Background

The use of pure methanol as an automotive fuel could allow the use of less expensive exhaust catalysts. Two important benefits are expected from the use of methanol compared to unleaded gasoline. The benefits are reduced levels of catalyst poisons, such as lead and sulfur, and reduced exhaust gas temperatures at the catalyst inlet. Both major mechanisms of catalyst deactivation, poisoning and thermal degradation, could be less severe.

The purpose of this program is to evaluate various exhaust catalysts at low mileage on a pure methanol-fueled Volkswagen Rabbit. HC, CO, NOx and formaldehyde emissions will be measured to identify which catalysts are the best candidates for durability testing in a later program. Catalyst formulations that are eventually selected for durability testing should cost no more, and preferably less, than the original catalyst on the vehicle.

All candidate catalysts should provide the capability to meet the 0.41 HC and 3.4 CO levels at low mileage with substantial margins of safety. Additionally, 3-way catalysts should provide emissions well below the 1.0 NOx level.

Conclusions

1. Several catalysts have been identified as good candidates for vehicle durability testing. All of these catalysts contain noble metals. The catalysts recommended for durability are 1) platinum and rhodium in a ratio of 5:1 at a loading of 40 grams/cubic foot (a loading identical to the original catalyst on the vehicle and identical to that used on the forty vehicles provided to the California Energy Commission), 2) platinum and palladium in a ratio of 3:2 at 20 grams/cubic foot, and 3) all palladium at a loading of 40 grams/cubic foot. All catalyst volumes would be 75 cubic inches. All catalyst substrates would be 400 cells per square inch with a wall thickness of 6 mils.

2. One catalyst was tested which was all base metal. It was pure copper mesh. The copper mesh provided some HC conversion over the highway cycle, but not much else. CO control over the FTP was poor with the catalyst, and it provided little NOx control with stoichiometric exhaust conditions.

3. One catalyst has been tested which includes substantial amounts of both base and noble metals. The inclusion of the base metals provided no significant emissions benefit in comparison to other palladium catalysts in this study.

Future Effort

The results which have been obtained so far will be provided to the vehicle and catalyst manufacturers who have assisted us in this program. We will request their advice on the following subjects.

- o how to improve the emissions control capability of previously tested and poorly performing catalysts,
- o which additional catalysts should be tested at low mileage,
- o how to further reduce the cost of durability-candidate catalysts, and
- o how to improve the durability emissions performance of those catalysts which performed well in our low mileage testing.

We now plan to further evaluate the copper mesh after an acid dip and with the addition of insulation to the exhaust system. The silver catalyst will be further evaluated with exhaust system insulation and possibly with some varying thermal pretreatments. A copper oxide catalyst will also be tested.

Based on our testing to date, it appears as though we may need to retain rhodium for achieving the lowest possible aldehyde levels. New catalyst candidates could include more lightly loaded platinum/rhodium catalysts in the 10-20 gram/cubic foot range and palladium/rhodium units in the same loading range and with Pd: Rh ratios of 5:1 or 10:1.

Test Vehicle Description

The test vehicle is a 1981 model year Volkswagen Rabbit. It was modified by Volkswagen to operate on methanol plus 5.5% isopentane. It is a 4-door sedan equipped with air conditioning, a 3-speed automatic transmission, and a 1.6 liter engine. The compression ratio of the engine is 12.5:1. Maximum power output is 88 horsepower at 5600 RPM (1)*. The tire size is 155 SR 13. The tires are Michelin XZX radials. It was tested at 2250 pounds inertia weight and 7.3 actual dynamometer horsepower.

The emission control system, as equipped by Volkswagen includes feedback controlled, continuous fuel injection (K-Jetronic) and a three-way catalyst. The catalyst provided by VW was 4.0 inches in diameter and 6.0 inches long. It contained platinum (Pt) and rhodium (Rh) in a ratio of 5:1 at a loading of 40 g/ft^3. The vehicle is described in more detail in Appendix 1, which was taken from a Volkswagen emission control status report (2) to EPA.

The emission control system was modified by EPA to include a pump-type air injection system. The air was injected into the exhaust at a location about a foot downstream from the oxygen sensor. A manually adjustable valve was installed in the line between the diverter valve and the exhaust inlet. This valve allowed us to vary oxygen concentration into the catalyst while operating the engine in the closed loop mode.

*Numbers in parenthesis are references listed at the end this report.

Test Sequence, Instrumentation, and Fuel

The initial plan included testing of the vehicle and each catalyst over the following sequence:

1975 Federal Test Procedure
Highway Test Procedure
20 mph steady state
30 mph steady state
40 mph steady state.

The sequence would be repeated twice for each catalyst at each of three exhaust oxygen levels. The higher two of the three exhaust oxygen levels were measured at the catalyst inlet using a Sun oxygen analyzer and were obtained at 30 miles per hour steady state. The three oxygen levels were stoichiometry (or near 0%), 3%, and 5%. By testing at different exhaust oxygen levels, we could evaluate each catalyst as a 3-way and also as an oxidizing catalyst.

As the project proceeded, idle and a 10 mph steady state were added to the sequence and the 40 mph steady state was deleted. HC, CO, NOx, MPG, methanol, methane, and aldehydes were initially measured over each test in the sequence. Aldehydes were deleted during steady states in more recent testing. Methanol was deleted for all testing as the program progressed.

Exhaust HC emissions, as reported here, were measured with a flame ionization detector (FID) from Beckman (model 400). No corrections in the results were made for either the FID response to methanol or the difference in HC composition with methanol as the fuel. NOx emissions were measured with a chemiluminescent NO/NOx analyzer from Beckman (model 951A). CO

was measured with infrared analyzers from MSA and Bendix. Methane was measured with a gas chromatograph (Bendix 8205 methane analyzer). Aldehydes were measured by high pressure liquid chromatography (HPLC). See Appendix 2 for more details. Gaseous methanol was measured by a gas chromatograph (Perkins-Elmer model 3920).

The test fuel which has been used is pure methanol. Three batches of the fuel have been used, and one has been analyzed. The fuel analysis is presented in Appendix 3.

FTP Test Results

The Rabbit has been tested with a total of nine different catalysts. Those catalysts are described in Table 1. Also, the vehicle has been periodically tested with no catalyst to assure that major changes in emissions without a catalyst have not occurred over the duration of the test program. The vehicle emissions with no catalyst as a function vehicle odometer reading are shown in Figures 1 and 2. There was an oxygen sensor change to the emission control system which may have resulted in a slight shift in FTP emissions at about 6,300 miles; however, HC, CO, NOx, and methanol emissions have been reasonably stable over the test program to date.

Aldehyde emissions were not as stable as desired. The cause of variablity in the aldehyde emissions is being investigated. We know the column was changed in the liquid chromatograph (to a nominally identical column) just prior to generating the value of about 130 mg/mi in Figure 2. The impact of the column change on the variability is unknown. It is possible that the aldehyde emissions are of such a small magnitude that we may not be able to get rid of the variability with this particular vehicle and test equipment.

In Table 1, the catalysts have been referred to by an an Abbreviated Catalyst Code. The original catalyst on the vehicle contained platinum and rhodium in 5:1 ratio at a loading of 40 grams per cubic foot of substrate volume. As an example of the Abbreviated Catalyst Code, this catalyst has been referred to as catalyst 5 Pt: Rh (40).

All catalysts in the group are of identical volume except for the 12 Pt:Rh (40)* catalyst and the Cu catalyst. The 12 Pt: Rh (40)* catalyst is a sample of 110 in^3. Initially we planned to test all samples in two volumes; however, the smaller noble metal samples were so active that increased catalyst volume would likely be able to provide little improvement in low mileage conversion efficiency. If durability testing is unsuccessful, then larger catalyst volumes may be one of several possible paths to take.

All catalysts used in the program were zero mile catalysts except for the original catalyst on the vehicle. Assuming this catalyst had been on the vehicle since manufacture, it had accumulated less than 3,000 miles prior to testing at EPA.

Tailpipe emissions from this vehicle with no catalyst at stoichiometric operating conditions averaged 0.92 HC, 7.52 CO, 2.08 NOx. In comparison to gasoline-fueled vehicles, these simultaneous CO and NOx levels are low for an engine operating at stoichiometry with no EGR.

Tables 2, 3, and 4 present summaries of the FTP results which were obtained at each exhaust oxygen level. Non-methane HC results are nearly identical to total HC results at all three oxygen levels with and without catalysts. This indicates that there is virtually no methane in the exhaust. Average HC and CO emssions are below levels of 0.2 HC, 2.0 CO for all except the silver (Ag), copper (Cu), and mixed metal (Pd + BM) catalysts at all oxygen levels.

Individual emission test results are presented in Appendix 4. Additional statistics, including standard deviations that correspond to the the mean values in Tables 2, 3, and 4 are shown in Appendix 5. A listing of unscheduled vehicle maintenance is provided in Appendix 6.

Average methanol emissions ranged from 0.21 to 0.82 gram per mile at stoichiometric exhaust conditions and with catalysts. At the 3 percent and 5 percent oxygen levels, methanol emissions with the catalysts ranged from 0.28 to 0.59 gram per mile.

The catalysts which contain rhodium were expected to have significant NOx activity when operated as 3-way catalysts. The other noble metal catalysts also had good NOx activity in these low mileage tests. Based on the performance of vehicles fueled with gasoline, this activity may not be retained over substantial mileage accumulation with the catalysts not having rhodium. As expected, none of the catalysts provided NOx activity under oxidizing exhaust conditions.

Aldehyde emissions were handled much like HC emissions by the catalysts. All the noble metal catalysts showed reductions in aldehydes. Aldehyde levels generally increased as exhaust oxygen level increased.

Catalyst efficiencies were calculated for each catalyst at each exhaust oxygen level. The results of these calculations are presented in Tables 5, 6, and 7. Catalyst efficiency as used here is defined as tailpipe emissions with no catalyst minus tailpipe emissions with a catalyst, the difference divided by tailpipe emissions with no catalyst.

HC efficiencies are greater than or equal to 79% for the noble metal catalysts, except silver, at all exhaust oxygen conditions. CO efficiencies exceed 73 percent for all noble metal catalysts, except silver, at all oxygen conditons. The lowest NOx efficiency for these catalysts (again excluding silver) is 59 percent at stoichometry. No NOx efficiency is

achieved during oxidizing conditions. Aldehyde efficiencies decrease as oxygen level increases. Aldehyde efficiency exceeds 64 percent up to 3 percent oxygen. If rhodium is used in the catalyst, aldehyde efficiency is 89% or higher at all oxygen levels.

The Cu catalyst has little impact on any FTP emission. The silver catalyst has 77 percent aldehyde efficiency at 0 percent oxygen and has modest HC efficiencies.

The palladium plus base metal (Pd + BM) catalyst does not exhibit the NOx efficiency of other Pd catalysts. Also, the HC and CO efficiencies are poorer than for other catalysts which contain Pd. Apparently the amount of palladium present was not utilized as well in this catalyst as in the others.

Evaporative Emissions

A series of SHED tests measuring evaporative emissions were performed in order to determine the effectiveness of activated charcoal canisters in controlling the evaporative emissions of methanol. The results of those tests are summarized in Table 8.

The first six SHED tests, performed on the car equipped with its stock canister, results in average evaporative emissions of 1.74 grams per test. In order to determine the effectiveness of the canister system, two additional SHED tests were performed with the canister vent lines disconnected and vented to the atmosphere. The results of those two tests averaged 1.73 grams per test. Those results seemed to indicate that the original canister was not (at that time) effective in controlling evaporative emissions. Since that lack of effectiveness might have resulted from the canister being saturated, additional testing was performed with the car equipped with new canisters. These tests also yielded results which were of the same order of magnitude. Thus, it appears that the activated charcoal canisters used in these tests are ineffective in controlling evaporative emissions from this methanol-fueled vehicle.

The flame ionization detector (FID) measurements in Table 8 were "corrected" to reflect the assumption that all the HC detected was in the form of methanol (CH_3OH), having a molecular weight of 32.04243. No attempt was made to further "correct" the table values to account for the fact not all the methanol is being measured by the FID. The relative response of the FID to methanol as compared to propane (the hydrocarbon commonly used to calibrate the FID response) has been found to range from 0.73 to 0.85 (3, 4, 5, 6).

Table 8

Evaporative Emissions*

* FID data "corrected" by assuming all hydrocarbons detected were methanol, having a molecular weight of 32.04243.

Highway Cycle Emissions

The noble metal catalysts, with the exception of silver, provide excellent HC and CO emissions over the highway test as shown in Tables 9, 10, and 11. HC emissions are .010 g/mi or less under all oxygen conditions. CO emissions are also very low at 0.33 or less. As on the FTP, NOx is substantially reduced by the noble metal catalysts, except silver, during stoichiometric exhaust conditions.

The mixed metal catalyst performed well on the highway test. HC and CO were highest at stoichiometry where they were .016 and 1.48 g/mi respectively. Some NOx reduction was also seen.

The copper catalyst showed some HC activity over the highway test. The HC activity increased as the exhaust oxygen level increased. CO, aldehydes, and NOx emissions were not strongly impacted by the copper catalyst. The silver catalyst has substantial HC and modest CO activity. Aldehyde emissions were only measured at stoichiometry, and they were very low (less than 3 mg/mi).

The copper and silver units have shown improved emission control capabilities over the highway cycle as compared to the FTP. Apparently the lack of a cold start and/or the higher catalyst inlet temperatures are permitting the catalysts to be more active. Additional efforts could be expended on these catalysts to further increase catalyst inlet temperature during all driving modes by insulation of the exhaust system.

Exhaust emissions over various steady state conditions were also measured in our testing. These results, from idle to 30 mph, are summarized in Appendix 7.

Cost and Efficiency per Dollar Estimates

An estimate of the sticker cost of each catalyst in this study has been generated using the methods of reference 7. Sticker cost means the cost to the consumer of the catalyst as it is reflected on the sticker of a new automobile at an automobile dealership. The information in reference 7 has been updated 1) to use 77 percent of the current producer prices for noble metals as stated in the May 13, 1983 edition of American Metal Market - Metalworking News Edition and 2) to account for inflation between 1977 and 1983 at an estimated rate of ten percent per year. We use 77 percent of producer price for noble metals to account for what we estimate are the discounts to the automobile manufacturers due to high volume, long term purchases.

Each catalyst has been evaluated as an oxidizing and 3-way catalyst on an "efficiency per dollar" basis. This means that for an oxidizing catalyst, the previously calculated catalyst efficiencies for HC, CO, and aldehydes were summed and then the total was divided by the estimated sticker cost. The only difference in the calculation for 3-way catalysts is that catalyst efficiency for NOx is added to the HC, CO, and aldehyde efficiencies.

The results of these calculations are presented in Table 12. The estimated sticker costs of the catalysts in our program range from $58 to $150. The costs shown in Table 12 indicate more accuracy in our cost estimates than we would like to convey to the reader. Normally we would round these costs off to the nearest 5 or 10 dollars. In this case, rounding to the nearest 5 dollars would mask real cost differences in the catalysts and would make non-identical catalysts appear to cost the same amount.

Table 12

Sticker Cost and Efficiency per Dollar of Each Catalyst

Catalyst	Sticker Cost ($)	------Efficiency Per Dollar at------- 0% Oxygen	3% Oxygen	5% Oxygen
5 Pt: Rh (40)	111	2.92	2.44	N/A
12 Pt: Rh (40)	110	3.13	2.51	2.46

Canned substrate only, no catalyst	56	N/A	N/A	N/A

* Racetrack others are round
**Does not include the cost of base metals.

Strictly on the basis of the efficiency per dollar calculations, durability selection for 3-way catalysts would be made in the following order of decreasing interest:

Pd (20),
Pd (40),
3 Pt: 2 Pd (20),
12 Pt: Rh (40),
5 Pt: Rh (40),
Pd + BM (35),
12 Pt: Rh (40)*,
Ag (150), and
Cu.

Additional consideration must be included, however, in the selection of durability candidates. First, we must consider that virtually all 3-way catalysts used for gasoline-fueled vehicles contain rhodium. This indicates that rhodium is likely needed for adequate emissions durability. The second consideration is that durability testing is so costly that we may want to test samples with the highest probability of success, not the samples with least cost. With these considerations our first priority samples for durability evaluation as 3-way catalysts are in decreasing order of importance:

5 Pt: Rh (40),
Pd (40), and
3 Pt: 2 Pd (20).

Durability testing with other samples is not recommended. The samples designated Cu, Ag (150), 12 Pt: Rh (40)*, and Pd + BM

were omitted on the basis of low efficiency per dollar. The Pd (20) unit was omitted because it is like the Pd (40) catalyst in all respects except that it contains only half as much palladium.

For durability operation as oxidizing catalysts, efficiency per dollar would dictate selections in this order:

at 3% Oxygen	at 5 % Oxygen
Pd (20),	Pd (20),
Pd (40),	Pd (40),
3 Pt: 2 Pd (20),	3 Pt: 2 Pd (20),
Pd + BM (35),	12 Pt: Rh (40),
12 Pt:Rh (40),	
5 Pt: Rh (40),	12 Pt: Rh (40)*,
12 Pt: Rh (40)*,	Pd + BM (35),
Ag (150), and	Ag (150), and
Cu.	Cu.

The selections at 3 percent and 5 percent oxygen are in nearly the same order. Except for the Pd + BM catalyst and one less catalyst to evaluate at 5% oxygen, the order is exactly the same.

Since rhodium content has not been of importance in oxidizing catalyst durability with gasoline-fueled vehicles, our recommendations for durability evaluation of oxidizing catalysts follow the efficiency per dollar calculations more closely. For durability testing as oxidizing catalysts we recommend that the following catalysts be considered as the highest priority samples:

Pd (40), and
3 Pt: 2 Pd (20).

Again the final four samples on the basis of efficiency per dollar were deleted from consideration. The Pd (20) sample again was deleted since it is identical to the Pd (40) sample except that it only has half as much palladium. Durability emissions in theory should be somewhat lower with the Pd (40) catalyst. The Pd + BM sample was not included since it consistently performed at lower efficiencies than the Pd (20) and Pd (40) catalysts.

Summary

Over the FTP:

- o Almost no methane is measured in the exhaust.
- o Excellent HC and CO control (less than 0.2 and 2.0 grams per mile, respectively) is achieved with all the noble metal catalysts, except silver, at all exhaust oxygen levels.
- o All the noble metal catalysts, except silver, achieve NOx levels below 1.0 gram per mile at stoichiometry.
- o The addition of base metals to a Pd catalyst did not improve the catalyst.
- o CO and NOx control are both poor with the base metal catalyst.

Over the highway cycle:

- o Exhaust emissions are generally much less than on the FTP on a gram per mile basis, except for NOx emissions. Excluding emissions with the copper catalyst (which is the least active of all catalysts) and CO emissions with the silver catalyst, little HC, CO, or aldehyde is emitted.

Based on cost, catalyst efficiency, and other considerations, several catalysts have been identified which merit durability testing as 3-way and as oxidizing catalysts. Additional catalysts will be evaluated and additional effort will be expended to improve emissions from catalysts which have performed poorly to date.

APPENDIX 1

Vehicle Description

III. RESULTS

A. VEHICLE DESCRIPTION

1981 Volkswagen Rabbit "L" 4-Door Sedan - Model 177243
VI# 1VWF80175BV012728 Engr. Car # 1285

Automatic transmission, air conditioning, 155 80R13 tires, radio and cloth interior. (A vehicle with Vinyl "leatherette" interior was not available at time prototype was built. This may have a small influence on evaporative losses, but this will be negligible once the "new car" background level deteriorates.)

B. DETAILED COMPARISON OF PRODUCTION vs. METHANOL POWERTRAIN AND FUEL SYSTEM

ITEM	1980 PRODUCTION	METHANOL VEHICLE
Basic Engine		
o Type	- 827	- 827
o Displacement	- 1.6 liter (1588cc)	- 1.6 liter (1588cc)
o Bore	- 3.13 inches	- 3.13 inches
o Stroke	- 3.15 inches	- 3.15 inches
o Compression Ratio	- 8.2:1	- 12.5:1 (new pistons)
o Valvetrain	- Overhead camshaft	- Overhead camshaft
o Rated Power	- 76 HP SAE net @ 5500 RPM	- Not measured
o Rated Torque	- 82.7 Ft. lbs. SAE net @ 3200 RPM	- Not measured
o Other	-	- GTI basic engine - European high performance engine to withstand higher loads - U.S. cylinder head.
Fuel System	- Bosch CIS Fuel Injection with Lambda feedback control.	- Same as Production with calibration for Methanol operation.

(Narrative description and schematic of system in Appendix I)

ITEM	1980 PRODUCTION	METHANOL VEHICLE
Fuel System (Continued)		
o Fuel Pump		
Pump Life	- Life of Vehicle	- 6 months to 1 year due to corrosiveness of Methanol.
Other	-	- Improved insulation on wiring exposed to fuel.
o Accumulator		
Maximum holding pressure	- 2.5 Bar	- 3.0 bar (due to fuel difference).
o Fuel Filter		- Bonding glue changed for fuel compatability.
		- One way check valve deleted (Incompatable with fuel).
o Fuel Distributor		
System pressure	- 4.6 - 4.8 bar	- 5.0 - 5.3 bar
Calibration	- Optimized for gasoline	- Optimized for Methanol.
Other	-	- Material changes for fuel compatability.
o Air sensor	-	- Modified airflow characteristics.
o Fuel Injectors	-	- Material change for fuel compatability.
		- Plastic screen replaced by metal screen.
o Cold Start Injector		
Quantity	- One	- Two
Function	- On for start only.	- Cold start valves pulse for 8 seconds beyond start mode, below zero degrees centigrade.

ITEM	1980 PRODUCTION	METHANOL VEHICLE
Other	-	- Calibration changed for Methanol. - Material changed for fuel compatability.
Fuel System (Continued)		
o Fuel Injection Wiring	-	- Modified for cold start pulse function and to accomodate relays and thermo switch.
o Air Conditioner Idle Load Compensation	- Ignition distributor vacuum advance controlled.	- Throttle body idle air flow bypass system controlled. (Same as 1982 Production)
o Idle Setting		- Specific to Methanol calibration (See Appendix II)
PCV	- PCV Valve with calibrated plunger and calibrated orifice.	- PCV valve with calibrated plunger - no orifice.
IGNITION		
o Distributor	- Transistor high energy with hall effect and digital idle speed control through spark advance.	- Slightly reduced maximum centrifugal advance and slightly modified vacuum advance/retard characteristics. (See Appendix III)
o Spark Plugs	- Bosch W175T30	- Bosch W260T2-Colder
OIL COOLING	- None	- Heat exchanged from engine oil to cooling water for high loads only (e.g. trailer hauling) not anticipated to be needed in normal operation.

ITEM	1980 PRODUCTION	METHANOL VEHICLE
TRANSMISSION	- Automatic 3-Speed	- Automatic 3-Speed (1981 Production Transmission)
o Torque Converter Ratio	- 2.44	- 2.44
o Stall Speed	- 1900-2200 RPM	- 2000-2200 RPM
o Gear Ratios		
1	- 2.55	- 2.55
2	- 1.45	- 1.45
3	- 1.00	- 1.00
Axle	- 3.76	- 3.57
FUEL TANK		- (European)
o Material	- Steel	- Steel
o Coating	- Terneplate	- Phosphated steel, exterior painted
o Seams & Fittings	- Soldered	- Brazed
o Cap	- Non-Locking	- European neck and locking cap
FUEL	- Unleaded gasoline	- Methanol with 5.5% Isopentane

APPENDIX 2

Formaldehyde Measurement

FORMALDEHYDE MEASUREMENT IN VEHICLE EXHAUST AT MVEL

Robert K. Gilkey

Measurement of exhaust formaldehyde at MVEL is performed using a DNPH (Dinitrophenylhydrazine) technique adapted from that of L.A. Hull[1]. Exhaust carbonyls (including formaldehyde) are reacted with DNPH solution forming hydrazone derivatives. The derivatives are separated directly from the DNPH solution using a liquid chromatograph (LC). Quantization is accomplished with a spectrophometer in the LC effluent stream driving an integrator unit which determines peak height and/or area.

SAMPLING SYSTEM

Figure #1 gives an overall view of the formaldehyde sampling system. Exhaust from the vehicle is ducted to the constant volume sampling (CVS) unit where it is quantitatively diluted with room air. The formaldehyde system draws off a small portion of the diluted exhaust through a probe within the CVS unit. The collection portion is attached directly to the CVS unit to keep the plumbing as short as possible. A flow measurement and control unit is mounted to the wall at the left. The sample pump is mounted to the floor under the flow unit and is not visable.

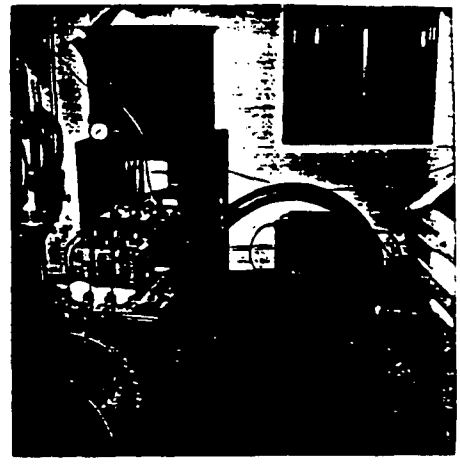

FIG 1

Figure #2 is a schematic of the sampling system. All of the solenoid valves are electrically connected to the CVS bag sampling switches. Activation of any one of these three switches automatically selects a unique set of impingers (bubblers) and isolates and vents the other two sets. Isolation and venting are required to prevent contamination of the CVS unit or the sample lines.

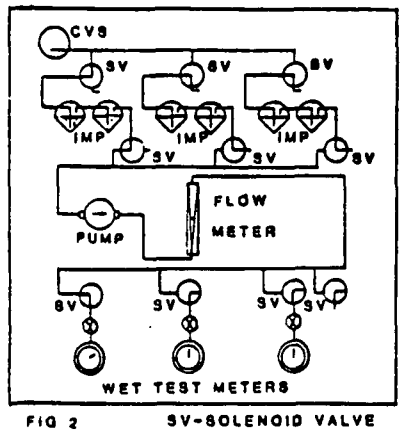

FIG 2 SV-SOLENOID VALVE
IMP-IMPINGER

The sample system is constructed of stainless steel, teflon, and glass upstream of the impingers. This part of the system is also maintained at 100°C. These precautions help prevent loss of formaldehyde within the system. Downstream of the impingers, construction materials and high temperature are not critical.

Two impingers are used in each set. Each is filled with five milliliters (ml) of DNPH solution and immersed in an ice bath during test. Two concentrations of this solution are used depending on the expected exhaust formaldehyde concentration. 0.25 g/l DNPH is used for most catalyst tests while 0.50 g/l DNPH is used for non catalyst tests. The DNPH is dissolved is slightly acidic acetonitrile (ACN).

1 L.A. Hull, "Procedures for 2, 4 - Dinitrophenylhydrazone Aldehyde-Keytone Air Analysis". Internal EPA, FTP memo, 1981.

Tests have shown that the efficiency of the first impinger is approximately 90% with two liters per minute sample rate.

ANALYSIS PROCEDURE

Upon completion of vehicle testing, the impingers are removed from the sampling system and refilled to 5 ml with ACN. Each impinger is permanently marked at 5 ml to facilitate this operation which restores evaporation loss. The solution is then transfered directly to a glass vial with a teflon lined septum which is compatible with the LC autosampler.

Separation of the carbonyl derivatives is done using a Waters Associates M-6000A chromatography pump with a Varian Micro pak MCH-10 reversed phase 30 cm x 4 mm column. A mixture of 65% ACN / 35% water is used as the carrier at a flow rate of 2 ml/minute. The column feeds directly into the primary absorbance cell of a Varian 635 UV-Visible spectrophotometer set to 360 nm wavelength. Sample injection is made through a 10 ul loop.

An overall view of the analysis system is shown in figure #3. The system is semi-automatic. (Baseline drift must be monitored and corrected during long runs to keep the integrator from being driven out of its range.)

FIG 3

Quantification is done using peak-height rather than area. Experiments indicate better repeatability and more consistant results with this method. The Hewlett Packard 3390A integrator permits reports in either peak-height or area or both.

Standards are run prior to each group of test vials to be analyzed. At least three are used to bracket the expected concentrations and a calibration curve is drawn. Generally this curve is linear, though corrections are made if it is not. (Non-linearity occurs when vehicle test conditions produce concentration differences greater than two orders of magnitude.)

Analysis system sensitivity is noise limited between $\pm$ 0.2 and $\pm$ 0.8 ug/ml of formaldehyde derivative. This translates roughly to 0.2 to 0.8 mg/mi for the FTP test and 0.05 to 0.25 mg/mi for the HWFE test. Repeatability is approximately $\pm$ 5% or better.

During test sample analysis, the Dupont 834 Automatic Sampler sequences a flush vial and a sample vial pair to the injection station. Every sample vial is injected twice. Each sample is allowed to elute for four minutes before the next injection or pair is introduced. The sampler will hold up to 47 pairs.

The Bewlett Packard 3390A Integrator is started upon injection of the first sample vial and allowed to run continuously until the last vial is finished. This unit generates a continuous trace of the spectrophotometer output anotated with the apparent retention time of each peak distinguished. A report is generated at the end of each run. This report gives peak information keyed to the retention time. The "formaldehyde" peaks are easily separated from the others by their relation to the DNPH peak. The integrator will hold information on over 1000 peaks which is adequate for very long runs. A typical vehicle vial analysis report is shown in Figure #4. Two injections were made of the same vial. The peaks at 2.38 and 6.46 minutes are formaldehyde/DNPH derivative. Unreacted DNPH peaks are at 1.91 and 6.00 minutes. (All three peaks preceding DNPH are tentively identified as species of NOx.) (In this case the vehicle was methanol fueled and equipped with a catalyst.) The total formaldehyde derivative concentration from the exhaust for this test was calculated as 3.1 ug/ml.

FIG 4

STANDARDIZATION

Standards are made by quantitative dilution from crystaline formaldehyde/DNPH derivative. This derivative (Formaldehyde 2, 4-Dinitrophenylhydrazone) is produced by reacting 40% aqueous formaldehyde solution with a hot saturated solution of 2, 4-DNPH in methanol. A drop of HCl is added and the derivative is precipitated with water. The crystals are filtered and recrystalized from a mixture of 3 parts methanol to 1 part water.

Primary liquid standards are made at 500 ug/ml and 200 ug/ml by dissolving the dried derivative in HPLC grade ACN. A micro balance is used for this operation. Successive dilution of the primary standards is used to give at least 10 concentrations down to 0.5 ug/ml. Once in solution, the standards are monitored for stability.

CALCULATIONS

Data are reported in terms of total formaldehyde per test phase and total formaldehyde per mile driven during the test phase. The primary equation is:

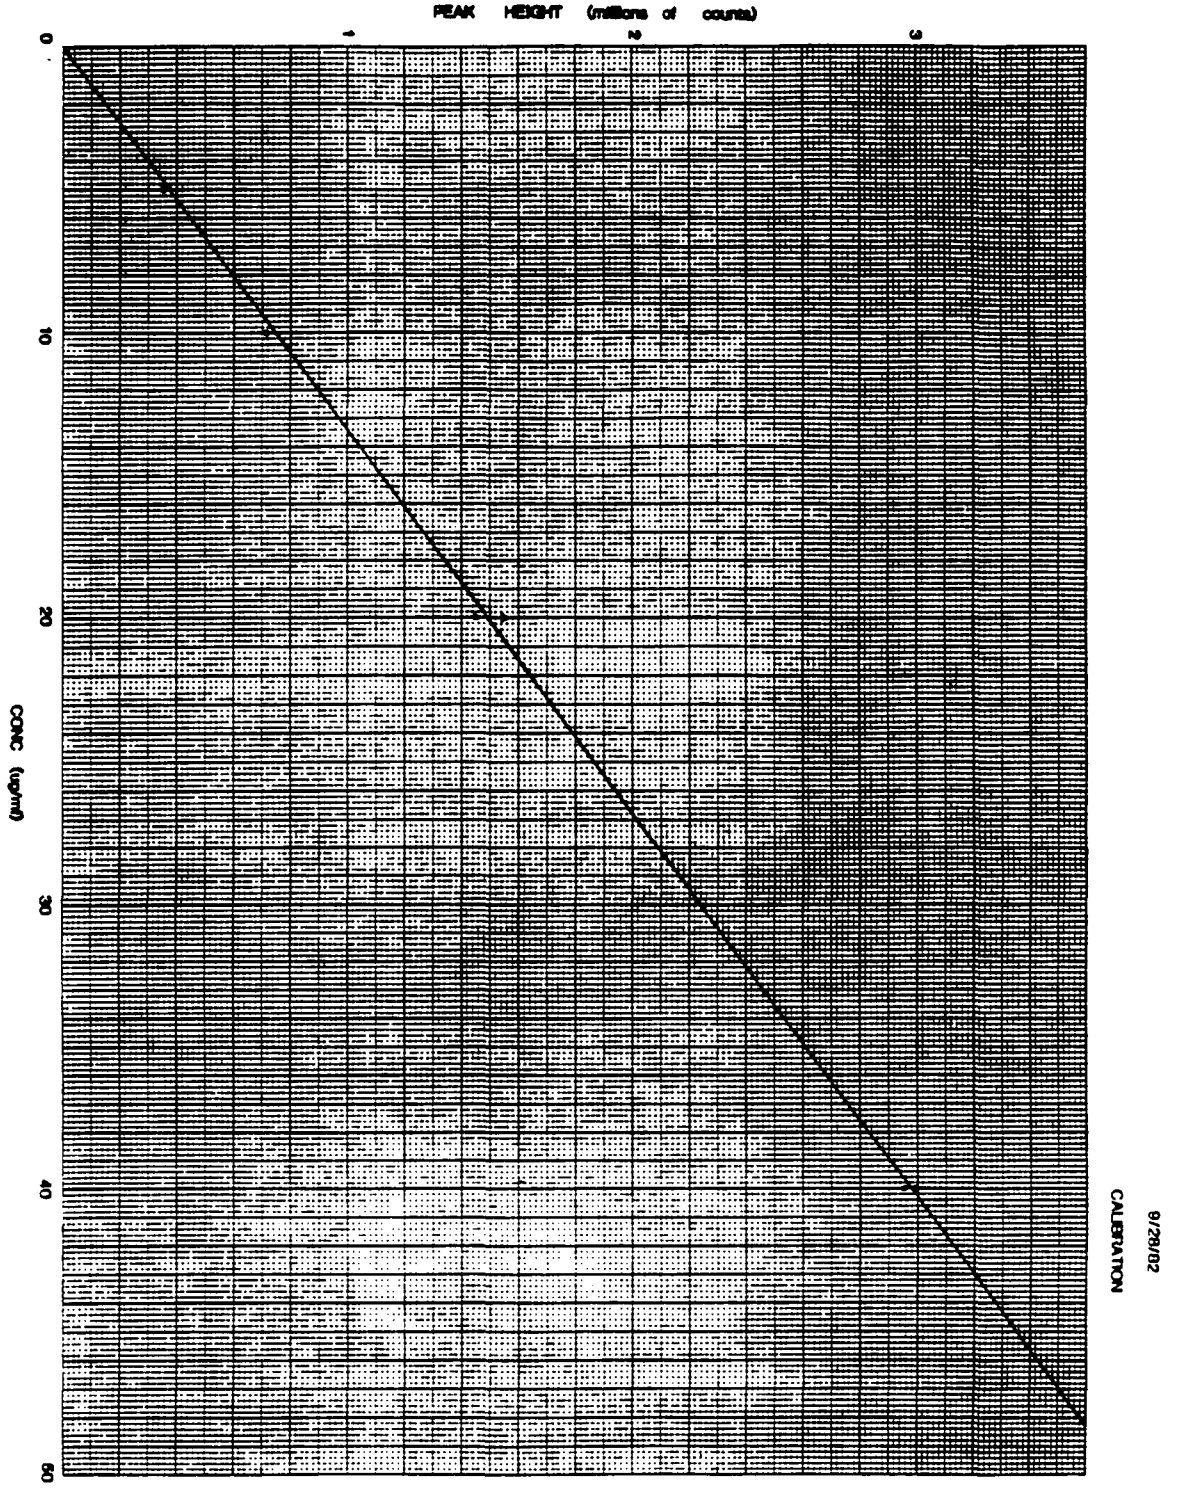
$$mg_F/mi = \frac{(.004046 * CONC * V_{imp} * VMIX)}{(VS * D)}$$

Where;

CONC = Concentration of derivative (ug/ml)
V_{imp} = Volume of impinger fluid (ml)
VMIX = Total CVS flow (ft^3)
VS = Volume of sample taken (l)
D = Distance driven during test (mi)

$$.004046 = \frac{MW_{Formaldehyde}}{MW_{Derivative}} * \frac{1/ft^3}{ug/ml}$$

$$= \frac{30.011}{210.04} * \frac{28.316}{1000}$$



PEAK HEIGHT (millions of counts)
0
10
20
30
40
50
CONC (ug/ml)
9/28/92
CALIBRATION

"CCNC" is determined from the formaldehyde peak height counts for each sample vial. The "best" peak is chosen from the two for each vial. If both are good, the last is chosen. The calibration curve for the run is then used to obtain the concentration from the height counts. "Best" is determined from integrator peak information and visual inspection.

"V_{imp}" is held constant at 5 ml of DNPH sampling solution in each impinger. Evaporation of the ACN solvent during test is a problem despite the ice bath in which the impingers are placed. The loss is always made up before the solution is transfered to the sample vials. Transfer of DNPH solution between or out of the impingers due to pressure imbalances is prevented by the isolating and venting solenoids.

"VMIX" is obtained directly for each test from the CVS control unit. The value represents the total volume of dilute exhaust produced by the vehicle during a test. VMIX is presented at standard conditions of 760 mm Hg and 68.0°F.

"VS" is measured by Precision Scientific 63111 or 63115 wet test meters. The meters are calibrated at nominal MVEL pressure and temperature conditions of 736 mm Hg and 73°F to correct readings to the above conditions. Corrections to actual test conditions are minimal and are neglected.

"D" is obtained as roll revolutions from the dynamometer control unit. A calibration factor is used to convert this reading to miles. This calibration rarely changes.

"MW" (Molecular Weight) for both formaldehyde and its DNPH derivative were calculated from their molecular formulas and generally available atomic weights. The formulas are:

2, 4-Dinitrophenylhydrazine (DNPH)..... $H_2 NNHC_6H_3(NO_2)_2$

Formaldehyde..... CH_2O

Formaldehyde 2, 4-Dinitrophenylhydazone... $CH_2 NNHC_6H_3(NO_2)_2$

One mole of formaldehyde reacts with one mole of DNPH to give one mole of derivative plus one mole of water.

A standard work sheet is used to collect data and report results. The results may be calculated from the equations and conversions given on the sheet. A "BASIC" program for the Apple Computer has been developed to complement the work sheet. This program generates a calibration equation of the form: Conc = A3*(Counts)^2 + A2*(Counts) + Ø. The curve is forced through zero, zero. The coefficients are then used in the reduction program presented in Figure 8.

Procedures for 2,4-Dinitrophenylhydrazone Aldehyde-Ketone Air Analysis

L.A. Hull, Dept. of Chemistry, Union College, Schenectady, New York,
on leave at U.S. EPA, in Gas Kinetics and Photochemistry Branch
Mail Drop 84, RTP, NC 27711

6/30/82

I. Reagents:

A. 2,4-Dinitrophenylhydrazine (DNPH) - Commercially available DNPH is recrystallized 2-3 times from HPLC grade acetonitrile (ACN)(Burdick and Jackson). To 50 ml of the ACN is added 3 gms of the DNPH. The solution is brought to a boil and decanted from any solid residue, allowed to cool to room temperature and then placed in an ice bath. The crystals are isolated by suction filtration with a minimum of atmospheric exposure to prevent the introduction of contaminants.

B. Sampling Solutions:

1. Ambient sampling (low ppb levels): In a 1.0 l volumetric flask 0.25 g of purified DNPH is dissolved in 1.0 l of HPLC grade ACN. To the resulting solution is added 0.2 ml of concentrated H_2SO_4.

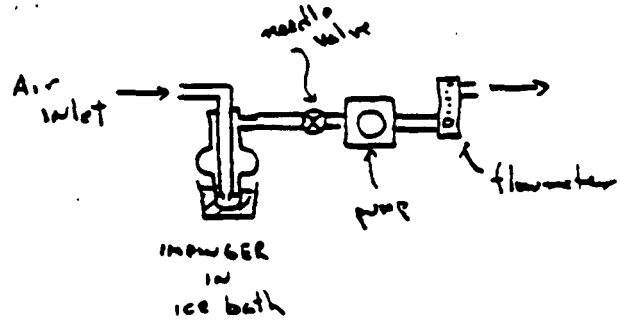
2. Laboratory sampling (ppm levels): The above concentrations are doubled.

II. Sampling Procedures:

A. Apparatus: A schematic of the apparatus is shown in Figure 1. The pump, flow controller, and flow meter all come after the impinger. The impinger is a non-frit type with the bubble tip within 3.0 mm of the bottom. The impinger should be calibrated for 2.0 and 4.0 ml of solution.

B. Ambient Samples: Without the bubbler the flow rate is adjusted for about 0.5 l/min with the needle valve. To the impinger is added 4.0 ml of the "ambient" sampling solution. The impinger is connected to the pump and the inlet lines and placed in an ice bath up to the level of the DNPH solution. The pump is then turned on and the flow readjusted to 0.5 l/min. The sampling continues for 60 minutes (30 liters). After

Figure 1. Schematic of DNPH sampling apparatus



sampling is complete the impinger is disconnected from the pump and inlet lines, caped and the solution warmed to room temperature. With the caps off the impinger the solution is made up to the 2.0 ml mark on the impinger by the addition of ACN through the inlet portion of the impinger. This serves to fix the final volume for concentration calculations latter and wash any material that collects before the sampling solution into the solution. The solution is then transferred to a teflon caped vial.

C. Laboratory sampling: The apparatus is the same except no ice bath is needed. Only 2.0 ml of DNPH laboratory sampling solution is required in the impinger and the sampling rates are from 0.1-0.5 l/minute with the total volumes from 0.25-2.0 l depending on how high the concentrations are. With the solution as constituted it would be best to keep the product of the carbonyl concentrations times the volume sampled less than 10 ppm-liters (10,000 ppb-liters) and the optimal product is 0.50 ppm-liter. For example if the carbonyl compound is at 0.5 ppm then a good sample size would be 1.0 l with the maximum being 20. liters. Another limitation arises if an accurate analysis of ketones is desired. In that case the amount of moisture introduced must be kept less than 50 microliters in the 2.0 ml of solution. The sampling volume may then be determined by taking into account the humidity of the air. After sampling the solution is made up to 2.0 ml with ACN addition (as described before) and then transferred to a teflon caped vial.

III. Analysis:

A. Standardization: Standards can be prepared in two ways.

1. Solid 2,4-Dinitrophenylhydrazones: Using standard methods (N.D. Cheronis, J.B. Entrikin, and E.M. Hodnett, Semimicro Qualitative Organic Analysis, 3rd Ed. Interscience Publishers, New York, 1965, pg. 499-501) the crystalline 2,4-dinitrophenylhydrazones of a number of the ketones and aldehydes were prepared. Weighed samples were then made up to known concentrations in ACN solution (approximately $2. \times 10^{-3}$ M) and the solutions used as standards.

2. Direct addition of the carbonyl compound to the reagent solution:

A measured volume of a liquid carbonyl compound (usually 1.0 microliter) is added to ACN (2.0 ml). An aliquot (usually 4.0 microliters) of that solution is then added to 2.0 ml of the laboratory sampling solution. Using the density of the carbonyl compound the concentration of the carbonyl compound (actually the 2,4-dinitrophenylhydrazone derivative) in the sampling solution can be calculated and the resulting solution used as a standard.

B. Analytical conditions: A Varian 5000 HPLC liquid chromatograph equipped with a built-in 254 nm ultraviolet absorbance detector connected to a Hewlett-Packard 7132A recorder, and a Variable Wavelength Spectra Physics SF 770 UV detector (set for 360 nm) connected to a Hewlett-Packard 3380S integrator were used. The analytical column was a Varian Micropak MCH-10 reversed phase 30 cm x 4 mm column. The analytical conditions are similar to those already described (K. Kuwata, M. Uebori and Y. Yamasaki, J. Chrom. Sci., 17, 264 (1979)). The HPLC conditions were 65% acetonitrile/35% water

(currently the analysis is done with 64% acetonitrile/36% water to compensate for some column degration) with a flow rate of 1.5 ml/min. In Table 1 are listed the retention times and calibration factors for those common compounds for which standards have been run. The standardization factors are based on a 30 l air sample having deposited its aldehydes/ketones in 2.0 ml of the DNPH reagent solution. For smaller air samples or larger volumes of collecting solution proportional factors can be used with the standardization figures in Table 1. In Table 2 are listed the retention times and standardization factors for some terpene carbonyl compounds run with solvent programming as follows: flow 1.5 ml/min, 65% ACN/H_2O-5 minutes, 65 to 75% ACN over the next 10 minutes.

C. Analytical Procedures: The sample solutions are transferred to a heavy-walled 2.0 ml reaction vessel fitted with a teflon cap (Supelco, Inc., Bellefonte, PA) and heated 15 mins in a water bath at about 70-80°C. The solution is then injected into the HPLC via a 10 microliter sampling loop. The solution is heated for another 15 minutes and the analysis repeated until successive injections agree to within 10%. For aldehydes the development is usually complete in 10-15 minutes. For simple ketones 30 minutes usually suffices, while the dicarbonyl compounds require as much as 3 hours heating.

Using the standardization factors and retentions times the peaks can be assigned and quantified. Because the formaldehyde peak overlaps the tail of the unreacted DNPH reagent the integration obtained is often distorted by baseline triggering problems. For a reliable formaldehyde concentration it is best to draw a baseline and use the absorbance measurement to determine the concentration.

1. Ambient samples: Because all the ambient samples are likely to contain significant quantities of water (greater than 0.2 ml) the ketone responses are virtually completely suppressed by the equilibrium shown below while the

$$\rangle C = O + H_2N\text{-}NHDNP \overset{H^+}{\rightleftharpoons} \rangle C = NNHDNP + H_2O$$

aldehyde responses are approximately 90% of their true ambient values. This result was obtained from experiments in which water was deliberately added, as well as sampling from moist bag samples. The data on ambient samples can then be handled as all aldehyde analyses and the values obtained as being approximately 90% of the true ambient values.

For high boiling (greater than 150-200°C) ketones (in particular the terpene carbonyl compounds) it is possible to evaporate off all the solvent (ACN and water) from the sample solution by gently heating the solution in a 10 ml beaker on a hot plate (remove the solution before the last of the solvent evaporates and let it do so without further heating). Redissolving the residue in 2.0 ml (or less, if enhanced sensitivity is desired) pure ACN removes the water interference problem.

2. Laboratory samples: If the quantity of water in the sample (as determined by the humidity of the sampled air and the volume sampled) is less than about 50 microliters/2.0 ml of sampling solution there is little if any interference in the analysis of any aldehyde or ketone so far sampled. Using 2 bubblers, bag sampling, and FT-IR cross checking of concentrations indicates collection efficiences are 100% as far as it can be determined for all the varieties of compounds listed in Tables 1 and 2 from the low ppb range up to several ppm.

3. Interferences: Besides the water interference in ketone analyses, as mentioned above, there is also a potential interference of simple aromatic compounds with the HPLC analysis at 254 nm. Because the 254 UV absorbance detection is sensitive to the presence of aromaticity, any species that collects in the ACN solutions and possesses an aromatic ring can potentially interfere with the 254 nm analysis. As a practical matter only benzene, toluene, (RT 3.74 min) and the xylenes (RT 4.5 min) are likely interferences. The 254 detector is 1/25 as sensitive to the above compounds as to the DNPH derivatives so only high concentrations would interfere with the analysis of particular carbonyl compounds. The use of 360 nm detector eliminates any such potential interference.

In experiments to date no interferences of O_3 (less than 0.5 ppm), NO (less than 5 ppm), NO_2 (less than 5 ppm), and HONO (less than 5 ppm) have been observed in the 1-2 liter laboratory sampling and none have been observed with ambient sampling.

IV. General Comments: The above described method for ambient aldehyde and laboratory aldehyde/ketone analyses is simpler than the aqueous impinger method described in the literature (see above, K. Kuwata reference) since it involves no extractions (which introduce solvent contamination problems and small volume handling problems) and in addition is efficient at collecting and quantifying carbonyl compounds of six or more carbons. In tests of the aqueous impinger method it was found to give, in our hands, less than 10% of the known gas phase concentration of benzaldehyde. Also even for high concentration ("laboratory") runs on ketones, because of the presence of water (as solvent) the aqueous impinger method was not useful for ketone determinations. While the above described method has drawbacks it is a useful tool for ambient aldehyde measurements and quite useful for aldehyde/ketone measurements in experiments where the water concentrations relative to the aldehyde/ketone concentrations are in the appropriate range.

The use of 360 nm detection (instead of 254 nm) also improves the sensitivity of the analysis. The increased sensitivity could allow 15 l ambient samples or 30 min sampling time and it eliminates any potential interferences from simple aromatic compounds. For laboratory analyses this will increase the sensitivity for which there is no water interference.

For routine analyses of high concentration samples (auto exhaust for example) where carbonyl compounds may be 1-10 ppm range it should be possible

to use 10-20 ml of the DNPH/ACN sampling solution ("laboratory") and collect 1-2 liters of exhaust over some convenient time (30 minutes). The resultant DNPH derivative concentrations should be ample and the water interference minimal (assuming the water is less than about 250 torr).

Care must be taken in the sampling to not unduly obstruct the flow of air into the sampling solution. It has been observed that significant decreases in the aldehyde/ketone concentrations (when in the ppb range) are observed if the gas sample passes through a simple 1 micro teflon filter.

Table 1. Retention Times and Calibration Factors for Simple Aldehyde/Ketone 2,4-Dinitrophenylhydrazones

Compound (DNPH derivative)	Retention Time (Mins) 254 nm	Absorption Cal. ($ppb/Abs.\ unit, \times 10^{-3}$) 254 nm	Integration (counts/ppb) 254 nm	Integration** (counts/ppb) 360 nm

Mr. Carl Scarbro
EPA
2625 Plymouth Rd.
Ann Arbor, MI 48105

Dear Mr. Scarbro:

We have completed the tests you requested on your Batch 100 methanol sample. The results were:

Test	Results
Heat of Combustion (ASTM D-240)	
Gross	10,292 Btu/lb
Net	9,143 Btu/lb
Water Content by Karl Fischer Titration (ASTM D-1744) wt. %	0.055%
API Gravity (ASTM D-287)	46.9° @ 60°F
Density (ASTM D-287)	0.7928 @ 15°C
Flash Point (ASTM D-93)	71.9°F
Acid Number (ASTM D-664) equiv. mg KOH/g sample	0.00
Lead by A.A. (ASTM D-3237)	3 ppm
Sulfur by Dohrmann Microcoulometer	N.D. (<0.001%)
Phosphorous by A.A.	1.7 ppm
Higher Alcohols by G.C.	N.D. (<0.1% ea.)

N.D.: None detected

All the above tests were performed in duplicate and the averages reported. The prices billed for these tests reflect an across-the-board price increase for our Division which became effective on October 1, 1982. As I mentioned in our telephone conversation, we performed these analyses last November (1982), but have held the results pending approval of payment-in-full for a previous purchase order (No. A-0579-NNSX) performed for Mr. Bill Clemmens, also dating from last November.

If you have any further questions, you may call me at (512) 684-5111, ext. 2144.

Sincerely,

Joseph Brock Fischer

APPENDIX 6

Unscheduled Maintenance on the Vehicle

Appendix 6

Unscheduled Maintenance on the VW Rabbit

Date	Problem	Repair
Aug. 06, 1982	Fuel pump failure	Replaced with pump from local VW dealer
Aug. 10, 1982	Ran out of fuel	Refueled (no catalyst on the vehicle)
Aug. 18, 1982	None	New methanol-protected fuel pump installed
Oct. 26, 1982	Stalls shortly after cold start	Replaced thermal switch, distributor cap and rotor
Nov. 02, 1982	Fuel guage inoperative	Replaced sending unit (Nov. 8)
Nov. 04, 1982	None	Hooked up digital idle stabilizer, per VW instructions.
Nov. 08, 1982	Starter wouldn't disengage	2 relays interchanged by local dealer, old thermal switch installed
Nov. 10, 1982	None	New thermal switch reinstalled
Nov. 19, 1982	High thermocouple reading in catalyst (over 1600°F)	Inspect catalyst, recorder malfunction
Dec. 02, 1982	Emissions change (NOx)	Fuel pump from dealer re-installed for diagnostic purposes
Dec. 07, 1982	Vacuum line to distributor found disconnected	Reconnected vacuum advance hose
Dec. 08, 1982	None	Methanol-protected fuel pump reinstalled
Feb. 07, 1983	NOx change	New O_2 sensor
Apr. 13, 1983	None	New battery installed

APPENDIX 7

Steady State Data at 0, 10, 20, and 30 Miles per Hour
