categorized as "extractive" or "in-situ," which are further categorized as "point," "multipoint," "limited-path," and "path" type monitors or as "single-pass" or "double-pass" type monitors.

2.2.1 Extractive Monitor. One that withdraws a gas sample from the stack and transports the sample to the analyzer.

2.2.2 In-situ Monitor. One that senses the gas concentration in the stack environment and does not extract a sample for analysis.

2.2.3 Point Monitor. One that measures the gas concentration either at a single point or along a path which is less than 10 percent of the length of a specified measurement line.

2.2.4 Multipoint Monitor. One that measures the gas concentration at 2 or more points.

2.2.5 Limited-Path Monitor. One that measures the gas concentration along a path, which is 10 to 90 percent of the length of a specified measurement line.

2.2.6 Path Monitor. One that measures the gas concentration along a path, which is greater than 90 percent of the length of a specified measurement line.

2.2.7 Single-Pass Monitor. One that has the transmitter and the detector on opposite sides of the stack or duct.

2.2.8 Double-Pass Monitor. One that has the transmitter and the detector on the same side of the stack or duct.

2.3 Span Value. The upper limit of a gas concentration measurement range which is specified for affected source categories in the applicable subpart of the regulations.

2.4 Calibration Gases. A known concentration of a gas in an appropriate diluent gas.

2.5 Calibration Gas Cells or Filters. A device which, when inserted between the transmitter and detector of the analyzer, produces the desired output level on the data recorder.

2.6 Relative Accuracy. The degree of correctness including analytical variations of the gas concentration or emission rate determined by the continuous monitoring system, relative to the value determined by the reference method(s).

2.7 Calibration Error. The difference between the gas concentration indicated by the continuous monitoring system and the known concentration of the calibration gas, gas cell, or filter.

2.8 Zero Drift. The difference in the continuous monitoring system output readings before and after a stated period of operation during which no unscheduled maintenance, repair, or adjustment took place and when the pollutant concentration at the time of the measurements was zero (i.e., zero gas, or zero gas cell or filter).

2.9 Calibration Drift. The difference in the continuous monitoring system output readings before and after a stated period of operation during which no

unscheduled maintenance, repair or adjustment took place and when the pollutant concentration at the time of the measurements was a high-level value (i.e., calibration gas, gas cell or filter).

2.10 Response Time. The amount of time it takes the continuous monitoring system to display on the data recorder 95 percent of a step change in pollutant concentration.

2.11 Conditioning Period. A minimum period of time over which the continuous monitoring system is expected to operate with no unscheduled maintenance, repair, or adjustments prior to initiation of the operational test period.

2.12 Operational Test Period. A minimum period of time over which the continuous monitoring system is expected to operate within the established performance specifications with no unscheduled maintenance, repair or adjustment.

3. Installation Specifications

Install the continuous monitoring system at a location where the pollutant concentration measurements are representative of the total emissions from the affected facility and are representative of the concentration over the cross section. Both requirements can be met as follows:

3.1 Measurement Location. Select an accessible measurement location in the stack or ductwork that is at least 2 equivalent diameters downstream from the nearest control device or other point at which a change in the pollutant concentration may occur and at least 0.5 equivalent diameters upstream from the effluent exhaust. Individual subparts of the regulations may contain additional requirements. For example, for steam generating facilities, the location must be downstream of the air preheater.

3.2 Measurement Points or Paths. There are two alternatives. The tester may choose either (a) to conduct the stratification check procedure given in Section 3.3 to select the point, points, or path of average gas concentration, or (b) to use the options listed below without a stratification check.

Note.—For the purpose of this section, the "centroidal area" is defined as a concentric area that is geometrically similar to the stack cross section and is no greater than 1 percent of the stack cross-sectional area.

3.2.1 SO₂ and NO_x Path Monitoring Systems. The tester may choose to centrally locate the sample interface (path) of the monitoring system on a measurement line that passes through the "centroidal area" of the cross section.

3.2.2 SO₂ and NO_x Multipoint Monitoring Systems. The tester may choose to space 3 measurement points along a measurement line that passes through the "centroidal area" of the stack cross section, at distances of 16.7, 50.0, and 83.3 percent of the way across it (see Figure 2-1).

Figure 2-1. Location of an example measurement line (L) and measurement points.

The following sampling strategies, or equivalent, for measuring the concentrations at the 3 points are acceptable: (a) The use of a 3-probe or a 3-hole single probe arrangement, provided that the sampling rate in each of the 3 probes or holes is maintained within 10 percent of their average rate (This option requires a procedure, subject to the approval of the Administrator, to demonstrate that the proper sampling rate is maintained); or (b) the use of a traversing probe arrangement, provided that a measurement at each point is made at least once every 15 minutes and all 3 points are traversed and sampled for equal lengths of time within 15 minutes.

3.2.3 SO₂ Single-Point and Limited-Path Monitoring Systems. Provided that (a) no "dissimilar" gas streams (i.e., having greater than 10 percent difference in pollutant concentration from the average) are combined upstream of the measurement location, and (b) for steam generating facilities, a CO₂ or O₂ continuous monitor is installed in addition to the SO₂ monitor, according to the guidelines given in Section 3.1 or 3.2 of Performance Specification 3, the tester may choose to monitor SO₂ at a single point or over a limited path. Locate the point in or centrally locate the limited path over the "centroidal area." Any other location within the inner 50 percent of the stack cross-sectional area that has been demonstrated (see Section 3.4) to have a concentration within 5 percent of the concentration at a point within the "centroidal area" may be used.

3.2.4 NO_x Single-Point and Limited-Path Monitoring Systems. For NO_x monitors, the tester may choose the single-point or limited-path option described in Section 3.2.3 only in coal-burning steam generators (does not include oil and gas-fired units) and nitric acid plants, which have no dissimilar gas streams combining upstream of the measurement location.

3.3 Stratification Check Procedure. Unless specifically approved in Section 3.2., conduct a stratification check and select the measurement point, points, or path as follows:

3.3.1 Locate 9 sample points, as shown in Figure 2-2, a or b. The tester may choose to use more than 9 points, provided that the sample points are located in a similar fashion as in Figure 2-2.

3.3.2 Measure at least twice the pollutant and, if applicable (as in the case of steam generators), CO₂ or O₂ concentrations at each of the sample points. Moisture need not be determined for this step. The following methods are acceptable for the measurements: (a) Reference Methods 3 (grab-sample), 6 or 7 of this part; (b) appropriate instrumental methods which give relative responses to the pollutant (i.e., the methods need not be absolutely correct), subject to the approval of the Administrator; or (c) alternative methods subject to the approval of the Administrator. Express all measurements, if applicable, in the units of the applicable standard.

3.3.3 Calculate the mean value and select a point, points, limited-path, or path which gives an equivalent value to the mean. The point or points must be within, and the limited-path or path must pass through, the inner 50 percent of the stack cross-sectional area. All other locations must be approved by the Administrator.

Figure 2-2. Location of 9 sampling points for stratification check.

3.4 Acceptability of Single Point or Limited Path Alternative Location. Any of the applicable measurement methods mentioned in Section 3.3.2, above, may be used. Measure the pollutant and, if applicable, CO₂ or O₂ concentrations at both the centroidal area and the alternative locations. Moisture need not be measured for this test. Collect a 21-minute integrated sample or 3 grab-samples, either at evenly spaced (7 ± 2 min.) intervals over 21 minutes or all within 3 minutes, at each location. Run the comparative tests either concurrently or within 10 minutes of each other. Average the results of the 3 grab-samples.

Repeat the measurements until a minimum of 3 paired measurements spanning a minimum of 1 hour of process operation are obtained. Determine the average pollutant concentrations at the centroidal area and the alternative locations. If applicable, convert the data in terms of the standard for each paired set before taking the average. The alternative sampling location is acceptable if each alternative location value is within ± 10 percent of the corresponding centroidal area value and if the average at the alternative location is within 5 percent of the average of the centroidal area.

4. Performance and Equipment Specifications

The continuous monitoring system performance and equipment specifications are listed in Table 2-1. To be considered acceptable, the continuous monitoring system must demonstrate compliance with these specifications using the test procedures of Section 6.

5. Apparatus

5.1 Continuous Monitoring System. Use any continuous monitoring system of SO₂ or NO_x which is expected to meet the specifications in Table 2-1. For sources which are required to convert the pollutant concentrations to other emission units using diluent gas measurements, the diluent gas continuous monitor, as described in Performance Specification 3 of this Appendix, is considered part of the continuous monitoring system. The data recorder may be an analog strip chart recorder type or other suitable device with an input signal range compatible with the analyzer output.

5.2 Calibration Gases. For continuous monitoring systems that allow the introduction of calibration gases to the analyzer, the calibration gases may be SO₂ in air or N₂, NO in N₂, and NO_x in air or N₂. Two or more calibration gases may be combined in the same gas cylinder, except do not combine the NO and air. For NO_x monitoring systems that oxidize NO to NO₂, the calibration gases must be in the form of NO. Use three calibration gas mixtures as specified below:

5.2.1 High-Level Gas. A gas concentration that is equivalent to 80 to 90 percent of the span value.

Table 2-1.—Continuous Monitoring System Performance and Equipment Specifications

Parameter	Specification
1. Conditioning period *	≥ 168 hours.
2. Operational test period *	≥ 168 hours.
3. Calibration error *	≤ 5 pct of each mid-level and high-level calibration value.
4. Response time.....	≤ 15 minutes (5 minutes for 3-point traversing probe arrangement).
5. Zero drift (2-hour) ^{b,c}	≤ 2 pct of span value.
6. Zero drift (24-hour) ^{b,c}	≤ 2 pct of span value.
7. Calibration drift (2-hour) ^b	≤ 2.5 pct of span value.
8. Calibration drift (24-hour) ^b	≤ 2.5 pct of span value.
9. Relative accuracy *	≤ 20 pct of the mean value of reference method(s) test data in terms of emission standard or 10 percent of the applicable standard, whichever is greater.
10. Calibration gas cells or filters	Must provide a check of all analyzer internal mirrors and lenses and all electronic circuitry including the radiation source and detector assembly which are normally used in sampling and analysis.
11. Data recorder chart resolution.	Chart scales must be readable to within ≤ 0.50 pct of full-scale.
12. Extractive systems with diluent monitors	Must use the same sample interface to sample both the pollutant and diluent gases. Place in series (diluent after pollutant analyzer) or use a "T." During the conditioning and operational test periods, the continuous monitoring system shall not require any corrective maintenance, repair, replacement, or adjustment other than that clearly specified as routine and required in the operation and maintenance manuals. ^b Expressed as the sum of the absolute mean value plus the 95 percent confidence interval of a series of tests divided by a reference value. ^c A low-level (5-15 percent of span value) drift test may be substituted for the zero drift tests.

5.2.2 Mid-Level Gas. A gas concentration that is equivalent to 45 to 55 percent of the span value.

5.2.3 Zero Gas. A gas concentration of less than 0.25 percent of the span value. Ambient air may be used for the zero gas.

5.3 Calibration Gas Cells or Filters. For continuous monitoring systems which use calibration gas cells or filters, use three certified calibration gas cells or filters as specified below:

5.3.1 High-Level Gas Cell or Filter. One that produces an output equivalent to 80 to 90 percent of the span value.

5.3.2 Mid-Level Gas Cell or Filter. One that produces an output equivalent to 45 to 55 percent of the span value.

5.3.3 Zero Gas Cell or Filter. One that produces an output equivalent to zero. Alternatively, an analyzer may produce a zero value check by mechanical means, such as a movable mirror.

5.4 Calibration Gas—Gas Cell or Filter Combination. Combinations of the above may be used.

6. Performance Specification Test Procedures.

6.1 Pretest Preparation.

6.1.1 Calibration Gas Certification.

The tester may select one of the following alternatives: (a) The tester may use calibration gases prepared according to the protocol defined in Citation 10.5, i.e. These gases may be used as received without reference method analysis (obtain a statement from the gas cylinder supplier certifying that the calibration gases have been prepared according to the protocol); or (b) the tester may use calibration gases not prepared according to the protocol. In case (b), he must perform triplicate analyses of each calibration gas (mid-level and high-level, only) within 2 weeks prior to the operational test period using the appropriate reference methods. Acceptable procedures are described in Citations 10.6 and 10.7. Record the results on a data sheet (example is shown in Figure 2-3). Each of the individual analytical results must be within 10 percent (or 15 ppm, whichever is greater) of the average; otherwise, discard the entire set and repeat the triplicate analyses. If the average of the triplicate reference method test results is within 5 percent of the calibration gas manufacturer's tag value, use the tag value; otherwise, conduct at least 3 additional reference method test analyses until the results of 6 individual runs (the 3 original plus 3 additional) agree within 10 percent or 15 ppm, whichever is greater, of the average. Then use this average for the cylinder value.

Figure 2-3. Analysis of Calibration Gases^a

Date _____ (Must be within 2 weeks prior to the operational test period)

Reference Method Used _____

Sample Run	Mid-level ^b ppm	High-level ^c ppm
1		
2		
3		
Average		
Maximum % Deviation ^d		

^a Not necessary if the protocol in Citation 10.5 is used to prepare the gas cylinders.

^b Average must be 45 to 55 percent of span value.

^c Average must be 80 to 90 percent of span value.

^d Must be $\leq +10$ percent of applicable average or 15 ppm, whichever is greater.

6.1.2 Calibration Gas Cell or Filter Certification. Obtain (a) a statement from the manufacturer certifying that the calibration gas cells or filters (zero, mid-level, and high-level) will produce the stated instrument responses for the continuous monitoring system, and (b) a description of the test procedure and equipment used to calibrate the cells or filters. At a minimum, the manufacturer must have calibrated the gas cells or filters against a simulated source of known concentration.

6.2 Conditioning Period. Prepare the monitoring system for operation according to the manufacturer's written instructions. At the outset of the conditioning period, zero and span the system. Use the mid-level calibration gas (or gas cell or filter) to set the span at 50 percent of recorder full-scale. If necessary to determine negative zero drift, offset the scale by 10 percent. (Do not forget to account for this when using the calibration curve.) If a zero offset is not possible or is impractical, a low-level drift may be substituted for the

zero drift, by using a low-level (5 to 15 percent of span value) calibration gas (or gas cell or filter). This low-level calibration gas (or gas cell or filter) need not be certified. Operate the continuous monitoring system for an initial 168-hour period in the manner specified by the manufacturer. Except during times of instrument zero, calibration checks, and system backpurges, the continuous monitoring system shall collect and condition the effluent gas sample (if applicable), analyze the sample for the appropriate gas constituents, and produce a permanent record of the system output. Conduct daily zero and mid-level calibration checks and, when drift exceeds the daily operating limits, make adjustments. The data recorder shall reflect these checks and adjustments. Keep a record of any instrument failure during this time. If the conditioning period is interrupted because of source breakdown (record the dates and times of process shutdown), continue the 168-hour period following resumption of source operation. If the conditioning period is interrupted because of monitor failure, restart the 168-hour conditioning period when the monitor becomes functional.

6.3 Operational Test Period. Operate the continuous monitoring system for an additional 168-hour period. The continuous monitoring system shall monitor the effluent, except during periods when the system calibration and response time are checked or during system backpurges; however, the system shall produce a permanent record of all operations. Record any system failure during this time on the data recorder output sheet.

It is not necessary that the 168-hour operational test period immediately follow the 168-hour conditioning period. During the operational test period, perform the following test procedures:

6.3.1 Calibration Error Determination. Make a total of 15 nonconsecutive zero, mid-level, and high-level measurements (e.g., zero, mid-level, zero, high-level, mid-range, etc.).

This will result in a set of 5 each of zero, mid-level, and high-level measurements. Convert the data output to concentration units, if necessary, and record the results on a data sheet (example is shown in Figure 2-4). Calculate the differences between the reference calibration gas concentrations and the measurement system reading. Then calculate the mean, confidence interval, and calibration errors separately for the mid-level and high-level concentrations using Equations 2-1, 2-2, and 2-3. In Equation 2-3, use each respective calibration gas concentration for R.V.

System Response Time (slower of A and B) = _____ min.

6.3.2 Response Time Test Procedure.

At a minimum, each response time test shall provide a check of the entire sample transport line (if applicable), any sample conditioning equipment (if applicable), the pollutant analyzer, and the data recorder. For in-situ systems, perform the response time check by introducing the calibration gases at the sample interface (if applicable), or by introducing the calibration gas cells or filters at an appropriate location in the pollutant analyzer. For extractive monitors, introduce the calibration gas at the sample probe inlet in the stack or at the point of connection between the rigid sample probe and the sample transport line. If an extractive analyzer is used to monitor the effluent from more than one source, perform the response time test for each sample interface.

To begin the response time test, introduce zero gas (or zero cell or filter) into the continuous monitor. When the system output has stabilized, switch to monitor the stack effluent and wait until a "stable value" has been reached. Record the upscale response time. Then, introduce the high-level calibration gas (or gas cell or filter). Once the system has stabilized at the high-level concentration, switch to monitor the stack effluent and wait until a "stable value" is reached. Record the downscale response time. A "stable value" is equivalent to a change of less than 1 percent of span value for 30 seconds or 5 percent of measured average concentration for 2 minutes. Repeat the entire procedure three times. Record the results of each test on a data sheet (example is shown in Figure 2-5). Determine the means of the upscale and downscale response times using Equation 2-1. Report the slower time as the system response time.

6.3.3 Field Test for Zero Drift and Calibration Drift. Perform the zero and calibration drift tests for each pollutant analyzer and data recorder in the continuous monitoring system.

6.3.3.1 Two-hour Drift. Introduce consecutively zero gas (or zero cell or filter) and high-level calibration gas (or gas cell or filter) at 2-hour intervals until 15 sets (before and after) of data are obtained. Do not make any zero or calibration adjustments during this time unless otherwise prescribed by the manufacturer. Determine and record the amount that the output had drifted from the recorder zero and high-level value on a data sheet (example is shown in Figure 2-6). The 2-hour periods over which the measurements are conducted need not be consecutive, but must not overlap. Calculate the zero and calibration drifts for each set. Then

calculate the mean, confidence interval, and zero and calibration drifts (2-hour) using Equations 2-1, 2-2, and 2-3. In Equation 2-3, use the span value for R.V.

6.3.3.2 Twenty-Four Hour Drift. In addition to the 2-hour drift tests, perform a series of seven 24-hour drift tests as follows: At the beginning of each 24-hour period, calibrate the monitor, using mid-level value. Then introduce the high-level calibration gas (or gas cell or filter) to obtain the initial reference value. At the end of the 24-hour period, introduce consecutively zero gas (or gas cell or filter) and high-level calibration gas (or gas cell or filter); do not make any adjustments at this time. Determine and record the amount of drift from the recorder zero and high-level value on a data sheet (example is shown in Figure 2-7). Calculate the zero and calibration drifts for each set. Then calculate the mean, confidence interval, and zero and calibration drifts (24-hour) using Equations 2-1, 2-2, and 2-3. In Equation 2-3, use the span value for R.V.

Note.—Automatic zero and calibration adjustments made by the monitoring system without operator intervention or initiation are allowable at any time. Manual adjustments, however, are allowable only at 24-hour intervals, unless a shorter time is specified by the manufacturer.

6.4 System Relative Accuracy. Unless otherwise specified in an applicable subpart of the regulations, the reference methods for SO₂, NO_x, diluent (O₂ or CO₂), and moisture are Reference Methods 6, 7, 3, and 4, respectively. Moisture may be determined along with SO₂ using Method 6. See Citation 10.8. Reference Method 4 is necessary only if moisture content is needed to enable comparison between the Reference Method and monitor values. Perform the accuracy test using the following guidelines:

6.4.1 Location of Pollutant Reference Method Sample Points. The following specifies the location of the Reference Method sample points which are on the same cross-sectional plane as the monitor's. However, any cross-sectional plane within 2 equivalent diameter of straight runs may be used, by using the projected image of the monitor on the selected plane in the following criteria.

6.4.1.1 For point monitors, locate the Reference Method sample point no further than 30 cm (or 5 percent of the equivalent diameter of the cross section, whichever is less) from the pollutant monitor sample point.

6.4.1.2 For multipoint monitors, locate each Reference Method sample traverse point no further than 30 cm (or 5 percent of the equivalent diameter of the cross section, whichever is less) from each corresponding pollutant monitor sample point.

6.4.1.3 For limited-path and path monitors, locate 3 sample points on a line parallel to the monitor path and no further than 30 cm (or 5 percent of the equivalent diameter of the cross section, whichever is less) from the centerline of the monitor path. The three points of the Reference Method shall correspond to points in the monitor path at 16.7, 50.0, and 83.3 percent of the effective length of the monitor path.

6.4.2 Location of Diluent and Moisture Reference Method Sample Points.

6.4.2.1 For sources which require diluent monitors in addition to pollutant monitors, locate each of the sample points for the diluent Reference Method measurements within 3 cm of the corresponding pollutant Reference Method sample point as defined in Sections 6.4.1.1, 6.4.1.2, or 6.4.1.3. In addition, locate each pair of diluent and pollutant Reference Method sample points no further than 30 cm (or 5

percent of the equivalent diameter of the cross section, whichever is less) from both the diluent and pollutant continuous monitor sample points or paths.

6.4.2.2 If it is necessary to convert pollutant and/or diluent monitor concentrations to a dry basis for comparison with the Reference data, locate each moisture Reference Method sample point within 3 cm of the corresponding pollutant or diluent Reference Method sample point as defined in Sections 6.4.1.1, 6.4.1.2, 6.4.1.3, or 6.4.2.1.

6.4.3 Number of Reference Method Tests.

6.4.3.1 For NO_x monitors, make a minimum of 27 NO_x Reference Method measurements, divided into 9 sets.

6.4.3.2 For SO₂ monitors, make a minimum of 9 SO₂ Reference Method tests.

6.4.3.3 For diluent monitors, perform one diluent Reference Method test for each SO₂ and/or NO_x Reference Method test(s).

6.4.3.4 For moisture determinations, perform one moisture Reference Method test for each or each set of pollutant(s) and diluent (if applicable) Reference Method tests.

Note.—The tester may choose to perform more than 9 sets of NO_x measurements or more than 9 SO₂ reference method diluent, or moisture tests. If this option is chosen, the tester may, at his discretion, reject up to 3 of the set or test results, so long as the total number of set or test results used to determine the relative accuracy is greater than or equal to 9. Report all data including rejected data.

6.4.4 Sampling Strategy for Reference Method Tests. Schedule the Reference Method tests so that they will not be in progress when zero drift, calibration drift, and response time data are being taken. Within any 1-hour period, conduct the following tests: (a) one set, consisting of 3 individual measurements, of NO_x and/or one SO₂; (b) one diluent, if applicable; and (c) one moisture (if needed). Whenever two or more reference tests (pollutant, diluent, and moisture) are conducted, the tester may choose to run all these reference tests within a 1-hour period. However, it is recommended that the tests be run concurrently or consecutively within a 4-minute interval if two reference tests employ grab sampling techniques. Also whenever an integrated reference test is run together with grab sample reference tests, it is recommended that the integrated sample be started one-sixth the test period before the first grab sample is collected.

In order to properly correlate the continuous monitoring system and

Reference Method data, mark the beginning and end of each Reference Method test period (including the exact time of day) on the pollutant and diluent (if applicable) chart recordings. Use one of the following strategies for the Reference Method tests:

6.4.4.1 Single Point Monitors. For single point sampling, the tester may: (a) take a 21-minute integrated sample (e.g. Method 6, Method 4, or the integrated bag sample technique of Method 3); (b) take 3 grab samples (e.g. Method 7 or the grab sample technique of Method 3), equally spaced at 7-minute (± 2 min) intervals (or one-third the test period); or (c) take 3 grab samples over a 3-minute test period.

6.4.4.2 Multipoint or Path Monitors. For multipoint sampling, the tester may either: (a) make a 21-minute integrated sample traverse, sampling for 7 minutes (± 2 min) (or one-third the test period) at each point; or (b) take grab samples at each traverse point, scheduling the grab samples so that they are an equal interval (7 ± 2 minutes) of time apart (or one-third the test period).

Note.—If the number of sample points is greater than 3, make appropriate adjustments to the individual sampling time intervals. At times NSPS performance test data may be used as part of the data base of the continuous monitoring relative accuracy tests. In these cases, other test periods as specified in the applicable subparts of the regulations may be used.

6.4.5 Correlation of Reference Method and Continuous Monitoring System Data. Correlate the continuous monitoring system data with the Reference Method test data, as to the time and duration of the Reference Method tests. To accomplish this, first determine from the continuous monitoring system chart recordings, the integrated average pollutant and diluent (if applicable) concentration(s) for each Reference Method test period. Be sure to consider system response time. Then, compare each integrated average concentration against the corresponding average concentration obtained by the Reference Method; use the following guidelines to make these comparisons:

6.4.5.1 If the Reference Method is an integrated sampling technique (e.g., Method 6), make a direct comparison of the Reference Method results and the continuous monitoring system integrated average concentration.

6.4.5.2 If the Reference Method is a grab-sampling technique (e.g., Method 7), first average the results from all grab-samples taken during the test period, and then compare this average value against the integrated value obtained from the continuous monitoring system chart recording.

6.5 Data Summary for Relative Accuracy Tests. Summarize the results on a data sheet; example is shown in figure 2-8. Calculate the arithmetic differences between the reference method and the continuous monitoring output sets. Then calculate the mean, confidence interval, and system relative accuracy, using Equation 2-1, 2-2, and 2-3. In Equation 2-3, use the average of the reference method test results for R.V.

7. Equations

7.1 Arithmetic Mean. Calculate the mean of a data set as follows:

$$\bar{x} = \frac{1}{n} \sum_{i=1}^n x_i \quad \text{Equation 1-2}$$

Where:

\bar{x} = arithmetic mean.

n = number of data points.

$\sum x_i$ = algebraic sum of the individual values, x_i .

When the mean of the differences of pairs of data is calculated, be sure to correct the data for moisture.

7.2 Confidence Interval. Calculate the 95 percent confidence interval (two-sided) as follows:

$$C.I._{.95} = \frac{t_{.975}}{n/\sqrt{n-1}} \sqrt{n \sum x_i^2 - (\sum x_i)^2} \quad \text{Equation 1-3}$$

Where:

$C.I._{.95}$ = 95 percent confidence interval estimate of mean value.

$t_{.975} = t_{(1-.05/2)}$ (see Table 2-2)

BILLING CODE 6560-01-M

Table 2-2.— t Values

n^*	.975	n^*	.975	n^*	.975

Figure 2-8. Relative accuracy determination

7.3 Relative Accuracy. Calculate the relative accuracy of a set of data as follows:

$$R.A. = \frac{|\bar{x}| + |C.I. 95|}{R.V.} \times 100 \quad \text{Equation 2-3}$$

- Where: R. A. = relative accuracy
 $|\bar{x}|$ = absolute value of the arithmetic mean
 (from Equation 2-1).
 $|C.I. 95|$ = absolute value of the 95 percent confidence interval (from Equation 2-2).
 R.V. = reference value, as defined in Sections 6.3.1, 6.3.3.1, 6.3.3.2, and 6.5.

8. Reporting

At a minimum (check with regional offices for additional requirements, if any) summarize the following results in tabular form: calibration error for mid-level and high-level concentrations, the slower of the upscale and downscale response times, the 2-hour and 24-hour zero and calibration drifts, and the system relative accuracy. In addition, provide, for the conditioning and operational test periods, a statement to the effect that the continuous monitoring system operated continuously for a minimum of 168 hours each, except during times of instrument zero, calibration checks, system backpurses, and source breakdown, and that no corrective maintenance, repair, replacement, or adjustment other than that clearly specified as routine and required in the operation and maintenance manuals were made. Also include the manufacturer's certification statement (if applicable) for the calibration gas, gas cells, or filters. Include all data sheets and calculations and charts (data outputs), which are necessary to substantiate that the system met the performance specifications.

9. Retest

If the continuous monitoring system operates within the specified performance parameters of Table 2-1, the operational test period will be successfully concluded. If the continuous monitoring system fails to meet any of the specifications, repeat that portion of the testing which is related to the failed specification.

Performance Specification 3— Specifications and Test Procedures for CO₂ and O₂ Continuous Monitors in Stationary Sources

1. Applicability and Principle

1.1 Applicability. This Specification contains (a) installation requirements, (b) instrument performance and equipment specifications, and (c) test procedures and data reduction procedures for evaluating the acceptability of continuous CO₂ and O₂ monitors that are used as diluent monitors. The test procedures are primarily designed for systems that introduce calibration gases directly into the analyzer; other types of monitors (e.g., single-pass monitors, as described in Section 2.2.7 of Performance Specification 2 of this Appendix) will be evaluated on a case-by-case basis upon written request to the Administrator, and alternative procedures will be issued separately.

1.2 Principle. Any CO₂ or O₂ continuous-monitor, which is expected to meet this Specification, is operated for a specified length of time. During this specified time period, the continuous monitor is evaluated to determine conformance with the Specification.

2. Definitions

The definitions are the same as those listed in Section 2 of Performance Specification 2.

3. Installation Specifications

3.1 Measurement Location and Measurement Points or Paths. Select and install the continuous monitor at the same sampling location used for the pollutant monitor(s). Locate the measurement points or paths as shown in Figure 3-1 or 3-2.

3.2 Alternative Measurement Location and Measurement Points or Paths. The diluent monitor may be

installed at a different location from that of the pollutant monitor, provided that the diluent gas concentrations at both locations differ by no more than 5 percent from that of the pollutant monitor location for CO₂ or the quantity, 20.9-percent O₂, for O₂. See Section 3.4 of Performance Specification 2 for the demonstration procedure.

4. Continuous Monitor Performance and Equipment Specifications

The continuous monitor performance and equipment specifications are listed in Table 3-1. To be considered acceptable, the continuous monitor must demonstrate compliance with these specifications, using the test procedures in Section 6.

5. Apparatus

5.1 CO₂ or O₂ Continuous Monitor. Use any continuous monitor, which is expected to meet this Specification. The data recorder may either be an analog strip-chart recorder or other suitable device having an input voltage range compatible with the analyzer output.

5.2 Calibration Gases. Diluent gases shall be air or N₂ for CO₂ mixtures, and shall be N₂ for O₂ mixtures. Use three calibration gases as specified below:

GEOMETRICALLY
SIMILAR
AREA
($<1\%$ OF STACK
CROSS-SECTION)

(a)

GEOMETRICALLY
SIMILAR
AREA
($<1\%$ OF STACK
CROSS-SECTION)

(b)

Figure 3-1. Relative locations of pollutant (P) and diluent (D) measurement points in (a) circular and (b) rectangular ducts. P is located at the centroid of the geometrically similar area. Note: The geometrically similar area need not be concentric.

Figure 3-2. Relative locations of pollutant (P) and diluent (D) measurement paths for (a) circular and (b) rectangular ducts. P is located at the centroid of both the geometrically similar areas and the pollutant monitor path cross-sectional areas. D is located at the centroid of the diluent monitor path cross-sectional area.

Table 3-1.—Performance and Equipment Specifications

Parameter	Specification
1. Conditioning period ^a .	≥ 168 hours.
2. Operational test period ^a .	≥ 168 hours.
3. Calibration error ^b ...	≤ 5 pct. of each (mid-range and high-range, only) calibration gas value.
4. Response time.....	≤ 15 minutes.
5. Zero drift (2-hour) ^b .	≤ 0.4 pct. CO ₂ or O ₂ .
6. Zero drift (24-hour) ^b .	≤ 10.5 pct. CO ₂ or O ₂ .
7. Calibration drift (2-hour) ^b .	≤ 0.4 pct. CO ₂ or O ₂ .
8. Calibration drift (24-hour) ^b .	≤ 0.5 pct. CO ₂ or O ₂ .
9. Data recorder chart resolution.	Chart scales must be readable to within ≤ 0.50 pct. of full-scale.
10. Extractive monitors	Must use the same interface as the pollutant monitor. Place in a series (diluent after pollutant analyzer) or use a "T."

^a During the conditioning and operational test periods, the continuous monitor shall not require any corrective maintenance, repair, replacement, or adjustment other than that clearly specified as routine and required in the operation and maintenance manuals.

^b Expressed as the sum of the absolute mean value plus the 95 percent confidence interval of a series of tests.

^c A low-level (5-15 percent of span value) drift tests may be substituted for the zero drift tests.

5.2.1 High-Level Gas. A CO₂ or O₂ concentration of 20.0 to 22.5 percent. For O₂ analyzers, ambient air (20.9 percent O₂) may be used as the high-range calibration gas; lower high-level O₂ concentration may be used, subject to the approval of the Administrator.

5.2.2 Mid-Level Gas. A CO₂ or O₂ concentration of 11.0 to 14.0 percent; for O₂ analyzers, concentrations in the operational range may be used.

5.2.3 Zero Gas. A CO₂ or O₂ concentration of less than 0.05 percent. For CO₂ monitors, ambient air (0.03 percent CO₂) may be used as the zero gas.

6. Performance Specification Test Procedures.

6.1 Calibration Gas Certification. Follow the procedure as outlined in Section 6.1.2 of Performance Specification 2, except use 0.5 percent CO₂ or O₂ instead of the 15 ppm. Figure 3-3 is provided as an example data sheet.

6.2 Conditioning Period. Follow the same procedure outlined in Section 6.2 of Performance Specification 2.

6.3 Operational Test Period. Follow the same procedures outlined in Section 6.3 of Performance Specification 2, to evaluate the calibration error, response time, and the 2-hour and 24-hour zero and calibration drifts. See example data sheets (Figures 3-4 through 3-7).

6.4 System Relative Accuracy. (Note: The relative accuracy is not determined separately for the diluent monitor, but is determined for the pollutant-diluent system.) Unless otherwise specified in an applicable subpart of the regulations, the Reference Methods for the diluent concentration determination shall be Reference Method 3 for CO₂ or O₂. For this test, Fyrite analyses may be used for CO₂ and O₂ determinations. Perform the measurements using the guidelines below (an example data sheet is shown in Figure 2-8 of Performance Specification 2):

6.4.1 Location of Reference Method 3 Sampling Points. Locate the diluent Reference Method sampling points according to the guidelines given in Section 6.4.2.1 of Performance Specification 2.

6.4.2 Number of Reference Method Tests. Perform one Reference Method 3 test according to the guideline in Performance Specification 2.

6.4.3 Sampling Strategy for Reference Method Tests. Use the basic Reference Method sampling strategy outlined in Section 6.4.4 (and related sub-sections) of Performance Specification 2.

6.4.4 Correlation of Reference Method and Continuous Monitor Data. Use the guidelines given in Section 6.4.5 of Performance Specification 2.

7. Equations, Reporting, Retest, and Bibliography. The procedure and citations are the same as in Sections 7 through 10 of Performance Specification 2.

[FRL 1378-3]

**Standards of Performance for New
Stationary Sources Continuous
Monitoring Performance
Specifications; Extension of Comment
Period**

AGENCY: Environmental Protection
Agency (EPA).

ACTION: Extension of Comment Period.

SUMMARY: The deadline for submittal of comment on the proposed revisions to the continuous monitoring performance specifications, which were proposed on October 10, 1979 (44 FR 58602), is being extended from December 10, 1979, to February 11, 1980.

DATES: Written comments and information must be received on or before February 11, 1980.

ADDRESSES: *Comments.* Written comments and information should be submitted (in duplicate, if possible) to: Central Docket Section (A-130), Attention: Docket Number OAQPS-79-4, U.S. Environmental Protection Agency, 401 M Street, S.W., Washington, D.C. 20460.

Docket. Docket Number OAQPS-79-4, containing material relevant to this rulemaking, is located in the U.S. Environmental Protection Agency Central Docket Section, Room 2903B, 401 M Street, S.W., Washington, D.C. 20460. The docket may be inspected between 8:00 a.m. and 4:00 p.m. on weekdays, and a reasonable fee may be charged for copying.

FOR FURTHER INFORMATION CONTACT: Mr. Don R. Goodwin (MD-13), U.S. Environmental Protection Agency, Research Triangle Park, N.C. 27711; telephone (919) 541-5271.

SUPPLEMENTARY INFORMATION: On October 10, 1979 (44 FR 58602), the Environmental Protection Agency proposed revisions to the Continuous Monitoring Performance Specifications 1, 2, and 3. The notice of proposal requested public comments on the standards by December 10, 1979. Due to delay in the shipping of copies of the performance specifications publication, a sufficient number of copies have been

unavailable for distribution to all interested parties in time to allow their meaningful review and comment by December 10, 1979. An extension of this period is justified as this delay has resulted in about a 5-week delay in processing requests for the document.

Dated: December 12, 1979.

Edward F. Tuerk,

*Acting Assistant Administrator for Air, Noise,
and Radiation.*

January 1980

To holders of Standards of Performance for New Stationary Sources, A Compilation:

This document contains those pages necessary to update the above mentioned publication through January 1, 1980. It is only an update and should be used in conjunction with the original compilation published by the U.S. Environmental Protection Agency, Division of Stationary Source Enforcement in November 1977 (EPA 340/1-77-015) and previous updates published in January 1979 (EPA 340/1-79-001) and July 1979 (EPA 340/1-79-001a) Copies of Standards of Performance for New Stationary Sources, A Compilation and updates may be obtained from:

U.S. Environmental Protection Agency
Office of Administration
General Services Division, MD-35
Research Triangle Park, N.C. 27711

Included in this update, with complete instructions for filing, are: a title page and table of contents; a new Summary Table; all revised and new Standards of Performance; the full text of all revisions and standards promulgated since July 1979; and all proposed standards or revisions.

Any questions, comments, or suggestions regarding this document or the previous compilation should be directed to: Standards Handbooks, Division of Stationary Source Enforcement (EN-341), U.S. Environmental Protection Agency, Washington, D.C., 20460.

INSTRUCTIONS FOR FILING

16. ABSTRACT The Federal regulations for control of air pollution emissions from stationary sources, Standards of Performance for New Stationary Sources (NSPS), are continually being revised and new regulations added. A handbook has been prepared which compiles these regulations as well as the full text of all amendments and proposed amendments. It will be revised and updated periodically through supplements.
