

Shawnee Flue Gas Desulfurization Computer Model Users Manual

**Interagency
Energy/Environment
R&D Program Report**

RESEARCH REPORTING SERIES

Research reports of the Office of Research and Development, U.S. Environmental Protection Agency, have been grouped into nine series. These nine broad categories were established to facilitate further development and application of environmental technology. Elimination of traditional grouping was consciously planned to foster technology transfer and a maximum interface in related fields. The nine series are:

1. Environmental Health Effects Research
2. Environmental Protection Technology
3. Ecological Research
4. Environmental Monitoring
5. Socioeconomic Environmental Studies
6. Scientific and Technical Assessment Reports (STAR)
7. Interagency Energy-Environment Research and Development
8. "Special" Reports
9. Miscellaneous Reports

This report has been assigned to the SPECIAL REPORTS series. This series is reserved for reports which are intended to meet the technical information needs of specifically targeted user groups. Reports in this series include Problem Oriented Reports, Research Application Reports, and Executive Summary Documents. Typical of these reports include state-of-the-art analyses, technology assessments, reports on the results of major research and development efforts, design manuals, and user manuals.

EPA REVIEW NOTICE

This report has been reviewed by the U.S. Environmental Protection Agency, and approved for publication. Approval does not signify that the contents necessarily reflect the views and policy of the Agency, nor does mention of trade names or commercial products constitute endorsement or recommendation for use.

This document is available to the public through the National Technical Information Service, Springfield, Virginia 22161.

DISCLAIMER

This report was prepared by the Tennessee Valley Authority and has been reviewed by the Office of Energy, Minerals, and Industry, U.S. Environmental Protection Agency, and approved for publication. Approval does not signify that the contents necessarily reflect the views and policies of the Tennessee Valley Authority or the U.S. Environmental Protection Agency, nor does mention of trade names or commercial products constitute endorsement or recommendation for use.

ABSTRACT

In conjunction with the U.S. Environmental Protection Agency (EPA)-sponsored Shawnee test program, Bechtel National, Inc., and the Tennessee Valley Authority (TVA) jointly developed a computer model capable of projecting preliminary design and economics for lime- and limestone-scrubbing flue gas desulfurization (FGD) systems. The model is capable of projecting relative economics for spray tower, turbulent contact absorber (TCA), and venturi-spray tower scrubbing options. It may be used to project the effect on system design and economics of variations in required SO_2 removal, scrubber operating parameters [gas velocity, liquid-to-gas (L/G) ratio, alkali stoichiometry, liquor hold time in slurry recirculation tanks], reheat temperature, and scrubber bypass. It may also be used to evaluate alternative waste disposal methods or additives (MgO or adipic acid) on costs for the selected process. Although the model is not intended to project the economics of an individual system to a high degree of accuracy, it allows prospective users to quickly project comparative design and costs for limestone and lime case variations on a common design and cost basis.

The users manual provides a general description of the Shawnee FGD computer model and detailed instructions for its use. It describes and explains the user-supplied input data which are required such as boiler size, coal characteristics, and SO_2 removal requirements. Output includes a material balance, equipment list, and detailed capital investment and annual revenue requirements. The users manual provides information concerning the use of the overall model as well as sample runs to serve as a guide to prospective users in identifying applications. The FORTRAN-based model is maintained by TVA, from whom copies or individual runs are available.

SHAWNEE FLUE GAS DESULFURIZATION COMPUTER MODEL

USERS MANUAL

EXECUTIVE SUMMARY

The Shawnee lime-limestone computer model was developed by Bechtel National, Inc., and the Tennessee Valley Authority (TVA) to model lime-limestone wet-scrubbing flue gas desulfurization (FGD) systems and is capable of projecting comparative investment and revenue requirements for these systems. The computer model has been developed to permit the rapid estimation of relative economics of these systems for variations in process design alternatives (i.e., limestone versus lime scrubbing, alternative scrubber types, or alternative sludge disposal methods), variations in the values of independent design parameters [i.e., scrubber gas velocity and liquid-to-gas (L/G) ratio, alkali stoichiometry, slurry residence time, reheat temperature, and specific sludge disposal design], and the use of additives (MgO or adipic acid). Although the model is not intended to compute the economics of an individual system to a high degree of accuracy, it is based on sufficient detail to allow the quick projection of preliminary conceptual design and costs for various lime-limestone case variations on a common design and cost basis.

PROGRAM DEVELOPMENT

The technical development of the Shawnee lime-limestone computer model is based on actual data obtained at the Shawnee test facility. Bechtel and TVA shared the responsibility of model development. Bechtel was responsible for analyzing the test results and developing the models which calculate the overall material balance flow rates and stream compositions. Bechtel provided these models to TVA. TVA was responsible for determining the size limitations of the required equipment to establish the minimum number of parallel equipment trains, accumulating cost data for the major equipment items, and developing models for projecting equipment and field material costs as a function of equipment capacity. Utilizing these relationships, TVA developed models to project the overall investment cost breakdown and a procedure for using the output of the material balance and investment models as inputs to a previously developed TVA model for projecting annual and lifetime revenue requirements.

The model has been periodically updated to include new or improved data and process developments in FGD. The basic processes in the current model consist of limestone and lime scrubbing; spray tower, turbulent contact absorber (TCA), and venturi-spray tower absorbers; and pond or landfill disposal. Process options include three alternative modes of forced oxidation

and provisions for MgO or adipic acid addition. Several dozen additional input and output options provide further flexibility in the use of the model.

The specific mathematical treatments of material balances, including SO₂ removal efficiencies, are not fully documented in published works. Descriptions of the mathematical treatment of SO₂ removal in spray tower and TCA are given in Shawnee test facility reports (1).

The absorption of SO₂ into scrubbing liquid approximates the mass transfer situation of absorption followed by a chemical reaction, a circumstance for which no comprehensive theoretical basis exists. Such treatment requires mathematical expressions of turbulent fluid behavior and reaction orders that cannot be rigorously defined. Overall mass transfer models are usually based on modifications of general theoretical treatments that differ in concept but mathematically approach similar conclusions in some cases. Standard references (2) and texts (3) provide discussions and access to the literature.

In practice, the mass transfer functions are reduced by a number of simplifying assumptions based on a knowledge of the system and the likely or probable important and unimportant factors. The mathematical expression at once becomes manageable and specific to the situation, to which it can be further correlated empirically. The development of such expressions is discussed in detail by Wen and Fan (4), Rochelle and King (5), Chang and Rochelle (6), and Wen and others (7), for specific FGD applications.

The Shawnee model expression is simplified by the assumptions that liquid-side resistance controls the absorption rate and that liquid-phase reactions are not limiting (that is, dissolved SO₂ does not significantly affect the absorption rate). Both of these assumptions are supported by experimental results (1).

$$SO_2 = 1 - \exp \left[- \phi \frac{K_L^0 a z}{Hv} \right]$$

The simplified expression for the fraction of SO₂ removed contains an enhancement factor, ϕ , to represent the effects of chemical reaction and a group (consisting of a liquid-side mass transfer coefficient, K_L^0 ; interfacial area, a ; vertical distance, z ; Henry's law constant, H ; and gas velocity, v) to represent physical absorption. The enhancement factor contains expressions for pH, effective magnesium, flue gas, SO₂ content, and in some cases, chloride concentration. The expression is fitted to Shawnee test facility data for each particular absorber and absorbent combination using eight coefficients. The fitted expressions have standard errors of estimate of about 4%. Pressure drop expressions for the three absorbers were developed by fitting expressions containing pertinent variables to Shawnee test facility data. The development of these expressions is discussed in the Shawnee test facility reports and symposium proceedings cited.

MODEL CAPABILITY

The Shawnee lime-limestone scrubbing model is capable of projecting a complete conceptual design package for these systems utilizing a spray tower, TCA, or venturi-spray tower absorber, each with or without use of additives; and with any of five sludge disposal options, including options with and without forced oxidation. Flow diagrams illustrating these process alternatives are shown in Appendix A. Ranges for basic design parameters are shown below.

Plant size	100-1,300 MW
Coal sulfur	2%-5% (1,500-4,000 ppm SO ₂)
Scrubber gas velocity	8-12.5 ft/sec
Liquor recirculation rate	25-120 gal/aft ³ (at scrubber outlet)
Slurry residence time	2-25 min
Scrubber slurry solids	5%-15%
Reheat (steam)	225°F maximum reheat temperature

Results for conditions outside these design ranges are not necessarily invalid but are subject to potential reduced accuracies.

The output of the model includes projections of annual and lifetime revenue requirements to allow comparison of the economics of the alternative system designs. The basis for these projections is described in the report appendices.

The process technology is divided into seven major areas to facilitate projection of the process design and the estimated capital investment. The facilities included in each area are identified in the process description along with the basis for design of the FGD system.

PROCESS DESCRIPTION

Processing Areas

The seven major processing areas used to define the limestone- and lime-scrubbing systems are identified below along with a description of the facilities included within the battery limits of each processing area, and the basis for design of these facilities.

Raw Material Handling--

This area provides for receiving either limestone or lime. For the limestone slurry process, the raw material-handling area includes equipment for receiving limestone by truck or rail, a storage stockpile, and live in-process limestone storage equipment.

For the lime slurry process, the raw material-handling area includes equipment for receiving lime by truck or rail and a storage silo.

The direct investment costs for the raw material-handling area includes costs for all of the lime-limestone receiving equipment and field construction materials up to and including the raw material feed bin.

Raw Material Preparation--

This area provides for preparation of a limestone or lime slurry for feed to the SO₂ scrubbing area. The raw material preparation area for the limestone slurry process includes gyratory crushers for crushing the limestone for feed to the wet ball mills. The wet ball mills grind the limestone to the desired size for feed to the scrubbers. The product slurry from the mills at a concentration of 60% solids is pumped to a slurry feed tank adjacent to the scrubbing area for distribution to the scrubbers.

The raw material preparation area for the lime slurry process includes equipment for slaking the lime at a concentration of 20% to 25% solids for feed to the scrubbers. The product slurry from each of the slakers overflows to a slurry receiving tank from which it is pumped to a common slurry feed tank. The slurry is then pumped to the scrubbing area for distribution to the scrubbers.

The direct investment costs for the feed preparation area include all preparation equipment and field construction materials from the raw material bin weigh feeder to the slurry feed tanks.

Gas Handling--

Flue gas from the power unit ducts is fed to a common plenum from which any number of scrubber trains can be fed. To minimize the problems associated with gas distribution for such a system, separate fans are included on each side of the plenum. The power plant fans are conventional induced-draft (ID) fans for balanced-draft boilers. The scrubber fans can be specified as forced-draft (FD) or ID and are designed to overcome the pressure drop of the pollution control facilities.

The direct investment costs for the gas-handling area include costs for the flue gas equipment and field materials downstream of the air heater up to, but excluding, the stack plenum. Costs for the scrubber fans are included; however, costs for the power plant fan, the stack plenum, and the stack are considered to be an integral part of the power plant and are, therefore, not included in the estimate.

SO₂ Scrubbing--

Flue gas is contacted with a lime or limestone slurry in either a spray tower, TCA, or venturi-spray tower. The absorbers are equipped with a chevron-vane mist elimination system designed for upstream and downstream wash with fresh makeup water. Makeup lime or limestone slurry from the slurry feed tank and recycled supernate or filtrate from the waste disposal area are fed to the absorber hold tanks where they are blended with the slurry draining from the absorber. The slurry recirculation loop can be designed for use of either one or two hold tanks below the absorber. For the 2-tank option, if forced oxidation is specified, air is injected into the tank which receives the effluent from the scrubber. Scrubber slurry is bled from this tank for

disposal. Overflow from this tank flows by gravity to the second tank where fresh limestone slurry is added. The combined slurry is then recirculated to the absorber and either the presaturator or venturi, depending on the process selected. The bleedstream is pumped to the waste disposal area where the sludge is dewatered. The supernate or filtrate is returned to the scrubbing and raw material preparation areas. The SO₂ scrubbing area can be designed without the use of additives or with the use of either (1) MgO or (2) adipic acid to enhance SO₂ removal.

The SO₂ removal model can be run with any of the following four options for relating stoichiometry, L/G ratio in the absorber, and SO₂ removal efficiency:

Option	Input	Calculate
1	Stoichiometry, L/G	SO ₂ removal
2	Stoichiometry, SO ₂ removal	L/G
3	L/G, SO ₂ removal	Stoichiometry
4	Stoichiometry, L/G, and SO ₂ removal	Force-through alternative, no calculation

Direct investment costs for the SO₂ absorption area include all slurry and SO₂ absorption equipment and field construction materials between the slurry feed tank and the waste disposal feed tank. Costs for a mechanical collector may be included optionally.

Oxidation--

This area is an optional area which provides for oxidation of the SO₂ absorbed as calcium sulfite to calcium sulfate to facilitate subsequent dewatering and disposal of the FGD wastes. If the forced-oxidation option is not specified, the model results are based on only natural oxidation occurring in the scrubbing loop with about 5%-20% of the absorbed SO₂ being in the oxidized (calcium sulfate) form. Two forced-oxidation alternatives are available: (1) within-loop forced oxidation in which air is sparged into the absorber hold tank and scrubber slurry is recirculated to the absorber and (2) bleedstream forced oxidation in which a bleedstream from the absorber is sparged with air in a separate tank with the bleedstream subsequently processed for disposal. In both oxidation alternatives, equipment, primarily compressors and air spargers for option (1) and compressors, air spargers, tanks, agitators, and pumps for option (2), are provided.

Direct investment costs for the oxidation area, when selected, include costs for the equipment and associated field construction materials.

Reheat--

The outlet gas from the scrubber is reheated to the desired temperature by either (1) indirect steam reheat, (2) blending scrubber outlet gas with hot flue gas which bypasses the scrubber (only available if overall SO₂ removal efficiency is less than 90%), or (3) a combination of (1) and (2). The reheater gas is discharged to the stack plenum.

Direct investment costs for the reheat area include costs for the reheater equipment and field construction materials for installation.

Waste Disposal--

The model has provisions for the following five alternate waste disposal options:

1. Onsite pond
 - a. Unlined pond
 - b. Clay-lined pond (cost and depth of clay lining is input)
 - c. Synthetic-lined pond (cost of liner is input)
2. Thickener - pond
3. Thickener - fixation fee
4. Thickener - filter - fixation fee
5. Thickener - filter - landfill

The onsite ponding options may also be run with fixation fees applied to them. For alternatives 3 and 4, the fixation fee must include costs for transportation and disposal of the fixed sludge offsite. For alternatives 1 and 2, however, only the costs for fixation need to be provided since the fixed sludge can be disposed of at the existing pond site. For alternative 5, a landfill-fixation option may be provided using model calculations. Using this option, the disposal facility is appropriately sized for the additional fixation volume requirements.

For the waste disposal alternatives, the model allows for the onsite facility to be sized larger or smaller than the normal projected lifetime capacity. This option has been incorporated (1) to account for variations in the sulfur content of fuel, (2) to evaluate design philosophy in construction of ponds or landfills for less than the total amount of sludge to be disposed (this requires assessment of additional costs for enlarging the waste disposal area later), or (3) to allow the feed preparation and scrubbing areas to be sized based on maximum sulfur contents expected while sizing the waste disposal area based on average sulfur contents.

Direct investment costs for the waste disposal area include costs for the equipment and field construction materials downstream of the waste disposal feed tank including those associated with the supernate return pumps and piping.

Process Equipment Design Basis

Based on results from the material balance model and some user-supplied variables, major process equipment is specified by area. The equations for

predicting equipment costs were updated in 1983. The design assumptions used as a basis for projecting the size or specifications of the major process equipment are given below for each major equipment item included in the alternative FGD options.

Gyratory Crushers--

Two parallel 50% capacity gyratory-type crushers are utilized to reduce the inlet stone size from minus 1-1/2 inches to minus 3/4 inch for feed to the ball mills.

Ball Mills--

The grinding mills are rubber-lined, open-circuit, overflow wet ball mills that have a 30% ball charge and produce a 60% slurry. The number of ball mills is determined by total mill horsepower calculated from the limestone throughput rate specified in the material balance, and the fineness of grind and limestone hardness factors which are program inputs. The fineness of grind index factor is related to the desired particle size distribution of the ground limestone. One-mill systems are used for horsepower less than 200 and two parallel mill systems for horsepower between 200 and 5,000. For horsepower greater than 5,000, the number of parallel mill systems is determined assuming a maximum mill size of 2,500 horsepower.

Lime Storage Silo--

A 30-day dead storage capacity is used to calculate the volume of the lime storage silos. The silos are concrete, with the height of the actual storage section of the silo assumed to be one and a half times the diameter. Total height of the silo is equal to the height of the actual storage section plus the height of the carbon steel hopper plus 5 feet. Parallel storage silos are used for storage volumes greater than the capacity of the largest silo (147,200 ft³).

Lime Slaker--

Lime is slaked at slurry concentrations of 20% to 25% solids in dual-compartment, overflow slakers which can be designed with slaking capacities of up to 33 ton/day. Parallel slaking trains are used for larger lime capacities. The number and size of parallel slakers required are determined based on the capacity of the largest size slaker available (33 ton/day).

Fans--

The fans are centrifugal (double width, double inlet) with radial impellers. The FD fans are constructed of carbon steel and the ID fans are constructed of Inconel 625. They are equipped with variable-speed fluid drives. Fan horsepower is calculated based on the inlet gas flow rate per train and the calculated pressure drop for the scrubber, mist eliminator, reheater, and duct.

Scrubbing Trains--

The following procedures are utilized for determining the size or specifications of the major process equipment in the scrubbing area. The number of parallel scrubbing trains is either an input to the program or is established as an override to the input value based on the minimum number of scrubber

trains required. The minimum number of trains is calculated considering the saturated flue gas velocity and volumetric flow rate at the scrubber outlet in conjunction with the maximum cross-sectional area assumed for the scrubber (1,370 ft²). Flue gas and slurry recirculation rates per train are calculated by dividing the total flow rates from the overall material balance model by the number of operating scrubbing trains.

Scrubbers--

Scrubber cross-sectional area is calculated considering the outlet flue gas rate per train in conjunction with the specified scrubber design gas velocity. Number of scrubber grids, beds, and height of spheres per bed are inputs to the program. The height of the scrubber is assumed to remain constant for all scrubber sizes and internal configurations. A presaturator compartment is included at the scrubber inlet for the TCA and spray tower, and chevron-type mist eliminators are included near the outlet. Materials of construction for the scrubbers and internals are listed below.

Venturi: Carbon steel with acid-resistant lining

Shell: Rubber-lined carbon steel

Grids: Type 316L stainless steel

Spheres: 1-1/2-inch-diameter, Nitrile foam

Mist eliminator, slurry header, and nozzles: Type 316L stainless steel

Tanks--

The size or specifications of tanks, agitators, and pumps for each of the areas are determined by utilizing the following procedures. Tank volume is calculated based on the residence time, which is either a program input or assumed. An additional 10% volume is added for freeboard. All tanks are constructed of carbon steel and the slurry tanks are flake glass lined. Except for the absorber bleed receiving tanks and the thickener overflow tanks, each tank is designed with diameter equal to height up to a maximum height of 60 feet. For tanks larger than 60 feet in diameter, tank height is fixed at 60 feet and diameter is calculated. Absorber bleed receiving tank height is equal to the effluent hold tank height and the diameter is calculated. Thickener overflow tank height is set equal to the height of the thickener and the diameter is calculated. As an override to the calculated diameter, a minimum diameter equal to one-half the height is fixed for all tanks. The thickener and filter feed tanks are not used unless more than one thickener or filter is required.

Agitators--

All slurry tanks are equipped with a 4-blade, pitched-blade, turbine agitator. Agitator horsepower requirements are calculated on the basis of total torque, which is a function of the degree of agitation required (expressed as torque/unit volume), total tank volume, tank diameter, and the

slurry specific gravity. Unit torque (torque/unit volume) for each tank is determined as a function of the percent solids in the slurry.

Slurry Pumps--

All slurry pumps are rubber lined, centrifugal with water seals, and are equipped with either a variable- or constant-speed drive. Pumps are usually spared, with the number of operating pumps determined by the maximum available pump size of 20,000 gpm.

Water Pumps--

Vertical, multiple-stage, turbine makeup water pumps capable of providing a static head of 200 feet are provided for each 10,000 gpm of water required. The pumps are carbon steel and spared.

Compressors--

The compressors are sized to provide sufficient air (oxygen) for oxidizing the $\text{CaSO}_3 \cdot 1/2\text{H}_2\text{O}$ to $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$. The stoichiometric quantity of SO_2 absorbed is multiplied by an input stoichiometry, usually 2.5, to determine the stoichiometric quantity of oxygen to be added. The quantity of air is then determined for sizing the compressors.

Reheaters--

Reheater cross-sectional area is calculated based on the superficial gas velocity (usually 20 to 25 ft/sec) which is input to the program and the volumetric gas flow rate per train at scrubber outlet conditions. Reheater surface area requirements are calculated in two steps: (1) surface area requirements for reheat to 150°F and (2) requirements for reheat to the specified reheat temperature. The portion of the reheater tubes required to reheat to 150°F are Inconel and the remaining tubes are Cor-Ten. Reheater design and costs are based on use of 1-inch tubes on a 2-inch square pitch.

Thickeners--

The thickeners are constructed of carbon steel tank walls coated with epoxy paint and 1-foot-thick concrete conical basins. Thickeners are equipped with rake mechanisms. A concrete underflow tunnel, including pumps and piping for transferring the slurry, is included. Total thickener cross-sectional area is calculated by the material balance portion of the model as a function of the settling rate and settled solids density, which are inputs into the program, and the quantity of sludge in the effluent slurry calculated in the material balance model. The number of thickeners required is determined assuming a maximum thickener diameter of 400 feet. Thickener height is calculated as a function of the diameter.

Filters--

Rotary drum vacuum filters constructed of carbon steel and equipped with a vacuum pump, a filtrate pump, and a vacuum receiver are utilized. Filter size is determined as a function of the filtration rate expressed in tons of dry solids/ft²/day, which is a program input, in conjunction with the total quantity of sludge. The minimum and maximum sizes of filters considered have effective filtration areas of 50 and 900 ft², respectively. Single filters are used up to required filtration areas of 100 ft². For total filtration

areas between 100 and 1,800 ft², two parallel filters are assumed. For total filtration areas greater than 1,800 ft², the number and size of parallel filters required are determined based on the capacity of the largest filter size.

Field Construction Materials Design Basis

Costs for field construction materials are based on the materials of construction or specifications discussed below.

Piping--

Carbon steel pipe and gate valves are used for all waterlines including pond supernate. For slurry lines less than 3-inch diameter, stainless steel pipe is used; whereas, for all larger size lines, rubber-lined carbon steel piping is used. Stainless steel strainers are used for pipes less than 4-inch diameter and rubber-lined strainers are used for 4-inch-diameter and larger pipes. For slurry lines less than 3-inch diameter, stainless steel plug valves are used. Eccentric plug valves are used for slurry lines between 3- and 20-inch diameter, and knife gate valves are used for lines greater than 20-inch diameter. Handwheel operators are used for valves less than 12-inch diameter and air cylinder actuators for larger valves. Typical piping layouts are assumed as functions of flow capacities and the number of trains and costs are correlated to flow rates in gal/min. Control valve costs are included in instrumentation. Costs are included for a rubber-lined downcomer from the scrubber to the effluent hold tank and a spare slurry disposal line to the disposal site.

Ductwork--

Costs are included for the inlet plenum and all ductwork between the inlet and stack plenums including insulation. Costs for the stack plenum are not included since this plenum is required even if an FGD system is not installed. Stack plenum elevation is set equal to effluent hold tank height with a minimum elevation of 20 feet for small hold tanks. Each scrubber train includes two guillotine dampers and costs for expansion joints.

Two partial scrubbing or emergency bypass ducts, each designed for a minimum of 25% of the total gas flow rate from the boiler, are included in the costs. Each duct includes two louver-type dampers and costs for expansion joints.

Materials of construction for all ductwork is 3/16-inch Cor-Ten with the exception of ductwork between the scrubber and reheater outlet which is 3/16-inch type 316 stainless steel. All ductwork is insulated with 2-inch rock wool. Duct size is based on a square cross section and a nominal design velocity of 3,000 ft/min at local inlet conditions.

Foundations--

Concrete foundations for each equipment item are fixed according to equipment sizes. Foundations for the structure are estimated on the basis of the weight of the structure.

Structures--

Structural estimates are based on the structure arrangement shown in the body of the report. The total quantity of structure required for each scrubber train and the corresponding costs are related to effluent hold tank volume, scrubber cross-sectional area, and number of scrubbing trains.

Electrical--

The electrical estimate is divided into four sections: (1) costs of feeder cables from the power plant transformer yard to field modules for each area; (2) transformer costs for each area; (3) costs of power supply from area field modules to individual motors; and (4) motor control costs between remote control center, field module location, and individual motors for each area. For each area, total connected motor horsepower is calculated for use in establishing costs for (1) and (2). Costs for (3) and (4) are based on individual motor sizes and number of connected motors. A typical layout is assumed for each area in reference to the power plant transformer yard, remote control center, and other areas.

Instrumentation--

Instrumentation costs are based on (1) fixed costs for instruments which do not change in size and cost with equipment and pipe size variations and (2) variable costs for instruments which increase in size and cost as equipment and pipe sizes increase. Each of these costs may be dependent upon number of scrubbing trains, number of ball mills, number of pumps, etc. Costs are included for control valves, graphic boards and panelboards, annunciator, air dryers and piping, and instrument cable and wiring systems.

Buildings--

The control room and motor control center are integrated with the power plant and prorated costs are included. Costs are included for a building to house the limestone-grinding or lime slaking facilities. Buildings to house the oxidation and/or disposal area equipment are included as appropriate. All buildings are sized as a function of the equipment size and number of equipment items and are constructed with concrete floors and corrugated aluminum siding, supported by a steel frame. They are insulated to a value of R-19 using fiberglass insulation.

Pond Construction--

Disposal pond size is calculated based on a square configuration with a diverter dike three-fourths the length of one side. A pond construction diagram is shown in Appendix B. The pond model is based on either unlined, clay-lined, or synthetic-lined design and includes the following options in running the program:

Fixed-depth pond

Optimum-depth pond based on minimum pond investment

Optimum-depth pond based on minimum pond investment with available acreage and maximum excavation depth as overriding constraints

In addition to specifying pond design, the model also itemizes the breakdown of projected pond costs.

Landfill Construction--

Disposal landfill size is calculated based on a square configuration with the cap sloping up to a point. A landfill construction diagram is shown in Appendix B.

A separate model is included to design and cost the onsite landfill. The landfill model is based on either unlined, clay-lined, or synthetic-lined design.

MODEL USAGE

The Shawnee model can be of use to utility companies or architectural and engineering firms involved in the selection and design of SO₂ removal facilities. The model also has potential for use by environmental groups or regulatory agencies. Although it is not intended to be used for projecting a final design, it can be used to assist in the evaluation of system alternatives prior to a detailed design. It should also be useful for evaluating the potential impact of various process variables on economics as a guide for planning.

Although the model was not meant to be used for comparing projected lime-limestone economics with economics for alternate processes, these comparisons should be valid as long as the bases for the alternate process economics are comparable to those included in the computer model for lime and limestone systems.

The body of this report contains information required to run the overall computer model.

SHAWNEE FLUE GAS DESULFURIZATION COMPUTER MODEL

USERS MANUAL

INTRODUCTION

The Shawnee flue gas desulfurization (FGD) computer model projects the major design and operating conditions and the detailed economics of various lime and limestone FGD process alternatives for coal-fired utility boilers from user-supplied input data. Development of the model was sponsored by the U.S. Environmental Protection Agency (EPA). The model is maintained by the Tennessee Valley Authority (TVA), from whom the complete model or individual runs are available. This manual provides a general description of the model and its uses. It includes additions and revisions to the model that have been made since publication of the previous users manual in 1981.

The model is general in nature and is capable of projecting conceptual designs and economics for a range of power plant and FGD conditions. The results are similar to those of preliminary conceptual design evaluations in which absolute accuracies are about -15% to +30% and comparative accuracies are about -10% to +10%. The model is most useful for projecting preliminary comparisons of FGD alternatives (type of absorbent, absorber design, and operating conditions, for example) and evaluation of the effects of design criteria [gas velocity, liquid-to-gas (L/G) ratio, SO₂ removal efficiency, and stoichiometry, for example]. As such, it is most useful in preliminary studies and screenings leading to detailed design studies and in planning research and development activities.

GENERAL INFORMATION

BACKGROUND

From 1968 to 1980, EPA sponsored the development of lime and limestone FGD technology at a test facility located at TVA's Shawnee Steam Plant near Paducah, Kentucky. TVA was the constructor and operator of the facility and Bechtel National, Inc., was the primary contractor. The test facility consisted of three prototype FGD systems, each with a capacity of 30,000 aft^3/min of flue gas (equivalent to 10 MW of generating capacity). One system had a venturi-spray tower absorber and one had a mobile-bed absorber [Turbulent Contact Absorber (TCA)]. The third system originally had a marble-bed absorber that was operated only briefly and eventually converted to a cocurrent absorber system.

Most of the test work involved operation of venturi, spray tower, venturi-spray tower, and TCA absorbers. Initially, an extensive series of lime and limestone FGD tests was made over a wide range of conditions. In 1976, forced-oxidation tests were begun and the use of magnesium oxide (MgO) to enhance SO_2 removal efficiency was investigated. In 1979 and 1980, an equally extensive series of tests using adipic acid to enhance SO_2 removal efficiency was made. In all, over a decade of almost continuous assessment and development of lime and limestone FGD technology was conducted, resulting in a very large and comprehensive body of information.

The main phase of the testing at Shawnee was conducted from 1974 through 1978 as the "Advanced Test Program," which has been reported in detail by Bechtel (1). The adipic acid tests were conducted after this period (8). Formal support of the test program by EPA ended in 1980. The facility is still operated by TVA for various FGD evaluations, but the results of most of these tests are not directly applicable to development of the Shawnee model.

The data developed during the tests sponsored by EPA were used to develop a computer model to project conceptual designs and economics for lime and limestone FGD processes. Bechtel developed computer procedures to project material balances, flow rates, and stream compositions. TVA developed computer procedures to project the economics of the processes. These were based on premises and procedures developed by TVA, EPA, and others for the evaluation of FGD economics. All of the computer procedures were combined into an overall model composed of two computer programs. One program projects the major equipment requirements and costs and the total capital investment. The second program projects the annual revenue requirements.

Since 1974, when development of the model began, the model has been periodically updated to reflect current technology and economic conditions. In 1979 and again in 1981 (9), users manuals were published for the model as it existed then. Since that time, further revisions and additions have been made. The major revisions consist of a refinement and expansion of the forced-oxidation and adipic acid options, inclusion of a waste fixation option and a landfill disposal option, and revision of the equipment and installation cost models to reflect base costs obtained in 1983.

DOCUMENTATION

This manual provides the information and procedures necessary to use the model but it does not describe the concepts and mathematics upon which it is based. No fully comprehensive description of this basis has been published because of the frequent revisions and additions that have been made during the course of its development. The original chemical equilibrium model which was developed by the Radian Corporation has been discussed (10), as have earlier versions of the model (11). The Advanced Test Program reports by Bechtel (1) discuss many aspects of the design and performance of the conceptual designs used. Process flowsheets and layout drawings are included in Appendix A for the alternative process and waste disposal options which are available in the model. The design and economic premises in Appendix B provide additional detail on the design basis and the economic calculations. Economic studies by TVA (12), based in whole or part on the Shawnee computer model, discuss design and economic aspects and provide examples of the economic evaluations and comparisons.

SCOPE OF THE MODEL

There are three absorber options: spray tower, TCA, and venturi, each of which can be used alone or as venturi-spray tower or venturi-TCA combinations with either limestone or lime absorbent. Forced oxidation in various configurations can be used with most of the absorber options. Adipic acid or MgO additive options are also available with most absorber configurations. Numerous design and operating condition options are available. Waste disposal options include ponding, landfill, and fixation and landfill.

The equipment size and layout configurations are based on power units between 100 MW and 1,300 MW in size and coal sulfur contents of 1% to 5%. The ranges of other critical variables are:

Absorber gas velocity	8-12.5 ft/sec
Absorbent liquid recirculation rate	25-120 gal/kaft ³
Hold tank residence time	2-25 minutes
Number of absorber trains	1-10
Flue gas SO ₂ concentration	600-4,000 ppm

The validity of results for conditions outside these ranges has not been determined. Results for intermediate-sized plants outside these ranges may be valid, however.

Several model runs may be required to fully analyze the combined effects of individual input conditions, especially if the ranges specified above are exceeded. The effects of variations in inputs (such as absorber gas velocity, L/G ratio, absorbent stoichiometry, SO₂ removal efficiency, and reheat temperature) can be assessed individually or the cumulative effect can be assessed by varying several conditions simultaneously.

AVAILABILITY

The model is available to the public through TVA under an information exchange agreement between EPA and TVA. Upon receipt of a written request, TVA provides a copy of the model suitable for loading onto an IBM-370-compatible computer system, along with FORTRAN program listings and the documentation required to execute the model. Under the same information exchange agreement, TVA will make model runs based on user-supplied input data. This allows users to analyze the capabilities of the model with a minimum amount of investigation and investment.

The model is based on the requirements and specifications of the G1 compiler and FORTRAN66 language. The model is executed in FORTRAN66 on the VS FORTRAN compiler using the FORTRAN66 option. It cannot be used with systems based exclusively on FORTRAN77 or VS FORTRAN.

Model options and input variables are added and modified on a regular basis. The latest version is usually supplied to users and is typically the basis for user runs made by TVA. Model and documentation availability is subject to limitations based on available funding and the costs that must be incurred in connection with a user request.

A detailed list of all of the model inputs is included in Tables C-1 and C-2 of Appendix C. These tables include a number of options for selecting process design and controlling model output. Types of options are listed below:

	<u>Variable</u>	<u>Line</u>	<u>Page</u>
● Print	-	1-3	9
● Particulate collection device removal	XESP	5	9
● Reheat	XRH	5	13
● Bypass and partial scrubbing	KEPASS, KPASO2	5	13-14
● Coal cleaning	KCLEAN	5	14

	<u>Variable</u>	<u>Line</u>	<u>Page</u>
• Input composition	INPOPT	6	17
• Particulate removal	IASH	6	18
• SO ₂ removal	IS02	7	20
• Operating parameter calculation	ISR	7	22
• Scrubbing absorbent (lime or limestone)	XIALK	7	24
• Chemical additive	IADD	7	24
• Forced oxidation	IFOX	8	29
• Fan	IFAN	8	34
• Absorber	ISCRUB	9	34
• Redundancy	NSPREP,NORED	9	37
• Waste disposal	ISLUDG	10	37
• Fixation	IFIXS	10	42,64
• Pond design	PSMAX,DISTPD	10	42

• Overtime	IOTIME	12	56
• Pond capacity	PNDCAP	14	62
• Operating profile	IOPSCH	14	66

Requests for copies of the computer model, model runs to be made by TVA, or additional information should be made to the authors at the following address: Division of Energy Demonstrations and Technology (ED&T), Tennessee Valley Authority, Muscle Shoals, Alabama 35660, telephone number (205) 386-2814 or (205) 386-2514.

MODEL DESCRIPTION

INPUT

The model requires a minimum of 15 lines of input. Free-form format is specified and blank spaces are required between variables except for the CASEID (line 4) and the END or NEXT variable (last line of data set) which are alpha-numeric format. Individual values may be specified to the desired precision provided the total characters, including separators, do not exceed 72 per line. Additional input is required when a user-specified operating profile is chosen instead of the built-in profiles. A detailed FORTRAN variable list of the model input is shown in Table C-1 of Appendix C. The variables are defined in Table C-2 of Appendix C. Ranges for key variables to aid in establishing input data to the model are shown in Table 1.

TABLE 1. VARIABLE RANGES

Item	Description
Power plant	New, 100-1,300 MW
Fuel sulfur content	1%-5%
Fuel SO ₂ content	1.7-9.0 <u>lb SO₂</u> MBtu
Absorber gas velocity	8-12.5 ft/sec
Absorbent recirculation rate	25-120 gal/kft ³
Hold tank residence time	2-25 minutes
Number of scrubbing trains	1-10
Number of spare scrubbing trains	0-10
SO ₂ removal efficiency	1%-100%
Fly ash removal efficiency	1%-99.9%
TCA pressure drop	≤3 in. H ₂ O/stage
Capital investment cost year	Midpoint of construction
Annual revenue requirement cost year	First year of operation

Note: The variable ranges were established for model development purposes. Values beyond these ranges are not necessarily invalid but the potential for error is greater when these ranges are exceeded.

As new options are incorporated, the required inputs are subject to change. When this occurs, the list of variables and the associated definitions will be updated and made available as necessary.

OUTPUT

The outputs of the Shawnee lime-limestone computer model provide a complete conceptual design package for lime or limestone scrubbing. They consist of: (1) a detailed material balance, including properties of the major streams; (2) a detailed water balance itemizing water availability and water required; (3) specifications of the scrubbing system design; (4) a display of overall pond or landfill design and costs; (5) specifications and costs of the process equipment by major processing area; (6) a detailed breakdown of the capital investment; (7) an itemized breakdown of the revenue requirements for the first year of operation of the system; (8) a lifetime revenue requirement analysis showing projected costs for each year of operation, as well as lifetime cumulative and discounted costs and equivalent unit revenue requirements; and (9) a particulate removal cost table which lists operating conditions and itemizes capital investment and annual revenue requirements for a cold-side electrostatic precipitator (ESP), a hot-side ESP, a baghouse, or a particulate scrubber. However, upstream particulate removal is independent of the FGD process and costs are not included in the FGD economic projections. These outputs are illustrated in the base case printout shown in Appendix D.

In addition to the outputs listed above, a diagnostic message file is generated each time the model is executed. This file contains informative messages related to processing such as data case number and title, possible conflicts between options, variable values that may be out of range, and fatal conditions that terminate model execution. In typical model runs made by TVA, the message file is listed between the printed output from the capital investment program and the printed output from the annual revenue requirements program, but this depends on the control language procedures used for execution. An example message file is shown in the base case printout in Appendix D.

OPTIONS

A detailed list of all of the model inputs is included in Tables C-1 and C-2 of Appendix C. These tables include a number of options for selecting process design and controlling model output. Some examples of the options are shown on the pages that follow. For illustration purposes, the appropriate input data line is shown and the particular option code is indicated. An explanation of each option and sample output resulting from its use is provided where necessary. Unless a value of zero is required, nonzero values for all variables must be entered for each case even though a variable value is being calculated by the model as a result of a user-specified option. In this case, the calculated value will override the input value. A value of zero may result in a zero divide operation in some cases. Spaces cannot be used to take the place of variables which have a value equal to zero.

Some user-specified input values result in the use of default values of other variables for consistency in the calculations. For the options that allow defaults, the option code that must be input and the default values that are assumed are described. All model output listings used to illustrate individual options are derived from the base case data shown in Appendix D. Only the variables related to options being illustrated are changed from the base case unless otherwise noted.

Print Options

<u>Line No.</u>	<u>Input data</u>
1	1 1 1 1 1
2	1 1 1 1 1 1 1 1 1 1 1 1
3	1 1 1 1 1
	<div style="display: flex; justify-content: space-around; margin-top: 10px;"> <div style="text-align: center;">↓ IRPT</div> <div style="text-align: center;">↓ IEQPR</div> </div>

The options on the first three lines of the input data control printed output from the model. The first print option on line 3 (IRPT) requires further explanation. This option controls the printout of the capital investment and annual revenue requirements. The short form printout is shown in Table 2 and may be compared with the long printout of the base case example in Appendix D. The other print option requiring further explanation is the third option on line 3 (IEQPR). This option controls the printing of all or selected portions of the equipment list. These options are described in the input definition list in Table C-2 of Appendix C.

Particulate Collection Device Option

<u>Line No.</u>	<u>Input data</u>
5	2 500 9500 11700 39 300 2 1 0 90 0 84.1 12.1 .3 175 470 751
	<div style="text-align: center; margin-top: 10px;">↓ XESP</div>

The particulate collection device option is controlled by the XESP variable. The value of XESP may be 0, 1, or 2. A zero value is used if no particulate removal device is to be considered. A value of 1 is used if a mechanical collector (33% efficient) is selected, and the code for upstream removal (line 6, ASHUPS, see Table C-2) should have an input value of 33% (% removal). If an XESP value of 2 is selected, a separate particulate removal cost model (13) projects the capital investment and annual revenue requirements for particulate removal. The results are listed in the output but are not included in the FGD costs. The percentage of particulate removal required for this option is specified by the ASHUPS variable. Example output showing the results of specifying mechanical collectors (XESP = 1) is shown in Table 3. Example output showing the results of using the built-in particulate removal cost model is shown in the base case printout in Appendix D.

Reheat Option

<u>Line No.</u>	<u>Input data</u>																
5	2	500	9500	11700	39	300	2	1	0	90	0	84.1	12.1	.3	175	470	751
							↓									↓	↓
							XRH									TSTEAM	HVS

The reheat option (XRH) allows for either an inline steam reheater for the scrubbed gas or for no reheating of the scrubbed gas. The inline steam reheater is the only type of reheater available in the current version of the model. When a reheater is specified (XRH = 2), the TSTEAM variable is used to specify the temperature of the reheater steam and the HVS variable is used to specify the heat of vaporization of the reheater steam. For the base case, steam at 470°F and 500 psia is used; a steam table should be used to determine the latent heat of steam for other steam conditions. Example output showing the results of specifying an inline steam reheater is shown in the base case in Appendix D. When no reheating is specified (XRH = 0), the reheater section is omitted from the printout. If partial scrubbing/bypass is used (variable KPASO2, line 5 below), the reheat requirements are determined by the final temperature of the recombined flue gas, which includes the heat contribution of the bypassed flue gas.

Emergency Bypass Option

<u>Line No.</u>	<u>Input data</u>																
5	2	500	9500	11700	39	300	2	1	0	90	0	84.1	12.1	.3	175	470	751
							↓										
							KEPASS										

The emergency bypass option (KEPASS) allows an emergency bypass around the FGD system for one-half of the flue gas normally scrubbed as specified in the premises (Appendix B). If only one operating scrubbing train is specified (line 9, NOTRAN) then the emergency bypass is sized for all of the gas normally scrubbed instead of only one-half. When both emergency bypass and partial scrubbing/bypass (line 5, KPASO2 and PSSO2X) are specified, the emergency bypass is sized for 50% of the gas normally scrubbed (100% of the gas normally scrubbed if only one operating train) plus the partial bypass normally used for the unscrubbed gas (the total cannot exceed 100%). The following values are used for the KEPASS option:

0 - No emergency bypass

1 - Emergency bypass

An example showing output when an emergency bypass is specified is shown in the base case printout in Appendix D.

Partial Scrubbing/Bypass Option

Line No.	Input data
5	2 500 9500 11700 39 300 2 1 1 90 0 84.1 12.1 .3 175 470 751
	<div style="display: flex; justify-content: space-around; align-items: center;"> <div style="text-align: center;">  <p>KPAS02</p> </div> <div style="text-align: center;">  <p>PSS02X</p> </div> </div>

The partial scrubbing/bypass option (KPAS02) allows FGD systems to be projected for partial conditions in which all of the flue gas does not have to be scrubbed to meet specified emission levels. The percent removal in the absorber is specified with the PSS02X variable and the model will calculate the percentage of flue gas that can be bypassed (if any) while still meeting the emission limit or overall removal percentage specified (line 7, ISO2 and XS02). The appropriate ductwork and reheater adjustments are made as required, depending on the amount of bypassed gas. When the partial scrubbing/bypass option is specified, the emergency bypass duct is also used for the gas normally bypassed, as discussed above. Partial scrubbing/bypass is not allowed when SO₂ removal is calculated from scrubber operating conditions (line 7, ISR = 3). The following values are used for the KPAS02 option:

0 - No partial scrubbing/bypass

1 - Partial scrubbing/bypass

Example output showing partial scrubbing/bypass specified is shown in Table 4 based on an emission limit of 1.2 lb SO₂/MBtu.

Coal-Cleaning Option

Line No.	Input data
5	2 500 9500 11700 39 300 2 1 1 90 1 84.1 12.1 .3 175 470 751
	<div style="display: flex; justify-content: space-around; align-items: center;"> <div style="text-align: center;">  KCLEAN </div> <div style="text-align: center;">  PREC </div> <div style="text-align: center;">  SPASH </div> <div style="text-align: center;">  WPRITE </div> </div>
5B	1.0 5.5 6.0 13000
	<div style="display: flex; justify-content: space-around; align-items: center;"> <div style="text-align: center;">  SMRW </div> <div style="text-align: center;">  SMCL </div> <div style="text-align: center;">  ASHCLN </div> <div style="text-align: center;">  HVCLN </div> </div>

The coal-cleaning option (KCLEAN) allows the model to be used in conjunction with a coal-cleaning process. The model calculates the composition and firing rate of cleaned coal based on the raw coal characteristics, the coal-cleaning conditions, and the boiler megawatt rating and heat rate. The corresponding flue gas composition is used to determine the SO₂ removal required in the FGD system.

In line 5, the variable PREC specifies the weight percent recovery in pounds of cleaned coal per 100 pounds of raw coal, SPASH specifies the weight

WET GAS SATURATION HUMIDITY = 0.087 LB H2O/LB DRY GAS

percent of sulfur in the cleaned coal, and WPRITE specifies the weight percent of pyritic sulfur in the raw coal. In line 5B, which is required only if the coal-cleaning option (KCLEAN = 1) is specified, SMRW specifies the surface moisture of the raw coal, SMCL specifies the surface moisture of the cleaned coal, ASHCLN specifies the ash content of the cleaned coal, and HVCLN specifies the heating value of the cleaned coal.

When the 1979 new source performance standards (NSPS) emission limit is automatically calculated by the model (line 7, IS02 = 4), the appropriate credit for coal cleaning will also be automatically calculated by the model on a raw coal basis. In all other cases, the emission limit or removal percentage (line 7, IS02 and XS02) must be specified on a cleaned coal basis or must be calculated by the model from FGD operating conditions (line 7, ISR = 3). Coal cleaning is not allowed when the flue gas composition is specified directly (line 6, INPOPT = 2). The following values are used for the KCLEAN option:

0 - No coal cleaning

1 - Coal cleaning

Input Composition Option

Line No.	Input data
	INPOPT
6A	1 66.7 3.8 5.6 1.3 3.36 .1 15.1 4.0 95 80 2 .06 .03
or	
6B	2 12.338 .006 .214 5.560 75.227 6.654 1154000 47500 100 100 2 .06 .03
	INPOPT

The input composition option (INPOPT) allows the flue gas composition to be specified directly instead of being calculated by the model from a coal composition. This allows the model to be used to project FGD systems for other than coal-fired boilers. The variables described for line 6A (C, H, O, N, S, Cl, ash, H₂O, etc.; see Table C-2) should be used when the coal composition is specified; the variables described for line 6B (CO₂, HCl, SO₂, O₂, N₂, H₂O, etc.; see Table C-2) should be used when the flue gas composition is specified directly. Coal cleaning (line 5, KCLEAN = 1) and the automatic calculation of 1979 NSPS emission levels (line 7; IS02 = 4) are not allowed when the flue gas composition is specified directly. The following values are used for the INPOPT option:

- 1 - Coal composition is specified (line 6A)
- 2 - Flue gas composition is specified (line 6B)

When a coal composition is specified, a "BOILER CHARACTERISTICS" section is included in the output. Example output showing the results of specifying a coal composition as input (INPOPT = 1) is shown in the base case printout in Appendix D. When a flue gas composition is specified, a "HOT GAS ANALYSIS" section is provided. Example output showing the results of specifying a flue gas composition as input is shown in Table 5.

Particulate Removal Option

<u>Line No.</u>	<u>Input data</u>
6	1 66.7 3.8 5.6 1.3 3.36 .1 15.1 4.0 95 80 2 .06 .03
	 IASH ASHUPS ASHSCR

The particulate removal variables are IASH, ASHUPS, and ASHSCR. The IASH option identifies the method for specifying particulate removal, i.e., as percent removal or as outlet emission in lb/MBtu. IASH may take values of 0, 1, 2, or 3. If IASH is equal to 0, upstream particulate removal (ASHUPS) and absorber particulate removal (ASHSCR) take default values of 33% and 99.2% removal, respectively. If IASH equals 1, ASHUPS and ASHSCR are input as percent removal. If IASH equals 2, ASHUPS and ASHSCR are input particulate loadings in lb/MBtu at the outlet of the upstream particulate collector and the absorber, respectively. If IASH equals 3, ASHUPS is input as percent removal and ASHSCR takes a default value of 75%. Regardless of the option chosen, the output listing provides the equivalent particulate emission as both percent removal and lb/MBtu. A summary of the options is shown below.

- IASH = 0 ASHUPS default value = 33% removal
ASHSCR default value = 99.2% removal
- IASH = 1 ASHUPS input value as percent removal
ASHSCR input value as percent removal
- IASH = 2 ASHUPS input value as lb/MBtu to absorber
ASHSCR input value as lb/MBtu from absorber
- IASH = 3 ASHUPS input value as percent removal
ASHSCR default value equals 75% removal

Example output showing the results of specifying particulate removal based on lb/MBtu (IASH = 2) is shown in the base case printout in Appendix D.

SO₂ Removal Option

Line No.	Input data																			
7	90	10	5	10	25	4	1.2	10	1	1.3	1	0	.15	0.0	1500	3	4.85	5	0	0
						↓	↓													
						IS02	XS02													

The model has five methods for specifying SO₂ outlet concentrations or removal. The controlling variables are the IS02 option and the actual value to be removed, XS02. If IS02 = 1, XS02 is input as the percentage of SO₂ to be removed. (The percentage of SO₂ to be removed is used as the percent removal by the absorber except when partial scrubbing is specified with the KPAS02 option on line 5.) If IS02 = 2, XS02 is input as the absorber outlet emission expressed as pounds SO₂/MBtu. If IS02 = 3, XS02 is input as ppm SO₂ in the absorber outlet stream. If IS02 = 4, SO₂ removal is automatically calculated by the model from the input coal composition based on the 1979 NSPS (14). Figure 1 illustrates the relationship between the SO₂ content of the raw coal and the controlled outlet emission levels used in the model for the 1979 NSPS. The fifth method for specifying SO₂ removal, SO₂ removal calculated, is described in the operating condition options section (line 7, ISR = 3). Regardless of the option chosen, the equivalent SO₂ removal in all three units is displayed in the model output. The input value is shown as having been specified and the other values are shown as having been calculated. A summary of the input options is shown below.

IS02 = 1 XS02 is input as percent removal

IS02 = 2 XS02 is input as pounds SO₂/MBtu at the absorber outlet

IS02 = 3 XS02 is input as ppm SO₂ in the absorber outlet stream

IS02 = 4 XS02 will be automatically calculated by the model based on the 1979 NSPS

Example output showing the results of specifying emission limits based on the 1979 NSPS is shown in the base case printout in Appendix D.

An important concept related to SO₂ removal calculations in the model should be emphasized here. The SO₂ removal options are based on long-term average sulfur content of the coal and are not necessarily representative of 3-hour or 24-hour averages. When sizing an FGD facility, the raw material-handling, feed preparation, and scrubbing areas should be based on the maximum sulfur content of the coal rather than the long-term average. The waste disposal area, however, should be sized on the long-term average sulfur content. This can be done by entering the weight percent sulfur as the maximum expected and then entering the waste disposal capacity factor (line 14, PND CAP) to adjust the total amount of waste generated back to the equivalent long-term average amount.

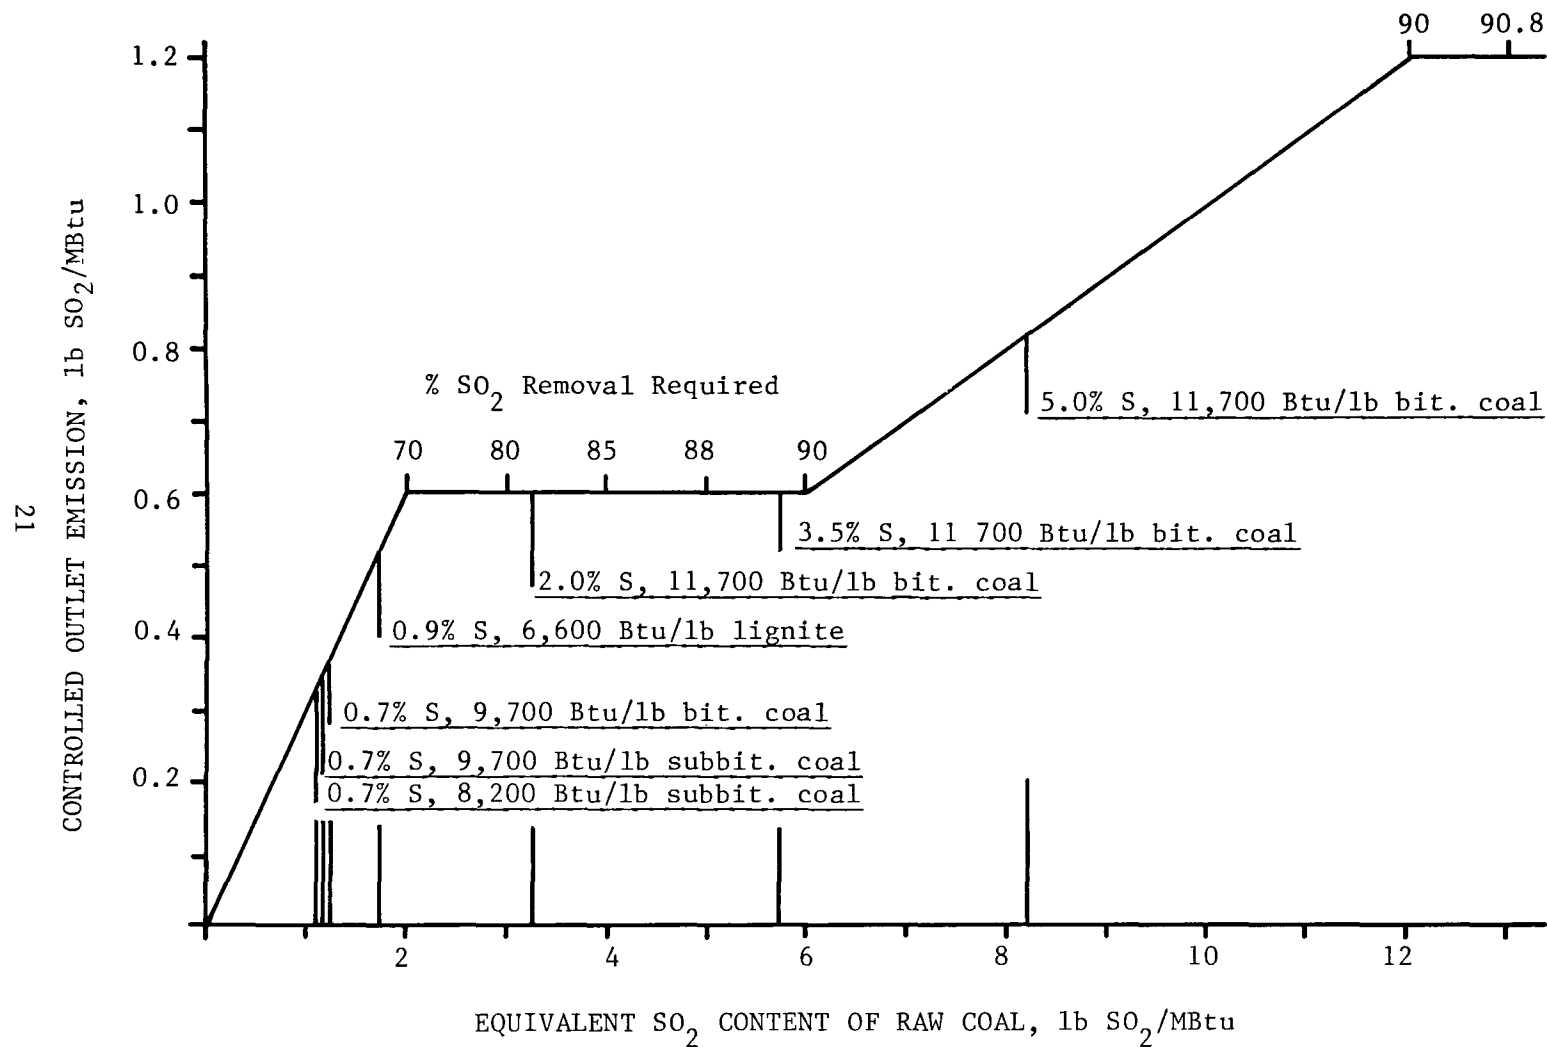

Figure 1. Controlled SO₂ emission requirements for 1979 NSPS. Premise coals, shown underlined, are based on premise boiler conditions.

Operating Condition Calculation Option

Line No.	Input data																				
	XLG				XS02		ISR		SRIN		XIALK		IADD		AD						
7	90	10	5	10	25	4	1.2	10	1	1.3	1	0	.15	0.0	1500	3	4.85	5	0	0	
8	15	40	.2	40	0	30	2.5	85	1.2	7.0	0	0	9	0	14.7	1					
																	PHLIME				

Four options are available in the model to allow either user input or model calculation of the major operating conditions which include L/G (expressed as absorber liquid recirculation rate in gallons per 1,000 ft^3 of flue gas at the absorber outlet), stoichiometry (expressed as mols CaCO_3 or CaO added per mol of $\text{SO}_2 + 2\text{HCl}$ absorbed), and SO_2 removal. The options differ slightly for the limestone system, the additive-enhanced limestone system, and the lime-scrubbing system so the description is divided into three sections.

For limestone scrubbing (line 7, XIALK = 1), the variables used are ISR, XLG, SRIN, and XS02. ISR is the controlling option and takes values from 0 to 3. If ISR has an input value of 0, the L/G (XLG), stoichiometry (SRIN), and SO₂ removal (XS02, units depend on IS02) are all user input values. Specifying ISR = 0 is referred to as "force-through" because no program checks are made for validity or consistency among the three input variables to ensure that specified L/G and stoichiometry can result in the input degree of removal. If ISR is equal to 1, XLG and XS02 are input and the model calculates stoichiometry. If ISR is equal to 2, SRIN and XS02 are input and the model calculates the L/G ratio. When ISR is equal to 3, XLG and SRIN are input and the model calculates SO₂ removal. Values of 1.03 or greater should be used for SRIN when it is specified as input because of logarithm mathematical requirements. A summary of the various options for a limestone-scrubbing system is shown below.

```
ISR = 0  XLG is input
         XS02 is input
         SRIN is input
```

```

ISR = 1  XLG is input
          XS02 is input
          SRIN is calculated

```

```
ISR = 2  XLG is calculated
         XS02 is input
         SRIN is input
```

ISR = 3 XLG is input
XS02 is calculated
SRIN is input

Example output showing the results of specifying ISR = 1 is shown in the base case printout in Appendix D.

Similar options are available for the adipic acid-enhanced limestone system (line 7, IADD = 2). The variable PHLIME is used to input the pH of absorber recirculating liquid. The pH has a critical effect on the calculation of L/G ratio and SO₂ removal and the user must understand the system so that anomalous results are not produced. The adipic acid option is discussed in more detail in Appendix E. A summary of the options is shown below. The PHLIME option specifies pH. The AD option specifies the quantity of adipic acid in the system in ppm.

ISR = 0 XLG is input
XS02 is input
PHLIME is input
AD is input

ISR = 1 XLG is input
XS02 is input
PHLIME is input
AD is calculated

ISR = 2 XLG is calculated
XS02 is input
PHLIME is input
AD is input

ISR = 3 XLG is input
XS02 is calculated
PHLIME is input
AD is input

Similar options are available in the lime-scrubbing option (line 7, XIALK = 2). The variable PHLIME replaces SRIN except when ISR = 0 because for lime scrubbing the model calculates the pH of the recirculation liquid instead of the lime stoichiometry. (When limestone is specified, the value of PHLIME is ignored. When lime is specified, SRIN is ignored except when ISR = 0, in which case PHLIME is ignored.) A summary of the options for a lime system is shown below.

ISR = 0 XLG is input
XS02 is input
SRIN is input

ISR = 1 XLG is input
 XS02 is input
 PHLIME is calculated

ISR = 2 XLG is calculated
 XS02 is input
 PHLIME is input

ISR = 3 XLG is input
 XS02 is calculated
 PHLIME is input

The output listing for the lime option is similar to that for the limestone option shown in Appendix D except that the stoichiometry is printed out for CaO instead of CaCO₃, as shown in Table 6. (An input value of 7.85 is used for PHLIME in this example.) For both the lime and limestone options, if input values are specified for the variables that are to be calculated by the model, the input values are ignored.

Scrubbing Absorbent Option (Lime or Limestone)

<u>Line No.</u>	<u>Input data</u>
7	90 10 5 10 25 4 1.2 10 1 1.3 1 0 .15 0.0 1500 3 4.85 5 0 0
	 XIALK

The absorbent option (XIALK) allows a choice of either lime or limestone. If XIALK = 1, limestone slurry is selected as the scrubbing medium. If XIALK = 2, lime slurry is selected. Example output showing the results of specifying limestone scrubbing (XIALK = 1) is shown in the base case printout in Appendix D. The scrubbing output and the raw material preparation area equipment list from the lime option output are shown in Tables 7 and 8, respectively.

Chemical Additive Option

<u>Line No.</u>	<u>Input data</u>
7	90 10 5 10 25 4 1.2 10 1 1.3 1 0 .15 0.0 1500 3 4.85 5 0 0
	 IADD XMG0AD AD ADDC

The chemical additive option (IADD) provides for the addition of either MgO or adipic acid to the slurry stream to improve scrubber efficiency and SO₂ removal rates. The following values are used for the IADD option:

- 0 - No chemical additive
- 1 - MgO added
- 2 - Adipic acid added

If IADD = 1, variable XMGOAD is used to specify the quantity of MgO added to the system (expressed as pounds of soluble MgO added per 100 pounds of alkali feed). When IADD = 2, variable AD is used to specify the concentration of adipic acid in the scrubber slurry [expressed as ppm (by weight) adipic acid] and variable ADDC specifies the degradation constant for adipic acid in the scrubber slurry (expressed as pounds of adipic acid to be added per pound of adipic acid remaining in the slurry after degradation).

Example output showing the results of adding adipic acid is shown in Table 9.

Forced-Oxidation Option

<u>Line No.</u>	<u>Input data</u>												
8	15	40	.2	40	0	30	2.5	85	1.2	7.0	0	9	0 14.7 1
			↓		↓	↓							
			RS		IFOX	OX							

The forced-oxidation option (IFOX) provides for oxidation of the sulfite slurry to gypsum by sparging air into one of the slurry tanks. Gypsum offers better disposal options such as easier dewatering, a higher settling rate, and a higher density. Variable RS is the thickener solids settling rate (ft/hr) and may be user specified or will be automatically calculated based on the percent oxidation of the scrubbing slurry by specifying a value of 0.0. The following values are used for the IFOX option:

- 0 - No forced oxidation
- 1 - Forced oxidation in a single effluent tank (within the absorber loop)
- 2 - Forced oxidation in the first of two effluent tanks (within the absorber loop)
- 3 - Forced oxidation in the disposal feed tank (bleedstream from the absorber loop); the number of effluent tanks depends on the ISCRUB variable (line 9)

The percent oxidation efficiency (0-99, in mol percent) in the system is specified with the OX variable and should be specified in agreement with the IFOX option. The number of tanks specified by the forced-oxidation option must not conflict with the number of tanks indicated by the absorber option

(ISCRUB, line 9). Example output showing the results of specifying forced oxidation in the first of two effluent tanks (IFOX = 2) is shown in Table 10. An example of one tank (IFOX = 1) is shown in Table 11.

Booster Fan Option

<u>Line No.</u>	<u>Input data</u>
8	15 40 .2 40 0 30 2.5 85 1.2 7.0 0 9 0 14.7 1
	↓ IFAN

The fan option (IFAN) allows either induced-draft (ID) fans or forced-draft (FD) fans to be specified to compensate for the pressure drop in the FGD system. The following values are used.

- 0 - Forced-draft fans
- 1 - Induced-draft fans

Example output showing the results of specifying ID fans is shown in the base case printout in Appendix D. The format of the output is similar for the FD fan option; however, the fan costs are different.

Scrubbing Option

<u>Line No.</u>	<u>Input data</u>
9	1 0 0 0 35 .0000005 32 10 5.70 1 4 1 .1
	↓ ISCRUB

The scrubbing option (ISCRUB) identifies one of the six absorber systems that can be used. The ISCRUB values and the corresponding systems are as follows:

- ISCRUB = 1 Spray tower (one effluent tank unless two tanks are specified by the forced-oxidation option, IFOX, on line 8)
- ISCRUB = 2 TCA (one effluent tank unless two tanks are specified by the forced-oxidation option, IFOX, on line 8)
- ISCRUB = 3 Venturi-spray tower with two effluent tanks (if forced oxidation is specified by IFOX on line 8, IFOX must be 2)
- ISCRUB = 4 Venturi-spray tower with one effluent tank (if forced oxidation is specified by IFOX on line 8, IFOX must be 1)

ISCRUB = 5 Venturi-TCA with two effluent tanks (if forced oxidation is specified by IFOX on line 8, IFOX must be 2)

ISCRUB = 6 Venturi-TCA with one effluent tank (if forced oxidation is specified by IFOX on line 8, IFOX must be 1)

There are no specific material balance models for the venturi-TCA scrubbing combination specified by options 5 and 6. These options are provided to allow comparative cost estimates for analysis and should normally be used only in "force-through" mode (see the operating condition calculation option, ISR, on line 7). Example output showing the results of specifying a spray tower is shown in the base case printout in Appendix D. Example output showing the results of specifying a venturi-spray tower with two effluent tanks is shown in Table 12.

Spare Equipment Options

<u>Line No.</u>	<u>Input data</u>
9	1 0 0 0 35 .0000005 32 10 5.70 1 4 1 .1
	NSPREP NOTRAN NOREDN

Options for spare equipment in the model apply to the raw material preparation area and the scrubbing area. The controlling input variables are NSPREP, NOTRAN, and NOREDN. NSPREP specifies the number of spare preparation units (ball mills for limestone or slakers for lime) and may be given any realistic value, 0, 1, 2, 3, NOTRAN specifies the number of operating absorbers. The model automatically overrides the value of NOTRAN if the specified number requires an absorber larger than the maximum available size. NOREDN indicates the number of spare absorber trains. The base case equipment list in Appendix D shows the output for a limestone-scrubbing system designed with spare ball mills and absorbers. For comparison, Table 13 shows similar output for a limestone system with no spare absorbers.

Waste Disposal Option

<u>Line No.</u>	<u>Input data</u>
10	5 0 0.0 9999 5000 25 25 5280 1 12 4.75
	ISLUDG IFIXS SDFEE DISTPD

Six basic waste disposal options are available in the model (usually these are based on a disposal site one mile from the FGD facility, as specified in feet by the variable DISTPD). The input variables are ISLUDG, IFIXS, and SDFEE and are illustrated below. ISLUDG takes values of 1, 2, 3, 4, or 5. Options 1 through 4 specify variations of pond disposal. Option 5 specifies dewatering and landfill disposal. IFIXS takes values of 0 or 1. IFIXS = 1 can be used only with ISLUDG = 5 and specifies an additional

fixation process which is described below. SDFEE is a user-specified fee in \$/ton of dry waste that can be used to specify a fee for additional costs not included in the model. It is normally used with ISLUDG values of 3 and 4 but it can also be used with the other ISLUDG options. In all options that involve dewatering, user-specified solids contents are used. These must be within practical limits to attain accurate results. The use of ISLUDG = 5 normally requires either the use of IFIXS = 1 or one of the forced-oxidation options because unoxidized sludge is not normally landfilled without fixation. A summary of the basic options is shown below.

ISLUDG = 1 Onsite pond disposal of untreated waste.

ISLUDG = 2 Dewatering in a gravity thickener followed by onsite pond disposal.

ISLUDG = 3 Dewatering in a gravity thickener with additional costs based on SDFEE to cover fixation and/or disposal cost.

ISLUDG = 4 Dewatering in a gravity thickener and a rotary vacuum filter with additional costs based on SDFEE to cover fixation and/or disposal costs.

ISLUDG = 5 Dewatering in a gravity thickener and a rotary vacuum filter followed by disposal in an onsite landfill.

ISLUDG = 5 Dewatering with a gravity thickener and a rotary vacuum filter, and followed by fixation by blending the filter cake with an equal IFIXS = 1 quantity of dry fly ash and 3.5% lime (both based on dry waste) for disposal in an onsite landfill.

The base case printout in Appendix D is an example of the forced-oxidation, landfill option (ISLUDG = 5, IFIXS = 0). Sample equipment lists corresponding to the output for the other waste disposal options are shown in Tables 14-16. Annual revenue requirements corresponding to fixation using the model and landfill disposal (ISLUDG = 5, IFIXS = 1) are shown in Table 17.

Pond Disposal Option

<u>Line No.</u>	<u>Input data</u>
10	1 0 0.0 9999 5000 25 25 5280 1 12 6.00
	<div style="display: flex; justify-content: space-around; align-items: center;"> <div style="text-align: center;">  PSAMAX </div> <div style="text-align: center;">  PDEPTH </div> <div style="text-align: center;">  PMXEXC </div> <div style="text-align: center;">  DISTPD </div> </div>

The design of the disposal ponds used in the model is described in Appendix B. The model has three options for defining the relationships between pond land area, excavation depth, and depth of waste in the filled pond.

Three variables, PSAMAX, PDEPTH, and PMXEXC are required inputs. The PSAMAX variable specifies the maximum land area in acres available for the pond, the PDEPTH variable specifies the final depth of waste in the filled pond, and the PMXEXC variable specifies the maximum depth of topsoil and subsoil (clay) that can be excavated and used for dike construction (excavation and dike construction calculations are based on the assumption that the excavated material compacts to 85% of the original volume). For a fixed depth pond, PSAMAX should be zero, PDEPTH should be set to the desired depth, and PMXEXC should be set to zero. For a pond based on minimum capital investment costs but subject to area and excavation limits, PSAMAX should be set to the maximum area in acres available for pond construction, PDEPTH should be set to zero, and PMXEXC should be set to the maximum excavation depth allowed. The pond based on minimum capital investment costs (with no area and excavation limits) is essentially the same as the second option except that the values specified for the area and excavation limits should be high enough not to realistically limit the optimized values; for example, PSAMAX = 9999 and PMXEXC = 25.

In all three options below, the pond is designed to minimize the sum of construction cost and land cost.

Fixed depth pond

PSAMAX = 0.0

PDEPTH = desired depth, feet

PMXEXC = 0.0

Optimum pond cost, subject to limits of area and excavation depth

PSAMAX = Maximum area available for disposal site, acres

PDEPTH = 0.0

PMXEXC = Maximum allowable excavation depth, feet

Optimized capital investment, assuming unlimited area and excavation depth

PSAMAX = Maximum area available for pond construction (maximum = 9999 acres)

PDEPTH = Maximum pond depth, feet

PMXEXC = Maximum excavation depth, feet

When the restricted area pond design option is used and calculations indicate that the total waste volume cannot be contained within the specified area and excavation limits, an error message is issued and the case is terminated. Example output showing the results of specifying a pond based on minimum capital investment costs and the available area constant is shown in Table 18.

The pond portion of the model can also be executed separately in an interactive mode. Execution of the pond portion of the model in this manner is discussed in Appendix F.

Landfill Disposal Option

<u>Line No.</u>	<u>Input data</u>
10	5 0 0.0 9999 75 85 5280 1 12 6.00
	<div style="display: flex; justify-content: space-around; width: 100%;"> <div style="text-align: center;">  PDEPTH </div> <div style="text-align: center;">  PMXEXC </div> </div>

The design of the landfill used in the model is described in Appendix B. Based on this design and the volume of waste to be disposed of, the transportation and landfill requirements are determined. The variable names used in executing the landfill model are the same as those used in executing the pond model, but are defined differently. In the landfill model, PDEPTH specifies the uncompacted waste bulk density in lb/ft³ (for transportation requirements) and PMXEXC specifies the compacted bulk density in lb/ft³ (for landfill volume determination). If bulk density values are unknown, the model will choose default values for FGD wastes as shown below. Example output showing the results of specifying a landfill based on minimum capital investment costs with a synthetic liner is shown in Table 19. As with the pond option, the liner is specified separately, as discussed below.

DEFAULT VALUES OF WASTE BULK DENSITIES

	<u>Bulk density, lb/ft³</u>	
	<u>In-process waste</u>	<u>Compacted</u>
<u>Waste Sludge</u>		
Sulfite (filtered)	70	85
Gypsum (filtered)	75	95
Fixed sulfite (filtered)	90	106
Fixed sulfate (filtered)	85	100

The landfill portion of the model can also be executed separately in an interactive mode. Execution of the landfill portion of the model in this manner is discussed in Appendix G.

<u>Line No.</u>	<u>Input data</u>
10	1 0 0.0 9999 5000 0 25 5280 1 12 6.00
	ILINER XLINA XLINB

The liner option allows a choice of an unlined, clay-lined, or synthetic-lined disposal site. The input variables are ILINER, XLINA, and XLINB. ILINER specifies the type of lining as illustrated below.

1 = Clay liner

2 = Synthetic liner

3 = No liner

For a clay lining (ILINER = 1), XLINA specifies the depth of clay in inches and XLINB specifies the clay lining installation cost (or the costs for reworking the clay subsoil into a lining) in $\$/\text{yd}^3$. For a synthetic lining (ILINER = 2), XLINA specifies the liner material cost in $\$/\text{yd}^2$ and XLINB specifies the installation cost in $\$/\text{yd}^2$. For no liner (ILINER = 3), XLINA and XLINB should be set to zero. Example output showing the results of specifying a synthetic liner is shown in Table 20.

Economic Premises Option

<u>Line No.</u>	<u>Input data</u>

	IECON PCTOVR XLEVEL CAPCHG PCTMKT
	or or or
	PCTADM UNDCAP PCTINS

The economic premises option (IECON) allows cost projections based on either the current EPA-TVA economic premises adopted December 5, 1979 (and expanded and amplified in March 1981), or the old premises that were used before December 5, 1979. Appendix B contains a description of the current premises. Four variables are used in conjunction with the economic premises option. The meaning of these variables depends on which set of premises is selected. If the current premises are specified (IECON = 1), the PCTOVR variable specifies the plant administrative overhead rate, applied as a percent of conversion costs less utilities; the XLEVEL variable specifies the levelizing factor to be applied to first-year operating and maintenance costs to develop levelized operating and maintenance costs for the total life of the

TOTAL FIXED INVESTMENT			11801.

LAND COST			847.

plant; the CAPCHG variable specifies levelized annual capital charges applied as a percent of total capital investment; and the PCTMKT variable specifies marketing costs applied as a percent of byproduct credit (applies only to processes with a salable byproduct). If the levelizing factor (XLEVEL) is set to zero then a lifetime revenue sheet is printed showing annual revenue requirements for each year of plant operation.

If the old premises are specified (IECON = 0), the PCTOVR variable specifies the plant overhead rate applied as a percent of conversion costs less utilities, the PCTADM variable specifies the administrative research and service overhead rate applied as a percent of operating labor and supervision, the UNDCAP variable specifies the annual capital charge basis for undepreciated investment, and the PCTINS variable specifies the rate for insurance and interim replacements applied as a percent of total capital investment.

Example output showing the results of specifying the current economic premises (IECON = 1) and a nonzero levelizing factor (XLEVEL = 1.886) is shown in the base case printout in Appendix D. The results of specifying a zero levelizing factor are shown in the example revenue requirements in Table 21. The results of specifying the old economic premises are shown in the example revenue requirements in Table 22.

Sales Tax and Freight Option

<u>Line No.</u>	<u>Input data</u>
12	1 4 3.5 6 0 1 1.5 1 2 1 8 5 10 0
	<div style="display: flex; justify-content: space-around; align-items: center;"> <div style="text-align: center;"> ↓ ITAXFR </div> <div style="text-align: center;"> ↓ TXRAT </div> <div style="text-align: center;"> ↓ FRRAT </div> </div>

The sales tax and freight option (ITAXFR) allows capital investment sales tax and freight to be applied as a percentage of material costs. The sales tax rate is specified with the variable TXRAT and the freight rate is specified with the FRRAT variable. When ITAXFR is 1, the specified rates are applied to material costs and included in the capital investment summary printout; when ITAXFR is zero, sales tax and freight are excluded. Example output showing the results of specifying sales tax and freight is shown on the capital investment summary sheet in the base case printout in Appendix D. An example investment summary sheet showing sales tax and freight excluded is shown in Table 23.

The overtime option (IOTIME) allows an overtime labor rate (OTRATE) to be applied to 7% of total capital investment labor as defined in the premises in Appendix B. When IOTIME is 1, the specified overtime rate is applied to 7% of all applicable labor costs; when IOTIME is zero, no overtime labor adjustments are made. The added costs for overtime labor are not shown separately in the model output, but a message is printed in the listing of the model inputs to indicate if overtime is specified. An example printout with overtime specified is shown in the base case printout in Appendix D.

Separate Waste Disposal Site Construction Indirect Investment Factors Option

<u>Line No.</u>	<u>Input data</u>													
12	1	4	3.5	6	0	1	1.5	1	2	1	8	5	10	0
	INDPND		PENGIN		PARCH		PFLDEX		PFEES		PCONT		PSTART	

The separate waste disposal indirect investment option (INDPND) allows the indirect capital investment for the waste disposal site construction to be calculated separately from the process indirect investment. The waste disposal site construction is usually less complicated than the FGD process construction and its indirect investment factors are usually lower. If INDPND is zero, the waste disposal site construction indirect investment is calculated using the same factors (ENGIN, ARCTEC, FLDEXP, FEES, CONT, and START) specified in line 11. If INDPND = 1, the factors specified by PENGIN (engineering design and supervision), PARCH (architectural and engineering contractor), PFLDEX (field expenses), PFEES (contractor fees), PCONT (contingencies), and PSTART (allowance for startup and modifications) are used to determine the waste disposal site indirect investment. All but PCONT and PSTART are calculated as a percentage of waste disposal site direct investment. If the current economic premises are used (IECON = 1 in line 11), the contingencies are a percentage of the sum of the waste disposal site direct investments plus each of the four preceding waste disposal site indirect investments. If the old economic premises are used (IECON = 0 in line 11), the contingency is calculated as a percentage of the waste disposal site direct investment only. The allowance for startup and modification is calculated as a percentage of the total fixed investment for waste disposal site construction. An example of output showing the use of separate indirect investment factors for landfill construction is shown in the example printout in Appendix D. An example of the use of a common indirect investment factor (INDPND = 0) for both the FGD process and the waste disposal site is shown in Table 24.

If the user wishes to specify an oversized waste disposal site to cover contingencies, or to specify an undersized site for applications in which the initial site is not designed for the full life of the plant, an appropriate PNDCAF factor, i.e., greater than or less than 1.0, can be specified.

The PNDCAF factor is also used automatically by the model to adjust the landfill size when fixation (ISLUDG = 5, IFIXS = 1 in line 10) is specified to account for the additional volume of the fly ash and lime. An example is shown in Table 25.

	IOPSCH ONCAP IYPROP

One of the most important variables affecting the economics of a power plant and an associated FGD system is the operating profile (number of years of operation and the hours of operation per year) over the life of the unit. The effects of the year-by-year profile on capital investment and annual revenue requirements are determined by the economic premises option (line 11, IECON), the operating and maintenance cost levelizing factor (line 11, XLEVEL) used with the current economic premises, and the waste disposal option (line 10, ISLUDG). The model provides five options for specifying this profile. The input variable for these options is IOPSCH. If IOPSCH = 1, the model uses the operating schedule shown in Figure 2 which is based on a profile developed by TVA for several past economic evaluations (15). If IOPSCH = 2, the operating schedule is based on historical Federal Energy Regulatory Commission (FERC) data (16) as shown in Figure 3. If IOPSCH = 3, the user must input the operating profile as shown below. If IOPSCH = 4, a levelized operating profile of 5,500 hours per year is used (see Appendix D). If IOPSCH = 5, the user supplies a fractional capacity factor, UNCAP, and the hours of operation each year are calculated by multiplying the fractional capacity factor by 8,760 hours per year. The cumulative hours of operation over the life of the plant are obtained by multiplying the resulting annual hours of operation by the number of years of operation, IYROP, which is also an input. A 30-year operating life is assumed for IOPSCH = 1, 2, or 4. The operating life in years must be specified by the variable IYROP when using IOPSCH options 3 and 5. When the operating profile is specified by the user (IOPSCH = 3), the projected operating life in years cannot exceed 50. Beginning on line 16, the total number of hour-per-year entries must be equal to the value of IYROP. The number of entries per line must be equal to 10. Less than 10 entries are allowed on the last line only, depending on the number of years required. An example using 25 years is shown below.

<u>Line No.</u>	<u>Input data</u>

19	END

Figure 2. Operating profile assumed for IOPSCH = 1 based on old TVA premises.

Figure 3. Operating profile assumed for IOPSCH = 2 based on historical Federal Energy Regulatory Commission data.

If levelized operating and maintenance costs under the current premises are used, a levelizing factor (line 11, XLEVEL) that corresponds to the operating profile should be used.

Example output resulting from the Figure 2 operating profile (IOPSCH = 1) is shown in Table 26. Table 27 illustrates the results of the Figure 3 FERC data operating profile (IOPSCH = 2). Example output resulting from a user-supplied operating profile (IOPSCH = 3) is shown in Table 28. The base case printout in Appendix D shows the results of specifying a levelized operating profile of 5,500 hours per year. Example output resulting from a user-specified operating capacity factor in conjunction with a 26-year operating profile is shown in Table 29.

USING THE MODEL

As previously discussed, a copy of the model can be made available for independent user execution; or TVA, under an information-exchange agreement with EPA, can make specific runs of the model based on user-supplied input data. This section is provided for potential users who wish to obtain the model for independent use.

The model was developed for, and is executed on, the TVA in-house IBM 370-compatible computer system. The current model consists of two FORTRAN programs written in FORTRAN66 that are compiled using either the IBM G1 or H extended compiler. The first program, which calculates investment costs, is relatively large; it contains over 14,000 lines of source code. The second program, which calculates revenue requirements, contains about 2,000 lines.

Core storage requirements for the first program are about 375,000 bytes; the use of overlays can reduce this requirement to about 200,000 bytes. The second program executes within 150,000 bytes of core storage with no overlays. In addition to the core storage required for program execution, temporary online storage (disk) is also required for intermediate files and the transfer of data between the two programs. The only input data required for model execution are the user input data; all other data for default assumptions and option-related calculations are assigned the necessary values internally within the program. Temporary online storage requirements depend on the number of cases run but typically do not exceed 200,000 bytes.

The model is executed in both interactive and batch modes. The input data can be provided in three ways, depending on the mode of execution. For batch execution (typically remote batch), the input data variables are punched on cards and inserted in a model execution run deck. The second method of providing data applies to interactive model execution. Input is solicited at the terminal during actual model execution and the user must respond with the appropriate values. The third method is used for both interactive and batch execution. A data file is created interactively (typically using a text editor); all variable values (including the options selected) are examined and corrected if necessary, then the model is executed (either interactively or a batch run is submitted from the interactive terminal) and the input is processed as a standard data file.

The third method of providing input data has been found to be preferable in most cases. When separate but similar model runs are required, the data file containing the input is copied to a second file, variables and options are modified as necessary, and a second model run is submitted. This reduces both input preparation time and the number of input data errors because only the variables and options that differ from a previous run must be modified.

The job control language (JCL) required to execute the model in batch mode is stored in a catalogued procedure file. An example procedure file is shown in Table 30. The catalogued procedure uses a system utility program, IEBGENER, which can be replaced if necessary by a user program to copy from input card data to disk storage and from disk storage to an output print file. The overall procedure consists of four steps to (1) copy the input data to a temporary online storage file (disk), (2) copy the input data to an output print file, (3) execute the first program of the model, and (4) execute the second program. The programs are executed from load modules to avoid recompiling each time they are executed.

The remaining JCL required to execute the model in batch mode is shown in Table 31. If the input data have been prepared on cards, a card deck similar to example 1 in Table 31 would be submitted with the data cards following the //LOAD.DATA DD * ... card. In example 2, the catalogued procedure (Table 31) is executed and the required input is read from a previously created data file. The JCL examples shown in Tables 30 and 31 generally apply whether the job is submitted interactively or with a card deck.

Table 32 shows two example interactive procedures for model execution. Example 1 in Table 32 shows an example procedure for directly entering the data during model execution. Example 2 shows a procedure for interactive execution using a previously created data file.

The amount of computer time required for model execution is a function of the number of cases of input data and the particular computer system. On the TVA system (AMDAHL V8 with JES3), the average CPU time required per case is about 0.5 second but some cases have exceeded 2 seconds.

The model is usually distributed on magnetic tape for independent usage. A fairly wide range of tape format options is available but typically the tape is unlabeled; the density is 1600 bpi; the block size is 4,000 characters (50 records, 80 characters per record); and the tape contains two files, one for each program.

MODEL STRUCTURE

As described previously, the overall model consists of two FORTRAN programs. The first program which calculates investment costs consists of a main program and 101 subroutines. An alphabetical listing of the subroutines in this program with a general description of their function is shown in Table 33. The second program which calculates revenue requirements consists of a main program and 10 subroutines. An alphabetical listing of the subroutines in this program with a general description of their function is shown in Table 34. Since the subroutines are not executed in either alphabetical order or the order in which they occur in the two programs, hierarchy charts showing the sequence for calling the various subroutines during batch program execution and identifying the main program and subroutines from which they are called are shown in Tables 35 and 36.

Further documentation of the overall model is beyond the scope of this manual.

TABLE 33. ALPHABETICAL LISTING OF THE SUBROUTINES IN THE INVESTMENT PROGRAM
IDENTIFYING THE FUNCTION OF EACH SUBROUTINE

Investment program subroutines	Function
ACTIVE	Allows investment program to be run interactively
ADAMGO	Calculates costs for adipic acid or MgO addition equipment
ADIPID	Calculates stoichiometry, L/G, SO ₂ removal efficiency, and pH for adipic acid addition option
ADIPMD	Calls ADIPID when adipic acid model is run interactively
BECHTL	Initializes variables and calls subroutines used for calculating material balance
BEQ	Calculates aqueous equilibrium constants
BEQPRT	Prints modified Radian equilibrium program results (not activated by Shawnee model)
BYPASS	Used in projecting material balance and bypass design for partial scrubbing options
CASO3	Calculates aqueous concentration of CaSO ₃ ·1/2H ₂ O at equilibrium
CASO4	Calculates aqueous concentration of CaSO ₄ ·2H ₂ O at equilibrium
CASOX	Calculates aqueous concentration of CaSO _x at equilibrium
CLARIF	Calculates size of the thickener-clarifier
CLEAN	Calculates composition and heating value of physically cleaned coal
CSA	Calculates cross-sectional area of scrubber
CSAFIL	Calculates required filtration area for dewatering FGD sludge
DUCWRK	Calculates design and costs for all ductwork, including dampers and expansion joints
DUST	Calculates fly ash contained in combustion products
EDIT	Checks validity of input data and determines which flags are set
EDIT1	Checks to determine if the correct number of variables are input when running in the batch mode
ELECTR	Calculates design and costs of electrical motors, wire, and conduit
EQCALL	Initializes equilibrium variables and coefficients
EQPSUM	Calculates sum of all FGD equipment costs
EQUIPR	Calls subroutines for printing equipment costs
EQUIPT	Calls subroutines for sizing all equipment
EQUPR1	Initializes equipment sizing-costing arrays
EQUPR2	Prints equipment lists for raw material and feed preparation areas
EQUPR3	Prints equipment lists for gas-handling, scrubbing, oxidation, and reheat areas

(Continued)

TABLE 33. (Continued)

Investment program subroutines	Function
EQUIPR4	Prints equipment list for solids separation area
EQUIPR5	Prints equipment list for landfill area
EQUIPR6	Prints equipment list for fixation area
FANS	Calculates equipment costs for ID and FD fans
FILTER	Calculates equipment costs for drum filters
FIXIT	Calculates design and costs for the fixation area
FOROXD	Calculates equipment costs for forced-oxidation air compressors and spargers
FOUNDT	Calculates design and costs for foundations
H2OBAL	Calculates overall water balance considering H ₂ O added through alkali and rainfall, and H ₂ O losses from evaporation, seepage, and entrainment
H2OPMP	Calculates costs of makeup water and supernate return pumps
HOTGAS	Calculates flow rate, composition, and wet bulb temperature of flue gas exiting the boiler
INSTRM	Calculates design and costs for instrumentation
KCALC	Calculates activity coefficients
LAND	Calculates land area required for FGD equipment and waste disposal
LANDC	Calculates design of the landfill
LANDP	Prints material balance, design, and cost of the FGD landfill
LANFIL	Allows landfill option to be run interactively
LIMEPR	Calculates costs of the lime raw material receiving and preparation equipment
LSPREP	Calculates costs of the limestone raw material receiving and preparation equipment
MATBAL	Calculates the material balance based on equilibrium models and the Radian program
MBCON	Initializes coefficients for calculating pressure drop
MECOLL	Calculates costs for the mechanical collector
NSPS	Calculates allowable emissions based on 1979 NSPS
PARTIC	Calculates costs of particulate removal equipment based on Argonne models
PDROP	Calculates flue gas pressure drop attributed to the FGD system
PIPES	Calculates design and costs for piping
PNDPCP	Prints pond cost versus capacity table (available only with interactive pond model)
PND CST	Calculates cost of waste disposal pond
PNDDEP	Prints pond cost versus depth table (available only with interactive pond model)

(Continued)

TABLE 33. (Continued)

Investment program subroutines	Function
PNDEXC	Calculates cost for pond excavation
PNDOPT	Calculates cost for optimum size-depth pond
PNDPRT	Prints design and costs for pond
PNDSGN	Calculates design for pond
PNDSE	Calculates dimensions of pond
PONDS	Allows pond model to be run interactively
PREPSM	Calculates ancillary investment costs for the raw material-handling and feed preparation areas
PRIN	Calls other subroutines for printing input data
PRIN01	Prints short version of program inputs
PRIN02	Prints boiler inputs, composition of raw coal, allowable emissions, and required removal
PRIN03	Prints composition and physical properties of the scrubbing alkali
PRIN04	Prints scrubber, forced-oxidation, and adipic acid inputs
PRIN05	Prints waste disposal, reheat, and water balance inputs
PRIN06	Prints economic premises inputs
PRINTI	Prints all FGD investment costs
PROUT	Calls subroutines for printing program outputs
PROUT1	Prints boiler design and hot gas to scrubber outputs
PROUT2	Prints wet gas from scrubber and flue gas to stack outputs
PROUT3	Prints steam reheater and water balance outputs
PROUT4	Prints scrubber system and system sludge discharge outputs
PROUT5	Prints flow rates of individual species and total flow rate for all liquid streams
READIN	Reads all inputs from unit 5 when model is run in the batch mode
REHEAT	Calculates design for oil-fired reheater option (option not available)
REHETR	Calculates costs for inline steam reheater
SCLAND	Initializes variables for landfill design model
SCRUBB	Calculates design and costs for the SO ₂ absorber
SLPUMP	Calculates costs for rubber-lined slurry pumps
SO2ELM	Calculates SO ₂ removal as % removed, equivalent emission in lbs SO ₂ /MBtu, or ppm SO ₂ in outlet gas
SOOTBL	Calculates costs of sootblowing
SPRINT	Prints short-form FGD investment costs
SRMOD(ICR)	Calculates L/G, stoichiometry, or SO ₂ removal when other scrubber parameters are input
STKGAS	Calculates flow rate and composition of flue gas exiting the stack

(Continued)

TABLE 33. (Continued)

Investment program subroutines	Function
STMRHT	Calculates design and costs for inline steam reheater
STREAM	Calculates composition of liquid FGD system streams
STRUCT	Calculates design and costs of structures
TANKS	Calculates costs for tanks and agitators
TCON	Initializes temperature dependent constants
THICK	Calculates costs for thickener
TOTALS	Sums costs for all components of the FGD system
TVAIN	Calls subroutines for calculating FGD investment costs
VPDROP	Calculates pressure drop or throat velocity for the venturi scrubber
WETGAS	Calculates flow rate and composition for gas exiting the scrubber
WORKCP	Calculates working capital component of FGD investment cost
WRITDS	Writes investment cost to a file for transfer to the revenue requirement model
ZERO	Initializes all major variables to zero

TABLE 34. ALPHABETICAL LISTING OF THE SUBROUTINES IN THE REVENUE REQUIREMENT
PROGRAM IDENTIFYING THE FUNCTION OF EACH SUBROUTINE

Revenue requirement program subroutines	Function
PROGM2	Initializes arrays for lifetime cost projections
PRTALF	Prints first-year annual revenue requirements table
PRTASF	Prints short form of first-year annual revenue requirements table
PRTBLF	Prints titles for lifetime revenue requirements table
PRTBSF	Prints short-print titles for lifetime revenue requirements table
PRTCLF	Prints lifetime revenue requirements projections
PRTCSF	Prints short-print lifetime revenue requirements projections
PRTDLF	Prints summation of lifetime revenue requirements
PRTDSF	Prints short-print lifetime revenue requirements summation tables
RVHEAD	Creates revenue requirements table headings

DESIGN AND ECONOMIC PREMISES FOR EMISSION CONTROL EVALUATIONS

DESIGN AND ECONOMIC PREMISES FOR EMISSION CONTROL EVALUATIONS

INTRODUCTION

These premises provide criteria for economic evaluations of emission control and related processes for electric utility power plants fired with pulverized coal. The design premises define representative coal and power unit conditions and emission control design practices. The economic premises are based on regulated utility economics; they prescribe procedures for determining capital investments and annual revenue requirements. The premises are directly applicable to economic evaluations of coal cleaning; flue gas desulfurization (FGD), nitrogen oxides (NO_x), and fly ash control; bottom ash handling; and ponding or landfill disposal of nonhazardous wastes.

The economic evaluations are based on a conceptual design based on the design premises and developed from engineering data such as flow diagrams, material balances, and equipment costs. Depending on the degree of accuracy specified, some costs are either scaled or developed from detailed design and operating data.

A new 500-MW power unit is used as a base case. Seven coals, representing typical steam coals used in the United States, are defined. Normally an eastern bituminous coal containing 3.5% sulfur and 16% ash (moisture-free basis) is used as the base case coal. The other coals represent eastern bituminous coals with different sulfur contents, western bituminous and subbituminous coals, and lignite.

These premises, updated in late 1983, are based on 1985 costs for capital investment and 1987 costs for annual revenue requirements. The cost basis and other premise criteria are updated periodically; usually the entire premise criteria are updated at one time rather than on a piecemeal basis to maintain the comparability of evaluations made over a period of time. The projection of new cost basis years using current economic factors is the major change from the previous premises, which were used since April 1980. The other changes are relatively minor revisions to the design premises: emission of 95% instead of 92% of the sulfur in eastern bituminous coals, updated spray dryer FGD designs, and a slightly modified landfill design.

DESIGN PREMISES

The design premises specify the coal properties; power unit conditions; emission control requirements; design features of NO_x, SO₂, and fly ash control processes; and waste-handling and disposal methodology.

COAL PREMISES

The premise coals consist of four eastern bituminous coals containing 5.0%, 3.5%, 2.0%, and 0.7% sulfur; a 0.7% sulfur western bituminous coal; a 0.7% sulfur western subbituminous coal; and a 0.9% sulfur North Dakota lignite. They are based on analyses of U.S. steam coals representative of the types in current use (17,18). The analysis data for each of these coals are summarized in Table B-1 and a fly ash analysis for each coal is shown in Table B-2.

TABLE B-2. FLY ASH COMPOSITIONS

Component	Bituminous fly ash, wt %	Subbituminous fly ash, wt %	Lignite fly ash, wt %
SiO ₂	50.8	39.7	23.0

As-fired coal refers to the coal entering the coal-cleaning plant or power plant. This coal is supplied in a 3-inch top size after large rocks and trash have been removed from the run-of-mine coal. Broken coal is assumed to have the particle size distributions represented by the Bennett form of the Rosin and Rammler equation,

$$R = 100e^{-(x/\bar{x})^n}$$

which can be plotted on special graph paper devised by the U.S. Bureau of Mines (BOM) (19) as shown in Figure B-1. In the equation,

x = particle diameter or width of screen aperture in millimeters. It is the abscissa in Figure B-1.

\bar{x} = a size constant, in millimeters, that is specific to each distribution line of particle size. In Figure B-1, it is the value of x when $R = 36.79\%$; in turn $R = 36.79\%$ when $\bar{x} = x$ in the Rosin and Rammler equation.

n = a size distribution constant. In Figure B-1, it is the arithmetical slope of a distribution line. Parallel distribution lines have the same value of n .

e = the base of the natural logarithm.

R = the weight percentage of coal retained on a screen whose aperture is x . R expresses cumulative oversize and is the ordinate in Figure B-1.

For all distribution lines in Figure B-1, the value of n is 0.8840. Values of \bar{x} for selected size distributions are given below.

Nominal top sizes	<u>Actual aperture size</u> (Tyler $\sqrt{2}$ series)		\bar{x} mm
	in.	mm	
3 in.	2.970	75.43	13.40
2 in.	2.100	53.34	9.478
1-1/2 in.	1.485	37.71	6.702
3/4 in.	0.742	18.86	3.351
3/8 in.	0.371	9.429	1.676
3 mesh	0.093	2.357	0.4189
14 mesh	0.046	1.179	0.2094
28 mesh	0.023	0.589	0.1047

B-8

Figure B-1. Rosin-Rammler plots of premise coal sizes.

POWER PLANT

The power plant site is assumed to be in the north-central region (Illinois, Indiana, Ohio, Michigan, Kentucky, and Wisconsin). The location represents an area in which coal-fired power plants burning coals of diverse type and source are situated (20). The design is based on standard design practices (21,22) and current trends in utility boiler construction (23). The base case power unit is a new, single 500-MW, balanced-draft, dry-bottom boiler fired with pulverized coal. The steam pressure is 2,400 psi. The superheat and reheat temperatures are 1,000°F.

Power unit size case variations consist of similar 200-MW and 1,000-MW units. For new units, the systems being evaluated are assumed to be installed during construction of the power plant. New units are assumed to have a 30-year life and to operate at full load for 5,500 hours/yr. For case variations, identical existing units with 20 years of remaining life at 5,500 hours/yr of full-load operation are used. The heat rates are shown in Table B-3. They are based on coal type, unit size, and unit age. To provide for equitable comparisons, the power units are not derated for energy consumption by the systems evaluated. Instead, the energy requirements are charged as independently purchased commodities. Normally, cost estimates are based on a single power unit independent of other units at the site. In cases in which a plant-wide process or system is evaluated, a plant capacity of 1,000 MW is normally used.

TABLE B-3. POWER UNIT HEAT RATE

Power unit size, MW:	New			Existing		
	200	500	1,000	200	500	1,000
Remaining life, years	30	30	30	20	20	20
Full load, hr/yr	5,500	5,500	5,500	5,500	5,500	5,500
Heat rate, Btu/kWh						
Bituminous coal	9,700	9,500	9,200	9,900	9,700	9,500
Subbituminous coal	10,700	10,500	10,200	11,000	10,700	10,500
Lignite	11,200	11,000	10,700	11,400	11,200	11,000

FLUE GAS COMPOSITIONS

Flue gas compositions are based on combustion of pulverized coal assuming a total air rate equivalent to 139% of the stoichiometric requirement (defined as air for combustion of carbon, hydrogen, and sulfur). This includes 20% excess air to the boiler and 19% additional air leakage to the flue gas in the air heater. It is assumed that 80% of the ash present in all coals is emitted

as fly ash. Sulfur emitted is dependent on the coal type; 95% of the sulfur in all eastern coals and 85% of the sulfur in all western coals and lignite are emitted as gaseous sulfur oxides (SO_x). The remaining sulfur is removed in the bottom ash and fly ash. No loss of sulfur in the pulverizers is assumed. Three percent of the sulfur emitted as SO_x is SO_3 and the remainder is SO_2 .

A flow diagram around the boiler is shown in Figure B-2 and detailed boiler material balances and flue gas composition summaries for stream 8, for each premise coal, are shown in Tables B-4 through B-17. The streams shown in the material balances have excess significant digits for cases in which higher accuracy is needed. These numbers are not to be published without rounding to four significant digits, no more - no less.

ENVIRONMENTAL REGULATIONS

Emissions from new coal-fired utility plants are regulated by the new source performance standards (NSPS), which are promulgated by the U.S. Environmental Protection Agency (EPA) under authority of the Clean Air Act as amended in 1970 and 1977 (24). This section requires EPA to set Federal emission limitations that reflect the degree of control that can be achieved by using the best available control technology (BACT). In 1971, EPA issued NSPS to limit emissions of SO_2 , NO_x , and particulate matter from utility power plants (25). The 1971 NSPS specify a maximum emission based on heat input of 0.10 lb/MBtu for particulate matter and 1.2 lb/MBtu for SO_2 . They apply to power units, for which construction began between August 1971 and September 1978. In 1979, EPA revised the NSPS (26) as shown in Table B-18. The controlled outlet SO_2 emission and SO_2 removal efficiencies for the premise coals are shown in Figure B-3 and tabulated in Table B-19.

Equation to determine equivalent SO_2 content of coal:

$$E = (S/H)(2 \times 10^4)$$

where: S = % sulfur in coal, as fired

H = heat content of coal, as fired

E = equivalent SO_2 content of coal as fired, lb equivalent SO_2 /MBtu

Equations to determine overall % sulfur removal required

$$E < 2.0$$

70% equivalent SO_2 removal required

$$2.0 < E < 6.0$$

$$\% \text{ equivalent } \text{SO}_2 \text{ removal required} = ((E - 0.6)/E)(100)$$

EMISSION CONTROL PROCESS DESIGN

With the exception of some standard designs and frequently used reference processes--most notably the limestone FGD process--detailed design features

that will be applicable to all evaluations cannot be specified. The diversities of processes and evaluation objectives and continuing technological advances make such an approach impractical. Most designs must be based on a thorough assessment of the objectives of the study, its relationship to past and possible future studies, and on aspects that enhance the scope and detail of the evaluation.

TABLE B-19. PREMISE COAL EMISSION STANDARDS FOR 1979 NSPS

Coal	Equivalent SO ₂ content of coal, lb SO ₂ /MBtu	Overall equivalent SO ₂ removal efficiency, %	Equivalent SO ₂ removal required in FGD system, % ^a	Controlled outlet emission, lb SO ₂ /MBtu

N.D. lignite, 0.9% S	1.73	70.0	64.7	0.52

a. Based on FGD system as the only SO₂ control device and the previously defined sulfur retention in the ash.

The standardized design features and procedures outlined in the following sections are followed to the maximum extent compatible with the objectives of the evaluation since this facilitates more detailed evaluations of significant design and operating features and more meaningful identification of cost elements. In all cases, the design and costing procedures are based on division of costs into definable functional areas so that the role of particular functions in determining costs can be identified.

Generic designs based on current practices and technology are usually preferable for evaluating technologies in which several vendors offer proprietary processes (limestone FGD, spray dryer FGD, and fabric filter baghouses are examples of the early 1980s). This approach allows a general assessment of the technology and of design trends and practices, less effected by the specific concepts and preferences of individual vendors.

Evaluations of proprietary designs depend on the nature and objectives of the evaluation. Standard design features are used as much as is consistent with the objectives of the evaluation. The vendor's specifications and suggestions are used for all features that represent and define the process while

preferences that have no effect on the function of the process are--to different degrees, depending on the nature of the features and the objectives of the evaluation--avoided if they reduce the comparability of the process economics.

Particulate Matter

Fly ash and bottom ash collection, handling, and disposal or utilization are included in the evaluation of other emission control processes when the inclusion is pertinent to the evaluation or is expected to be in related future evaluations. (However, these costs are not included in the FGD costs from the Shawnee FGD computer model.) The standard bottom ash system consists of conventional vee-bottom water-filled hoppers with clinker grinders, a hydraulic conveying system with a combined ejector pump and centrifugal pump system, and a dewatering system one-fourth mile from the boiler.

Normal fly ash control consists of rigid-frame cold-side (after the air heater) electrostatic precipitators (ESPs) for coals with 2% or more sulfur and rigid-frame hot-side ESPs for coals with less than 2% sulfur. Fabric filter baghouses may be used in place of ESPs, particularly hot-side ESPs in low-sulfur coal cases, if this favors the evaluation. Baghouses are used with spray dryer FGD for particulate collection. Normally, economizer and air heater (and reactor for NO_x control, if used) and ash hoppers are included in fly ash costs.

Vacuum conveying systems are used for conveying distances less than 300 feet. Vacuum-pressure systems are used when longer conveying distances are necessary. In this case, the vacuum system is used to convey the solids from the collection hoppers to one or more collection points, from which they are conveyed to storage silos in the pressure system. Normally, the vacuum-pressure system is used when more than 24 collection hoppers are involved. The design of the waste conveying system is based on standard industry practices.

The bottom ash dewatering bins, fly ash silos, and spray dryer waste silos are sized for a 64-hour capacity to allow a 5-day, 2-shift disposal operation. The bins and silos are elevated for direct discharge to trucks. Silos for eastern coal fly ash are provided with moisturizer-mixers to add water to the ash as it is discharged.

Flue Gas Desulfurization

The FGD system consists of two or more trains of absorbers supplied by a common inlet plenum into which the flue gas from the power unit duct system discharges. The plenum allows optimization of the FGD system design by making it independent of the power plant duct configuration. The plenum and all equipment between it and the stack plenum are included in the FGD costs. This is based on the premise that in the absence of the FGD system, the flue gas discharged to the inlet plenum would be discharged directly to the stack plenum.

Unless process requirements dictate otherwise, the absorber trains have a maximum size of 125 MW or 513,000 sft³/min (60°F), whichever is larger. All systems with capacities of 200 MW or more, or processing 340,000 aft³/min of flue gas, have two or more absorber trains. Each train is assumed to have an annual availability of 85%. Spare trains are included to provide an excess capacity of at least 25%. (This allows the use of an emergency bypass, as discussed below.) All trains, including the spares, are identical although this results in a spare capacity over 25% in some cases: a 200-MW system would have three 100-MW trains, for example. The 500-MW systems with full scrubbing have four operating trains and one spare train and the 1,000-MW systems have eight operating and two spare trains.

All wet-scrubbing systems that do not include prescrubbers such as venturis are equipped with presaturators to cool the flue gas to the saturation temperature (approximately 127°F). Usually these are modified sections of inlet duct equipped with spray headers to spray the flue gas with absorbent liquid. The absorbers are also equipped with mist eliminators and reheaters as required to produce a stack temperature of 175°F. Booster fans are provided to compensate for the pressure drop in the system. Normally, these are induced draft (ID) fans in each train downstream from the reheater.

Emergency Bypass--

Because the 1979 NSPS allow emergency bypass around the FGD system under some conditions if spare scrubbing capacity is provided, spare scrubbing trains and bypass of 50% of the gas that would normally be scrubbed are included. An emergency bypass of 50% of the scrubbed gas is assumed to be an economic balance between the higher cost of providing additional bypass and the small likelihood of multiple scrubbing train failures, which would make higher bypass rates necessary. The bypass is installed as two identical ducts from each end of the inlet plenum to the stack plenum downstream from the scrubbing trains. Particulate collection equipment is not bypassed.

Partial Scrubbing--

In some cases, depending on the sulfur content of the coal and SO₂ removal requirements, scrubbing a portion of the flue gas at a high removal efficiency and combining it with the remaining flue gas may be more economical than scrubbing all of the flue gas at a lower removal efficiency. In such cases, the bypassed gas duct requirements and the emergency bypass capability are combined in the same duct. The ducts are sized to handle both the flue gas normally bypassed and emergency bypass of 50% of the flue gas scrubbed. Depending on sulfur content of the coal, for the 500-MW power unit, partial scrubbing could involve scrubbing as little as 375 MW of flue gas. Three operating scrubbing trains and one spare scrubbing train are provided for this case.

Ductwork--

Square ductwork with 2-inch insulation (in standard cases) is used for the inlet plenum and absorber trains. To prevent ash settling, a gas velocity of 50 ft/sec is used for the inlet plenum, all ductwork, and the emergency bypass. A gas velocity of 25 ft/sec is used for the reheater section. Duct

material is usually 3/16-inch Cor-Ten steel when the gas temperature is higher than 150°F and 3/16-inch stainless steel when the gas temperature is lower than 150°F.

Removal Efficiencies--

It is assumed that 50% of the SO_3 , 95% of the HCl , none of the NO_x , and 50% of the remaining fly ash in the flue gas are removed in the FGD system. For systems requiring a presaturator or humidifier, it is assumed that 5% of the SO_2 is removed in the presaturator and that the remaining SO_2 removal takes place in the FGD absorber.

Mist Eliminator--

The mist eliminator is a fiberglass-chevron-baffle type. The mist eliminator reduces entrained moisture to a maximum level of 0.1% (by weight) of the flue gas. This maximum level is used for calculation of the amount of flue gas reheat required.

Flue Gas Reheat--

A reheater consisting of a steam-heated tube bank is provided in each train to provide a stack temperature of 175°F. This is considered necessary to evaporate corrosive liquid not removed by the mist eliminator and to provide adequate plume buoyancy. The size of the reheater is determined by the temperature of the scrubbed flue gas (which is assumed to be 125°F for wet-scrubbing systems), the quantity of flue gas bypassed, and the heat of compression through the ID booster fans--which is assumed to be equivalent to an adiabatic compression equal to the pressure drop in the FGD system. Necessary information for calculation of the steam requirements and reheater surface area is shown in Table B-20 and a sample calculation is shown in Table B-21.

For full-scrubbing processes, the reheater tubes are Inconel 625 for corrosion resistance below 150°F and the remainder are Cor-Ten steel. In cases in which the scrubbed flue gas is not heated to 175°F (as in the case of partial bypass), the quantity of Inconel tubes remains the same and the quantity of Cor-Ten tubes is reduced.

Piping--

Carbon steel piping is used for water and other noncorrosive and non-abrasive liquids. Stainless steel is used for slurry and other corrosive or abrasive liquid lines 3 inches in diameter or less; neoprene-lined carbon steel is used for larger lines carrying these liquids. For slurry lines, plug valves are used for lines up to 3 inches in diameter; eccentric plug valves are used for 3- to 20-inch lines; and knife gate valves are used for lines larger than 20 inches in diameter. Pneumatic actuators are provided for valves 12 inches in diameter or larger.

Buildings--

Metal buildings are provided when it is necessary to provide weather protection. The buildings have 6-inch concrete floors, insulation, electrical heating, overhead doors, and other features required for their function. Normally, buildings are provided for feed preparation, waste dewatering,

only.

Spare Equipment--

Spare equipment is provided in accordance with general practice. For most processes, the following spares are provided:

- A spare train of crushing and grinding equipment
- Slakers
- Waste filters
- Pumps
- A spare scrubbing train or trains

NO_x Control

Reduction of NO_x emissions to meet the 1979 NSPS is assumed to be met by modifications to the boiler combustion system. Evaluations of NO_x control processes are normally based on an 80% reduction of these emissions.

With the exception of selective catalytic reduction (SCR) processes, NO_x control processes are usually based on proprietary designs. These vary considerably, from various forms of combustion modification and furnace injection to--conceivably--wet scrubbing. The designs in these cases are dealt with on an individual basis, usually following the vendor's specification. For processes that control both NO_x and SO₂, the comparative processes are the standard limestone FGD process and a generic SCR process.

A generic SCR process design is based on the designs of U.S. vendors of the process. For the base case conditions, parallel vertical reactors up to 250 MW in size (two reactors for the 500-MW base case) are used. Flue gas is ducted from the outlet of the boiler economizer to the reactors and from the reactors to the boiler air heater. The air heater is modified to accommodate the buildup of ammonia salts and the incremental costs are included in the NO_x control costs. An economizer bypass to maintain the flue gas temperature during low-load operation and an emergency bypass for the reactors are also included. No spare reactor trains are provided. The assumed catalyst life is equivalent to the catalyst life generated by process vendors and the catalyst volume is based on maintenance of the design NO_x reduction over the catalyst life. Boiler operation is assumed to be unaffected by the process (catalyst changes and other maintenance occur during boiler outages).

WASTE PROCESSING AND DISPOSAL

For processes producing a waste, either landfill or pond disposal is provided. Normally, an onsite disposal facility one mile from the process facility is used. The size of the disposal facility is based on the lifetime volume of waste. Both the landfill and pond designs and costs are determined using the landfill and pond models in the Shawnee computer model.

Normally, landfill disposal is used for ash and insoluble FGD waste. Ponds are used for wastes such as coal-cleaning fines that are not normally dewatered. Ponds, which serve as solid impoundments, are also used for soluble wastes such as sodium-based FGD waste.

Waste storage facilities are normally based on truck transport and landfill disposal on a 2-shift, 5-day-week schedule. A 64-hour silo and stockpile storage capacity is provided to allow the landfill operating schedule. For pond disposal--which may be used in special studies or for waste that is normally ponded--an 8-hour storage tank is provided. The waste is pumped directly to the pond and the supernate is returned for reuse.

Waste Properties

The densities upon which equipment sizes and storage volumes are based are shown in Table B-22. Settled and compacted moisture contents and bulk densities are also shown for use in disposal site designs, which are discussed below. These are used in conceptual design evaluations in which uniform representative values are more useful than specific values or in which specific data are unavailable. The values in Table B-22 are based on published data and are representative of the rather large range over which the moisture contents and bulk densities of most wastes vary, depending on the conditions under which they were produced. In evaluations based on specific wastes, measured values or more specific estimates should be used.

TABLE B-22. WASTE BULK DENSITIES

	<u>Model defaults bulk density, lb/ft³</u>	
	<u>In-process waste</u>	<u>Compacted</u>
<u>Waste Sludge</u>		
Sulfite (filtered)	70	85
Gypsum (filtered)	75	95
Fixed sulfite (filtered)	90	106
Fixed sulfate (filtered)	85	100
Dry FGD waste	70	85

FGD Waste Processing and Handling

High-sulfite slurry (70% $\text{CaSO}_3 \cdot 1/2\text{H}_2\text{O}$ and 30% $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$) is normally dewatered and mixed with dry fly ash and lime (100% fly ash and 3.5% lime, both based on the dry weight of FGD solids) for landfill disposal. The slurry from the absorbers is first dewatered to 30% solids in a thickener, then filtered to 55% solids in rotary vacuum filters. The filter cake is mixed with the fly ash and lime in a pug mill and conveyed to a radial-arm stacker that stacks it in a 64-hour capacity stockpile for removal to a landfill.

Gypsum waste (95% $\text{CaSO}_4 \cdot \text{H}_2\text{O}$ or more) is thickened to 30% solids and filtered to 85% solids in rotary vacuum filters. The filter cake is stacked in a 64-hour capacity stockpile by a radial-arm stacker from which it is removed to a landfill.

Waste Transportation

Trucks are used for transportation of solid wastes. Bottom ash and fly ash are discharged directly from the elevated dewatering bins and silos into the trucks. A moisturizer-mixer mounted on the storage silo is used to add water to fly ash from eastern bituminous coal (the quantity of water is based on the optimum compaction moisture) to control dusting. Other fly ash and spray dryer FGD waste, which is likely to have cementitious properties, is moisturized with similar truck-mounted moisturizers at the disposal site.

Wastes in slurry form are sluiced to the disposal site and the supernate is returned for reuse. If the slurry is abrasive (ash and coal-cleaning waste), an abrasion-resistant ash-sluicing pipe is used. Equipment for control of the return water pH and scaling potential is included in all wet sluicing systems.

Disposal Site

Both the pond and landfill design and costs are determined using the Shawnee flue gas desulfurization computer model, which allows numerous design variations. The standard conditions are described below. The disposal site is normally situated one mile from the process facility. Sufficient land is provided for disposal during the remaining life of the facility. The disposal site is assumed to be an area of low relief with sufficient soil for dike construction or landfill requirements.

Pond--

Disposal ponds are square, earthen-diked enclosures with a medium diverter dike. Dikes are constructed from material removed from the impoundment area as shown in Figure B-4. The entire impoundment area is lined with 12 inches of clay (assumed available onsite). Pond size and depth are normally adjusted to minimize the sum of land and construction costs. Pond costs include a 6-foot security fence around the perimeter dike, security lighting, a topsoil storage area, and one upstream and three downstream groundwater monitoring wells.

Landfill--

The landfill, one mile from the fixation area, has a square configuration with a 20-foot rise and a 6-degree cap, as shown in Figure B-5. After topsoil removal, the landfill area is lined with 12 inches of clay (assumed available onsite) with a drain system to a sump and 24 inches of bottom ash is placed on the liner. Surface runoff drains into a catchment ditch around the perimeter. The ditch drains into a catchment basin for pH adjustment. Land requirements include the landfill, the catchment basin, an office, equipment storage area, topsoil storage area, and a 50-foot perimeter of undisturbed land. Costs for access roads; a 6-foot security fence around the total landfill area; security lighting; and topsoil stripping, replacement, and revegetation are included. One upstream and three downstream groundwater monitoring wells are also included.

Figure B-5. Landfill design.

ECONOMIC PREMISES

Schedule and Cost Factors

The construction schedule used as a cost basis is shown in Figure B-6. A 3-year construction period, from early 1984 to late 1986, is used. Mid-1985 costs are used for capital investment. Mid-1987 costs are used for annual revenue requirements. These costs represent the midpoint of construction expenditures and the midpoint of the first year of operation. Costs are projected from Chemical Engineering cost indexes (27), as shown in Table B-23. Frequently used costs are shown in Table B-24.

Capital Cost Estimates

Four grades of capital cost estimates are prepared depending upon the intended use and the amount of information available. The grades, in increasing order of accuracy, are (1) order of magnitude, (2) study, (3) preliminary, and (4) definitive. The two grades normally used are the study and preliminary grades. The purpose, information required, and predicted accuracy are listed in Table B-25.

A typical capital investment sheet is shown in Table B-26. The capital investment sheet is divided into three major sections: direct investment, indirect investment, and other capital investment.

Direct Investment--

Direct investment consists of total process capital; services, utilities, and miscellaneous; and waste disposal investment. Total process capital is determined from the equipment list. Using standard estimating techniques (28,29,30) and the Chemical Engineering cost indexes and projections shown in Table B-23, the equipment cost and installation costs of each area are estimated. The installation costs include charges for all piping, foundations, excavations, structural steel, electrical equipment, instruments, ductwork (all ductwork is included in the gas-handling area), paint, buildings, taxes, freight, and a premium for 7% overtime construction labor as shown in Figure B-7. The total process area costs are summed on the area summary sheet shown in Figure B-8 to give the total process capital.

Service facilities such as maintenance shops, stores, communications, security, offices, and road and railroad facilities are estimated or allocated on the basis of process requirements. Included in the utilities investment are necessary electrical substations, conduit, steam, process water, fire and service water, instrument air, chilled water, inert gas, and compressed air distribution facilities. Services, utilities, and miscellaneous are in the range of 4% to 8% of the total process capital. For most cases, 6% is to be used, higher for processes and lower for waste disposal facilities. The base case limestone-scrubbing process is charged 6% for services, utilities, and miscellaneous.

All equipment and direct construction costs associated with waste disposal are included in waste disposal costs. For ponds, this includes pond

1985 Land Cost

\$6,000.00/acre

These cost factors are based on a north-central plant location.

TABLE B-25. CAPITAL COST ESTIMATE CLASSIFICATION

Grade	Purpose	Minimum information required	Predicted accuracy,	
			+%	-%
Order of magnitude (ratio estimate)	Preliminary feasibility study to determine whether continued investigation is merited. Rough comparison of alternatives.	General design basis, ^a flowsheet and material balance, heat and energy balance. For the order-of-magnitude estimates, this information is of a tentative nature, developed from a preliminary process concept.	>50	>50
Study (factored estimate)	Comparison of alternatives. Preliminary screening. Preliminary budget preparation. Authorization for funding for an engineering study or for development of additional information.	All of the above on a firm, rather tentative basis plus overall layout of manufacturing and nonmanufacturing facilities, sized equipment and instrument lists, and performance data sheets.	40	20
Preliminary (initial budget or scope estimate)	Preliminary budget approval. More accurate comparison of alternatives. Follow up of an order-of-magnitude or study estimate.	All of the study estimate requirements plus process control diagrams, process piping sketches with sizes, plan and elevation drawings, offsite descriptions, including sizes and capacities.	30	15
Definitive (project control estimate)	Final capital authorization. Project cost control. Follow up on order-of-magnitude, study, or preliminary estimates for more accurate information. Generally reserved for a real construction project with a known site.	All of the preliminary estimate requirements plus piping plan and elevation drawings integrated with the equipment plan and elevation drawings, electrical layout single line drawings, detailed piping and instrumentation flowsheets, layout of non-manufacturing facilities, design sketches for unusual equipment items, and specific site data, including utilities and transportation availability, soil bearing, wind and snow loads.	20	10

a. General design basis includes product, product specifications, plant capacity, storage requirements, operating stream time, provisions for expansion, and raw materials and their storage requirements.

construction costs from the computer pond model. For landfills, mobile equipment and construction costs are included. All mobile equipment involved in loading and transporting the waste from the in-process storage area, as well as working the landfill, is included in solids disposal equipment. The landfill construction cost, as calculated from the landfill computer model, is listed separately from the solids disposal equipment. The sum of total process capital; services, utilities, and miscellaneous; and the waste disposal cost is the total direct investment.

Indirect Investment--

Indirect capital investment covers fees for engineering design and supervision, architect and engineering contractor, construction expense, contractor fees, and contingency. Listed in Table B-27 are the ranges to be used to calculate the process and waste disposal indirect investments. The base percentages are normally used. The low and high ranges are used if the process being studied is either much more complex than the typical system (the higher percentage factors are used) or much less complex (the lower percentage factors are used). The limestone- and lime-scrubbing processes use the low percentages for a 1,000-MW unit, base percentages for a 500-MW unit, and the high percentages for a 200-MW unit. Contingency is included to compensate for unforeseen expenses. The contingency varies depending on the process and the waste disposal method, as shown in Table B-28. The limestone- and lime-scrubbing processes are assessed a contingency of 10% for the process and 20% for the landfill.

Other Capital Investment--

The allowance for startup and modifications is applied as a percentage of the total fixed investment. Since the startup and modification costs for the waste disposal area are assumed to be negligible, this allowance is calculated as a percentage of the total process fixed investment only. The values used are shown in Table B-29. The limestone- and lime-scrubbing processes are assessed at a rate of 8% for this charge.

The cost of borrowed funds (interest) during construction is 15.6% of the total fixed investment (both process and waste disposal). This factor is based on an assumed 3-year construction schedule and is calculated with a 10% weighted cost of capital with 25% of the construction expenditures in the first year, 50% in the second year, and 25% in the third year of the project construction schedule. Expenditures in a given year are assumed uniform over that year. Startup costs are assumed to occur late enough in the project schedule that there are no charges for the use of money to pay startup costs. Table B-30 illustrates the calculation of the interest during construction for 3- through 6-year construction schedules.

Most processes will include a one-time royalty charge using either an actual royalty obtained from the vendor or 1% of the total process capital involved. Processes exempt from royalties due to their generic design are limestone and lime processes, including those with forced oxidation or adipic acid or both, and the magnesia process.

1-0	0.9538	1.0484

Land--

All land associated with the process and waste disposal area is charged to the process. The cost of land is \$6,000 per acre.

Working Capital--

Working capital is the total amount of money invested in raw materials, supplies, finished products, accounts receivable, and money on deposit for payment of operating expenses. For these premises, working capital is defined as the equivalent cost of 1 month's raw material cost, 1.5 months' conversion cost, 1.5 months' plant and administrative overhead costs (all of the above are found on the annual revenue requirements sheet), and 3% of the total direct capital investment (from the capital investment sheet). One month is defined as 1/12 of annual costs. The equation is shown below:

$$\begin{aligned}\text{Working capital} = & 1/12 (\text{total raw materials cost}) + \\ & (1.5) (1/12) (\text{total conversion cost}) + \\ & (1.5) (1/12) (\text{plant and administrative overhead}) + \\ & 0.03 (\text{total direct investment})\end{aligned}$$

Battery Limits--

Since battery limits costs typically include most of the associated indirect investments, battery limits costs have their own indirect investment factors as shown below:

	<u>% of battery limits cost</u>
Engineering design and supervision	6
Architect and engineering contractor	1
Construction expense	14
Contractor fees	0
Contingency	10

Retrofit Factor--

For existing plant cases, a retrofit factor is assigned to cover the additional investment required. Each of the area investments (i.e., material handling, etc.) is multiplied by the retrofit factor. Retrofit factors vary widely depending on the process and the site involved (31). For emission control processes which are coupled to the boiler, the following retrofit factors are used:

<u>Process</u>	<u>Retrofit factor</u>	<u>Reason</u>
Limestone scrubbing	1.3	These scrubbing systems are add-on in that they require no boiler modifications. This factor for the retrofit cases is due to the need to fit the equipment into available space.
Spray dryer	1.5	These scrubbing systems require relatively minor modifications to the boiler and ductwork. This factor also includes the expense of fitting the equipment into the available space.
NO _x FGT (SCR)	1.7	These control systems require extensive modifications to the boiler economizers and air heaters and the associated ductwork. This factor also includes the expense of locating the equipment in the available space.

It is assumed that most FGD systems will be of the add-on type and, therefore, use the 1.3 retrofit factor.

Annual Revenue Requirements

Annual revenue requirements consist of various direct and indirect operating and maintenance costs and capital charges. Annual revenue requirements normally vary from year to year as operating and maintenance costs change and capital charges decline. Thus, no single year is necessarily representative of the lifetime costs, nor can single-year undistorted comparisons be made among processes with different ratios of operating costs to capital charges. In addition, it is necessary to take into account the effect of time on the value of money (for inflation, the future earning power of money spent, and other factors).

Frequently these factors are accounted for by levelizing (32). Levelization converts all the varying annual revenue requirements to a constant annual value, such that the sum of the present worths of the levelized annual revenue requirements equals the sum of the present worths of the actual annual revenue requirements. The levelized value is calculated by multiplying the revenue requirements for each year by the appropriate present worth factor and summing the present worth values. Then the single present worth value is converted to equal annual values by multiplying the result by the capital recovery factor.

In these premises, the operating and maintenance costs are levelized by multiplying the first-year operating and maintenance cost by a levelizing factor. The levelized capital charges are determined by levelizing the percentage of capital investment applied yearly as capital charges. The

levelizing factor includes a discount factor reflecting the time value of money and an inflation factor reflecting the effects of inflation during the operating life of the system. The discount rate used is 10% and the inflation rate used is 6%. The levelizing factor produced varies with the remaining life of the system. Calculation of the levelizing factor for operating and maintenance costs and of levelized capital charges is discussed below.

A typical annual revenue requirement tabulation is shown in Table B-31. Direct costs consist of raw material and conversion costs. These, combined with overheads, are the operating and maintenance costs. For processes that produce a salable byproduct, byproduct sales are applied as a credit to the operating and maintenance costs. Levelized capital charges are calculated as a percentage of the capital investment and added to the operating and maintenance costs to provide the first-year annual revenue requirements. The levelized annual revenue requirements are determined by multiplying the operating and maintenance costs by the levelizing factor and adding the product to the same levelized capital charges used in the first-year annual revenue requirements.

Operating and Maintenance Costs--

Frequently used raw material costs and standard conversion costs are shown previously in Table B-24. Other costs are obtained from vendors or published information. These costs are converted to 1987 costs using the cost indexes in Table B-23 or industry projections.

Raw materials--Consumables required for their chemical or physical properties, other than fuel for the production of heat, are classified as raw materials. Raw material costs are determined as necessary from vendor quotations or published sources and escalated to 1987 costs. All costs are delivered costs.

Operating labor and supervision--Unit labor costs for 1987 were shown in Table B-24. The allocation of operating labor and supervision depends on the process complexity, number of process areas, labor intensity of the process, and operating experience.

Utilities--Services used, such as steam, electricity, process water, fuel oil, and heat credits, are charged under the utilities heading. Unit 1987 costs are shown in Table B-24. Costs for steam and electricity are based on the assumption that the required energy is purchased from another source. This simplifying assumption eliminates the need to derate the utility plant. Process water requirements are defined as any water used by the process being evaluated and are usually determined by the material balance. Steam requirements are for flue gas reheat and process requirements. Electrical power requirements are determined from the installed horsepower of operating electrical equipment (excluding the horsepower of spare equipment). Each motor in operation is assumed to be operating at rated capacity, although this results in higher power consumptions than would actually occur. Electrical requirements are obtained from the equipment list, where the motor horsepower is identified, plus an additional amount for functions such as lighting. A sample calculation is shown in Table B-32.

TABLE B-31. ANNUAL REVENUE REQUIREMENTS SHEET

TABLE B-32. SAMPLE ELECTRICAL REQUIREMENT CALCULATION

Electricity requirements are determined by summing the horsepower of all operating electrical equipment and multiplying by a factor of 0.7457 kW/hp. It is assumed that the instantaneous load factor and the power load factor are equal and thus cancel. Additional electricity is added for functions such as lighting. For the limestone and lime processes, 100 kW is added. For other processes, more or less electricity, depending on the process type, size, and complexity, may be necessary.

Sample Calculation

<u>Area</u>	<u>Total operating hp</u>
Materials handling	70.5
Feed preparation	797.5
Gas handling	3,580.0
SO ₂ absorption	6,189.0
Stack gas reheat	0.0
Oxidation	4,903.0
Solids disposal	<u>71.0</u>
Total	15,611.0 hp
15,611 hp x 0.7457 kW/hp =	11,641 kW
	<u>+ 100 kW</u>
	11,741 kW
11,741 kW x 5,500 hr =	64,575,500 kWh

Maintenance--Process maintenance costs are 3% to 10% of the total direct process capital investment depending on process complexity, process equipment, materials handled, process areas, and unit size. The percentages shown in Table B-33 are used under most circumstances. For specific FGD processes, the maintenance percentages shown in Table B-34 are used. For example, a 500-MW limestone-scrubbing process normally has a maintenance factor of 8%.

Waste disposal maintenance costs are estimated from the appropriate model and are typically 3% of the waste disposal site construction costs. Maintenance costs for waste disposal are not shown separately. If no other information is available, the maintenance material-to-labor ratio can be assumed to be 60:40.

TABLE B-33. MAINTENANCE FACTORS

Process conditions	% of total direct investment excluding waste disposal		
	Low	Base	High
Corrosive or abrasive slurry	6	8	10
Solids, high pressure, or high temperature	4	5	6
Liquids and gases	3	4	5

TABLE B-34. MAINTENANCE FACTORS FOR SPECIFIC FGD PROCESSES

	Maintenance, % of total direct investment			
	FGD system			Waste disposal
	200 MW	500 MW	1,000 MW	
Limestone and lime (generic)	9	8	7	3
Double alkali	7	6	5	3
Wellman-Lord	7	6	5	-
Magnesia	8	7	6	-
Lime spray dryer (including baghouse)	7	6	5	3

Analysis--Analysis costs are based on process complexity and are listed as a single entry.

Plant and Administrative Overheads--Plant and administrative overheads include plant services such as safety, cafeteria, and medical facilities; plant protection and personnel; general engineering (excluding maintenance), interplant communications and transportation; and the expenses connected with management activities. Plant and administrative overheads for the FGD process are 60% of the total conversion costs less utilities.

Marketing Overhead--This is calculated as 10% of byproduct sales income.

Byproduct Credit--Total revenue from the sale of byproducts is applied as a credit to processes in which a byproduct is salable.

Capital Charges--

Capital charges are those costs incurred by construction of the facility that must be recovered during its life. They consist of returns on equity and debt (discount rate), depreciation, income taxes, and other costs such as insurance and local taxes. In keeping with common practice for investor-owned utilities, the weighted cost of capital is used as the discount rate. Depreciation is stated as a sinking fund factor to simplify calculations. An allowance for interim replacement is included to compensate for possible early retirement of the facility. Credits are also included for tax preference allowances. The capital charges are shown in Table B-35. In keeping with standard practice, book, tax, and economic lives are used in the following calculations. In these premises, however, all three are assumed to be equal.

TABLE B-35. LEVELIZED ANNUAL CAPITAL CHARGES

Remaining life, years	Levelized annual capital charge as % of total capital investment			
	15	20	25	30
Weighted cost of capital	10.00	10.00	10.00	10.00
Depreciation (sinking fund factor)	3.15	1.75	1.02	0.61
Annual interim replacement	0.72	0.67	0.62	0.56
Levelized accelerated tax depreciation	(1.44)	(1.43)	(1.40)	(1.36)
Levelized investment tax credit	(2.39)	(2.14)	(2.00)	(1.93)
Levelized income tax	3.96	4.08	4.20	4.31
Insurance and property taxes	<u>2.50</u>	<u>2.50</u>	<u>2.50</u>	<u>2.50</u>
Levelized annual capital charge	16.5a	15.4a	14.9a	14.7a

a. Rounded to three significant figures.

The capital structure is assumed to be 35% common stock, 15% preferred stock, and 50% long-term debt. The cost of capital is assumed to be 11.4% for common stock, 10.0% for preferred stock, and 9.0% for long-term debt. The weighted cost of capital (WCC) is 10.0%. The discount rate (r) is equal to the weighted cost of capital.

Other economic factors used in financial calculations are a 10% investment tax credit rate, 50% State plus Federal income taxes, 2.5% property tax and insurance, and an annual inflation rate of 6%. Salvage value is assumed to be less than 10% and equal to removal cost.

Weighted cost of capital is calculated as follows:

$$\text{WCC} = (\text{fraction long-term debt}) (\text{long-term debt cost, \%}) + \\ (\text{fraction preferred stock}) (\text{preferred stock cost, \%}) + \\ (\text{fraction common stock}) (\text{common stock cost, \%})$$

The sinking fund factor method of depreciation is used since it is equivalent to straight-line depreciation leveled for the economic life of the facility using the weighted cost of capital. The use of the sinking fund factor does not suggest that regulated utilities commonly use sinking fund depreciation. All factors and rates are expressed as decimals. The equation is:

$$\text{SFF} = (\text{WCC}) / ((1 + \text{WCC})^{\text{Ne}} - 1)$$

where: SFF = sinking fund factor
WCC = weighted cost of capital
Ne = economic life in years

An annual interim replacement (retirement dispersion) allowance of 0.56% for new plants and 0.67% for existing plants is also included as an adjustment to the depreciation account to ensure that the initial investment will be recovered within the actual rather than the forecasted life of the facility. Since power plant retirements occur at different ages, an average service life is estimated. The type S-1 Iowa State (33) retirement dispersion pattern is used. The S-1 pattern is symmetrical with respect to the average life axis and the retirements are represented to occur at a low rate over many years. The interim replacement allowance covers replacement of individual items of equipment with typical lifespans less than the life of the power plant. Repair of other equipment is covered by the maintenance charge.

Tax preference allowances are incentives designed to encourage investment as a stimulus to the overall economy. The basic accounting method used is the flow-through method which passes the tax advantage to revenue requirements as soon as they occur.

Using the sum of the years digits method, which allocates costs early in the life of the facility, the accelerated tax depreciation (ATD) is calculated as follows:

$$\text{ATD} = (2)(\text{CRF}_e)(\text{N}_t - (1/\text{CRF}_t)) / (\text{N}_t)(\text{N}_t + 1)(\text{WCC})$$

where: CRF_e = capital recovery factor (WCC + SFF) for the economic life
CRF_t = capital recovery factor (WCC + SFF) for the tax life
N_t = tax life in years

Levelized accelerated tax depreciation is calculated as follows:

$$\text{LATD} = (\text{ATD} - \text{SLD})(\text{ITR})/(1 - \text{ITR})$$

where: SLD = straight-line depreciation
 $= 1/N_b$
 N_b = book life in years
 ITR = income tax rate

The levelized investment tax credit is calculated as follows:

$$\text{LITC} = (\text{CRF}_e)(\text{investment tax credit rate})/(1 + \text{WCC})(1 - \text{ITR})$$

The levelized income tax is calculated as follows:

$$\text{LIT} = (\text{CRF}_b + \text{AIR} - \text{SLD})(1 - ((\text{debt ratio} \times \text{debt cost})/\text{WCC}))(\text{ITR})/(1 - \text{ITR})$$

where: LIT = levelized income tax
 CRF_b = capital recovery factor ($\text{WCC} + \text{SFF}$) for the book life
 AIR = annual interim replacement

The capital charges are applied as a percentage of the total capital investment, including land and working capital. Although land and most of working capital cannot be depreciated and are not subject to investment tax credit, their inclusion has an insignificant effect on capital charges.

Levelized Operating and Maintenance Costs--

Assuming a constant inflation rate, the levelized operating and maintenance costs are determined by multiplying the first-year operating and maintenance costs by an appropriate levelizing factor, L_f . The levelizing factor is calculated as follows:

$$L_f = \text{CRF}_e (K + K^2 + K^3 + \dots + K^N)$$
$$= \text{CRF}_e (K(1 - K^N))/(1 - K)$$

where: CRF_e = capital recovery factor ($\text{WCC} + \text{SFF}$) for the economic life (see the discussion of capital charges)
 K = $(1 + i)/(1 + r)$; present worth of an inflationary value
 i = inflation rate
 r = discount rate
 N_b = book life in years

An inflation rate of 6% ($i = 0.06$) and a discount rate of 10% ($r = 0.10$) are used for new units. Values of L_f for power units with a remaining life of

15, 20, 25, and 30 (new unit) years are shown in Table B-36. The first-year operating and maintenance costs are multiplied by the appropriate L_f to obtain the levelized operating and maintenance costs.

TABLE 36. LEVELIZING FACTORS

Book ^a life, N_b	$K = \frac{1+i}{1+r}$	$\frac{K(1-K^{N_b})}{1-K}$	CRF _b ^b (r, N_b) ^b	Levelizing factor, L_f
15	0.96364	11.2965	0.13147	1.485
20	0.96364	13.8669	0.11746	1.629
25	0.96364	16.0028	0.11017	1.763

a. Same as economic life (N_e) and tax life (N_t).

b. Discount rate (r) of 10%.

c. New units.

SI SYSTEM NOTATION

The SI system of metric units is not used as the primary numerical system in these premises because of the widespread use of traditional units in correlative and supportive literature and general practice. Use of the SI system is not standardized in the utility industry, although steps in this direction are being made (34). The SI system specifies a number of rules of usage, form, and style in addition to the numerical standards. These too are part of the SI system and should be followed when using it. Detailed procedures for use of SI conventions in the primary data or conversion to SI convention are readily available in the literature. A detailed general guide to SI convention is available in ASTM E 380 79 (35). To provide uniformity in the comparison of data developed from these premises, such a guide should be consulted in using the SI system.

Appendix C

DETAILED DESCRIPTIONS OF MODEL INPUT VARIABLES

TABLE C-1. MODEL INPUTS - FORTRAN VARIABLE NAMES

Line	
1	XINPUT XBC XALK XSSV XSRHT
2	OUTPUT XHGAS XWGAS XRAIR XRGAS XSRHO XSKGAS XSSO XDIS XSTR XGPM XIT
3	IRPT IFAST IEQPR IWTBAL NOPART
4	Case identification (up to 72 alphanumeric characters)
5	XESP MW BHR HVC EXSAIR THG XRH KEPASS KPASO2 PSSO2X KCLEAN PREC SPASH WWRITE TSK TSTEAM HVS
5B	SMRW SMCL ASHCLN HVCLN
6A	INPOPT WPC WPH WPO WPN WPSUL WPCL WPASH WPH20 SULO ASHO IASH ASHUPS ASHSCR
6B	INPOPT VCO2 VHCL VSO2 VO2 VN2 VH20 SCFM WASH SULO ASHO IASH ASHUPS ASHSCR
7	XLG VLG VTR V VRH ISO2 XS02 TR ISR SRIN XIALK IADD WPMGO XMGOAD AD ADDC WPI WPM ASHCAO ASHMGO
8	WPS PSD RS PSC IFOX OX SRAIR PSF FILRAT PHLIME IVPD VPD DELTAP PRES IFAN

11	ENGIN ARCTEC FLDEXP FEES CONT START CONINT XINT PCTMNT PDMNTP XINFLA IECON PCTOVR XLEVEL/PCTADM CAPCHG/UNDCAP PCTMKT/PCTINS
12	ITAXFR TXRAT FRRAT SERVRT ROYALT IOTIME OTRATE INDPND PENGIN PARCH PFLDEX PFEEES PCONT PSTART
13	UC(1) - UC(11) XINDEX YINDEX INVYR IREVYR
14	IOPSCH ONCAP IYROP PNDCAP BAGDLP BAGRAT BGCOST BGLIFE EFFPS ESPDLP RESIST SCARAT ICEPYE CEPNDX
15	IA(1) - IA(10)
16	IA(11) - IA(20)
17	IA(21) - IA(30)
18	END or NEXT

Note: Line 5B is needed only if KCLEAN ≥ 1 . Lines 15-18 are needed only if IOPSCH = 3. The number of entries required on lines 15-17 depends on the number of years specified with the IYROP variable on line 14. Although 30 years is normally used as a maximum plant life, up to 50 years are allowed and up to two additional lines may be used for IA(31) - IA(50).

TABLE C-2. MODEL INPUT VARIABLE DEFINITIONS

Line No.	Variable	Definition	Unit or value
1	XINPUT	Option to control the printing of input data variables. If a value of zero is selected, no input data variables are printed; the options to individually control the printing of input variables are ignored.	0 = no input data printed 1 = print input variables according to individual input print options
1	XBC	Controls the printing of boiler characteristics input variables.	0 = no print 1 = print
1	XALK	Controls the printing of alkali input variables.	0 = no print 1 = print
1	XSSV	Controls the printing of scrubber system input variables.	0 = no print 1 = print
1	XSRHT	Controls the printing of steam reheater input variables.	0 = no print 1 = print
2	OUTPUT	Option to control the printing of model output. If a value of zero is selected, no output listings are printed and the options to individually control the printing of output listings are ignored.	0 = no output data printed 1 = print output listings according to individual output print options
2	XHGAS	Controls the printing of calculated properties of hot gas to scrubber.	0 = no print 1 = print
2	XWGAS	Controls the printing of calculated properties of wet gas from scrubber.	0 = no print 1 = print
2	XRAIR	Controls the printing of calculated properties of reheater air.	0 = no print 1 = print
2	XRGAS	Controls the printing of calculated properties of reheater gas (oil-fired reheater only).	0 = no print 1 = print

(Continued)

TABLE C-2. (Continued)

Line No.	Variable	Definition	Unit or value
2	XSRHO	Controls the printing of calculated properties of inline steam reheater.	0 = no print 1 = print
2	XSKGAS	Controls the printing of calculated properties of stack gas.	0 = no print 1 = print
2	XSSO	Controls the printing of calculated scrubber system parameters.	0 = no print 1 = print
2	XDIS	Controls the printing of calculated properties of system discharge stream.	0 = no print 1 = print
2	XSTR	Controls the printing of calculated properties of scrubber system internal streams (excluding sludge discharge and makeup water). This option does not affect the printout of total stream flow rate.	0 = no print 1 = print
2	XGPM	Controls the printing of total flow rates (gpm and lb/hr) of internal streams (excluding sludge discharge and makeup water).	0 = no print 1 = print
2	XIT	For the iterative calculation of stoichiometry, this option controls the printing of the iteration number and of the current and the preceding stoichiometry values.	0 = no print 1 = print
3	IRPT	Option to select either a short-form printout (totals only) or a long-form printout.	0 = short print 1 = long print
3	IWAST	Controls the printing of calculated waste disposal flow rates, physical properties and resulting costs.	0 = no print 1 = print

(Continued)

TABLE C-2. (Continued)

Line No.	Variable	Definition	Unit or value
3	IEQPR	Controls the printing of equipment list.	0 = no print 1 = print entire list 2 = print only material-handling and feed preparation area lists 3 = Print only gas-handling, SO ₂ scrubbing, oxidation, and reheat area lists 4 = Print only solids separation area list 5 = Print only landfill area list
3	IWTBAL	Controls the printing of calculated properties of water balance scrubber.	0 = no print 1 = print
3	NOPART	Controls the printing of input design conditions and calculated properties projected by the Argonne particulate removal model.	0 = no print 1 = print
4	CASEID	Case identification - this field is free form and may be up to 72 characters in length.	
5	XESP	Particulate collection option No mechanical collector available Mechanical collector available Print internal model examples (costs are not included in FGD costs).	0 1 2

(Continued)

TABLE C-2. (Continued)

Line No.	Variable	Definition	Unit or value
5	MW	Electric power output	megawatts
5	BHR	Boiler heat rate	Btu/kWh
5.	HVC	Heating value of coal	Btu/lb
5	EXSAIR	Excess air	%
5	THG	Temperature of hot gas to scrubber	OF
5	XRH	Reheat option No reheat Inline steam reheater (XRH value = 2) is the only type of reheat available at this time.	0 2
5	KEPASS	Emergency bypass option No emergency bypass Emergency bypass	0 1
5	KPASO2	Partial scrubbing/bypass option No partial scrubbing/bypass Partial scrubbing/bypass	0 1
5	PSSO2X	Percent SO ₂ removal in the scrubber when partial scrubbing/bypass is specified	% removal
5	KCLEAN	Coal-cleaning option No coal cleaning - line 5B must not be input Coal cleaning - line 5B is required input	0 1
5	PREC	Percent weight recovery (lb clean coal per 100 lb raw coal) when coal cleaning is specified	%
5	SPASH	Weight percent of sulfur in cleaned coal when coal cleaning is specified	wt %
5	WPRITE	Weight percent of pyritic sulfur in raw coal when coal cleaning is specified	wt %

(Continued)

TABLE C-2. (Continued)

Line No.	Variable	Definition	Unit or value
5	TSK	Temperature of stack gas	OF
5	TSTEAM	Temperature of reheater steam	OF
5	HVS	Heat of vaporization of reheater steam	Btu/lb
5B	SMRW	Surface moisture of raw coal	wt %
5B	SMCL	Surface moisture of cleaned coal	wt %
5B	ASHCLN	Ash content of cleaned coal	wt %
5B	HVCLN	Heating value of cleaned coal	Btu/lb
<p>The composition input specified on either line 6A or 6B depends on the composition option, INPOPT. If a coal composition will be input (INPOPT = 1) then line 6A is used. If a flue gas composition will be input (INPOPT = 2) then line 6B is used.</p>

TABLE C-2. (Continued)

Line No.	Variable	Definition	Unit or value
6A	SULO	Sulfur to overhead as SO ₂ gas (remainder goes to bottom ash).	wt %
6A	ASHO	Ash to overhead as particulates (remainder goes to bottom ash).	wt %
6A	IASH	Unit of measure option for particulate removal Default to model assumptions Percent removal Pounds particulates per MBtu Upstream removal (percent) with scrubber default (The actual values for particulate removal are provided by the ASHUPS and ASHSCR variables that immediately follow.)	0 1 2 3
6A	ASHUPS	Value for particulate removal upstream from scrubber. (Unit of measure is indicated by the IASH option above.)	
6A	ASHSCR	Value for particulate removal within scrubber. (Unit of measure is indicated by the IASH option above.)	
6B	INPOPT	Composition input option Flue gas composition will be input using line 6B	2
6B	VC02 }		
6B	VHCL }		
6B	VS02 }	-- Amount of component (CO ₂ , HCl, SO ₂ , O ₂ , N ₂ , and H ₂ O) in flue gas	vol %
6B	VO2 }		
6B	VN2 }		
6B	VH2O }		

(Continued)

TABLE C-2. (Continued)

Line No.	Variable	Definition	Unit or value
6B	SCFM	Standard cubic feet per minute (60°F), gas from boiler	sft ³ /min
6B	WASH	Pounds of ash per hour in hot gas from boiler	lb/hr
6B	SULO	Should be set to 100 when flue gas composition is input	
6B	ASHO	Should be set to 100 when flue gas composition is input	
6B	IASH	See line 6A	
6B	ASHUPS	See line 6A	
6B	ASHSCR	See line 6A	
7	XLG	L/G ratio in scrubber (Refer to the ISR option on the following page.)	gal/kaft ³
7	VLG	L/G ratio in venturi	gal/kaft ³
7	VTR	Venturi/oxidation hold tank residence time. This variable is used to specify residence time in the second effluent tank when two tanks are specified. Two tanks may be specified by the forced- oxidation option (IFOX, line 8), the scrubber option (ISCRUB, line 9), or both. VTR should be set to zero when only one effluent tank is used (see the TR variable below).	min
7	V	Scrubber gas velocity (superficial)	ft/sec
7	VRH	Superficial gas velocity through reheater (face velocity)	ft/sec

(Continued)

TABLE C-2. (Continued)

Line No.	Variable	Definition	Unit or value
7	IS02	Unit of measure option for SO ₂ removal SO ₂ to be removed is a percent value SO ₂ emission concentration is a pounds SO ₂ /MBtu value SO ₂ emission concentration is a ppm value 1979 NSPS (The actual value for SO ₂ removal is provided by the XS02 variable that immediately follows.)	1 2 3 4
7	XS02	Value for SO ₂ to be removed. Unit of measure is indicated by the IS02 option above; refer to the ISR option below for additional requirements. The value for XS02 is automatically calculated when IS02 = 4 and any input value will be ignored.	
7	TR	Recirculation/oxidation hold tank residence time. This variable is used to specify residence time in the effluent tank when only one tank is specified. If two tanks are specified, TR specifies residence time in the first tank (see the VTR variable above).	min
7	ISR	Stoichiometry, L/G in scrubber, and SO ₂ removal option. This option controls model processing of the stoichiometry value, SRIN, below; the L/G ratio in the scrubber, XLG, on the preceding page; and the SO ₂ to be removed, XS02, above (if XS02 is required then IS02 is also required).	
		SRIN, XLG, and XS02 (also IS02) will be processed as input variables. (No checks are made for validity or consis- tency among the specified values.)	0

(Continued)

TABLE C-2. (Continued)

Line No.	Variable	Definition	Unit or value
		XLG and XS02 (also IS02) will be processed as input variables and SRIN will be calculated by the model.	1
		SRIN and XS02 (also IS02) will be processed as input variables and XLG will be calculated by the model.	2
		SRIN and XLG will be processed as input variables; the value for S02 to be removed (XS02) will be calculated by the model; and all three units of measure (IS02) will be provided in the calculated results. Any user input values for IS02 and XS02 will be ignored.	3
7	SRIN	Value for stoichiometry (refer to the ISR option above)	mols CaCO ₃ added as limestone per mol SO ₂ + 2HCl absorbed
7	XIALK	Alkali addition option	
		Limestone	1
		Lime	2
7	IADD	Chemical additive option	
		No chemical additive	0
		MgO added	1
		Adipic acid added	2
7	WPMGO	Soluble MgO in limestone or lime	wt % dry basis
7	XMGOAD	Soluble MgO added to system (applied only when MgO added, see IADD above)	lb soluble MgO/100 lb limestone
7	AD	Adipic acid in scrubbing liquid (applied only when adipic acid added, see IADD above)	ppm (wt)

(Continued)

TABLE C-2. (Continued)

Line No.	Variable	Definition	Unit or value
7	ADDC	Adipic acid degradation constant (applied only when adipic acid added, see IADD above)	
7	WPI	Insolubles in limestone-lime additive	wt % dry basis
7	WPM	Moisture in limestone-lime additive	lb/100 lb dry additive
7	ASHCAO	Soluble CaO in particulates	wt %
7	ASHMGO	Soluble MgO in particulates	wt %
8	WPS	Solids in recycle slurry to scrubber	wt %
8	PSD	Solids in sludge discharge	wt %
8	RS	Thickener solids settling rate	ft/hr
8	PSC	Percent solids in thickener underflow	wt %
8	IFOX	Forced-oxidation option	
		No forced oxidation	0
		Forced oxidation in a single effluent tank	1
		Forced oxidation in the first of two effluent tanks	2
		Forced oxidation in the disposal feed tank	3
8	OX	Oxidation of sulfite in scrubber liquid	mol %
8	SRAIR	Air stoichiometry value	g-atoms O/g-mol SO ₂ absorbed
8	PSF	Percent solids in filter cake	wt %
8	FILRAT	Filtration rate	tons/ft ² /day
8	PHLIME	Recirculation liquor pH for lime and adipic acid enhancement systems (value is ignored for limestone system)	

(Continued)

TABLE C-2. (Continued)

Line No.	Variable	Definition	Unit or value
8	IVPD	Venturi ΔP option	
		ΔP is input in in. H ₂ O	0
		Throat velocity (ft/sec) is input and the corresponding VPD is calculated	1
8	VPD	Value for either ΔP or throat velocity indicated by the IVPD option above	in. H ₂ O or (ft/sec)
8	DELTAP	Override ΔP for entire system	in. H ₂ O
8	PRES	Scrubber pressure	psia
8	IFAN	Fan option	
		Forced-draft fans	0
		Induced-draft fans	1
9	ISCRUB	Scrubbing option	
		Spray tower	1
		TCA	2
		Venturi-spray tower, two effluent tanks	3
		Venturi-spray tower, one effluent tank	4
		Venturi-TCA, two effluent tanks	5
		Venturi-TCA, one effluent tank	6
9	XNS	Number of TCA stages	
9	XNG	Number of TCA grids	
9	HS	Height of spheres per stage	in.
9	RAIN	Annual rainfall	in./yr
9	SEEPRT	Seepage rate	cm/sec
9	EVAPRT	Annual evaporation	in./yr
9	WINDEX	Limestone hardness work index factor value 5-15. (Example: 10)	wi
9	HPTONW	Fineness of grind index factor (see Table C-3)	hp/ton
9	NSPREP	Number of spare preparation units	(0-9)

Line No.	Variable	Definition	Unit or value
9	NOTRAN	Number of operating scrubber trains	(1-10)
9	NORED	Number of spare scrubber trains	(0-10)
9	PCNTRN	Entrainment level as percentage of wet gas from scrubber (Example: 0.1)	wt %
10	ISLUDG	Sludge disposal option	
		Onsite ponding	1
		Thickener - ponding	2
		Thickener - fixation (fee)	3
		Thickener - filter - fixation (fee)	4
		Thickener - filter - landfill fixation fee	5
10	IFIXS	Sludge fixation option	
		No fixation specified	0
		Sludge - fly ash - lime fixation	1
10	SDFEE	Sludge disposal fee (Either an actual value or a zero value must be provided; refer to the ISLUDG option above.)	\$/ton dry sludge
10	PSAMAX	Total available land for construction of pond	acres
10	ACRE\$	Land cost	\$/acre
10	PDEPTH	Final depth of sludge in pond (when ISLUDG = 1-4)	ft
10	PDEPTH	Uncompacted bulk density of waste (when ISLUDG = 5)	lb/ft ³
10	PMXEXC	Maximum excavation depth (when ISLUDG = 1-4)	ft
10	PMXEXC	Compacted bulk density of waste (when ISLUDG = 5)	lb/ft ³
10	DISTPD	Distance from scrubber area to disposal site	ft

(Continued)

TABLE C-2. (Continued)

Line No.	Variable	Definition	Unit or value
10	ILINER	Disposal site lining option Clay liner Synthetic liner No liner (Refer to the XLINA and XLINB variables that immediately follow.)	1 2 3
10	XLINA	If ILINER = 1, XLINA = clay depth If ILINER = 2, XLINA = material unit cost If ILINER = 3, XLINA = 0	in. \$/yd ²
10	XLINB	If ILINER = 1, XLINB = clay cost If ILINER = 2, XLINB = labor unit cost If ILINER = 3, XLINB = 0	\$/yd ³ \$/yd ²
11	ENGIN	Engineering design and supervision	%
11	ARCTEC	Architect and engineering contractor	%
11	FLDEXP	Construction field expenses	%
11	FEES	Contractor fees	%
11	CONT	Contingency	%
11	START	Allowance for startup and modifications	%
11	CONINT	Interest during construction	%
11	XINT	Cost of capital	%
11	PCTMNT	Maintenance rate, applied as percent of direct investment excluding disposal site cost	%
11	PDMNTP	Disposal site maintenance rate, applied as percent of direct disposal site investment	%
11	XINFLA	Inflation factor (used only when unlevel- ized lifetime revenue requirements are calculated, see Appendix B)	%

(Continued)

TABLE C-2. (Continued)

Line No.	Variable	Definition	Unit or value
11	IECON	Economic premises option	
		Current premises	1
		Premises prior to 12/5/79	0
11	PCTOVR	Plant overhead rate, applied as percent of conversion costs less utilities	%
11	XLEVEL/ PCTADM	The use of this variable depends on the economic premises specified (IECON, line 11). If new premises are specified (IECON = 1), XLEVEL specifies the levelizing factor to be applied to first-year operating and maintenance cost to obtain leveled lifetime costs. If XLEVEL is set to zero, there is no levelizing and a lifetime revenue sheet is generated. If old premises are specified (IECON = 0), PCTADM specifies the administrative research and service overhead rate, applied as a percent of operating labor and supervision.	%
11	CAPCHG/ UNDCAP	If new premises are specified (IECON = 1) CAPCHG specifies leveled annual capital charges applied as a percent of total capital investment. If old economic premises are specified (IECON = 0), UNDCAP specifies the annual capital charge basis for undepreciated investment.	%
11	PCTMKT/ PCTINS	If new premises are specified (IECON = 1), PCTMKT specifies marketing costs applied as a percent of byproduct credit (applies only to processes with a salable byproduct). If old economic premises are specified (IECON = 0), PCTINS specifies the rate for insurance and interim replacements applied as a percent of total capital investment.	%

(Continued)

TABLE C-2. (Continued)

Line No.	Variable	Definition	Unit or value
12	ITAXFR	Sales tax and freight option No sales tax or freight Sales tax and freight rates as specified by TXRAT and FRRAT below	0 1
12	TXRAT	Sales tax rate (applied only when ITAXFR above set to 1)	%
12	FRRAT	Freight rate (applied only when ITAXFR above set to 1)	%
12	SERVRT	Services, utilities, and miscellaneous, applied as a percent of total process capital	%
12	ROYALT	Royalties, applied as a percent of total process capital	%
12	IOTIME	Overtime construction labor option No overtime labor Overtime labor on 7% of total labor based on the OTRATE rate below	0 1
12	OTRATE	Overtime labor rate (applied to 7% of total labor). (Example: 1.5)	
12	INDPND	Separate indirect investment factors option for construction No separate indirect factors for disposal waste site construction (same as process indirects) Separate indirects for waste site construction specified by PENGIN, PARCH, PFLDEX, PFEEES, PCONT, and PSTART below	0 1
12	PENGIN	Disposal site construction engineering design and supervision expenses (applied only when INDPND above set to 1)	%

(Continued)

TABLE C-2. (Continued)

Line No.	Variable	Definition	Unit or value
12	PARCH	Disposal site construction architect and engineering contractor expenses (applied only when INDPND above set to 1)	%
12	PFLDEX	Disposal site construction field expenses (applied only when INDPND above set to 1)	%
12	PFEES	Disposal site construction contractor fees (applied only when INDPND above set to 1)	%
12	PCONT	Disposal site construction contingency (applied only when INDPND above set to 1)	%
12	PSTART	Allowance for disposal site startup and modification (applied only when INDPND above set to 1)	%
13	UC (1)	Limestone unit cost	\$/ton
13	UC (2)	Lime unit cost	\$/ton
13	UC (3)	MgO unit cost	\$/ton
13	UC (4)	Adipic acid unit cost	\$/ton
13	UC (5)	Operating labor and supervision unit cost	\$/man-hr
13	UC (6)	Landfill labor and supervision unit cost	\$/man-hr
13	UC (7)	Steam unit cost	\$/klb
13	UC (8)	Process water unit cost	\$/kgal
13	UC (9)	Electricity unit cost	\$/kWh
13	UC (10)	Diesel fuel cost	\$/gal
13	UC (11)	Analyses unit cost	\$/hr

TABLE C-2. (Continued)

Line No.	Variable	Definition	Unit or value
13	XINDEX	<u>Chemical Engineering</u> material cost index (see premises)	
13	YINDEX	<u>Chemical Engineering</u> labor cost index see premises)	
13	INVYR	Investment year cost basis	yr
13	IREVYR	Revenue requirement year cost basis	yr
14	IOPSCH	Operating profile option	
		TVA profile	1
		FERC profile	2
		User input profile [Refer to the IYROP and IA(n) options on lines 14-17.]	3
		Levelized operating profile, 5,500 hr/yr	4
		Calculated input operating profile	5
14	ONCAP	Onstream capacity factor (Example .6)	decimal
14	IYROP	Years remaining life (lines 15 through 17 are needed only if the IOPSCH variable, line 14, is set to 3). Although only 30 years is shown, up to 50 years may be used.	
14	PNDCAP	Expected disposal site capacity (controls site design capacity; if 100% of sludge is to be disposed over the life of the unit, input 1.0; if 80% of sludge is to be disposed, input 0.80).	
14	BAGDLP	Baghouse pressure drop	in. H ₂ O
14	BAGRAT	Baghouse ratio (typically = 0.8)	$\frac{\text{open ft}^2}{\text{actual ft}^2}$
14	BGCOST	Bag cost	\$/ft ²
14	BGLIFE	Bag life	yr

(Continued)

TABLE C-2. (Continued)

Line No.	Variable	Definition	Unit or value
14	EFFPS	ESP rectification efficiency (Example - .65)	decimal
14	ESPDLP	ESP pressure drop	in. H ₂ O
14	RESIST	Resistivity option (high or low) ^a Assume ω = 20 ft/min Assume ω = 30	1 2
14	SCARAT	SCA ratio Contingency or safety factor (fractional) to apply to calculated collection area.	
14	ICEPYE	<u>Chemical Engineering</u> plant index year	yr
14	CEPNDX	<u>Chemical Engineering</u> plant index (see premises)	
15	IA(1) - IA(10)	Operating hr/yr (input only 10 years per line)	
16	IA(11) - IA(20)	Operating hr/yr (input only 10 years per line)	
17	IA(21) - IA(30)	Operating hr/yr (input only 10 years per line)	
18	END or NEXT	"END" terminates further execution. "NEXT" execution will continue with the next group of input variables. (If variable IOPSCH on line 14 is not equal to 3, line 15 will be the "END" or "NEXT" line.)	

a. Required for sizing hot ESP. Drift velocity (ω) is related to percent sulfur in the cold ESP model, but is an input for the hot ESP model.

TABLE C-3. LIMESTONE FINENESS OF GRIND INDEX FACTOR

<u>Ground limestone product size distribution</u>			<u>Index factor (HPTONW)</u>
<u>80%- micron</u>	<u>% -200 mesh</u>	<u>% -325 mesh</u>	<u>hp/ton</u>
129	60		1.11
113	65		1.22
98	70		1.35
85	75		1.51
74	80		1.72
62	85		2.04
58	86	70	2.19
51	90	75	2.54
44	93	80	3.04
40	95		3.40
37		85	3.64
31		90	4.44
24		95	5.70 base

Data from KVS Rock Talk Manual, Kennedy Van Saun Corporation, Danville, Pennsylvania, 1974. Total ball mill horsepower is calculated using the limestone hardness work index factor, wi, and the fineness of grind index factor as follows: $hp = (\text{ton/hr limestone})(wi)(\text{fineness of grind index factor})$.

ADIPIC ACID INTERACTIVE MODEL

ADIPIC ACID INTERACTIVE MODEL

The adipic acid computerized model in the Shawnee computer model is available as an interactive model that allows the user to optimize the adipic acid enhanced flue gas desulfurization (FGD) system by calculating operating conditions at various input conditions. The optimized values can then be input to the Shawnee model and executed in "forced-through mode" to determine the entire system design and cost.

Adipic acid is an organic acid which serves to buffer the pH of the limestone slurry in the range of 4.6-5.8, thus maintaining a higher driving force for SO_2 removal while operating at a lower limestone stoichiometry. It has been found at the Shawnee test facility at TVA's Shawnee Steam Plant that a stoichiometric ratio of 1.07 mol CaCO_3 /mol ($\text{SO}_2 + 2\text{HCl}$) absorbed provides the optimum conditions. Higher stoichiometric ratios have little effect on SO_2 removal, can cause scaling, and will increase operating costs.

The data generated at the test facility have been reduced to mathematical equations that project a material balance based on input L/G, SO_2 removal, adipic acid concentration, and pH. It is recommended that both pH and limestone stoichiometries be input with the values described above. The model projects the remaining condition when any two of the values for L/G, SO_2 removal, or adipic acid concentration are input.

The adipic acid model requires user knowledge of adipic acid-enhanced systems. Unless L/G, SO_2 removal, or adipic acid concentrations are known or specified, it is recommended that the model be executed several times to optimize conditions.

The FORTRAN variable names are presented in Table E-1 and they are defined in Table E-2. An example COMMAND procedure to interactively execute only the adipic acid model is presented in Table E-3. The results of an interactive computer run are illustrated in Table E-4.

TABLE E-1. FORTRAN VARIABLE NAMES FOR
ADIPIC ACID INTERACTIVE MODEL

POND INTERACTIVE MODEL

POND INTERACTIVE MODEL

The pond model in the Shawnee computer model can be executed in an interactive mode to project pond designs and costs independent of the scrubbing model. In this mode, the pond design is based on the final volume of the waste, which is specified by the GPMSS and THRS input variables. GPMSS specifies the waste input rate in gal/min using the final dry bulk density and THRS specifies the lifetime hours of pond disposal site operation.

The FORTRAN variable names are presented in Table F-1 and they are defined in Table F-2. An example COMMAND procedure to interactively execute only the pond model is presented in Table F-3. The results of an interactive computer run are illustrated in Table F-4.

12. SPONSORING AGENCY NAME AND ADDRESS EPA, Office of Research and Development Industrial Environmental Research Laboratory Research Triangle Park, NC 27711				13. TYPE OF REPORT AND PERIOD COVERED Final; 10/81 - 1/85	
				14. SPONSORING AGENCY CODE EPA/600/13	
15. SUPPLEMENTARY NOTES AEERL project officer is J. David Mobley, Mail Drop 61, 919/541-2612.					
16. ABSTRACT The manual describes a Shawnee flue gas desulfurization (FGD) computer model and gives detailed instructions for its use. The model, jointly developed by Bechtel National, Inc. and TVA (in conjunction with the EPA-sponsored Shawnee test program), is capable of projecting preliminary design and economics for lime- and limestone-scrubbing FGD systems, including spray tower, turbulent contact absorber (TCA), and venturi/spray-tower scrubbing options. It may be used to project the effect on system design and economics of variations in required SO2 removal, scrubber operating parameters (gas velocity, liquid/gas ratio, alkali stoichiometry, and liquor holdtime in slurry recirculation tanks), reheat temperature, and scrubber bypass. It may also be used to evaluate alternative waste disposal methods or additives (MgO or adipic acid) on costs for the selected process. Although the model is not intended to project the economics of an individual system to a high degree of accuracy, it allows prospective users to quickly project comparative design and costs for limestone and lime case variations on a common design and cost basis. The manual describes and explains the user-supplied input data which are required (e.g., boiler size, coal characteristics, and SO2 removal requirements). Outputs include a material balance, equipment list, and capital investment/annual revenue needs.					
17. KEY WORDS AND DOCUMENT ANALYSIS					
a. DESCRIPTORS		b. IDENTIFIERS/OPEN ENDED TERMS		c. COSATI Field/Group	
Pollution Scrubbers		Pollution Control		13B 13I	
Mathematical Models		Stationary Sources		12A	
Flue Gases Calcium Oxides				21B 07B	
Desulfurization Limestone				07A, 07D 08G	
Design Waste Disposal				14G
