## FOREWORD

The National Eutrophication Survey was initiated in 1972 in response to an Administration commitment to investigate the nation-wide threat of accelerated eutrophication to fresh water lakes and reservoirs.

#### **OBJECTIVES**

The Survey was designed to develop, in conjunction with state environmental agencies, information on nutrient sources, concentrations, and impact on selected freshwater lakes as a basis for formulating comprehensive and coordinated national, regional, and state management practices relating to point-source discharge reduction and non-point source pollution abatement in lake watersheds.

## ANALYTIC APPROACH

The mathematical and statistical procedures selected for the Survey's eutrophication analysis are based on related concepts that:

- a. A generalized representation or model relating sources, concentrations, and impacts can be constructed.
- b. By applying measurements of relevant parameters associated with lake degradation, the generalized model can be transformed into an operational representation of a lake, its drainage basin, and related nutrients.
- c. With such a transformation, an assessment of the potential for eutrophication control can be made.

#### LAKE ANALYSIS

In this report, the first stage of evaluation of lake and water-shed data collected from the study lake and its drainage basin is documented. The report is formatted to provide state environmental agencies with specific information for basin planning [§303(e)], water quality criteria/standards review [§303(c)], clean lakes [§314(a,b)], and water quality monitoring [§106 and §305(b)] activities mandated by the Federal Water Pollution Control Act Amendments of 1972.

Beyond the single lake analysis, broader based correlations between nutrient concentration (and loading) and trophic condition are being made to advance the rationale and data base for refinement of nutrient water quality criteria for the Nation's fresh water lakes. Likewise, multivariate evaluations for the relationships between land use, nutrient export, and trophic condition, by lake class or use, are being developed to assist in the formulation of planning guidelines and policies by EPA and to augment plans implementation by the states.

#### ACKNOWLEDGEMENT

The staff of the National Eutrophication Survey (Office of Research & Development, U.S. Environmental Protection Agency) expresses sincere appreciation to the California State Water Resources Control Board and the nine Regional Water Quality Control Boards for professional involvement, to the California National Guard for conducting the tributary sampling phase of the Survey, and to those California wastewater treatment plant operators who voluntarily provided effluent samples and flow data.

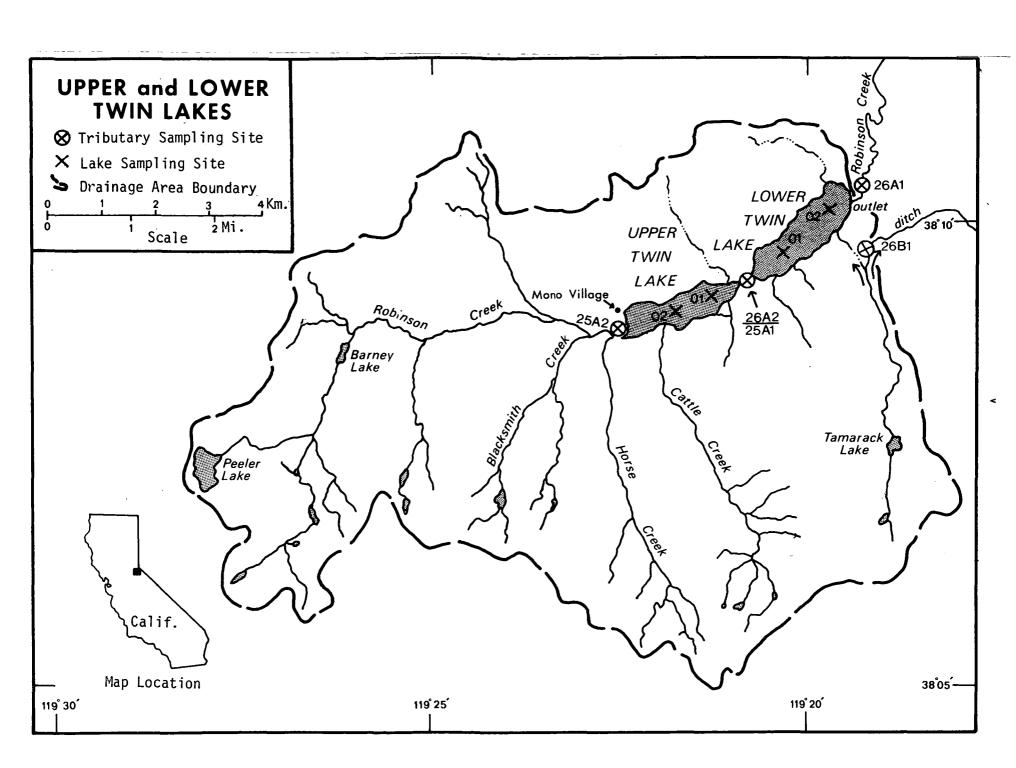

The staff of the Division of Planning and Research of the State Water Resources Control Board provided invaluable lake documentation and counsel during the Survey, coordinated the reviews of the preliminary reports, and provided critiques most useful in the preparation of this Working Paper series.

Major General Glen C. Ames, the Adjutant General of California, and Project Officer Second Lieutenant Terry L. Barrie, who directed the volunteer efforts of the California National Guardsmen, are also gratefully acknowledged for their assistance to the Survey.

#### UPPER TWIN LAKE

#### **STORET NO. 0625**

#### I. CONCLUSIONS

#### A. Trophic Condition\*:

Survey data indicate that Upper Twin Lake is early mesotrophic. It ranked fifth in overall trophic quality among the 24 California lakes and reservoirs sampled in 1975 when compared using a combination of six water quality parameters\*\*. Seven of the water bodies had less median total phosphorus, four had less and two had the same median dissolved orthophosphorus, none had less and four had the same median inorganic nitrogen, eight had less mean chlorophyll <u>a</u>, and three had greater mean Secchi disc transparency. Essentially no depression of dissolved oxygen occurred at depths as great as 31.4 meters.

Survey limnologists observed some submerged macrophytes but no surface concentrations of algae. Extensive macrophyte growths are reported to **o**ccur at the west end of the lake (Bailey, 1977).

Others have noted that the water quality of Upper Twin Lake is good and have assessed the lake as oligotrophic (Johns, 1975).

### B. Rate-Limiting Nutrient:

The algal assay results are not considered representative of conditions in the lake at the times samples were taken.

<sup>\*</sup> Trophic Assessment is based on levels of nutrients, dissolved oxygen, and chlorophyll a; phytoplankton kinds and numbers; and transparency (Allum et al., 1977).

\*\* See Appendix A.

The lake data indicate nitrogen limitation in June and November and phosphorus limitation in July.

## C. Nutrient Controllability:

1. Point sources--No known wastewater treatment plants impacted Upper Twin Lake during the sampling year. Septic tanks serving Mono Village and lakeshore dwellings accounted for an estimated 1.2% of the total phosphorus load, but a shoreline survey would have to be conducted to determine the actual inputs from those sources. However, septic tank failures in the past have resulted in contamination and enrichment of the adjacent waters (Johns, 1975).

The present phosphorus loading of 0.84 g/m²/year is less than that proposed by Vollenweider (Vollenweider and Dillon, 1974) as a eutrophic loading but is more than his suggested oligotrophic loading (see page 11). Because the lake is phosphorus limited much of the time, all phosphorus inputs should be minimized to the greatest practicable extent to protect the existing quality of this water body.

2. Non-point sources--Non-point sources accounted for 98.9% of the total phosphorus input during the sampling year. Robinson Creek contributed 65.9%, and the ungaged minor tributaries and immediate drainage contributed an estimated 30.7%.

## II. LAKE AND DRAINAGE BASIN CHARACTERISTICS<sup>†</sup>

## A. Morphometry<sup>††</sup>:

1. Surface area: 1.07 kilometers<sup>2</sup>.

2. Mean depth: 14.3 meters.

3. Maximum depth: 34.1 meters.

4. Volume:  $15.301 \times 10^6 \text{ m}^3$ .

5. Mean hydraulic retention time: 136 days.

## B. Tributary and Outlet: (See Appendix C for flow data)

#### 1. Tributaries -

	Name	Drainage area (km²)*	Mean flow (m³/sec)*
	Robinson Creek Minor tributaries &	54.4	0.889
	immediate drainage -	20.9	0.414
	Totals	75.3	1.303
2.	Outlet -		
	Robinson Creek	76.4**	1.303

## C. Precipitation\*\*\*:

- 1. Year of sampling: 8.1 centimeters.
- 2. Mean annual: 14.5 centimeters.

†† Uttormark (in press).

<sup>+</sup> Table of metric conversions -- Appendix B.

<sup>\*</sup> For limits of accuracy, see Working Paper No. 175, "...Survey Methods, 1973-1976".

<sup>\*\*</sup> Includes area of lake.

<sup>\*\*\*</sup> See Working Paper No. 175.

## III. WATER QUALITY SUMMARY

Upper Twin Lake was sampled three times during the open-water season of 1975 by means of a pontoon-equipped Huey helicopter. Each time, samples for physical and chemical parameters were collected from a number of depths at one station in June and from two stations in July and November (see map, page v). During each visit, a single depth-integrated (4.6 m to surface) sample was composited from the stations for phytoplankton identification and enumeration; and during the first and last visits, a single 18.9-liter depth-integrated sample was composited for algal assays. Also each time, a depth-integrated sample was collected from each of the stations for chlorophyll <u>a</u> analysis. The maximum depths sampled were 28.7 meters at station 1 and 31.4 meters at station 2.

The sampling results are presented in full in Appendix D and are summarized in the following table.

## 2. Chlorophyll $\underline{a}$ -

Sampling Date	Station <u>Number</u>	Chlorophyll <u>a</u> (μg/l)
06/10/75	1 2	2.5
07/01/75	1 2	2.5 3.1
11/06/75	1 2	4.5 4.1

## C. Limiting Nutrient Study:

The algal assay results are not considered representative of conditions in the lake at the times the samples were collected (06/10/75 and 11/06/75) due to significant changes in nutrient concentrations in the samples during shipment from the field to the laboratory. However, the lake data indicate that nitrogen was limiting in June and November and phosphorus was limiting in July; i.e., the mean inorganic nitrogen/orthophosphorus ratios were 5/1 in June, 21/1 in July, and 7/1 in November.

## IV. NUTRIENT LOADINGS (See Appendix E for data)

For the determination of nutrient loadings, the California National Guard collected monthly near-surface grab samples from each of the tributary sites indicated on the map (page v), except for the high runoff months of March and May when two samples were collected. Sampling was begun in November, 1974, and was completed in September, 1975.

Through an interagency agreement, stream flow estimates for the year of sampling and a "normalized" or average year were provided by the California District Office of the U.S. Geological Survey for the tributary sites nearest the lake.

In this report, nutrient loads for sampled tributaries were calculated using mean annual concentrations and mean annual flows.

Nutrient loads for unsampled "minor tributaries and immediate drainage" ("ZZ" of U.S.G.S.) were estimated using the mean concentrations in Robinson Creek at station A-2 and the mean annual ZZ flow.

The nutrient contributions of the Mono Village wastewater treatment facilities were estimated at 0.1134 kg P and 4.263 kg N/capita/year; and the contributing population was estimated on the basis of flow  $(0/3785 \text{ m}^3/\text{capita/day})$ .

Robinson Creek	11	395

<sup>\*</sup> Estimate based on 12 lakeshore dwellings; see Working Paper No. 175. \*\* See Working Paper No. 175.

## E. Yearly Loads:

In the following table, the existing phosphorus loadings are compared to those proposed by Vollenweider (Vollenweider and Dillon, 1974). Essentially, his "dangerous" loading is one at which the receiving water would become eutrophic or remain eutrophic; his "permissible" loading is that which would result in the receiving water remaining oligotrophic or becoming oligotrophic if morphometry permitted. A mesotrophic loading would be considered one between "dangerous" and "permissible".

Note that Vollenweider's model may not be applicable to water bodies with short hydraulic retention times.

	Total Total	Phosphorus Accumulated	Tota Total	Nitrogen Accumulated
grams/m²/yr	0.84	0.26	3 <b>0</b> .9	loss*
Vollenweider phosph (g/m²/yr) based or hydraulic retention	n mean depth	and mean	:	
"Dangerous" (e	utrophic loa	ading)	1.16	

0.58

"Permissible" (oligotrophic loading)

<sup>\*</sup> There was an apparent loss of nitrogen during the sampling year. This may have been due to nitrogen fixation in the lake, solubilization of previously sedimented nitrogen, recharge with nitrogen-rich ground water, underestimation of septic tank contributions, or (possibly) insufficient outlet sampling in relation to the hydraulic retention time of the lake. Whatever the cause, a similar nitrogen loss has occurred at Shagawa Lake, Minnesota, which has been intensively studied by EPA's former National Eutrophication and Lake Restoration Branch (Malueg et al., 1975).
