The groundwater recovery system was specifically designed to prevent off-site migration of groundwater containing dissolved PHCs at the site perimeter via a network of recovery wells. Design assumptions were based upon several years of field investigation and numerical modeling. Each of the existing site-perimeter recovery wells is a fully penetrating well screened from 10 feet below land surface to the bottom of the water table aquifer (75 to 78 feet). The maximum flowrate of groundwater extracted will be 400 gpm, with a normal flowrate of 360 gpm.

Preconditioning System

This system and all subsequent treatment processes are designed to handle a maximum flowrate of 400 gpm. The preconditioning system will receive water from the recovery wells and adjust the influent parameters to conditions more ideal for microbial growth before the water enters the recycle stream of the biological reactors. Water from the recovery wells will be delivered to a carbon steel collection tank (8,000 gallons). Nutrients (nitrogen and phosphorus), a carbon source (sodium acetate) and a defoaming agent will be added in-line prior to entering the tank. Flow equalization will take place in this tank. Water will be pumped from this tank by a horizontal, centrifugal wastewater feed pump. (The system also includes one installed spare pump.) High level and low level control in the collection tank will be connected to the groundwater well pumps and the wastewater feed pump. The groundwater will be heated in-line from the wastewater feed pump to the biotowers using a direct fired (natural gas), fin-tube water heater.

Biological Treatment System

The aerobic biological treatment system will consist of two packed biotowers. The main components of each biotower system are the biotower, the bioseeder and the recycle loop. Each system also contains support components for pH adjustment and air addition.

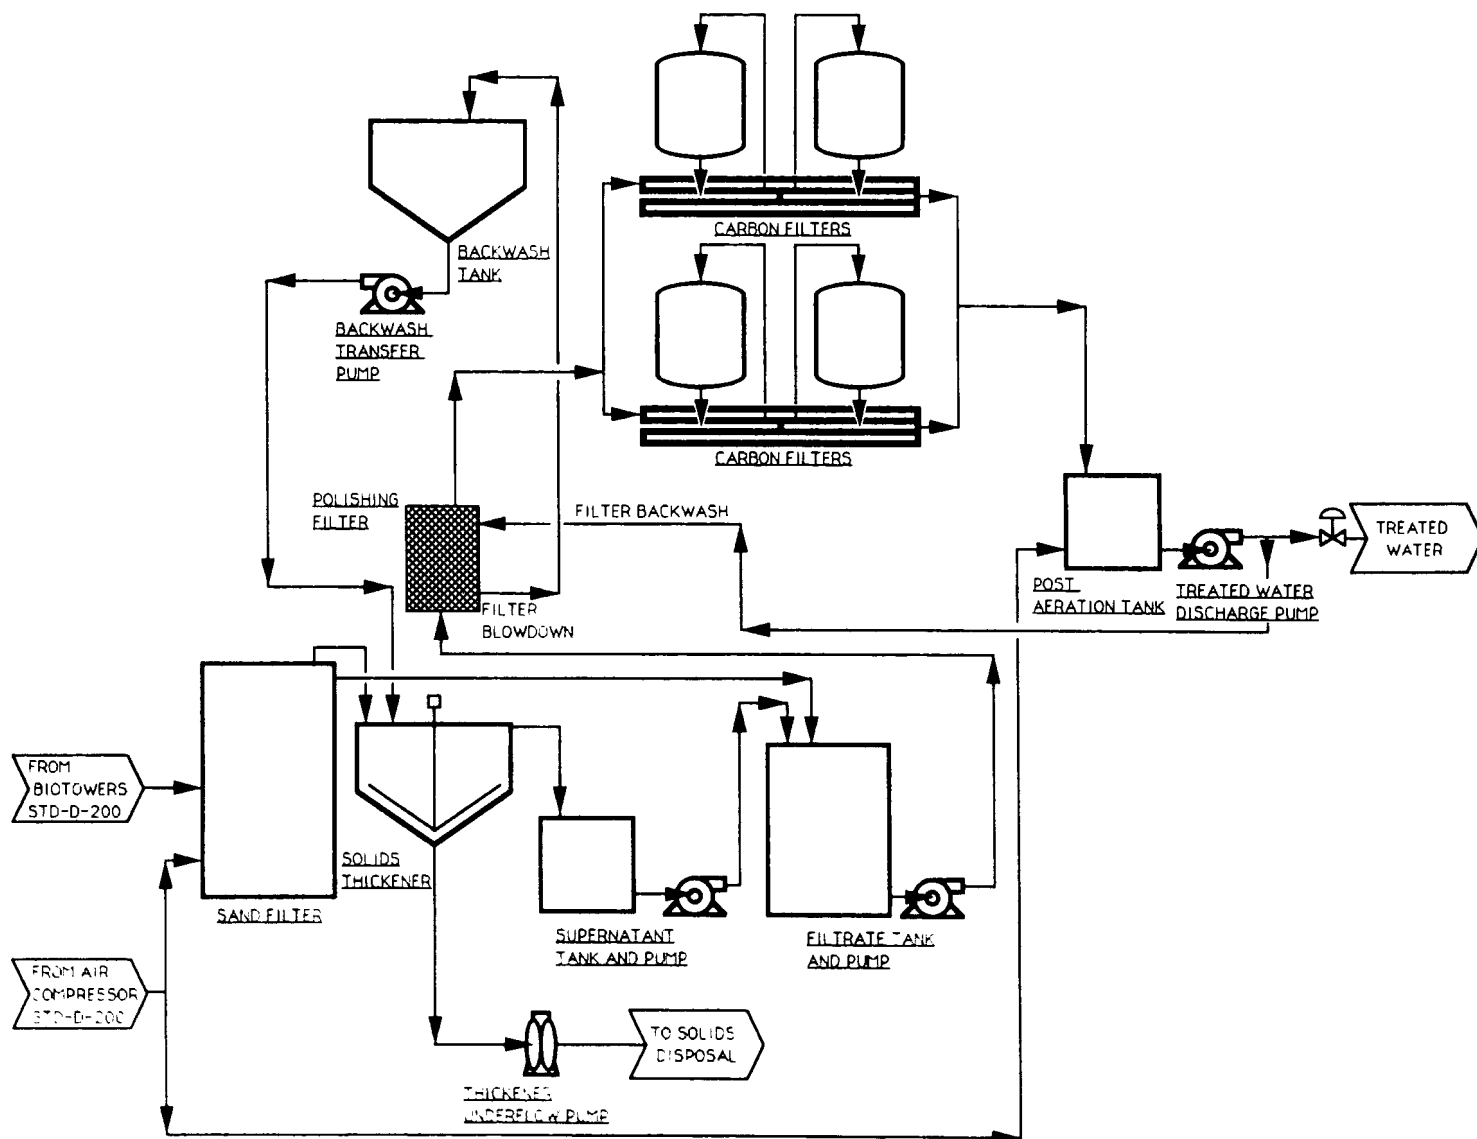
The total installed height of each biotower is 33 feet. The static growth attachment medium used in the biotower is specified as plastic and will have a total height of 22 feet. The BOD loading of each tower is estimated to be 20 pounds of $BOD_5/1,000/ft^3$/reactor volume/day. The HRT in each tower is designed to be 1 hour, achieved by an influent flowrate of 180 to 200 gpm per reactor. Centrifugal pumps will be used to continuously provide recycle flow in each biotower. Oxygen requirements for each biotower will be met via a blower and an air distribu-


Figure 3
Process Flow Diagram

tion system at the bottom of each biotower. Approximately 60 scfm of air at 15 psig will be supplied to each biotower. Higher air flowrates will be used periodically to scour excess bacteria from the media. A system will be used to supply an initial inoculum of active biomass and to maintain a sufficient biomass in the biotower, as needed.

Post-Conditioning System

The post-conditioning system consists of a sand filter, a solids thickener, a supernatant tank, polishing filters and two 40,000-pound twin-cell carbon adsorption units.

The filter (Parkson DynaSand) will continuously remove suspended solids in the biotower effluent to an effluent quality of 10 mg/L of suspended solids. The effluent will flow from the sand filter, by gravity, into the filtrate tank.

The reject stream from the DynaSand filter, containing water and solids, will flow to a 12-foot diameter, 10-foot high, cone bottom, carbon steel solids thickener. A mixer mechanism (rake) in the thickener tank is used to enhance solids settling and to convey the settled solids to the center of the conical bottom. The supernatant from the thickener will overflow to a 900-gallon carbon steel tank. The supernatant will be pumped to the filtrate tank by a pump on level control. The solids (approximately 2% solids by weight) will underflow from the thickener and be pumped with a mechanical diaphragm pump as waste solids for disposal.

The thickener waste solids will be applied to an on-site land treatment system during months when the temperature is above freezing. The solids will be applied with a pump and a distribution system. During the winter months, the solids will be pressed in a plate and frame filter press and the pressed sludge will be stored in an outside staging area until conditions permit land application. The sand filter effluent will be collected in an 8,000-gallon carbon steel filtrate tank. Flow equalization for carbon adsorption cells will be achieved in this tank. One pump will feed the water to the polishing filters and the carbon units. Water from the filtrate tank will be filtered to remove fine particles in the range of 20 to 30 μm using an external backwashing multiplex filter rated for a flow rate of 400 gpm.

Two 40,000-pound total, dual-cell (20,000 pounds of carbon per cell) carbon adsorption units will treat the biotower effluent. The valving system will allow the units to be switched on- or off-line as needed. Each twin-cell is capable of treating 200 gpm. Each cell will be filled with 20,000 pounds of Filtrasorb 300 carbon. This carbon has a surface area of 950 to 1,050 m^2/g and a bulk density of 27 to 28 pounds per cubic foot.

The water from the carbon cells will flow into a 6-foot diameter, 10-foot high, carbon steel post-aeration tank. Approximately 20 scfm of air will be supplied to increase the dissolved oxygen to 6 mg/L in the water prior to discharge under a NPDES permit. The tank will also provide enough head to permit gravity flow to the discharge point.

A rough order-of-magnitude cost estimate (in 1989 dollars) for the design, equipment purchase, construction and operation (20 years) was completed and is summarized in Table 10. Based on an average flowrate of 360 gpm for 20 years, the cost to remediate the PHC-contaminated groundwater is approximately $0.01/gallon.

Solid Phase Remediation of Petroleum-Contaminated Soil

Geoffrey C. Compeau, Ph.D.

ABSTRACT

Biological processes have been used to remediate petroleum hydrocarbons, pesticides, chlorinated solvents and halogenated aromatic hydrocarbons. Biological treatment of contaminated soils may involve solid-phase, slurry-phase or in situ treatment techniques. This paper will review the general principle of solid-phase bioremediation and discuss the application of this technique for the cleanup of total petroleum hydrocarbons.

Up to 280,000 cubic yards of soil on the site of a former oil refinery tank farm are contaminated with up to 15,000 part per million (ppm) of petroleum hydrocarbons and crude oil. The site posed significant challenges due to its size as well as the depth and range of contamination. The implementation of biological remediation required the design of a Land Treatment Unit (LTU) and a remedial program which would support the treatment of a significant amount of contaminated soil within a restrictive time schedule. Once this scenario was developed, the LTU was prepared for treatment and excavation and placement of soils was initiated. Currently, the LTU area encompasses 27 acres of a 45-acre site.

A mobile laboratory has been placed on-site and is staffed with chemists and microbiologists who analyze up to 150 soil samples per day. This laboratory has been designed and equipped to provide the necessary chemical and biological analyses to fully support the excavation and bioremediation program. On-site biological treatment activities include irrigating, aerating and tilling the soil to bring microorganisms, contaminants and oxygen into contact with each other to promote biological degradation. Chemical and microbiological monitoring conducted throughout the remediation process ensure that treatment levels are being met.

A multicomponent cleanup program is currently underway at a former marketing fuel terminal in the Western United States. The site, owned by a major oil company, contains approximately 60,000 cubic yards of soil contaminated with petroleum hydrocarbons at a mean concentration of 2,660 parts per million (ppm). The primary contaminants are weathered gasoline and diesel fuel. Initial site activities involved the development of a Remedial Action Plan which served as a basis for negotiations between the client and lead regulatory agency and resulted in the signing of a voluntary Consent Order. In addition, laboratory treatability evaluations were conducted to assess treatment options and cleanup levels achievable by those options.

After demolition of existing structures on the site, the majority of contaminated Area 1 soil (approximately 20,000 cubic yards) was excavated, screened and transported via conveyor system to Area 2 for solid-phase biological treatment. Additional soil is being treated in Area 1. Solid-phase treatment involves the excavation and processing of the contaminated soil with a carefully controlled combination of oxygen, water and specific nutrient mixtures. This treatment promoted

the rapid growth of naturally occurring bacteria present in the soil to metabolize and degrade the hydrocarbon contaminants. When treatment is complete, the Area 2 soil (approximately 25,000 cubic yards) will be treated in the same manner. Some of the treated soil may be used as backfill and compacted.

These remedial programs will reduce total petroleum hydrocarbon contamination from the mean concentration of 2,660 ppm to less than the 200 ppm cleanup criterion for soil and less than the 15 ppm cleanup criterion for groundwater. Over 20,000 cubic yards of soil have been treated by solid-phase treatment to date. The in situ system operation is effectively producing biodegradation in the subsurface. The project is approximately one third complete.

INTRODUCTION

Carbon is distributed in the environment in a variety of chemical compounds that range from gases (methane and carbon dioxide) to liquids (benzene and toluene) to solids (simple sugars and polymers such as cellulose, and asphaltic components of crude oil). The biological degradation of many of these compounds is a naturally occurring reaction. The rate of this reaction, however, is highly dependent on a variety of factors including the specific structure of the compound; the availability of nutrients, oxygen and water for the microorganisms; and the nature of the soil or other matrix in which the compound resides. In some cases, certain compounds can be biologically degraded in hours, while other compounds, such as asphaltics, are virtually totally nondegradable.

The susceptibility of petroleum products to biodegradation varies with the types and sizes of the component molecules. Since there are several hundred individual component molecules in any given crude oil, which can vary with its origin, the rate and extent of degradation is not easily predictable. Thus, the overall degradability of a specific petroleum product will depend on the proportion of degradable compounds of which it is composed. For example, alkanes of intermediate chain length $(C_{10}-C_{24})$ are degraded most rapidly. However, very long chain alkanes become increasingly resistant to biodegradation, and after exceeding a molecular weight of 500 to 600, they cease to serve as carbon sources. Branching structures typical of asphaltics also reduce the rate of biodegradation, and aromatic compounds are degraded more slowly than alkanes. Some hydrocarbons and hydrocarbon biodegradation products are highly resistant to ultimate biodegradation, that is, mineralization. Condensed polycyclic aromatics and cycloparaffins, as well as high-molecular-weight alkanes, are mineralized only very slowly. Solid-phase biological treatment processes involve establishing an environment conducive to microbiological growth and degradation of organic contaminants. The availability of nutrients and oxygen have significant effects on petroleum degradation. In particular, nitrogen and

phosphorus fertilizers, as well as oxygen, accelerate biodegradation. Additionally, proper pH and temperature also produce favorable effects.

Techniques employed in bioremediation are designed to remove constraints which slow degradation rates, such as limited nutrients and oxygen, in order to bring about rapid rates of degradation. Because of the variability in the source of petroleum hydrocarbon contamination, the chemical nature of contaminated soil and other concerns, treatability studies of contaminant reduction in specific soils are the most appropriate way of establishing proper treatment conditions. Such conditions include nutrient concentrations, moisture levels and treatment duration. Treatability studies also determine the extent of degradation that can be achieved for a given compound.

Biological treatment technologies for contaminated soils and groundwater fall into four main categories: (1) solid-phase biotreatment (landfarming); (2) slurry-phase biotreatment; (3) in situ biotreatment; and (4) combined technologies with chemical or physical treatment. The specific treatment process required is a function of the physical/chemical nature of the contaminant and the matrix in which it is found. The focus of this paper is the solid-phase remediation of petroleum-contaminated soils.

Solid-Phase Biotreatment

Soil provides a rich source of microorganisms, many of which have the potential to degrade hydrocarbons. Solid-phase biotreatment relies on principles applied in agriculture in the biocycling of natural compounds. The conditions for biodegradation are optimized by regular tilling of the soil and by the addition of nutrients and water. The natural indigenous microbial populations of soil are diverse and many of the appropriate microorganisms which degrade many contaminants are found in the contaminated soils.

The rates of bioremediation of contaminated soils are enhanced by optimizing the conditions of the site for oxygen levels, moisture content, available nutrients such as nitrogen and phosphorous, pH and contact between the appropriate microorganisms and the contaminants. This technique has been successfully used for years in the managed disposal of oily sludge and other petroleum refinery wastes through a process called landfarming. Solid-phase biotreatment of contaminated soils is probably the most widely used and cost-effective biotreatment technology currently in application today. Typically, the process is used for petroleum- and creosote-contaminated soils. Typical costs for this type of treatment are $40 to $120/cubic yard but are highly dependent on conditions at the site and materials handling costs. New federal regulations (RCRA, Land Bans) may prohibit some current disposal techniques and require alterations to the system due to fugitive emissions and leaching of organics and metals. A variety of options are available to control these emissions.

A solid-phase biotreatment program involves careful manipulation of oxygen, nutrient and water levels in the soil within the treatment unit to promote optimal degradation rates. Oxygen is supplied to the soil by tilling either with disk aeration equipment or heavier recycling equipment to a depth of 18 inches. Periodic turning of the soil to deeper depths (24 inches) may occasionally be conducted. The tilling frequency is determined by a number of factors including temperature, moisture levels, contaminant concentration levels and soil type. The soil generally is tilled with a frequency of 1 to 7 days depending on time and equipment limitations.

Nutrients normally are added in an aqueous form and applied with either a spray assembly attached to the disk aerator or by specialized equipment such as a terragator. Nutrient levels are monitored and nutrients are applied as needed to maintain optimum degradation rates based on treatability data for specific con-taminants. Specific nutrient formulations are added to the soil to maintain nitrogen, phosphorus and other trace minerals.

Moisture control is critical to optimum operation of the treatment unit. Low water activity restricts biological activity and results in less than optimal treatment rates. More than optimal moisture can create a number of significant difficulties, including slow treatment rates due to lower aeration potential, difficulties in the operation of treatment equipment and recontamination of the uppermost treatment lift by con-taminants from lower lifts if tilling equipment cannot be maintained at constant depth in the soil.

Optimal moisture levels are typically in the 12 to 15% by weight range. However, presence of a clay fraction in otherwise sandy soil may result in a 12 to 15% moisture range creating a moisture content that is too high. As a result, soil moisture levels are maintained at 10 to 12% to promote optimal degradation rates in some soils and as high as 16 to 17% in other soils. A more consistent measure of water activity is field holding capacity. Maximal microbial activity occurs at approximately 40 to 50% of the maximum field holding capacity.

Moisture at the site is controlled by careful irrigation and rainfall control, if required. An irrigation system at a small site (3 to 4 acres) is comprised of a number of radial sprinkler lines that provide the appropriate water application rate. At larger sites, this approach and the logistics of implementation are not practicable and a terragator type water truck is most practical.

In areas of high rainfall, rainfall control may be achieved through the use of large plastic tarp systems that minimize the amount of rainfall that comes in contact with the soil in the treatment unit. Tarps as large as 50 feet by 650 feet have been successfully employed; they are installed by a hydraulic roller attached to the bulldozer equipment used during treatment. Modifications of typical solid-phase remediations may include systems for control of volatile emissions and leachate collection as well as composting and heap leaching. A modified solid-phase bioremediation system was used successfully by ECOVA to control volatiles and leachate. The system consisted of a treatment bed lined with a high-density liner. A perforated leachate collection system and clean sand are placed on the liner for protection of the liner and proper drainage and collection of contaminated water as it leaches from contaminated soils placed on the treatment bed. The lined soil treatment bed is completely covered by a modified plastic film greenhouse. An overhead spray irrigation system contained within the greenhouse provides for moisture control and a means of distributing nutrients and microbial inocula (as needed) to the soil treatment bed.

Volatile compounds released from the soil are swept through the structure to the air management system. Biodegradable volatile organic compounds can be treated in a vapor phase bioreactor. Nonbiodegradable volatile organic compounds can be removed from the effluent gas stream by adsorption on activated carbon. Contaminated leachate which drains from the soil is transported by the drain pipes and collected in a gravity-flow lined sump. Leachate is then pumped from the collection sump to an on-site bioreactor for treatment. Treated leachate can then be used as a source of microorganisms and reapplied to the soil treatment bed through an overhead irrigation system, after adjusting for optimum nutrients and environmental parameters.

Soil heap bioremediation is a modification of solid-phase treatment used when available space (area) is limited. In soil heap bioreclamation, contaminated soil is excavated and stockpiled into a heap on a lined treatment area to prevent further contamination. Microbial inoculum (as needed) and nutrients are applied to the surface of the stockpile and allowed to percolate down through the soil. The pile can be covered and an air emissions recovery system installed as described above. A leachate collection system is used to collect the fluid, which is recycled. An internal piping system may also be installed in order to blow air upwards through the soil and thus accelerate the biodegradation process through the addition of oxygen. During operation, pH and moisture content are maintained within ranges conducive to microbial activity. Typical costs are similar to conventional solid-phase treatment.

Composting processes are another modification of solid-phase treatment in which the system is operated at higher temperature due to increased biological activity. This technology is used for highly contaminated soils, treatment of poorly textured soils and in areas where temperature is critical to the sustained treatment process. Contaminated soils are mixed with suitable bulking agents, such as straw, bark or wood chips, and piled in mounds. The bulking agent improves soil texture for aeration and drainage. The system is optimized for pH, moisture and nutrients using irrigation techniques and can be enclosed to contain volatile emissions. Care must be taken to control leaching, to control volatile emissions, and to ensure that the bulking agent does

not interfere with the biodegradation of the contaminants (preferential carbon source).

CASE HISTORY: BIOREMEDIATION OF BUNKER C FUEL HYDROCARBONS

Soil remediation activities are being conducted at a former tank farm facility in southern California. The soil undergoing remediation consists of berm soils and soils underlying a former 20-acre concrete-lined surface impoundment which was used to store bunker fuel oil. The quantity of soil treated will be in excess of 280,000 cubic yards and is being treated in eight separate treatment cells at the site. The petroleum contamination contained hydrocarbons in the range of C-10 to C-35 carbon chain length. The oil-contaminated soil was found not to be hazardous based on the 96-hour Acute Aquatic Toxicity Bioassay tests.

Treatment Concentrations

An initial treatability evaluation was conducted to determine the optimal concentration for treatment in the land treatment unit. It was determined that a starting concentration of approximately 4000 ppm total petroleum hydrocarbon would be optimal and that it was potentially possible to treat up to 5000 to 6000 ppm TPH in these soils.

Since the excavation program required continued progress and the sequential stacking of lifts of soil to accommodate the excavation requirements, an area was set aside at the treatment site and an LTU was charged with 5500 cubic yards of high concentration (average 5595 ppm TPH) soil. The data from this LTU treatment verified the upper limit of bioremediation to meet scheduling requirements.

TPH Monitoring

The project involved treating more than 280,000 cubic yards of soil contaminated with petroleum hydrocarbons in concentrations of up to 6,000 ppm as total petroleum hydrocarbons (TPH). The analytical method used was U.S. EPA method 418.1 and the cleanup standard was 1000 ppm TPH. In order to guide the excavation of the soil and facilitate process monitoring of the solid-phase process, a mobile laboratory (Figure 1) was placed on-site and staffed with environmental chemists and microbiologists. The laboratory has analyzed up to 150 samples per day during peak periods of production from the excavation and land treatment units. More than 20,000 samples have been analyzed in the laboratory at this stage of the project.

During one phase of the project, a gas chromatograph was installed in the laboratory to guide the remediation of light kerosene-like solvent residues located in a separate disposal area on the site. For this aspect of the remediation, the analytical protocol was U.S. EPA method 8015 and the cleanup standard was 100 ppm TPH. These soils were incorporated into a separate LTU for treatment in several consecutive lifts.

The gas chromatograph also was used to qualitatively evaluate the progress of the remediation by determining what fraction of hydrocarbons had been treated and what fraction remained.

Nutrient and Biological Monitoring

In addition to contaminant chemistry, the site support laboratory supported the nutrient addition program and monitored biological activity in the LTUs. Ammonia and nitrate nitrogen as well as phosphate were routinely analyzed for in the LTU. It was found that random sampling of the LTU at approximately five samples per acre gave adequate coverage for the nutrient, moisture and microbiological monitoring.

To evaluate biological activity, total heterotrophic organisms in the treatment soils were enumerated. The microbial analysis program at the site was augmented with plating of soil onto mineral media containing specific hydrocarbons as the sole source of carbon for growth. The development trends for the hydrocarbon-degrading population could be evaluated in this way.

A variety of treatments were attempted to stimulate overall microbial activity as well as specific hydrocarbon degraders. These studies indicated that treatments selected for scale-up effectively stimulated the activity of the hydrocarbon-degrading populations.

Laboratory evaluations of the soil from the remediation and small-scale studies were conducted to more clearly establish the population of organisms involved and the community interactions responsible for the degradation of hydrocarbons. Obvious changes in the microbial population occurred over time in the LTUs. The evaluation of hydrocarbon-degrading activity has helped to clearly define the importance of these changes. A dominant organism in the remediation, distinguished by a distinctive orange pigment, was identified as possessing the ability to metabolize a wide range of hydrocarbon substrates. To better understand the full substrate range of the orange organism, media plates were made using mineral salts broth, purified agar and hydrocarbon. Clear evidence of growth was demonstrated on pentadecane (C-5), octadecane (C-18), pristane (C-15 branched), docosane (C-20) and hexacosane (C-26). A preliminary study on C-30 hydrocarbons also is being undertaken. Control plates which contained no hydrocarbons did not demonstrate growth. Interestingly, the organism produces a mucopolysaccharide when attempting growth on longer chain hydrocarbons. These types of responses are known to be important in the solubilization of heavier hydrocarbons.

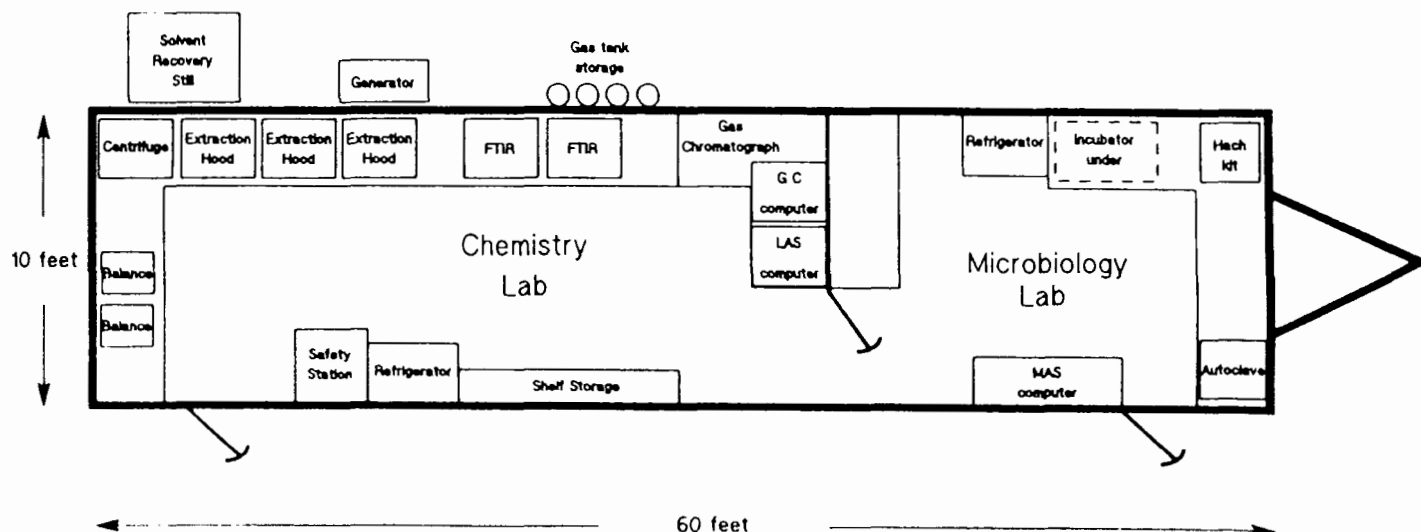
To follow the occurrence and development of these organisms, soils from selected LTUs were plated on substrate specific hydrocarbons every other week. In this way, the population of specific hydrocarbon-degrading organisms was followed during the remediation. This required no additional resources or expenditure for the project.


Figure 1
ECOVA Mobile Laboratory

Data Management

The Laboratory Data Management System is a PC-based software package designed and written for ECOVA mobile laboratory operations. The system provides direct data input for each sample from the moment it is taken (via a laptop-mounted computer) through the actual analysis to the final customized report. In addition, we can transfer selected blocks of data between system modules and/or commercial software packages such as spreadsheet or graphics programs.

Data integrity is assured through the use of triple-redundant data bases, automatic backup to floppy disk and a complete audit trail facility. The audit trail facility tracks and records every change made to a sample record. The audit trail data base is invisible to, and totally inaccessible by, mobile laboratory personnel.

Finally, the remote access feature uses a specialized telecommunications package which allows home office personnel to support the system even while it is unattended. This system allows quality assurance checks, data transfers or software modifications to be performed after normal working hours, eliminating system downtime for normal procedures.

Summary of Remediation Data

Figure 2 is a representative of TPH data from treatments employed during the remediation. The pattern of degradation presents a similar pattern to that observed in earlier LTU soils. A high initial rate is followed by a period of reduced rate as the composition of the petroleum hydrocarbon and microbial community changes. After these changes, the rate of remediation increases.

Figure 3
LTU 5-2
Overall Microbial Analysis

these pigmented organisms possess the ability to degrade an extremely wide range of petroleum hydrocarbons from hexane (C-6) through hexadecane (C-16), pristane (branched C-15), octodecane (C-18) and hexadocosane (C-26). The physiology and ecology of this organism may be pivotal to the control of the rate of hydrocarbon degradation in the remediation. This is currently being evaluated.

Figure 2
LTU 5-2
Performance TPH
Figure 4
LTU 5-2
Analysis of Populations

There is a critical period of time in the remediation in which the rate slows. This occurs during the period of from 6 to 9 weeks in soils which have a starting concentration of approximately 5,000 ppm. This phenomenon is not observed in LTU soils which have starting TPH concentrations below approximately 3,500 ppm.

The significance of the changes in TPH degradation are borne out by the overall changes in nutrient concentrations and the heterotrophic (including petroleum hydrocarbon-degrading) microbial populations which occur during this period. The increased presence and activity of organisms that do not degrade hydrocarbons, but potentially compete for ammonia (an essential nutrient for hydrocarbon metabolism) is supported by the general, but slight, decrease in heterotrophic organisms during the course of the remediation (Figure 3) and changes in the ratio of forms of nitrogen present in the soil.

The analysis of the heterotrophic population indicates that significant changes occur after 7 weeks of treatment (Figure 4). Over the final 5 weeks of the remediation, brightly pigmented bacteria emerge from the population. Heterotrophic organisms in general decrease; the proportion of the hydrocarbon degrading organisms increases. As stated,

The nutrient concentrations attained during the study were sufficient to evaluate the effect of increased concentrations on bioremediation. The increased nutrient concentrations did not have an effect on the rate of degradation. It is also possible that increasing the concentration of nutrients may have the negative effect of stimulating populations of organisms that do not degrade TPH.

CONCLUSIONS

The solid phase remediation program implemented for this site has been extremely successful. More than 150,000 cubic yards of soil have been treated and removed from the LTUs to date. Approximately 120,000 cubic yards of soil remain to be treated. More than 20,000 samples of soil from excavation, process monitoring, verification sampling of the LTUs and backfilling operations have been taken throughout the course of the remediation. Several optimization studies are being conducted on-site during the remediation at an incremental cost to the remediation. These studies assure that the optimal rate of remediation is occurring and provide valuable information to the client for use at other sites which are candidates for bioremediation.

CASE HISTORIES: PETROLEUM MARKETING TERMINAL REMEDIATION

A former marketing terminal in the Western United States had been contaminated by losses incurred during the handling of petroleum products during 65 years of operation. More than 60,000 cubic yards of soil are contaminated with petroleum hydrocarbons at a mean concentration of 2,660 parts per million (ppm). Groundwater analyses identified benzene as the compound of concern. Ethylbenzene, toluene and xylenes are present at low concentrations.

ECOVA Corporation was hired to assist in the development of a Remedial Action Plan (RAP) for the fuel terminal site. A laboratory treatability evaluation to assess treatment options and cleanup levels achievable from those options was conducted. Options studied included excavation and off-site disposal; off-site treatment; and on-site treatment focusing on bioremediation. Activities managed in support of the RAP included preliminary design of cleanup systems and regulatory liaison and public involvement activities.

The RAP served as the basis for negotiations between the client and the lead regulatory agency which resulted in the signing of a voluntary Order on Consent. The voluntary Order on Consent was finalized in November 1988.

Two recommended treatment alternatives, on-site solid-phase biotreatment and in situ biotreatment, were selected because of the destruction of the contaminants and significant cost savings compared with off-site disposal. Bioremediation of the contaminated soil reduces the hydrocarbon contaminant level to below the agreed to cleanup level of 200 ppm. Water cleanup criteria for the contaminants are as follows: total hydrocarbons-15 ppm; benzene-40 parts per billion (ppb), and ethylbenzene-3.5 ppm. Once these levels are achieved, the site will be rendered clean and suitable for development.

ECOVA Corporation was awarded the full-scale remediation contract in February 1989 after winning a competitive bid over 30 other major environmental contractors. The multimillion dollar project is the largest biological remediation project undertaken in the State of Washington.

The first task involved preparation of a detailed Work Plan and initiation of permitting. The Work Plan contained the final design of the remedial systems and a detailed description of the installation and operation procedures to be followed during the remediation. Once the necessary permits were obtained, the remedial program was initiated.

The remedial program involved demolition, installation and operation of in situ systems and excavation and treatment of contaminated soil. This paper describes the activities and results obtained to date related to the solid-phase biotreatment component of the remedial program. A discussion of the activities and results to date related to the in situ biotreatment component of the remedial program can be found in another paper within these proceedings by Nelson and others.

The site is divided into four areas (Figure 5). The original plan called for contaminated soil from Area A to be treated in Area B and then returned to Area A for replacement and compaction. Transportation of the contaminated soil to Area B is accomplished with a conveyor system running through an existing pipe tunnel under the major street separating Areas A and B. Solid-phase biotreatment of contaminated soil in Area B would then follow. Contaminated zones in Areas C and D are treated by in situ biotreatment and soil oxygenation.

Demolition activities began in May 1989. Surface and subsurface structures were demolished and significant quantities of demolition debris, including concrete rubble, pipe, brick and wood were removed. Excavation of contaminated soil in Area A indicated that the extent of contamination was greater than the preliminary investigation determined. As a result of the increased volume of contaminated soil, Area A is used as a solid-phase treatment area as well, and the treated soil from Areas A and B is transported off-site for disposal after treatment to below the 200 ppm cleanup criteria. Solid-phase biotreatment began in Area B in September 1989 and in Area A in October 1989.

Figures 6 and 7 present some operational data for the solid-phase treatment program to date. Figure 6 indicates that the average lift volume is approximately 2,800 cubic yards. The lift volume varies due to a number of factors. The area available for treatment varies between treat-
Figure 5
Site Map

ment area and the surface area which is affected by stockpile side-slope requirements and other site activities. Also, the lift size varies depending upon whether or not all cells within the lift are treated to below the treatment criteria. If there are cells that have not reached the treatment criteria, these cells remain in the treatment unit and are incorporated into the next treatment lift.
Figure 6
Average Treatment Lift Volume

Figure 7 shows the actual treatment time required for each lift and the running average treatment time for all lifts to date. The bench-scale treatability studies for the site indicated that treatment times should be in the 3 to 6 week time frame, if optimal degradation rates are maintained. This optimal treatment range is represented in Figure 7 as two horizontal lines. As can be seen in the figure, 8 of the 12 lifts completed to date are within the 3- to 6-week treatment time frame estimated by the treatability study. Four lifts have required longer treatment times.

Lifts 4 through 6 were treated during the winter months when ambient temperatures were colder than normal and snow accumulated and remained on the ground for 2 weeks. This colder temperature significantly reduced the treatment rates. The general rule of thumb is that for every 10°F decrease in temperature, there is an associated 50% decrease in degradation rates. In addition, the rainwater control tarp systems were not fully operational. As a result, the soil moisture levels
Figure 7
Treatment Time by Lift

were higher than optimal which further contributed to the decreased treatment rates and the associated increase in treatment times.

The treatment time for Lift 8 was significantly longer than the 3- to 6-week treatment time frame estimated by the treatability study. A number of factors are responsible for the extended treatment time requirements for this lift. The primary factor is excessive soil moisture.

In early June, the lift was within 1 week of reaching the cleanup criteria in more than 80% of the cells in the lift. However, before the verification samples were collected, an unanticipated storm saturated the upper 24 to 36 inches of the lift before the rainwater control tarp systems could be deployed. Efforts to reduce the amount of soil moisture by tilling resulted in contaminated soil and water from lower lifts being brought up to within the current treatment lift. As a result, the next sampling indicated that the concentrations in all cells were at or above the original starting concentrations. Therefore, the entire treatment process had to start again and resulted in a lift that had a treatment time approximately double (12.4 weeks) the maximum treatment time requirement indicated by the treatability study.

Figure 7 also indicates that subsequent treatment times have been on the lower end of the 3- to 6-week treatment time range. This improved performance is due to the warmer temperatures that occurred during the later part of the summer and early fall. The average treatment time, which has been shifted higher by the four lifts discussed above, is back within the 3- to 6-week treatment time range.

To date, approximately 32,000 cubic yards of contaminated soil have been treated to below the 200 ppm cleanup criterion and disposed off-site. An additional 25,000 to 30,000 cubic yards of contaminated soil from Areas A and B will be treated before the solid-phase component of the remedial program is concluded.

Abiotic Immobilization/Detoxification of Recalcitrant Organics

ABSTRACT

In contrast to many remedial techniques that simply transfer hazardous wastes from one part of the environment to another (e.g., off-site landfilling), in situ restoration may offer a safe and cost-effective solution through transformation (to less hazardous products) or destruction of recalcitrant organics. Currently, the U.S. Environmental Protection Agency and U.S. Department of Energy are encouraging research that addresses the development of innovative alternatives for hazardous waste control. One such alternative is biotic and abiotic immobilization and detoxification of polynuclear aromatic hydrocarbons (PNAs) as associated with the soil humification process. This paper discusses: (1) the possibility of using abiotic catalysis (with manganese dioxide) to polymerize organic substances, (2) aspects associated with the thermodynamics and kinetics of the process and (3) a simple model upon which analyses may be based.

INTRODUCTION

Humic materials are natural organic substances that are common in the environment and are involved in a nonstop polymerization process with organic molecules. Polymerization of humus material (humification) involves the breakdown, convolution, and transformation of organic matter into long, complex, amorphous organic molecules with numerous reactive functional groups and bridges that are similar to the reactive groups added to aromatic compounds by microbial enzymatic action. Functional groups include hydroxyl, carboxyl, ketonic, phenolic, quinone, ester, ether, carbonyl, imino and amino groups, with dihydrodiol and dione (e.g., quinone) structural formations showing promise in promoting polymerization. During humus formation, reactive compounds are linked through biotic-enzymatic and/or abiotic-chemical reactions, resulting in complexes of polymerized molecules. Biotically induced polymerization, for example, can result in oxidative coupling of nonreactive organics (e.g., anilines) into active organic polymerization processes (e.g., using dichlorophenols).[1] More recently, scientists have noted that abiotically catalyzed polymerization may also represent an important aspect of humification.[2-5] For example, manganese-bearing silicates have demonstrated catalytic effects in enhancing the polymerization of polyphenols (e.g., hydroquinone).[5]

ABIOTIC CO-POLYMERIZATION

Research at Utah State University (USU) has indicated that multiple-ringed constituents might be humified. Soil samples spiked with a ^{14}C-labelled benzo(a)pyrene [B(a)P] [the structure of which is shown in Figure 1] have shown activity in humic and fulvic acid soil samples, which previously had been extracted with methylene chloride. The extraction procedure did not remove all of the radiolabelled carbon, suggesting some sort of binding process between the B(a)P molecule or a portion of it and the humus material. These results suggest that the B(a)P [or B(a)P intermediate or product] was structurally bound in some way to the humic/fulvic material and humin that was formed. These results occurred for both sterile and nonsterile samples. The results suggest that: (1) co-polymerization of multiple-ringed constituents might be possible and (2) abiotically catalyzed polymerization may also be occurring and may be as important as microbially mediated polymerization in humification. If one reviews the structures of humus (Figure 2) and those of B(a)P metabolites (Figure 3), one notes functional-group similarities. Jeftic and Adams[6] presented a general reaction scheme for the anodic oxidation of B(a)P, illustrating its transformations and polymerization properties.

Bollag,[2] whose research focuses on enzymatically induced polymerization, stated that abiotically mediated catalysis also may be important. One result of his research was the indication that most reactants appeared to move through a transitional quinone-like structure prior to the final humified product. Senesi and Schnitzer[7] have proposed similar pathways for abiotically induced polymerization. They suggested that hydroquinone $[1,4-C_6H_4(OH)_2]$ goes to the semiquinone
Figure 1
Structure of Benzo(a)pyrene

radical [$\bullet C_6H_4O(OH)$] and that this radical forms a quinone ($1,4$-$C_6H_4O_2$) where all reactions are reversible (Figure 4):

$$C_6H_4(OH)_2 = \bullet C_6H_4O(OH) + H^+ + e^- \qquad (1)$$
$$\bullet C_6H_4O(OH) = C_6H_4O_2 + H^+ + e^- \qquad (2)$$
Shindo and Huang[5,8] explained the polymerization of hydroquinone in the following manner, using oxidation-reduction potentials (E°)[9,10] for manganese dioxide (MnO_2) and hydroquinone:

$$MnO_2 + 4H^+ + 2e^- = Mn^{2+} + 2H_2O \quad E^\circ = +1.224 \text{ V} \quad (3)$$
$$C_6H_4(OH)_2 = C_6H_4O_2 + 2H^+ + 2e^- \quad E^\circ = -0.6992 \text{ V} \quad (4)$$
Thermodynamically, the overall oxidation-reduction reaction is $+0.525$ V, indicating that the oxidation of diphenol (i.e., hydroquinone) by manganese dioxide is favorable. Shindo and Huang[11] took a similar approach to explain the catalytic polymerization of hydroquinone by primary minerals, especially the olivine tephroite (Mn_2SiO_4). Schnitzer[12] suggested that the rate-determining step in the synthesis, by oxidative polymerization of humic acids from simple phenols and phenolic acids, is the formation of a semiquinone radical involving a one-electron transfer reaction. These relatively unstable and reactive semiquinone radicals will couple with each other to form a stable humic acid polymer. Shindo and Huang[5] noted that because the coupling of radicals requires no activation energy (in contrast to electron transfer reactions), coupling of semiquinones rather than the formation of quinones should be kinetically the preferred reaction path. Therefore, diphenols should be converted to humic acid through semiquinones during the reduction of Mn(IV) oxides. Senesi and Schnitzer[7] noted that the semiquinone radical can form a semiquinone radical ion [($\bullet C_6H_4O_2$)-] and then a semiquinone dianion [($C_6H_4O_2$)$^{2-}$], where all reactions are reversible (Figure 4):

$$\bullet C_6H_4O(OH) = (\bullet C_6H_4O_2)^- + H^+ \qquad (5)$$
$$(\bullet C_6H_4O_2)^- = e^- = (C_6H_4O_2)^{2-} \qquad (6)$$
In previous work, Kononova[13] and Schnitzer and Kahn[14] made a statement similar to that of Shindo and Huang[5] regarding the polymerization of hydroquinone through a semiquinone radical.[15,16] Wang et al.[16] also reported that in the absence of an electrophilic substituent in the ring of the hydroquinone, phenolic hydroxyl groups act like weak acids, and with an increasing pH solution, the hydroquinone dissociates to a semiquinone anion {[$C_6H_4O(OH)$]$^-$}:

$$C_6H_4(OH)_2 = [C_6H_4O(OH)]^- + H^+ \qquad (7)$$
Upon oxidation by, for example, a manganese oxide [in which manganese acts as an electron acceptor and becomes reduced (acting as a Lewis acid)], the semiquinone anion is converted into a semiquinone radical (Figure 4).

$$[C_6H_4O(OH)]^- = \bullet C_6H_4O(OH) + e^- \qquad (8)$$
Benzo(a)pyrene-cis-9,10-Dihydrodiol   Benzo(a)pyrene-3,6-Dione

Figure 3
Structures of Biologically Mediated
Benzo(a)pyrene Intermediates

Under neutral or higher pH conditions and in the presence of air (i.e., oxygen, which acts as an electron acceptor) and MnO_2, the dissolved Mn^{2+} is rapidly oxidized to form MnO_2 through auto-oxidation:
Figure 2
Illustrative Structure of Humus

$$Mn^{2+} + \tfrac{1}{2} O_2 + H_2O = MnO_2 + 2 H^+ \qquad (9)$$
The terminal electron acceptor of the abiotic-catalytic process is free oxygen.

Proposed Relationships Between Quinone, Semiquinone Radical, Hydroquinone, Semiquinone Radical Ion and Semiquinone Dianion [After Senesi and Schnitzer[7] and Wang et al.[16]]

PROPOSED MODEL DESCRIBING REDUCTIVE DISSOLUTION AND AUTO-OXIDATION

Stone[17] notes that rates of reductive dissolution of transition metal oxide/hydroxide minerals are controlled by rates of surface chemical reactions and that transition metal oxides/hydroxides differ in their ability to oxidize organic compounds. He listed reduction potentials for nickel, manganese, cobalt and iron. Based on their thermodynamic data, their oxidant strength decreased in the following order: $Ni_3O_4 > MnO_2 > MnOOH > CoOOH > FeOOH$. Because manganese is a relatively strong oxidant that is readily found in soil, its reductive dissolution and autooxidative characteristics are reviewed.

Stone and Morgan[18] proposed a simple model for describing reductive dissolution of Mn(III) with phenol. Based on their work, a simple illustrative model is proposed herein for the reductive dissolution and autooxidation of Mn(IV) and transformation of hydroquinone. The following assumptions apply to this analysis:

- Manganese(IV) represents the oxidized form of the metal.
- The oxidized organic product is represented as a radical, because under aerobic conditions a radical represents the most likely product for polymerization reactions.[5,8,11,15-26]
- Transport-controlled reactions are assumed not to occur.[27] The dissolution rate is controlled by the rates of surface chemical reactions (assuming for this paper inner-sphere complexation) and not by diffusion.[28]
- The release of the reduced metal ion is independent of the product concentrations, indicating that the release of the reduced metal from the oxide surface is unidirectional.[27]
- The availability of the oxidized metal surface [i.e., $\equiv Mn^{IV}(OH)_2$] is not limiting in the proposed reactions, and the total number of surface sites remains constant as a new site is generated when a reduced manganese ion is released. This assumption does not address the potential for the oxide surface to readsorb reduced manganese (i.e., dissolved Mn^{2+}) or dissolved oxidized organics. Stone and Morgan[27] investigated the potential for readsorption of Mn^{2+} and determined that the loss of Mn^{2+} was less than 2% of the amount of manganese added. The number of moles of surface sites is assumed to equal 6% of the number of moles of total manganese added to

the system. Stone and Morgan[27] estimated the number of manganese oxide surface sites (based on moles) in their experimental setup to be between 3.5 and 9.0% of the total oxide added to the system.

- The organic substrate (i.e., hydroquinone) is in excess, and its mass changes negligibly in the system. The hydroquinone is assumed to represent a simple surrogate for other dione- and diol-configured organics.

This paper presents a simple model for describing reductive dissolution and autooxidation. It illustrates the importance of oxygen and the impact that autooxidation has on Mn^{2+} concentrations. The remaining portions of this paper describe the general stoichiometric equations associated with the process and present a brief analysis illustrating their application.

Half Reactions and Inner-Sphere Mechanism for Reductive Dissolution of Mn(IV)

The half-reactions associated with the reductive dissolution of Mn(IV) and the oxidation of hydroquinone (i.e., QH_2) are presented in Table 1.[29] Stone and Morgan[18] have mechanistically described these equations in four steps: (1) precursor-complex formation (i.e., reductant adsorption), (2) electron transfer, (3) release of oxidized organic product and (4) release of reduced metal ion. Precursor-complex formation may be either an inner-sphere reaction, when incoming organics bind directly to the surface metal centers, or an outer-sphere reaction, where a layer of coordinated hydroxyl groups or water molecules separate the organic from the surface metal centers.[18] Hydroxyl groups exist at the surface of the manganese dioxide mineral [i.e., $Mn^{IV}O_2(s)$]; these hydroxyl groups are used to balance the charge at the surface - water interface and can be expressed as $\equiv Mn^{IV}(OH)_2$, where "$\equiv$" refers to the oxide surface. The following four steps can be used to describe the inner-sphere complex formation between hydroquinone and the manganese dioxide surface:[18]

- Precursor-Complex Formation (Reductant Adsorption):

$$\equiv Mn^{IV}(OH)_2 + 2\ QH_2 \underset{k_{-1}}{\overset{k_1}{\rightleftarrows}} \equiv Mn^{IV}(QH)_2 + 2\ H_2O \qquad (10)$$
where k_1 and k_{-1} are rate constants in the forward and reverse directions, respectively.

- Electron Transfer:

$$\equiv Mn^{IV}(QH)_2 \underset{k_{-2}}{\overset{k_2}{\rightleftarrows}} \equiv Mn^{II}(\cdot QH)_2 \qquad (11)$$
where k_2 and k_{-2} are rate constants in the forward and reverse directions, respectively.

- Release of Oxidized Organic Product:

$$\equiv Mn^{II}(\cdot QH)_2 + H_2O \underset{k_{-3}}{\overset{k_3}{\rightleftarrows}} \equiv Mn^{II}OH_2 + 2\ (\cdot QH) \qquad (12)$$
where k_3 and k_{-3} are rate constants in the forward and reverse directions, respectively, and $\cdot QH$ is a semiquinone radical. By noting that Mn(II) still resides on the oxide surface, the Mn(II) products of Equation 12 can also be written as follows, because the right- and left-hand sides of Equation 13 are equivalent:

$$\equiv Mn^{II}OH_2 = \equiv Mn^{IV}O_2 \cdot (Mn^{II}OH_2) \qquad (13)$$
where "$\equiv Mn^{IV}O_2 \cdot (Mn^{II}OH_2)$" represents the reduced metal complex on the Mn(IV) surface prior to Mn(II) release.

- Release of Reduced Metal Ion:

Stone and Ulrich[30] noted that protons frequently assist in the metal-detachment step of dissolution reactions and that studies have generally found the number of protons involved to be equal to the valence of the detached metal (i.e., 2).[31] They continued to note that the actual number of protons involved in reductive dissolution is not known with

certainty, because the presence of two or more oxidation states on the metal surface may alter the pH dependence of the metal·release step. The release of the reduced metal ion from the surface is expressed as follows:

$$\equiv Mn^{IV}O_2\text{-}(Mn^{II}OH_2) + 2\ H^+ \xrightarrow{\ k_4\ } \equiv Mn^{IV}(OH)_2 + Mn^{2+} + H_2O \quad (14)$$
where k_4 is a rate constant. In experiments to determine the effect of varying amounts of Mn^{2+} on the rate of dissolution of $MnO_2(s)$, Stone and Morgan[27] found that the initial rates of dissolution with varying amounts of Mn^{2+} in solution had no effect on the kinetics. Based on these results, one might conclude that Equation 14 is not rate-limiting and can be considered to be unidirectional. The amount of Mn^{2+} in solution does not influence the rate of its formation. This conclusion appears to be confirmed by the fact that Mn(II) has a larger radius than Mn(IV) and does not appear to fit into the solid structure of $MnO_2(s)$ very well. As such, the Mn(II) ion is readily released from the matrix.

Table 1
Half Reactions for Reductive Dissolution

$$Mn^{IV}O_2(s) + 4\ H^+ + 2\ e^- = Mn^{2+} + 2\ H_2O \quad (1)$$

$$2\ QH_2 = 2\ (\cdot QH) + 2\ H^+ + 2\ e^- \quad (2)$$

net: $$Mn^{IV}O_2(s) + 2\ QH_2 + 2\ H^+ = Mn^{2+} + 2\ (\cdot QH) + 2\ H_2O \quad (3)$$
Proposed Polymeric Products of Mn(IV) Dissolution/Auto-Oxidation

Research has indicated that oxygen promotes oxidative coupling reactions, creating dimers, trimers and other less soluble, more surface-active oxidation products.[5,8,11,15-26] These reactions can be expressed as follows:

$$\cdot QH + \cdot QH \longrightarrow \text{polymeric oxidation products} \quad (15)$$
Auto-Oxidation of Mn(II) to Mn(IV)

Stumm and Morgan[32] presented reactions for the oxidation of Mn(II) to Mn(IV). They felt that the reactions might be visualized as proceeding according to the reactions presented in Table 2. They also note that the Mn^{2+} concentration decreases with time with an apparent autocatalytic effect. Based on Stumm and Morgan[32] and Morgan,[34] Benefield et al.[33] describe the autocatalytic oxidation of Mn(II) in the following manner:

$$d[Mn^{2+}]/dt = -k_5\ [Mn_T]\ [P_{O_2}]\ [OH^-]^2\ [Mn^{2+}]\ [Mn_T\ Mn^{2+}] \quad (16)$$
where k_5 is a rate constant, Mn_T is the total manganese in the system, and $[PO_2]$ is the partial pressure of oxygen. Although Mn(II) is oxidized according to Equation 16, it is unclear what valence that manganese is oxidized to [i.e., Mn(III) or Mn(IV)]. To be a true catalyst, Mn^{2+} would have to be oxidized to Mn(IV) to regenerate the oxidative surfaces and maintain zero net change.

KINETICS OF REDUCTIVE DISSOLUTION AND AUTO-OXIDATION

This section proposes algorithms describing the kinetics of reductive dissolution and autooxidation. The analysis presented above does

Table 2
Half Reactions for Autooxidation

$$\tfrac{1}{2}\ Mn^{2+} + \tfrac{1}{2}\ O_2 + \tfrac{1}{2}\ H_2O \xrightarrow{\ slow\ } \tfrac{1}{2}\ Mn^{IV}O_2(s) + H^+ \quad (1)$$

$$\tfrac{1}{2}\ Mn^{2+} + \tfrac{1}{2}\ Mn^{IV}O_2(s) \xrightarrow{\ fast\ } \tfrac{1}{2}\ (\equiv Mn^{IV}O_2\text{-}Mn^{II}) \quad (2)$$

$$\tfrac{1}{2}\ (\equiv Mn^{IV}O_2\text{-}Mn^{II}) + \tfrac{1}{2}\ O_2 + \tfrac{1}{2}\ H_2O \xrightarrow{\ slow\ } Mn^{IV}O_2(s) + H^+ \quad (3)$$

net: $$Mn^{2+} + \tfrac{1}{2}\ O_2 + H_2O = Mn^{IV}O_2(s) + 2\ H^+ \quad (4)$$
not account for the removal of radical products [Equation 12] that are consumed in the polymerization process, although Taylor and Battersby[35] note that the rate of disappearance of phenolate radicals through dimerization has been clearly shown to follow second-order kinetics.

Figure 5 presents a schematic illustration of the surface-site mass balance for reductive dissolution and autooxidation, based on Equations 10 through 14 and Equation 16. Included in this figure are formulae for the characteristic times associated with the reaction for each rate. Assuming that the only species that contribute to the surface mass balance equation are $\equiv Mn^{IV}(OH)_2$, $\equiv Mn^{IV}(QH)_2$, $\equiv Mn^{II}(\bullet QH)_2$ and $\equiv Mn^{II}OH_2$ and that other competing anions are not considered, the surface mass balance equation can be written as follows:

$$S_T = [\equiv Mn^{IV}(OH)_2] + [\equiv Mn^{IV}(QH)_2] + [\equiv Mn^{II}(\cdot QH)_2] + [\equiv Mn^{II}OH_2] \quad (17)$$

where S_T is the total moles of surface sites per liter of solution (M). Under the assumption that each reaction can be described as an elementary reaction, rate expressions are proposed for $\equiv Mn^{IV}(OH)_2$, $\equiv Mn^{IV}(QH)_2$, $\equiv Mn^{II}(\bullet QH)_2$, and $\equiv Mn^{II}OH_2$, using Equations 4 through 7:

$$d[\equiv Mn^{IV}(OH)_2]/dt = k_1\ [QH_2]^2\ [\equiv Mn^{IV}(OH)_2] + k_{-1}\ [\equiv Mn^{IV}(QH)_2] + k_4\ [H^+]^2\ [\equiv Mn^{II}OH_2] \quad (18)$$

$$d[\equiv Mn^{IV}(QH)_2]/dt = k_1\ [QH_2]^2\ [\equiv Mn^{IV}(OH)_2]\ (k_{-1} + k_2)\ [\equiv Mn^{IV}(QH)_2] + k_{-2}\ [\equiv Mn^{II}(\cdot QH)_2] \quad (19)$$

$$d[\equiv Mn^{II}(\cdot QH)_2]/dt = k_2\ [\equiv Mn^{IV}(QH)_2]\ (k_{-2} + k_3)\ [\equiv Mn^{II}(\cdot QH)_2] + k_{-3}\ [\cdot QH]^2\ [\equiv Mn^{II}OH_2] \quad (20)$$

$$d[\equiv Mn^{II}OH_2]/dt = k_3\ [\equiv Mn^{II}(\cdot QH)_2]\ (k_{-3}\ [\cdot QH]^2 + k_4\ [H^+]^2)\ [\equiv Mn^{II}OH_2] \quad (21)$$

The rate expressions for the remaining nonsurface-constituent concentrations (i.e., $[Mn^{2+}]$, $[QH_2]$, and $[\bullet QH]$) are as follows:

$$d[Mn^{2+}]/dt = k_4\ [H^+]^2\ [\equiv Mn^{II}OH_2]\ k_5\ [Mn_T]\ [P_{O_2}]\ [OH^-]^2\ [Mn^{2+}]\ [Mn_T\ Mn^{2+}] \quad (22)$$

$$d[QH_2]/dt = 2\ k_1\ [QH_2]^2\ [\equiv Mn^{IV}(OH)_2] + 2\ k_{-1}\ [\equiv Mn^{IV}(QH)_2] \quad (23)$$

$$d[\cdot QH]/dt = 2\ k_3\ [\equiv Mn^{II}(\cdot QH)_2]\ 2\ k_{-3}\ [\cdot QH]^2\ [\equiv Mn^{II}OH_2]\ \text{polymerized products} \quad (24)$$

Solutions to the Kinetic Rate Expressions

This section presents an illustrative example of the effects of kinetic rate constants and other parameters in determining the importance of reductant adsorption, electron transfer, surface release of oxidized organics, surface release of the reduced metal Mn^{2+} and autooxidation. The response to variations in parameters contained in Equations 10 through 14 and in Equation 16 are determined through solutions of Equations 17 through 24, which have been solved using Euler's method.[36] The solutions to these equations assume that the systems are well buffered (constant pH).

As noted earlier, Schnitzer[12] suggested that the rate-determining step in the synthesis, by oxidative polymerization of humic acids from simple phenolic constituents and acids, is the formation of a semiquinone radical involving a one-electron transfer reaction. This illustrative example investigates the conditions when the formation and release of the semiquinone radical is rate-limiting. To meet this condition, either the electron transfer step [i.e., formation of the radical on the oxide surface, Equation 11] or the release of the oxidized organic radical from the oxide surface [Equation 12] is rate limiting. For illustrative purposes, the latter (i.e., release of radical from the surface) is assumed to be the rate-limiting step.

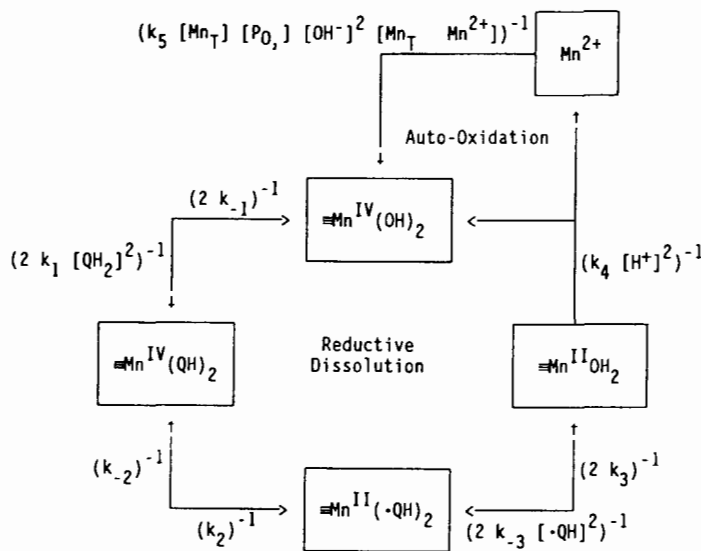
The assumptions associated with this analysis are presented in Table 3. Stone and Ulrich[30] arbitrarily assigned numerical values for the parameters presented in this table, which have been modified for this example. The initial concentrations for $[S_T]°$, $[\equiv Mn^{IV}(OH)_2]°$, and $[QH_2]°$ are also given in Table 3. All other initial concentrations (i.e., $[\bullet QH]$, $[Me^{2+}]$, $[\equiv Mn^{IV}(QH)_2]$, $[\equiv Mn^{II}OH_2]$, and $[\equiv Mn^{II}(\bullet QH)_2]$) are assumed as zero.


Figure 5
Schematic Illustration of the Surface-Site Mass Balance Equations (Expressions containing rate constants represent characteristic times.) [After Stone and Morgan[18]]

Table 3
Parameter Values for the Illustrative Example

Parameter	Value	Parameter	Value
k_1	1.50E+02 1/M²/min	P_{O_2}	0.21 atm
k_{-1}	5.00E-02 1/min	$[S_T]$.	4.80E-06 M
k_2	1.00E+00 1/min	pH	7
k_{-2}	5.00E-01 1/min	Mn_T	5.00E-04 M
k_3	1.00E-03 1/min	$[\equiv Mn^{IV}(OH)_2]$.	8.00E-05 M
k_{-3}	0.00E+00 1/M²/min	$[QH_2]$.	2.00E-02 M
k_4	1.00E+14 1/M²/min	k_5	1.00E+22 1/M⁴/atm/min

The results of the simulation are presented in Figure 6. When release of the oxidized organic from the metal surface is rate-limiting (i.e., small k_3), equilibrium conditions between $\equiv Mn^{IV}(OH)_2$, $\equiv Mn^{IV}(QH)_2$, and $\equiv Mn^{II}(\bullet QH)_2$ may occur. $\equiv Mn^{IV}(OH)_2$ is converted to $\equiv Mn^{IV}(QH)_2$, which in turn is converted to $\equiv Mn^{II}(\bullet QH)_2$. Under steady-state conditions, these concentrations do not change. Figure 6 also shows that the $[\equiv Mn^{II}OH_2]$ concentration is nearly zero, because once $[\equiv Mn^{II}OH_2]$ is formed it is immediately converted to Mn^{2+} [Equation 14]. The Mn^{2+} concentration (theoretically) would continue to rise with time. Figure 7 illustrates that autooxidation would counterbalance the increase until steady-state conditions were reached between Mn^{2+} formation from reductive dissolution and its disappearance due to autooxidation.

CONCLUSIONS

By understanding the environmental consequences of polymerization of aromatics and the incorporation of these compounds into the humification process, recalcitrant organics could become constituent parts of the soil humus, resulting in immobilized and/or detoxified bound residues. Immobilization and detoxification could be a valuable decontamination method for certain types of waste prod!ucts. These wastes would then be accessible to more and better engineer-designed cleanup

Enhancement of PCP and TCE Biodegradation By Hydrogen Peroxide

Judith B. Carberry, Ph.D.
University of Delaware
Newark, Delaware

ABSTRACT

Two model toxic chemicals were previously identified as recalcitrant to biodegradation by activated sludge and selected microbial consortia. Each model toxic chemical was subjected to chemical oxidation, both by hydrogen peroxide and by Fenton's reagent. Chemical oxidation rates and biodegradation rates before and after chemical oxidation were measured. Fenton's reagent was a particularly effective oxidizing agent. Subsequent microbial degradation was enhanced by Fenton's reagent pretreatment. Chloride ions were produced by both chemical oxidation and microbial degradation.

INTRODUCTION

Pentachlorophenol (PCP) and its sodium salt are widely used pesticides in the United States. The advantages of using PCP and its derivatives are that they are effective biocides and soluble in both oil and water. Although PCP and its derivatives have many uses, by far the major application is for wood preservation. Trichloroethylene (TCE) is a very useful cleaner and spot remover and is widely used as an industrial, household and military degreaser.

Economical bioremediation of contaminated soil can be carried out before a plume of toxic chemical penetrates an underground aquifer. Since recalcitrant organics in contaminated soils are degraded only slowly, pre-oxidation of recalcitrants and persistent toxic chemicals into more readily degradable substances may be useful to improve soil bioremediation techniques.

This enhancement occurs if the initial oxidation step of the sequential microbial mineralization process can be carried out chemically, rather than biologically. The initial rate-limiting step for the microbes, therefore, is bypassed by the addition of aqueous chemical oxidants and the resulting partially oxidized products become more polar, more soluble and more easily degraded than the parent toxic organic chemical. In addition, the resulting residual decreased toxic chemical concentration becomes less toxic to the microorganisms and is, therefore, more quickly degraded.

In our laboratory, a generic microbial selection process is utilized. Selected microbial consortia (SMC) for various model toxic chemicals are developed from contaminated soils obtained at nearby toxic waste sites prior to any remediation. Then reactor conditions are optimized for each aqueous solution of specific chemical and its consortium and resulting biodegradation rates are measured by a respirometer. A replicate aqueous solution of each specific chemical is then subjected to chemical oxidation by hydrogen peroxide solution and by Fenton's reagent (a mixture of hydrogen peroxide and Fe^{+2}). Respirometric measurements due to microbial biodegradation of the resulting oxidation products are then conducted as before. A replicate set of experiments is also carried out using a stock culture of activated sludge microbes

in order to determine any decrease in toxicity due to chemical pre-oxidation treatment.

BACKGROUND

In the United States, 78% of the PCP produced is used by the wood preserving industry, 12% in production of Na-PCP, 6% in plywood and fiberboard waterproofing, 3% in domestic use and 1% as a herbicide.[1] Though PCP-treated products do not appear to represent a threat to the environment, accidental spillage and improper disposal of PCP at the approximately 600 United States manufacturing plants and at wood-preserving facilities have resulted in extensive contamination of soil, surface water and groundwater aquifers.[2,3] Pentachlorophenol is presumed to be the most resistant chemical to microbial degradation; however, the feasibility of biological treatment of pentachlorophenol has been the subject of numerous research papers.[4-11]

Early studies on TCE biodegradation produced anaerobic degradation products which were toxic.[12-14] Wilson and Wilson[15] cited TCE as a compound resistant to biodegradation in aerobic subsurface environments, but Parsons, et al.[16] conducted experiments indicating that biological activity was responsible for tetrachloroethylene and TCE transformations in aerobic microcosms containing cultured bacteria. Recently, additional workers have been conducting aerobic studies with methanogenic and other bacterial cultures.[17-19]

Other researchers have investigated whether microbial degradation could be enhanced if the toxic carbon source could be oxidized to a metabolite which is more readily degraded by microorganisms. Bishop, et al.[20] conducted an experimental study on uncharacterized municipal wastewaters containing a wide variety of refractory organics using peroxide-ferrous ion solutions producing hydroxyl radical. Bowers, et al.[21] also examined the preoxidation of uncharacterized industrial wastewaters with hydrogen peroxide and found reduced toxicity of oxidation products when compared to the original wastes. The reactions to illustrate peroxide mechanisms are discussed below.

Peroxide can dissociate into water and oxygen to provide an oxygen source, as follows:

$$2H_2O_2 \rightarrow 2H_2O + O_2 \tag{1}$$

In contrast, Fenton's reagent reacts to produce both the hydroxyl ion and the hydroxyl radical, as follows:

$$Fe^{+2} + H_2O_2 \rightarrow Fe^{+2} + OH^- + {}^{\cdot}OH \tag{2}$$
The hydroxyl radical can then attract a hydrogen atom from an organic substrate to produce an organic radical, as follows:

$$RH + {}^{\cdot}OH \rightarrow {}^{\cdot}R + H_2O \tag{3}$$
The organic radicals exist as transient intermediates and may be further oxidized by Fe^{+3} oxygen, or hydroxyl radical to form final, stable oxidation products. The oxidation products may be more easily biodegraded than the parent organic chemicals such as PCP.

The total oxidation reactions of PCP and TCE are expressed as follows:

$$PCP \ C_6OHCl_5 + 11.5H_2O_2 \rightarrow 6CO_2 + 12H_2O + 5Cl^-$$

$$TCE \ C_2HCl_3 + 4.5H_2 2O_2 \rightarrow 2CO_2 \rightarrow 5H_2O \rightarrow 3Cl^-$$
These reactions were used to determine peroxide and Fenton's reagent doses that would only partially oxidize the model chemicals for subsequent microbial biodegradation.

The chemicals were subjected to microbial biodegradation respirometric measurements before and after chemical oxidation, and reactions rates were calculated using Equations 4 and 5.

$$R = - \frac{\Delta St}{\overline{X}} = - \frac{S_t - St - t_o}{(X_o + X_t) /2} \quad (4)$$

where
S is the substrate concentration
t is time
X is microbial biomass concentration

Subscripts o and t represent initial and anytime t, respectively, and superbar denotes an average value.

The values of R at each S were then evaluated using a Michaelis-Menten function, expressed in Equation 5:

$$R = \frac{K_o S}{K_s + S} \quad (5)$$

where

k_o is the maximum substrate uptake rate constant
K_s is the half velocity constant, or substrate concentration at which specific substrate uptake, R, is half the maximum rate.

METHODS AND MATERIALS

Details of experimental procedures have been described previously.[22,23] Briefly, the following experimental variations were examined:
- Set 1. Hydrogen peroxide and PCP or TCE
- Set 2. Hydrogen peroxide, ferrous ion and PCP or TCE
- Set 3. Hydrogen peroxide, PCP, or TCE and selected microbial consortia (or activated sludge)
- Set 4. Hydrogen peroxide, ferrous ion, PCP or TCE and selected microbial consortia (or activated sludge)

Replicate reactors and controls were run for each respirometric experiment. For each analysis, a 5-mL sample was withdrawn by syringe through the rubber septum of each reactor vessel. For TCE determinations, the aqueous sample was extracted using a MIXXOR (GENEX Corporation, Maryland) in 5 mL of n-pentane with 20 strokes. Two mL of the extracted TCE in n-pentane was mixed with 2 mL of dibromodichloromethane (DBDCM) in a 10-mL vial. One μL samples of this solution were analyzed by a Varian Gas Chromatograph equipped with an FID detector at 310°C and a 30-m DB-5 (J & W Scientific) capillary column. A temperature program of 35°C (1 min), increasing to 70°C at 5°C/min temperature gradient was used. The injector temperature was 85°C. Nitrogen carrier gas flow rate was 10 mL/min. With the above conditions, the retention times for TCE and DBDCM were 3.08 and 7.80 minutes, respectively. The ratio of peak heights was converted to concentration units using previously determined calibrations. This procedure minimized TCE volatilization losses

and experimental results were compared to control runs to insure consistency.

Residual PCP concentration was determined by HPLC (Varian Model 2550) using a reverse-phase column (25 cm NUCLEOSIL C_{18} packed column) with a UV detector at 280 nm. The aqueous sample was filtered through 0.22 μm (Millipore, MILLEX-GX) before each 40 μL injection. The isocratic eluent was pumped at a rate of 1 ml/min and it was composed of 88% methanol with 1% acetic acid and of 12% deionized water with 1% acetic acid. The results were printed in analog and digital modes on a Varian integrator, model 4290.

Soluble chemical oxygen demand (SCOD) was determined by using the micro COD digestion and titrimetric procedure manufactured by the HACH Company. Chloride ion concentrations were determined with a Fisher 825 MP digital pH meter equipped with a chloride-specific electrode (Orion 94-17B). Chloride concentration was determined by using a calibration curve plotted from the molarity of a series of KCl standards versus millivolts. The potassium iodide-sodium thiosulfate titration method was used to determine residual concentration of hydrogen peroxide in each system.[24]

RESULTS AND DISCUSSION

Chemical PreOxidation

Chemical oxidation of PCP when preoxidized with Fenton's reagent was faster and more extensive than when just peroxide was added alone. The results of chemical oxidation by Fenton's Reagent are shown in Figure 1.
Figure 1
Residual PCP Concentration Following
Oxidation by Fenton's Reagent

By comparison, the chemical oxidation of TCE by both hydrogen peroxide alone and with Fenton's reagent was significant. Both a faster rate and higher level of oxidation with Fenton's reagent resulted, however, than when just hydrogen peroxide was used. TCE chemical oxidation using Fenton's reagent is shown in Figure 2. If Figures 1 and 2 are compared, it is evident that chemical doses were relevant to both the rate and level of oxidation occurring for PCP. For TCE, however, a minimal dose of Fenton's reagent was just as effective as a dose 10 times greater. Analyses of residual peroxide indicated that the oxidizing chemical was not detectable after four hours. These results indicated that the chemical reactions shown in Equations 1 and 2 for peroxide and Fenton's reagent occurred at approximately the same rate. Even though the disappearance of hydrogen peroxide in Fenton's reagent was very fast, the chain reaction described in Equation 3 for Fenton's Reagent occurred slightly more slowly.
Figure 2
Residual TCE Concentration Following
Oxidation by Fenton's Reagent

Figure 3
Residual PCP Concentration Due to Biodegration
by a Selected Microbial Consortium Following
Chemical Oxidation by Fenton's Reagent

Chemical Oxidation Followed by Selected Microbial Consortia Degradation

When chemical oxidation was followed by microbial degradation, the rate of PCP disappearance was faster than when due to chemical oxidation alone. For systems to which a selected microbial consortium (SMC) were added following chemical oxidation by Fenton's reagent, the biodegradation rate constant was an order of magnitude larger than that due to chemical oxidation alone. Figure 3 illustrates the resulting degradation following Fenton's reagent preoxidation. Comparison of Figure 1 for chemical oxidation alone and Figure 3 for subsequent microbial degradation indicates that chemical dose became less relevant for the selected microbes than for just chemical oxidation alone.

For the TCE case, volatilization occurred, as indicated in the control plot of Figure 4. The loss due to volatilization was not apparent, however, until repeated aliquots were removed from the reactor. In fact, this plot defines a maximum loss due to volatilization, for in the other plots showing microbial degradation, the TCE lost early to the gas phase will subsequently be transferred back to the aqueous phase as biodegradation proceeds with time. This transfer back to the aqueous phase is caused by a shift in the chemical potential for TCE as biodegradation depletes the aqueous concentration. The decrease in aqueous chemical potential compared to gas phase chemical potential causes a spontaneous transfer from the gas phase, controlled by Henry's Law constant for TCE, in order to reestablish a constant equilibrium concentration ratio for TCE between the two phases.

The degradation plots shown in Figure 4 for the three doses of Fenton's reagent indicate that the level of biodegradation was a function of the oxidant dose. This bacterial response with respect to oxidant dose was apparently different than for PCP where oxidant dose made less difference to the degradation by its SMC. Work is being carried out in an attempt to identify both chemical oxidation products and intermediate microbial metabolites by GC/MS, but a preliminary comparison can be made by examining the microbial Cl⁻ production level, Cl⁻ production rate and oxygen uptake rate for the two compounds. A typical Cl⁻ production rate for the PCP SMC is shown in Figure 5. This figure indicates a large concentration of Cl⁻ was produced at a significant rate which was barely reaching an asymptotic value after 12 days. In addition, the Cl⁻ production appears to be independent of the Fenton's reagent dose. In contrast, the Cl⁻ production by TCE selected microbial consortium was one-fourth the amount of the PCP case, the produc-
Figure 4
Residual TCE Concentration Due to Biodegradation
by a Selected Microbial Consortium Following
Chemical Oxidation by Fenton's Reagent

tion rate diminished to a very low level after Day 4 and the production rate and level were proportional to the dose of Fenton's reagent. All of these observations suggest that Fenton's reagent is a much more effective oxidant for TCE than for PCP. Examination of the chemical oxidation reactions presented previously indicate that a three-fold molar ratio increase of oxidant was required for PCP degradation compared to TCE. Therefore, even a small dose of Fenton's reagent was effective for oxidizing TCE as shown in Figure 2. The subsequent microbial response was proportional to the oxidant dose for both the degradation rate of parent TCE and the production rate and level of Cl⁻. All of these results are consistent with the hypothesis that the hydroxyl radical produced from hydrogen peroxide attacks the chloro-substituents on the hydrocarbon skeletal matrices of TCE and PCP. The results for PCP oxidation and PCP preoxidation followed by SMC degradation indicated

that comparable oxidant doses for this chemical were not large enough to cause significant oxidation. Cumulative oxygen uptake rates were comparable for both TCE and PCP SMC when each parent toxic chemical was dosed either with hydrogen peroxide alone or with Fenton's reagent. For both SMC, the oxygen uptake rates were slightly higher when Fenton's reagent was used.

TIME (DAYS)
Figure 5
Chloride Ion Production Due to Biodegration
of PCP by a Selected Microbial Consortium
Following Chemical Oxidation by Fenton's Reagent

Chemical Oxidation Followed by Activated Sludge Degradation

Microbial degradation of both TCE and PCP by activated sludge was slower than by each SMC, whether the parent toxic chemicals were untreated or pretreated by hydrogen peroxide alone or by Fenton's reagent. Production of Cl⁻ and oxygen uptake rates were also slower. Activated sludge degradation of both parent toxic chemicals was fastest following Fenton's agent pretreatment. Enhancement of activated sludge biodegradation of TCE was greater than for PCP.

$k_{(SMC)}$: Biodegradation Rate by SMC (Selected Microbial Consortium)
$K_{(AS)}$: Substrate Concentration at Half the Maximum Velocity for Activated Sludge (Half Velocity Constant)
$K_{(SMC)}$: Substrate Concentration at Half the Maximum Velocity for SMC (Half Velocity Constant)

SUMMARY OF RESULTS

Data from all the degradation tests were used to calculate biodegradation rate constants and half velocity constants according to Equations 4 and 5. These tabulations indicate quantitative values of the differences in results described above.

Table 2
Specific Substrate Uptake Rate Constants
and Half Velocity Constants for TCE Under
Varying Treatment Conditions

Environmental condition	$K_{s(AS)}$	$K_{m(AS)}$	$K_{s(SCM)}$	$K_{m(SMC)}$
Untreated system	0.00019	78.0	0.00020	78.0
Pretreated with hydrogen peroxide at molar ratios of hydrogen peroxide:PCP				
0.1:1	0.00026	53.1	0.00027	51.3
0.5:1	0.00027	50.8	0.00030	49.6
1.0:1	0.00029	46.1	0.00031	46.1
Pretreated with Fenton's reagent at molar ratios of hydrogen peroxide:PCP				
0.1:1	0.00034	51.9	0.00043	49.6
0.5:1	0.00034	48.7	0.00040	48.5
1.0:1	0.00036	46.7	0.00059	44.7

In addition, the half velocity constants and oxygen uptake rates indicate that preoxidation treatment reduces the toxicity of the substrates for both activated sludge and both SMC. The Cl⁻ production levels and rates indicate that both the chemical oxidation and microbial degradation mechanisms sequentially remove chlorine substituents from the molecule.

CONCLUSIONS

Selected microbial consortia for TCE and PCP degraded these parent toxic compounds faster and more efficiently than unacclimated activated sludge microbes. Preoxidation of the parent model toxic chemicals enhanced the subsequent microbial degradation by both activated sludge and selected microbial consortia. Pretreatment of TCE and PCP with oxidants, particularly with Fenton's reagent, reduced the toxicity of these substrates to both activated sludge and selected microbial consortia. Chloride ion was produced as a result of both chemical oxidation and microbial degradation.

Treatability of Contaminated Groundwater Using Biological Processes

Mark E. Zappi
Cynthia L. Teeter
Norman R. Francingues
Environmental Engineering Division
U.S. Army Engineer Waterways Experiment Station
Vicksburg, Mississippi

ABSTRACT

Treatability of contaminated groundwater from the Ninth Avenue Superfund Site, Gary, Indiana, was evaluated using bench-scale biological reactors (bioreactors). Aerobic treatment and aerobic treatment with the addition of powdered activated carbon (PAC) were evaluated. All bioreactors were configured to simulate a complete mix activated sludge system. The groundwater was contaminated with various organic contaminants including: 278 mg/L total ketones, 25 mg/L chlorinated solvents, 6 mg/L total phenols and 10 mg/L of benzene, toluene, ethylbenzene and xylene (BTEX) compounds. The groundwater also contained approximately 90 mg/L and 230 mg/L of iron and manganese, respectively.

A microbial culture collected from a local municipal wastewater treatment system was acclimated over a period of 6 wk to the contaminants in the groundwater using a 15-L bioreactor. Once the microbial culture was acclimated, biological treatability testing was performed in four 3-L bioreactors. The groundwater influent had sufficient nitrogen, but the addition of phosphate was required.

The reduced iron and manganese in the groundwater were oxidized and precipitated in the aeration chamber of the bioreactors. The precipitate caused substantial bulking of the activated sludge; however, the bulking did not seem to affect the activity of the biomass. The organic contaminants were reduced to trace levels in both treatment systems. The aerobic bioreactors without PAC addition achieved a BOD reduction in excess of 95%, but only achieved COD and TOC removals in excess of 50%. The aerobic bioreactors with PAC addition achieved a 95% BOD removal. The addition of PAC improved the percent removals of COD and TOC to over 80%. The PAC also increased microbial activity.

INTRODUCTION

The Ninth Avenue Superfund Site, which is listed on the NPL, is scheduled for cleanup under the Superfund Acts of 1980 and 1986. The site is a 17-ac inactive chemical waste disposal area located in Gary, Indiana.

Both solid and liquid wastes are reported to have been disposed at the site. Solid wastes deposited there include industrial construction and demolition wastes. Liquid wastes disposed at the site include oils, paint solvents and sludges, resins, acids and other chemical wastes. Waste disposal operations took place between 1973 and 1980.

The site groundwater is contaminated with a variety of inorganic and organic contaminants. Inorganic contaminants are mainly in the form of road salts (sodium chloride). Organic contaminants detected in significant concentrations in the groundwater are ketones, benzene, toluene, xylenes, ethylbenzene and chlorinated ethenes.

This treatability study was performed for the U.S. Army Corps of Engineers Omaha District and the U.S. EPA RI/FS Region V

This treatability study was performed for the U.S. Army Corps of Engineers Omaha District and the U.S. EPA Region V as part of the RI/FS. Four treatment technologies were evaluated by the U.S. Army Engineer Waterways Experiment Station during the treatability study. The technologies evaluated were activated carbon, air stripping, activated sludge and activated sludge with powdered activated carbon addition. The results of the evaluation of the latter two technologies are presented in this paper.

STUDY OBJECTIVE

The objective of this study was to evaluate, on the laboratory bench-scale level, the potential of biological processes to remove organic contaminants from a composite of groundwater samples collected from six site observation wells. Activated sludge (AS) and activated sludge with powdered activated carbon addition (PAC/AS) were evaluated for their ability to reduce the biochemical oxygen demand, chemical oxygen demand, total organic carbon and organic contaminants listed on the U.S. EPA's Priority Pollutant List from the groundwater composite.

DESCRIPTION OF PROCESSES

Activated Sludge

AS is a biological process that utilizes acclimated bacteria for the aerobic degradation of contaminants in wastewater. Figure 1 is an illustration of a typical AS treatment system. The term "acclimated" means that the bacteria consortium are capable of utilizing the organic contaminants in the influent as their food source.

Biological treatment processes (which include both AS and PAC/AS) are destruction technologies requiring no ultimate disposal of treatment residuals containing hazardous or toxic constituents (assuming that the waste sludges do not contain parent and/or intermediate contaminants). In contrast, activated carbon or air stripping are not destruction technologies. They are phase change technologies that simply transport the contaminants from one phase to another, with activated carbon systems requiring the disposal or regeneration of the spent carbon.

The populations of bacteria in the aeration tanks of AS systems are so great that the air-activated organic biological solids which are made up primarily of dense colonies of bacteria are referred to as activated sludge. The activated sludge/wastewater slurry in
Figure 1
Activated Sludge Treatment System

the aeration tank is commonly known as the mixed liquor (ML). The ML is kept in suspension in the aeration tank by using either mechanical mixers or diffused air. Since biological solids are volatile, bacterial populations in the mixed liquor are often measured using mixed liquor suspended solids (MLSS) or mixed liquor volatile suspended solids (MLVSS).

Influent is added to the aeration tank at a rate that is carefully controlled to achieve a specific hydraulic retention time (HRT). HRT has units of time and theoretically describes the amount of time a particle of water and theoretically describes the amount of time a particle of water is retained in the aeration tank. As fresh influent enters the aeration tank, treated water or effluent flows out of the aeration tank into the clarifier. The clarifier is a sedimentation tank used to separate the activated sludge from the effluent. To keep a constant population of bacteria in the aeration tank, a portion of the thickened sludge is returned to the aeration tank. Also, since bacteria are constantly reproducing, some of the thickened sludge must be wasted from the bottom of the clarifier or directly from the aeration tank to maintain a constant bacterial population in the aeration tank. The amount of bacteria wastes is determined based on the solids retention time (SRT) of the biological solids. The SRT or sludge age is theoretically the amount of time a particle of solid matter remains in the aeration tank. SRT also has the units of time.

Powdered Activated Carbon/Activated Sludge

PAC/AS is a treatment process that incorporates the benefits of both activated carbon and activated sludge for the removal of organic contaminants from wastewater. PAC/AS systems are usually configured identically to AS systems except that PAC is periodically added to maintain a specific PAC suspended solids (PACSS) in the mixed liquor.

The PAC/AS treatment process relies heavily on biological degradation for the removal of the majority of the organic compounds from the influent. However, if compounds that are not easily degraded are present, then these compounds can be adsorbed into the PAC, thus preventing the loss of these compounds in the effluent resulting in incomplete treatment. PAC has also been added to the AS system to reduce the amount of volatile compounds from off-gasing the treatment system via volatilization in the aeration tank. Once adsorbed, many of the adsorbed contaminants can be degraded directly from the PAC by either the suspended bacteria coming in contact with them or by attached growth microbes using the PAC as a structural substrate.

LITERATURE REVIEW

AS Treatment Process

The suitability of AS for the degradation of a variety of complex xenobiotic compounds has been demonstrated by many researchers.[8, 10, 14] Most of the research activities reviewed generally used the same technical approach selected for this study. The technical approach uses a microbial consortium containing an extremely diverse variety of microbial types, such as mixed liquor from an AS system, as a source of microbial seed for biological reactors. The microbes are slowly exposed to the contaminants in the test influent until all or a portion of the original bacterial

population become acclimated to the target contaminant(s). The chance of successfully establishing a consortium of acclimated bacteria is high because microbe populations capable of mineralizing the contaminants are usually present in activated sludge.

Sanford and Smallbeck[13] used a mixed consortium of bacteria and yeast to degrade a synthetic wastewater comprised of 100 mg/L acetone, 50 mg/L 2-butanone and 125 mg/L methyl isobutyl ketone in bench-scale chemostats. They concluded that treatment of ketones was successful within 48 hr of batch treatment utilizing a stable consortium of microorganisms and yeast.

Kim and Maier[9] evaluated the acclimation and biodegradation potential of chlorinated organic compounds in the presence of various cometabolites. They were able to acclimate a consortium of bacteria from a municipal AS plant capable of degrading 2,4-D (2,4 dichlorophenoxyacetic acid) and 3,5-DCB (3,5 dichlorobenzoate) under aerobic conditions. Combined contaminant concentrations as high as 100 mg/L were successfully degraded. Kim and Maier concluded that seed bacterial consortia should contain as diverse a population of microorganisms as possible to increase the probability of plasmid exchange. In addition, they also suggest that the acclimation phase begin with an influent containing very low concentrations of the target compounds to avoid inhibitory effects.

Bieszkiewics and Pieniadz-Urbaniak[2] evaluated the effect of benzene and xylene at concentrations as high as 75 mg/L and 150 mg/L, respectively, on the work of an AS system. They concluded that increased concentrations of the target compounds generally decreased the COD removals, increased sludge volume index (SVI), increased the number of bacteria and, finally, altered the morphology of the bacterial flocs.

Rozich and Gaudy[12] evaluated the response of an AS system to quantitative loadings of phenol. Phenol concentrations of 500 mg/L were evaluated as a base influent concentration. Initially, shock loadings of 1,000 mg/L of phenol were imposed on the AS system without significant disturbances in treatment occurring. The AS system was then shocked with 2,000 mg/L of phenol which resulted in the collapse of the stability of the system. They concluded that design engineers should design AS systems that will be treating possible inhibitory and/or toxic compounds with high SRTs; especially systems that could be subjected to periodic shock loadings of contaminants.

PAC/AS Treatment Process

There has been considerable research on the feasibility of applying PAC/AS to treat a variety of wastewaters.[4, 5] Nayar and Sylvester[11] evaluated PAC addition to an AS system for increased removal of phenol. Concentrations of phenol as high as 1,300 mg/L were successfully removed. They concluded that the addition of PAC to the aeration tank did not enhance bacterial growth); however, PAC addition could be used to prevent shock loadings of contaminants at toxic levels from disrupting the biological system.

Chao, Yeh and Shieh[3] evaluated the use of PAC/AS systems to remove total phenols and cyanides at concentrations as high as 160 mg/L and 80 mg/L, respectively. They concluded that the PAC addition did not have an appreciable effect on phenol removal; however, they did observe increased cyanide removals with PAC addition.

Hoffman and Oettinger[7] investigated the performance of a two-stage PAC/AS and activated carbon system for the removal of trichloroethylene, 1,4-dichlorobenzene and 2-chlorophenol at a combined concentration of approximately 100 mg/L from a landfill leachate. They concluded that 99.8% removal of the contaminants could be achieved using the two stage system, with only 0.31% of the contaminants removed via air stripping from the aeration tank.

TECHNICAL APPROACH

The following steps were used to implement this study:

Table 1
Chemical Analysis of Groundwater Composite

Activated Sludge Bioreactor Used in Study

- Acclimate a consortium of bacteria to degrade the contaminants in the groundwater composite using mixed liquor from a local activated sludge system treating municipal wastewater
- Determine an optimal SRT for an AS system using multiple bioreactors
- Examine the potential benefits of PAC addition to an AS system
- Determine an optimal PAC dose in a PAC/AS for reducing effluent pollutant concentrations.

MATERIALS AND METHODS

Materials

The contaminated water used in this study was a composite of groundwater samples collected from six site observation wells. Table 1 lists the major chemical constituents detected in the groundwater composite.

The bench-scale bioreactors used in this study are illustrated in Figure 2. Two bioreactor sizes were used. The acclimation phase used a single 20-L bioreactor having a 15-L aeration chamber and a 5-L clarifier, while the AS and PAC/AS phases of study used multiple bioreactors with 2.0-L aeration chambers and 1.0-L clarifiers. Influent was delivered to the aeration tank of the bioreactors using peristaltic pumps. Sludge wasting was accomplished through the sludge wasting port located on the side of the bioreactor (Fig. 2). The waste sludge was settled in graduated cylinders of various sizes dependent on the amount of sludge requiring wasting (determined by SRT). The supernatant from the settled waste sludge was mixed with effluent and returned to the bioreactor to make up for the volume of water lost due to sludge wasting.

A bacterial inoculum was obtained from the aeration tank of the City of Jackson, Mississippi, Wastewater Treatment System (JWWTS). This system is a contact stabilization process with a 50-mgd capacity.

The PAC used in this study was obtained from the Calgon Carbon Corporation of Pittsburgh, Pennsylvania. A pulverized version of Filtersorb 300 marketed as BL Type PAC was selected based on recommendations by Calgon personnel after review of the chemistry of the groundwater composite contaminant concentrations.

Acclimation of Bacterial Consortium

The 15-L acclimation bioreactor was completely filled with the mixed liquor from the JWWTS. The bioreactor was initially fed influent to a trickling filter of City of Vicksburg, Mississippi, Wastewater Treatment System (VWWTS). Over a 4-wk period, influent to the acclimation bioreactor was proportionally switched on a volumetric basis from VWWTS influent to the groundwater composite. The groundwater composite contained appropriate nitrogen levels in the form of ammonia; however, phosphate nutrient was added to the influent in the form of potassium monobasic phosphate to achieve a carbon to nitrogen to phosphate ratio of appriximately 100:10:5. This C:N:P ratio was considered adequate because analysis of the effluent indicated that sufficient nitrogen and phosphate nutrients were present in the effluent to prevent the biological system from becoming nutrient-limited.

Acclimation of the bacterial consortium to the contaminants in the groundwater composite was based on the acclimation bioreactor receiving a constant organic loading based on influent 5-day BOD. The rate at which the ratio of groundwater composite to VWWTS influent was increased was determined assuming that the bacterial consortium would easily acclimate to the groundwater compolsite, with little or no lag phase, when acclimated using a constant system influent organic loading. Therefore, the acclimation bioreactor was operated at different HRTs depending on influent composition and respective BOD. The SRT of the bioreactor throughout the acclimation phase was 10.0 days.

During the acclimation period when groundwater was proportionally replacing the VWWTS influent: BOD, COD and TOC removals were determined twice weekly and the MLVSS/MLSS ratio daily. This monitoring was done to ensure that the contaminants in the groundwater composite were not adversely affecting biological activity. If adverse effects such as significant reductions in BOD, COD and TOC removals or dramatic decreases in the MLVSS/MLSS ratio were noted, then these effects could be reversed or minimized by decreasing the rate of groundwater composite addition.

The VWWTS influent had an average BOD of 70 mg/L; therefore glucose was added to increase the influent BOD to approximately 200 mg/L to achieve an organic loading of approximately 0.015 lb BOD/day on the system. The organic loading was adjusted daily by changing system influent feed rates accordingly as influent BOD changed due to the increased proportion of groundwater composite making up the influent. Once the system influent consisted only of groundwater composite, the acclimation bioreactor was operated at a HRT of 3.0 days and a SRT of 10 days (these operational parameters were selected prior to testing based on a literature review of systems treating similar wastes). When

the percent removal of gross pollutants and the MLVSS/MLSS ratios were constant, then the consortium was considered acclimated. Acclimation of the bacterial consortium took approximately 6 wk.

Operation of the AS Bioreactors

After the acclimation process was considered complete, approximately 3L of mixed liquor from the acclimation bioreactor were added to the four 2-L bioreactors. Each AS bioreactor was operated at an HRT of 1.0 day. The AS bioreactors different from each other by SRTs of 2, 4, 8 and 16 days. The purpose of varying the SRTs was to determine an optimal SRT.

Operation of the PAC/AS Bioreactors

After completion of the AS study, the mixed liquors from each of the four AS bioreactors were composited into the 15-L bioreactor used in the acclimation phase of study. The compositing of the mixed liquors was done to ensure that the bacterial consortiums used in the PAC/AS bioreactors initially contained similar microbial populations (AS systems operated at different SRTs can contain different types of bacteria). The 15-L bioreactor was operated at the optimal SRT from the AS study and an HRT of 1 day. The large bioreactor was operated for a period of three SRTs, then approximately 10 L of mixed liquor were added to four of the 2-L bioreactors.

The PAC/AS bioreactors differed by PAC dose. PAC dosages of 1.0, 2.0, 5.0 and 8.0 mg/L were added to the 2-L bioreactors. The amount of PAC removed each day in the waste sludge was replaced with equal amounts of fresh PAC after sludge wasting operations were completed. New PAC was added into the PAC/AS bioreactors by slurrying the fresh PAC with enough effluent to make up for the volume of water lost from the sludge wasting activities.

Chemical Analyses

All gross pollutant, suspended and volatile solids, and oil and grease analyses were performed using methods described in *Standard Methods for the Examination of Water and Wastewater.*[1] Priority pollutant analyses were performed using U.S. EPA Methods SW 846-8270 and SW 846-8260 for volatile compounds and base neutrals/acid extractables, respectively.[6] Chemical analysis of bioreactor off-gases for volatile organic priority pollutants was performed using gas-tight bioreactors equipped with Tenax(TM) traps. Approximately 3.0% of the total off-gas flow from the bioreactors (52 mL/min) was passed through the Tenax traps at a retention time of 12.0 min. The "loaded" Tenax traps were then purged with helium to remove the contaminants. The helium gas was analyzed for volatile organic compounds using a modified version of U.S. EPA Method 846-8270.[6]

STUDY RESULTS

Acclimation of Bacterial Consortium

The operational data for the acclimation bioreactor are presented in Table 2. Table 2 also presents the solids and influent and effluent BOD concentrations over the 23 day period when the influent was proportionally being switched from VWWTS influent to the groundwater composite. The BOD loading on the acclimation bioreactor was kept at approximately 0.015 lb BOD/day throughout the acclimation phase of study (Table 2).

The impact of the groundwater addition on the biological system is illustrated in Figures 3 through 6. Influent and effluent BOD concentrations versus time are presented in Figure 3. In Figure 3, it can be seen that the effluent responded with very slight increases in BOD concentration as influent BOD strength increased; however, the effluent BOD concentration generally remained constant throughout the acclimation period. Figures 4 and 5 illustrate the variation in TOC and COD influent and effluent concentrations as a function of time. The TOC and COD data did indicate a slight increase of these parameters in the effluent, suggesting the existence of some refractory compounds in the groundwater composite. At the end of the acclimation period, the bioreactor was achieving BOD, COD and TOC removals of 97.9, 71.4 and 74.8%, respectively.

As the ratio of groundwater composite to VWWTS influent de-

creased, the color of the mixed liquor changed from a light brown color to an orange-rusty color indicating that reduced iron and manganese in the influent were being oxidized and then precipitated in the aeration chamber. The accumulation of the precipitated cations in the aeration chamber caused a dramatic increase in MLSS. Figure 6 illustrates the MLSS and MLVSS of the acclimation bioreactor throughout the acclimation period. The MLVSS remained constant, while the MLSS increased approximately eight-fold. The constant MLVSS values and gross pollutant (BOD, COD and TOC) removals indicated that a lag phase in biological activity did not occur. Surprisingly, the increased fixed solids concentration did not significantly affect the gross pollutant removal efficiencies of the bioreactor. An analysis of total iron and manganese in the waste sludge indicated iron and manganese concentrations of 35,700 mg/kg and 1,510 mg/kg, respectively.

Table 3 presents the results of organic priority pollutant analysis of the acclimation bioreactor effluent. It can be seen from Table 3 that all priority pollutants previously detected in the influent were removed to levels below the analytical detection limit.

Activated Sludge Evaluation

Table 4 lists the average operating parameters for each of the four 2-L bioreactors. Also listed in Table 4 are volatile organic compound (VOC) measurements of the headspace above the aeration tanks of each of the bioreactors which were measured

using an HNU™ meter which measures air phase VOC concentrations using an ultraviolet photoionization detector. All of the HNU readings were below 1.0 ppm, indicating that volatilization of contaminants (detectable by a HNU meter) was minimal. This information infers that the ambient air around a bioreactor operating in the field probably will contain little or no measurable VOCs.

Chemical analysis for organic priority pollutants in the off-gas from the eight day bioreactor (Bioreactor No. 3) using the Tenax traps was performed to determine the fraction of organic priority pollutants being removed via volatilization from the aeration tank. This analysis indicated that approximately 4.0% of the

However, the ketones could probably be further degraded if the AS system were operated at SRTs greater than 16 days (i.e., extended aeration mode) or if biological sludge digestion methods were used on-site to reduce the quantity of sludge requiring disposal, thereby further degrading the ketones.

The results of the gross and priority pollutant organic analyses of the AS bioreactor effluents indicated that the four AS bioreactors had lower contaminant removals than the acclimation bio-

organic priority pollutants were being removed due to volatilization. Therefore, it was concluded that contaminant removal due to volatilization from the aeration tank was minimal compared to the amount of contaminant being biologically degraded. This conclusion was consistent with the contaminant composition of the groundwater which was comprised primarily of ketones which are relatively nonvolatile at standard temperature and pressure.

Table 5 contains influent and effluent BOD, COD and TOC analyses along with the percent removals achieved in each bioreactor. There was little difference observed in the performance of the various bioreactors for removal of the gross pollutants (BOD, COD and TOC). Therefore, at an HRT of 1 day there was no appreciable difference in BOD, COD and TOC removals for the range of SRT evaluated.

Table 6 lists the results of the priority pollutant analyses of the four bioreactors' effluents. The effluent from Bioreactor No.3 had more organic contaminants detected than the other three effluents. However, except for acetone, the concentrations detected in the Bioreactor No. 3 effluent were all near the analytical detection limits of the respective contaminants.

To complete the mass balance of organic contaminants around the AS bioreactors, a priority pollutant analysis on a composite of waste sludges from all of the bioreactors was performed. The

reactor. There are two factors that could have individually or jointly contributed to the difference in the performance of the acclimation bioreactor versus the performances of the four AS bioreactors. The first factor was that the hydrodynamic difference in terms of mixing efficiency between the large and small bioreactors affected bioreactor performance by reducing the contact frequency of the microbes with the contaminants. From visual observations made during both study phases, the larger bioreactor seemed to mix the ML more efficiently than the smaller units. The 2-L bioreactor had problems keeping the ML properly suspended. The second, and probably more important, factor was that the 2.0-L bioreactors were operated at a lower HRT, indicating that some of the contaminants may require longer treatment times.

PAC/Activated Sludge Evaluation

The operating parameters and treatment conditions for the PAC/AS bioreactors are presented in Table 8. The PAC/AS bioreactors were operated at an HRT of 1 day and an SRT of 8 days. The 8-day SRT was selected because relatively little difference in the quality of the effluents from the four AS bioreactors was observed during the AS study. Of the four bioreactors evaluated in the AS study, the 8-day SRT bioreactor (Bioreactor No. 3) had the lowest removals of TOC and COD. Since there was not an apparent optimal SRT, an 8%-day SRT was selected to evaluate the benefit of PAC addition to an AS system that was not removing extremely high percentages of the TOC and COD from the influent.

In Table 8, we report the concentrations of VOCs in the off-gases from each PAC/AS bioreactor measured using the HNU meter; all VOC concentrations were less than 1.0 ppm. Chemical analysis for organic priority pollutants in the off-gas from the 8.0-g/L PAC/AS bioreactor was performed to assess the amount of contaminant removal achieved via volatilization. This analysis indicated that approximately 2.6% of the priority pollutants were being removed via volatilization from the aeration tank of the PAC/AS bioreactor. Therefore, as was the case with the AS bioreactor, it was concluded that the majority of the priority pollutants were being removed due to biological degradation.

To fully evaluate the benefits of PAC addition to the activated sludge systems, the removal efficiencies obtained in the PAC/AS bioreactors were compared to those of the 8-day SRT AS biore-

actor. The 8-day SRT AS bioreactor will be referred to herein in this section as the control bioreactor.

Table 8 also lists the ratios of MLVSS/MLSS for each PAC/AS bioreactor. As PAC dose increased, the MLVSS and MLVSS/MLSS ratio also increased, indicating an overall increase in biological activity with increasing PAC dose. Several explanations for the increase in biological activity with increased PAC dosage were postulated. One explanation is that the PAC removed contaminants that were inhibiting biological activity resulting in a liquid phase more conducive to biological activity. A second explanation is that an attached growth population of microorganisms were using the PAC as a structural substrate. The attached growth consortium may be better suited for degradation of the more difficult-to-degrade compounds that were making up the TOC and COD in the effluents from the AS bioreactors. The third explanation is that the PAC was adsorbing compounds that were kinetically slower to degrade. Once adsorbed, these compounds can be utilized by the bacteria as an additional food source. As PAC dose increased, the overall adsorptive capacity of the bioreactor increased, thereby concentrating the amount of food available to the microbes.

The results of the gross pollutant analyses of the four PAC/AS and control bioreactor effluents are presented in Table 9 and illustrated in Figure 7. The removal of TOC and COD increased dramatically with increasing PAC dose. The removals of the gross pollutants also increased with increasing VSS/SS ratios which is illustrated in Figure 7. The observed increase in biological activity is further substantiated by the increased removal of the gross pollutants. The BOD removals achieved in the AS bioreactors were already high; therefore, only a slight improvement in BOD removals was observed with increased PAC dose (Fig. 7).

BODo: Influent BOD
CODo: Influent COD
TOCo: Influent TOC

■ VSS/SS   • BOD/BODo   ▲ COD/CODo   × TOC/TOCo

Figure 7
PAC/AS MLVSS/MLSS
Ratios and Gross Pollutant Removals
Figure 8
Effect of Increasing PACSS on Oil and Grease Removal

Table 10 lists the results of priority pollutant analyses of the four PAC/AS and control bioreactors. There was not an appreciable difference between any of the bioreactors (including the control) in the removal of priority pollutant compounds. The 8,0-g/L PAC bioreactor does indicate slightly better phenolic compound removal due to the absence of these compounds in the effluent.

Although not analyzed in the AS phase of study, the influents and effluents from the four PAC/AS bioreactors were analyzed for oil and grease concentrations. These data are summarized in Figure 8. As the PAC does increased, the removal of oil and grease also increased.

CONCLUSIONS

The acclimation phase of this study indicated that an inoculum from a suspended growth municipal wastewater treatment plant could be acclimated to the contaminants in the Ninth Avenue Site groundwater composite samples without an observed lag in biological activity. Reduced iron and manganese in the groundwater composites caused a dramatic increase in the MLSS due to cation oxidation.

Based on analysis for organic priority pollutants of the off-gases from both biological systems (AS and PAC/AS) and of a composite sample of waste sludge, it was concluded that biological degradation accounted for a majority of the priority pollutant removal achieved by both biological systems.

The activated sludge process exhibited a potential for removing contaminants in the site groundwater. BOD removals were always in excess of 95%. However, TOC and COD removals were only in excess of 50%. Few priority pollutants were detected in the effluents from the AS bioreactors. Those priority pollutants detected, except for acetone, were at concentrations very near their respective analytical detection limits.

The addition of PAC to the activated sludge did improve the removal of COD and TOC from the influent. The removal of the gross pollutants increased with increased PAC dose. A PAC dose of 8.0 g/L resulted in percent removals in excess of 80% for the COD and TOC in the groundwater composite. Also, fewer priority pollutants were detected in the 8,0-g/L PAC dose bioreactor

effluent than the effluents from the other PAC/AS bioreactors.

In summary, AS treatment augmented with the addition of PAC seemed to be more effective than the AS biological system alone for removing the gross pollutants and organic priority pollutants from the groundwater composite.

ABSTRACT

In January 1988, officials of a state environmental agency became concerned about an ongoing accumulation of stormwater within an inactive hazardous waste impoundment containing principally coke plant wastes. The structural integrity of the impoundment was suspect, the three million gallon stormwater accumulation was approaching the impoundment's capacity and several downstream drinking water supplies were threatened. The agency notified the U.S. EPA, which determined that a CERCLA Section 106 removal action was required. A consent decree requiring removal of the impounded water was issued in August 1988.

The initial treatment technology implemented evolved from an agency recommendation and the practicalities of a remote site lacking utilities. This technology (air stripping and activated carbon) was in place by mid-December, and treated water discharge began in late December. Discharging was stopped shortly thereafter due to elevated levels of contaminants in the discharge.

The agency was satisfied that the immediate danger had been relieved by the removal and treatment of 15% of the accumulated water. Therefore, they agreed to postpone further removal until a laboratory treatability study could be conducted by the consulting engineers retained by the PRPs. The study demonstrated that biological treatment offered the most effective and least costly treatment approach. The results from this study will be discussed.

A temporary treatment basin was constructed adjacent to the first impoundment in May and June of 1989. The wastewater was transferred and seeded with bacteria in mid-July. An additional accumulation of contaminated water was transferred in late August. Aeration/oxidation time was nine weeks. The COD reduction was in general agreement with the predicted oxygen transfer rate of the aeration equipment, and wastewater quality was in agreement with that predicted from laboratory studies. Approximately 82% percent removal of TOC was achieved.

The paper will also illustrate the effectiveness of biological treatment on a wide range of organic compounds, the predictability of full-scale performance from bench-scale testing and the expeditious manner in which biological treatment can be implemented.

INTRODUCTION

The Municipal and Industrial Disposal Company (MIDC) operated a hazardous waste disposal facility in Southeastern Allegheny County, Pennsylvania from 1979 to August 1983. Operations ceased when the Pennsylvania Department of Environmental Resources (PaDER) suspended the MIDC permit because of permit and consent order violations. The site has remained inactive since 1983. Waste materials known to have been disposed at the site include coal tar decanter sludge, spent solvents and metal-bearing wastes.

The Phase I Disposal Pit was created by constructing dike walls above the existing grade and then placing waste material within the lined diked area. Waste material was not covered when operations ceased and rainwater accumulated within the diked area. Through constant contact with the waste material, soluble chemical compounds contaminated the estimated 3.5 million gallons of accumulated water.

In 1988, PaDER officials became concerned that a dike failure would threaten several downstream drinking water supplies. PaDER notified the U.S. EPA of their concerns at MIDC. After an assessment of the situation, the U.S. EPA determined that a CERCLA Section 106 removal action was warranted.

Later that year, the U.S. EPA and the potentially responsible parties (PRPs) entered into a Consent Order and Agreement to conduct a removal action at the MIDC site. One requirement of the Order was to remove the liquid layer contained in the Phase I Disposal Pit.

The initial treatment technology implemented evolved from an agency recommendation and the practicalities of a remote site lacking utilities. The PRPs implemented the agreed technology (air stripping and activated carbon), and the treatment system was in place by mid-December. After verification of the quality of the treated water by sampling and analysis, discharge from the on-site treatment system began in late December. Discharging was stopped shortly thereafter due to elevated levels of contaminants in the discharge.

The system could not respond to fluctuating influent characteristics and overall influent concentrations which were greater than expected. More rigorous sampling and characterization of the pond water showed conspicuous stratification (Table 1) and greater organic loads than anticipated from the previously available data. Water treatment operations eventually revealed that the selected technology could not consistently meet the stipulated technology based effluent quality limitations. Acetone, methyl ethyl ketone (MEK) and methyl isobutyl ketone (MIBK) proved particularly difficult to remove to the specified limits by the selected treatment scheme. The treatment system was subsequently dismantled and demobilized.

Approximately 15% of the impounded water had been treated and discharged before cessation of operations. The agencies were satisfied that the immediate danger posed by the site had been at least temporarily relieved. Therefore they agreed to postpone further action until consulting engineers retained by the PRPs could evaluate other alternatives.

A number of on-site and off-site water management schemes were considered. Off-site methodologies investigated were incineration, the use of RCRA Treatment, Storage and Disposal Facilities and Publicly Owned Treatment Works. On-site treatment schemes investigated were incineration, solidification and biological treatment. Biological degradation of numerous solvents and of organics associated with coal coking operations, was well documented.[1-25] Table A-1 contains numerous

citations of wastewater treatment efficiency for specific compounds based on the type of treatment and source of the wastewater stream. The data in this table were taken from a literature search in "Estimation of Removal of Organic Chemicals During Wastewater Treatment," in 1986, for the U.S. EPA, The original data are from research conducted on pilot- and full-scale treatment systems.

The consulting engineers had participated in the successful utilization of biological treatment for the organic chemicals of concern and were satisfied of its utility and cost-effectiveness. In addition, the PRPs had had good experience with biological treatment of comparable wastewaters within their own facilities.

The preliminary review of potential treatment and disposal methodologies concluded that biological treatment processes held the most promise for successful management of the impounded water because of their ability to remove a wide variety of organic compounds from contaminated water at varying concentrations at a reasonable cost. The agencies agreed to postpone further removal until a laboratory treatability study could be conducted to demonstrate the effectiveness of biological treatment.

BACKGROUND

Sampling of the feed to the air stripper/carbon treatment system showed inconsistencies with earlier data collected by the agencies in 1988. To establish a basis for design of a new treatment system, it was necessary to accurately determine the volume and composition of the impounded water.

Liquid samples were collected from the Phase I Disposal Pit from approximately one foot below the liquid surface and from approximately one foot above the waste/liquid interface. The pit was divided into quadrants and samples were obtained at two depths in the center of each quadrant.

The samples were analyzed for the following indicator parameters and nutrients: Suspended Solids, Chemical Oxygen Demand, Dissolved Solids, Phosphorus, Volatile Solids, Ammonia, Total Organic Carbon,

Oil and Grease (Freon Extractables), Soluble Organic Carbon, and Phenolics.

These parameters were selected to:

- Determine the physical nature of the majority of contaminants (dissolved or suspended)
- Evaluate the potential for biological treatment enhancement by nutrients
- Determine initial operating parameters and loading for the biological treatability scenarios

Results of these analyses are presented in Table 1 for the shallow and deep samples.

Composite samples generated from the set of shallow samples and deep samples were subjected to these analyses: cyanide, sulfide, ignitability, Btu, metals, acid extractable organics, and base neutral extractable organics. The organic scans included the "tentatively identified compounds" library search procedure on both fractions. Table 1 also shows the analytical results.

The final group of parameters is the volatile organic compounds, including a library search. Since the U.S. EPA protocols specify that samples intended for analysis of volatile compounds are to be grab samples, two discrete samples were selected; one shallow and one deep.

These analytical data indicate that contaminants in the impounded water are generally more concentrated closer to the waste material, i.e., deeper in the liquid layer. Typically each analyte was three to five times more concentrated in the deep samples.

Concurrent with sample activities, depth soundings were taken throughout the impoundment. From depth sounding data, it was estimated that approximately 3.5 million gallons of water had accumulated within the Phase I Disposal Pit as of the date of sampling.

BIOLOGICAL TREATABILITY STUDY

Three scenarios were considered for the treatability study. The scenarios are described in the next sections of the paper.

Scenario No. 1: Blending and Biological Treatment at Nearby Coke Works

A nearby coke works, owned by a PRP, utilized an activated sludge process to treat coal coking wastewaters. Phase I Disposal Pit wastewater and the coke works wastewater were blended at a 1:20 ratio consistent with expected hauling and receiving capabilities. A bench-scale bioreactor was seeded with sludge from the coke plant and operated at an F/M (Food/Microorganism ratio defined as the gram COD applied/gram MLVSS per day) of 0.3 after blending.

Scenario No. 2: Treatment On-Site Using Mobile Equipment

For this scenario, modular, transportable equipment was envisioned for treatment of the impounded water. A low load activated sludge system was selected as the most promising approach, due to availability and proven performance. To simulate this scenario, a bench-scale activated sludge process was selected for testing at F/Ms of 0.1 and 0.2.

Scenario No. 3: In Situ Treatment

In situ treatment would consist of the introduction of surface aerators to the Phase I Pit and the addition of seed bacteria and nutrients. The seed bacteria preferably would have some degree of acclimation to the pond organics, as would occur with biological sludge from a nearby coke works wastewater treatment plant. To simulate this scenario, a small bench-scale reactor was operated.

The experimental design is summarized in Table 2.

MATERIALS AND METHODS

A laboratory treatability study was conducted to evaluate all three scenarios. Two activated sludge reactors were set up to simulate Scenarios 1 and 2. Each consisted of a stirred, aerated compartment of 5 gallons, separated by a vertical baffle to provide quiescent conditions at the overflow. Operating conditions were set to allow the reactors to operate at F/M ratios of 0.3 (Scenario 1), 0.2 and 0.1 (Scenario 2). All reactors were seeded with sludge from a local coke works biological wastewater treatment facility. Nutrients were added to the reactors to supplement the bacteria and ensure new cell growth.

Type	Continuous	Continuous	Batch
Description	Activated Sludge	Activated Sludge	Aerobic Digestion
F/M	0.3	0.2 0.1	N/A N/A

To determine when stable conditions had been attained at a given F/M, selected parameters were routinely monitored until constant values were obtained. Total organic carbon (TOC), methyl ethyl ketone (MEK), biochemical oxygen demand (BOD) and flow were monitored in the influent. In the mixed liquor, the concentrations of mixed liquor suspended solids (MLSS) and mixed liquor volatile suspended solids (MLVSS) were monitored and, in the effluent, TOC and MEK were monitored. Weeks were required for reactor conditions to stabilize; during that time the biomass acclimated to the new substrate. Large variations in sludge and mixed liquor characteristics were observed during the stabilization period.

The batch reactor study to simulate the in situ treatment, Scenario 3, was designed based on initial toxicity tests (dissolved oxygen uptakes) to determine at what concentration the pond water could be mixed with

activated sludge without toxicity. Initial testing did not indicate any toxicity problems. Seventy-five percent of the pond water and twenty five percent of the coke plant aeration tank mixed liquor were combined for the uptakes. An 8-gallon reactor was used to simulate the Phase I Pit holding the impounded water. In order to be conservative, the reactor was prepared with water samples drawn from the bottom of the impounded water layer, where the highest organic levels were observed.

The first batch reactor was seeded to a MLVSS of approximately 500 mg/L. The reactor was then vigorously aerated and monitored. A second test was conducted to check/confirm the results of the first test. The second reactor used all the settled sludge from the first reactor. After adding impounded water, the second reactor was vigorously aerated and monitored. The treatment performances for the biological reactor were monitored for BOD_5, TOC, COD, MEK and organic compounds analysis.

RESULTS AND DISCUSSION

Reactor Performance

Scenario 1: Blending and Biological Treatment at Nearby Coke Works

The organic removal increased with time due to acclimation of the bacteria to the wastewater. After approximately four weeks of acclimation, the average organic removal based on BOD was 88% (Table 3). MEK was removed by approximately one order of magnitude, but the required removal rate could not be achieved without the 20:1 dilution provided by the other wastewater streams. Overall, this reactor did not perform as well as the on-site continuous or batch reactors.

Table 3
Summary of Reactor Performance; MIDC Impoundment Water Treatability Study; MIDC Site

Scenario	R-1 (Continuous Blend)	R-2 (Continuous)		R-3 (Batch)	
	1	2a	2b	3a	3b

MEK	79	85	99	>99*	>99

*Estimated

All data shown are averaged during steady state

Scenario 2: Treatment On-Site Using Mobile Equipment

The continuous reactor showed better performance at a reduced loading. The initial average F/M loading (gram COD/gram MLVSS/day) was 0.2. The second F/M loading was 0.1. At these loadings, the removals based on BOD were 69% and 97%, respectively (Table 3). MEK dropped to below the expected 1000 ug/L effluent limitation at the lower loading.

Scenario 3: In Situ Treatment

The batch reactor showed the best performance overall (Table 3). After 10 days of operation, the organic removal based on BOD exceeded 99% (Table 3), and the projected effluent limit for MEK was achieved. The second batch test confirmed the results of the initial test and showed that MEK removal exceeded 99% after 10 days of operation.

The operating data and the results of the batch reactor performance

are summarized in Tables 3 and 4. In all cases, the previously applied discharge limits were attained or approached. In some cases, detection limits were too high to determine whether or not discharge limits could be attained. This finding was attributed to interferences from other organics in the matrix, which often occur in high strength wastewaters.

Table 4
Operating Data for Batch Treatability Tests; MIDC site

	Test A	Test B
Volatile Suspended Solids (Avg)	3600	4400
Time for TOC removal, days	<6.0	<3.0
Time for MEK removal, days	13	13
Total test duration, days	24	13

BOD removal was computed as an average value from mean performance data. Scenario 3 offered the best removals in the shortest period of time for the least cost. Therefore, this scenario was recommended for implementation. High detection limits occurred in Scenario 3 at least once with the following parameters: cyanide, MIBK, phenanthrene, 2-hexanone, and fluoranthene. The discharge limits were not achieved for the following parameters: phenol, arsenic, boron, manganese and nickel. Therefore, one recommendation of the treatability study was to renegotiate the limits applied to these compounds.

Proposed limits were submitted to PaDER by the PRPs (Table 5). The acceptability of these limits was vigorously debated by the PRPs and the involved agencies and was not resolved until immediately before discharge of the treated impoundment water.

FULL-SCALE IMPLEMENTATION

In Situ Biotreatment System Design

The bench-scale reactors yielded performance data, but no data that were readily utilizable for sizing aeration equipment. The bench-scale reactors were vigorously aerated to assure that performance would not be limited by oxygen requirements or by the quantity of biomass in suspension and to demonstrate the concept in the available time. In full-scale operation, aeration would be less vigorous to avoid disturbing the wastes at the bottom of the impoundment. The minimum recommended power level for mixing and aeration in lagoons is approximately 30 hp/mg.[14] Typical horsepowers commonly used in aerated lagoons range from 10 to 60 hp/mg. A range of anticipated performance information is shown in Table 6. Based on an anticipated waste volume of 3.5 million gallons, initial volatile suspended solids of 400 mg/L and aeration horsepower of 30 hp/mg were selected as objectives.

Table 6 indicates that MLVSS would be rate-limiting and that the required BOD removal could be accomplished in 26 to 65 days, depending on oxygen transfer efficiency and on the concentration of

Table 6
Anticipated In Situ Performance; MIDC Site

Case	Units	Expected	Worst
Total Mixing Power	HP	105	105
Total BOD in Pond (Avg. of 3000 mg/l)	lb	40000	40000

biomass (MLVSS) maintained in suspension. Additional time would be required for the seed to acclimate, to settle the biological solids and to discharge the treated water. There also was concern that removal of organics could be anticipated to become less efficient as the BOD decreased, which would extend the treatment period. Total time from seeding to an empty pond was predicted to be twelve to eighteen weeks.

Implementing On-Site Treatment

In May 1989, another emergency condition was declared at the MIDC site due to increased seepage at the toe of the eastern dike and rising water levels within the Phase I Disposal Pit from heavy precipitation. An emergency construction project was initiated to buttress and strengthen the dikes. Although batch biological treatment within the Phase I Disposal Pit would have been the most expeditious and effective alternative to implement, two major drawbacks were evident:

- The persistent threat of dike overtopping by the rising water level would not be quickly alleviated because of the time period necessary for proper treatment and
- Leaving the impounded water in the Phase I Pit and in contact with the waste material would complicate the aeration application and possibly prolong treatment by enhancing the flux of contaminants from the solid phase to the liquid phase

The alternate plan developed to implement batch treatment involved construction of a lined treatment basin, transferring the water from the Phase I Disposal Pit into the treatment basin and proceeding with treatment. Since this plan eliminated the drawbacks of in situ treatment, it was endorsed by the agencies.

The temporary treatment basin was constructed adjacent to the Phase I Disposal Pit in approximately 6 weeks of extremely inclement weather. The aeration system consisted of ten floating aerators positioned throughout the temporary basin. Nine 10-horsepower units and one 15-horsepower unit provided a total system aeration/mixing power of 105 horsepower (Table 6). As the water level in the Phase I Pit was drawn down, a minimal amount of infiltration was observed. However, one month after the initial water removal, another one foot of infiltration and precipitation had accumulated in the Phase I Pit and was transferred into the treatment basin.

Startup

To aid mixing, nutrients and biomass were added to the temporary basin during the transfer pumping of the impounded water from July 6 to July 13. A review of the nutrient characteristics of the raw water (Table 1) suggested that the available nutrients could not support the kind of biological growth anticipated to be necessary for expedient biological degradation of the wastewater constituents. However, it was believed that a high ratio of endogenous respiration and nutrient cycling would occur.
Therefore, the consulting engineers elected not to supplement the existing ammonia, but to add 110 gallons of 75% technical grade phosphoric acid. Approximately 20,000 gallons of 5% solids biological sludge were shipped from the local coke plant wastewater treatment facility and used to seed the new impoundment. Seeding took place from July 11 to 14. Aeration began on July 12.

The results of TOC, COD, TSS, VSS and BOD analyses performed are summarized in Figure 1; MEK analysis results are shown in Figure 2. A summary of the analytical data is shown Table 7. COD, TOC, BOD and MEK levels appeared to decline exponentially. Biological activity began approximately one week after seeding. Initial

Process Monitoring Data

dissolved oxygen concentrations were positive, indicating that the aerators were adequately sized to match the initial load (Figure 3). Later dissolved oxygen levels rose as residual CODs dropped. Biological degradation was essentially complete in approximately one month.

The transfer of additional run-on and infiltration water from the Phase I impoundment (on August 25, 1989) resulted in a 63% increase in COD within the pond. Again biological degradation was essentially complete in approximately one month. The pond completely exhausted its potential for biological degradation in another three weeks. A summary of the monitoring data is shown in Table 7.

Conclusion of the treatment process was indicated by three conditions: leveling off of TOC valves, BOD below 50 mg/L, and MEK (2-Butanone) below 1 mg/L. Representative samples were then collected at five locations at varying depths (Table 8). The data demonstrated that the pond was essentially homogeneous.

Upon review of the data, the involved agencies agreed to a mass-based discharge limit based on residual levels of several polynuclear aromatic compounds. This limited the discharge rate from the pond to 100 gpm. The water was discharged in 20,000 gallon batches. Each batch was tested for soluble COD. Batches with CODs in excess of 1800 mg/L were returned to the pond. Discharge began on November 8, 1989 and concluded on January 28, 1990. Comparison of effluent analyses between the bench-scale reactor and the biotreatment process is shown in Table 9.

Evaluation of Biokinetic Constants

During the process of biooxidation of a complex substrate, the reaction rate decreases independently of the decrease in substrate concentration. As a result, efforts to describe the overall reaction rate by a first order equation is considered. At the same time, it is quite clear that the reaction rate constant (k) from the first order equations will decrease with the progress of the biochemical reaction of a complex substrate. Typically, substrate levels are represented by an indicator parameter such as BOD or COD.

While kinetic data have not been studied extensively for this study, it should be noted that the exponential decay coefficients for COD and TOC varied with initial loadings. The biokinetic constants were determined by fitting TOC and COD data to the first order kinetic equation:

$$S = S_o exp(-kt) \qquad (1)$$

where
S = substrate concentration at time t
So = initial substrate concentration
k = first order kinetic constant
t = time

Estimation of the numerical values of the biokinetic constants presents a complex problem, because one has to choose an equation which fits the data. Several investigators have utilized non-linear regression techniques to fit the data and estimate the biokinetic constants. This approach is applied with difficulty. It is possible to obtain numerical values which have little physical meaning; nonetheless, such a problem did not occur in obtaining the numerical values of first order biokinetic constants for substrate concentrations measured as TOC and COD, summarized in Table 10. The goodness of fit is also shown as correlation coefficients in the same table. The decay constants reported here seem to be comparable to one another (for both TOC and COD measurements). In Phase I, k was 0.043 day^{-1}, and 0.044 day^{-1} for TOC and COD, respectively. In Phase II, k was 0.025 and 0.018 day^{-1} for TOC and COD, respectively. MEK was removed at a faster rate of 0.19 day^{-1}.

Table 10
Biokinetic Constants; MIDC Site

TOC DATA	Phase I	Phase II

CORRELATION COEFFICIENTS (r)	0.997	0.93
MEK DATA	Phase I	
FIRST ORDER KINETIC CONSTANT (k), 1/day	0.228	
INITIAL SUBSTRATE CONCENTRATION, mg/l	11	
CORRELATION COEFFICIENTS (r)	0.996	

The physical, chemical and biochemical characteristics of these reported organic compounds become important during biological treatment because of the combined possibilities of stripping, adsorption and biological oxidation. Most kinetic design models available to date have originated from a substrate mass balance assuming substrate removal based on biological consumption. Stripping and biological adsorption are not included in this balance, and the amount of substrate stripped is not predicted.

Tables 3 and 7 show the comparison of the MEK removal achieved in batch reactors; one test was performed as a bench-scale experiment and the other as a biological treatment process. In a bench-scale system (Scenario 3), more than 99% of MEK was removed in 14 days; in the pond treatment process, 99% of MEK was removed in one month. This difference might reflect rate limiting conditions in the pond, i.e. oxygen transfer.

CONCLUSIONS

The batch biotreatment process achieved comparable removals to those found in the bench-scale study. Bench-scale testing was a good predictor of reactor performance.

New Orleans, Louisiana

INTRODUCTION

In this paper, the principles of biological treatment have been reviewed. This first section of the paper includes a discussion of the environmental requirements and kinetics of biological systems. This introductory material is followed by a discussion of the fundamental reasons for limitations of conventional bioprocesses in treating hazardous wastes. Identification of such fundamental reasons leads to understanding how any innovative bioprocess should be developed and evaluated for application to treatment of hazardous wastes. Some examples show how the innovative processes can enhance the successful biodegradation of hazardous organic compounds.

PRINCIPLES OF CONVENTIONAL BIOTREATMENT

Environmental Requirements

The environmental requirements shown in Table 1 must be provided for the growth of organisms to facilitate biotreatment. These requirements are only general conditions applying to all microorganisms. For a specific organism or group of organisms, knowledge of more specific requirements is required.

Table 1
Environmental Requirements for Bioprocesses

Carbon-Source

Temperature
Absence of Toxicity
Mixing and Mass Transfer
SKT

The organic matter in wastewater is used as substrate by the organisms. These organics serve as the energy source (electron donor) and carbon-source. The organisms also need an electron acceptor for electron balance. Different groups of organisms need different electron acceptors. For aerobic bacteria, the electron acceptor is oxygen. Denitrifiers, which are anoxic organisms, use nitrate (NO_3^-) as the electron acceptor. Sulfate reducing bacteria use sulfate (SO_4^{--}) and methanogens use CO_2 as electron acceptors. The organic matter serves as both electron acceptor and elec-tron donor to fermentative bacteria.

Using thermodynamics, it can be shown that, energetically, oxygen is the most preferred electron acceptor followed by nitrate, sulfate and carbon dioxide. A simple experiment makes this concept clear. If a closed vessel contains a glucose solution (or any other easily biodegradable substrate, i.e., electron donor), oxygen, nitrate, sulfate and CO_2, the aerobic bacteria will start biodegrading glucose as long as dissolved oxygen is available. After depletion of oxygen, the denitrifying bacteria will start biodegrading glucose using nitrate as the electron acceptor. After the nitrate disappears, the sulfate reducers will start utilizing glucose. Finally, the methanogens will start consuming CO_2, leading to the formation of methane. From the hazardous waste perspective, it is important to note that various toxic organic compounds may have different adverse effects on these different groups of bacteria. One group of organic compounds may be biodegraded effectively by one group of organisms, whereas the other groups of organisms may fail to do so.

Phosphorous and nitrogen are considered as macronutrients. Some researchers consider sulfur as a macronutrient for methanogenic bacteria. Examples of micronutrients are metals (such as Fe, Mg, Ca, Co, Ni, etc.) and vitamins. In addition to the carbon source and N, P and S, the organisms need several elements in minute quantities for proper growth. Without these micronutrients, the organisms may still grow but such growth will not be "healthy" and there may be long-term adverse effects. From a biotreatment perspective, the problem is to know exactly which micronutrients are necessary and more importantly what concentrations are optimum. Quantitative information often is lacking in this area. Engineers are advised to add all these micronutrients (especially the metals) to the feed if they were not already present in the wastewater.

Most organisms require a neutral pH for optimal growth. Depending on the process, the optimum temperature may vary. For conventional aerobic treatment, the optimum temperature is normally 20 to 25° C whereas for mesophillic anaerobic treatment, the optimum temperature is 35° C. Thermophillic anaerobic treatment requires a temperature of 55° C.

One requirement for biotreatment is the "absence of toxicity." The significance of this requirement is that the hazardous organics can be treated only if they were not toxic to the organisms. But toxicity is not a simple concept. Toxicity depends on concentration, mode of application, ability to acclimate, etc. Almost any substance could be toxic if the concentrations were very high. A slug dose may have very different effects compared to a gradual increase in concentration since the latter mode of addition

gives the organisms the ability to acclimate to the toxic substances.

Adequate mixing is necessary for the transport of substrate and nutrients to the bacteria. Even if all other environmental requirements were fulfilled, lack of adequate mixing could lead to system failure. Mixer design becomes a challenge for engineers when they try to utilize biotreatment with sludge having a high solids concentration (> 5% total solids). Without an innovative process, engineers may fail when they try to apply biotechnology to the treatment of contaminated soil. Permeability and other characteristics of the soil such as particle size and type of soil also need to be considered.

The last factor in Table 1 is solids (i.e., bacterial) retention time (SRT). SRT is a measure of the length of time the bacteria spend in a bioreactor. The longer the bacteria are in a reactor, the higher the biodegradation is assuming all other requirements listed in Table 1 are fulfilled. SRT is defined as the mass of organisms in the system divided by the mass of organisms removed (wasted) per day. The engineers can control the solids wasting rate to control SRT. It is not unreasonable to say SRT is the most important variable in the biotreatment of both hazardous and nonhazardous wastewaters. The discussion of kinetics in a later section of this paper will clarify the importance of SRT.

Another important point to realize is the difference between hydraulic retention time (HRT) and SRT. For continuous-fed, complete-mix systems without solids (organisms) recycle, SRT equals HRT. For continuous-fed, complete mix systems with recycle or continuous-fed, fixed-film systems, SRT could be many times higher than HRT. In an ideal system, HRT is low and SRT is high. Low HRTs allow higher feed flow rates for the same bioreactor, and high SRTs lead to effective degradation of the organic compounds.

Scope of Innovation

Based on the discussion thus far, the areas appearing to need more R&D work are noted below.

Use of Various Types of Bacteria

It is useful to know which electron acceptor can best treat a certain organic waste (electron donor). In other words, more work is required to know which types of bacteria (aerobic, anaerobic, etc.) are most suitable for biodegrading various toxic organic compounds.

Use of Other Organisms

Recently, there is a renewed enthusiasm with white rot fungi for treatment of complex organics in wastewaters. White rot fungus belongs to a family of wood-rotting fungi found throughout the northern hemisphere. Lignin, normally resistant to decay, is the primary noncarbohydrate constituent of wood. White rot fungus naturally produces a group of enzymes that degrade lignin. White rot fungus enzymes are unique because they have a low specifity, meaning they can react with a wide variety of substances.[1]

It is expected that white rot fungus will offer a potential solution for groundwater and soil cleanup problems that currently cannot be managed using conventional methods. Although researchers expect the technology to be relatively low in cost, the pilot-scale demonstrations will define specific costs. Other organisms may prove to be very useful in biodegrading toxic organic compounds.[1]

Enhanced Bioavailability/Mass Transfer

Engineers need to find a way to increase mass transfer for treatment of wastes containing high solids and contaminated soil. No matter how simple it sounds, a successful innovative process could be to "mix" domestic wastewater or domestic sludge with contaminated soils for combined treatment. The wastewater or sludge will provide enough water content to facilitate mass transfer in the mixed waste.

Innovative Techniques to Increase SRT

During the 1980s, a significant amount of research was performed in this area. Researchers have recognized that fixed-film processes such as anaerobic filters, fluidized beds, etc., have an inherent advantage over complete-mix systems. It is important to realize that there is nothing innovative about this concept because this should be understood from the fundamentals of biokinetics. The part that is innovative is the design of a system that satisfies the fundamental requirements. Unless a process is fundamentally sound, it is not going to be of any value. For this reason, the fundamental aspects have been stressed in this paper while discussing the scope of innovation.

Kinetics of Bioprocesses

Before successful evaluation of innovative biological processes, the kinetics of bioprocesses need to be understood. The less understood areas in kinetic modeling need to be recognized.

One popular model in biokinetics is the Monod Model.[2] The organic matter (C-source and electron donor) in a waste is the substrate, S_O, for the bacteria. The bacterial mass, X, increases as S_O is utilized. The utilization of substrate and the growth of bacteria are simultaneous events. To quantify this phenomenon, a set of simultaneous differential equations is used as follows:[3]

$$\frac{dS}{dt} = -\frac{K_S X}{K_S + S} \tag{1}$$

$$\frac{dX}{dt} = Y\frac{dS}{dt} - bX \tag{2}$$

where:

$\frac{dS}{dt}$ = rate of microbial substrate utilization per unit volume, mass per volume-time

$\frac{dX}{dt}$ = net growth rate of microorganisms per unit volume of reactor, mass per volume-time

k = maximum rate of substrate utilization per unit weight of microorganisms, time^{-1}

Ks = half velocity coefficient, equal to the substrate concentration when dS/dt = 0.5 k, mass per volume.

Y = growth yield coefficient, mass per mass

b = microorganism decay coefficient, time^{-1}

X = microbial mass concentration, mass per volume

S = concentration of substrate surrounding the microorganisms, mass per volume

Each organism has a characteristic set of kinetic parameter values. For example, for acetate-utilizing methanogens, the values are: k = 2.5 day^{-1}, K_S = 10 mg/L, Y = 0.05 and b = 0.01 day^{-1}.[4] These values are constants; the engineers cannot change these values by using any innovative processes. However, when the bacteria undergo mutation, these values might change.

Mutation, which is commonly referred to as acclimation by engineers, is possible after exposing the organisms to toxic chemicals. Engineers regard mutation (or acclimation) as the ability of the organisms to develop "some resistance" to toxicity and also the ability to develop "some mechanism" (for example, growth of certain enzymes) which leads to enhanced biodegradation. When this happens, the values of the kinetic parameters might change. The engineers could successfully make such changes work to their advantage by controlling the HRTs/SRTs.

The methods for determining the values of the kinetic param-

eters are not included in this paper but are easily available in text-books on Environmental Engineering.[5]

The engineers need to know the values of the kinetic parameters for effective design of biosystems. Solving equations (1) and (2) for complete-mix, continuous systems at steady-state yields:

$$S = \frac{K_S (1 + b\,\theta_C)}{\theta_C (Yk - b) - 1} \qquad (3)$$

$$X = \frac{Y(S_O - S)}{1 + b\,\theta_C} \cdot \frac{\theta_C}{\theta} \qquad (4)$$

where:

θ_C = solids retention time (SRT), days

θ = hydraulic retention time (HRT), days

S_O = substrate (pollution) concentration in feed, mass per volume

Equation 3 is useful to calculate the effluent substrate (pollution) concentration after biotreatment. It is important to note that for complete-mix systems the substrate concentration inside the bioreactor equals the effluent substrate concentration. It is useful to be able to predict S, because when we measure soluble BOD in the effluent, we get a measure of S. Equation 4 is also useful because it gives the bacterial concentration, X, at steady state. Hence, from this equation and with known flowrates, one can calculate the amount of sludge generated from the biotreatment system.

In Equations 3 and 4, all the terms on the right hand sides are constants except θ_C, θ and S_O. Assuming no variation in the influent substrate concentration S_O, the only two parameters that the engineers need to control are θ and θ_C. The HRT (or θ) is easy to control by controlling the flowrate of the influent. The SRT, on the other hand, can be controlled by selecting the amount of sludge to be wasted from the complete-mix system. As discussed before, a successful innovative process is one which minimizes the HRT and maximizes the SRT. A short HRT will facilitate the treatment of large volumes of wastewater; a long SRT should help satisfy the effluent quality requirements.

LIMITATIONS OF BIOPROCESSES IN TREATING HAZARDOUS WASTES

Some of the organic and inorganic compounds present in a waste may be classified as hazardous. Both organics and inorganics may cause inhibitions/toxicity to bioprocesses. The toxic organics might also be biodegraded under favorable conditions.

Toxicity Kinetics

To quantify toxicity, the following models are useful:

For Noncompetitive Inhibition

$$\frac{dS}{dt} = - \frac{kSX}{K_S + S}\left(1 + T_X/K_I\right) \qquad (5)$$

For Competitive Inhibition

$$\frac{dS}{dt} = - \frac{kSX}{K_S\left[1 + (T_X/K_I) + S\right]} \qquad (6)$$

where:

T_X = concentration of toxicant, mass per volume

K_I = inhibition coefficient, mass per volume

The concepts of noncompetitive and competitive inhibition are based on biochemistry. More information on these models is available in the literature.[6,7]

At steady-state ($dS/dt = 0$, $dX/dt = 0$), the model equations reduce to simple algebraic equations which can be solved to determine the effluent substrate concentration:

Competitive:

$$S_t = [K_S(1+b\theta)(1+T_X/K_I)]/[\theta(Yk-b)-1] \qquad (7)$$

Noncompetitive:

$$S_t = [K_S(1+b\theta)]/[\theta(Yk-b(1+T_X/K_I))-(1+T_X/K_I)] \qquad (8)$$

Equation 7 can be rewritten as follows:

$$S_t = S + S(T_X/K_I) \qquad (9)$$

where:

S_t = effluent substrate concentration under toxic conditions

S = effluent substrate concentrations without toxicants

Equation 9 indicates that the effluent substrate concentration increases linearly with increasing toxicant concentration. Equation 8 can be simplified further to indicated that, unlike competitive inhibition, noncompetitive inhibition does not have a proportional effect on effluent substrate concentration. That means, when noncompetitive inhibition occurs, the effluent concentration remains unaltered up to a "limiting" toxicant concentration. When this limiting concentration is exceeded, a total system failure is possible.[7]

The inhibition coefficient, K_I, is a measure of the bacterial resistance to toxicity. The engineers cannot change this coefficient (i.e., if an organism does not have the ability to resist toxicity, no innovative process can help it). On the other hand, as indicated earlier, it might be possible for the organisms to undergo mutation (which the engineers call acclimation) which might lead to an increase in resistance to toxicity, i.e., increase in value of K_I.

If it were known how the organisms increase their resistance, it would be easier for the engineers to provide the favorable conditions to enhance such acclimation. Since the mechanism of acclimation is not understood in most cases, the Environmental Engineer's general approach should be to provide maximum possible SRT without making the HRT impractical. As discussed before, a low HRT will facilitate treatment of sufficient volume of wastewater.

A significant limitation of the application of the concept of toxicity kinetics is that more research is necessary to develop data so that the environmental professionals can find out which compounds cause which type of inhibition. Researchers have shown that organics such as formaldehyde cause competitive inhibition whereas inorganics such as ammonia and nickel cause noncompetive inhibition.[8,9,10]

Are the Concentrations of the Hazardous Organics High Enough to Cause Toxicity to the Biotreatment Processes?

The earlier discussion of toxicity kinetics is limited to scenarios where high concentrations of hazardous substances may end up in existing treatment plants designed for conventional, nonhazardous, domestic and/or industrial wastewaters. It is quite common to face a situation where the hazardous organic compounds are too low in concentration to cause any toxicity to the organisms in the treatment plant. But removal of these low concentrations of the organics could still be critical because these low concentrations which do not kill the bacteria might have a long-term effect on human health. Some organic compounds are potentially carcinogenic even at very low concentrations.

Fate of Toxic Substances in Biotreatment Processes

When the concentrations of the toxic organics are too low to cause any adverse effects on the microorganisms in the treatment system, the following factors will determine the fate of these hazardous organic substances:

- Volatilization
- Adsorption
- Biodegradation

When dealing with hazardous materials, the most desirable fate is biodegradation (assuming that biodegradation will not lead to any toxic intermediates). Volatilization of organics might create air pollution. In conventional aerobic processes, volatilization is difficult to prevent, indicating the need for closed systems such as anaerobic processes. Adsorption of the hazardous substances in the biological sludge will make the sludge hazardous. Hence, if an innovative process can control sludge efficiently, it will be of value to the client.

No innovation can change the amount of sludge that will be generated because of bacterial growth as long as the same organisms are used. However, by proper choice of bacteria, the amount of sludge can be minimized. For example, anaerobic bacteria will generate almost an order of magnitude lower amount of sludge than aerobic processes.

Biodegradation will also depend on the choice of bacteria. Engineers can do very little about biodegradation except to provide the "proper conditions" for acclimation. The problem is that in most cases the "proper conditions" are unknown.

A unified model is very useful to simultaneously predict the extents of volatilization, adsorption and biodegradation of hazardous substances. Development of such models is not easy. A General Fate Model has been proposed by Namkung and Rittmann.[11] Their work showed that for VOCs (toluene, benzene, ethylbenzene and methylene chloride), biodegradation is the most important mechanism of removal in an activated sludge plant. Volatilization and adsorption are not significant compared to biodegradation when the latter occurs. When biodegradation is not important (for example, for chloroform), volatilization is the main removal mechanism. These conclusions were based on a study of a wastewater treatment plant.[11]

Can the Organisms Biodegrade Very Low Concentrations of Hazardous Organic Substances?

We have seen that organisms use organics as their carbon and energy source. Up to what concentration levels can the organisms use the organics as their primary carbon source? This question is very important for biotreatment of hazardous organic compounds since many of these compounds could be carcinogenic at ug/L levels. That means the concentrations of these compounds might be too low for biodegradation but too high to cause toxicity to humans.

The limiting concentration at which the bacteria can use a substance as their primary carbon source is denoted by S_{min} which is the limiting condition when growth equals decay. Using the Monod kinetics discussed earlier, it can be written:

Growth	=	Decay
$\dfrac{Y k S_{min} X}{K_s + S_{min}}$	=	bX
$Y k S_{min}$	=	$bK_s + bS_{min}$

$$S_{min} = \frac{bK_s}{Yk - b} \qquad (10)$$

Equation 10 shows that the minimum substrate concentration depends on the four kinetic parameters k, K_s, Y and b. The values of these parameters are characteristics of the organisms used for biotreatment. The values cannot be changed by using innovative processes, but engineers need to realize that depending on the type of organism, S_{min} can vary considerably. The following examples will make this point clear.

Example 1

Assume:
b	=	0.01 day^{-1}
K_s	=	10 mg/L
Y	=	0.05
k	=	0.3 day^{-1}

Calculated S_{min} = 20 mg/L

Example 2

Assume:
b	=	0.01 day^{-1}
K_s	=	1 mg/L
Y	=	0.03
k	=	2.0 day^{-1}

Calculated S_{min} = 0.2 mg/L

Example 3

Assume:
b	=	0.01 day$_{-1}$
K_s	=	1 mg/L
Y	=	0.05
k	=	2.5 mg/L

Calculated S_{min} = 0.087 mg/L

These examples show that with apparently small changes in the values of the kinetic parameters, the S_{min} value can change significantly. It should be noted that most volatile compounds generally are present in very low concentrations in the wastewaters. These concentrations might be too low for biodegradation unless cometabolism occurs as discussed in the following section.

Is Biodegradation Impossible with Concentrations Lower than the Required Minimum Substrate Concentration?

Biodegradation of organics with concentrations lower than S_{min} is still possible if the organisms can use the organics as secondary substrates or cometabolites. A primary carbon source is required. In POTWs, domestic wastewater is the primary carbon source. This means that if low concentrations of toxic organic substances were discharged to POTWs, the only way these substances could be biodegraded is the use of these compounds as secondary substrates by the existing organisms in the treatment plant. However, acclimation and other fate mechanisms such as volatilization and adsorption need to be addressed.

In a recent U.S. EPA pilot-scale project, the fates of several RCRA and CERCLA compounds were studied.[12] The results indicate that stripping of volatile compounds, such as chlorinated hydrocarbons, in the activated sludge process could be significant. Some semivolatile compounds, on the other hand, could be treated more efficiently using a conventional activated sludge process. The concentration of each compound spiked to the influent domestic wastewater was 0.5 mg/L which is presumably below the respective S_{min}. Even though no mechanism study was possible in this pilot study, it might be assumed that secondary utilization was the reason for biodegradation.[12]

SELECTED INNOVATIVE BIOPROCESSES

Since it is difficult to list and discuss all innovative bioprocesses, the focus of this part of the paper will be to study how some of the innovative bioprocesses satisfy the fundamental requirements. The most important question to be addressed in this section is: "If the fundamental requirements of bioprocesses were satisfied, would a bioprocess work successfully or are there some 'other' requirements that we have overlooked so far?"

The discussion thus far has shown that an ideal bioprocess for treatment of hazardous substances should have a proper selection of organisms and adequate SRT. Table 2 lists some bioprocesses applicable to hazardous wastewater treatment.

Table 2
Selected Bioprocesses for Treatment of Hazardous Wastes

1. Aerobic Attached Growth Processes
2. Sequencing Batch Reactors
3. Anaerobic Attached Growth Processes
4. Combined Aerobic, Anoxic and Anaerobic Processes
5. Composting of Hazardous Wastes
6. In situ Bioprocesses

Aerobic Attached-Growth Processes

All attached-growth processes are generally favored for bio-treatment of toxic organic compounds. One argument in favor of attached-growth systems is that since the organisms are not wasted from the systems, "the SRTs are very high." However, one should be very careful about using the concept of SRT in attached-growth systems. SRT is applicable to suspended growth systems only. The kinetics of bioprocesses discussed earlier (Equations 3 through 10) is good for complete-mix, suspended-growth systems only. It is true that organisms are attached to the media (plastic, stones or any innovative substance could be used), but that does not necessarily mean that a very high value of SRT can be substituted in the Model Equation discussed earlier. Such an approach would be misleading. The Models for attached-growth systems are not discussed in this paper, but the information if easily available in the literature.[13]

Examples of aerobic attached-growth processes are trickling filters, rotating biological filters and aerobic fluidized bed reactors. It is well established that fluidized bed systems are more efficient than other fixed-film processes.

Sequencing Batch Reactors

A Sequencing Batch Reactor (SBR) is a self-contained treatment system incorporating equalization, aeration and clarification by using a draw and fill approach. SBRs have been used to treat wastewater from two hazardous waste sites in Buffalo, New York and Chicago, Illinois.[14] The SBR is not necessarily limited to aerobic organisms. This simple but efficient process satisfies the fundamental requirements and also is efficient for sludge handling. More applications of SBRs are expected for hazardous waste treatment, especially small-scale processes.

Anaerobic Attached-Growth Systems

Anaerobic attached-growth processes, such as anaerobic filters, anaerobic fluidized bed reactors and upflow anaerobic sludge blanket (UASB) systems, have the same inherent advantages as those of aerobic attached-growth processes. For applications of anaerobic processes, however, attached growth systems are even more useful because anaerobic organisms have very low Y values compared to those for aerobic organisms. This means that when the same amounts of a waste are independently treated aerobically and anaerobically, the amount of sludge (i.e., new organisms) generated from the aerobic process is generally an order of magnitude higher than that from the anaerobic process. It is important to note that the anaerobic organisms should not be called "slow-growers." Their k values are not low in spite of having low Y values. It is the value of k which determines how fast a waste can be biodegraded.

Combined Bioprocesses

Many Superfund sites have mixtures of organic compounds. Some of these organic compounds such as the aromatics are efficiently degraded by the aerobic organisms. However, compounds such as volatile, chlorinated hydrocarbons are not suitable for aerobic processes. It has been well established that the latter group of compounds are efficiently degraded by methanogens. Researchers have started documenting the list of respective compounds which are efficiently degradable by aerobic, anoxic and anaerobic processes. When this information becomes easily available, combined bioprocesses (involving any combination of aerobic, denitrifications, sulfate reduction and methanogenesis) will become more common.

Hazardous leachates contain a mixture of several organic compounds and heavy metals. A U.S. EPA study showed that anaerobic treatment (using an upflow anaerobic filter with plastic pull rings) followed by conventional activated sludge treatment is a feasible process for treatment of hazardous leachate.[15] More field studies are necessary before this innovative process can be implemented. However, if this process becomes successful, leachates from hazardous waste sites can be anaerobically pretreated in POTWs and can be safely discharged to the existing wastewater treatment systems.

Other anaerobic processes such as anaerobic fluidized bed systems with or without activated carbon could be more efficient and effective for such pretreatment of hazardous leachate. Several U.S. EPA pilot-scale research projects are currently being run to study these innovative processes.[16] It can be safely predicted that many problems in Hazardous Waste Treatment will be solved by innovative combinations of several bioprocesses.

One common question to be asked about combined processes is which process, the aerobic or the anaerobic, should come first. The general answer is the anaerobic process should be followed by the aerobic process for at least two reasons. First, the anaerobic process is generally more suitable for treatment of volatile compounds for both microbiological reasons and because of the fact that these are closed systems which minimize volatilization. Second, aerobic processes are more suitable as polishing systems. Effluents from anaerobic processes contain sulfide which contributes to COD. We should expect to see more anaerobic/aerobic processes than aerobic/anaerobic processes. In some cases, an aerobic/anaerobic/aerobic process could be the best option.

Composting

Even though composting is a rather "old" process, it has been listed in Table 2. Composting has generally been used for stabilizing sewage sludge. Parameters such as pathogen removal and BOD reduction were the focus of many earlier studies. Currently, there is renewed enthusiasm for composting, especially for treatment of explosive wastes. It appears that facultative systems with anaerobic pockets are more common in compost piles than a strict aerobic environment. Oxygen transfer and nutrient transfer problems need to be solved before complete success can be achieved.

In situ Biotreatment

At many Superfund sites, excavation and treatment of contaminated soils would be cost-prohibitive even for biotreatment. An in situ process could be the only solution. Bioprocesses need significant innovation before these processes can compete with successful in situ or physical processes such as In Situ Vitrification (ISV). The latter process is quick and reliable. Improved mass transfer is the key to future success of in situ bioprocesses. Properties of soil such as permeability could be the main issues to address.

CONCLUSION

The basis of evaluation of innovative bioprocesses should be the fulfillment of fundamental requirements of bioprocesses. Practical problems, such as sludge handling, need to be solved. One should not try to ignore the limitations of organisms. Proper selection of organisms is critical. Combined processes apparently are a good solution for Superfund sites with mixtures of various organics. However, combined processes do not necessarily "combine the advantages only." These processes could create new problems and should be evaluated based on pilot-scale data.

More improvements are required for applications of bioprocesses such as in situ remediation of contaminated soils.

Energy Recovery From Waste Explosives and Propellants Through Cofiring

Craig A. Myler
Janet L. Mahannah
U.S. Army Toxic and Hazardous Materials Agency
Aberdeen Proving Ground, Maryland

ABSTRACT

The growing problem of environmentally safe disposal options for waste explosives and propellants along with the knowledge that budget reductions are the rule, not the exception, prompts the development of clean, safe, economical processes for the elimination of these wastes. While there are many potential processes for elimination of these wastes, most do not consider the energy content of the materials. While alone these materials exhibit relatively poor fuel properties, mixtures of explosives with other fuels such as oil provide suitable combustion mixtures. Initial studies of explosives cofiring processes indicate an economic advantage to explosives supplemented fuels. As supplemented fuels can be handled safely, it remains to show that they can be utilized in an environmentally sound manner. A background of the use of explosives as supplemental fuels will be presented as well as current research in the use of explosives and propellants as fuel supplements.

INTRODUCTION

Disposing of waste energetic compounds has become more difficult as a result of the end of interim status for incinerators under the RCRA. Open Burning/Open Detonation (OB/OD) of energetic wastes requires a Subpart X permit. Subpart X operations remain under interim status until Nov. 1992. OB/OD operations are of significant environmental concern and whether or not they will be allowed to continue in their current form is unknown. Means of disposing of energetic wastes have been under intense investigation since 1973. In fact, Brown[1] is convinced that sufficient knowledge has been amassed on disposing of these wastes in his 1976 study on incineration of propellants, explosives and pyrotechnics (PEP) that he felt he need only mention the following options for disposal:

- Ocean Dumping
- Open Burning (OB)
- Open Detonation (OD)
- Disassembly and Recycle
- Controlled Incineration

Brown points out that at the time of his study ocean dumping was banned, recycling was limited and OB/OD were severely restricted. The energy consciousness of the country was just emerging and the focus on hazardous waste was in the future. Even so, Brown recognized the potential for energy recovery as a possibility.

INCINERATION

While more exotic forms of elimination of waste explosives are being developed, incineration under controlled conditions will be the prevalent form of destruction. To safely incinerate a pound of TNT by currently available methods requires mixing bulk explosive in water, often with a size reduction step, followed by incineration using propane or fuel oil to vaporize the water and allow controlled combustion of the explosive. The water slurry typically consists of approximately 1 part energetic to 3 parts water. The bulk of the energy supplied externally is used to vaporize the water in the energetic slurry. Subsequently, incineration of the explosives is costly, as energy must be supplied to the system while no product is produced.

SUPPLEMENTAL FUELS ECONOMICS

Rather than destroying the explosives by incineration, some means of utilizing them for the energy they contain was sought. In 1985, Lackey[2] described scenarios whereby energetic compounds might be economically used to generate steam and/or electricity in industrial combustors. To better define the costs of using energetic compounds in this manner, he compared the costs associated with cofiring explosives in fuel oil in a boiler to other waste energetic management options including incineration and continued storage. Lackey's findings provided a rough indication of the economic competitiveness of cofiring.

An alternative approach to determining the economics of energetics-supplemented fuels is to compare them to the current manner in which they would be used, namely industrial boilers. The economic analysis can be broken down into three areas; raw materials, capital costs and labor costs.

Fuel Costs

The raw materials for the production of steam in industrial boilers are fuel and water. In the current case of supplemental fuels, the water requirements are assumed to be equal to those using nonsupplemented fuels. There are additional electrical costs for pumping and controls, but these also will be assumed to be roughly equal for this analysis. The baseline for comparison will be a 20 MM Btu/hr (5.86 MW) industrial boiler operating 6570 hours/year fired with #2 fuel oil. The boiler is assumed to be 80% efficient for both the nonsupplemented fuel and the supplemented fuel cases. Table 1 lists the physical properties and costs used in subsequent analyses. The base line fuel cost is $856,812/year from the following calculation:

2×10^7 Btu/hr x 6570 hr/yr x 1 lb #2 fuel/18,947 Btu x 1 gal #2 fuel/7.31 lb #2 fuel x $0.7225/gal #2 fuel x 1/0.8 (efficiency factor) = 856,812 $/year

A fuel oil supplemented with TNT will be compared to the baseline. Consider a fuel comprised of 55% #2 Fuel Oil, 15% TNT and 30% toluene. The cost of one pound of this fuel is $0.09311 from the following calculation:

(0.55 x $0.7225/gal #2 fuel x 1 gal/7.31 lb #2 fuel)

+ (0.30 x $0.93/gal toluene x 1 gal/7.2 lb toluene) =
0.09311 $/lb supplemented fuel

The heating value of the supplemented fuel is also necessary and is found to be 16,880 Btu/lb according to the following:

| #2 Fuel Oil | toluene | TNT |

$[(0.55 \times 18,947) + (0.30 \times 18,302) + (0.15 \times 6,454)]$ Btu/lb = 16,880 Btu/lb of supplemented fuel

The estimate above assumes heats of solution to be negligible. With these estimates, the yearly fuel cost for operating the same boiler as in the baseline case can be determined. The following calculation yields a yearly cost of $906,002/year.

2×10^7 Btu/hr x 6570 hr/yr x 1 lb supplemented fuel/16 880 Btu x $0.09311/lb supplemented fuel x 1/0.8 (efficiency factor) = 906,002 $/yr

The net cost of operating the baseline boiler using the explosive supplemented fuel is:

(906,002   856,812) $/yr = 49,190 $/yr

This figure is based on current (Mar. 1990) fuel and toluene prices. Figure 1 describes the particular sensitivity to fuel oil costs at constant toluene cost. The break-even point for fuel cost occurs at a cost for #2 fuel oil of $ 0.83/gallon at constant toluene cost of $0.93/gallon. Should fuel prices rise above this point, there would be a net profit for burning the supplemented fuel (not counting capital and labor costs).

Table 1

Density	7	15.08 lb/gal	1.806 gm/cm3
Cost			

Capital Cost

Capital cost estimates will be based on the assumption that the existing boiler will be used with the supplemented fuels without retrofit. This yields a zero cost for the baseline case. The feed system is the only capital equipment required to burn the supplemented fuel. A daily volume of supplemented fuel required for operating the baseline boiler is 3500 gallons. A feed tank of 5000 gallons could be specified for operations. Other equipments and estimated costs are given in Table 2. If the final capital cost is considered over a 20 year period at 0% interest, the yearly capital cost expenditure is $57,687.

Labor Cost Estimate

Finally, a labor cost estimate is required. It is assumed that a two-man operation is sufficient to prepare the supplemental fuel. A supervisor is included at one quarter of the work time. Table 3 details the labor cost estimate.
Figure 1
Yearly Fuel Cost Required to Operate a
20 MM Btu/he Industrial Boiler (80% Efficiency)

Table 2
Capital Cost Estimate for 5000
Gallon Feed System

Major Equipment Costs

ITEM	CAPACITY	COST ($)
Feed Tank	5000 gal, SS	64,200
Mix Tank	2250 gal, SS	47,900
Toluene Storage Tank	7500 gal, CS	22,800
Acetone Storage Tank	7500 gal, CS	22,800
Agitators (4)	15 hp, SS	16,400
Pumps (5)	15 gpm, SS	13,500
	TOTAL	187,600

Langs factor for solid-fluid processing plant fixed capital is 4.18

Capital Cost Estimate = $187,600 x 4.1 = $ 769,160

A factor of 1.5 is applied to the capital cost as an estimate to account for explosives requirements not included in equipment estimates

Final Capital Cost Estimate = 1.5 x $ 769,160 = $ 1,153,740

Table 3
Labor Cost Estimate

2 operators (@ $25,000/year)		$50,000
1 Supervisor (@ $40,000/year) x 0.25		$10,000
	Subtotal	$60,000
Overhead	(@75 % labor rate)	$45,000
	Labor Total	$105,000/year

Overall Cost Comparison

The total cost to operate the supplemental fuel fired boiler is then the sum of the fuel cost differential, the capital cost and the labor cost. The total is $211,877/year. The amount of TNT consumed is 1,167,792 pounds/year which results in a total cost for TNT destruction of $0.1814/pound or $363/ton. This analysis was performed on a basis of a 20 MM Btu/hr boiler to provide a realistic implementation scenario. The 20 MM Btu/hr boiler is a median size expected to be available for use at all military industrial locations. A similar calculation for Composition B (nominal 60% TNT, 40% RDX) supplemented fuel results in a per ton cost of $376. Comparison to currently available treatment methods can be made using the above per ton costs. If incineration capital and labor costs are assumed equal (an extremely conservative

assumption), the cost to destroy a ton of TNT would be a minimum of $609 using water per TNT slurry fed to a rotary kiln. The current cost of OB/OD operations is approximately $260/ton of explosive.[9] The above costs would indicate a median cost for elimination of TNT using supplemented fuels. While the costs of incinerating or open burning/open detonating of energetics are expected to rise, the cost associated with utilizing them as fuel supplements may actually decrease. As the price of #2 fuel oil increases, the value of the supplemented fuel increases. Figure 2 shows the resultant total costs associated with burning a TNT-supplemented fuel at varying toluene concentrations with change in fuel oil cost. Note that a 10% toluene, 75% #2 fuel oil, 15% TNT fuel mixture would result in a TNT destruction cost TNT less than current OB/OD costs.

EXPERIMENTAL PROGRAM

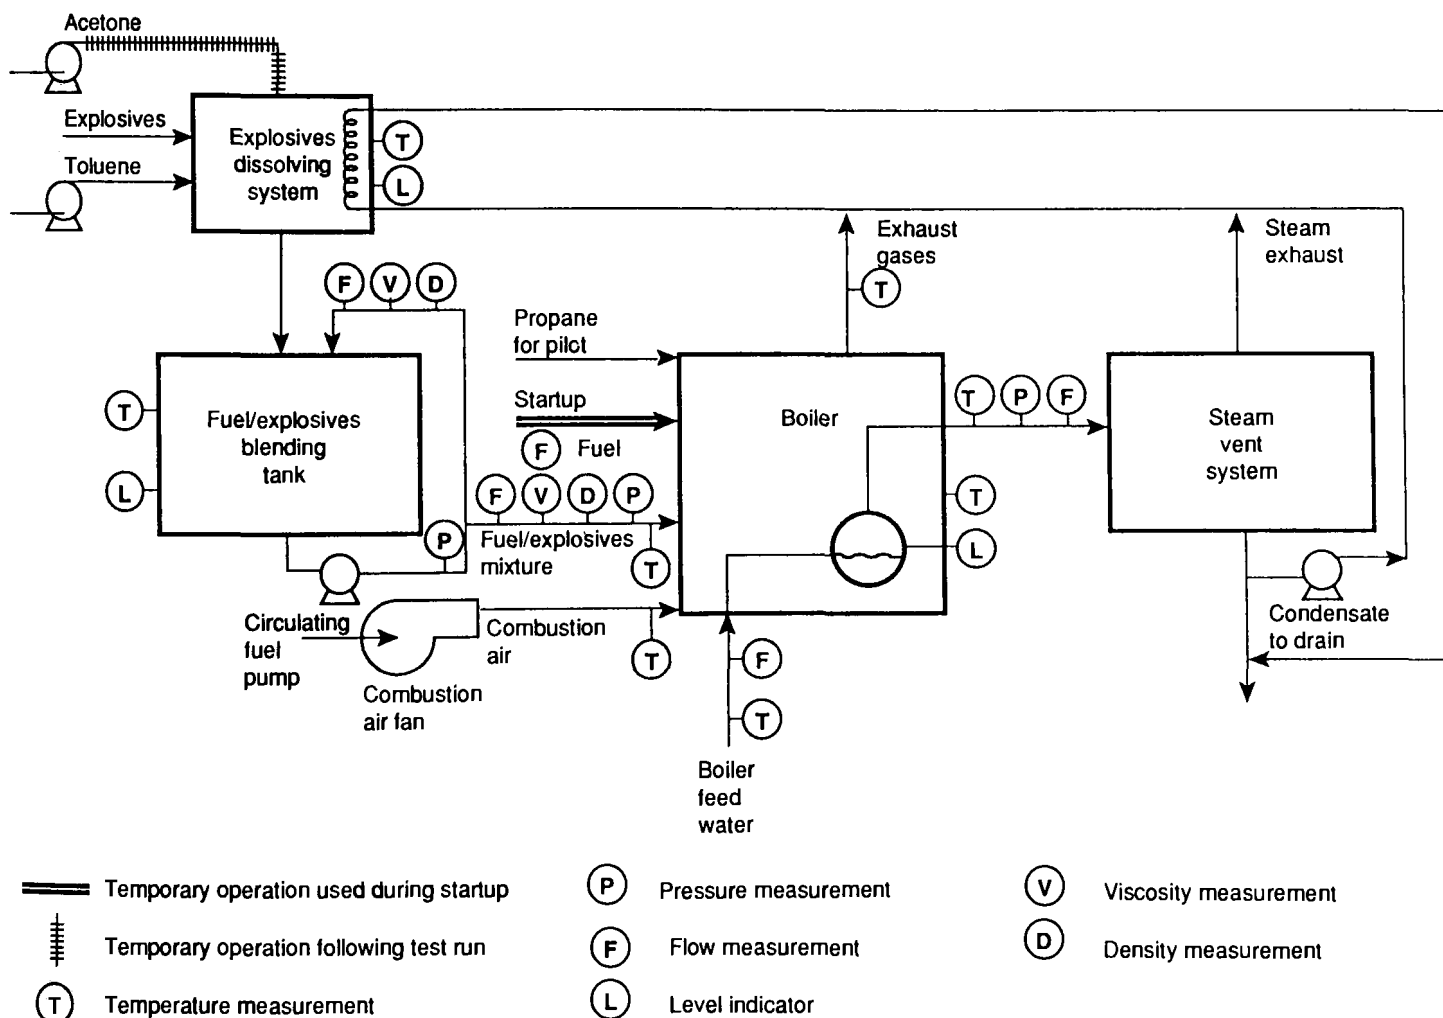
The economic estimates presented above are encouraging but need further refinement. A well designed test program is currently underway to verify assumptions and to provide design data for implementation. Previous study of the stability, handling and safety aspects of explosives-supplemented fuel mixtures has been conducted with promising results.[10] It was demonstrated that these mixtures are stable and can be handled without detonation propagation. More recently, similar studies have been conducted with nitrocellulose.[11] While these mixtures are stable and can be safely handled, the mixtures themselves become gelatinous in three-phase mixture. Further study will have to be performed to utilize propellant mixes.
Figure 2
Cost Per Ton of TNT Destroyed in a
20 MM Btu/hr with Change in Fuel Oil Cost
Cat Varying Toluene Concentration


Figure 3
Schematic of Pilot-Scale
Supplemental Fuel System[13]

A proof of principle test program conducted in 1987 determined that it was "clearly feasible to cofire explosives and fuel oil."[12] The proof of principle testing also identified operational requirements for cofiring explosives which must be considered.

Current Program Synopsis

With the background testing completed, a pilot program was initiated in 1989. The objective of the pilot program is to conduct an evaluation of the use of explosives as fuel oil supplements in army industrial boilers. Equipment currently is being developed for this test program. Upon acceptance by the Department of Defense Explosives Safety Board (DDESB), TNT and Composition B will be used to supplement fuel fed to a 1.7 MM Btu/hr commercial boiler. The feed system will allow blending, heating and feeding of the fuel mixtures under complete automatic control. Automatic data acquisition will allow material and energy balances to be performed. A schematic of the pilot system is shown in Figure 3.

While the economics appear feasible, two items related to cofiring supplemented fuels appear critical. First, the resultant destruction and removal efficiency (DRE) from normal boiler operations should be above 99.99% for the explosives. Secondly, how much of NOx is formed is a key concern. Data on these operational peramaters will be obtained during extensive stack testing.

CONCLUSIONS

The concept of economically utilizing the energy content of energetic materials is being developed with the expectation of safely burning energetics mixed with fuel oil. Solvents will be used to put the explosives TNT and RDX into solution. This approach does not seem feasible for propellants at this time, but it may be possible to economically burn pure propellant slurries. Comparisons of this technology with incineration and OB/OD were made. Supplemented fuels depend on costs of the raw materials being used and may compete economically with open burning/open detonation. A testing program is currently underway to obtain the necessary data to implement this technology.

Incineration of Contaminated Soil at a Superfund Site: From Pilot Test to Remediation

Kathy K. DiAntonio, Sr. Engr.
David A. Tillman, Ph.D.
Ebasco Environmental
Lyndhurst, New Jersey
Bellevue, Washington

ABSTRACT

Soil contaminants at the Bog Creek Farm Superfund site include a wide range of volatile and semivolatile organics and heavy metals. The site is currently being remediated by on-site incineration. The purpose of this paper is to discuss the results of activities leading up to this remedial action; namely, incineration pilot tests, remedial design, preparation of bid specifications and selection of the on-site incineration system.

INTRODUCTION

The Bog Creek Farm CERCLA site is located on a 12-acre tract in a rural section of Howell Township, New Jersey. It is alleged that in 1973 and 1974, paint manufacturing wastes in the form of bulk liquids and sludges, disinfectants and trash were disposed of on-site, on the ground and in trenches, by the site owners. During the period from 1983 to 1985, NUS Corporation performed an RI/FS for the site which resulted in an ROD, issued by the U.S. EPA in 1985. The ROD called for a first operable unit which would require that waste deposits, pond and bog sediment and highly contaminated soil be incinerated either on-site in a temporary unit or off-site in a RCRA facility. The ROD then called for a further study of the residual soil and groundwater contamination to determine the need for further remedy.

During 1987, Ebasco Environmental performed a supplemental RI to support the Remedial Design (RD) of the first operable unit and the second-phase FS. The RD involved characterizing the waste, soil and sediment to be incinerated, determining the volume of material to be incinerated, performing incineration testing and, finally, preparing technical bid specifications for the site cleanup to be issued by the US Army Corps of Engineers (USACOE).

CONTAMINATION AT THE BOG CREEK FARM SITE

The Bog Creek Farm Site is contaminated by a wide range of volatile and semivolatile organics and heavy metals as shown in Table 1. Soil contamination levels reported in the NUS RI ranged from 180,000 ppm for toluene, 26,000 ppm for methylene chloride, 14,000 ppm for xylenes, 8,900 ppm for benzene and 19,000 ppm for lead. Based on these results, the ROD required that all waste deposits and soil with greater than 10,000 ppm of total volatile organics (TVO) be excavated for incineration.

Ebasco Environmental's 1987 supplemental RI indicated lesser levels of organics in the waste deposits and soils and higher levels of contamination in the sediment than the previous RI. Based on these results, approximately 15,000 yd³ of soil and sediment should be excavated for incineration which would result in residual soil contamination orders of magnitude lower than 10,000 ppm TVO required by the ROD.

Ebasco Environmental's RI also included performing ultimate and proximate analyses of the waste, soil and sediment as shown in Table 2, in order to characterize these materials for incineration. Treatability tests were then designed and performed in order to provide information on the residual or ash characteristics and to support a conceptual incineration design.

remediation. Consequently, several key technical issues were addressed in this study including the following:

- What are the time and temperature requirements in the kiln for removal of organics from the contaminated materials?
- What is the effect of different materials from the site on the time at temperature requirements of the kiln?
- What are the characteristics of the organics being removed from the materials? This issue facilitates the design of afterburner equipment.
- What is the fate of toxic metals in the site material when the materials are thermally treated? Of specific interest are the tradeoffs between removal of organics from the solid and the vaporization of volatile metals such as As, Cd, Hg and Pb which form a fine fume that is difficult to capture in particulate control devices.
- How much acid gas is produced when the materials are thermally cleaned? Again, the answer to this question will dictate what type (if any) of acid removal system will be required for the flue gas.

TREATABILITY TESTS

The testing was accomplished in a unique incinerability test facility shown in Figure 1. This facility can be used to define the time at temperature requirements necessary to decontaminate solids under realistic incinerator conditions. Specifically, the facility simulates the conditions that exist within full-scale rotary kilns including the contacting of gases and solids, the mixing of the solid beds, the time at temperatures and the gas phase conditions.

TEST FACILITY

The experimental test facility consists of a horizontal rotating refractory lined cylinder coupled with a stationary, vertical-controlled temperature tower furnace. The rotating section is designed to simulate a rotary kiln environment, while the vertical section can be used to simulate an afterburner. In this test, the afterburner was not used, but was maintained in a "hot" condition, in order to maximize the information obtained regarding kiln behavior. The kiln zone is batch fed with the test sample, and the sample is thermally treated for a specific solids residence time in the rotating high temperature environment. The time the batch spends in the simulator is translateable to the time an individual charge would remain in the kiln of a full-scale system. In the simulator, the solid temperature is monitored directly via thermocouples that extend into the bed as the rotation of the kiln brings them in contact with the test batch and indirectly via the thermocouples in the walls of the test zone. Solids can be removed after thermal treatment for specified times and temperatures and subsequently analyzed for ultimate analysis, metals, leachability of metals and hydrocarbons.
Figure 1
Rotary Kiln Test Facility

At the same time, the gaseous emissions from the kiln are monitored as the waste is thermally decomposed. The emissions of CO, O_2, CO_2, NO and total hydrocarbons are measured continuously. Low concentration volatile and semivolatile hydrocarbons are measured using Tenax and XAD traps exposed over the entire test period; standard U.S. EPA procedures are employed. Particulate samples are measured in the incinerator exhaust gas and analyzed for toxic metals. Finally, the total emissions of HCl are measured during the run by passing the incinerator effluent through a liquid scrubbing train followed by titration using ASTM procedures.

The test conditions used in this study are summarized in Table 3. The conditions were selected to allow a definition of the impacts of time and temperature, residence time and sample type. The times and temperatures were selected based upon the conditions expected to exist in full-scale equipment.

TREATABILITY TEST RESULTS

Influence of Kiln Temperature

The time at temperature required to remove organics from the waste sample was first evaluated using the ultimate analysis of samples treated in a kiln. Results of the carbon analysis as a function of time at different temperatures are provided in Figure 2. The initial sample carbon concentration (at time zero) was highly variable due to the heterogeneous nature and moisture content of the material, varying from 1.2 to 28.27. Temperature had a pronounced effect on the rate of carbon evolution. At the highest kiln temperature (1,800°F), the carbon was almost completely removed in the first 15 minutes of treatment. More than 30 minutes, however, were required to remove the carbon at a kiln temperature of 1,000°F. At any temperature, the carbon concentration could be reduced to less than 1% of the original value in less than 1 hour of thermal treatment.

Figure 2
Influence of Time and Temperature on Carbon Content
of Residuals from Heat Treatment of Waste Samples

The continuous emission monitors also demonstrated the impact of temperature on the thermal destruction processes. Figures 3 and 4 illustrate the behavior of gas phase CO, CO_2 and O_2 as a function of time after the kiln was charged for two different operating temperatures. At high temperatures, the evolution of carbon is apparently fast enough to consume all available oxygen in the first 4 minutes after charging. There is a pronounced peak of CO in this initial period. After 5 minutes, the rapid reaction has ceased and emissions return to normal. For the low temperature run (1,000°F), the level of O_2 in the exhaust gas, is

depressed, indicating consumption of the organic carbon over a 20-minute period. This impact of temperature points out a key issue with rotary kiln incinerators. Rapid thermal decomposition of the waste can result in a "puff," and consumption of local oxygen. In practice, this phenomenon is seen as an excursion in CO in the flue gas just after a charge of material is put into the kiln. These results suggest that moderate kiln temperatures may be desirable for the Bog Creek Farm incinerator.

The Fate of Organic Compounds

The volatile and semivolatile trace organics measured in the solid before and after thermal treatment for one hour and at different temperatures are shown in Figures 5 and 6. The open bars in the diagrams represent the samples before treatment. After thermal treatment for 60 minutes, all organics were removed from the samples to below the detection limit of approximately 600 ppb as shown as black bars. This removal occurred even at temperatures as low as 1,000°F.

or partial reactions of the compound present in the waste sample. These species, sometimes referred to as products of incomplete combustion (PICs), are generally polyaromatic hydrocarbons such as pyrene, phenanthrene and chrysene. Thus, the afterburner design must be chosen to destroy these types of organic species as will be discussed in the next section.

The Fate of Heavy Metals

In this study the fate of the metals was determined by analysis of the test samples, analysis of the solid residuals and analysis of a total particulate catch for toxic metals. The feed and residual concentration of the metals in the bottom ash of interest are provided in Table 4.

As expected, the metals content of the ash was generally lower than the feed concentrations with higher kiln temperatures promoting greater

temperature are shown in Figures 7 and 8. As seen from these figures, most of the organics were destroyed in the kiln zone. However, several organic species were apparently produced in the kiln zone via cracking

removal of certain metals than lower term parameters. The metal enrichment in the particulates relative to the untreated waste stream is shown in Figure 9 for two different temperatures. At low temperatures, enrichment was slight and was within the bounds of the variability of metals in the waste stream. At high temperature (1,800 °F), the particulates were highly enriched in most metals except chromium. Arsenic, cadmium and lead were more concentrated in the fly ash particles. At the intermediate temperature (1,460 ° F), arsenic and cadmium were still highly enriched in the fly ash. Lead enrichment was less pronounced. Antimony, copper and zinc were no longer enriched relative to the untreated waste sample.

Metals Content of the Feed and Residuals
for Selected Samples

Metal (ppm)	FEED (WASTE)		ASH	
	1800°F	1460°F	1800°F	1460°F
Antimony	6.7	180	1.2	11.0
Arsenic	1.56	2.33	0.287	0.302
Beryllium	0.17	<0.139	<0.098	<0.097
Cadmium	11.7	20.7	0.142	0.896
Chromium	135	942	12.9	107
Copper	18.4	209	6.36	36.5
Lead	683	3800	234	2160
Mercury	0.995	3.70	<0.047	<0.048
Nickel	5.98	9.47	<1.96	4.36
Selenium	<0.219	0.822	<0.196	<0.194
Zinc	86.8	263	31.6	59.6

Ash leaching results as a function of temperature are summarized in Figure 10. As shown, the results are generally favorable although for two samples, lead and cadmium exceeded the EP Tox standards (5 mg/L and 1 μg/L, respectively) at lower temperatures.

In summary, the kiln temperature performs two important roles in the thermal cleaning of the waste material from the Bog Creek site. In order to remove all organic carbon and hydrogen, longer times will be required at lower temperature; however, after 30 minutes even at low temperatures (1,000 °F), all organic material will be removed from the treated waste. For target hazardous organics originally in the waste, removal was complete even for low temperatures and short times. Metal vaporization and enrichment of toxic metals in fly ash was found to be a problem at higher operating temperatures, particularly for arsenic, cadmium, lead and antimony.

Influence of Material Type

In this study, four different materials wastes were tested for their thermal treatability behavior. These waste samples were taken from different locations on the Bog Creek site and were designated as waste (Sample No. 1), waste (Sample No. 2), soil and bog sediment.

The very different nature of the material and their behavior upon heat treatment are shown in Figure 11. Upon heat treatment of 1,460 °F, the waste samples and soil lose carbon very rapidly. In the first 5 minutes the carbon content for these materials was reduced to less than 1%. At 30 minutes the carbon level is below 0.1%. However, the bog sediment carbon content apparently increased (as-received basis) over the first 15 minutes of heat treatment as a function of drying and subsequently fell. The lowest level of carbon content achieved for the sediment after 60 minutes was 0.6%.

The delay in the release of organic matter from the sediment is attributable to the high moisture content of this material. The high water content of the sediment suppresses the material temperature in the bed until the moisture evaporates. For these conditions, the evaporation time can be substantial (approximately 30 minutes). Over this time period
Figure 9
Metals Enrichment Relative to Waste Composition of Particulate Catch from Kiln Off-gas After Thermal Treatment at Different Temperature

there is little carbon evolution; consequently, the as-received carbon content increases due to the loss of moisture. Thus, for the high moisture material from the bog sediment, there are two apparent time scales: drying time and devolatilization time.

CONVERSION OF TREATABILITY TESTS INTO A CONCEPTUAL DESIGN

The treatability test results demonstrated that:

- Primary reactor temperatures of 1,400 °F and 2,200 °F (bed temperatures of 1,000 °F to 1,800 °F) with residence times of 30 to 40 minutes are adequate for devolatilization of Bog Creek Farm materials
- Moderate primary reactor temperatures will minimize the potential

Time in the Rotary Kiln Simulator for Different Materials
(T = 1460°, 10 lb Charges)

for "puffs," and consequent overloading of the afterburner

• Afterburner temperatures in excess of 1,650°F are adequate for final destruction of contaminants

On this basis, the conceptual design was developed by Ebasco Environmental as nonbinding guidance for bidders and as a basis for cost

estimation. Critical elements in the conceptual design included selection of the basic system, selection of the incineration regime, development of process flowsheets and heat and material balances, determination of post-combustion air quality and solid residue treatment systems and then the development of equipment lists.

THE BASIC INCINERATION SYSTEM

The conceptual design focused upon a transportable rotary kiln based thermal destruction unit. The basic elements of this system included the kiln, secondary combustion chamber or afterburner, quench tower, air quality control system and ash quench system. The kiln installation for this site does not require its own wastewater treatment system due to the presence of a larger wastewater system for remediation of other site groundwater. A rotary kiln was chosen as the basis for thermal destruction unit conceptual design, while recognizing that vendors of all incinerator types could bid to performance specifications.

PROCESS FLOW DIAGRAMS AND HEAT BALANCES

Once the basic incineration process was selected, process flow diagrams were developed highlighting the thermal destruction unit itself, the air quality control system and the interfaces between the incinerator and the other site remediation activities. The development of a process flowsheet led to the calculation of heat and material balances around the thermal destruction unit and about the air quality control system. The heat and material balance about the incinerator was based upon the following assumptions:

• No. 2 distillate oil would be used as fuel for the incinerator
• Air atomization would be used rather than steam atomization
• Soil and sediments would be fed separately
• Unit capacity would be 5 tons/hour

The heat balance was used to assist in determining an appropriate incineration regime. As shown previously, the treatability tests demonstrated that any bed temperature greater than 1,000°F will volatilize the organics in the Bog Creek Farm materials. Consequently, kiln and afterburner heat balances were constructed for bed temperatures ranging from 1,000°F to 1,600°F and with afterburner temperatures ranging from 1,600°F to 2,000°F. Finally, the calculations were based upon 50% excess air for combustion in the kiln and 25% excess air for combustion in the secondary combustion chamber.

The results of preliminary heat balance calculations showed that the optimum fuel consumption (Btu/ton) occurs with a kiln bed temperature of 1,200° F, a kiln gas temperature of 1,600°F and an afterburner temperature of 1,800° F. Since the treatability studies demonstrated that such temperatures are adequate for thermal treatment of the Bog Creek Farm soils and sediments with significant "insurance" margin, they were chosen for the conceptual design. The final heat balances for the conceptual design are shown in Figures 12 and 13. Post-combustion controls for the facility were selected based upon the mobile nature of the installation, the low concentration of acid gases expected in the

products of combustion and the behavior of metals as shown in the treatability studies and discussed previously. This system is shown in Figure 14.

The system, as configured for advisory purposes, is a relatively simple process. Based upon the test burn/treatability studies, this incinerator should achieve the objectives of the site remediation program. Further, it should be readily integrated into the overall site remediation effort.

TECHNICAL BID SPECIFICATIONS

Ebasco Environmental's RD effort resulted in a complete bid document which was issued by the USACOE in early 1988. The entire remediation program requires that incineration be integrated with numerous other on-site activities. The technical bid specifications therefore covered not only incineration, but also all aspects of the site remediation including soil and sediment excavation, dewatering, dewatered groundwater treatment, site restoration, health and safety and quality assurance.

A complete list of the standard sections of the bid specification package prepared by Ebasco Environmental according to USACOE format is shown in Table 5. Section 13180—Incineration contained performance-type specifications for either on-site or off-site incineration. The treatability test results and conceptual design report were appended to the specification package for informational purposes only.

Performance requirements and bid information for both the on-site and off-site incineration options were provided in the following categories:

• General requirements

• Applicable regulations
• Construction submittals which included a system backup report and emergency response manual
• Waste, soil and sediment characteristics
• Equipment requirements specifics for the waste feed, ash handling and air quality control subsystems
• Process development and demonstrated performance
• Erection/installation for on-site incineration
• Disposal/treatment of residuals
• Incineration performance requirements
• Procedures to verify performance
• System rectification
• System operation and maintenance

Of particular interest is the issue of disposal/treatment of residuals, particularly the on-site treated soil/sediment or ash. Since the treatability tests indicated that the ash could possibly be suitable as backfill without further treatment, such as stabilization, the specifications cited on-site backfilling as the preferred disposal method for on-site incineration but did not require ash treatment prior to backfilling on-site. Rather, Ash Acceptance Criteria, shown in Table 6, were developed to set acceptable ash contaminant levels, and the TCLP limits were cited as the compliance levels that must be demonstrated prior to backfill.

The specifications also provided considerations relating to on-site trial burning after installation in order to verify performance, including selection of POHCs based on the site contamination; specifically, benzene and tetrachloroethylene were suggested as the volatile POHCs and di-n-butyl phthalate was included as the semivolatile POHC. Also,

suggestions were made with regard to spiking the feed with a surrogate, such as carbon tetrachloride or hexachlorobenzene, to demonstrate DRE (Destruction and Removal efficiency).

ON-SITE INCINERATION

As a result of the bidding process, a remediation contractor was selected by the USACOE and construction was initiated in 1989. An on-site, temporary incinerator was installed and successfully operated. Remediation of the on-site waste, soil and sediment was essentially completed at the time of the writing of this paper (in August of 1990).

A schematic diagram of the on-site incineration system is shown in Figure 15, and some operating parameters are given in Table 7. The selected incinerator was a rotary kiln system which included a cyclone prior to the afterburner to remove solids from the off-gas, a quench tower, baghouse and acid gas scrubber and a wet ash quench system. This system was modified during construction to include oxygen enrichment in order to meet the New Jersey particulate emission requirement of 0.03 gr/dscf (N.J.A.C. 7:26-10.7).

During operation, ash was stockpiled until test results confirmed acceptability for backfilling. At the time of writing this paper, all the tested ash had passed the acceptance criteria although some data were still outstanding. Treated groundwater obtained from the dewatering operation during soil and sediment operation, was used for off-gas and ash quenching and scrubber water was recycled back to the groundwater treatment system. This process eliminated the need for any treated effluent discharge. Approximately 15,500 yd^3 of waste/soil and sediment were incinerated in approximately 3 months of operation.

CONCLUSION

Ebasco Environmental's remedial design effort, which culminated in the on-site incineration of contaminated soil and sediment at the Bog Creek Farm site, included thermal characterization, treatability testing and conceptual design. These activities were proven useful in the subsequent preparation of bid specifications as well as providing site-specific information to potential remediation system selection and on-site operation.

Remediation of Gasoline-Contaminated Groundwater:
Spray Aeration/Internal Combustion Oxidation

Mark L. Rippberger
Harding Lawson Associates
Newbury Park, California

ABSTRACT

The use of a heated vacuum chamber for spray aeration enhances the rate of evaporation of gasoline from contaminated groundwater. The gasoline vapors are thermally oxidized by feeding them to the intake of an internal combustion engine, where they are burned as part of the combustion process.

A vacuum will increase the rate at which the gasoline evaporates, as does the addition of heat. Separating gasoline from the groundwater is the first obstacle; the gasoline vapors in the air stream must also be treated before release to the atmosphere. Both problems can be solved by thermal oxidation. The vapors in the air stream are below the flammability level, thus it is not possible merely to burn them. However, by feeding the vapors to an internal combustion engine which is powering the system pump and creating the vacuum, the vapors are consumed as part of the combustion process. The emission exhaust levels of the engine are unchanged because the vapors become part of the fuel. Thus, this system efficiently treats the effluent stream from the spray aeration unit.

This system is a fully self-contained remediation system that uses thermal vacuum spray aeration and compressive thermal oxidation. It costs considerably less than conventional systems of air strippers with carbon absorption or catalytic thermal oxidation.

INTRODUCTION

Gasoline-contaminated soil and groundwater have become major concerns in recent years as more and more leaking underground storage tanks have been discovered. Currently, two methods are typically used to remediate groundwater before it is discharged to a reinfiltration gallery, sewers or storm drains: carbon filtration and air stripping. Carbon filtration is not desirable on highly contaminated sites, as the costs of carbon and its associated handling and disposal become prohibitive. With air stripping, if direct venting is allowed, the cost to replace fouled packing is the only major maintenance expense. However, in areas where emissions are controlled and risk assessments based on benzene concentrations are the governing factor, as is the case in the metropolitan areas of California, vapor phase carbon treatment for air polishing after air stripping is required. On highly contaminated sites, carbon costs again become prohibitive.

A logical alternative for eliminating gasoline vapors is to burn them. On most sites the level of hydrocarbons present in the vapor stream is insufficient for combustion to be maintained by these vapors alone. Either additional fuel must be added to sustain combustion, or a catalyst must be used to maintain combustion. A system has been developed to utilize the energy of the heat of combustion of the vapors and supplemental fuel. Part of the heat is converted to work to operate the pumps of the system while the remaining heat is utilized to enhance the separa-tion of hydrocarbons from the water.

This system combines a thermal oxidation unit with a unique spray aeration unit. Although the aeration unit operates on the same principle as an air stripper, it has no packing, thereby eliminating efficiency problems due to fouled packing. The spray aeration system sprays heated water in a vacuum chamber. The engine develops a vacuum on the spray aeration tank and also provides a vacuum on the well(s) for vapor extraction.

PRINCIPLES OF OPERATION

The entire system is self-contained and needs no additional power source. The engine furnishes all power to drive the other components. The technologies behind this system are spray aeration enhanced by heat and vacuum and internal combustion of hydrocarbons in an engine. Both of these are well proven concepts. Spray aeration has been proven effective on both large and small scales to separate dissolved hydrocarbons and water. The technology for controlling internal combustion engine emissions has been effectively demonstrated by the automotive industry.

This remediation system combines three separate methods of remediation and is more efficient than any of the methods alone:

- Vapor extraction from soil
- Spray aeration
- Thermal oxidation using an engine for combusting hydrocarbon-laden vapors and a catalytic converter to control the exhaust

The soil vapor extraction system uses a vacuum pump driven by the internal combustion engine; alternatively, the vacuum may be developed by the engine itself. The vacuum on the well causes the hydrocarbons to volatilize and flow with the air into the well and up to the vacuum pump.

Water contamination is remediated using a spray aerator. In this system, water-hydrocarbon separation is enhanced by both vacuum and heat; by lowering pressure, the temperature at which the hydrocarbons vaporize decreases; increasing the temperature further increases the potential for the hydrocarbons to vaporize. The spray aerator takes advantage of both these principles by spraying heated water in a vacuum (Fig. 1).

Spray aeration works on the same principle as an air stripper. In an air stripper, air is moved quickly over the surface of the hydrocarbon-laden water to volatilize the hydrocarbons. In spray aeration, hydrocarbon-laden water droplets move quickly through the air causing the hydrocarbons to volatilize; however, in the spray aerator, there is no packing to foul or replace. In the spray aerator, heated water is sprayed in a vacuum. Lowering the pressure in the spray tank increases the rate of evaporation of the hydrocarbons. Heat has the same effect. By adding

heat and lowering the pressure, the hydrocarbons are boiled or flash-evaporated off the water droplet surface. A vacuum of 12 inches of mercury is developed on the tank and the water is heated with waste heat from the engine's cooling system. There are limits to the level of vacuum on the tank and the quantity of heat added to the water which must be maintained to avoid evaporating a large quantity of water along with hydrocarbons. As an example, at 110°F and 27 inches of mercury, all the water would evaporate and be passed to the engine. To ensure sufficient hydrocarbon removal, the water is recirculated through a second set of spray nozzles (Fig. 2).

vapors. In the prototype test, water mixed with 1,700 ppm of hydrocarbons was fed to the spray aeration unit at approximately 3 gpm. Vacuum on the tank was maintained at 12 in. of mercury and the recirculating water was heated to 100°F. The vapor flow rate was 40 cfm. The discharge had an average total petroleum hydrocarbon (TPH) concentration of 32 ppm, the cleanup efficiency was 98%. These results are 18% higher than spray aeration without vacuum or heat.

Figure 1
Spray Aerator
Figure 2
Remediation System

The vapors drawn by the vacuum are directed to the intake of the engine where they are mixed with the primary fuel and then combusted in the engine, thus consuming the total hydrocarbon mixture. The engine's air:fuel ratio is adjusted to maintain efficient combustion when the vapor from the wells and the spray aerator are combined with supplemental air or fuel, thus resulting in minimum emissions from the engine. The exhaust from the engine is passed through a small automotive catalytic converter to ensure complete combustion (Fig. 3).

Because the entire system is under vacuum until the vapors enter the cylinders of the engine for combustion, any possible leaks of seals or connections are into the system, with no loss of hydrocarbons to the atmosphere. If there is no combustion, the engine stops running. The engine is the power source for all other equipment; all systems stop when the engine stops, thus preventing uncontrolled releases of hydrocarbons to the atmosphere. The well pumps are pneumatically powered from an air compressor driven by the engine; therefore, well pumping also ceases if the engine shuts off. In addition, the engine has shutoff devices triggered by loss of vacuum, low oil pressure or engine overheat.

TEST RESULTS

Currently there are more than 25 units permitted and operating on the west coast.

Initial tests were conducted on the prototype spray aeration system and the engine to determine the basic efficiency of the equipment in remediating gasoline-contaminated water and thermally oxidizing the

Figure 3
I/C Engine and Catalytic Converter

The engine exhaust was analyzed for hydrocarbons using a continuous infrared meter and by taking samples and analyzing them in a gas chromatograph. These tests showed the emitted hydrocarbons to be, on the average, below 70 ppm in the exhaust stream. At this level, less than 1 lb/day of hydrocarbons is emitted from the exhaust while more than 125 lb of hydrocarbons are consumed by the engine during the same time period. The benzene concentration in the exhaust stream

was near 1 ppm. By adjusting the air-fuel ratio, the benzene level was lowered to less than 0.1 ppm, resulting in emissions of less than 0.003 lb/day of benzene. This level is low enough to pass risk assessment criteria in the Los Angeles area. Current sites have hydrocarbon vapors as high as 140,000 ppm going into the engine with only 15 ppm TPH being measured in the exhaust steam and benzene at less than 1 ppm.

The following are the results from a typical site. The system was connected to three wells. Free product was present in two of the wells; the third well had no free product. A vacuum was placed on the first well and the air:fuel ratio was adjusted.

This first well produced enough vapors to run the engine with no additional fuel; moreover the flowrate from the well had to be restricted to avoid running in an over-rich state of combustion. The well, which had been bailed of free product before the system was started, had 1 foot of free product in it after 1.5 hrs. of operation. Prior to the introduction of a vacuum on this well, a 1 foot recovery of free product would take 48 hrs. or longer. The well was restarted and the same results occurred; free product flow to the well increased.

No free product is pumped to the spray aerator. The free product is evaporated in the well by the vacuum and this vapor is extracted by the vacuum on the well and fed directly to the engine. Water out of the well was tested and found to have 8.9 ppm TPH with benzene at 3.5 ppm. Initially, there was approximately 90% reduction of contaminants. The discharge from the system was tested and found to be below the detection limits of 0.1 ppm TPH and 0.7 ppb benzene. These results are typical for the 25 sites at which the systems are in operation. These particular units are designed for 8-10 gpm. This system has shown itself to be effective on typical service station size lots for remediating soils and groundwater. The system is capable of remediating up to 150 lb of hydrocarbons per day.

COSTS

Currently this system costs approximately $60,000. It is ready to operate when unloaded from the delivery truck and needs only to be connected to the wells from which water and air are to be extracted and supplied with supplemental fuel of propane or natural gas fuel.

However, operating at the maximum combustion of the extracted vapors, the engine needs no supplemental fuel. Operations and maintenance for the system costs are the costs of weekly oil and filter changes, a monthly tuneup and an annual overhaul on an engine running 24 hours per day. These maintenance expenses require approximately 4 hours of labor per week (at approximately $50 per hour) and approximately $50 in parts and supplies per week, resulting in a total operations and maintenance cost of $250 per week.

An equivalent system using carbon adsorption for vapor and water phase would require 1500 lb of carbon per day. Comparable operations and maintenance costs for a carbon system would include carbon replacement costs; the costs for electricity to operate three down well pumps, a circulation pump and vapor extraction pump; and labor costs. Carbon replacement costs would be approximately $21,000 per week; 625 kilowatt hours of electricity would be used per week at $0.15 per kilowatt hour to run the pumps in the system; and weekly labor (at $50/hr) would be approximately 3 hours, including carbon changeout time. This results in weekly costs of: $108 for electricity; replace 1500 lbs of carbon per day at $2 per lb; and $150 for labor yields a total cost $21,258 a week for operations and maintenance of the carbon system. Obviously there is a significant cost savings in using the combustion system at a heavily contaminated site.

Even at low vapor concentrations, this new system is more economical than a carbon system. For a site for which only 1% of the fuel for the engine is supplied by extracted vapors, the cost of supplemental fuel (99% natural gas) is approximately $50 per week, resulting in a new total operations and maintenance cost of $300 per week for the combustion system. Comparing this system again to a carbon treatment system for such a site, we find that the carbon usage rate would be approximately 15 lbs per day, while all other costs for the carbon system remain the same. At this carbon usage rate, the weekly cost of carbon would be $210 per week, resulting in a total operations and maintenance of $418 per week, over $100 more than for the combustion system.

Comparison of this system to an air stripper/vapor extraction unit with a catalytic oxidation system for vapor control results in the following operations and maintenance cost analysis. Assuming no supplemental heat is needed to maintain the catalytic reaction, power requirements are approximately 1 kw per hour for water pumping to the air stripper, 4 kw per hour for air and water pumping through the air stripper and 3 kw per hour for the vapor extraction pumps resulting in 8 kw per hour or 1340 kilowatt hours per week. At $0.15 per kilowatt hours, the electrical costs would be $1,201 per week. Add three hours of technician time and weekly operations and maintenance costs would be $1,351. Again the spray aeration/internal combustion system is significantly more cost-effective than an air stripper/vapor extraction system with a catalytic oxidation unit.

CONCLUSIONS

Vacuum enhanced spray aeration with thermal oxidation has been demonstrated to be an effective method of removing hydrocarbons from contaminated groundwater and oxidizing the contaminants so that they are no longer a significant health hazard. The vacuum to the well effectively increases the flow of free product to the well as it extracts vapors from the well for combustion. This system has been demonstrated to be an economical and practical alternative to carbon canisters and their associated costs.

The vacuum spray aeration tank has been demonstrated to have an effectiveness equivalent to a packed-tower air stripper, without the problems of packing fouling or the expense of packing replacement costs. Savings are realized in both the initial cost of equipment and the operating costs of a conventional system using vacuum extraction, a packed-tower air stripper and carbon polishing.

While optimization of operating parameters is being further defined, this system has been shown to be both practical and cost-effective for remediation of gasoline-contaminated groundwater and contaminated soil vapors.

Hazardous Waste Minimization and Control at Army Depots

Ronald Jackson
U.S. Army Toxic and Hazardous Materials Agency
Aberdeen Proving Ground, Maryland

Jeffrey S. Davis
PEI Associates, Inc.
Cincinnati, Ohio

ABSTRACT

The U.S. Army Toxic and Hazardous Materials Agency (USATHAMA) recently conducted visits to eight Army depots involved in the maintenance of tactical equipment. The purpose of these visits was to identify research needs related to hazardous waste minimization in addition to control of volatile organic compounds VOCs emitted during operations. The focus of the information collected related to methods of paint application and removal, degreasing operations, and wastes generated from electroplating operations. The information was used to identify several research projects that are currently being conducted to address specific waste minimization issues at selected facilities.

A total of sixty-nine potential waste minimization and VOC reduction/control projects were identified at the depots visited. Three of these projects were selected for research/demonstration projects that will be conducted and implemented at appropriate depots. The three projects selected involve: (1) The evaluation of paint application systems to increase transfer efficiency to reduce VOC emissions and paint waste generation, (2) the extension of chromic acid bath lives via electrodialysis, and (3) the extension of the lives of alkaline paint-stripping baths to reduce the amount of generated wastes.

Findings of the depot visits and subsequent technical efforts described in this paper.

INTRODUCTION

U.S. Army depots are involved in the maintenance of tactical equipment. Maintenance operations generate large amounts of hazardous waste and air pollutants as a result of paint application, paint removal, degreasing and plating processes. Control, treatment and/or disposal of air pollutants and hazardous waste are expensive.

Preventing the generation of hazardous waste at the source reduces the amount of waste materials that must be tracked, treated and/or disposed of, and often results in significant cost savings for the depots. Waste minimization also reduces the long-term liability associated with the generation of hazardous waste.

U.S. Army Toxic and Hazardous Materials Agency (USATHAMA) personnel are conducting research and development projects pertaining to hazardous waste minimization (HAZMIN) at Army depots. Hazardous waste minimization is a viable method for solving some of the problems created by the generation of hazardous waste. Additionally, HAZMIN can create a safer work environment.

Anniston (Alabama), Corpus Christi (Texas), Letterkenny (Pennsylvania), Red River (Texas), Sacramento (California), Sharpe (California), Tobyhanna (Pennsylvania) and Tooele (Utah) Army Depots were visited between April and July 1989. The purpose of these visits was to identify research needs related to HAZMIN and/or control of volatile organic compounds (VOCs) emitted during depot operations. The information was used to define several research projects that are currently being conducted as part of USATHAMA's Pollution Abatement and Environmental Control Technology (PAECT) program.

A total of sixty-nine potential waste minimization and VOC emissions control projects were identified at the eight depots visited. Of these, 24 were identified as short-term, high priority projects. The projects ranged widely in technical effort and scope of work required. Three projects were selected for demonstration testing based on the current scope of work, interest of depot personnel, applicability of the projects at several depots and potential for hazardous waste and/or VOC reduction. Each of the three projects is currently being initiated at an appropriate Army maintenance facility. Testing and evaluations will be conducted during the fall of 1990.

This paper presents the some of the findings of the depot visits and describes subsequent technical efforts in hazardous waste minimization and VOC control/reduction.

PAINT APPLICATION

Paint application is a major source of hazardous waste generation and VOC emissions at Army depots. Each waste generation problem of this operation is addressed separately.

Generation of Hazardous Waste

Painting operations at Army depots produce large amounts of hazardous waste. Waste results from excess paint, paint overspray, use of cleaning solvents and the capture of paint particulates to prevent their release into the atmosphere. Paint wastes are hazardous because components of the paints are often toxic and/or flammable.

All the depots visited used dry filters on some paint booths to capture the particulates from overspray during painting operations. The filters become clogged as the overspray accumulates and must be replaced. Some of the depots dispose of all filters as hazardous waste, whereas other depots have determined that some of their filters are nonhazardous waste.

The water-wash paint booth is another type of control device used by the depots to remove paint particulates from overspray. In these booths, water flows down a wall at the rear of the paint booth and over an air vent through which the booth exhaust flows. The air containing the paint overspray is vented through the water and the particulates are captured. The resulting water and paint mixture (sludge) is collected in a trough.

Paint sludge from water-wash booths is a major hazardous waste problem at many of the installations. Some of the depots are attempting to reduce the amount of sludge by separating the paint residue from water through the use of cyclone separators combined with the addition of detackifying agents. Several facilities have expressed interest

in using filter presses to decrease the volume of collected sludge.

Other methods of minimizing the generation of hazardous waste during depot painting operations are being implemented by the installations:

- Development of alternative methods for capturing particulates
- Recharacterization of waste materials
- Segregation of hazardous from nonhazardous waste
- Replacing paints which have hazardous characteristics
- Increasing transfer efficiencies of paint application systems

VOC Emissions

Most depots are undertaking steps to reduce VOC emissions to levels required by state or federal statutes. The depots located in California and Pennsylvania are under regulatory pressure to decrease VOC emissions. Even in states without stringent VOC regulations, depots are expected to attempt to reduce VOC emissions and to complete a health and safety evaluation before regulatory authorities will permit new VOC sources.

VOC control technology is very expensive and may not be practical because the sources of VOC emissions often are located in different sections of the installation. Most depots are focusing on reducing VOC emissions by switching to paints with low VOC contents and improving the transfer efficiencies of paint application systems.

Paint application operations at Army depots are production oriented. Consequently, painting as rapidly as possible often is essential. Increased rates of production often are achieved by increasing nozzle pressure and/or using a wider paint gun nozzle angle. Overspray also increases as a result of these changes, resulting in higher VOC emissions and lower transfer efficiency. The use of high efficiency painting equipment will reduce the amount of overspray and VOC emissions. Consequently, less hazardous waste in the form of spent dry filters and sludge from water-wall paint booths will be generated.

One of the USATHAMA HAZMIN projects presently being initiated is the evaluation of transfer efficiencies of paint application systems at Sacramento Army Depot (SAAD). Several high volume low pressure (HVLP) spray guns will be purchased and tested to determine their effectiveness in decreasing VOC emissions. The information obtained from this project will be used by depot personnel to identify and implement high efficiency painting systems.

The test equipment will be evaluated on an actual production line at SAAD. The following variables will be measured to assess the effectiveness of the paint application equipment:

- Transfer efficiency
- Speed of paint application to achieve a high quality coating
- Ability to meet coating specifications

A final report will be available in early 1991.

PAINT REMOVAL

Paint stripping operations generate large amounts of hazardous waste at Army depots. They are also a significant source of VOC emissions.

The method of paint removal depends on the tactical equipment being processed and often varies between depots. Chemical and mechanical paint removal will be discussed separately.

Chemical Paint Removal

Chemical stripping compounds commonly used during paint removal are either methylene chloride- or alkaline-based formulations. Methylene chloride-based strippers are targeted for replacement because of health and safety concerns. Many chemical strippers also contain VOCs.

Equipment parts to be stripped of paint usually are submerged in a tank containing the stripping solution. This method of paint removal generates large amounts of hazardous waste in the form of spent stripping solutions and paint sludge. Paint removal operations at Army depots are also large generators of wastewater.

Army depots are exploring several methods for hazardous waste minimization during paint stripping operations:

- Replacement of strippers containing hazardous components

- Increasing the lives of stripping solutions
- Decreasing the volume of sludge via filter press

The removal of paint residues generated during stripping operations from paint stripping baths may be a viable method for extending the useful life of chemical stripping solutions. The solid residue remains in the bath after paint is removed from equipment parts and continues to chemically react with the stripping reagents. Eventually, these reactions will deplete the stripper. Removal of the residues may result in longer bath lives, fewer tank changes and a reduction in hazardous waste generation.

Another project selected for USATHAMA demonstration testing is to extend the life of a chemical stripping solution by removing solid residues from the stripping bath. The project will be conducted on an alkaline paint stripping bath at Letterkenny Army Depot. During this project, the reduction in waste generation will be quantified. Process variables of the filtration system will be determined and factors that may affect the life of the process bath will be studied. Data obtained during this demonstration test will help implement the technology at other depots. A final report detailing the results of this task will be available in early 1991.

Abrasive Paint Stripping

Many different abrasive blast media are used at Army depots. Types of media used include walnut shells, steel shot, aluminum oxide, peridot, sand, glass and plastic beads. Spent media usually are disposed of as hazardous waste because of heavy metal contamination from paint pigmentations and surface finishes removed from equipment during blasting operations.

Several waste minimization efforts were identified during the visits to the depots:

- Implementing or improving recycling of blast media
- Use of media with longer usable lives
- Alternative blast methods
- Optimization of blast parameters

Some of the depots indicated a desire to replace methylene chloride-based chemical strippers with plastic media blasting (PMB). PMB generates less hazardous waste than chemical strippers. Indications are that plastic media do not damage sensitive substrates and are more recyclable than many other types of blast media.

DEGREASING OPERATIONS

Army depots use various chemicals in degreasing and cleaning processes. These compounds are sources of VOC emissions and hazardous waste generation at the installations. The primary degreasing solvent used at the depots 1,1,1-trichloroethane.

Several depots have tried to recycle 1,1,1-trichloroethane. However, efforts to recover the spent solvent have been plagued by equipment failure, acidification of the solvent and low recovery rates.

Some of the installations are investigating the use of heated fluidized beds to remove paint and degrease equipment. In the fluidized bed process, paints and grease are pyrolized and the gaseous emissions from the bed are destroyed in an afterburner. Fluidization of the bed medium results in efficient heat transfer.

PLATING AND SURFACE FINISHING OPERATIONS

Normal surface finishing operations at Army depots include cadmium and chromium plating, anodizning and metal electrostripping processes. Other metals such as brass, copper, gold, nickel, silver, tin and zinc also are plated.

Several waste streams are generated during these operations at Army depots. Process solutions, such as chromic acid and chromate conversion coatings, are frequently replaced and disposed of as hazardous waste. Rinse water becomes contaminated due to carryover from the process baths and must be treated as hazardous waste. Treatment of the rinse water results in the generation of sludge. The plating baths are rarely dumped and are not a large source of hazardous waste.

Hazardous waste minimization efforts can be targeted at the process

tank, at wastewater from rinse tanks, or at the sludge from wastewater treatment. The HAZMIN target areas are discussed separately.

Hazardous Waste Minimization for Process Solutions

Army depots are undertaking efforts to minimize waste from plating and surface finishing operations at the source - the process solutions. Several depots have eliminated cyanide-based cadmium electroplating by using other types of process baths. Some installations have expressed interest in replacing some cadmium plating operations with aluminum ion vapor deposition (AIVD).

Another method directed at the process tank is to increase the life of the process solution. Contaminants that shorten the lives of the process solutions generally consist of metals introduced by carryover. The effectiveness of using an electrodialysis unit to remove metal contaminants from a chromic acid bath will be demonstrated as an USATHAMA HAZMIN project. Chromic acid may be continuously rejuvenated during the process by oxidizing trivalent chromium to its hexavalent form. The electrodialysis unit will be installed and tested on a process tank at Corpus Christi Army Depot (CCAD). A final report will be available in 1991.

Reduction of Wastewater Generation

The amount of wastewater generated during plating and surface finishing operations can be decreased by reducing dragout from process tanks. Some depots use a spray rinse to remove and return most of the dragout to the process tank. The water from the spray rinse can be used in the process tank to replace water lost through evaporation. Other depots rinse parts directly over plating baths and use drainage boards between process and rinse tanks.

Army depot personnel have expressed interest in reclaiming metals from the rinsewater. Metals can be efficiently recovered from wastewater and returned to process tanks by such methods as ion exchange, evaporation, reverse osmosis and electrodialysis. CCAD personnel, for example, are presently trying to implement a closed-loop process that will use ion exchange and electrodialysis to remove chromium and other metals from rinsewater. The rinsewater could be recycled and the chromium converted to its useful form for reuse in a chromic acid bath. This system, in conjunction with the USATHAMA test system, has the potential for zero discharge of hazardous waste.

Reduction of Hazardous Sludge Volume

Wastewater from Army depot plating and surfacing operations requires treatment before discharge to the environment. Generally, metals in the wastewater are precipitated out as metal hydroxides at the installation's industrial wastewater treatment plant (IWTP). The resulting sludge usually is disposed of as hazardous waste. Consequently, HAZMIN efforts can be applied to the treatment of wastewater once the water reaches the IWTP.

Several methods have been, or are now being, implemented to minimize hazardous sludge generation. Some depots combine wastewater streams, and all sludge generated from wastewater treatment is considered hazardous. Segregation of hazardous and nonhazardous wastewater streams will reduce the amount of sludge classified

as hazardous waste. At some of the facilities, the heavy metal concentrations may be low enough that the sludge produced is not EP toxic. The sludge is being recharacterized and may be delisted if it is not EP toxic. Several depots have achieved sludge volume reductions through the use of filter presses.

OTHER USATHAMA HAZARDOUS WASTE MINIMIZATION EFFORTS

Commercially available, state-of-the-art technology is being evaluated in support of the Army depots' hazardous waste minimization efforts. Three additional USATHAMA demonstration projects are outlined below.

Alternative Chemical Paint Strippers

The identification of commercially available chemical paint strippers which may be viable alternatives to methylene chloride-based strippers is presently being conducted. The evaluation of the stripping performance of one of the formulations identified is under way on an operational paint stripping line at SAAD.

The elimination of methylene chloride-based chemical paint stripping solutions will aid in the reduction of total toxic organics (TTO) and VOC emissions. The use of less hazardous strippers will also significantly decrease the generation of hazardous waste at the depots.

Fluidized Bed Paint Stripper/Degreaser

The feasibility of using a heated bed of fluidized aluminum oxide to remove grease and paint from tactical equipment parts is being evaluated at Red River Army Depot. The results of this demonstration test will be available in mid 1991.

A fluidized bed can directly replace chemical degreasers and paint strippers for parts that can tolerate temperatures up to 850° F. This system can substantially reduce the generation of hazardous waste and provide a safer work environment.

Aluminum Ion Vapor Deposition

The feasibility of using aluminum vapor plating in lieu of cadmium plating is being evaluated at Anniston Army Depot. Cadmium plating is a large source of hazardous waste generation at most Army depots. A report detailing the results of this project will be available in mid 1991.

During aluminum vapor plating, the metal is deposited directly on the part to be plated. Aluminum ion vapor deposition does not require the use of hazardous materials and does not generate hazardous waste. Aluminum also has been shown to provide a superior corrosion resistance compared to cadmium.

CONCLUSION

U.S. Army depots are making progress towards the Army's goal of a 50% reduction of the total hazardous waste generated in fiscal year 1985 by the end of 1992. The technologies currently being evaluated by USATHAMA may assist the depots in meeting the Army HAZMIN goal. However, significant obstacles still remain, including lack of resources available to implement proven technology and lack of sufficient technical information transfer among the installations.

The Installation Restoration Program Information Management System (IRPIMS) and An Overview of Air Force Hazardous Waste Investigations

Philip M. Hunter, P.G.
Air Force IRP Program Office
Human Systems Division
Brooks Air Force Base, Texas

ABSTRACT

The Installation Restoration Program Information Management System (IRPIMS) was developed by the Air Force Human Systems Division, IRP Program Office to support the data management needs of its Air Force hazardous waste program. The system was designed in 1986 and was operational in 1987. Approximately 80% of the technical data stored consists of analytical sampling results. Data continue to be loaded into the system as IRP project data become available. More than 600,000 analytical records have been entered into the system.

The system stores information on more than 2000 hazardous waste sites that are distributed across 196 Air Force installations and 14 Major Commands. More than 7000 sampling locations (monitoring wells, soil borings, etc.) are identified from which analytical results can be retrieved and evaluated. In addition, the system stores and processes data related to general site and sampling location information, lithologic descriptions, monitoring well completion information, groundwater levels and sampling test methods.

The intent of this paper is: (1) to provide an overview of the roles and capabilities of IRPIMS and (2) to describe the Air Force's Installation Restoration Program in terms of the investigative effort performed, the types and concentrations of contamination found and the association of contaminants detected in groundwater at a variety of hazardous waste site types.

INTRODUCTION

The Air Force Human Systems Division Installation Restoration Program (IRP) Program Office (HSD/YAQ) is one of three service centers providing IRP technical and contract administration support to Air Force installations and Major Commands (e.g., Strategic Air Command, Tactical Air Command, etc.). IRP projects generate technical reports containing large volumes of hydrogeological and chemical data that are difficult to manage with manually maintained systems. Mere storage and availability of these reports containing large amounts of hard-copy data does not represent information, in the modern sense, without the ready access and computational capability of a main frame computer equipped with the query tools of a relational data base. It was with these factors in mind that the Installation Restoration Program Information Management System (IRPIMS) was designed for use by the IRP Program Office and its customers.

IRPIMS was designed by a multidisciplinary team of professionals consisting of hydrogeologists, chemists, applied statisticians, system analysts and IRP project managers. The major emphasis in designing the system in 1986 was to provide an application tool to assist technical, contract-administrative and program managers. The design of the system took approximately one year and the first generation system was operational in 1987. Major changes in system architecture were made in 1988

and the second generation system was developed within a year. Since 1989 there have been relatively minor changes in the data structure and more attention has been drawn to technical applications.

IRPIMS hardware consists of a Digital Equipment Corporation VAX 8650 Computer. Data are entered into, stored and managed by Oracle, a commercially-available relational data base. Other application software, existing both in the VAX and personal computer (PC) environment, supports the system relative to data entry, graphics, statistics, reporting and groundwater modeling.

Component Data Bases

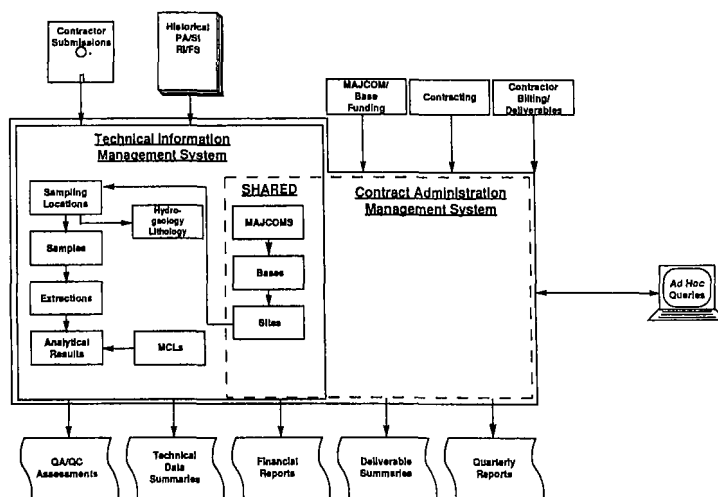
IRPIMS consists of three component databases: (1) the Technical Information Management System (TIMS), (2) the Contract Administration Management System (CAMS) and (3) IRPTRACK, a Project Timeline Management System. IRPTRACK is presently undergoing major modifications and will be replaced by a second generation full-functioned program-management/program-control system. All three of these existing data bases share data. TIMS and CAMS represent the two most important data bases, both in terms of size and functional capabilities. Figure 1 provides an overview of the IRPIMS database and the relationship that exists between the two major data bases. The TIMS data base, however and the technical information associated with it will be the primary focus of this paper.


Figure 1
IRPIMS Data Archive

Technical Data

The types of data stored can be broken down into major categories as shown in Figure 2. These main data categories represent the foundation of the data structure and are the keys by which data are queried and retrieved from the system.

Operating Unit	Substance Class	Sampling Medium	Location Types	Site Types	Dates	Other Categories

Figure 2
Major IRPIMS Data Categories

More than 125 different types of technical data (data fields) are stored in TIMS. The bulk of this information, more than 80% of the total data base, relates to analytical sampling results and data pertaining to sampling events, analytical methods, or miscellaneous tests performed. Hydrogeological data consist primarily of monitoring-well completion information, groundwater level data, lithologic descriptions and hydraulic parameters. Other data relate to general site and sampling location information. Figure 3 shows the relative size of the various data tables stored in IRPIMS. A detailed discussion of the various types of data stored in IRPIMS can be found in the IRPIMS Data Loading Handbook.[1]

When designing an information management system, it is the forethought that is dedicated to developing the data structure (i.e., the types of data captured and how the information will be categorized for access) where most of the time and effort should be spent. Great flexibility should be built into the data structure to accommodate a myriad of "what if" queries and information requests from the user community. Once the data structure has been defined and the system developed, any changes to the data structure can pose major impacts and complications to the management and operation of the system. Therefore, great attention and detail should be paid to the principles of configuration management when a change in data structure is being considered.

Data Entry

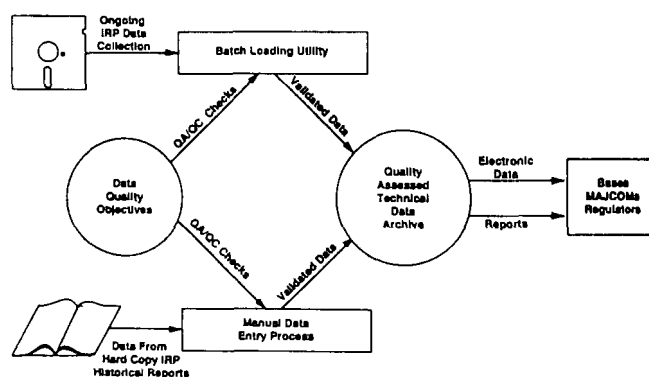
Data enter the system through two mechanisms: (1) manual entry from hard-copy reports ("keyed" data) and (2) batch entry from floppy disk or magnetic tape (Fig. 4). Manually-entered data generally are associated with historical IRP reports that were generated from completed hazardous waste investigations. These data were captured originally from Preliminary Assessment/Site Investigation (PA/SI) and Remedial Investigation/Feasibility Study (RI/FS) investigations. Data-entry staff key the hard-copy data into terminals that are configured with data entry screens. The batch-entry system is designed for ongoing projects where IRP contractors are tasked to prepare data submissions. Data from these submissions are uploaded into IRPIMS via a series of batch-loading software utilities. Before data are uploaded, they undergo a series of QA/QC checks to verify data integrity and format compliance.


Figure 4
IRPIMS Data Entry

As the data are entered into the system, they are inserted into a series of 10 data tables where they are ultimately stored for access. One data table, for example, may consist of general site location information, whereas another table may consist of the analytical results that are associated with the site locations of interest. Many of the routine data queries require that tables be electronically joined to retrieve the necessary information. This process is done through standard techniques available to the query language in Oracle.

Capabilities

Aside from functioning as a data archive, IRPIMS was designed to be used extensively for technical data analysis and information transfer. Current capabilities involve QA/QC of analytical data, risk assessment support and technical oversight of IRP contractors. The assistance that IRPIMS provides to the Air Force IRP staff to oversee technical interpretations made by contractors is especially critical since the IRP Program is heavily dependent on contractors.

Several menu-driven reports exist to support routine technical data queries. The information generated by these reports varies from general program-wide inquiries (across all Air Force installations) to reports specific to a particular Air Force installation, site or sampling location. Sampling results can be retrieved over a particular point in time as well as in space (both in the horizontal and vertical sense). Con-

taminant analysis reports are available to retrieve sampling data that exceed a particular health-risk threshold such as a Maximum Contaminant Level (MCL). Menu-driven reports are developed after the user community has expressed a need for accessing a routine data query.

Ad hoc reports also are possible, and they are generated when special information needs arise. Recently, ad hoc queries have been developed to identify sites that would be suitable to certain remedial technologies based on the types of contaminants present, constituent concentration levels and the particular conditions posed by the hydrogeologic setting (e.g., depth to groundwater). This capability affords a particularly powerful approach to identifying sites for remediation across the entire Air Force IRP program.

Other capabilities involve sophisticated three-dimensional graphics, statistical data analysis and groundwater modeling. These types of applications have proven critical to supporting Air Force litigation proceedings in the past and have been responsible for rendering a favorable legal decision that saved the government an estimated $10 million in monitoring and remediation expenses.

Statistical procedures are used to assess the precision and accuracy of analytical data submitted by support laboratories. Statistical analysis also is used to identify data outliers (anomalously high or low data values) that may have escaped other data validation checks.

A Defense Priority Model (DPM) interface currently is being developed. DPM is the hazard ranking model currently adopted by all military services in the Department of Defense (DoD) for purposes of prioritizing cleanup and remediation at hundreds of IRP sites. This interface will allow DPM scorers to access IRPIMS to retrieve the front-end data necessary to run the hazard ranking model. This interface will save the operators needless hours in preparing raw data before running the model, particularly since the data-preparation phase has been identified as the most time-consuming aspect of running the model and generating DPM scores.

A Geographical Information System (GIS) supporting sophisticated graphics for spatial analysis and volumetrics is planned for the near term. This system will support users who have the expertise to perform their own interpretations using the spatial data found in the IRPIMS archive.

Regarding the future of IRP in the Long-Term Monitoring and the Remedial Design/Remedial Action arenas, IRPIMS is designed to accept data from these investigations as they become available. IRPIMS will serve as the obvious technical tool to verify that remedial actions have effectively improved the environment. This process will be accomplished by analyzing trends in constituent levels detected in affected media prior to, during and after remediation.

User Community, Support and Access

The IRPIMS' user community consists of staff located at the IRP Program Office, at individual Air Force installations and at Air Force Headquarters where program managers determine broad policy and oversee the direction of IRP. Currently, information is transferred to organizations outside the IRP Program Office via hard-copy; however, direct remote access to the system is now being planned for the entire Air Force community. This expanded access is due to recent decisions that have identified IRPIMS as the central data repository for the Air Force.

Various scenarios for access have teen identified, and it is likely that the level of access will vary depending on the needs of the user organization. Some of the larger Air Force installations which have enormous data management needs, for example, may require a replicated data base installed on-site. This arrangement essentially clones IRPIMS for use on an on-site computer at that particular installation. In other instances at installations where IRP activities and technical staff are limited, hard-copy access to the system may suffice.

Users are supported by various documents such as user's manuals, data loading manuals and, in the near future, a quarterly newsletter. On-site training will be provided as the user community expands to other outside organizations. Government contractors will be trained on data format requirements and on the use of software to assist data loading and QA/QC of analytical data.

OVERVIEW OF AIR FORCE IRP INVESTIGATIONS

The discussions that follow will provide an overview of Air Force IRP investigations based on data that are currently stored in IRPIMS. Emphasis will be placed on environmental data that are associated with the groundwater media. The discussions that follow are qualified by the fact that the data base is not entirely complete and, at this writing, represents a subset of data collected from one of three Air Force technical service centers. The amount of data stored, however, is so large that statistically significant conclusions can be drawn, particularly in regards to quantitative estimates and summary information of constituents detected in the environment. An ongoing program, nonetheless, is in place to load IRP data for the entire Air Force IRP program. Funding for this effort has been approved for the 1991 fiscal year.

Data Base Size

The data universe at this time (Table 1) represents information on more than 2000 hazardous waste sites that are distributed within and outside the contiguous United States across 196 Air Force installations and 14 Major Commands. More than 7000 sampling locations have been entered into the data base for which more than 630,000 sampling results can be retrieved for analysis. More than 725 chemical substances compounds are identified in the system and can be associated with analytical results. As of this writing, 260 compounds have been detected in various sampling media. Approximately 3500 monitoring wells have been installed and the borehole footage exceeds 231,000 feet.

The Air Force Base as an IRP Facility

Based on the information in IRPIMS, the typical Air Force installation has an average of 12 sites. The largest number of sites that exists on an Air Force facility is 132. The average number of monitoring wells installed on an installation is 46, whereas the median number of wells installed per base is 25. The maximum number of wells installed on a particular base exceeds 460. A typical site has an average of 4.5 wells installed with a median of 3 wells. The largest number of wells installed on a given site is 60. The average depth of monitoring wells installed across all Air Force bases is approximately 35 feet.

Sites and Site Types

Information on approximately 2250 sites has been entered into IRPIMS. Air Force IRP sites can be grouped into at least 13 site categories. Figure 5 illustrates the frequency of occurrence of these various site categories. The site types that are found most frequently are: (1) landfills, (2) waste disposal lagoons or waste pits, (3) spill sites, (4) fire training areas and (5) underground storage tanks. By far the most common sites are those that fall into the landfill category.

Sample Location Types

IRPIMS stores information on 14 different sampling location types. Figure 6 illustrates the frequency of occurrence of these sampling types across the entire Air Force IRP program. Monitoring wells are the most

common type of sampling location as indicated by Figure 6. As noted above, information on more than 3500 monitoring wells is available at this time in IRPIMS.

Sampling Location Types

Common Organic Compounds Detected in Groundwater

Figure 7 shows a ranked listing of the 10 most common compounds detected in groundwater across the Air Force IRP Program. The constituents are ranked based on a frequency analysis of the total number of sampling locations where organics were detected. Not surprisingly, the constituents that are detected most commonly on Air Force installations are those associated with solvents and fuels which have been released by activities related to airplane maintenance and fuels storage/handling. As Figure 7 indicates, Trichloroethylene (TCE) is certainly the most common contaminant detected. Other constituents such as toluene and benzene also are commonly detected in groundwater. These compounds are found on Air Force installations are typical of those compounds found on other large industrial complexes.

Table 2 shows representative concentration levels for the top 10 compounds. As commonly found in environmental data, the frequency distributions for these compounds are typically skewed towards the higher concentration levels; hence, the mean or average concentrations tend to be much higher than the median levels. This result is common to frequency distributions that vary significantly from a normal distribution. The median is a better measure than the mean of central tendency in the data and thus represents a concentration that one could expect to detect in the field in most instances. The mean concentrations tend to exaggerate representative constituent levels and thus are not recommended for this type of analysis.

Because of the large sample size of data available in IRPIMS, statistically significant estimates of the median and other parameters

(Based on number of detects)
IRPIMS Data Summary

Figure 7
Most Common Organic Compounds
Detected in Groundwater

can be made. It is not likely, therefore, that the median levels for the various constituents will vary significantly even as considerably more data are added to the data base over time.

1,1-DCA	5	137	8,800

(Note: All values in µg/L)

Common Organic Compounds Detected at Selected Site Types

When planning sampling protocols (choice of analytical method, etc.) for the common site types, it is of interest to assess the variety of compounds likely to be detected. Figure 8 illustrates the variety of organic compounds detected at selected site types, based on the number of distinct chemical substances encountered during sampling. As one might expect, landfills are the sites that demonstrate the greatest variety in organic constituents detected; nearly 80 different compounds have been detected across the Air Force.

Figure 8
Variety of Organic Constituents Detected in Groundwater at Selected Site Types

Table 3 lists the top 10 constituents most frequently detected at selected site types. Of these compounds, TCE, toluene, benzene, ethylbenzene, PCE, trans-1,2-dichlorothene and 1,1,1-trichloroethane occur in the respective lists across all of the selected site types. Table 4 illustrates median levels for these constituents as calculated separately for each of the selected site types. One can determine from this table that the median concentrations at underground storage tanks for all constituents, particularly for benzene, are significantly elevated above those levels associated with the other sites. This analysis indicates that leaking underground storage tanks/pipelines tend to pose the greatest environmental threat based simply on the high concentrations likely to be detected.

CONCLUSIONS

The Human Systems Division developed IRPIMS to support and automate the data management needs of the IRP Program. The system is designed around two principal data bases: (1) a technical information management system and (2) a contract administration management system. Both of these systems share data.

The major design and development phase of the system has largely been accomplished. Large volumes of data are now available for meaningful interpretation and analysis to support IRP decision-makers at various levels within the Air Force.

More than 80% of the data stored in IRPIMS consists of analytical sampling results. Other technical data captured by the system relate to general site location information, lithologic descriptions, well completion information, groundwater level data and the like.

Trichloroethylene (TCE), toluene and benzene are the most commonly detected compounds in groundwater. These compounds are associated with solvents and fuels handling and are common to large industrial complexes. With the large sample size that is available in IRPIMS, it has been possible to estimate representative concentrations of constituents that would commonly be detected in the field across the Air Force program. Occurrences of commonly detected compounds have also been associated and identified with the important site types. Sampling protocols designed for routine site investigations have been derived based on these constituent/site associations.

Beyond the ongoing data loading process, the current focus is to expand and further develop the various technical applications that are possible with IRPIMS. In addition, the system is soon to support the entire Air Force as the central data repository. This development will vastly increase the size of the data base and will pose a significant expansion to the user community. Remote access to the system will be developed to improve the transfer of information to support various Air Force customers.

The current IRPIMS data structure has future applications and is designed to accept other types of data as the RD/RA and the Long Term Monitoring programs respond to new data demands. In addition,

IRPIMS will play an important role in verifying the effectiveness of remediation as various remedial alternatives are implemented and sampling data becomes available for analysis.

ABSTRACT

The Naval Air Station (NAS) Pensacola, Florida, is an active naval flight training and aircraft rework facility located in the northwest Florida panhandle. It is also one of the oldest Naval facilities in the United States. The facility has recently been added to NPL and currently has 37 sites on the Station which require investigations under the Naval Installation Restoration Program (IRP). The sites will be investigated in accordance with conditions and schedules outlined in a Federal Facilities Agreement between the Navy, the U.S. EPA and the State of Florida.

All sites were classified as Solid Waste Management Units in RCRA/HSWA permit for NAS Pensacola. Seventeen of the sites have been identified as requiring RCRA Facility Investigations, and all 37 sites will be investigated under the CERCLA regulations.

Given that all 37 sites need to be addressed under the Navy IRP, an approach has been developed to conduct a multimedia environmental investigation which incorporates the requirements of both RCRA/HSWA and CERCLA regulations. In addition, the 37 sites were combined into 15 groups for maximum efficiency throughout the investigative process. Site groupings were principally based on: (1) similarity of documented or suspected contaminants; and (2) geographic proximity. Some of the sites have documented contamination, whereas other sites are only suspected of or have a low probability of contamination. As a result, a phased approach to conducting the contamination investigations is planned. This phased approach will allow efficient identification of sites where environmental contamination has actually occurred, and also will allow elimination of noncontaminated sites to be eliminated from the program in the most environmentally sound, cost-effective and timely manner possible. Sites identified as being contaminated will be further investigated through the completion of an RI/FS and, ultimately, design and remediation. This overall investigative approach and compliance strategy for NAS Pensacola will ensure the most optimal and streamlined procedure in meeting the objectives of the multiple regulatory requirements of this Naval facility.

INTRODUCTION

In recent years, the United States Naval Air Station (NAS) Pensacola has taken an active role in evaluating past and present hazardous waste practices. As a result, the Navy, under its Installation Restoration Program (IRP), has implemented an investigation and cleanup strategy designed to bring sites identified at NAS Pensacola into conformance with the RCRA, HSWA and CERCLA. The entire facility was added to the NPL in late 1989, providing further impetus for an extensive cleanup effort.

NAS Pensacola is located on 5,874 acres in southwest Escambia County, Florida (Fig. 1). Two major industrial tenant commands are located at NAS Pensacola: the Naval Aviation Depot and the Public Works Center. These industrial facilities support all Naval training activities which operate at the base. This support includes fuel storage and transportation systems and maintenance and repair of aircraft. Throughout the years, these support facilities have generated a variety of materials, the majority of which have been disposed of on the base. These materials include construction debris; municipal solid waste and wastewater treatment plant sludge; and miscellaneous industrial wastes,

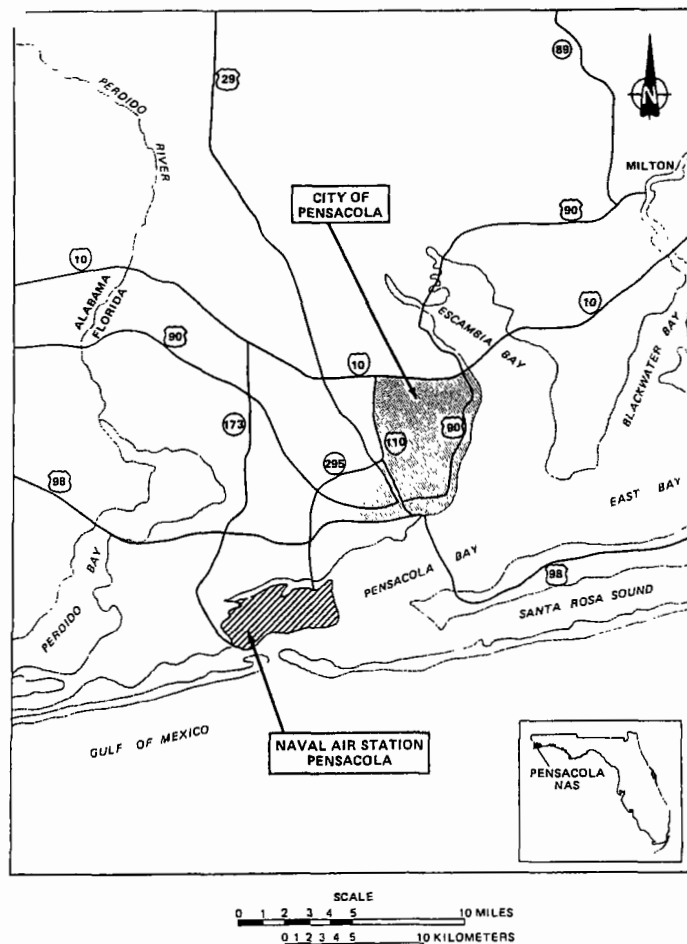
SCALE


Figure 1
Location of NAS Pensacola

including waste oils, solvents, paints, electroplating liquids and spilled fuels. The 37 potential sites of contamination identified at NAS Pensacola (Fig. 2) are a result of the past generation and disposal practices of these materials.

HISTORY

The NAS Pensacola location has been associated with military activities dating as far back as 1528, when the first European settlement in North America was established at this site.[1] Until the early 19th century, this location served as a fortification point for both the British and the Spanish.

In 1825, a naval yard was constructed by the U.S. Navy at the NAS Pensacola site. Although activity at the yard was in turmoil throughout the remainder of the 19th century and into the early 20th century, the U.S. Navy kept the installation. Subsequently, in 1914, the Navy's first permanent air station was established at this site. Throughout World War I and World War II, this base became the Navy's premier aviation training facility. Along with the training facility, the Navy developed all the required support systems for the various aviation activities which occurred at the site.

In addition to the long time Naval Air Station command at Pensacola, several tenant commands have been established at this base. These tenants include the Naval Education and Training Command, the Navy Public Works Center (PWC) and the Naval Aviation Depot (NADEP). The Education and Training command manages all Naval training activities. The PWC is responsible for all utilities and transportation functions for the Navy's activities in this area. The NADEP serves as a repair and maintenance facility for various Naval aircraft.

ENVIRONMENTAL SETTING

Physiography

NAS Pensacola is located in the Gulf Coastal Lowlands Subdivision of the Coastal Plain Province physiographic division.[2] The 5,800-acre facility is located on a peninsula and is bounded on the east and south by Pensacola Bay and Big Lagoon and on the north by Bayou Grande. The most prominent topographic feature on the peninsula is an escarpment or bluff which parallels the southern and eastern shorelines and on which Fort Barrancas was built. Seaward of the escarpment is a nearly level marine terrace with surface elevations of approximately five feet above mean sea level (MSL). The central part of the peninsula, located landward of the escarpment, is a broad, gently rolling upland area with surface elevations up to 40 feet above MSL.[3,4]

Hydrogeology

There are three principal hydrogeologic units of importance which underlie the NAS Pensacola site. These are, in descending order, the Sand-and-Gravel Aquifer, the Intermediate System and the Floridan Aquifer System.

The Sand-and Gravel Aquifer occurs from land surface to a depth of approximately 300 feet at NAS Pensacola and is composed of a sequence of unconsolidated to poorly indurated clastic deposits.[5,6] The sediments making up this aquifer belong to all or part of the Pliocene to Holocene Series, which, in this area, consist mainly of the Citronelle Formation overlain by a thin cover of marine terrace deposits. In the Pensacola area, the Sand-and-Gravel Aquifer is the primary source of potable drinking water, and groundwater within the aquifer is classified by FDER as G-1 (sole source). Given that the Sand-and-Gravel Aquifer is contiguous with land surface and recharge occurs principally by the direct infiltration of precipitation, the aquifer is particularly susceptible to contamination from surface sources.

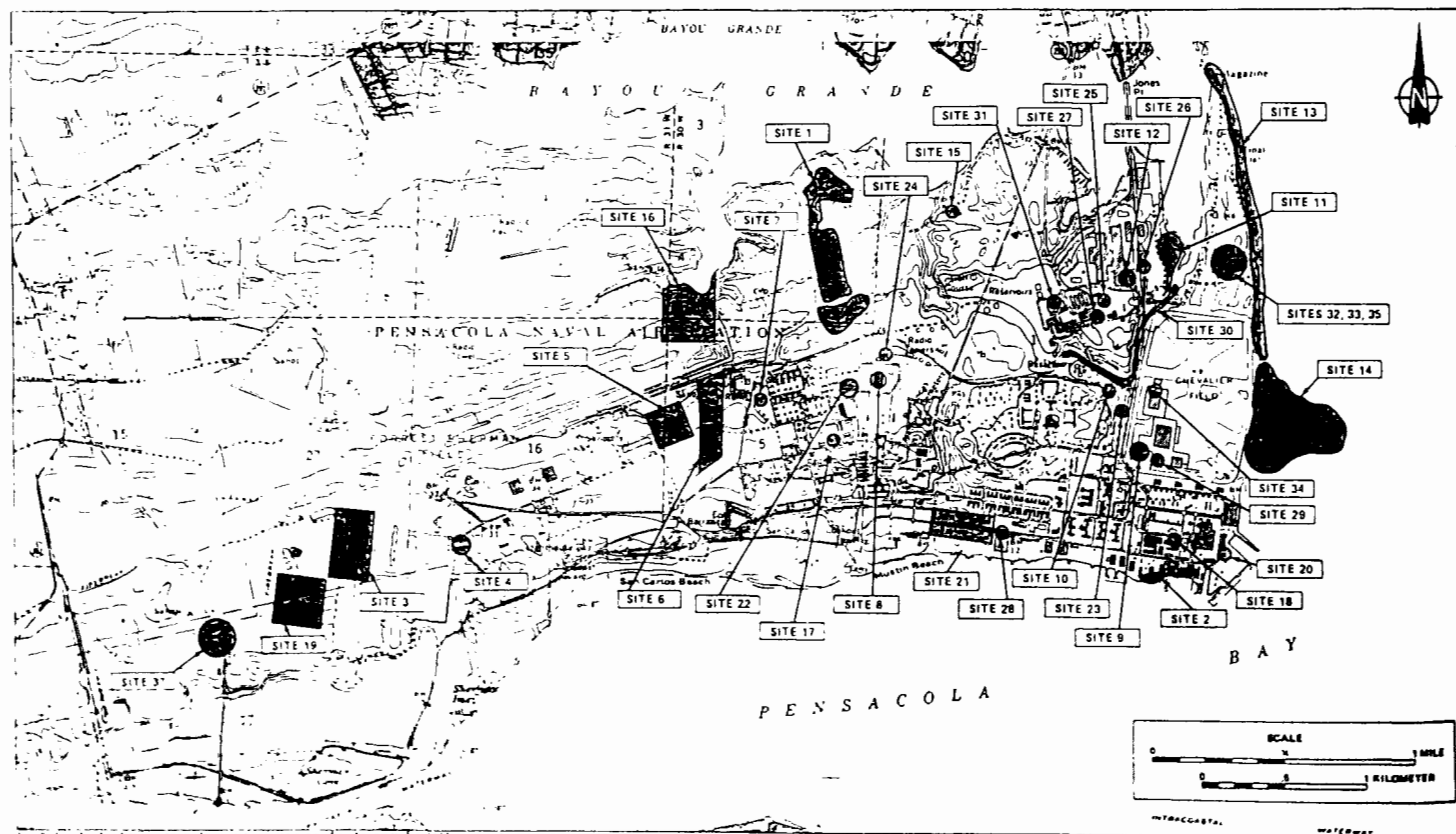
The lower limit of the Sand-and-Gravel Aquifer coincides with the top of a regionally extensive and vertically persistent hydrogeologic unit of much lower permeability. This unit is known as the Intermediate System. In the NAS Pensacola area, the Intermediate System is approximately 1,100 feet thick and is composed of the lower portion of the Miocene Coarse Clastics, the Upper Member of the Pensacola


Figure 2
NAS Pensacola Site Locations

Clay, the Escambia Sand Member of the Pensacola Clay and the Lower Member of the Pensacola Clay; all of Miocene Age. In general, the Intermediate System consists of fine-grained sediments and functions as an effective confining unit which retards the exchange of water between the overlying Sand-and-Gravel Aquifer and the underlying Floridan Aquifer System.[5]

Immediately underlying the Intermediate System and occurring at a depth of approximately 1,500 feet below land surface at NAS Pensacola is the Floridan Aquifer System. The Floridan Aquifer in this area is composed of the Middle to Lower Miocene Chickasawhay Limestone and undifferentiated Tampa Stage Limestone. Groundwater within the Floridan Aquifer in this area is highly mineralized and is not used for water supply.[5]

Surface Water

The NAS Pensacola facility is located on a coastal peninsula bounded by Bayou Grande to the north, Pensacola Bay to the south and east and Big Lagoon to the southwest. These surface water bodies have been classified by FDER as Class III (i.e., suitable for recreation and propagation of fish and wildlife). Pensacola Bay and Big Lagoon are partially separated from the Gulf of Mexico by Santa Rosa Island and Perdido Key, both of which are barrier islands.

There are no naturally occurring perennial streams on NAS Pensacola; however, there are approximately 10 naturally occurring intermittent streams and numerous manmade drainage pathways, which include many stormwater outfalls. Discharge is mainly to the south into Pensacola Bay; however, some small intermittent streams discharge into Bayou Grande to the north from Sherman Field and Chevalier Field.[3,4] The southwestern and northern portions of NAS Pensacola contain areas of freshwater wetlands.

The discharge of surface waters into Pensacola Bay, Bayou Grande, and the coastal wetland areas presents the potential for transport of contaminants into these systems. This system could have a significant impact on seagrass and other sensitive plant communities as well as on shell fishing, recreational fishing and swimming in these coastal zones. Discharges, either through the surface water or groundwater, into wetland areas found on-site could also have a significant impact on the biotic communities that are dependent on those habitats.

Biological Resources

The NAS Pensacola facility encompasses approximately 15 terrestrial and aquatic habitats. The majority of the land on the eastern side of the facility is developed for military use or is designated as a historical or cultural resource. However, the NAS Pensacola installation has approximately 3,500 acres in natural or seminatural (plantation) condition, primarily in the western portion of the facility.

A number of threatened and endangered species have been identified in the vicinity of the NAS Pensacola facility.[7] Many rare, threatened and endangered species are associated with the wetland or bog habitats. Any site remediation and, more importantly, any assessment of environmental endangerment must consider the water level requirements of rare and endangered plant species and the foraging activities of birds in the waters surrounding the NAS Pensacola facility, as well as nesting and feeding animals on the facility grounds.

NAVY INSTALLATION RESTORATION PROGRAM

The Navy IRP was established in 1986 to direct the investigation and remediation of uncontrolled hazardous waste disposal sites associated with naval operations. Prior to 1986, these investigation/remediation activities had been managed under the Navy Assessment and Control of Installation Pollutants (NACIP) program.

In accordance with the NCP, the Navy IRP currently is being implemented in full compliance with the statutory requirements of CERCLA and SARA. Furthermore, since CERCLA/SARA specifies the inclusion of all applicable or relevant and appropriate requirements (ARARs), the Navy IRP incorporates compliance with RCRA and the HSWA of 1984, where applicable.

The Navy IRP can be viewed as a five-step investigation and remediation process:

- Site discovery or notification
- Preliminary assessment (PA) and site investigation (SI)
- Establishment of priorities for remedial action (RA)
- Remedial Investigation/Feasibility Study (RI/FS)
- Remedial Design/Remedial Action (RD/RA)

Each of the above steps includes substeps or subdivisions.

In order to supplement the IRP and in an effort to keep interested parties abreast of activities at the NAS Pensacola facility during this investigation, a Technical Review Committee (TRC) was formed. The TRC for this project consists of the U.S. EPA, FDER, an Escambia County official and a representative of private citizens. All documents generated by the Navy for work conducted as part of this investigation are submitted to the TRC for review and comment.

PREVIOUS INVESTIGATIONS

Three major investigation programs have been conducted at NAS Pensacola under the NACIP/Navy IRP programs: Initial Assessment Study (IAS);[1] Verification Study (VS); and Confirmation Study (CS). The IAS was conducted from 1982 to 1983 by the Naval Energy and Environmental Support Activity (NEESA) to identify and assess NAS Pensacola sites that could pose a potential threat to human health or the environment as a result of contamination derived from past naval operations. The VS, conducted in 1984 and the CS, conducted from 1985 to 1986, were carried out by a previous Navy contractor to confirm/refute the presence of contamination at specific sites identified in the IAS.

In addition to the above NACIP/Navy IRP programs, a RCRA Facility Assessment (RFA) has been completed at NAS Pensacola and a RCRA/HSWA permit was issued to the installation by the U.S. EPA on July 27, 1988. Seventeen of the sites were identified on the permit as Solid Waste Management Units (SWMUs) which required RCRA Facility Investigations. A RCRA permit had previously been issued to NAS Pensacola by the Florida Department of Environmental Regulation (FDER) on September 29, 1987.

Table 1 lists the 37 known and potential sites of environmental con-

tamination that have been identified on NAS Pensacola. Site locations are shown in Figure 2.

FEDERAL FACILITIES AGREEMENT

The Federal Facility Agreement (FFA) is an interagency agreement which exists between the Navy, U.S. EPA and FDER. The FFA outlines the conditions and schedules to be followed during the course of the investigations at NAS Pensacola. The general purpose of the FFA is to:

- Ensure that the environmental impacts associated with past and present activities at NAS Pensacola are thoroughly investigated and appropriate CERCLA response/RCRA corrective alternatives are developed and implemented as necessary to protect the public health, welfare and the environment;
- Establish a procedural framework and schedule for developing, implementing and monitoring appropriate response action at NAS Pensacola in accordance with CERCLA/SARA, RCRA, the NCP and U.S. EPA/state-issued guidance and policy relevant to remediation at NAS Pensacola;
- Facilitate cooperation, exchange of information and participation of the Navy, U.S. EPA and FDER in such actions.

INVESTIGATIVE APPROACH

As discussed previously, 17 of the sites are listed on the NAS Pensacola RCRA/HSWA permit as SMWUs, and the investigations of these sites are governed by RCRA requirements. The remaining 20 sites are covered by CERCLA regulations. In an effort to avoid confusion and duplication of effort in this multisite investigation, an integrated approach was developed. This approach complies with the intent and general requirements of both regulatory programs, but is specifically neither. As a result, the investigation terminology has been modified somewhat from the prevailing RFI for sites covered by RCRA and the Remedial Investigation (RI) for sites covered by CERCLA. For simplicity, the investigations of all NAS Pensacola sites will be referred to as Contamination Assessment/Remedial Activities Investigations.

In order to provide for maximum efficiency in the generation of investigation work plans and the implementation of fieldwork for the NAS Pensacola program, the 37 sites have been clustered into 15 groups, as shown in Table 2. Several criteria were established to generate the work plan groups, including: (1) geographic proximity of sites; (2) similarity of contaminant types; (3) similarity of potential investigation methods; and (4) potential scope and complexity of the investigation.

In addition, a phased approach has been developed for performing the NAS Pensacola site investigations. Phase I (Field Screening) is directed toward identifying the principal area(s) and primary contaminants of concern at a site, thereby providing a mechanism for focusing sampling and analytical efforts during subsequent phases of the investigation. The field screening phase will employ a variety of field investigation tasks, including surface geophysics, habitat/biota surveys, soil gas surveys, hydrologic assessments and the collection of surface water, soil, sediment and groundwater samples for laboratory analysis. However, the analysis of these samples will be subject to less rigorous QA/QC requirements, which reflect the "focusing" objective of this phase rather than a formal contaminant quantification objective. Each field screening task will utilize all existing information from preceding tasks, including aerial photograph analysis, to adjust the locations of the various surveys and sampling locations, thereby achieving optimum results.

Phase II (Characterization) is directed toward the formal confirmation and quantification of the full spectrum of site contaminants (if any), thereby allowing determination of whether further investigation is warranted. The primary objectives of the Phase II field investigation are as follows:

- To characterize the nature and magnitude of the full spectrum of potential site contaminants;
- To confirm and validate the contaminant distributions indicated by the Phase I analytical screening results by collecting and analyzing samples under rigorous QA/QC requirements;

Table 2

- To support the preliminary identification, screening and evaluation data requirements of potential remedial alternatives.

Phase II characterization will consist of limited soil sampling; biota sampling; the installation, development and sampling of shallow monitoring wells and the sampling of existing wells; a continuation of the hydrologic assessments; and air sampling, if necessary.

The necessity of implementing Phases III and IV (Extent Delineation) will depend on the results of Phases I and II. Phases III and IV, if required, will be directed not only toward fully identifying the horizontal and vertical extents of contamination, but also toward providing the quantitative data base necessary to support the screening and evaluation of potential remedial alternatives.

The main objectives/advantages of this phased approach are as follows:

- Efficient identification of those sites where environmental contamination has actually occurred as a result of past and/or present operations, thereby allowing noncontaminated sites to be eliminated from the program in the most environmentally sound, cost-effective and timely manner possible;
- Focused placement of sampling locations and focused selection of analytical parameters in later phases of the investigation, thereby allowing full characterization of site contamination in the most environmentally sound, cost-effective and timely manner possible;

• Early screening of potential remedial alternatives, which, in turn, allows critical parameters necessary to the evaluation of these alternatives to be incorporated into the analytical program in later phases of the investigation.

All sites at NAS Pensacola will be investigated through Phases I and II. However, it is anticipated that some of the NAS Pensacola sites may not require investigation beyond Phase II. On the other hand, sites which have documented contamination will likely require the additional phases of work and hence will comprise full-scale CERCLA/RCRA RFI/RI/FS-type investigations. As discussed above, however, the investigations for all NAS Pensacola sites will be referred to as Contamination Assessment/Remedial Activities Investigations. The final results of investigations at all sites will be incorporated into a Contamination Assessment Report. Where appropriate, sites will be recommended for No Further Action. The final results of site investigations that require work beyond Phase II will be incorporated into a Remedial Investigation Report which will provide all the information necessary for the development and completion of a Feasibility Study.

Any new sites discovered during the process of investigating known sites will be incorporated into the established approach, depending on regulatory provisions applicable to the site.

Included in the investigative process is the base line risk assessment to characterize current and potential risk to human health and the environment posed by the site. The primary objectives of the base line risk assessment are to identify the contaminants of concern, assess their toxicity and identify the exposure pathways for both the public and the environment. The base line risk assessment provides a preliminary indication of risk before the FS is conducted to identify cleanup alternatives. If little or no threat to human health or the environment from a site is identified, no further action, or only limited action, will be required for cleanup and the FS will be scaled-down appropriately.

As the RFI/RI process is completed, each particular site group will be evaluated promptly for the need of a feasibility study/corrective measures study (FS/CMS) and subsequent remedial design-remedial action/corrective measures implementation (RD-RA/CMI). The strategy for performing these remedial engineering/construction activities at NAS Pensacola will be, in general, similar to that for the fieldwork. Essentially, sites with contaminant similarity and close geographic proximity will be remedially analyzed as a single entity or as a larger group to whatever degree possible.

CONCLUSIONS

NAS Pensacola, Florida, has recently been added to the NPL. This installation has 37 potentially contaminated sites, all of which will be assessed and remediated under an integrated approach which combines the requirements of RCRA and CERCLA. An FFA between the Navy, U.S. EPA and FDER has been developed which details the procedure by which remedial activity will occur at the facility, including the RCRA and CERCLA integration and the responsibilities of each party of concern.

Given that full-scale RI/RFI/FS/CMS investigations may be required for most of the 37 sites, an optimal technical and economic strategy has been implemented to achieve all necessary regulatory requirements.

This optimization strategy prioritizes the sites for investigation as well as groups the 37 sites into 15 more manageable units for the purposes of work plan development, fieldwork implementation and remedial selection and implementation. The strategy also identifies a phased investigative approach to allow noncontaminated sites to be eliminated from the program while providing full characterization of sites where contamination has occurred. This overall approach will provide the maximum great degree of efficiency, with respect to economics and schedule, to such an extensive remedial program.

ABSTRACT

Section 120 of SARA provides a mechanism for remediation of federal facilities through federal facilities agreement (FFA). This paper discusses implementation of the FFA for the New Brighton/Arden Hills Superfund site in Ramsey County, Minnesota. The site is owned by the U.S. Army. It covers an area of approximately 25 mi^2, which includes a 4-mi^2 area of the Twin Cities Army Ammunition Plant (TCAAP) and off-TCAAP areas contaminated by the migration of contaminants from TCAAP. The soils and groundwater at the site are contaminated with metals and VOCs. The groundwater contamination emanating from the TCAAP site has threatened water supplies of several communities downgradient of the site that use groundwater as a potable water supply.

This FFA was the first agreement in the country pursuant to Section 120 of SARA. The agreement was intended to ensure that the environmental impacts associated with the TCAAP site are thoroughly investigated and that appropriate steps are taken to protect public health, welfare and the environment. The agreement specifies a shared responsibility for conducting RI/FS at the site. The U.S. Army is responsible for conducting RIs for on-TCAAP areas, the Minnesota Pollution Control Agency (MPCA) is lead agency for conducting RIs for off-TCAAP areas (approximately 25 mi^2) and U.S. EPA is responsible for preparing risk assessments (RA) of on-TCAAP and off-TCAAP areas. Upon completion of the RIs and RAs, the U.S. Army will conduct an FS to identify and evaluate feasible response actions for remediation of contaminated soils and groundwater.

Successful implementation of an agreement of this magnitude and complexity requires innovative management on the part of all participants. Meeting schedules, whether they are the Army's or the U.S. EPA's, is critical to the credibility of the Section 120 process.

This paper highlights the oversight of the RI/FS activities and the resources and approaches needed to meet the rigorous review schedule specified in the FFA. It discusses major features of the FFA, progress made to date, resolutions of disputes among three organizations (U.S. EPA, MPCA and U.S. Army) and schedules and workloads relevant to the implementation of the FFA.

INTRODUCTION

The New Brighton/Arden Hills Superfund site consists of the Twin Cities Army Ammunition Plant (TCAAP), located in Ramsey County, Minnesota and all other areas contaminated by the migration of hazardous substances or contaminants from TCAAP. The U.S. Army owns the TCAAP facility and Federal Cartridge Corporation (FCC) has been operating the facility during most of its existence. TCAAP has been used to manufacture, store and test small arms ammunitions and related materials since 1941. Presently, the plant is inactive, having been on standby status since August 1976. However, two major private companies still use part of the facility for commercial and defense-related operations. These companies are Minnesota Mining and Manufacturing Company and Honeywell, Inc.

Information from past studies indicates that between 1941 and 1981 waste material was disposed of at 14 disposal areas or sites within TCAAP. The U.S. EPA and the Minnesota Pollution Control Agency (MPCA) have determined that there have been releases of hazardous substances, pollutants, or contaminants into the environment. As a result of these releases, the New Brighton/Arden Hills site has been ranked No. 43 on the NPL.

The U.S. Army, U.S. EPA and MPCA entered into a federal facilities agreement (FFA) in 1987 to ensure that the environmental impacts associated with the TCAAP site are thoroughly investigated and that appropriate steps are taken to protect the public health, welfare and the environment. In accordance with the FFA, the U.S. Army initiated remedial activities under the Department of Defense Installation Restoration Program to remove and treat contaminated groundwater at several locations, extract contaminated vapors from soils at two source areas (source areas D and G) and excavate and incinerate PCB-contaminated soils at one source area (source area D) (part of the TCAAP site). Argonne National Laboratory (ANL), a contractor to the U.S. Army, has prepared a remedial investigation (RI) report on the contaminated areas within the boundary of TCAAP. Concurrently, Camp, Dresser & McKee, Inc. (CDM), a contractor to the MPCA, prepared an RI report of off-TCAAP areas to determine the extent of contaminant migration from TCAAP. PRC Environmental Management, Inc. (PRC), oversight contractor to U.S. EPA, performed a risk assessment of the New Brighton/Arden Hills Superfund site.

SITE DESCRIPTION

The New Brighton/Arden Hills Superfund site is located in the northern part of the Minneapolis-St. Paul metropolitan area (Fig. 1). As presently defined, the site covers much of the U.S. Geological Survey's New Brighton, Minnesota, 7.5-minute quadrangle. For historical and administrative reasons, the site is divided into two areas. TCAAP is the source area. As shown in Figure 2, TCAAP includes 14 individual source areas plus the remainder of the installation. The off-TCAAP portion of the site includes portions of several municipalities. The outer boundaries of the site include all areas affected by contamination originating within TCAAP.

Within the New Brighton/Arden Hills study area, groundwater is found in both bedrock and glacial deposit aquifers. There are two major bedrock aquifers in the area—the Prairie du Chein/Jordan Sandstone and the Mt. Simon/Hinckley. There are also four minor bedrock aquifers in the Twin Cities Basin—the Ironton/Galesville, the Reno Member of the Franconia Formation, the St. Peter Sandstone and the

Platteville/Decorah. The St. Peter Sandstone and the Platteville/Decorah units are in direct contact with the overlying glacial deposits in the New Brighton/Arden Hills and Roseville areas, respectively.

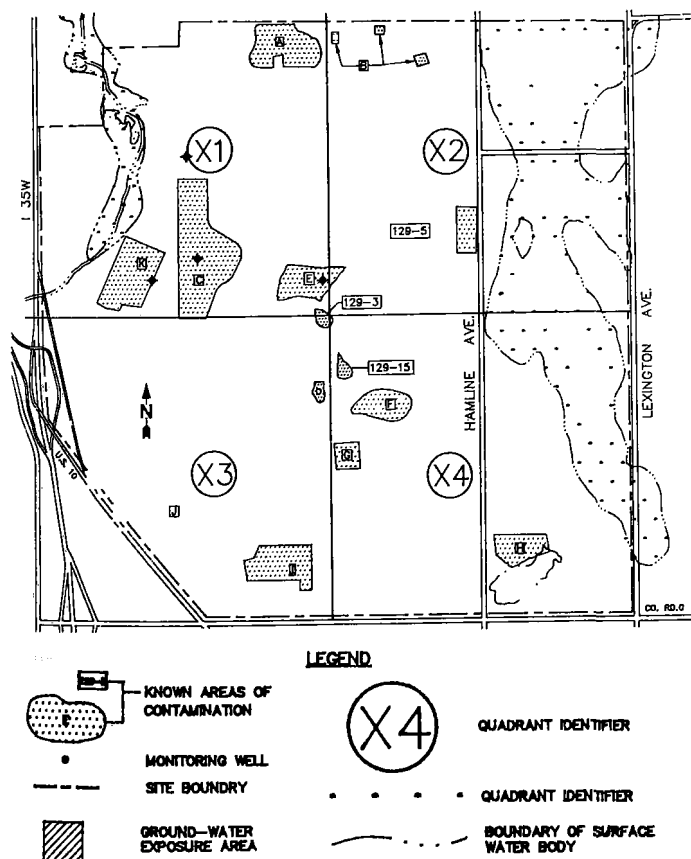

Figure 2
TCAAP Site Map

On top of the irregular bedrock surface, a series of unconsolidated glacial sediments has been deposited. Several of these units are water-bearing and have been affected by the spread of contaminants from TCAAP. In general, there are four aquifer units at the site. Unit 1 is composed of the surficial lacustrine deposits that form the shallow unconfined aquifer. Unit 2 is composed of glacial Twin Cities Till, which acts as an aquitard, preventing hydraulic communication between the surface and the underlying major glacial aquifer. Unit 3 is composed of the Hillside and Arsenal Sands and is the major glacial aquifer in the area. Unit 4 is the uppermost bedrock aquifer beneath the site. It may be hydraulically connected to the overlying Unit 3 aquifer.

SITE BACKGROUND

In 1978, the U.S. Army Toxic and Hazardous Materials Agency (USATHAMA) performed an assessment of TCAAP, which identified 14 disposal areas at the site. These areas were used for the disposal of waste solvents, acids, caustics, heavy metals and other production wastes. Approximate boundaries of the disposal areas are shown in Figure 2.

Subsequent groundwater sampling and analyses conducted by MPCA and the Minnesota Department of Health (MDH) found VOCs in production wells at TCAAP, the Arden Manor trailer park well in Arden Hills and a number of residential wells in Arden Hills, Shoreview, New Brighton and St. Anthony.

The following events occurred as a result of the identification of VOC-contaminated groundwater:

• The City of New Brighton abandoned several municipal wells and either placed on standby or deepened several others.
• The Village of St. Anthony used U.S. EPA/MPCA funds to decommission one well and connected a portion of the village with Roseville water supplies for an indefinite, but temporary period.
• A number of New Brighton/Arden Hills residents drawing contaminated drinking water were provided municipal water through construction of U.S. EPA/MPCA-funded water main extension.
• Residents of the Arden Manor Trailer Park drawing contaminated drinking water were provided with new wells finished in an aquifer with potable water. The wells were provided by Arden Manor Trailer Park, which was later reimbursed by the Army.
• A New Brighton resident was provided MPCA Superfund money for reimbursement for connection to the New Brighton municipal water supply.

Army reports of investigations and studies at TCAAP (Phases I, II and III) in 1983 and 1984 identified major and minor disposal areas on the facility that were sources of release or threatened release of hazardous substances (mainly VOCs). In their review of these reports, MPCA and the U.S. EPA noted inadequate investigations and studies, the need to address the extent and magnitude of contaminated groundwater and the need to complete an assessment of the disposal areas identified on TCAAP.

In 1984 and 1985, Honeywell submitted (via the Army) investigative reports addressing VOC contamination at Honeywell-leased TCAAP Buildings 103 and 502 (Sites I and K). The reports indicated that the buildings' operations were a source of VOC-contaminated groundwater migrating toward Rice Creek from Building 103 and also to the west or southwest from the Building 502 area. As a result of these findings, Honeywell announced a three-phase off-TCAAP investigation on July 28, 1984, to supplement work being conducted by MPCA to identify off-TCAAP sources of release.

On May 28, 1985, MPCA released the Phase I RI report titled *Phase I Final Report, New Brighton/Arden Hills, Minnesota Multi-Point Source Remedial Investigation*. The report identified four potential source areas of release of VOCs in the study area that had possibly contaminated the area groundwater. The source areas included two areas at TCAAP and two areas adjacent to TCAAP. Phase IA RI activities were initiated in July 1986. The purpose of the Phase IA RI was to further define the nature and extent of groundwater contamination in off-TCAAP areas.

In the spring of 1985, the U.S. EPA initiated an investigation of the force mains off-TCAAP because a number of documented breaks had

occurred in the line in the study area and because VOCs and other hazardous wastes and metals had been detected in the sewer sediments on-TCAAP.

On June 6, 1985, the Army announced a plan to begin addressing groundwater contamination detected on-TCAAP. The plan included a proposed groundwater pump-and-treat system to address TCAAP groundwater contaminated with VOCs. The plan also identified Honeywell as the coordinator of the TCAAP groundwater cleanup effort. In 1986, the Army activated an in situ volatilization system at Sites D and G to remove VOCs from the unsaturated zone.

THE AGREEMENT

To facilitate cleanup of TCAAP, the Army entered into a federal facility agreement (FFA) with the U.S. EPA and the State of Minnesota pursuant to Section 120 of the SARA. The TCAAP FFA, which became effective on December 31, 1987, was the first agreement to be negotiated between the U.S. EPA and any federal agency since the enactment of SARA in 1986. The FFA calls for the on-TCAAP RI to be carried out by the Army, while the off-TCAAP RI is to be done by the state and the U.S. EPA. Following completion of both RIs, the Army will prepare the FS to evaluate alternatives for remediating the entire area of contamination.

Section 120 (e)(2) and (e)(4) of SARA require the U.S. EPA and the head of the responsible federal agency to enter into an interagency agreement at the end of the RI/FS to specify the agreed-upon final remedial action and to expedite its completion. In addition, Section 120 (e)(1) provides that the state and the U.S. EPA administrator will publish timetables and deadlines. The TCAAP agreement is an effort to combine these requirements into an integrated and more efficient document that involves U.S. EPA headquarters and the state, as well as the Army and the U.S. EPA regional office as participants and takes effect before the Army has finished the TCAAP RI/FS process. Thus, this FFA is an agreement "under Section 120" rather than strictly the interagency agreement described in SARA Section 120 (e).

Prior to entering into the FFA, the Army viewed the regulatory agencies, U.S. EPA and MPCA, in an advisory capacity only. Most often, these agencies were notified of the Army's intended actions after these actions were finalized and the agencies' abilities to influence or impact the actions were inhibited.

Purposes of the Agreement

The general purposes of this agreement are to:

- Ensure that the environmental impacts associated with past and present activities at TCAAP are thoroughly investigated and that appropriate remedial actions are taken to protect the public health, welfare and the environment
- Establish a procedural framework and schedule for developing, implementing and monitoring appropriate response actions in accordance with CERCLA/SARA, the National Oil and Hazardous Substances Pollution Contingency Plan, Superfund guidance and policy, RCRA and RCRA guidance and policy
- Ensure cooperation, exchange of information and participation of the parties in such actions

The specific purposes of the agreement are to:

- Identify interim remedial action alternatives appropriate for preventing further migration of contaminated groundwater prior to the implementation of final remedial action(s) for the site
- Establish requirements for the performance of an on-TCAAP RI to determine fully the nature and extent of the threat to the public health, welfare, or the environment caused by the release and threatened release of hazardous substances, pollutants or contaminants at TCAAP and to establish requirements for the performance of an FS for the site to identify, evaluate and select alternatives for the appropriate remedial action(s) to prevent, mitigate or abate the release or threatened release of hazardous substances, pollutants or contaminants at the site in accordance with CERCLA and SARA
- Identify the nature, objective and schedule of response actions to be taken at the site; response actions at the site shall attain that degree

of cleanup of hazardous substances, pollutants or contaminants mandated by CERCLA and SARA

- Implement the selected interim and final remedial action(s)
- Assure compliance with federal and state hazardous waste laws and regulations for matters covered by the agreement

Major Features of the Agreement

The TCAAP FFA contains 11 major features, which are presented below:

- *Point of Contact*: It provided a point of contact to assume responsibility for the Army. This was important to the U.S. EPA because it often could not identify the correct individual to contact regarding issues relevant to TCAAP.
- *Shared Responsibility*: It specified a shared responsibility among the regulatory agencies and the Army for conducting RI/FSs for the site.
- *Reimbursement of Oversight Cost*: It provided means of reimbursement to the U.S. EPA of past and future oversight costs as well as reimbursement of these costs to MPCA and the Minnesota Department of Health.
- *Specific Statement of Work*: It provided a specific statement of work for RI/FS, remedial design (RD) and implementation of remedial actions (RA) at the site.
- *Implementation of Interim Remedial Measures*: It provided for implementing interim remedial actions at the site, a device that the U.S. EPA has used extensively for remediation of contamination at the site (see next section).
- *Integration of RCRA, Section 3004(u) and (v)*: Currently, the U.S. EPA is in the process of delegating RCRA 3004(u) corrective action authority to states. Conforming with the terms of the FFA will satisfy the procedural requirements of Section 3004(u) and (v) and should accomplish the following:
  - Preserve cost-effectiveness as a criterion for selecting remedies
  - Bypass additional, needless and duplicative RCRA requirements, preventing increase of paperwork burden, staff time and administrative costs
  - Provide for unity of program management and more efficient allocation of resources
- *Dispute Resolution Process*: If, after proceeding through a multilayered dispute resolution process, the parties are unable to unanimously agree on the resolution of any given issue, the U.S. EPA administrator will make the final decision, providing a national, rather than a regional, perspective. Without giving written notice to the Secretary of the Army, the U.S. EPA administrator may not delegate this decision-making authority.
- *Exemption from Permits*: This provision precludes the time-consuming permit application process. The Army agrees to abide by all ARARs which such permits would have included.
- *Applicability of Citizens Suits*: While the terms and conditions of the FFA are enforceable by citizen suits brought pursuant to Section 310 of SARA, the actual effects of citizen suits are expected to be ameliorated by the provisions for *Schedule Modifications* and *Extension of Schedules*. The procedures for extending deadlines, if invoked in a timely manner, should revise schedules affected by delays due to circumstances that are beyond the Army's control (i.e., mechanical breakdowns, equipment shortages, harsh or hazardous weather conditions, contractor strikes, etc.), thereby providing the Army with a measure of extra protection from baseless or frivolous complaints.
- *Army to Reimburse the U.S. EPA and the State*: The costs incurred for oversight, investigation, new wells, etc., must be reasonable, consistent with the NCP under CERCLA (including the cost-effectiveness criterion) and subject to Army audit before being reimbursed.
- *Applicability of Penalties*: The U.S. EPA (not the state) may administratively levy fines against the Army for failure to comply with the requirements of the FFA. The fines stipulated in the FFA are lower than the maximum stated in SARA and should be avoidable as long as the Army uses the provisions for schedule modification/extension and dispute resolution. Moreover, if fines are imposed but

are accepted by the courts as constituting "diligent prosecution," citizen suits to enforce the FFA will be effectively precluded.

PROGRESS TO DATE

To date, significant progress has been made for remediation of contaminated soils and groundwater at the site. Some of the response actions were implemented by the U.S. Army before signing the FFA and some were implemented after the agreement. The response or cleanup actions may be divided into four groups: (1) alternative water supplies, (2) unilateral removal authority actions by the U.S. Army, (3) actions with U.S. EPA and state concurrence and (4) other actions initiated by the U.S. EPA and/or the U.S. Army.

Alternative Water Supplies

The alternative water supplies include a number of hookups of individual well owners to city water supplies and construction of interconnecting pipelines between cities. For the city of St. Anthony, an interconnect to the neighboring city of Roseville was made so that St. Paul municipal water supply already used in Roseville could be transported to St. Anthony via Roseville. The State of Minnesota currently has a cooperative agreement with the U.S. EPA to construct a carbon treatment system to treat water from the contaminated St. Anthony wells.

Another alternative water supply is a carbon treatment system for the City of New Brighton. This system was formally operational in June 1990 and was funded by the U.S. Army as part of a litigation settlement. While the U.S. Army signed a ROD for the New Brighton carbon system, the U.S. EPA never concurred with the ROD, but viewed it as an acceptable [to U.S. EPA] means for settling the litigation of the U.S. Army by the City of New Brighton.

Unilateral Actions by the U.S. Army

Unilateral removal actions by the U.S. Army are actions taken by the U.S. Army using its own delegated removal authorities under CERCLA Section 104. Most of these actions were implemented prior to the signing of the FFA. The two most successful actions in this group are the in situ soil vapor extraction (ISV) system for remediation of contaminated soils at Site D and Site G of TCAAP (Fig. 2). These ISV systems were implemented in 1986 and since then, each system has removed approximately 45 tons of VOCs per site. Their operational status is continually reported to the U.S. EPA and the state, with all modifications to the systems mutually agreed to by all three organizations. Other actions in this group are groundwater pump-and-treat systems at sites A, I and K.

The groundwater at Site A is contaminated with VOCs. To remove and treat contaminated groundwater at the site, an interim remedial action was initiated by the Army in 1988. This remedial action consists of a groundwater extraction and treatment system using liquid phase activated carbon. Sites I and K contain VOC-contaminated soils under buildings. Leaks from floor drains and sewer lines are identified as the likely source of contamination. Honeywell, an Army tenant, currently operates these buildings and has performed remedial actions. These actions were implemented in 1988 and include contaminated groundwater extraction and treatment by air stripping. The treated groundwater from Site K is discharged to a sewer under the NPDES permit issued by the state. The treated groundwater from Site I is discharged to the TCAAP groundwater recovery system (TGRS) for further treatment.

Actions with U.S. EPA and State Concurrence

The most significant action under this group includes the TGRS, which includes five source control (SC) wells downgradient of Sites D and G and a boundary groundwater recovery system (BGRS) along the southwest side of TCAAP. The objective of the BGRS was to contain and prevent continued migration of contaminants downgradient of TCAAP. To implement BGRS, the U.S. EPA prepared an ROD in September 1987. The ROD provided the specific criteria for the BGRS. After extensive negotiations among the U.S. EPA, MPCA and the U.S.

Army, the BGRS was implemented in late 1987. This phase of the BGRS included six Unit 3 extraction wells and three air stripping units for treating extracted contaminated groundwater.

A review of a 90-day performance report of the system by the U.S. EPA and MPCA indicated that the BGRS was not in compliance with the remediation criteria (full capture of the contaminated plume) established in the ROD. To comply with these criteria, the BGRS was expanded in 1989 to include six additional wells (two in Unit 3 and four in Unit 4) and one additional air stripping unit. The treated groundwater must meet maximum contaminant levels (MCL) established under the Safe Drinking Water Act before it may be discharged to a gravel pit on-TCAAP. Except for some background metals, all other discharge criteria are met. The capture criteria for the contaminants require the capture of all contaminated groundwater plume migrating off-TCAAP in excess of 10^{-6} cancer risk or a hazard index of one. It is up to the U.S. Army to demonstrate adequate capture to the satisfaction of the U.S. EPA and MPCA.

Other actions under this group include on-TCAAP RI, off-TCAAP RI, risk assessment of on- and off-TCAAP areas, FS, remedial design of appropriate response actions (RD) and implementations of these actions (RA). The on-TCAAP RI is prepared by the U.S. Army, the off-TCAAP RI is prepared by the state, the risk assessment is performed by the U.S. EPA and FS/RD/RA will be conducted by the U.S. Army. In addition, the U.S. Army will prepare annual monitoring reports covering more than 300 groundwater monitoring wells and IRAs. All documents prepared by the U.S. Army are reviewed by the U.S. EPA and the state for consistency and compliance with the requirements of the FFA.

The total mass of contaminants removed since implementation of the above interim remedial actions is presented in Table 1. The groundwater contamination plume for trichloroethene (TCE) in aquifer Units 3 and 4 are presented in Figures 3 and 4.

Table 1
Status of Interim Remedial Actions at TCAAP

IRA	Start Date[1]	Mass Contaminant Removed (lbs.)[2]	
Site A	09/13/88	2.1[3]	by December 1989
Site D	01/29/86	96,300[4]	by December 1989
Site G	02/20/86	90,000[5]	by December 1989
Site I	08/15/86	NA	NA
Site K	08/15/86	NA	NA
BGRS (6 wells)	10/19/87	6,800[6]	by January 1989
Expand BGRS (12 wells)	01/31/89	87,000[7]	by June 1989
SC Wells 2 to 5	01/31/89	25,000[7]	by June 1989

Notes:

1. Interim remedial actions at these sites are ongoing with anticipated completion dates when final remedial actions are implemented.

2. Cumulative mass of organic compounds removed by the dates indicated.

3. Between the start date and December 1989, approximately 2.5 million gallons of ground water have been treated at the site. Information was obtained from monthly operations report, dated January 1, 1990.

4. In the summer of 1989, approximately 1,400 cubic yards of PCB-contaminated soil were treated at the site using an infrared thermal treatment process. Information was obtained from ISV operation reports, dated January 2, 1990.

5. Information was obtained from ISV operation reports, dated January 2, 1990.

6. Estimated VOC removal based on BGRS Annual Monitoring Report, dated May 1989 (4,800 lbs. through October 21, 1988), and projected to be 6,800 lbs. by January 1989.

7. Estimated total VOC removal based on expanded BGRS (12 wells included Site I SC-1) and SC wells 2 to 5 (downgradient of Sites D and G) contaminant concentration data in the first and second quarterly monitoring report for 1989 by Army/Honeywell dated December 5, 1989; and ground-water extraction data in Table 1 of Draft ROD for PGRS by Honeywell dated May 15, 1989.

NA = Information is not available.

Other Actions Initiated by the U.S. EPA and/or the U.S. Army

Several other actions implemented at the site were initiated by either the U.S. EPA or the U.S. Army. Some of these significant actions are presented below:

- Thermal treatment of 1,400 yd^3 of PCB-contaminated soils at Site

D; the U.S. EPA prepared the ROD and risk assessment report
- Water management study to evaluate feasible alternatives for the disposal of treated groundwater anticipated from the future remedial measures; Phase I of this study has been completed and Phase II is currently underway
- Force main RI (Site J) and subsequent cleanup measures
  - Investigation and remediation of 83 aboveground and below ground storage tanks

RESOLUTION OF DISPUTES

The FFA set forth a procedure for resolution of disputes among the three organizations, the U.S. EPA, the state and the U.S Army. The disputes are resolved at the project manager's level. If project managers cannot reach an agreement on any issue within 14 days, then any party may elevates the dispute to the Dispute Resolution Committee (DRC) for resolution. If none of the parties elevate the dispute to the DRC within this 14-day period, the position of the U.S. EPA's project manager is final with respect to resolution of the dispute. The designated members of DRC are the Waste Management Divisional Director of U.S. EPA Region 5, the MPCA Executive Director and the Army's Deputy for Environmental Safety and Occupational Health.

Since the implementation of the FFA at TCAAP, no major disputes have arisen. The primary issues have included schedule of deliverables, hydrogeologic interpretations and technical aspects of the deliverables. These issues have been resolved at a project manager's level in a cooperative manner. The schedule of deliverables has generally been adjusted to ensure that quality of the documents is not sacrificed by the need to meet a deadline. The hydrogeologic interpretations and technical issues have been resolved by calling special meetings, with enough lead time for each party to assemble his/her data and to pre-

sent his/her viewpoint. This process of resolving issues or disputes at project manager and technical levels has resulted in good cooperation among all parties.

SCHEDULES AND WORKLOAD

A schedule of activities for the TCAAP site is shown in Figure 5. As shown in this schedule, several activities are currently underway, including the operation and maintenance of several interim remedial actions. All documents submitted by the U.S. Army, including performance evaluation of the interim remedial actions, are reviewed by the U.S. EPA and state for technical adequacy and consistency with the requirements of the agreement. The review time established in the agreement is 40 calendar days. However, the complex documents, such as on- and off-TCAAP RIs or other similar documents that require longer review time, have been granted mutually agreeable extensions. This is to ensure that quality of the documents is not compromised by the need to meet the rigorous and stringent schedules.

In general, considering the large magnitude and complexity of the site, the number and length of delays have been similar to or better than other Superfund sites in the region. Individual documents sometimes appear to take a long time to finalize (6 months for example), but this is due to resolving any issues on the drafts and then delaying the final issuance while resources are focused on more time-critical projects (e.g., the completion of the design of an IRA).

CONCLUSION

This paper presents highlights of the first federal facilities agreement in the country pursuant to Section 120 of CERCLA/SARA for remediation of soils and groundwater contamination at the New Brighton/Arden Hills Superfund site in Ramsey County, Minnesota. It discusses the

Figure 3
TCE Groundwater Contamination Plume in Unit 3

Figure 4
TCE Groundwater Contamination Plume in Unit 4

Figure 5
Schedule of Activities for TCAAP Site

experiences gained and progress made through the implementation of the agreement at this very large and complex site.

The agreement requires that all documents submitted by the U.S. Army be reviewed by the U.S. EPA and the state for technical consistency within 40 calendar days. There are several activities concurrently being conducted at the site. To perform consistency tests within the specified schedule is and has been a challenge for the three organizations and their contractors. To meet this challenge and ensure high quality work has required innovative management procedures and prompt allocation of resources on the part of all participants. The spirit of cooperation shown by all participants in resolving technical and schedule-related issues has been crucial in successfully implementing the agreement.

Field Detection Kits for TNT and RDX in Soil

Hanover, New Hampshire

ABSTRACT

The U.S. Army Toxic and Hazardous Materials Agency (USATHAMA) and the Naval Weapons Center, China Lake, jointly developed an indicator tube in the mid-1980s for the detection of TNT in Army Ammunition Plant effluents. The tubes were later adapted for use in field detection of TNT in groundwater and soil. These tubes have been used extensively by the Army to assist in locating explosives-contaminated areas and in placing monitoring wells.

Recently, the U.S. Army Cold Regions Research and Engineering Laboratory (CRREL) and USATHAMA have developed a simpler, faster and more quantitative method for TNT determination in soil. Soils are extracted with acetone and quantitation is based on production of the highly colored Jackson-Meisenheimer anions with strong base. Measurement is obtained with a field-portable spectrophotometer at 540 nm.

A similar method has also been developed for RDX. The soils are extracted with acetone and the extracts are passed through a disposable, strong anion exchange resin to remove any nitrate and nitrite present. RDX is then reacted with zinc and acetic acid to produce nitrite, and the nitrite concentration is measured using the two-step Griess reaction. Measurement is also obtained colorimetrically at 540 nm.

INTRODUCTION

One of the most serious environmental problems facing the U.S. Army today is the presence of soil contaminated with munitions residues at military installations throughout the United States. TNT and RDX are the two explosives most commonly observed in munitions-contaminated soils because of their widespread use and their long-term stability in the environment. Further, because of their mobility in the soil profile, TNT and RDX pose an immediate problem for groundwater contamination.

Field screening methods can be rapid, inexpensive tools for locating explosives-contaminated surface soils. They can be useful in initial site surveys to locate zones of high contamination and select samples for more in-depth laboratory analysis. They also can be used during site cleanup to accurately locate the clean soil/contaminated soil interface.

Background of TNT Test

As early as 1891, Janovsky[1] observed that colored reaction products were formed when polynitroaromatic compounds reacted with alkali such as potassium hydroxide. Meisenheimer[2] and Jackson and Earle[3] independently proposed a quinoidal structure to explain this phenomenon. Equation 1 shows the production of the Jackson-Meisenheimer anion from 2,4,6-trinitrotoluene (TNT). In general, Jackson-Meisenheimer anions for dinitroaromatics are blue to purple

in color, while those from trinitroaromatics are red.[4]

$$ (1) $$
When sulfite ion is present along with hydroxide, addition of sulfite to the aromatic ring also can occur.[5] This anion is more stable than the anion formed from hydroxide alone,[6] with stabilities extended from approximately 30 minutes for the hydroxide complex[7] to at least six hours.[6]

When the base-catalyzed reaction takes place in a ketone solution such as acetone (Janowsky reaction), addition of the carbanion (Equation 2) can also result.[8]

$$ (2) $$
These reactions have been used analytically for a number of applications. Yinon and Zitrin[9] show examples of their use for forensic detection of TNT in post-blast debris. Heller et al.[10] used the reaction of strong base with TNT as the basis of a field kit for detection of low levels of TNT in water. The use of this kit was later extended to estimation of TNT in soil extracts.[11] A discussion of their procedure, its method of detection, and an assessment of its utility are presented elsewhere.[12] In general, the kit provides a field method to detect the presence of TNT in soil, but is less useful for estimating concentration.

Background of RDX Test

Colorimetric chemical methods for RDX have been developed for forensic application.[9] These procedures generally rely on sequential reactions where RDX is first converted to nitrous acid using the Franchimont reaction (Equation 3). The nitrous acid is used to nitrosate an aniline derivative such as sulfanilic acid (Equation 4) and the resulting diazo cation couples to a naphthylamine (Equation 5) to form a highly colored azo dye (Griess Reaction). Several other pairs of reagents may be used to produce azo dyes.[13] A reagent containing procaine and N,N-dimethyl-naphthylamine is used for the test described in this paper. Wyant[14] tested several reagents and found this combination to be best in terms of detection capability and shelf life. The authors are not aware

of a field method for RDX in soil based on this reaction sequence.

$$\text{RDX} + \text{Zn} \xrightarrow{\text{Acetic Acid}} 3\,HNO_2 \qquad (3)$$

Franchimont Reaction (1897)

$$HNO_2 + \text{(aniline)} \rightarrow \text{(diazonium)} \qquad (4)$$

$$\text{(diazonium)} + \text{(naphthylamine)} \rightarrow \text{Azo Dye} \qquad (5)$$

Griess Reaction (1864)   Azo Dye
OBJECTIVE

The objective of the research described here is to develop simple, rapid field methods to estimate TNT and RDX concentrations in soil. The chemicals and equipment needed should be usable under field conditions by analysts with only minimal chemical expertise. The method should not require electrical power so that measurements can be made at the site of potential pollution. It should be rapid enough to allow decision-makers on-site to utilize the results to make judgments regarding the need to take additional samples for laboratory analyses or, under a cleanup scenario, continue or halt soil excavation.

EXPERIMENTAL

Analytical Standards

Analytical standards for 2,4,6-trinitrotoluene (TNT) and hexahydro-1,3,5-trinitro-1,3,5-triazine (RDX) were prepared from Standard Analytical Reference Material (SARM) obtained from the U.S. Army Toxic and Hazardous Materials Agency (USATHAMA), Aberdeen Proving Ground, Maryland. The SARMs were dried to constant weight in a vacuum desiccator in the dark, and standards were prepared in HPLC grade acetone.

Soils

Soils used for laboratory extraction studies included field-contaminated and uncontaminated soils from a number of present and former military installations in 10 different states. Interference tests utilized a commercial potting soil obtained locally that was rich in humus and uncontaminated soils from a variety of military installations.

Soil Extraction

Soils were extracted by manually shaking a 20-g sample for 3 minutes with 100 mL of acetone and filtering the extracts with Millex-SR disposable syringe filters.

Removal of Nitrate and Nitrite

Nitrate and nitrite ions were removed from acetone soil extracts by passing 10 mL of the extract through a disposable strong anion exchanger (Supelco, Alumina-SAX) at 5 mL/min.[22]

Generation of Jackson-Meisenheimer Anions for TNT Test

A pellet of potassium hydroxide (KOH) and approximately 0.2 g of sodium sulfite were added to 20 to 25 mL of acetone soil extracts. Samples were manually shaken for 3 minutes, then filtered through a Millex-SR filter unit into a cuvette. Absorbance was read at 540 nm.

Production of Azo Dye from RDX

Acetone soil extracts were passed through an Alumina-A strong anion

exchange cartridge at 5 mL/min to remove any nitrate and nitrite which could be present. A 5-mL aliquot was acidified with 0.5 mL glacial acetic acid and reacted with 0.3 g of zinc dust in the barrel of a syringe fitted with a disposable filter unit. This solution was rapidly filtered into a vial containing 17 mL of a Griess color developing solution. The color developing solution was prepared by dissolving 0.35 g each of procaine and N,N-dimethylnaphthylamine in 100 mL of 1/1 glacial acetic acid-water. Prior to use, this solution was further diluted 5/12 v/v with water.

Spectrophotometers

Spectrophotometers were used to measure absorbance at various wavelengths in the visible region of the spectrum. A Coleman Junior II (Model 6/20) was used for laboratory tests and either a Hach DR/2 or DR/2000 was used in the field.

DEVELOPMENT OF TNT METHOD

Absorbance Spectra of Analyte Anions in Acetone

A 2.1-mg/L solution of TNT was prepared in 95% acetone—5% water and Jackson-Meisenheimer anions generated as described above. The absorbance spectrum was obtained from 400 to 600 nm (Fig. 1). Two λ_{max} were observed, at 462 and 540 nm, the molar absorptivities being 2.70×10^4 and 1.77×10^4 L/cm · mole, respectively. This solution was visually red.

A number of other nitroaromatics, nitramines, nitrate esters and polynitrophenols were tested under similar conditions and the visible spectrum of their anions obtained (Table 1). Clearly, several other

polynitroaromatics and polynitrophenols also give colored anions under these conditions that would be very difficult to distinguish from TNT. During site cleanup activities, however, the ability to detect tetryl or TNB as well as TNT may be quite useful.

Effects of Variable Concentrations of Water in Acetone Extracts

Extraction of moist field soils with acetone will result in extracts containing variable concentrations of water. A test was conducted to assess the effect of variable water concentrations on the absorbance of TNT anions in acetone.

A series of 1.9-mg/L solutions of TNT in acetone was prepared with water contents ranging from 0 to 53% by weight. Jackson-Meisenheimer anions were generated and absorbances obtained at 540 nm (Table 2).

Table 2
Effect of Various Water Contents on the Absorbance of TNT Anions in Acetone

Concentration of water in acetone (% by weight)	Corresponding* soil moisture content (% of wet weight)	Absorbance (540 nm) for 1.9 mg/L TNT solution (AU)
0.0	0.0	0.076
3.0	12.2	0.183
5.9	24.8	0.181
8.9	38.7	0.158
11.7	52.5	0.140
17.4	83.4	0.136
28.2	**	0.054
53.4	**	0.014

* Corresponding soil moisture contents on a wet weight of soil basis if 20 g of soil is extracted with 100 mL of acetone.

** Exceeds possible water present in 20 g of wet soil.

The results indicate that absorbance is dependent on the amount of water present in the acetone. At intermediate concentrations of water in acetone (1 to 17%), however, similar absorbances (+/− 15%) are obtained. If a 20-g sample of wet soil is extracted with 100 mL of acetone, the 1 to 17% range of water in acetone would correspond to soil moisture contents ranging from 5 to 83% (on a wet weight of soil basis). This range of moisture content should include the large majority of surface soils from potentially contaminated sites.

Reagent Contact Time

Experiments were conducted to determine if reagent (KOH, Na_2SO_3) contact time had an effect on measured absorbance.[19] Contact time was varied from 1 to 18 minutes, after which solutions were filtered and absorbances measured. All experiments were conducted at laboratory temperatures (22° +/− 2°C).

Maximum absorbance was obtained by 3 minutes in all cases. Exposure to the reagents for longer periods resulted in reduced absorbance at 540 nm. Thus, a 3-minute reaction time was selected.

Field tests at Eagle River Flats, Alaska, indicated that at lower reaction temperatures, 3 minutes was not sufficient for full color development. An experiment to relate proper reaction time to ambient temperature is planned. Under field conditions, a standard solution can be used to select the time appropriate for a specific circumstance.

Experiments were conducted to determine the stability of the color after filtering.[15] The results indicate that color in filtered solutions is stable for at least 2 hours.

Instrument Calibration

Experiments were conducted to determine whether this procedure results in linear calibration curves.[15] Using least-squares regression analysis at the 95% confidence level and lack-of-fit testing, linearity and zero intercept were established for the concentration range 0.5 to

50 $\mu g/g$ (absorbances less than 0.9 AU). Thus for daily calibration a replicated single point standard is sufficient.

Background Absorbance of Blank Soils

Experiments with a variety of blank soils indicated that the color of acetone extracts will vary from colorless to yellow. An example of the visible absorbance spectrum of a commercial potting soil before and after addition of the reagents is shown in Figure 2. The initial absorbance of the soil extract was considerably greater between 400 and 500 nm than between 500 and 600 nm. After the extract was allowed to react with KOH and Na_2SO_3, the absorbance approximately doubled over the entire range of wavelengths, with rather large absorbances toward 400 nm.
Figure 2
Visible Absorbance Spectrum of Acetone Extract
of High-Humus Potting Soil, Before and After Addition
of KOH and Na_2SO_3

The results of this test indicate that a blank absorbance measurement must be made on acetone soil extracts prior to addition of KOH and Na_2SO_3 to account for background absorbance of humic materials that could be present in the extracts. To determine if the factor-of-two increase in absorbance for the potting soil extract is typical of other soils, extracts from a series of blank soils from eight different military sites were tested. The ratio of the absorbance at 540 nm after reagent addition to that before reagent addition ranged from 1.1 to 3.5 with a mean value of 2.1 (Table 3). Thus, to correct for background absorbance, the initial blank reading should be doubled and subtracted from the absorbance reading obtained after addition of the reagents.

Extraction Efficiency of Field Procedure

For a field method to provide accurate estimates of TNT concentration in the soil, the extraction step must be rapid. Previous extraction

studies indicated that long extraction times were required when acetonitrile or methanol were used as the extraction solvent.[16]

In order to determine how rapidly acetone will extract TNT from soil, 16 field-contaminated soil samples from nine different sites were extracted with acetone using 3 minutes of manual shaking. An aliquot of the extract was removed and the remaining soil/acetone slurries were placed in an ultrasonic bath for 18 hours. Both sets of extracts (3 minutes and 18 hours) were analyzed by RP-HPLC as described elsewhere;[15,17] the results are presented in Table 4. The average recovery after 3 minutes of manual shaking with acetone was 96.1% of that obtained with the more exhaustive procedure, indicating that acetone is an excellent extraction solvent with respect to its extraction kinetics.

Comparison of TNT Concentration Estimates for Soil Extracts

The extracts obtained after manually shaking the soil with acetone, as described above, were also analyzed by a colorimetric procedure utilizing the Jackson-Meisenheimer anions. A 20-mL sample of the extract was placed in a scintillation vial, KOH and sodium sulfite were added and the vials were shaken manually for 3 minutes. The vials were allowed to stand for 5 minutes and the solution filtered into a clean cuvette. The initial absorbance, before the reagents were added, was doubled and subtracted from the absorbance obtained after reagent addition, and the resulting difference was used to estimate TNT con-

* Obtained from a separate subsample using acetonitrile extraction, as described in Jenkins et al. (17).

centration. TNT estimates for the 16 field-contaminated soils are given in Table 5. For comparison, the results of analysis of the extracts for TNT by the standard RP-HPLC procedure[17] also are presented, along with the estimates of TNB concentration obtained from a separate subsample extracted with acetonitrile. TNB could not be reliably determined in acetone extracts due to its instability in acetone.

The colorimetric results were correlated with both the TNT estimate by HPLC and the sum of TNT and TNB. The correlation with TNT alone resulted in a slope of 0.59 and an R^2 of 0.943. The correlation with TNT plus TNB resulted in a slope of 0.86 and an R^2 of 0.985 (Fig. 3). A paired t-test indicated that the concentration estimates for TNT from the colorimetric method and the sum of TNT and TNB by the HPLC procedure were not different at any level of significance. Thus it appears that the colorimetric results are best represented as the sum of TNT plus TNB. The slope of 0.86 indicates that, in general, the colorimetric procedure gives a slightly greater estimate for TNT than can be accounted for by TNT and TNB (Fig. 3). One interpretation of these results is that other TNT degradation products such as trinitrobenzoic acid, trinitrobenzyl alcohol, and trinitrobenzaldehyde,[18] which are not identifiable by RP-HPLC analysis of the extracts, form colored Jackson-Meisenheimer anions.

$$Y = 2.614 + 0.858 [x]$$
$$R^2 = 0.985$$
$$N = 16$$
Figure 3
Correlation of Concentration Estimate Using Colorimetric Method for TNT Versus the Sum of TNT and TNB from RP-HPLC Analyses

Estimation of Detection Capability

The reporting limit for this procedure was established using the method of Hubaux and Vos[19] as described in USATHAMA.[20] The calculated certified reporting limit was 0.72 µg/g. A lower CRL would be obtained, however, if lower spike levels were included in the test.[21]

Field Testing

The method was given an initial field test at Umatilla Army Depot, Umatilla, Oregon. Since TNT concentrations were expected to be very high, a smaller subsample of soil was used and the extracts were diluted before reacting with KOH and Na_2SO_3.[15] This field test was conducted before the importance of reagent contact time was understood. Contact times of 10 minutes were used here.

The remainder of each soil/sediment sample was returned to the laboratory and analyzed for TNT using the standard laboratory procedure.[17] The results are included in Table 6 for comparison.

Except for sample 8a, the results of laboratory analysis are higher than those obtained using the field method. Correlation analysis of the field and laboratory results was conducted. Sample 8a was not included in the correlation analysis since very different behavior was observed

Table 6
Comparison of Results of Field Samples from Umatilla Depot Using Field and Laboratory Methods

Both laboratory and field method results are reported on a dry weight of soil basis to allow direct comparison.

Results for this sample were very different than observed for others and, because of very high values, the results were not included in correlation analysis.

for this sample and the TNT concentration was an order of magnitude higher than for any of the other samples. The correlation for the remaining 10 samples was excellent, with an R2 value of 0.865 which was significant at the 99% confidence level. The slope of the best fit relationship was 0.627, indicating the field procedure, on the average, gave results only about 63% as high as the laboratory results.

Two factors may have contributed to the low results for the field method. First, an excessively long reagent contact time prior to filtration was used. Thus, the absorbance would have been reduced relative to its maximum value. Second, the TNT concentrations in the Umatilla soil were much higher than those in the other field-contaminated soils tested, and the percentage extracted in the short extraction time used by the field method could have been reduced compared to the 18-hour extraction with acetonitrile used in the laboratory procedure. Nevertheless, the field results were encouraging for a first test.

An additional field test was conducted at Eagle River Flats, Alaska. All soils except one were determined to be free of TNT and other nitroaromatics by the field procedure, and these results were verified by the standard laboratory method.[17] One yellowish extract developed
Figure 4
Visible Absorbance Spectrum of the Azo Dye Produced from RDX

a greenish color upon reaction with KOH and Na_2SO_3 and was found to contain 2,4-DNT at about 30 μg/g. Reaction with 2,4-DNT standards produces a bluish color which, when combined with the yellowish background, results in the observed greenish color. This color faded rather quickly, however, unlike color produced by TNT.

DEVELOPMENT OF RDX METHOD

Absorbance Spectra for Azo Dye Produced from RDX

A 4.0-mg/L solution of RDX was prepared in 97% acetone-3% water and the azo dye produced as described above. This solution had a bright pink color. The absorbance spectrum shows a λ_{max} at 535 nm (Fig. 4), and the molar absorptivity is 1.67 x 10^4 L/cm · mole. The same azo dye also is produced when HMX, NG, NC or PETN are treated under similar conditions.

Effects of Variable Concentrations of Water in Acetone Extracts

In the field, soil extracts will be obtained by manually shaking 20 g of soil with 100 mL of acetone. Since the soil will be moist in most cases, water will be a component of the soil extracts. An experiment was performed to see how variable amounts of water affect the production of the azo dye.

To simulate the extracts obtained from soils with moisture contents ranging from 5 to 100% (wet weight basis), 10-mL aliquots of a solution containing 2.3 mg/L of RDX were mixed with either 0.1, 0.2, 0.3, 0.5, 1.0 or 2.0 mL of water. The azo dye was produced as described previously. Absorbance was found to vary with the amount of water present (Table 7), with maximum absorbance for the case simulating a soil with a moisture content of 25% (wet weight basis).

Table 7
Effects of Various Water Contents on the Absorbance Obtained from RDX Tests

Volume (mL) water added to 10 mL acetone	Corresponding soil moisture content (% of wet weight)*	Absorbance (540 nm) for 2.3-mg/L RDX solution	
0.1	5.0	0.150	
0.2	10	0.3	0.3
0.5	25	0.425	
1.0	50	0.421	
2.0	100	0.399	

*Corresponds to soil moisture content if 20 g of wet soil is extracted with 100 mL of acetone.

Reagent Contact Time

Development of the azo dye from RDX is a two-step procedure. First, the RDX is reacted with zinc dust and acetic acid to produce nitrous acid. The nitrous acid then reacts with a Griess color reagent to produce the azo dye.

The amount of time the RDX is allowed to react with the zinc dust and acetic acid is critical.[22] Initial experiments with RDX dissolved in acetone indicated that a 10-minute contact time was required to reduce RDX. However, if a small amount of water was present in the acetone, as will be the case with soil extracts, the reaction kinetics were much faster. Contact times exceeding 30 seconds resulted in less nitrous acid production, presumably because the nitrous acid was further reduced to ammonia. Once the nitrous acid is produced, the solution must be filtered to remove the zinc dust. Because of the fast kinetics, this filtration is conveniently performed by reducing the RDX in the barrel of a syringe fitted with a disposable filter unit as described previously. Once the filtered solution is added to the color developing solution, full color development takes approximately 15 minutes (Fig. 5). The color is stable for several hours.

Background Absorbance from Blank Soils

The acetone extracts from soils high in humic material will be yellow. However, once the acetone extract is acidified and mixed with the color reagent, the humic material precipitates and may be removed by filtration. Experiments[22] with a wide variety of blank soils showed that background was negligible in all cases.
Figure 5
Kinetics of Color Development for Griess Reaction

Extraction Efficiency of Field Procedure

The field method described previously for TNT was used for RDX and compared to the standard laboratory procedure (Table 8). For the seven soils tested, the average recovery obtained by manual shaking with acetone was 98.4% of that obtained by the sonic bath procedure.

Table 8

† Relative to laboratory procedure.

Comparison of RDX Concentration Estimates for Soil Extracts

Eleven field-contaminated soils were used to compare the RDX concentrations estimated by the field method with those obtained by RP-HPLC analysis.[17] The results using the field method were correlated with those obtained by the HPLC method for both RDX alone and the sum of RDX and HMX (Table 9). The correlation for RDX resulted in a slope of 1.1 and an R^2 of 0.986 (Fig. 6). The correlation with RDX plus HMX resulted in a slope of 1.2 and an R^2 of 0.990. Paired t-tests indicated that the estimates of RDX concentration obtained by the field procedure were not significantly different from those obtained by the HPLC procedure for RDX alone or for the sum of RDX and HMX.

Effect of the Presence of TNT in Soil Extracts

For the RDX field method, the presence of RDX is indicated by the development of a pink color. As shown in Table 9, some other colors were produced from extracts of field-contaminated soils. Red was produced in those soils containing very high concentrations of RDX (i.e., greater than 1 mg/g). Orange was produced in those soils containing high concentrations (i.e., greater than 50 µg/g) of TNT or

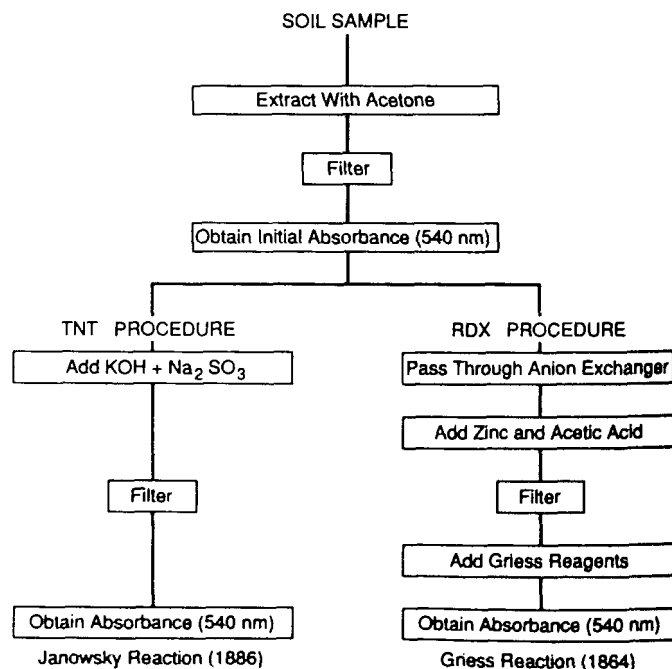

Figure 7
Flow Chart for Field Methods for TNT and RDX

TNB, as determined by RP-HPLC. While standards of TNT or TNB alone do not produce a color, standards containing RDX and TNT result in the same orange observed in some soil extracts. Nitroaromatic compounds, such as TNT and TNB, may be reduced to aminoaromatic compounds in the presence of zinc and acid. We speculate that these reduction products can be nitrosated by the nitrous acid produced from RDX and, like sulfanilic acid or procaine, couple to the naphthylamine in the color-developing reagent, producing another azo dye. Thus, in the field, development of a pink to red color indicates that RDX is the principal contaminant, while development of an orange color is evidence for both TNT and RDX together.

One soil extract developed a brownish-yellow color. As determined by RP-HPLC, this soil was also contaminated with TNT (>745 μg/g), 2,4-DNT (42.7 μg/g) and 2-amino-4,6-DNT (37.1 μg/g). A standard containing these analytes at concentrations similar to the soil extract resulted in a yellow color.

Estimation of Detection Capability

The reporting limit of RDX concentration using this field procedure was estimated using the method of Hubaux and Vos[19] as described in USATHAMA.[20] The calculated certified reporting limit was 1.4 μg/g.

Field Testing

This method was field tested at Eagle River Flats, Alaska. Of the 40 soils tested, no soil produced a positive result for RDX. All soils were also analyzed by RP-HPLC and no evidence of RDX was found. The method was found to be usable under field conditions, but certain precautions have to be taken. The color- developing reagent will turn pink if not protected from sunlight. Glacial acetic acid must be kept from freezing to allow volumetric addition; it has a melting point of 16.6°C. Lastly, high humidity will cause the zinc dust to clump; therefore, it should not be placed into the syringe barrel until immediately before use.

CONCLUSION

A flow chart of the two field procedures is given in Figure 7. For these field methods, soils are extracted by manually shaking a 20-g portion of soil with 100 mL of acetone for 3 minutes. A 25-mL aliquot is removed for the TNT test and filtered through a Millex SR disposable filter assembly and the initial absorbance obtained at 540 nm. One pellet of KOH and approximately 0.1 to 0.5 g of Na$_2$SO$_3$ are added and the extracts are manually shaken for 3 minutes. The solutions are immediately filtered through another Millex SR filter and the absorbance at 540 nm is measured again. Absorbance was found to follow the Beer-Lambert Law through the absorbance of 0.91 AU.

For the RDX test, approximately 10 mL of the acetone soil extract are filtered through a Millex SR disposable filter unit and then passed through an Alumina-A anion exchange cartridge. This procedure is necessary to remove nitrate and nitrite that would otherwise give a false positive result for RDX. Next, the plunger of a 10-mL syringe is removed and a filter unit is fitted to the syringe tip. A measuring spoon is used to add 0.3 g of zinc dust to the syringe barrel. A 5-mL aliquot of the filtered soil extract is acidified with 0.5 mL glacial acetic acid, swirled to mix and poured into the barrel of the syringe. After approximately 15 seconds, the plunger is fitted to the syringe and depressed. The solution is filtered into 17 mL of a Griess color-developing reagent and, after 15 minutes, the absorbance is read at 540 nm. If the solution is cloudy due to precipitation of humic material, the solution is filtered prior to measuring absorbance.

TNT and RDX concentrations were estimated using these field methods for a number of field-contaminated soils, and the results were compared with those from the standard laboratory procedure. Excellent linear correlations were obtained in both cases.

Field tests of these procedures were conducted and the methods were found to be quite usable under field conditions.

ABSTRACT

Regional, three-dimensional, groundwater flow and solute-transport models were constructed at the Louisiana Army Ammunition Plant (LAAP). This work was performed in support of a Feasibility Study/Risk Assessment primarily focused on the problems of nitroaromatic contamination of the shallow groundwater at the site.

LAAP is located in the northwest portion of the State of Louisiana on lands situated in Bossier and Webster parishes, 22 miles east of Shreveport. Previous investigations have revealed groundwater problems from several sources: (1) wastewater (pink water) leaching pits, (2) unlined ponds containing metals manufacturing wastes, (3) abandoned landfills, (4) explosive loading areas and (5) burning ground areas.

One of the primary waste products of an ammunitions plant is pink water, the common name for wastewater contaminated with explosives such as 2,4,6-TNT or RDX. Pink water was dumped in various lagoons across the site for nearly forty years. Some of the explosive compounds and their by-products are toxic. The objective of this modeling study was to predict the future concentrations of these toxic compounds and their location in groundwater as part of the feasibility study risk assessment.

MODFLOW, a numerical model published by the U.S. Geological Survey, was used to simulate the regional groundwater flow at the site. The flow system was represented as three aquifers. The top aquifer was an unconfined aquifer in the upper Pleistocene section. The second aquifer included the lower Pleistocene and the upper Eocene Sparta Sand. The third aquifer comprised the Paleocene/Eocene Wilcox-Carrizo aquifer.

The output from MODFLOW was used as input to a translation program, PREMOD3D, to convert potentiometric heads to three-dimensional velocity vectors, which are in turn used as input to RAND3D, the solute-transport program.

RAND3D is a three-dimensional solute transport model based on the random walk algorithm. Several significant improvements were made to the model for this study. The program allows the user to simulate the movement of contamination and includes the effects of advection, dispersion, retardation and decay. The temporal progression of the plume is graphically displayed on the computer screen during the simulation at a scale selected by the user. RAND3D simulated the fate of the contamination at each of the six sites.

INTRODUCTION

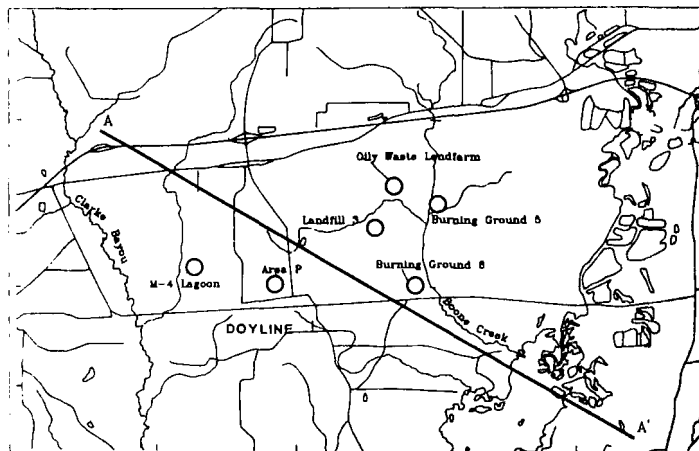
The objective of the study was to define the regional flow system and the fate of the groundwater contamination at six areas within the Louisiana Army Ammunition Plant (LAAP) in support of the feasibility study/risk assessment being performed. The Louisiana Army Ammunition Plant is a government-owned and contractor-operated facility in northwestern Louisiana where munitions are loaded and packed. The plant was constructed in 1942 and has been in continuous operation since. Munition loading and waste disposal operations have contaminated groundwater at this site in a number of specific locales: Area P, Burning Ground No. 8, Burning Ground No. 5, Landfill No. 3, the Oily Waste Landfarm and the M-4 Lagoon. Figure 1 shows the locations of these areas and the general location of LAAP.


Figure 1
LAAP Study Sites

The area of greatest concern is Area P. Pink water, the common name for water containing dissolved nitroaromatic compounds, was dumped into unlined lagoons at Area P for nearly forty years. Previous investigations have yielded conflicting information on the size of the plumes and the direction of contaminant movement. Contamination has been found off-site and in what were thought to be up-gradient monitoring wells. Some of the more pressing questions included:

* Where is the contamination going? Previous studies suggest a west-southwest movement off the site toward the municipal well field of Doyline.
* Are any of the three municipal well fields located within a 3-mile radius of Area P going to be affected and when?
* Is the LAAP well field itself drawing the contamination into deeper horizons?
* What will be the effect on the contaminant plumes if the LAAP is decommissioned and on-site pumping stops?

A regional, steady-state three-dimensional groundwater flow model was developed and calibrated to both steady-state and transient conditions. This flow model was used as input to a random walk solute transport model.

GEOLOGY

The flow system at the LAAP was represented by three aquifers (Fig. 2) At the surface there are Pleistocene terrace deposits composed of alternating beds of mixed sands, silts and clays typical of Mississippi Coastal Plain sediments. For purposes of hydrogeologic modeling, the Pleistocene interval was divided into two aquifers. The aquifer boundaries were defined by the water table surface on the top and a semicontinuous clay layer on the bottom, and it is known as the Upper Terrace. This clay was used as the boundary between the top and the middle aquifer. However, the Upper Terrace is not continuous and pinches out in the southeast section of the model area.
Figure 2
Regional Geographical Section

Constant head nodes were used at the edges of all layers to simulate the continuation of the aquifers. The constant heads were based on historic water levels, topography and adjustments made during calibration where data were sparse.

The middle aquifer is comprised of the lower Pleistocene terraces and the Eocene Sparta sand below. The hydrogeologic characteristics of the lower Pleistocene are similar to the Sparta and the two units were combined into one aquifer known as the Lower Terrace/Sparta. The Sparta lies unconformably below the Pleistocene terraces and consists of nonmarine massive sands, silty sands and silty shales, with occasional lignite and lignitic shales.

Below the Sparta is the Cane River Formation, the middle member of the Eocene Claiborne Group. It consists primarily of marine clay with abundant foraminifera, but also contains some silt and shale. The Cane River, where present, forms the confining layer between the second and third aquifers.

The deep aquifer, though it is called the Wilcox-Carrizo, is actually composed of mostly Wilcox Group at the LAAP site. The Wilcox group sediments consist mainly of nonmarine, white to grey, thin-bedded, micaceous sands and sandy shales with numerous thin lignites which lie on the Midway Group. The group is from upper Paleocene to lower Eocene in age. Regionally, the sequence varies in thickness from 350 to 1000 feet; however, thicknesses at LAAP only reach 550 feet.

The Midway Group was formed during the stand of the early Tertiary Sea and consists of the basal uniform marine black shale 500 to 600 feet thick. The clays are described as dense and are considered to be an effective lower confining layer to the aquifer system.

FLOW MODEL

The USGS MODFLOW model was used to simulate the regional groundwater flow at the arsenal. The groundwater flow system was set up as a three-layer model. The first layer was the Upper Terrace in the unconfined top Pleistocene terrace interval. The second layer was made up of the Lower Terrace/Sparta in the confined aquifer made up of the bottom Pleistocene terrace interval plus the Sparta sand that lies beneath. The bottom aquifer was the Wilcox-Carrizo located between the Cane River Formation and Midway confining beds. The Cane River Formation was modeled as a confining layer.

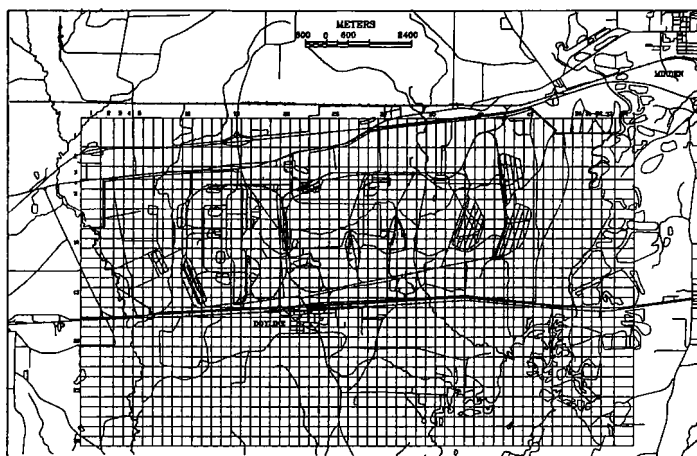
A 54-column by 30-row model grid was developed (Fig. 3) to simulate an area large enough to permit accurate simulation of well-field pumping on the LAAP and local municipalities; the grid also is spaced close enough for contamination simulation. The minimum grid spacing was 900 feet. The model was calibrated at steady-state using the monitoring well level data for all three aquifers. The average difference between the model and actual data was 0.06 feet and the root-mean-square difference was 4.76 feet (73 wells in the Upper Terrace and Lower Terrace/Sparta aquifers). The calibrated water levels for the three layers are shown in Figures 4 to 6.


Figure 3
Model Grid
Figure 4
Calibrated Water Levels Upper Terrace Aquifer

SOLUTE TRANSPORT

Solute transport was simulated at each site separately, as differentiated from the regional flow model. The program PREMOD3D calculated the groundwater velocities at each contamination site based on the calibrated water levels. The three-dimensional random walk

model RAND3D utilized these velocities to simulate the solute transport at the six sites.

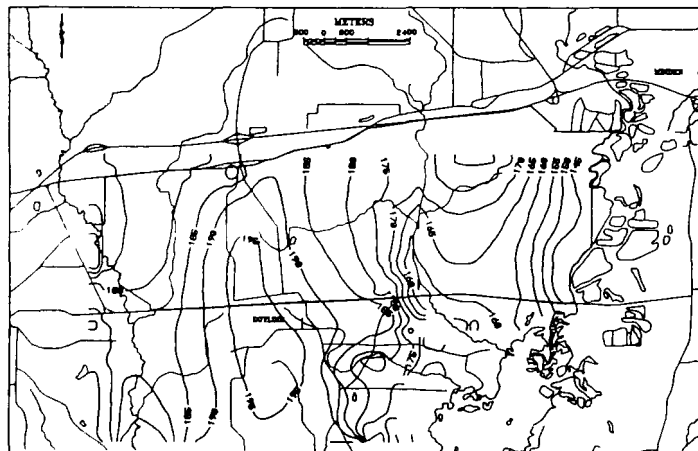
The explosive compounds simulated were the compounds found in the greatest concentrations and presented the greatest potential risks based on their toxicity. The most common contaminant was RDX, but other pollutants such as TNT, DNT and TNB also were simulated. Initial conditions of the pollutants were taken from previous remedial investigations. Figure 7 shows the initial RDX plume at Area P for the Upper Terrace aquifer and Figure 8 shows the initial RDX plume for the Lower Terrace/Sparta aquifer.


Figure 5
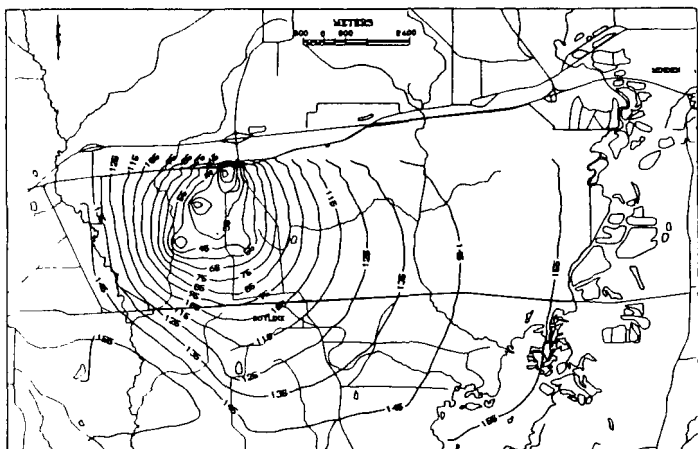
Calibrated Water Levels Lower Terrace/Sparta Aquifer


Figure 6
Calibrated Water Levels Wilcox-Carrizo Aquifer

The RAND3D model simulated solute transport for a total of 100 years at time steps of five years. Figures 9 and 10 show the RDX plumes after 50 years for the Upper Terrace and Lower Terrace/Sparta aquifers, respectively. Figure 11 shows the corresponding screen graphics displays of plan view and cross-sectional view generated by the RAND3D program for the simulation of 50 years. Figures 12 to 14 show the results after 100 years of simulation. Note that at this point RDX is shown seeping into Boone Creek via the Lower Terrace/Sparta aquifer.

Similar simulations were undertaken at the other five sites. Like Area P, four other sites, Burning Grounds No. 5 and 8, Landfill No. 3 and the Oily Waste Landfarm, showed contamination seepage into Boone Creek during the 100 year transport simulation. The M-4 Lagoon in comparison had contamination seepage into Clarke Bayou.

Sensitivity analyses were performed because of the uncertainty in the input parameters. The sensitivity of assumptions regarding adsorption, dispersivity, porosity, recharge at Area P and plant closure of the LAAP was tested.

CONCLUSION

A successful flow model of the LAAP groundwater was created with three layers: the Upper Terrace aquifer, consisting of Pleistocene alluvial terraces; the Lower Terrace/Sparta aquifer, consisting of Pleistocene

alluvial terraces and the Eocene Sparta member of the Claiborne Group; and the Wilcox-Carrizo aquifer, consisting of the Eocene Carrizo Sand and Wilcox Group. The Lower Terrace/Sparta aquifer and the Wilcox-Carrizo aquifer are hydraulically separated by the Eocene Cane River Formation, a thick marine clay.

Lower Terrace Aquifer

The groundwater flow in the shallow aquifers (Upper Terrace and Lower Terrace/Sparta) at LAAP is dominated by the surface topography and surface water system. The direction of groundwater flow is generally towards the streams which bisect the LAAP. Boone Creek is the major groundwater discharge area with five of the six sites showing contamination seepage into this stream.

The Cane River Formation is a clay layer underlying the Upper Terrace and Lower Terrace/Sparta aquifers under most of the LAAP (and all of the area known to be contaminated). It effectively stops contamination in the shallow aquifers from migrating to the Wilcox-Carrizo aquifer which is the source of drinking water for the LAAP and other nearby towns. This conclusion is supported by the results of the intensive water level monitoring program.

Area P was the major disposal area for pink water at the LAAP. It is the area most heavily contaminated with explosive compounds. RDX, TNT and total DNT were simulated for this site. The simulation results

indicate the existing groundwater contamination at Area P will travel east through the Lower Terrace/Sparta aquifer to Boone Creek, which is in the opposite direction of Doyline community. After 100 years, 2% of the existing (1989 RDX concentrations in groundwater) RDX enters Boone Creek or its tributaries. After 100 years, 3% of the existing (1989 TNT concentrations in groundwater) TNT enters Boone Creek or its tributaries. After 100 years, 12% of the existing total DNT (1989 2,4 and 2,6 DNT concentrations in groundwater) reaches Boone Creek or its tributaries. Under the model setup assumptions, no explosive contamination from Area P crosses the LAAP boundaries.

9371

9371
Figure 14
Area P RDX Plume after 100 Yrs
RAND3D Screen Display

Burning Ground 5 (BG5) is an area used for the disposal (burning) of explosives. Open burning was practiced before 1986. RDX, TNT and total DNT were simulated for this site. This site is adjacent to Boone Creek and a tributary. The simulation results indicate the existing groundwater contamination at BG5 will travel to the adjacent streams with most of the RDX, TNT and DNT contamination reaching surface water within twenty-five years.

Burning Ground 8 (BG8) was an area used for the disposal (burning) of explosives and as a sanitary landfill. There were also pink water lagoons at this site. RDX, TNT and TNB were simulated for this site. The simulation results indicate the existing groundwater contamination at BG8 will travel east to Boone Creek through the Lower Terrace/Sparta aquifer. After 100 years, approximately 80% of the existing RDX, TNT and DNT contamination enters Boone Creek.

Landfill 3 (LF3) was the site of pink water lagoons and later a landfill for construction debris. RDX was simulated at this site. The simulation results indicate the existing groundwater contamination will travel west to Boone Creek through the Upper Terrace and Lower Terrace Sparta aquifers. After 100 years, 98% of the existing RDX enters Boone Creek or its tributaries.

The Oily Waste Landfarm (OWL) is an area where oily wastes and chlorinated solvents were disposed of by landfarming. TCE has been detected in groundwater at this site in small concentrations. A theoretical slug source of contamination representing a conservative pollutant was simulated. After 50 years, 99% of the contamination has entered Boone Creek and its tributaries.

The M-4 Lagoon was used for the retention of wastewater from an electroplating operation until 1964. No groundwater contamination was detected by monitoring wells at this site. A theoretical release of a conservative pollutant was simulated at this site. The pollutant travels west to Clarke Bayou and after 100 years, 98% of the contamination enters Clarke Bayou.

The largest uncertainty in the above predictions is the travel time of contaminant movement. The source of this uncertainty is the lack of knowledge regarding the adsorption of the explosive chemicals onto the aquifer sediments. Adsorption retards the movement of the chemicals. Sensitivity analysis was performed to quantify the magnitude of the uncertainty. The following table shows the impact of different adsorption assumptions on the speed of contaminant travel. Data in Table 1 report the number of years when 50% of the initial contamination seeps from the aquifer into surface water.

Table 1
Retardation Sensitivity - Years for 50% Removal

Site	Contaminant	Retardation Base Case	Assumption None	High
Area P	RDX	>100(98%)	48	>100(100%)
	TNT	>100(97%)	50	>100(100%)
	DNT	>100(88%)	48	>100(100%)
BG5	RDX	7	5	60
	TNT	7	4	37
	DNT	6	3	30
BG8	RDX	11	5	>100(55%)
	TNT	5	3	13
	TNB	7	4	21
LF3	RDX	24	7	99
OWL		23	23	>100(64%)
M-4 Lagoon		60	60	>100(100%)

In the above table, where the time to 50% removal from the aquifers is greater than 100 years, the percentage of the initial contamination remaining in the aquifers after 100 years is in parentheses.

Dispersion is another source of uncertainty in the model predictions. Higher dispersion causes the initial plumes to spread out more, thus lowering concentrations. The mean travel path of the plume is not changed.

Another source of uncertainty in the model is effective porosity. Porosity increases travel times for larger porosities. Thus the impact is similar to that of adsorption. Porosity varies over a much smaller range than adsorption (retardation), however, so it is a much less sensitive parameter.

The impact on contaminant transport of shutting off the LAAP water supply wells was simulated. Shutting off the water supply wells caused water levels in the Wilcox-Carrizo aquifer to recover. The recovery was virtually complete within five years. There were no changes in the water table and potentiometric surface of the Upper Terrace and Lower Terrace/Sparta aquifers; thus, the shut-down of the water supply wells will have negligible impact on the predictions of contamination fate and transport.

The impact of leakage from the Area P lagoons on groundwater flow was simulated. The steady-state groundwater flow rerun was performed with a significant mound in the water table at the Area P lagoons. This mound in the water table changed groundwater velocities slightly. The contamination in Area P spread out radially from its initial position and after 100 years, the plume was distributed over a wider area to the north, west and south than it was with the calibrated steady-state flow model. The fate of almost all of the contamination, however, was still Boone Creek and its tributaries. A very small amount (< 1%) traveled south and west in the Lower Terrace/Sparta aquifer at Area P.

Arsenic-Contaminated Groundwater Treatment Pilot Study

ABSTRACT

Groundwater treatment for the removal of contaminants may be needed at a number of U.S. Army installations, including Army depots. Treatability testing of potentially applicable technologies may be needed to facilitate design and operation of treatment systems. The study described here is a treatability test for the removal of arsenic from groundwater. The goal of the study was to evaluate the effectiveness of ion exchange (IE), granular activated carbon (GAC) and activated alumina (AA) for the removal of arsenic from groundwater.

Laboratory IE, GAC and AA isotherms were conducted to select the two best performing carbon and resin types and the operating pH for the carbon and alumina media for further testing. Pilot-scale continuous flow column tests were conducted at Sharpe Army Depot in Lathrop, California, using the two carbons (Calgon Filtrasorb 400 and Hydrodarco 3000) and the two resins (Amberlite IRA 402 and Ionac A-641) selected during the isotherm studies. Alcoa F-1 AA was also used during the pilot-scale continuous flow column tests. The carbon and AA were tested at an adjusted pH of 4.0 and the resin was tested at natural pH. A pilot-scale, conventional packed column air stripper was used to remove volatile organics (primarily trichloroethene) from the groundwater prior to treatment by the pilot-scale columns. The data from the laboratory and pilot study were analyzed and a report was prepared to present the results and conclusions. The study concluded that arsenic can be removed to the U.S. EPA MCL for arsenic of 50 ug/L and that AA provided significantly longer runs (as measured by bed volumes of water treated) than either GAC or IE resins.

INTRODUCTION

Groundwater treatment for the removal of contaminants may be needed at a number of U.S. Army installations, including Army depots. Treatability testing of potentially applicable technologies may be needed to facilitate design and operation of treatment systems. Sharpe Army Depot (SHAD), located in Lathrop, California, presently has a groundwater treatment system for the removal of trichloroethylene (TCE). The groundwater also contains arsenic, possibly of natural origin, and there may be a need to remove the arsenic prior to discharge.

The goal of this study was to examine, via pilot-scale testing, the possibility of arsenic removal from SHAD groundwater by ion exchange (IE), granular activated carbon (GAC) and activated alumina (AA) processes.

BACKGROUND

Arsenic (As) can occur in four oxidation states in water (+5, +3, 0 and -3), but generally is found in the trivalent and pentavalent states. At low pH, pentavalent arsenic (As (5)) exists primarily as H_3AsO_4. Between pH 3.0 and approximately pH 6.5, the predominant form is $H_2AsO_4^-$, while from pH 6.5 through pH 12.5, $HasO_4^{-2}$ predominates. Above pH 12.5, Aso_4^{-3} is the predominant species. At all pH values below approximately pH 9, trivalent arsenic (As (3)) exists primarily as the undissociated weak acid H_3AsO_3. The distribution between As (3) and As (5) species is determined by the redox condition of the water, with As (3) being stable under reducing conditions and As (5) under oxidizing conditions.[1] Thus, depending upon both pH and redox potential, various arsenic species may be present.

Among the various treatment methods for arsenic removal, including complexation with polyvalent metal species, coprecipitation with a metal hydroxide, coagulation, lime softening, adsorption on activated carbon, AA and IE, the literature suggests that the use of AA is the most promising treatment alternative for treatment of low levels of arsenic in groundwater. Much of the available literature on the AA treatment method involves the use of AA for the removal of arsenic from drinking water.

The pH (as well as other anionic species) of feedwater, arsenic concentration, sulfate concentration, chloride concentration and fluoride concentration play a major role in determining the AA capacity for arsenic removal.[2] The presence of other anions, such as sulfate and fluoride, reduced the amount of arsenic removed by as much as 80%. Substantial removals of As (5) by AA reportedly have occurred within a pH range of 4 to 7.[3]

AA has an equilibrium capacity for As (5) up to 10 times greater than that for As (3). This capacity is because at a pH of below 9, As (3) is present in a unionized form as H_3AsO_3.[4] Oxidation of As (3) to As (5) is necessary to achieve effective arsenic removal. Chlorine has been successfully used to accomplish this oxidation.[5] Results from pilot tests on AA systems indicated that with an empty bed contact time (EBCT) of 7.5 minutes, pH adjustment to 6.0 and oxidation of As (3) to As (5), up to approximately 16,000 bed volumes could be processed prior to reaching a maximum contaminant level (MCL) of 50 ug/L in the treated water, with a raw water As (5) concentration of approximately 100 ug/L.[6]

When the adsorptive capacity of the AA is reached, it can be regenerated with a 4 to 5% sodium hydroxide (NaOH) solution. The general procedure for regeneration, which has been successfully used in pilot tests, includes upflow treatment followed by downflow treatment with NaOH, raw water rinse and neutralization with sulfuric acid. The regeneration of an AA system would generate a concentrated waste containing elevated levels of arsenic that may require disposal in an approved hazardous waste landfill. It has been reported in the literature[6] that the volume of the waste products generated during the regeneration of the AA system would be approximately 0.1% of the production of the system (quantity of treated water).

Limited information is available in the literature on activated carbon

treatment of arsenic-contaminated water and wastewater. In one study involving arsenic removal from a potable water supply using activated carbon adsorption, 70% removal of As (5) was achieved with a raw water arsenic concentration of 200 ug/L.[7] Another study indicated that the optimum pH for adsorption of As (5) on activated carbon is 4.0.[3] A recent study in which activated carbon was used for treating a synthetic solution of arsenic (prepared by dissolving As_2O_3 in distilled water) indicated a GAC adsorption capacity of 2.5 lbs As (5) per 100 lbs of carbon.[8] Batch adsorption experiments to evaluate GAC for arsenic removal from the groundwater at SHAD indicated an ultimate capacity for arsenic at an influent concentration of 734 ug/L, 0.05 lb As (5) per 100 lbs carbon.[9] This result is significantly lower than the GAC adsorption capacity reported in the previously mentioned study. The difference could have been due to the different sources of water with different chemical compositions used in the studies.

The IE process for arsenic removal involves the use of a strong-base anion resin that allows the exchange of chloride ions attached to the resin with negatively charged arsenate ions ($H_2AsO_4^-$) in the raw water. When the adsorptive capacity of the resin is reached, the resin must be regenerated using a concentrated sodium chloride (NaCl) solution that replaces the $H_2AsO_4^-$ with chloride ions.

The results of pilot-plant testing of ion exchange treatment for removal of arsenic from drinking water at the Fallon, Nevada, Naval Air Station indicated that with a 5 minute EBCT, approximately 300 bed volumes could be processed before reaching the MCL of 50 ug/L in the treated water with a raw water arsenic concentration of approximately of 100 ug/L.[10] The results further indicated that the efficiency of treatment using a strong-base anion exchange resin is dependent on the quantity of other anions in the water, particularly sulfate, which are preferentially removed before arsenic. Successful treatment of wastewater containing arsenate and arsenite with a strong-base resin, at pH values ranging from 4 to 13, is reported in the literature.[7]

In an experimental study using the IE process, soluble As (5) at a concentration of 500 ug/L was completely removed from storm run-off water.[11] An EBCT of 3.6 minutes, hydraulic loading of 4.2 gpm/ft[2] and bed depth of 2 ft were employed in the 1-in. diameter column used in the study.

One potential benefit of using a strong-base ion exchange resin over AA occurs during regeneration, where sodium chloride could be used instead of caustic soda followed by an acid neutralization. The initial cost of the resin probably will be higher than AA, but the lower cost of NaCl and its easier handling may make an IE process less expensive in the long run.[4]

Precipitation of alkalinity (i.e., calcium carbonate) in the IE vessel is a possible complication with an IE system.[6] This process would require the additional expense of removing the cations with a softener (cation exchanger) prior to arsenic removal.

MATERIALS AND METHODS

All tests performed during this project employed groundwater from wells at SHAD as the test water. Wells MW-403A, 407A and 431A were used for the isotherm studies, and well MW-440A was used for the pilot-scale tests. Contaminant concentrations in these wells varied during the test period. Table 1 presents the analytical data obtained from initial sampling of wells 403A, 407A and 431A.

Isotherm Laboratory Tests

Isotherm tests were performed for selected IE resins, activated carbon types and a single AA at Roy F. Weston, Inc.'s (WESTON's) Environmental Technology Laboratory (ETL) in Lionville, Pennsylvania. Groundwater was collected at SHAD and shipped to ETL for testing.

Since treatment for arsenic removal at SHAD would likely be implemented following removal of TCE in the existing air stripper, the contaminated groundwater from SHAD was pretreated for TCE removal by batch aeration using spargers. For isotherms to be conducted at other than natural pH,[12] the pH of the groundwater was adjusted to the desired value using sulfuric acid. Isotherm tests were then conducted on the pretreated groundwater samples.

[a]Laboratory control standards for copper and lead were outside the control limits of 80-120%.
[b]Measured as nitrite nitrogen after reduction of nitrate; MCAWW Method 353.1.
[c]Samples analyzed beyond regulated holding time.

Note: u = Compound was analyzed but not detected. The associated numerical value is the sample detection limit.

Seven 250-mL aliquots were used for each isotherm. Tests were conducted in polyethylene bottles. Preweighed quantities of adsorbent media were added to the groundwater aliquots to provide the required dosages. The bottles were sealed to preclude liquid and vapor losses during agitation. Samples were agitated at room temperature on a rotating laboratory shaker for a period of 24 hours. Each isotherm test included one blank, containing no adsorbent medium.

Following agitation, each sample (including the blank) was filtered through a Whatman 0.45 micron GF/F filter into a clean filter flask to remove the contaminant-laden adsorption medium. Each filtrate sample was then analyzed for total arsenic concentration.

From these data, the equilibrium concentration of arsenic in the solution (Ce) and the arsenic loading on the adsorbent medium (qe) were calculated. These data were plotted on log-log paper in accordance with the Freundlich equation for adsorption:

$$q_e = X/M = KC_e^{1/n} \tag{1}$$

where,

q_e = Adsorbent loading.
X = C_o-C_e the amount of arsenic adsorbed for a given volume of solution.
M = Weight of adsorbent added.
C_o = Initial amount of arsenic.
C_e = Amount of arsenic remaining in solution.
K and $1/n$ are empirical constants.

The results of these tests were used to select media to be testing in the pilot-plant study phase of the project.

Pilot-Plant Studies

The objective of pilot-plant studies was to evaluate potential operating characteristics of selected adsorbent types under actual operating conditions, with respect to such parameters as adsorbent bed depth, hydraulic loading rate and EBCT. Pilot-scale testing of the media selected from the isotherm data was conducted at SHAD using a skid-mounted transportable activated carbon column pilot plant designed and built for USATHAMA. The system can be used to evaluate treatment using GAC, IE or AA technologies. The plant consists of three skids and accessory tankage. One skid consists of the motor control center, feed

pumps and utility pumps. Each of the other two skids contains four plexiglas columns which hold the adsorption medium to be tested. This pilot plant was designed to provide a high degree of operating flexibility, using variable bed depths and wastewater flow arrangements. Additional tanks and pumps are provided to allow for groundwater retention, pH adjustment and flow control as necessary.

An air stripper 8 in. in diameter by 23 ft high with 15 ft of packing, designed for a water flow rate of 5 gpm, was used to remove TCE in the groundwater prior to treatment for arsenic.

In addition to the treatment units described above, the following additional tankage was added to the GAC/IE/AA pilot treatment system:

• Two 3,000-gal influent holding tanks to receive and hold groundwater from the selected well

• One 2,000-gal equalization tank between the air stripper and the GAC/IE/AA unit. When required by the Test Plan,[12] pH adjustment was carried out in this tank

• Two 3,000-gal effluent holding tanks to retain the treatment effluent to be discharged after testing

Figure 1 shows the schematic configuration of the combined air stripping/GAC/IE/AA pilot system that was used in this study. As shown, there were three GAC/IE/AA treatment trains. These three trains were operated in parallel to allow for study under three different experimental conditions at the same time.

In order to evaluate the need for an arsenite oxidation step during the pilot study, portions of samples from candidate wells were subjected to arsenic speciation analysis. These specialized analytical services were provided by the Benedict Research Laboratory of the Academy of Natural Sciences.

ANALYTICAL METHODS

Samples were analyzed for total arsenic at WESTON's Stockton, California, laboratory by USATHAMA-certified Method SD01. Samples were analyzed for TCE at WESTON's Lionville, Pennsylvania, and Stockton, California, laboratories by U.S. EPA Method 8010.

EXPERIMENTAL RESULTS AND DISCUSSION

Isotherm Testing

A single round of isotherm testing was conducted for the purpose of examining equilibrium adsorption characteristics of the various adsorption media and to select media for use in pilot testing. Preliminary selection of media types for isotherm testing was based upon literature and vendor information.

The isotherm tests performed during this study indicated that each of the major media types (IE resin, GAC and AA) may be capable of treating arsenic-bearing groundwater at SHAD to less than 50 ug/L. The lowest required dosages (weight of adsorbent per volume of contaminated water) and highest qe values for equilibrium adsorption were observed with Alcoa Type F1 AA. In general, the selected IE resins appeared to perform better than activated carbon when compared on the basis of adsorbent dosages, with GAC achieving equilibrium arsenic concentrations less than 50 ug/L only at high carbon dosages. Table 2 summarizes the results of isotherm testing in terms of the media selected for pilot-scale evaluation.

Arsenic Speciation

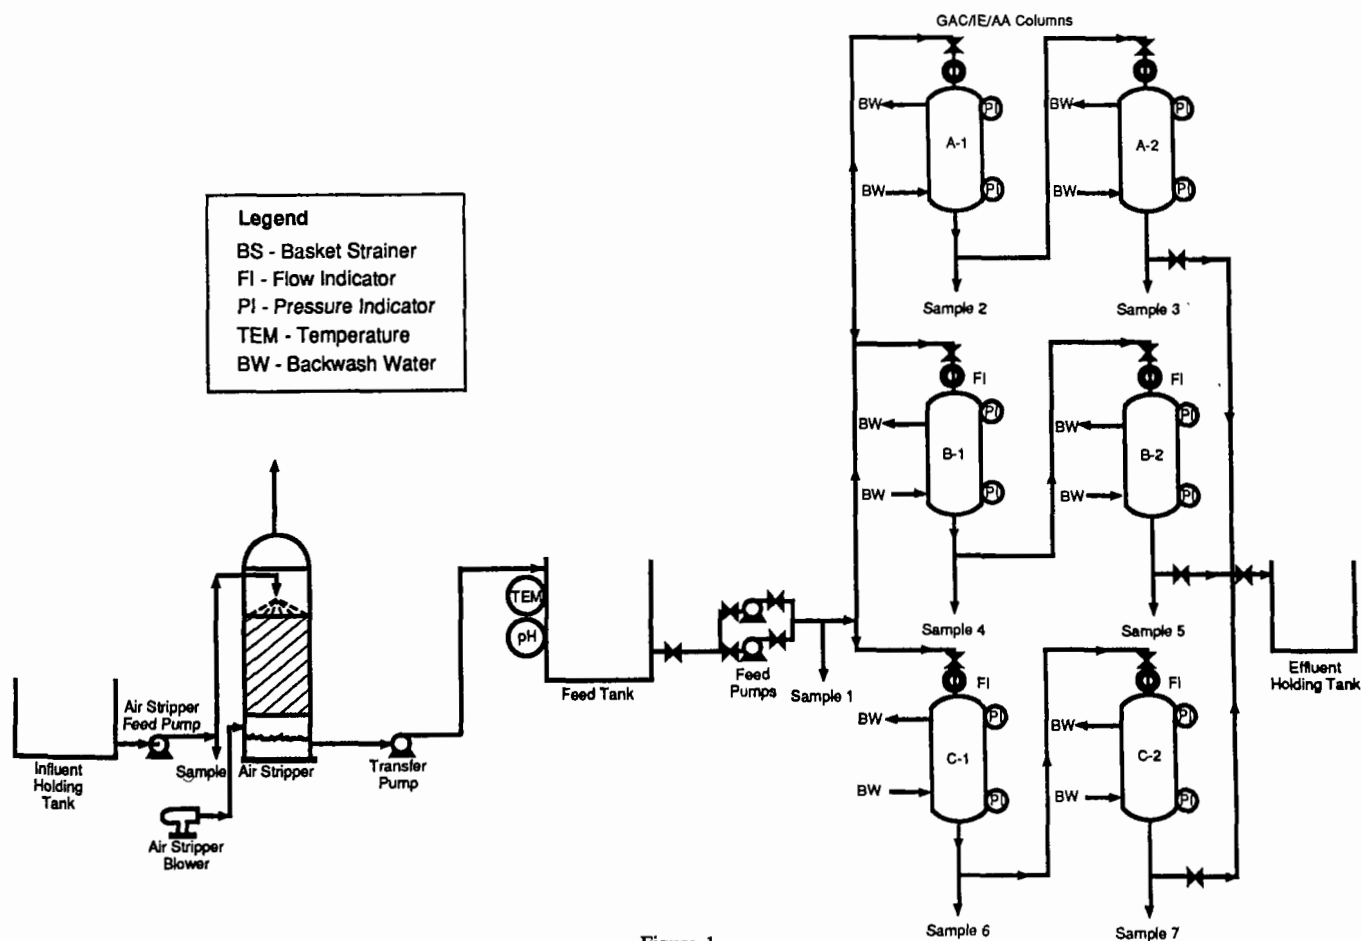
Arsenic speciation in the potential pilot study supply wells was evaluated in order to determine the need for an oxidation step during the


Figure 1
Pilot Treatment Unit Configuration

pilot study. If the groundwater at SHAD contained predominantly As^{+5}, a pre-oxidation step using chlorine as the oxidant was planned.

Sampling for the initial characterization of arsenic speciation in MW403A, 407A and 431A took place on February 28, 1990. Additional sampling, from MW440A and at the actual pilot plant influent, took place on May 23, 1990, during the pilot-plant phase of the study. Arsenic speciation data from these samples are presented in Table 3. These data demonstrate that arsenic in the sampled wells existed almost entirely ($\geq 99.5\%$) as the oxidized As^{+5} form.

The finding that the arsenic to be treated existed in the oxidized form obviated the need for a chlorine oxidation step in the pilot study. Since As^{+3} concentrations were all well below the MCL of 50 μg/L, effective removal of the pre-existing As^{+5} would likely permit attainment of the discharge standard. The incremental increase in bed life (before breakthrough at 50 μg/L total arsenic) that might be achieved by oxidation of the low levels of As^{+3} likely would be slight.

Table 2
Summary of Media Selection

Adsorbent	Adsorbents Screened in Isotherms	Adsorbents Selected for Pilot Testing
Ion Exchange Resin Amberlite	Rohm and Haas Amberlite IRA-402	Rohm and Haas IRA-402
	Rohm and Haas Amberlite IRA-900 Sybron Ionac A-641 Sybron Ionac ASB-1	Sybron Ionac A-641
Activated Carbon	Calgon Filtrasorb 200 Calgon Filtrasorb 300 Calgon Filtrasorb 400 Hydrodarco 3000 Hydrodarco 4000	Calgon Filtrasorb 400 Hydrodarco 3000
Activated Alumina	Alcoa Type F-1, 28-48 Mesh	Alcoa Type F-1, 28-48 Mesh

Therefore, based upon the results of the initial arsenic speciation analysis, as confirmed in subsequent resampling during the pilot-study phase, chlorine oxidation of the influent groundwater was not employed in this study.

Pilot-Scale Testing

The overall objective of the pilot scale test program was to evaluate the potential performance of the selected media under continuous flow conditions simulating those likely to be employed in a full-scale treatment system. Specific objectives pertinent to this effort included:

- To determine the effectiveness of the medium in removing arsenic to the MCL (50 ug/L) under continuous flow conditions
- To determine the adsorption capacities of the medium
- To select the best performing medium

- To evaluate potential operating conditions for a treatment system, including hydraulic loading rate and EBCT

These objectives were addressed in a test program conducted at SHAD using USATHAMA's skid-mounted transportable pilot system described earlier. The overall duration of the pilot test program (not including mobilization and demobilization) was approximately 17 weeks. The test program encompassed a total of seven experimental runs. Table 4 presents a summary of the test program.

Each adsorbent bed rested upon a 1-ft thick base consisting of a layer of stone sandwiched between two layers of borosilicate glass wool, specified as being free from heavy metals, fluorine and alumina. Adsorption media were prepared as water slurries, allowed to soak overnight and then be added to the columns to provide a settled bed depth of 4 ft. The column was sealed, leak tested and backwashed prior to commencing each test run. Once begun, each test ran continuously until breakthrough with the exception of brief shutdowns for necessary repairs. Breakthrough was defined as the MCL of 50 μg/L.

Each column was backwashed as needed during the run to remove accumulated solids at the head of the column which interfered with flow and contributed to excessive head loss across the column. In general, columns were backwashed when the head loss across the column exceeded 5 psi, as indicated by the pressure gauges mounted on the inlet and outlet of each column. During backwashing, the adsorbent bed was also generally broken up, minimizing plugging or channeling of flow through the bed. The duration of the backwashing operation was approximately 15 minutes.

This study evaluated the potential treatment of arsenic-contaminated groundwater by three different technologies: IE, GAC adsorption and AA. While the specific mechanism of arsenic removal may vary, the implementation of each of these technologies is similar, each likely employing a series of fixed bed down flow treatment columns (although other configurations are possible) with varying degrees of pretreatment and/or post treatment. Therefore, the performance of the different media can be compared in part on the basis of the quantity of contaminated water, normally expressed in terms of bed volumes, which can be treated prior to breakthrough.

Table 5 summarizes the results of pilot tests conducted in this study in terms of the quantity (bed volumes) of contaminated groundwater treated under various operating conditions prior to breakthrough in the primary column effluent, with breakthrough being defined as effluent arsenic concentrations equal to or exceeding the Safe Drinking Water Act MCL of 50 μg/L.

DISCUSSION

These data indicate that both IE resins and AA can provide treatment of SHAD groundwater to levels below the MCL. The longest bed lives were achieved with AA at reduced pH, relatively low hydraulic loading rates and contact times on the order of 9.8 to 14.7 min. Bed

lives on the order of 3,000 or more bed volumes of water treated appear to be achievable in a single activated alumina column operating under these conditions. Figure 2 is a plot of the arsenic breakthrough curve for AA Run 5A. By contrast, ion exchange bed lives on the order of 200 to 500 bed volumes of water might be obtained.
Figure 2
Plot of the Arsenic Breakthrough Curve for AA Run 5A

Granular activated carbon does not appear capable of meeting the arsenic treatment requirements under the conditions used in this study, as shown in Table 5.

Definite selection between the two treatment technologies exhibiting satisfactory performance in this study would depend upon analysis of the relative treatments costs and the operating advantages/disadvantages associated with each technology. This comparative analysis would consider the capital equipment requirements as dictated by such factors as hydraulic loading and contact time, pre and posttreatment requirements, regeneration requirements and the attrition rate and replacement costs of the media. For example, although AA exhibited the longest bed lives in this study, the data indicate that a pH adjustment step is required and that relatively low hydraulic loading rates and long contact times (corresponding to relatively large adsorption units) are required. By contrast, IE data suggest relatively little dependence on loading rate and contact time over the ranges evaluated; thus relatively smaller adsorbers operating at higher loadings may prove suitable.

Table 6
Regeneration Requirements

Ion Exchange

Example: IRA-402:

1. NaCl, 5-10% solution, : 4 lb. salt/ft³ resin, at 0.25
    1.0 gpm/ft³

2. Rinse with water.

Activated Alumina

1   Regeneration, NaOH, 1% solution, 4 bed volumes.
2   Rinse with water, 8 bed volumes minimum.
3   Acid rinse, 0.05 N H₂SO₄, 1 bed volume minimum.
4   Final rinse, water, 1 bed volume.

Source: References 11, 12, and 13

Regeneration of media was not addressed in this study. Since the adsorption capacities of regenerated media may differ in some respects from these of virgin media, this aspect should be addressed prior to

design of a treatment system. Based upon previous research and manufacturer's recommendations (summarized in Table 6), regeneration of either IE resins or AA is a relatively straightforward operation requiring conventional reagents, and attrition of the media during regeneration can be controlled.

With respect to media replacement, it should be noted that the IE resins recommended by vendors for use in this study were relatively expensive as compared to, for example, conventional softening resins. The recommended resins cost approximately \$230/ft³. By contrast, the cost for the AA is relatively low, at approximately \$71/ft³ (\$1.65/lb).

CONCLUSIONS

The following conclusions are drawn from the data obtained in this study:

• Strong base anion exchange resins (specifically Rohm and Haas IRA 402 and Sybron Ionac A-641) and AA (specifically Alcoa Type F-1, 24 to 48 mesh) are capable of treating arsenic-contaminated groundwater from well MW-440A at SHAD to effluent concentrations below the Safe Drinking Water Act MCL of 50 μg/L (as total arsenic). The granular activated carbons tested were not capable of effective arsenic treatment under the conditions evaluated in this study.

• Of the successful media, AA provided the longest bed lives (in terms of bed volumes of water treated prior to breakthrough at the MCL level).

• The use of AA requires a pH reduction step. Hydraulic loading rates of 2 to 3 gpm/ft² and EBCTs of 9.8 to 14.7 minutes provided the longest bed lives.

• IE resins exhibited less dependence on hydraulic loading rate or EBCT than did activated alumina. However, bed life at all loading rates was lower than with AA.[13]

• Analytical data from wells MW-403A, MW-407A, MW-431A and MW-440 indicate that pentavalent arsenic (As^{+5}) is the predominant arsenic species present in SHAD groundwater and that trivalent arsenic (As^{+3}) is present only in small amounts. In fact, removal of As^{+5} alone would be sufficient to achieve the SDWA MCL for total arsenic of 50 μg/L. As a result, no oxidative pretreatment step was required or employed in this study and, as long as this situation prevails, oxidative pretreatment should not be required in a full-scale system.

ABSTRACT

The Rocky Mountain Arsenal (RMA) in Adams County, Colorado, has been identified as a priority site on the Superfund National Priority List. The Program Manager's Office of RMA announced in early 1990 their intention to implement installation of a state-of-the-art incineration plant to treat the most complex and controversial waste stream on the site.

Established in 1942, the Arsenal served as an Army manufacturing center for chemical agents such as mustard gas, white phosphorus, napalm and GB nerve agent. Parts of the site were also leased to Shell Oil Company which manufactured pesticides and other agricultural chemicals at this location between 1952 and 1982.

To support these activities, the Army operated a 93-acre surface impoundment called Basin F for collection and evaporation of chemical wastewaters. As a result of the wide variety of wastes received and concentrated at Basin F, and early treatment attempts, its contents became a unique chemical cocktail. By the time that a formal interim response action for remediation was initiated in 1985, the Basin composition consisted of a multiphase fluid and sludge including supersaturated levels of inorganic salts; 30% or more organics such as pesticides, military agent byproducts, degradation products and solvents; high levels of ammonia compounds and bound nitrogen; and percent levels of copper, arsenic and other metals.

Selection of a remedial alternative involved 12 years of characterization studies and 11 years of treatability testing programs encompassing the universe of containment, encapsulation, stabilization, component separation, thermal, electrical, chemical and biological degradation technologies. The program resulted in the selection of a state-of-the-art down-fired liquid incinerator for destruction of aqueous organic contaminants in metallic salt matrices.

The treatability demonstration and technical justification for selecting the T-Thermal submerged quench incinerator for this application are the subject of this paper.

INTRODUCTION

The Rocky Mountain Arsenal (RMA) was established in 1942 on rural property located in Adams County, Colorado, 10 miles from downtown Denver. The Arsenal production facilities have been used for the manufacture of materials such as mustard gas, white phosphorous, nerve agents and napalm; filling of munitions with agents and incendiary materials; and the destruction or "demilitarization" of chemical weapons.

Between 1952 and 1982, a series of private firms ending with Shell Chemical Company (now Shell Oil Company) manufactured agricultural chemicals, primarily pesticides, at the Arsenal.

During the 1980s an extensive battery of characterization studies, conceptual process studies and treatability tests were conducted to develop potential remedial alternatives for the Basin F contents which had been tentatively linked to groundwater contamination downgradient of the Basin. Also during this period, the 8.5 million gallons of liquid contents were removed from the Basin and placed in above ground storage. In late 1988, Woodward-Clyde Consultants began a concentrated effort to evaluate and interpret the prior studies, and identify and justify a preferred alternative for destruction of the former Basin contents. This selection of a preferred alternative has since been published and approved by the Army, Shell Oil and all the responsible regulatory authorities.

BACKGROUND

In 1956, Basin F, a 243-million gallon evaporation pond was constructed in a natural depression by lining it with an approximately 1/2-inch catalytically blown asphalt surface, covered by a 1-foot protective layer of earth. This Basin was the last in a series of linked surface basins used for the evaporation of wastewaters from the Army and industrial chemical activities at the site. From August 1957 until its use was discontinued in early 1982, Basin F was the only evaporation pond at the Arsenal containing a liner. Wastewaters entered the former Basin F for more than 20 years, directly or indirectly, from three different manufacturing sources: the Army North Plants, the Army South Plants and Shell South Plants.

Army North Plants

The North Plants complex operated from 1953 to 1984 for the manufacture, munitions filling and later demilitarization of GB nerve agent. During the period between 1953 and 1973 the plant produced bulk GB agent and loaded GB into munitions. During that period the plant also filled munitions with agents produced elsewhere, such as VX-nerve agent, and manufactured other devices such as microgravel mines and button bombs. From 1973 to 1984 the North Plants served as a "demilitarization" (demil) facility for destruction of GB agent; VX agent, Adamsite phosgene bombs and DDT-contaminated equipment.

Wastewaters from these manufacturing and demil operations were discharged indirectly to both Basin A and Basin F. Waters were caustic neutralized in a disposal sump and then pumped to these Basins for evaporation.

Army South Plants

The South Plants operated from 1942 through 1969, producing Lewisite, mustard gas and incendiary mixes, and filling munitions with incendiary materials and phosgene. During World War II, the plant produced Lewisite (a blister agent) and sulfur mustard. Phosgene was not manufactured, but was purchased from private industry and used to fill bombs in the plant. The South Plants also produced or used

napalm gel, cluster bomb incendiary mixtures, button bomb pyrotechnic mixtures, white phosphorous and hydrazine preparation for missile fuels.

The plant was used for destruction of bulk mustard from 1971 to 1974. Wastes from the Army processes and demilitarization were managed in a variety of ways including incineration, neutralization and evaporation in surface impoundments, including Basin F.

Shell South Plants

After WWII, portions of the South Plants area were leased to private chemical manufacturers. The most significant lessees included Julius Hyman and Co. and Shell Chemical Company, which manufactured Chlordane, Aldrin, Dieldrin, Endrin, Vapona, Nemagon and other organochlorine and organophosphorus pesticides and nematocides between 1947 and 1982. Some wastewaters from these processes were discharged to the evaporation basin system and ultimately to Basin F.

Other Sources and Factors

Other factors contributed to the creation of the unique mixture of components in the Basin as well. The most significant factor involved early attempts at remediation of the contents. In the late 1950s it became obvious that Basin F was not large enough to handle all the wastewaters generated on-site. The U.S. Army Chemical Corps considered deep well disposal, and in 1960 the Corps of Engineers attempted to modify Basin F for the purpose of pretreatment prior to disposal. A chemical addition area was constructed at the Basin, and 100 tons of ammonium phosphate were added to the Basin contents in an attempt to simulate microbial activity and liquify some of the solids. Although injection wells were drilled and injection was attempted in the early 1960s, the pretreatment was never successful and ultimately the injection attempts were abandoned. However, the presence of the additional 200,000 pounds of ammonium salts had a significant long-term affect on the behavior of the liquids.

The final contributor to the Basin's properties was the very action for which the Basin was designed. Years of warm-weather evaporation at high altitude contributed to the creation of a supersaturated body of liquid by the time characterization and remediation studies began in 1978. The residuals from the evaporation were so concentrated, in fact, that during repeated Corps of Engineers attempts to sample the Basin in the 1980s the sample devices acted as seeds for precipitation and caused instantaneous crystallization.

THE TECHNICAL PROBLEM

As a result of the processes and actions described above, Basin F liquids evolved into a mixture unique among chemical wastewaters. The Basin F contents are generally an aqueous mixture consisting of approximately one-third water, one-third organics and one-third dissolved solids, primarily salts and metals.

Table 1 lists some of the organic components identified in Basin F, primarily agent byproducts and pesticides and their intermediates and byproducts. Most individual organic species reported have been identified as present at concentrations from 1 to 1000 ppb, with the exception of two pesticides and three pesticide byproducts present at concentrations from 2000 to 100,000 ppb. However, no single organic component is a significant contributor to the liquid's properties.

The liquid's properties appear to be driven by the high concentrations of inorganic salts and metals. Table 2 shows the levels of selected inorganic components. Table 3 describes some properties of the liquid including those particularly affected by inorganic constituent levels such as conductivity and density. In general, Basin F can be described as:

- Supersaturated with salts (30 to 35%)
- Unusually high in ammonia (5%)
- Contaminated with environmentally significant levels of nerve agent byproducts, pesticide-related compounds and arsenic
- Prone to off-gassing
- Highly corrosive

While the above items represent significant engineering handling and treatment problems, three beneficial properties of the liquid are that it is not: (1) radioactive, (2) flammable or (3) explosive.

Table 1
Selected Organic Chemical Components Detected in Basin F Liquids During Characterization Studies 1978 to 1988

Component	Source
Aldrin	insecticide
Isodrin	insecticide intermediate

THE ADMINISTRATIVE PROBLEM

Two administrative agreements which govern the RMA remedial activities were signed in February 1989 by Shell Oil Company, the Army and Federal Agencies responsible for oversight of the cleanup. The Federal Facility Agreement (FFA) and the Settlement Agreement (SA) define the mechanisms for selection of remedial actions and the technical and financial responsibilities for each party. The FFA also defines how the Interim Response Actions (IRAs) will be carried out. The Basin F Action was identified as an IRA. The signed agreements required that the liquids, which by this time had been removed from the Basin and stored in three above ground tanks and a lined surface pond, would be permanently destroyed within 5 years of the date they were placed in the tanks. The 5-year period was based on the assumed design life

of the tanks and implies that the liquids have to be destroyed by mid-1993. This deadline complicated an already tough engineering problem by requiring that a selected alternative must involve equipment that was already proven for corrosive service on aqueous organic brines and immediately commercially available.

THE APPROACH

Characterization and treatment studies for remedial alternatives for the liquid were conducted by multiple organizations from 1978 to December 1989. The technologies considered and tested during this period spanned the entire spectrum of currently available treatment approaches and included:

- Thermal destruction
- Electrical destruction
- Non-combustion thermal oxidation
- Chemical biological photolytic oxidation
- Separation and component recovery
- Stabilization and immobilization

More than 40 different conventional and innovative technologies were addressed. The technologies addressed included some as commonplace as mechanical filtration and some as new and developmental as supercritical water oxidation. More than a dozen different bench-scale and pilot-scale test programs were conducted. Based on the governing Federal Facilities Agreement, any technologies which were to be retained from the foregoing studies for detailed evaluation needed to meet the following criteria:

- The technology and equipment had to be suitable for the complex properties of Basin F liquids.
- It had to be generally capable of meeting Applicable or Relevant and Appropriate Requirements (ARARs).
- It must have been successfully demonstrated on actual Basin F liquids.
- It had to be commercially available at full scale within the 5-year time frame.

As a result, six technologies were retained for a detailed alternatives evaluation conducted by Woodward-Clyde Consultants during 1988 and 1989. They were:

- Electrical Melter Furnace (EMF)
- Solidification
- Submerged Quench Incineration (SQI)
- Wet Air Oxidation (WAO)
- Wet Air Oxidation with Powdered Activated Carbon Biotreatment (PACT)
- Off-site commercial incinerator

The detailed evaluation consisted of two major components - a risk evaluation and an engineering evaluation using quantitative scoring and sensitivity studies to rank alternatives in the context of the CERCLA evaluation criteria.

Risk assessments considered short- and long-term risks from both the operations and the materials transport (feed chemicals and residual products) for each proposed alternative. In general, the transportation risk from export of untreated liquids outweighed the risks arising from on-site treatment.

The engineering evaluation involved a numerical scoring of each alternative per each of seven of the nine standard CERCLA criteria. Two criteria, community acceptance and State acceptance, were not utilized in the ranking study because they were evaluated explicitly through a multistep community involvement program conducted after the study. The ranking study, based on multiattribute utility theory, used a variation in weights on the CERCLA criteria to study the singular effects of individual criteria and to model various viewpoints. This process resulted in the identification of on-site submerged quench incineration as the technically preferred alternative. In general, however, despite the extensive decision methods utilized, it was basically the properties of the Basin F liquids that caused each of the other alternatives to be ranked low or be ruled out altogether. That is, each other alternative had a potential "fatal flaw" with respect to the liquid properties that could ultimately render it unsuitable.

Electric Melter Furnace

The electric melter furnace is a high temperature furnace used for the production of glass from liquid or solid feeds with the addition of silicates; no flame is present in the combustion chamber. Initially, this equipment which is designed to handle fluids with high solids and high metals content seemed like a strong candidate for a one-step process to destroy Basin F's organics and stabilize its metals. But Basin F's two other key components, salts and ammonia, posed significant potential problems for this process.

The equipment is designed to run with a single-phase melt flowing continuously along the bottom of the thermal chamber. Basin F, with or without addition of glass formers, would create a two-phase melt with salts lying above, and interfering with the purging of, the metals stream. More importantly, at the high temperatures of this process (2500°F), the ammonia nitrogen in Basin F was expected to form NO_x compounds at rates that could not meet Denver air standards even after selective catalytic reduction, thermal $DeNO_x$ or other NO_x treatment steps.

Solidification

This process may have been suitable if Basin F's metallic aqueous brine contained no organics or ammonia. While solidification of contaminated soils and sludges is frequently a straightforward one- or two-step process, the process needed for material with Basin F's composition would have been extraordinarily complex. First, due to the high content of ammonia and the normally high pH of many solidification additives, numerous ammonia sequestering additives were needed to prevent escape of large quantities of gas. Second, many of the organic components were not only not amenable to stabilization themselves, but also interfered with the inorganic matrix formation that was to bind metals and inorganic ions. In total, this approach would have required so much chemical addition it would have increased the treated volume to a minimum of 3 to 5 times the untreated waste volume.

Wet Air Oxidation

This process represented a possible way to achieve primary destruction of organic components without the high temperatures common to incineration processes that tend to create NO_x emissions. High pressure oxidation reactors have been utilized industrially on a variety of rich and lean aqueous organic mixtures. However, Basin F's composition posed serious technical problems in the design of such equipment. The manufacturers had difficulty identifying materials of construction for high pressure, small diameter, high velocity reactor tubes in corrosive and abrasive service which could be guaranteed to survive for the life of the project.

Wet Air Oxidation with PACT

This approach was considered as a potential means of enhancing WAO's overall destruction efficiency by utilizing microorganisms in a polishing step on the WAO product. However, even though the WAO effluent would have smaller, less toxic organic molecules than the Basin F feed that may be suitable for biodegradation, the effluent still would contain two other Basin F components - ammonia and copper. While microorganisms utilize ammonia nitrogen as a nutrient, the copper serves as a relatively potent biocide and must be removed. The flow sheet incorporating removal of copper-ammonium salts between WAO and PACT became so complicated as to render the overall process potentially impossible to startup and bring to steady-state.

Off-site Incineration

Most commercial incinerators, whether liquid injection type or kiln type with liquid afterburners are capable of accepting waste with some level of "ash content," that is, noncombustible inorganics. However, despite a nationwide survey and several acceptance test trials, no commercial installation could be identified that would guarantee acceptance of Basin F once they understood its chemical composition. Two properties caused the most concern: (1) the "ash content," due to the supersaturation of salts, was much higher than they felt they could pump, purge from their equipment and stabilize with their product ash;

and (2) the ammonia content relative to the low Btu content was likely to drive their operation above acceptable NO_x emission levels.

THE SOLUTION - SUBMERGED QUENCH INCINERATION

The first and foremost requirement of the incinerator is the complete destruction of the highly sensitive organics. However, the presence of approximately 1,500 pounds per hour of salts and heavy metals dictated an incinerator from which those materials could be continuously removed. The high concentration of bound nitrogen and chlorides also require that the incinerator be of a controlled atmosphere type to limit NO_x and other secondary pollution problems. The submerged quench fits all of those parameters.

The incinerator chamber of the SQI is a vertical cylinder instead of horizontal as is common for most other incinerator designs. The burner and waste injectors are located at the top of the chamber and are downfired. This orientation allows the salts which are molten liquids at typical incineration temperature to flow down the chamber walls carrying any other inorganic metals with them. The outlet of the incinerator chamber is the submerged quench system. The submerged quench is a unique design which not only cools the gases, but also provides for excellent mass transfer, lowering the demands on the downstream pollution control system to neutralize acids and remove particulates. The hot corrosive gases and molten salts enter the quench via a downcomer. The downcomer is a metal tube which extends into the quench water bath. The bottom of the downcomer is open, allowing the salts to drop into the quench tank solution and redissolve. The quench solution for the system is a concentrated salt solution to which caustic is added to react with the acid gases.

The gases exit the downcomer through holes in its side. These holes are 24 inches below the solution level in the quench tank and are designed with enough pressure drop to provide a jet sparging effect of the gases into the water. As the gases exit the holes, they rise as millions of small bubbles providing extended surface area for heat and mass transfer. In the quench tank, almost all of the acid gases are neutralized and more than 99% of the particulates including heavy metals above 2 microns are removed from the gases before they enter the downstream pollution control equipment.

The destruction efficiency of the highly sensitive organics present in the waste has to meet U.S. EPA incinerator standards. However, the presence of the other inorganic compounds containing large concentrations of carbon monoxide, chloride and nitrogen required an incinerator system in which the atmosphere could be controlled and in which the destruction could be achieved at temperatures at which those compounds would not create secondary air pollution problems.

The SQI combustion is carried out at approximately 1900°F and 3.5% O_2, with a 2 second retention time. These parameters were derived through pilot plant tests at the existing pilot facility at Conshohocken, Pennsylvania, which were conducted both prior to and during the design. At that set of parameters the destruction of organics exceeds 99.99%, and the CO is less than 100 ppm corrected to 7% O_2. The low oxygen concentrations ensured that the chlorine present forms as HCl versus free Cl_2, therefore improving its scrubbing efficiency. The SQI accomplishes all of this because of the high turbulence in the chamber providing excellent mixing of the vaporized waste, combustion air and hot burner combustion products which initiates the waste oxidation reactions. The high turbulence is derived from the Vortex burner and optimized design of the chamber, waste injectors and secondary combustion air nozzles.

The SQI system represents the state-of-the-art for handling this type of waste today as well as it did almost 20 years ago when it was first utilized. Therefore, not only can it be considered innovative, but it also has been proven in over 125 installed systems around the world. The operating experiences from those systems have resulted in improvements to this system which will increase its reliability and safety.

CONCLUSIONS

Basin F Liquid is a unique chemical mixture that poses a significant treatment engineering problem due to its physical and chemical properties including:

- Supersaturation of salts
- High concentration of complex organics
- Corrosivity
- Tendency to ammonia off-gassing
- Tendency to precipitate salts

As a result, the selected alternative for permanent remediation of this liquid required use of equipment that could not only destroy the organic components, but could also simultaneously:

- Withstand the corrosive activity of the dissolved solids
- Continually purge itself to prevent accumulation of salts
- Process high rates of ammonium nitrogen throughput

The singular piece of equipment that was able to meet both the CERCLA criteria and the demands of treating this problematic liquid was the submerged quench incinerator.

Abandoned Well Closure Program
at a Hazardous Waste Facility
Rocky Mountain Arsenal Denver, Colorado

ABSTRACT

At the Rocky Mountain Arsenal in Denver, Colorado, more than 1500 wells have been installed into various aquifers during the past 50 years. This concern over the integrity of these wells prompted the identification, examination and closure of wells which could contribute to aquifer cross-contamination.

The well closure program at Rocky Mountain Arsenal was conducted using a three-phase approach. Phase 1 involved a records search and compilation of available data on wells; Phase 2 was a two-tiered field search for the wells, involving data review, visual inspection, geophysical survey and land survey; and Phase 3 involved the actual well closure.

Of 493 wells identified and approved for closure at Rocky Mountain Arsenal, 352 have been located and closed. The various materials used in the construction of these wells included polyvinylchloride (PVC), steel of varying grades, concrete and brick. Wells ranged in size from two inches to six feet in diameter and were completed to depths up to 780 feet. Drilling methods employed in the closure of the wells included auger, rotary, reverse circulation with cable tool or air hammer operations. Casings and obstructions were removed or drilled out during the closure operations. Conventional and unconventional "fishing" tools were used to remove casing. If casing could not be removed, then the casing was perforated. After the casing was removed or perforated, the sand zones and contacts within each of the wells were sealed following Colorado regulations on well closure/abandonment. The materials used to seal the wells included a grout mixture, bentonite, pea gravel and commercial concrete.

INTRODUCTION

The Rocky Mountain Arsenal (RMA) occupies more than 17,000 acres (27 mi^2) northeast of Denver, Colorado (Fig. 1). The Arsenal was established in 1942 and has been used for the manufacture of chemical and incendiary munitions as well as the demilitarization of chemical munitions. Additionally, RMA lessees manufactured pesticides and herbicides from 1947 to 1982. RMA is currently an active Superfund site undergoing remediation. Part of the remediation involves the closure of unused or abandoned wells to prevent the vertical migration of contaminants through these wells.

More than 1,500 wells have been identified at RMA, with as many as 250 of these water wells historically used for irrigation, stock watering and domestic use. Most of these wells were constructed prior to the establishment of RMA in 1942 and are hand-dug, ranging from 24 to 60 inches in diameter with completion depths up to 100 feet and are constructed of brick or concrete. Since the establishment of RMA, hundreds of monitoring wells have been installed on the property. The concern over the potential for contaminant migration through unused or abandoned wells prompted the Program Manager for RMA to develop

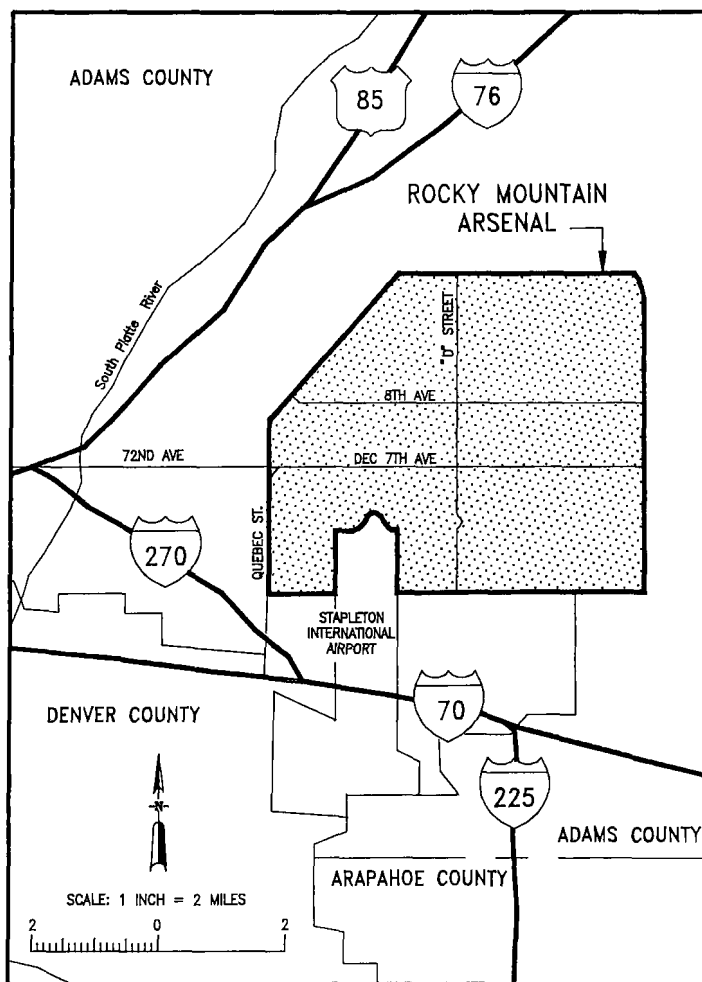
a task to locate, examine and close wells that could contribute to cross-aquifer contamination. Two hundred eighty-eight of these monitoring wells had either poor construction or no potential future use and were therefore targeted for closure. These wells varied from 2 to 10 inches in diameter and ranged in depth from 6 feet to 250 feet. This initial list was expanded to include 493 wells, of which 352 wells have been


Figure 1
Rocky Mountain Arsenal—Site Location

located and closed.

The scope of work for the RMA well closure program included: compilation of a well inventory and closure list, field location of wells, cleaning and closure of all located wells and documentation of closure activities.

WELL INVENTORY AND CLOSURE LIST DEVELOPMENT

The compilation of a well inventory and preparation of a data base provided a means for evaluating and documenting historical well closure information. Information sources utilized for the well inventory and database included: existing databases, hard copy historical records and field data collected during well search and closure activities.

Well closure was evaluated on:

- Past, current and future use of the well
- Evaluation of well construction details
- Subjective evaluation of reported well construction
- Proximity or location to active/known contaminant plumes
- Quality of groundwater (if known)

After completing the evaluation, a list of wells targeted for closure was compiled.

WELL CLOSURE PLAN

Upon approval of the well closure list, well characteristics were evaluated and appropriate well closure techniques determined. These decisions were based on the Well Closure Plan which included the following:

- Well closure specifications—in compliance with all Applicable or Relevant and Appropriate Requirements (ARARs)
- Procedures for well cleaning and data collection—in compliance with Federal and State ARARs
- Compilation of topographic and elevation survey data
- Procedures for related support activities (i.e., waste management)
- Procedures for field drilling techniques
- Procedures for data management and Quality Assurance (QA)

FIELD LOCATION OF WELLS

All wells identified for potential closure were subjected to a two-tiered search. The first level field search involved a historical data review followed by a detailed visual inspection of the reported well location followed by a detailed sweep of the suspected area with a hand-held magnetic gradiometer. Any wells found visually during the first level field search were surveyed and assessed for their physical characteristics and current condition. Wells not visually located during the first level field search were subjected to a second level field search. If necessary, a detailed geophysical survey using a magnetometer was conducted in the suspected area to further define the areas to be excavated. If no geophysical anomalies were detected, no further search efforts were conducted and the search was canceled. If an anomaly was identified, then a visual field check was performed and recommendations were made for a more detailed geophysical survey or an excavation to determine the source of the anomaly.

Geophysical Survey

During the closure program, 90 suspected well locations were subjected to gradiometer/magnetometer surveys. Approximately 35% of the wellheads were located. Survey grids used at the site were 300 feet on a side with 25-foot spacings. Additional fill-in surveys were conducted on 10-foot grid spacings over smaller areas to locate the source of any detected anomaly.

A SAGA Geophysics GSM-19 gradiometer/magnetometer was used to conduct the surveys. The SAGA GSM-19 permitted simultaneous measurement of vertical magnetic gradient and total field readings using a dual sensor arrangement.[1]

Data obtained in the field were stored in the SAGA GSM-19 computer. These data were downloaded to a PC computer. A contouring program was used to create contour maps of the total magnetic field and vertical magnetic gradient. These contour maps allowed a means to evaluate anomalies and anomaly signatures.

Well Inspection and Cleaning

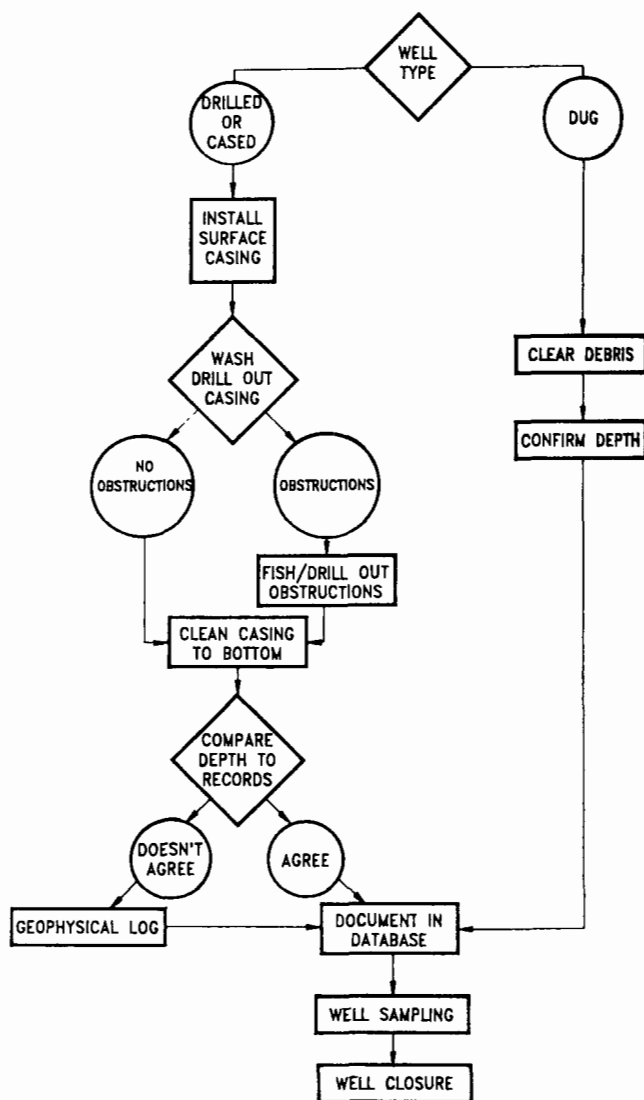
Well closure and cleaning procedures are dependent on the actual amount of debris or obstructions within wells and the type, construction, diameter and depth of each well. For this reason, the accurate collection and field verification of well condition and construction details are of critical importance. Well cleaning was conducted prior to closure to verify that well depth information were accurate, ensuring effective closure techniques were selected. Figure 2 illustrates recommended steps involved in the well inspection and cleaning process. Well construction data generated during the field investigation was checked against existing records to verify or reconstruct well construction details. In some cases, it was necessary to remove debris or redrill a well to clear obstructions prior to closure/cleaning.


Figure 2
Well Inspection and Cleaning

Geophysical Logging Techniques

Borehole geophysical logging methods were utilized in wells deeper than 200 feet to define downhole characteristics such as casing and screen condition and location, hole condition and stratigraphy. Geophysical logging included casing collar locator (CCL), neutron and gamma logging. The information compiled from caliper logs, CCL logs, gamma logs and neutron logs helped in confirmation or identification of well construction and stratigraphy. The stratigraphy of the borehole was particularly important in the determination of zones to be perforated

to properly seal the well bore.

Caliper logging (three-arm tool) was conducted to determine the diameter of the well or well bore and to identify washout zones, locate swelling clay zones and detect holes in the casing material. The CCL log was conducted to help determine the condition of the hole, casing and screen.

Gamma logging consists of a measurement of naturally occurring radiation emitted from materials encountered in and adjacent to the borehole.[2] The gamma log helped define the stratigraphy of the hole and was run in association with a neutron log. Neutron logs employ a neutron source with either a gamma-ray detector or neutron detector. Combining the data gathered from the neutron log with the gamma log helped to identify the stratigraphy and lithology of the well bore. This process located permeable, sandy zones or contacts important in determining the best zones for casing perforation.

WELL CLOSURE DRILLING TECHNIQUES

The variety of wells encountered at RMA include PVC, steel, brick and concrete, ranging from 2 inches to 72 inches in diameter, with reported depths of up to 1,000 feet (Fig. 3). Due to the wide range of well construction, various conventional drilling techniques were used for well closure (Fig. 4). Closure ideally included the removal of well casing, screen and all well construction materials. Since wells were assessed on a case-by-case basis for closure, a variety of modifications from conventional methods were employed during well closure. Conventional drilling techniques included: auger, direct rotary, reverse rotary, hammer and modified use of cable tools.

Auger Drilling Method

Continuous-flight hollow-stem augers (HSA) cut a borehole using excavation methods and carry cuttings up the hole along the flights (Fig. 5). Hollow-stem augers were used to overdrill PVC (and some steel casing) 2 to 6 inches in diameter and up to 180 feet deep. The CME-75 and CME-750 auger rigs were selected for the work at RMA due to capability of the rig.

PVC wells, 2 inches to 6 inches in diameter, were measured with tape or drill rod to verify depth within 10[4] of the historical record. If

WELL TYPE	CONSTRUCTION MATERIAL	SIZE RANGE	DEPTH RANGE
Domestic	Concrete Brick, Steel	24" 72"	20 ft. – 90 ft.
Domestic	Steel Stovepipe	3" – 20"	20 ft. – 1000 ft.
Monitoring	Steel PVC	3" – 10"	6 ft. – 260 ft.
Figure 3
Wells Encounter at Rocky Mountain Arsenal

WELL DEPTH	WELL DIAMETER	CONSTRUCTION MATERIAL	RECOMMENDED METHOD
6' – 150'	2" – 6"	PVC, GALVANIZED	HOLLOW STEM AUGER PERCUSSION HAMMER
50' – 200'	6" – 24"	PVC, GALVANIZED, BRICK	MUD ROTARY REVERSE CIRCULATION
20' 100'	24" – 60"	GALVANIZED, BRICK	REVERSE CIRCULATION ORANGE PEEL BUCKET
150' – 1000'	3" – 5"	GALVANIZED	MUD ROTARY

Figure 4
Well Closure Techniques
Figure 5
Hollow Stem Auger Drilling

the well was open, a center rod was inserted to help the HSA stay centered on the well during overdrilling. If the hole was closed by grout, the drilling speed was reduced and cuttings were observed for indications of drilling across the well. If problems of staying on the well occurred, the center bit was inserted in the HSA and the well casing was removed by drilling.

Drilling methods chosen for PVC wells with a diameter greater than 8 inches were considered on a case-by-case basis. Some were drilled out with a center bit. In other cases, rotary drilling was used to remove well debris. The auger rig and/or a rotary rig were used in some of these cases.

Steel, galvanized, or "stovepipe" wells generally ranged from 5 to 8 inches in diameter. Rotary drilling methods (with the auger rig) were used to clean these wells of sediment and obstructions. Verification of recorded depth was conducted by drilling through the bottom of the well into the formation below. Due to the size ranges of these types of wells, methods of overdrilling and pulling casing were determined on a case-by-case basis.

ROTARY DRILL METHOD
Drilling fluid is pumped down through
the drill pipe to the bit, to lubricate
and cool the bit, and jet material
from the bottom of the hole.
The fluid is then displaced upward
in the annular space between the
drill rod and casing or borehole wall,
carrying cuttings in suspension. At the
surface the drilling fluid is channeled
into a mud pit where cuttings
settle out before fluid recirculates.

Rotary drilling was used to
close wells exceeding 200'.
Figure 6
Rotary Drilling Method

Once a well was successfully overdrilled to remove construction materials, attempts were made to pull the casing by: sand locking, plugging off the lead auger or using fishing tools. If PVC casing could not be retrieved, the hole was redrilled with a center bit in the HSA. Cuttings were observed to verify that the well was drilled out. Generally, there were no problems in pulling the steel well casing in the shallow holes.

Some problems that occurred with the auger method included:

- Wells not installed straight generally required the well to be drilled with a center rod in place, making it difficult to determine that the well construction materials were removed.
- Wells not installed straight may have been drilled across during over-drilling, possibly pushing casing to the side wall of the closure boring.
- Difficulty was encountered in pulling the larger diameter steel casing.
- Crooked steel wells and twisted well casing caused augers to wedge in the hole.

Direct Rotary Drilling Method

Direct rotary drilling was used to circulate material out of a well to clean the well of obstructions. In direct rotary drilling, the drill string (Kelly, drill pipe, collar and bit) advances by rotation that breaks the formation or accumulated sediments. As the bit is rotated, drilling fluid is pumped down through the drill pipe to the bit to lubricate and cool the bit and to jet material from the bottom of the hole to the surface. The fluid is displaced upward in the annular space, between the drill rod and well casing or borehole wall, carrying cuttings in suspension to the surface.[3] At the surface, the drilling fluid is channeled to a mud pit where cuttings settle out before fluid recirculates down the hole. Figure 6 contains a summary of the direct rotary drilling method. Mud pits were generally excavated at the site; however, portable mud pits were used on occasion. The bit generally used to clean the hole was a roller bit or tricone bit.

Direct rotary drilling was used to clean out wells up to 1,000 feet deep, ranging from 3 inches to 16 inches in diameter, including some

Table 1
Fishing Tools, Operation and Application

Fishing Tool		Operation and Application
Taper tap		Internally engages larger, heavy objects such as drill pipe or well casing. Tool is constructed with flutes or threads from a small end and tapered to a larger diameter end that is rotated until it internally engages.
Die collar (box tap)		Externally engages over the top of drill pipe, well casing, or pump rod by rotation. The inside of the collar is threaded; guides can be used to engage over the top of an object.
Releasing spear		Internally catches drill pipe or well casing on rotation. A grapple above the nose of the spear grabs onto the fish.
Overshot	Circulating	Slips over the top of the fish and expands on circulation. Used to retrieve twisted-off drill pipe or pump rods.
	Releasing	Release or engage on rotation over the top of the fish. Used to retrieve twisted-off drill pipe or pump rods.
Junk mill		Bit with tungsten carbide on the grinding surface to chew (chip) up an object (fish). Material is circulated or a basket is used to catch the material from the fish.
Wireline grab		Harpoon-type spear with jagged edges to engage snarled/twisted wireline.
Magnet		Magnetic tools with a controlled permanent magnetic field, used to pick up small objects (usually irregular shaped).
Impression block		Lead-filled cylinder used to make an impression of the top of the fish to determine size and shape.

* From Wilson Downhole Services Fishing Seminar [5]

shallow holes closed by the auger rig. After a hole was cleaned out, total depth verification/determination was conducted by drilling through the bottom of the well into the formation. Wells greater than 200 feet deep were then subjected to borehole geophysical logging as described earlier. Logs were then assessed to verify reported well construction and stratigraphy and to aid in determining the proper sealing method for final closure. Wells deeper than 200 feet generally required perforation of the well casing to achieve proper sealing.

Colorado state regulations[4] require that a minimum of 50 feet of casing into the formation below the alluvium be removed. To help in the removal of the casing, washover pipe was used to overdrill the casing to a selected depth below the formation contact. As the washover pipe was rotated and advanced, cuttings from the boring were circulated out of the hole as previously described. After the depth was achieved, attempts were made to "fish" casing out of the hole using conventional petroleum industry fishing tools. Fishing tools were also used to remove any solid obstructions encountered in the well during well cleaning activities. The fishing tool was attached to the drill string, lowered to the obstruction and rotated until the tool was firmly engaged. Table 1 summarizes the fishing tools and operation used during the Closure Program.[5]

Problems encountered with the direct rotary drilling method included:

- Crooked wells created problems of tools or drill pipe stuck in hole
- Site accessibility was difficult because of rig and equipment size
- Large volume of water used for circulation created mud pits that required recontouring and reseeding of the site

Reverse Circulation Rotary Drilling Method

Reverse circulation rotary drilling was used to remove accumulated sediment and debris from wells that were constructed of concrete, brick and, occasionally, steel or stovepipe. The wells closed with this method ranged from 16 inches to 72 inches in diameter to depths of 150 feet. Some wells had cased or screened extensions below the concrete or brick casing.

The reverse circulation rig utilizes large capacity centrifugal or jet pumps to aid in the removal of cuttings from the borehole. Drill pipe (threaded or flanged) is larger in diameter than direct rotary drill pipe to accommodate drill cutting removal and to drill larger diameter holes up to 72 inches. The drill string is rotated from a Kelly table instead of a Kelly pipe (bar) due to the higher torque required to rotate the larger and heavier drill string. The formation or accumulated sediment are cut by drag bits or reamer bits.

In reverse circulation rotary drilling, the flow is reversed from the direct rotary method (Fig. 7). The drilling fluid and suspended cuttings move upward inside the drill pipe (string) by a centrifugal pump and are discharged into the mud pit. Cuttings are allowed to settle out in the mud pit prior to the drilling fluid returning to the borehole by gravity flow. The fluid flows down the annular space, between the drill pipe and well casing or borehole wall, to the bottom of the hole, picks up

REVERSE CIRCULATION ROTARY DRILLING
The drilling fluid/water flows from the mud pit down the borehole outside the drillrods. Fluid is then pulled through the bit into the drillrod carrying cuttings. Fluid is pulled upward, flowing through the swivel and mud pump and into the mud pit, where the cuttings settle out.

Reverse Rotary Drilling was utilized to close larger diameter holes 24" – 72").

Figure 7
Reverse Circulation Drilling Method

cuttings and re-enters the drill pipe through ports in the bit carrying cuttings in suspension back up through the drill pipe. Cobbles or boulders that cannot pass through the drill pipe are removed with an orange-peel bucket.

The orange-peel bucket was used to excavate accumulated sediment and/or debris in the wells. The heavy metal bucket, fitted with four leaves that form a steel jaw, opens outward from the bottom. The bucket is dropped into the well on a cable system with the bucket jaws open. The weight of the bucket digs the jaws into material at the bottom of the hole. The jaws then close on a load of material, which is withdrawn from the hole and dumped at the surface. Smith and Schneider[6] describe the use of the orange-peel bucket for well installation. Large diameter wells selected for closure at RMA were initially drilled with the orange-peel bucket until no further advancement could be made. Then reverse circulation drilling was employed to complete the closure.

The bottom of a well was verified based on observation of cuttings and drill rig reaction. Most wells closed with this method were constructed in the alluvium with screen set just above consolidated material. Indications that the bottom of the well had been reached included: stiff drilling, refusal, consolidated material, lack of well debris or lack of accumulated sediment.

Some problems encountered with the reverse circulation rotary drilling method included:

- Limitation of accessibility at sites due to rig size
- Large amount of water supply for circulation also requires large mud pit
- Surface collapse problems caused by the use of a large amount of water for circulation in unconsolidated (sandy) material
- Flowing sands and collapse of well casing

Some of these problems were solved by using conductor casing set inside the well casing to help keep the well open and allow circulation.

Percussion Hammer Drilling Method

A percussion (casing) hammer drill drives a double-walled steel casing into the ground with a diesel pile-driving hammer. The drilling method

can rapidly penetrate unconsolidated material including sand, gravels and cobbles.

Reverse-air circulation cools the bit and removes cuttings from the boring. Air is forced down the drill pipe that escapes through ports on the bit, lifting the cuttings back to the surface and into a cyclone where the cuttings drop out of the circulated air.[3] The cuttings can then be collected in a drop box or drums to contain any contaminated material. Water-based drilling fluid can also be used to help in the removal of drill cuttings. At RMA the dual walled drill pipe was driven over PVC casings up to 6 inches in diameter and up to 100 feet deep. Successful attempts were made to pull the well casing prior to drilling, then the boring was redrilled to remove well construction matter. This type of drilling helped alleviate the problems encountered with crooked wells. The bottom of the well was determined based on cuttings and drill rig reaction. The borings were cleaned with the reversed air circulation and grouted.

Problems encountered with the Percussion Hammer Drilling method included:

- Drilling across crooked PVC wells
- Limitations on site accessibility due to weight of the rig
- Material becoming lodged in return line (safety hazard due to potential breaking of return line)
- Drilling problems in flowing sands

WELL CLOSURE

Recommended closure methods employed during the program included standard procedures commonly used in the water well and/or petroleum industries. Modifications to these procedures were made on a case-by-case basis. All closures were performed in compliance with the requirements of the State of Colorado[4] as well as USATHAMA[7] and SDWA (UIC).

Each well to be closed was evaluated individually, with careful consideration given to the well construction characteristics and the geologic setting. Closure techniques were then adapted for each individual well to accommodate well depth and the volume of grout required to effectively seal the well was calculated. If artesian conditions existed, the sealing operation was designed to confine the water and prevent transfer of groundwater between aquifers.[4]

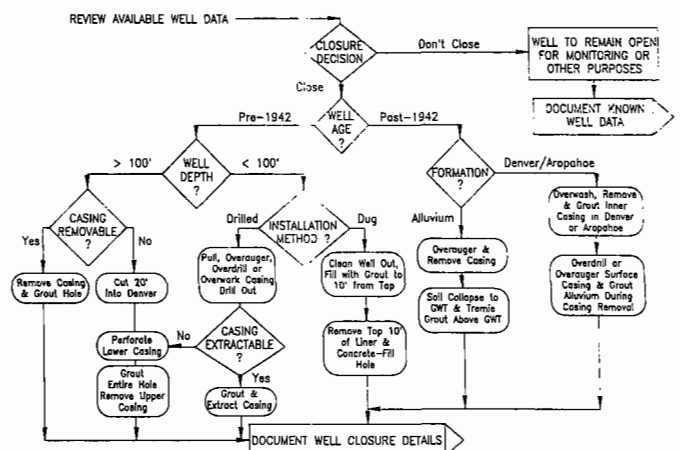
Standard closure practices included removal of all materials which would hinder the sealing operation, including screen and casing (Fig. 8). If the casing was in good condition, an attempt was made to remove it by fishing with cables, tools or sand-locking techniques. If the casing was in poor shape, an attempt was made to either overdrill or wash out the soil surrounding the casing to facilitate its removal. If the casing could not be removed, it was cut, torn or perforated to allow the grout to completely seal the annular space. At a minimum, casing was removed 50 feet into the formation below the contact with the alluvium (as specified by Colorado regulation). The targets for perforations were


Figure 8
Standard Well Closure

zones of permeability, sand zones or contacts, where it is important to have a good seal to prevent potential cross-aquifer contamination.

Large-Diameter Hand Dug Wells

Wells at RMA with diameters of 24 to 60 inches and depths of 30 to 90 feet (hand dug or drilled) were typically constructed with cement, stone, or brick liners. Prior to closure, debris was removed from these wells by fishing tools with cables, reverse rotary drilling or cable tool methods. The bottom of each well was then inspected for drilled, cased extensions. These types of wells were closed by filling the wells with sand to within 10 feet of the surface, followed by capping with commercial concrete to three feet below grade. The remaining space was allowed to collapse and fill with matrix soil (Fig. 9). Those wells found to have drilled, cased extensions were closed as drilled wells by grouting in the extension portion, followed by closure of the upper portion as described above.
Figure 9
Well Closure Methods

Deep Drilled Wells

Methods selected for the closure of deep (>200 feet) drilled wells were based on available well construction information review. These wells were effectively cleaned and closed using mud rotary methods. Due to the depths of these wells, geophysical logs were run to determine the condition of the casing in the well and to aid in decision-making on perforations and casing removal.

Borehole geophysical logs were evaluated for determination of screened intervals and lithology of the borehole. The condition of the casing and the location of casing and screen connection joints (CCL log) were taken into consideration to help define zones that needed perforation to seal the well.

Mechanical perforation methods were originally proposed but determined to be unfeasible due to poor well conditions and small well diameters. Class A explosives in shaped charges were utilized to cut holes in steel casing, concrete and the formation behind the casing.

Following perforation activities, the well was grouted from the bottom to a preselected interval. The grout was allowed to cure for 24 hours, then well casing overdrilling was used to remove the upper portion of the well. Following removal of the well casing, the boring was grouted from the bottom to the ground surface (Fig. 9).

Shallow Monitoring Wells

Shallow monitoring wells were usually constructed of PVC or steel casings with short screened intervals in unconsolidated alluvial materials or water-bearing formations. Auger or hammer drilling methods were normally used to close the wells following the procedure outlined in the well cleaning and closure sections. If removal or perforation of the casing was not possible, the closure technique was modified and included: backfilling the screened portion of the well with clean sand and filling the remainder of the borehole with grout to the ground surface, or drilling out the casing. If the depth of the well and the location of the screened interval extended across more than one aquifer, the entire casing and screened interval was required to be filled with grout to the ground surface (Fig. 9).

Grout Placement in Small Diameter Wells

Following removal or perforation of the casing materials, grout was mixed and placed in the borehole of small (<24 inches) diameter wells. A slurry of Type I-II cement and approximately 3 to 5% bentonite powder was prepared. This slurry was pumped under pressure through a tremie pipe to within one foot of the bottom of the borehole by the Brandenhead method. With this method, mud channels are minimized.

Grout mixtures of this composition are reported to attain an approximate density of 14 lb/gal.[9] This density is sufficient to displace the drilling fluid column. After allowing the grout column to cure, the grout column was topped off to bring the grout level to within two feet of the surface.

CONCLUSION

Contamination of aquifers is a major environmental concern to PRPs, industry and government. The closure of abandoned or unusable wells is an important method for controlling this potential migration pathway for aquifer cross-contamination.

If a well is unused, abandoned or of questionable integrity, the well should be assessed for potential current or future use for monitoring, dewatering, injection, etc. If the well does not comply with applicable regulations, then closure should be recommended.

Methods of well closure are modified from those used in the well drilling industry and vary depending upon the physical characteristics of the well. The wells must be located, if they have been damaged or buried, and characterized by visual inspection or investigation with appropriate drilling and geophysical technologies. The actual closure of the well and associated boring will be dependent upon local regulations and conditions. Well closure programs are important in minimizing or providing control to potential aquifer cross-contamination.

Remediation of a Surface Impoundment Basin F—
Rocky Mountain Arsenal

Edwin W. Berry III
Office of the Program Manager
Rocky Mountain Arsenal
Commerce City, Colorado

INTRODUCTION

In Feb. 1989, the Department of the Army, Shell Chemical Company, the U.S. EPA, the Department of Interior and the Agency for Toxic Substances and Disease Registry, entered into a Federal Facility Agreement (FFA) to establish a procedure through which the organizations will cooperate in the implementation of response actions at Rocky Mountain Arsenal. One provision of the Agreement provides that specified Interim Response Actions which are compatible with long-range cleanup goals will be implemented in advance of a final Record of Decision, not planned until 1994. The remediation of Basin F is one of 13 IRAs identified in the FFA.

Use of the Interim Response Action provisions of CERCLA at this NPL site significantly accelerated the time-frame for remediation as compared to the time that would be required for remediation after the Record of Decision. It is estimated that six years were saved by using this approach to a remedial action.

This paper presents a case history of the remediation of "Basin F," a 93-acre hazardous waste surface impoundment and as reported by other Superfund project site managers relates the challenges above and beyond typical construction project events and problems. Problems resulting from unusual weather conditions, community relations issues and reprogramming activities are highlighted rather than discussions of the normal construction and historical events.

PROJECT OBJECTIVES

Objectives of the Basin F interim action were: (1) eliminate future emissions of volatile chemicals from the basin; (2) to prevent infiltration of Basin F contaminated liquids into underlying groundwater; and (3) to eliminate potential adverse impacts to wildlife that otherwise would come in contact with the contaminated liquids, sludges and solids. All of the objectives were achieved.

IMPOUNDMENT DESCRIPTION

Basin F was constructed at Rocky Mountain Arsenal in 1956 for disposal of contaminated liquid wastes from Army and lessee chemical manufacturing operations. When constructed, Basin F was provided a 3/8 inch thick catalytically blown asphalt membrane liner. This liner was covered with a 12 inch protective soil/sand cover. Basin F covered approximately 93 acres and had a capacity of 240 million gallons. Design and construction of Basin F was a cooperative effort of the Bureau of Reclamation and the Army Corps of Engineers (COE). In addition to its life as a solar evaporation pond at RMA for 32 years, Basin F was used as the settling basin for liquid waste prior to its treatment and injection into the 12,000 foot deep well. The injection well has also been closed.

Project Phrasing - Major Events

After the contract for the remediation project was awarded, the COE issued a notice to proceed in February 1988. Site preparation began in March 1988. Initial work was designed to provide health, safety and administrative facilities for the 180 personnel who would work at the site for approximately one year. Special decontamination facilities were constructed to accommodate the 110 workers who would enter the heavily contaminated portion of the site. Initial activity included installation of a 360° air monitoring network of high volume samplers and initiation of a sampling program to characterize the surface characteristics. Borings were placed on 50 foot centers to develop waste volume estimates and to determine the extent of deposition of sludge material.

Pumping of the liquid from the impoundment into 4,000,000-gallon capacity storage tanks began in May 1988 with expectations that this storage capacity would be adequate. Stainless steel tanker trucks were utilized to transport the liquid due to its extremely difficult material handling properties.

The first of several major weather complications to impact on the project arrived in May 1988 in the form of a 20-year rain event, yielding 3.5 inches of precipitation before it ended. The immediate effect was to increase the volume of chemically-contaminated liquid to 14,000,000 gallons, 10,000,000 million gallons in excess of tank capacity. This increased volume of contaminated water also affected the site condition by expanding the shoreline to the point that it covered the planned construction areas for a 16-acre waste pile. This waste pile was supposed to contain the 480,000 cubic yards of dried waste that would be generated by the time the project ended.

Immediate relief was achieved by constructing two double lined waste ponds with 8,500,000 and 5,000,000 gallon capacities. The excess liquid was transferred to these ponds, which then were covered. These ponds also were used to collect leachate from the waste pile.

The second major weather event occurred in June 1988, with a tornado moving from west to east across the northern perimeter of the site. The tornado caused damage to heavy equipment and, as we later discovered, also placed contaminated soil particles between the layers of HDPE liner as the ponds were being constructed. It was not until one year later that contaminated leachate was found in the collection systems. This development gave rise to questions concerning the integrity of the newly constructed ponds.

Increasing volume estimates continued during later project phases. At completion of the liquid pumping, it was determined that bottom elevations used to calculate waste volumes were incorrect and that deposition of crystallized waste into a hardened solid form had dramatically misled project planners. New exploratory excavation revealed that another 4 feet of crystal waste and yet another 4,000,000 gallons of liquid waste remained entrenched in layers above the asphalt

liner.

This discovery led the Army, the U.S. EPA and the COE to begin a phase known as constructive suspension of the project to evaluate engineering and cost alternatives. To the credit of the managers involved, schedule and cost growths were authorized and a planned winter work shutdown was canceled concurrent with a decision to move forward through the winter of 1988 and to complete the project as nearly as possible to the original completion dates.

Odor Problems and Community Involvement

In parallel with increased volumes, cost growth and expanded schedules, odor problems developed in the community one mile from the site; community concerns arose in August 1988. Prior to construction, numerous air monitoring studies had evaluated the potential for VOCs emissions; no potential off-site health hazard was identified. Nonetheless, local citizens soon complained of odors causing symptoms of nausea, headaches and choking. In retrospect, it is clear that these odor problems caused decreased public confidence in the program, which, in turn, necessitated major program modifications to: evaluate and implement odor control measures; reevaluate of acute and chronic health effects (conducted concurrently by six health organizations); and operate an odor control team which responded to a telephone hot-line around-the-clock.

Unique to this project was the delivery of 40 room air purifiers to the residents to control odors in their homes. While odor problems have been reported at other cleanup sites, this factor weighed heavily on com-munity acceptance of the project even though Basin F had been known in the community for 32 years at the time of remediation.

A series of public site tours, public data exchange opportunities and question and answer sessions was implemented to respond to community concerns regarding the odor problem. Ultimately, legal action was initiated by citizens who considered themselves harmed by the odors. All parties involved acknowledged that the Basin F project was being conducted in a commercial/industrial/residential mixed area with numerous odor sources. These factors will be considered well in advance of future cleanup activity.

Again, the sponsor and regulatory agencies had to evaluate alternatives in order to proceed with the project with the potential of choose between slowing down the cleanup and extending the schedule or proceeding with controlled activity and finish as soon as possible, thereby shortening the nuisance time. Assurances from senior health officials, based on the air monitoring data and toxicological evaluation that air quality was safe, provided the answer.

BASIN F - A SUCCESS STORY

In evaluating the events at Basin F, in retrospect, one learns that not all Superfund cleanups progress smoothly. Examples exist of sites partially finished that remain on some federal court docket. Work was never begun at other sites after years of RI/FS study and analysis. Evaluation of remediated site conditions today shows that the area is safely protected from the environment as stated in project objectives. On some projects, only persistence will win the day.

Evaluation of Adsorption Processes for the Removal of Residual Chemicals from Water Treated by an Ultraviolet/Chemical Oxidation System

Commerce City, Colorado

ABSTRACT

As one of several Interim Response Actions (IRAs) being conducted at Rocky Mountain Arsenal (RMA) under CERCLA, the Program Manager for Rocky Mountain Arsenal (PMRMA) chose ultraviolet (UV)/chemical oxidation as the best process for treatment of approximately 300,000 gallons of hydrazine-contaminated rinsewater at RMA. The rinsewater is contaminated with hydrazine and hydrazine-derivative compounds, such as unsymmetrical dimethylhydrazine or 1,1 dimethylhydrazine (UDMH) and monomethyl hydrazine (MMH), in concentrations in excess of 1,000 mg/L, as well as N-nitrosodimethylamine (NDMA) and organic compounds such as organochlorine pesticides and chlorinated hydrocarbons.

Because the project action level for NDMA is 1.4 pg/L (ppt) and because the hydrazine fuels decompose before NDMA is destroyed to the action level, 1.4 pg/L of NDMA was targeted as the goal for treated effluent. The UV/chemical oxidation process typically can treat hydrazine compounds in 16 hours, while 35 hours are required to decrease the NDMA concentration to approximately 1 to 2 ppb (μg/L), which does not meet the treatment goal of 1.4 pg/L.

Investigating a possible secondary treatment that could reduce NDMA concentrations even further, RMA and the U.S. Army Engineer Waterways Experiment Station (WES) attempted to achieve a lower effluent level without costly additional UV/chemical oxidation treatment. Three adsorption processes, granular activated carbon (GAC), organic-based ion exchange resins and activated alumina, were evaluated by WES. None of the adsorbent manufacturers could provide any information on the NDMA removal performance and adsorptive capacity of their products. Therefore, a bench-scale treatability study was initiated at WES to evaluate the three adsorption processes for removing trace amounts of NDMA from the UV/chemical oxidation system effluent.

Results from the study indicate that GAC is the best adsorbent evaluated because of its ability to reduce NDMA levels consistently below 2 μg/L. An economic analysis comparing GAC treatment to additional UV/chemical oxidation treatment was performed and the results show that significant cost and time savings can be achieved by using GAC as a secondary treatment process.

INTRODUCTION

The Hydrazine Blending and Storage Facility (HBSF) at Rocky Mountain Arsenal (RMA) in Denver, Colorado, is owned by the U.S. Air Force (USAF) and was operated by RMA between 1962 and 1982 as a depot to receive, blend, store and distribute hydrazine fuels. The primary operation was the blending of anhydrous hydrazine and unsymmetrical dimethyl hydrazine (UDMH) to produce Aerozine 50, a rocket propellant, in response to requests by the USAF. The materials were manufactured elsewhere and shipped to RMA for blending. Other operations performed at the HBSF included loading and unloading rail cars and tank trucks carrying hydrazine fuels, destruction of off-specification batches of Aerozine 50 and storage of Aerozine 50, anhydrous hydrazine, monomethyl hydrazine (MMH), monopropellant hydrazine, hydrazine 70, UDMH and hydrazine.

Hydrazine and UDMH are ignitable, corrosive and reactive, thus meeting the identification criteria for the characteristics of a hazardous waste as defined by 40 CFR 261.[1] They are unstable in the natural environment and rapidly decompose when exposed to the atmosphere. One of the decomposition products of UDMH is N-nitrosodimethylamine (NDMA), a suspected carcinogen.[2] The NDMA detected in wastewater samples is an intermediate generated during the production of UDMH using nitrosation and the catalytic reduction of dimethylamine.[3]

When the OSHA inspected the HBSF in 1982[4] and found airborne NDMA, RMA ceased operations and closed the HBSF to all but essential personnel. All blending materials were removed and the tanks and piping were decontaminated. These activities resulted in the generation of 300,000 gallons of rinsewater, which contains approximately 1,000 mg/L of hydrazine, 160 mg/L of MMH, 1,100 mg/L of UDMH and 180 μg/L NDMA.

In the Decision Document for the HBSF cleanup, the Army agreed to attempt treatment of the NDMA in the wastewater to 1.4 pg/L, the Ambient Water Quality Criterion for NDMA. Although not applicable, the value is considered a relevant and appropriate requirement (ARAR), thus serving as the ARAR governing the cleanup of the HBSF. The 1.4 pg/L level is well below the analytical detection limit for NDMA, making verification of successful treatment very difficult.

SELECTION AND DESCRIPTION OF A TREATMENT PROCESS

After a thorough review of the possible treatment alternatives, an ultraviolet (UV) light-catalyzed chemical oxidation process was selected for the destruction of the hydrazine fuel compounds (hydrazine, UDMH and MMH) and NDMA present in the wastewater. Three UV/chemical oxidation systems were evaluated based on the results of bench-scale treatability tests performed by each vendor on samples of wastewater supplied by RMA. The treatability tests were performed by each vendor at their respective laboratories, while chemical analyses were performed by an RMA contract laboratory.[5-7] A UV/hydrogen peroxide (H_2O_2) system marketed as Perox-Pure by Peroxidation Systems, Inc. (PSI), was selected based on the results of the treatability tests. The Perox-Pure system utilizes medium-pressure UV lamps with a proprietary UV spectrum and injection of a 50% hydrogen peroxide solution.

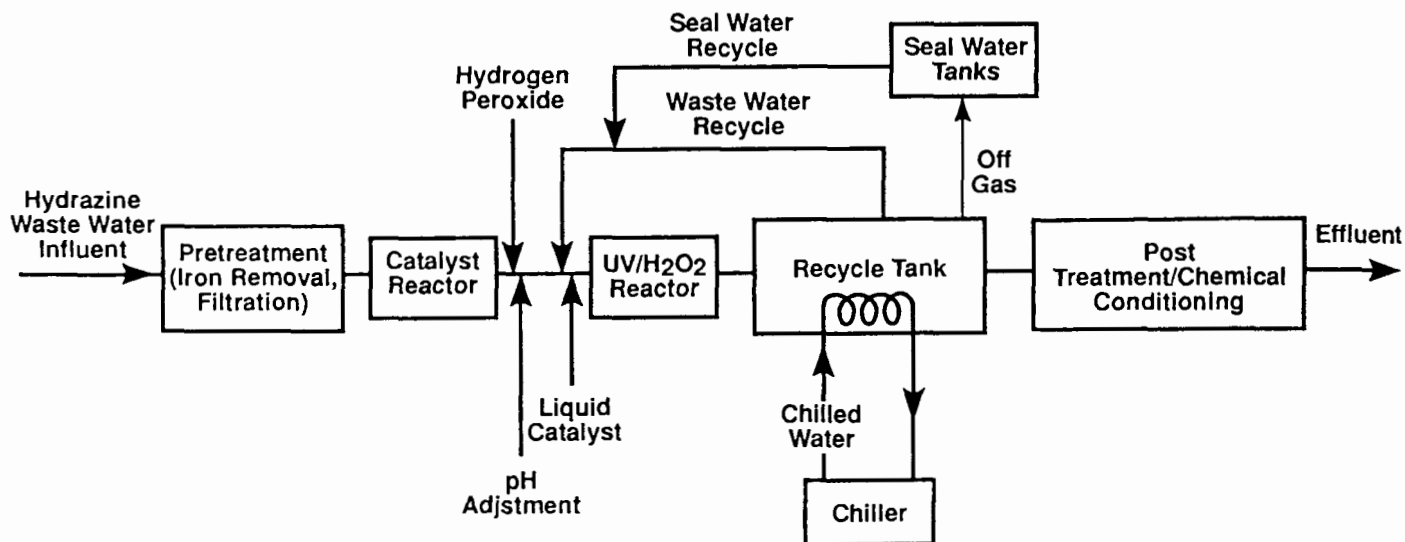
Destruction of contaminants in UV/H_2O_2 treatment systems is


Figure 1
Process Flow Schematic
Hydrazine Wastewater Treatment Facility
Rocky Mountain Arsenal HBSF

accomplished by: (1) photolysis via UV irradiation, (2) chemical oxidation by the hydrogen peroxide and hydroxyl radicals, which are strong oxidizers produced during photolysis of hydrogen peroxide and (3) the synergistic effects of both the chemical oxidizer species and the UV light.

Based on the treatability results generated by PSI, a Model No. CW-180 was selected because of its ability to provide appropriate reactor volume and flexibility. The system is housed in a newly constructed building at RMA. A general process flow schematic of the RMA Hydrazine Wastewater Treatment Facility (WWTF) constructed to treat the hydrazine wastewater is presented in Figure 1. The total system batch capacity is 1,300 gallons.

The wastewater treated by the WWTF is pumped from a steel tank located at the HBSF through a pretreatment system for the removal of iron and suspended solids and then is stored in a feed tank. Process chemicals, including hydrogen peroxide, caustic soda, catalyst and sulfuric acid, are fed into the wastewater at a chemical injection header upstream of the UV/H_2O_2 reactor. When required, these chemicals are dispersed through the wastewater by an in-line static mixer located downstream of the inlet header. After passing through the static mixer, wastewater enters through a pressure vessel containing vertical tungsten rods arranged in a bundle. The tungsten serves as a catalyst for the hydrazine/chemical oxidizer species reaction. Before entering the UV/H_2O_2 reactor, the wastewater passes through a bag filter located downstream of the catalyst pressure vessel. The bag filter removes iron flocs carried over from the feed tank.

Treatment of the wastewater is accomplished in batch mode. A recycle module allows continuous recirculation of wastewater through the UV/H_2O2 reactor and its associated recycle tank during treatment. In the context of this report, batch time represents total system (UV/H_2O_2 reactor, chiller and recycle tank) hydraulic retention time, but actual UV/H_2O_2 reactor hydraulic retention time is 25% of the total batch time for a 1,000-gallon batch. The recirculated wastewater is cooled via a chiller module, which circulates coolant through coils in the recycle module tank to remove excess heat generated during the UV/oxidation process. The temperature of the wastewater is maintained at 125 to 140 °F.

The UV/H_2O_2 process is operated at the initial pH of the wastewater brought in from the storage tank. Because the wastewater is a basic solution with a pH of 9.1 to 9.3, the hydrazine fuels act as a reducing agent. As the destruction process takes place in the UV/H_2O_2 chamber, the favored reaction for hydrazine is oxidation to N_2.[3] The rate of hydrazine fuel destruction is measured by the decrease in pH and the

change in oxidation reduction potential (ORP) from a negative value to a positive value. Once the pH levels off at approximately 7.0, the destruction of hydrazine fuels is complete (Fig. 2).

Following treatment in the UV/H_2O_2 reactor, the wastewater is pumped to one of two effluent holding tanks for analytical characterization and pH adjustment, if necessary, prior to disposal.

DESTRUCTION EFFICIENCIES

Bench-scale studies performed by the Illinois Institute of Technology Research Institute (IITRI) and PSI indicate that hydrazine fuel compounds are initially destroyed at a rapid rate, but the rate decreases as the concentration of hydrazine fuel compounds decreases. Based on the experimental results, PSI[5] and IITRI[8] conclude that destruction of hydrazine fuels and NDMA can be accompanied by the UV/H_2O_2 process and that during the UV/H_2O_2 process, hydrazine is decomposed prior to NDMA destruction.

Pilot testing was performed by Harding Lawson Associates (HLA) under PMRMA contract using the full-scale UV/H_2O_2 treatment system to confirm the bench-scale treatability test results. The bench-scale testing indicated that hydrazine and NDMA destruction could be accomplished in 16 hours. The pilot-scale testing verified that the hydrazine fuels are decomposed prior to limited NDMA destruction and determined that the time required for successful treatment of NDMA and the hydrazine fuels is dependent on the influent concentration of NDMA. Further pilot testing indicated that treatment time of more than 50 hours may reduce the NDMA concentration below 1 $\mu g/L$, unfortunately at a significant increase in treatment cost, but still may not reach the target effluent levels of 1.4 pg/L of NDMA.

ADSORPTION COLUMN TESTING

Because of the low target treatment levels and the extremely long time required for the UV/H_2O_2 process to reach those levels, if they could indeed be reached (Fig. 3), various adsorption processes were evaluated for removal of the residual NDMA from the UV/H_2O_2 reactor effluent after hydrazine compounds were destroyed (approximately 20 hours of treatment). This evaluation was performed in hopes of meeting the NDMA action level at an appreciable cost and time savings over additional UV/H_2O_2 treatment beyond the hydrazine compound destruction end-point, which can be detected during system operation by monitoring UV/H_2O_2 reactor pH and oxidation reduction potential (ORP).
Figure 2
Total Hydrazine Fuel Destruction Utilizing
UV/H₂O₂
Figure 3
NDMA Destruction Utilizing UV/H₂O₂
Treatment Process

Adsorption column testing was performed at the U.S. Army Engineer Waterways Experiment Station (WES). Test influent for this study was collected from the UV/H$_2$O$_2$ system effluent tank, had a pH of 2.45, had an NDMA concentration of 66 μg/L and was shipped to WES in two 55-gallon drums.

The adsorbents evaluated at WES were granular activated carbon (GAC), activated alumina and two synthetic resins. Table 1 lists the manufacturing source, trade name and vendor for each absorbent. The columns were constructed of Plexiglas and measured 2.0 feet in length and 0.17 feet in diameter. The columns were run in an upflow mode using peristaltic pumps and flowmeters to control the influent flow rate (Fig. 4). Stainless steel screens were placed over the inflow and outflow ports of the columns to prevent the adsorbents from exiting the columns.

Table 1
Adsorbent Types and Sources

Adsorbent	Type	Brand Name	Manufacturer
Activated Carbon	Coconut Shell	CC 601	Westates

Ion Exchange	Polyaromatic	XAD-4	Rohm and Haas
Ion Exchange	-SO3-H+ Based	Amberlyst 15 WET	Rohm and Haas
Figure 4
Adsorption Column Test Apparatus

The adsorbents were soaked for 24 hours in distilled, deionized (DDI) water before they were loaded into the columns. The columns were filled with DDI water prior to loading them with the adsorbents so that the adsorbents would stay wetted. As the adsorbents were added to the column, DDI water was removed to prevent the columns from overflowing. Each column was completely filled with the appropriate adsorbent.

All columns were run at a flow rate of 0.15 L/min, which equates to a hydraulic flux of 2.0 gpm/ft^2. The empty bed contact time (EBCT) for all columns was 8.25 minutes. NDMA samples were collected from each column at 5, 10, 20, 40 and 70 bed volumes. A bed volume constitutes an amount equal to the total volume of the empty column.

COLUMN TESTING RESULTS

The effluent NDMA concentrations from each column and the respective bed volumes at the time the samples were collected are listed in Table 2. Figure 5 is a plot of NDMA concentrations versus bed volumes passed through each column.

At 40 bed volumes, the effluents from all columns experienced increases of varying magnitudes in NDMA concentration (Fig. 5). The reason for this increase in effluent NDMA concentration is unknown. The first of the two drums containing the test influent was emptied after 40 bed volumes had passed through each column, requiring that a sample

Table 2
Adsorption Column Effluent NDMA Concentrations

Bed Volumes	Activated Carbon (ppb)	Activated Alumina (ppb)	XAD-4 (ppb)	Amberlyst 15 WET (ppb)
5	0.576	201.000	0.755	0.180
10	0.189	0.756	0.206	0.167
20	0.078	1.170	0.585	0.265
40	1.210	14.400	2.510	1.670
70	0.020	0.020	0.717	1.660

from the second drum be used to complete the study. It is possible that changing drums may have upset the adsorbent/adsorbate equilibrium, due to slight differences in influent quality, causing desorption of NDMA to occur until equilibrium was again reached with the new influent.

Table 2 shows that the activated alumina column had the highest effluent NDMA concentrations of the four adsorbents. However, activated alumina did provide significant removal of NDMA from the influent, except for bed volume No. 5 which had a concentration of 201 μg/L and was not plotted because the high value would have distorted the plot. The activated alumina bed volume No. 5 concentration is approximately three times higher than the influent NDMA concentration. The reason for this increase in NDMA concentration through the column is not understood. It is possible that sample bottle or analytical contamination could have occurred, but the QA/QC procedures associated with the NDMA analysis indicated no such problems. A second possibility is that the activated alumina initially contained NDMA produced during the manufacturing process; however, the NDMA removal achieved during subsequent bed volumes does not substantiate this conjecture unless all of the NDMA was washed from the activated alumina prior to sampling of bed volume No. 10.

The two synthetic resins had appreciable NDMA removals throughout the 70 bed volumes. The Amberlyst 15 WET resin performed slightly better than the XAD-4 resin. Also, the two resins did seem to have more consistent NDMA effluent concentrations than the other two adsorbents.

In Table 2, it can be seen that the activated carbon generally had either the lowest (bed volumes 20, 40 and 70) or the second lowest (bed volumes 5 and 10) NDMA concentrations. All of the activated carbon column effluents were less than 1.5 μg/L, with only one sample (bed volume 40) greater than 1.0 μg/L. This result is surprising because some activated carbons are actually used to purify amine compounds.

Based on the results of the adsorption studies, GAC was considered the best adsorption process because: (1) GAC generally had the lowest NDMA effluent concentrations; (2) GAC seemed less sensitive to system upset than the other adsorbents and (3) resins traditionally, are very sensitive to changes in influent quality, but GAC is much more flexible in its ability to respond positively to influent changes.

ECONOMIC ANALYSIS OF TREATMENT ALTERNATIVES

Because NDMA breakthrough was not detected in the effluent from the activated carbon column after 70 bed volumes, for sake of economic comparison it was assumed that the activated carbon column could treat at least 70 more bed volumes before NDMA breakthrough. At this loading, approximately 130 gallons of column influent could be treated per pound of activated carbon.

The cost of the activated carbon used in this study was $1.59/lb. Thus, using activated carbon to treat all 300,000 gallons of the post-UV/H$_2$O$_2$-treated water for an additional 30 hours would cost approximately $13,000 and would take approximately 600 hours. This cost estimate does not include labor or energy costs because they were considered minimal; the operation of small adsorber systems is neither labor-intensive nor energy-intensive. Labor associated with operating a low-flow (<10 gpm) GAC canister system consists of turning the system on and off daily and periodically changing the exhausted GAC canister; operator supervision of this type of system usually is not required. Energy costs associated with a low-flow GAC system consist of the operation of a small influent pump.

Conversely, labor and energy associated with the UV/H$_2$O$_2$ system costs are significant; the additional 30 hours of treatment requires direct operator system supervision and the reactor uses approximately 110
Figure 5
NDMA Adsorption Study

kw/operating hour. The cost of treating 1,000 gallons with the UV/H$_2$O$_2$ reactor for an additional 30 hours is approximately $1,450. Therefore, the cost of treating all 300,000 gallons of wastewater for the additional 30 hours is $435,000 and the time involved is 9,000 hours.

These estimated costs show that using the activated carbon system as a secondary treatment unit will result in a cost savings of approximately $423,000, which is significant compared to the overall cost of treating the 300,000 gallons of water. In addition, the time saved by using activated carbon in the test configuration is approximately 8,400 hours for all 300,000 gallons.

ADDITIONAL RESEARCH EFFORTS

Further testing will be performed using the coconut shell-based activated carbon to determine whether increased EBCTs and/or pH adjustment would result in reduced NDMA effluent concentrations from the activated carbon column and to determine actual activated carbon NDMA-adsorption capacity.

CONCLUSIONS

All adsorbents were able to remove NDMA from the test influents, except for activated alumina during the initial bed volumes. The Amberlyst 15 WET resin performed slightly better than the XAD-4 resin. Activated carbon was considered the best of the four adsorbents evaluated and will be further optimized in future studies. Also, the effluent from the GAC had consistently lower NDMA concentrations than the effluent from the UV/H$_2$O$_2$ system. It is believed that effluent

NDMA concentrations less than 100 pg/L can be reached using GAC as a secondary treatment process. Economic analysis indicates that using GAC as a secondary treatment system after 20 hours of UV/H$_2$O$_2$ treatment would result in a net savings of $423,000 and 8,400 hours of treatment time.

Hazardous Waste Incineration: Remedy Selection and Community Consensus Building at Rocky Mountain Arsenal

Steven E. James
Woodward-Clyde
Oakland, California

ABSTRACT

This paper discusses the selection of a technical solution to a major serious hazardous waste problem and development of widespread community support for that solution; it is a success story. Rocky Mountain Arsenal is located in the Denver metropolitan area and has frequently been called the "most contaminated piece of ground in the United States," or the nation's most serious hazardous waste site. The single most pressing and urgent problem at Rocky Mountain Arsenal is destruction of approximately 9 million gal of toxic liquid waste from Basin F, an evaporative pond dating to the 1950s. In 1989 and 1990, a remedy selection process was conducted under CERCLA, and a submerged quench incinerator was selected. The remedy selection process is of interest for several reasons:

- First, the waste is unique and has physical and chemical properties that make it hard to treat in most conventional processes (therefore this was technically challenging)
- Second, the work was done under a regulatory arrangement that made it necessary to accommodate the concerns and interests of five federal agencies, a private company and the State of Colorado
- Third, a 10-yr history of (mostly unsuccessful) treatability studies and the potential availability of promising (but untested) new technologies presented an uneven set of technical data
- Fourth, for practical and legal reasons, the remedial decision had to be made, and the cleanup completed, within about a 40-mo time frame
- Fifth, the selected remedy called for installing a hazardous waste incinerator within the Denver metropolitan area, a traditionally environmentally active area
- Sixth, a significant part of the remedy selection task was an innovative community relations program that was aimed at building consensus for a decision to avoid post-decision opposition (the Army issues a "decision document" in lieu of ROD)

The most interesting aspect of all was that no widespread public opposition to this incineration proposal was experienced when the decision was announced; on the contrary, the U.S. EPA, State of Colorado and several local citizen groups endorsed the decision. The incineration plant is being designed and will be built and operated without formal permits, and the cleanup is expected to be completed on or ahead of schedule. The key elements of this controversial and successful process are:

- A broad and imaginative technology screening process

- Early and intensive use of quantitative risk analysis (as a technology screening tool, for building public consensus for an on-site vs. off-site decision and for the detailed evaluation of remedial alternatives)
- Use of formal decision analysis techniques (to clarify issues and tradeoffs, rank the alternatives, and predict/resolve concerns arising out of the points-of-view of the many public and private groups affected by the decision)
- Consensus building through direct public participation in the technical decision, in a community relations program

PROBLEM OVERVIEW

For several years preceding 1988, remediation program managers at Rocky Mountain Arsenal (RMA) had accumulated waste treatability data that suggested that selection of an incineration remedy seemed possible if not likely at this site. In mid-1988, the Army agreed to a cleanup completion date for Basin F liquids that meant that studies, design, construction, testing and operation had to be completed in 5 yr, which is less than half of the normally required time for a hazardous waste incinerator, if that was to be the chosen remedy. Given this tight time schedule, delays of any length could not be tolerated; indeed, there was a pressing need to accelerate the program. To meet this challenge, a technical study was needed that not only addressed the subject matter and made a credible remedy selection, but also anticipated the concerns and likely reactions of the public and regulators and resolved these concerns prior to making a final decision. Furthermore, some type of community involvement program was needed that would give the public a role and a voice in the final decision, thereby building consensus and reducing the possibility of delays from local political pressure or litigation of local origin.

HISTORY OF BASIN F LIQUIDS

Rocky Mountain Arsenal

Rocky Mountain Arsenal (RMA) is an installation of the U.S. Army Armament, Munitions and Chemical Command (AMCCOM). RMA occupies more than 17,000 acres (approximately 27 mi^2) in Adams County, adjacent to and directly northeast of metropolitan Denver, Colorado. RMA is bounded on the south by industrial uses and Stapleton International Airport, on the west and northwest by residential neighborhoods ranging from medium to low density and on the north and east by agricultural lands, mostly rangeland. To the casual observer, RMA appears to be wide open, gently rolling prairie with a few widely dispersed concentrations of buildings or industrial facilities.

Wildlife is abundant, including a few threatened and endangered species such as bald eagles.

RMA was established in 1942 and has been the site of manufacture of chemical incendiary munitions and chemical munitions demilitarization. Following World War II, Congress directed the leasing of portions of RMA to private commercial interests; some of the industrial production facilities at RMA were leased to chemical companies. Agricultural chemicals including pesticides and herbicides were manufactured at RMA from 1947 to 1982. Present-day contamination problems at RMA result from both the military and agricultural chemicals manufacturing activities. All industrial activities at RMA ceased in 1982, and the Army's attention focused on cleanup of the contaminated land and water resources. Initial remedial activities were planned and implemented by the Corps of Engineers; in recent years, the mission of RMA has been redefined to be contamination cleanup, and the remediation program is now managed directly by AMCCOM, through the RMA Program Manager's Office.

Disposal practices at RMA have included routine discharge of industrial and munitions waste effluents to evaporation basins. Spills of raw materials, process intermediates and final products have occurred within the manufacturing complexes at RMA. Many of the compounds are mobile in groundwater.

History and Status of Basin F

In 1956, an evaporation pond called Basin F was constructed in the northern part of RMA. Basin F had a surface area of 92.7 ac and a capacity of approximately 243 gal. The basin was created by constructing a dike around a natural depression and lining it with a 0.375-in. catalytically blown asphalt membrane. An earth blanket approximately 1-ft thick was placed on top of the membrane to protect it. A vitrified clay pipe with chemically resistant sealed joints was installed between Basin F and the facilities where the wastes were generated. In 1962, a low dike was placed across the southeast corner of the basin to enclose an area of approximately 8 ac. From August 1957 until its use was discontinued in December 1981, Basin F was the only evaporative disposal facility in service at RMA. In 1982 the Army, Shell Oil Company, the U.S. EPA and the Colorado Department of Health agreed to start a cooperative development plan for a comprehensive remedy for the environmental situation at RMA. In 1986, the Army, Shell and the U.S. EPA, with input from the Colorado Department of Health, agreed that an accelerated remediation be undertaken pursuant to CERCLA to contain the liquids and contaminated soils in and under Basin F.

In the first part of Basin F remediation, Basin F liquids were transferred to three lined steel storage tanks and to one double-lined covered pond. Transfer of Basin F liquids to tanks and the surface pond for interim storage was initiated in May 1988 and completed in December 1988. Prior to this time, additional liquid storage capacity in the form of a lined north surface pond had been planned, since seasonal precipitation had increased the volume of liquid beyond the initial estimate. Presently, approximately 4 million gal of liquid are stored in the tank tank and 4.5 million gal in a portion of the north surface pond called Pond A.

The present Interim Response Action (IRA) for Basin F liquids addresses treatment and disposal of the contents of the storage tanks and Pond A. This IRA was initiated in September 1988. It includes characterization of the stored Basin F liquids, selection of a treatment alternative for the liquids, a community relations program that was integrated with the remedy selection process, pilot-scale demonstration of the selected treatment technology and detailed engineering design of the remedial treatment process. The first steps of this work, characterization of the liquids and selection of a preferred treatment alternative, were done in accordance with the five-step process for remedy selection prescribed generally by Section 121 of CERCLA and detailed in the NCP (Sections 300.415 and 300.430 (e)). The community rela-

tions program was in accordance with EPA guidance for community relations programs for NPL sites. The remaining steps, pilot testing and detailed engineering design, are underway and are planned to be completed by the end of 1990. This schedule will lead to completion of construction and testing in late 1991 or early 1992 and completion of the cleanup action (destruction of Basin F liquids) by mid-1993.

Characteristics of Basin F Liquid

In this study, characterization of the Basin F liquids consisted of sampling and analyzing the wastes to determine their chemical and physical properties in relation to engineering design and performance requirements of potential treatment processes and to provide the basic chemical parameters needed for a risk analysis of alternatives selected for detailed evaluation.

This testing confirmed that Basin F liquids are nearly saturated with common salts and ammonia gas. They also contain heavy metals such as copper and arsenic. In addition, they contain low levels of pesticides and byproducts of pesticide and chemical warfare agent manufacturing. The characteristics of Basin F liquids constrain the choice of treatment and disposal techniques and may require special design of treatment alternatives. For example, Basin F liquids may precipitate solid salts or release ammonia gas when stirred or combined with certain chemicals. The amounts of heavy metals, particularly copper, in the Basin F liquids may rule out certain treatments for the organic compounds also contained in the liquids. The high salt content of the liquids is corrosive to many kinds of treatment equipment.

REGULATORY FRAMEWORK

The cleanup of Basin F liquids is subject to two principal regulatory imperatives: CERCLA, and the Federal Facility Agreement for RMA. In addition, a number of other regulations and policies (ARARs) have been applied to the remedy selected for Basin F liquids, and certain other regulatory positions were considered in forming the remedial decision.

Remedial Authority

The destruction of Basin F liquid is an "interim response action" planned to be completed prior to an Arsenal-wide cleanup that is being defined in RI/FS studies. These RI/FS studies, which will lead to "final response actions," are being conducted under the Remedial Authority of CERCLA. The guidance for these RI/FS studies exists in a number of well-known U.S. EPA guidance documents with titles like, Guidance for Conducting Remedial Investigations Under CERCLA.

The interim response actions, on the other hand, are conducted under the Federal Facility Agreement and CERCLA. Guidance for studies to select appropriate interim remedies CERCLA is less well developed, occurring in sketchy form in the NCP. At the time that the Basin F remedy selection studies were conducted, no formal guidance documents existed for treatment assessment and remedy selection, and only draft guidance existed for conduct of community relations programs.

In general, CERCLA encourages a practical and expedient approach to selecting and implementing a short-term remedy for urgent contamination problems. In developing the final response actions, a comprehensive remedial investigation and risk assessment followed by a systematic feasibility study are required. For an interim response action, no remedial investigation is required and the surrogate for a feasibility study is a loosely defined "engineering evaluation/cost analysis," where cost and technical performance are the only factors that need to be considered in choosing a remedy.

The Basin F Liquids interim response action followed procedures similar to a removal under CERCLA, calling the Basin F Liquids study a "Treatment Assessment" rather than a feasibility study. The study was patterned after a CERCLA feasibility study

and was accompanied by an extensive community relations program. The treatment assessment and remedy selection were similar in appearance to a CERCLA feasibility study, but differed notably in several ways:

- Detailed engineering performance data on a number of treatment alternatives were considered at an early stage in the study, and the detailed evaluation of alternatives was limited to a small set of technical options.
- Quantitative risk analysis was included in the comparison of alternatives.
- A community relations program was relied upon for technical input to the remedy selection.

All of these measures were oriented to obtaining a practical and widely-accepted decision that could be implemented in the short 5-yr time frame. The decision that was reached could be evaluated and defended in terms of CERCLA. The process used to reach the decision was streamlined by the implementation of CERCLA at the site through the Federal Facility Agreement.

Federal Facility Agreement

In 1989, a Federal Facility Agreement (FFA) was signed by the U.S. EPA, the Army and Shell; the State of Colorado, which is given certain rights in this agreement, did not sign the Agreement, but participates in the activities outlined in the FFA. In the FFA, the Army and Shell agreed to share certain costs of the remediation, which was to be developed and performed under the oversight of the U.S. EPA, with opportunities for participation by the State of Colorado. The long-term remediation is a complex task that will take several years to complete.

The Federal Facility Agreement specified 13 Interim Response Actions determined to be necessary and appropriate to remove active sources of contamination and to prevent the spread of contaminants. Remediation of Basin F liquids, sludges, and soils is one of the 13 IRAs and is to be addressed in two parts. The first part, now completed, was removal of the liquids to secure storage and removal and stockpiling of the soils and sludges to a double-lined and capped temporary waste pile. The second part concerns Basin F liquids disposal. The time frame for completion of the second part is tied to agreed-upon limits to interim storage of Basin F liquids, and is set at 5 yr from May 1988.

The FAA states that all studies and cleanup done pursuant to the FAA will be done in accordance with CERCLA, insofar as practical, and the FFA calls for community relations programs to be implemented in accordance with CERCLA. The FFA requires that studies done under its authority conform to numerous review and comment procedures involving all the parties to the FFA.

Other Regulatory Influences

The State of Colorado has long maintained that at least a portion of the RMA cleanups are RCRA closures rather than CERCLA actions, and that the State should have privacy in directing these actions. (This disagreement is the primary reason why the State is not a signatory of the FFA.) The Army dismisses this claim specifically, but generally follows the substantive requirements of RCRA as ARARs to interim response actions planned at RMA, consistent with the expeditious implementation of solutions to urgent contamination problems. In the case of the Basin F Liquids interim response action, most of the substantive technical requirements of a typical RCRA permitting process were incorporated as ARARs, while many of the time-consuming administrative requirements of RCRA were not.

REMEDY SELECTION PROCESS

The remedy selection process consisted of three parts: a technical study, a regulatory process and a community relations program. These are discussed separately below.

Technical Study

The technical study to identify feasible treatment or disposal alternatives and select a preferred alternative consisted of five steps:

- Waste characterization
- Screening of technologies and development of alternatives
- Treatability studies
- Detailed evaluation of alternatives
- Selection of a preferred alternative

Waste Characterization

For the Basin F Liquids interim response action, characterization of the Basin F liquids consisted of sampling and analyzing the wastes to determine their chemical and physical properties in relation to engineering design and performance requirements of potential treatment processes and to provide the basic chemical parameters needed for a risk analysis of alternatives selected for detailed evaluation.

Two samples of the Basin F liquids were taken from Pond A. These samples were submitted for chemical testing and the results were compared to those from other recent Basin F liquid sampling efforts.

Screening of Technologies and Development of Alternatives

Forty different treatment technologies were identified and evaluated for their ability to tolerate the chemical and physical characteristics of Basin F liquid and achieve the general cleanup objectives of the IRA. The forty technologies encompassed all four of the basic strategies known to treatment science:

- Thermal destruction
- Immobilization
- Separation
- Chemical/biological treatment

Certain technical objectives controlled the identification and screening of alternative technologies:

- Ability to process the waste within the 5-yr time frame
- Demonstrated ability to treat the waste, based on bench-scale or pilot tests
- Ability to meet ARARs
- Orientation to the primary remedy selection objective of CERCLA, to achieve overall protectiveness of human health and the environment
- Orientation to the CERCLA guidance stressing permanent solutions that reduce toxicity, mobility or volume of hazardous substances

Of the 40 technologies, only 12 were found to be potentially feasible, given the physical and chemical properties of Basin F liquids. No separation technology was found to be feasible. The 12 potentially feasible technologies were studied further in terms of overall protectiveness, implementability within the stipulated time frame and ability to meet Applicable or Relevant and Appropriate Requirements (ARARs). In the end, five technologies were judged to be feasible, implementable within five years, protective of human health and the environment and able to meet ARARs:

- Electric Melter furnace (thermal destruction process)
- Solidification (immobilization process)
- Submerged Quench Incineration (thermal destruction process)
- Wet Air Oxidation (chemical process)
- Wet Air Oxidation with Biotreatment (chemical-biological process)

In developing remedial alternatives that would use these technologies, both on-site and off-site locations were considered. The alternatives evaluated included the following:

- Off-Site Alternatives
  - Existing Off-Site Army Facilities
  - Existing Off-Site Commercial Facilities
    - Deep Well Injection
    - Hazardous Waste Incinerators
  - Associated Transport Facilities
    - Pipeline
    - Tank Trucks
    - Rail Cars
- On-Site Alternatives
  - Existing Arsenal Facilities
  - Newly Constructed Arsenal Facilities
    - Electric Melter Furnace
    - Solidification
    - Submerged Quench Incineration
    - Wet Air Oxidation
    - Wet Air Oxidation with PACT

A brief summary of the technical characteristics and the strengths and weaknesses of these treatment alternatives is given below. All of the on-site, newly constructed treatment alternatives were capable of being designed and implemented to be protective of the community and the workers and to meet ARARs to the maximum extent practicable. Alternatives which reduce contaminant toxicity, mobility or volume are more protective of human health and the environment than alternatives that do not.

The greatest differences between the alternatives considered were seen in the areas of treatment efficiency (reduction of toxicity, mobility and volume) and implementability (feasibility, reliability and availability). The following discussion focuses on characteristics of the alternatives that make each alternative distinctive from the others.

Because of the history of the Basin F Liquids Disposal Interim Response Action, three types of alternatives which often are considered in the remedy selection process for CERCLA are not considered here. These types of alternatives include the No Action, Monitoring and Institutional Controls alternatives. Since the Interim Response Action discussed here directs the Army to choose a strategy for treatment and disposal of Basin F liquids now in storage, the No Action, Monitoring and Institutional Controls alternatives were, in a peremptory fashion, judged unacceptable for application to Basin F liquids.

Alternatives evaluated for treatment of Basin F liquids are discussed in the following sections.

Off-Site Alternatives

Existing Off-Site Army Facilities

Several U.S. Army installations operate or have operated hazardous waste incinerators for the demilitarization of chemical warfare agents or other military hazardous wastes. However, each of these facilities was constructed to address specific wastes from its respective site and none has equipment designed to operate on the particular admixture of wastes found in Basin F liquids. Thus, these incinerators are technically unsuitable. Moreover, construction of a new, technically suitable incinerator for Basin F liquids at these sites is contrary to the intent of CERCLA, which prefers on-site waste remediation where possible.

Existing Off-Site Commercial Facilities (Deep Well Injection)

With reference to off-site (or on-site) deep well injection, it was concluded that direct disposal approaches which involve no treatment are in opposition to the objectives of the Federal Facility Agreement. Specifically, these approaches will not meet the requirement of providing "permanent and significant" reduction of toxicity, mobility or volume. In addition, the deep well injection approach is irreversible and offers no opportunity for later treatment.

The Federal Facility Agreement stipulates that the Basin F liquids remediation will attain ARARs to the maximum extent practicable. Primary guidance (U.S. EPA, 1988) defines reduction of toxicity, mobility or volume as "permanent and significant reduction" through "destruction of toxic contaminants, reduction of the total mass of toxic contaminants, irreversible reduction in contaminant mobility, or reduction of total volume of contaminated media" (Section 7.2.3.3, Draft Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA, U.S. Environmental Protection Agency, 1988). Finally, deep well injection of Basin F liquids was tried in the past at RMA and failed due to the physical properties of the waste.

Existing Off-Site Commercial Facilities (Hazardous Waste Incinerators)

A survey of the capabilities of existing commercial hazardous waste incinerators showed that among all of the facilities in the nation, only three sites with liquid injection incinerators were equipped to treat Basin F liquids. However, the actual technical suitability of equipment at these installations had not been proven. In addition, each of these three commercial facilities has indicated that they would require a treatment contract that would allow the facility to refuse, at any time and at their discretion, receipt of Basin F liquids for treatment. Thus, the commercial facilities would not guarantee that Basin F liquids would be treated within the agreed-upon time frame, nor would they guarantee completion of treatment of all Basin F liquids.

Newly Constructed Off-Site Facility

A new treatment facility for Basin F liquids could be built off-site in a location that the Army could purchase or lease. Such a facility could be located such that it would be physically removed from any populated area, and thereby could presumably present a lower operational risk to humans. A new off-site facility, like any of the on-site options, could be designed and built to attain ARARs and achieve cleanup objectives. The drawbacks of a newly constructed off-site facility are the time required for permitting and the requirement to transport the waste.

On-site facilities would be constructed as a CERCLA action at a CERCLA site and would not require environmental permits from Federal, State or local agencies. An off-site facility, on the other hand, would not be considered a CERCLA facility, but rather would be viewed as a new waste treatment, storage or disposal facility (TSD) and subject to permitting and regulation under RCRA. The amount of time currently required to secure a RCRA permit for a TSD in Colorado is 3 to 5 yr, due to the complexity of application data requirements and the number and duration of agency and public reviews. When the permitting time is added to the time required to design, test, build and operate the treatment facility for Basin F liquids, the total time required for this off-site option exceeds the time available, as agreed to by the parties to the Federal Facility Agreement.

Associated Transport Facilities (Pipeline)

Conveyance of Basin F liquids through a pipeline to an off-site hazardous waste facility was considered. Although trans-state and interstate pipelines exist to convey fuel products, such as natural gas and guel oils, no pipeline suitable for liquid hazardous waste presently exists. Therefore, a separate pipeline would have to be built to transport Basin F liquids. The potential for leakage of Basin F liquids due to joint failure, corrosion failure and freeze damage under Colorado weather conditions is substantial. Additionally, since Basin F liquids are a saturated or supersaturated brine solution, they could not be piped long distances without considerable dilution to prevent salt precipitation and line pluggage. Thus, the volume of wastes would be substantially increased. The cost of constructing a suitable pipeline and supplying the power to pump the Basin F liquids long distances would

be greater than the cost of either off-site bulk transport or construction of an on-site treatment unit.

Associated Transport Facilities (Tank Trucks)

Appropriate tank trucks exist that can safely transport Basin F liquids over public highways. The scenario used here consisted of tank trucks of approximately 5,000-gal capacity used to transport Basin F liquids off-site for treatment. These trucks would be owned and furnished by a transportation contractor. To complete treatment of Basin F liquids in 1.5 yr, approximately 500,000 gal would have to be transported per month. Depending on the location of the treatment facility, this could require using more than 20 tank trucks per month (assuming five round trips each per month) to transport Basin F liquids. Based on a survey of transportation contractors, we determined that this number of tank trucks did not appear to be available from one company.

Most available tank trucks are constructed of stainless steel material, which may not be compatible with highly corrosive Basin F liquids. There were only a few lined tank trucks available at the time of the survey. The risk assessment reported in the Treatment Assessment Report indicated that the risk of transporting Basin F liquids off-site by truck was significantly higher than the risk of transporting the liquids by rail car.

Associated Transport Facilities (Rail Cars)

The use of rail cars, typically of 20,000-gal capacity, was also evaluated. The risk of transporting Basin F liquids off-site for treatment by rail car was estimated to be low relative to any other transportation mode. Specialized rolling stock exists in sufficient numbers to accommodate shipments of Basin F liquid to an off-site location. Some of the rolling stock is lined; depending on the supplier, some tank cars might need to be lined prior to receiving Basin F liquid.

On-Site Alternatives

Existing Arsenal Facilities

No treatment facilities exist at RMA that are technically appropriate, or can be modified to be technically appropriate, for Basin F liquids.

Newly Constructed Arsenal Facilities

This group of alternatives includes the five technologies identified in the screening step of the Treatment Assessment Study. They are presented here in alphabetical order.

Electric Melter Furnace

The electric melter furnace would operate at high temperatures—approximately 2300° F—to destroy organic compounds in Basin F liquids. In the furnace (similar to a glass-making furnace), the organic compounds in Basin F liquids would be destroyed almost completely. The metals would form a molten salt that would float on top of the pool of glass which lines the bottom of the furnace. The molten salt would be removed from the furnace periodically, poured into forms and cooled in preparation for final disposal. The exhaust gases would include a mixture of oxides of nitrogen and other gases. Exhaust gases released to the atmosphere from this process would be passed through air pollution control devices and would meet government standards; these exhaust gases would be monitored to assure adherence both to regulated conditions and nonregulated health risk-based operating goals.

Operation of the electric melter furnace would require the transportation of 8100 yd³ of pure liquid anhydrous ammonia and 4400 yd³ of sodium hydroxide into the Arsenal each year. Both compounds would be used in the air pollution control process. However, the risk assessment indicated that the amount and concentration of ammonia transported to the site for this alterna-

tive could present a health hazard. The electric melter furnace process would produce salts, containing metals, of about 10% of the volume of the original Basin F liquids. These salts could be disposed in a hazardous waste landfill. The form and chemistry of produced salts are not suitable for subsequent metals recovery. Of the five on-site treatment alternatives evaluated, the electric melter furnace ranked at the low end of the mid-range of costs, with an estimated total project cost of $21.1 million. The electric melter furnace has not been commercially demonstrated to be feasible for destruction of wastes like Basin F liquid.

Solidification

The solidification process would mix various chemicals with the Basin F liquids to immobilize the metals and produce a solid. Organic compounds in Basin F liquids would be incorporated into the solid but would not be destroyed or immobilized and could be leached from the solid material. Because Basin F liquids contain large amounts of ammonia and nitrogen-containing compounds, chemicals would be added to react with these compounds and prevent the release of ammonia during mixing and curing of the solid. The Basin F liquids would be pumped into two batch mixing units and mixed with Portland cement, fly ash, soil and agents to reduce ammonia emissions. Mixing units would be sealed during operation. The moist mixture would be discharged into disposable 50-gal drums and held in an adjacent building for 15 days to complete the curing process.

Control measures will be used to reduce fugitive emissions from the solidification process. Exhaust from the mixing and curing areas would be treated by air pollution control equipment to control particulates and gases. The exact nature and concentrations of emissions of organic chemicals as well as dust are not known or readily estimated for the solidification process. Due to the quantities of mixing materials handled, dust emissions could be substantial.

Solidification would require the transportation into the Arsenal of 17300 yd³/yr of phosphoric acid, plus comparably large quantities of other compounds, primarily used to reduce the amount of ammonia released during mixing. Solidification would produce solids of approximately three times the volume of Basin F liquids, which would be disposed in a hazardous waste landfill.

Solidification is a common technology for many types of wastes, but is not known to have been applied to saturated brine, ammonia-bearing wastes like Basin F liquid in a commercial-scale operation. The solidified products of this process will meet present hazardous waste landfill leachability requirements, but are close to the acceptance threshold, and leachability testing prior to disposal may be required. Of the on-site treatment alternatives evaluated, solidification ranked as the most costly, with an estimated project total cost of $71.8 million.

Submerged Quench Incineration

The submerged quench incineration process would use a vertical downfired liquid incinerator. The liquid to be incinerated would be injected at the top of the furnace along with a supplementary fuel. Burning the liquid at high temperature (approximately 1900° F) would destroy the organic compounds in Basin F liquid almost completely. After incineration, the hot gases would be forced downward and cooled in a liquid quench task to aid in washing out particulates and cleaning the exhaust gases. The high temperatures would melt noncombustible components of the Basin F liquids, producing molten salts which would flow down the walls of the incinerator and also be cooled in the quench chamber. The brine from this process could be dried to produce a salt. The exhaust gases, which would include a mixture of oxides of nitrogen and other gases, would be passed through air pollution control devices. Exhaust gases released to the atmosphere from this process would meet government standards and would

be monitored to assure adherence both to regulated conditions and nonregulated health risk-based operating goals.

Operation of the submerged quench incineration process would require the transportation into the Arsenal of 26 rail cars (200,000-lb capacity each) per year of sodium hydroxide, a caustic compound used in the air pollution control process. The submerged quench incineration process would produce salts, containing metals, of about 10% of the original volume of the Basin F liquids. These salts could be disposed in a hazardous waste landfill. The form and chemistry of the dried salts would permit a subsequent metals recovery step that would result in an innocuous residual salt product. Compared to the other on-site treatment alternatives evaluated, submerged quench incineration is the least costly, with an estimated project total cost of $19.1 million. This process has been demonstrated commercially on saturated brine wastes like Basin F liquid.

Wet Air Oxidation

In the wet air oxidation and spray drying process, Basin F liquids would be fed under pressure to an oxidation chamber operating at approximately 500° F. In the chamber, organic compounds in Basin F liquids would break down into simpler, less toxic compounds. A minimum of 95% of the toxic organics would be destroyed. The metals and many organic compounds would remain in the liquid, although some gas also would be released by the reaction. The liquid from the oxidation chamber would be treated to neutralize ammonia. Then the liquid and gas from the oxidation chamber would be fed to a spray dryer. The dried salts containing metals would be separated and packaged for shipment to a hazardous waste landfill.

The gases, which would contain some volatile organic compounds and ammonia, would be passed through air pollution control devices. Exhaust gases released to the atmosphere from this process would meet government standards and would be monitored to assure adherence both to regulated conditions and nonregulated health risk-based operating goals.

Operation of the wet air oxidation process would require the construction of a large building to house the process and the transportation into the Arsenal of 260 railroad cars (100-ton capacity each) per year of highly concentrated sulfuric acid and 22 railroad cars of 50% sodium hydroxide. The sulfuric acid would be used to neutralize ammonia, and the sodium hydroxide would be used in the air pollution control process. The wet air oxidation and spray drying process would produce salts, containing metals and some simple organic compounds of approximately 10% of the total original volume of Basin F liquids. These salts could be disposed in a hazardous waste landfill. The form of the dried salts would permit a metals recovery step, but the organic content of the salts could affect the purity of recovered metals and would remain in the salts to some degree anyway; hence, metals recovery for this process is of questionable utility. Compared to the other on-site alternatives evaluated, the wet air oxidation and spray drying process is in about the midrange of costs, with an estimated project total cost of $48.2 million.

Wet Air Oxidation with Powdered Activated Carbon Bio-Treatment (PACT)

Wet air oxidation, PACT and spray drying would destroy organic compounds in Basin F liquids by subjecting them to high pressure and moderately high temperatures in the presence of air. After passing through the pressurized oxidation chamber (operating at approximately 500° F), the liquids would be further treated by biological action to destroy organics. In the chamber, organic compounds would break down to simpler, less toxic compounds. The metals and many organic compounds would remain in the liquid, although some gases would be released by the reaction.

Before liquid from the oxidation process was treated in the

PACT process, it would be pretreated to remove copper and ammonia and diluted. The liquid then could be sent to enclosed aeration basins for PACT biotreatment. The carbon would adsorb and retain organic compounds in the aeration basins so that microorganisms would have time to break them down. After PACT treatment, the liquid would be concentrated and spray-dried in a dryer similar to that used in the wet air oxidation and spray drying process.

The exhaust gases from the dryer, which would contain some VOCs and ammonia, would be passed through air pollution control devices. Exhaust gases released to the atmosphere from this process would meet government standards and would be monitored to assure adherence to both regulated conditions and nonregulated health risk-based operating goals. Overall, the wet air oxidation, PACT and spray drying process would destroy a minimum of 99% of the toxic organics in Basin F liquids.

Operation of the process would require the construction of several large buildings to house the process and the transportation into the Arsenal of 260 railroad cars (100-ton capacity each) per year of highly concentrated sulfuric acid and 22 railroad cars of 50% sodium hydroxide. The sulfuric acid would be used to neutralize ammonia, and the sodium hydroxide would be used in the air pollution control process. The process would produce dried salts, containing some metals and simple organic compounds, of approximately 20% of the volume of the original Basin F liquids. These salts could be disposed in a hazardous waste landfill.

The process includes a metals removal step and produces a brine with very low levels of residual organics; no further metals recovery or treatment of organics is feasible for the final residual brine. Compared to the other on-site alternatives evaluated, wet air oxidation, PACT and spray drying is in the top of the midrange of costs, with an estimated project total cost of $56.2 million.

Results of Screening

The screening process concluded with the development of seven remedial alternatives:

- On-site electric melter with solid residuals
- On-site solidification with solid residuals
- On-site submerged quench incineration with solid residuals (spray drying of brine product)
- On-site submerged quench incineration, brine product, metals removal and PACT treatment of brine, no residuals
- On-site wet-air oxidation with spray drying, solid residuals
- On-site wet-air oxidation, brine product, metals removal, PACT treatment of brine, no residuals
- Off-site incineration at an existing commercial facility, with rail transportation of untreated Basin F liquid

Preliminary Risk Assessment

In conjunction with the screening of technologies and development of alternatives, a preliminary quantitative risk assessment was performed. Risks of both on-site and off-site treatment alternatives were evaluated, and the results indicated that there should be very low potential cancer risks and no significant non-cancer health hazards from any of the treatment processes themselves. However, the risk assessment indicated that there may be some potentially significant health hazards associated with the transportation of Basin F liquids (to an off-site treatment facility) or from the transportation of treatment chemicals (on-site for the electric melter furnace, one of the treatment processes evaluated).

The potential health hazard risks were associated with possible exposure to the ammonia content of Basin F liquids and possible exposure to the pure liquid anhydrous ammonia which would be required for the electric melter furnace process.

Based on this preliminary health risk assessment, off-site treatment options were not considered further in the technical study.

Treatability Studies

Bench-scale or pilot plant tests were performed on Basin F liquids using each of the 12 technologies identified in the initial screening step as potentially feasible. These treatability studies were done over an 11-yr period from 1978 to 1989. Successful bench-scale or pilot-test data exist for all of the five technologies retained in screening and used in the development of remedial alternatives, i.e., all of the alternatives selected for detailed evaluation had been demonstrated to be capable of treating Basin F liquid.

Detailed Evaluation of Alternatives

Five alternatives remained for detailed evaluation (all newly-constructed on-site facilities). Each alternative was designed at a conceptual level, and an assessment of probable performance was made. This assessment included preparation of a detailed process description; sizing of the treatment alternative to meet the waste volume and schedule for this IRA; preparation of a materials balance to estimate volumes and quantities of feed, process, discharge and residuals streams; assessment of technical performance in terms of reduction of toxicity, mobility and volume; evaluation of the implementability of the process (technical maturity, track record, etc.); estimates of capital and operating costs; and identification of regulatory issues. This information was used in the selection of a preferred remedial alternative.

Briefly stated, this is how the alternatives compared:

- *Overall Protectiveness.* Of the on-site options, the electric melter furnace and submerged quench incineration have the highest organic chemical destruction efficiencies and are therefore the most protective of human health and the environment. Wet air oxidation with PACT and wet air oxidation alone will destroy 90% or more of the organic chemicals. Solidification does not provide any treatment to organics.
- *Air Emissions.* Of the on-site options, all processes but solidification will produce emissions that meet government standards and will have monitoring to assure adherence to regulated conditions and negotiated operating goals. Solidification emissions, particularly fugitive dust, will be difficult to estimate and will present monitoring and control problems.
- *Use of hazardous chemicals.* All of the on-site options will require importation of process materials to RMA. The chemicals required for the electric melter furnace present higher risks than chemicals required for any other process. The chemicals required for submerged quench incineration present lower risks than chemicals required for any other process.
- *Residuals.* The two incineration processes produce as residuals a metal-bearing salt that can be landfilled. The salts from the submerged quench process are suitable for a subsequent metals recovery step, while the salts from the electric melter furnace are not. The wet air oxidation processes produce as interim or final residuals a metal-bearing and organic bearing salt that is not generally suitable for metals recovery, although removal of impure metals will permit subsequent organics removal (PACT) and reduce the quantity of hazardous residuals. Solidification produces a hazardous waste that can be landfilled, but which is leachable for organics and to a lesser degree for metals. The residual is not suitable for subsequent treatment steps.
- *Waste volume.* The two incineration processes and wet air oxidation produce a volume of residuals that is approximately 10% of the waste volume. The wet air oxidation process with PACT produces a volume of residuals that is approximately 20% of the waste volume. The solidification process produces a waste product that is 300% to 500% of the original waste volume.
- *Commercially demonstrated process.* Of the on-site options, the submerged quench incinerator and the wet air oxidation processes have been demonstrated commercially on saturated brine wastes like Basin F liquid. Solidification has been demonstrated commercially on many types of wastes, but not on saturated brine, ammonia-bearing wastes like Basin F liquid. The electric melter furnace has not been commercially demonstrated for liquid hazardous wastes.
- *Cost-effectiveness.* Of the on-site options, the electric melter furnace and submerged quench incinerator are the least expensive. The wet air oxidation processes are two to two and one half times as expensive as incineration, and solidification is three to three and one half times as expensive as incineration.

Selection of a Preferred Alternative

A semiquantitative scoring and ranking technique was used to evaluate the five remedial options and select a preferred alternative. The technique derived from, and was based on, multiattribute utility theory and applications of these techniques in similar decision analysis exercises. CERCLA guidance (Section 121(b) and NCP Section 300.430(e)) identify seven evaluation criteria to be used in selecting a preferred remedial alternative. These criteria are:

- Overall protection of human health and the environment
- Compliance with Applicable or Relevant and Appropriate Requirements (ARARs) to the maximum extent practicable
- Reduction of toxicity, mobility and volume
- Short-term effectiveness
- Long-term effectiveness
- Implementability
- Cost

The first step in the evaluation procedure was to develop formally correct quantitative evaluation criteria out of these seven CERCLA remedy selection criteria. To do this, these seven criteria were broken down into more specific technical factors related to the set of alternatives under review (in accordance with U.S. EPA guidance); a total of 19 technical factors was assessed for each alternative. For example, short-term effectiveness was broken down into worker safety, community protectiveness and operational environmental impact factors. A panel of chemical and environmental engineers and a risk assessment specialist assigned technical scores to each factor for each alternative, using discrete interval scales developed in consultation with a decision analyst.

The next step was to establish tradeoffs between evaluation criteria, to provide for the correct handling of preferential information in the evaluation procedure. Weights (importance values) for each of the 19 factors were elicited from the technical panel by a decision analyst, using lottery and consensus techniques. Using the factor scores and the tradeoff values, an evaluation formula was established; technical factor scores were multiplied by the weights to yield weighted factor scores, and these scores were summed to yield an overall score for each alternative. The alternatives were then ranked in accordance with the scores. Controls introduced by the decision analyst in the construction of the discrete interval scales and the elicitation of weights kept this evaluation procedure formally correct and logically rigorous, but the written record of the evaluation and the results were easily understood by the lay public.

Sensitivity studies were done on the ranking by varying the weights (importance values) for the 19 ranking factors. These studies showed how the rank order would change if some factors were considered to be more important and others less important. This approach was used to model many hypothetical points of view, such as a point of view that emphasized protection of nearby residents over all other factors, or another point of view that emphasized all factors related to short-term or long-term risk and deemphasized factors related to cost. More than a dozen hypothetical points of view were modeled, including some extreme points of view (in which one or two factors received all the weight

and all other factors were suppressed). In addition, several other diagnostic sensitivity tests were run to understand better which factors were most influential in ranking. The sensitivity studies were used to identify a set of weights and a corresponding rank order that was reasonable and realistic and could be shared by many points of view. This rank order was recommended. The top ranking alternative in this rank order is the preferred alternative.

Results

In this analysis, the on-site submerged quench incinerator was consistently the highest ranking alternative, and only under extreme and unrealistic points of view could the submerged quench incinerator be made to rank second. The poorest performer in this ranking analysis was solidification, and only under extreme points of view could it be made to rank higher. The "middle" alternatives of wet air oxidation and electric melter generally ranked far below submerged quench. The recommended rank order was:

1. Submerged Quench Incinerator
2. Wet Air Oxidation
3. Wet Air Oxidation with PACT
4. Electric Melter Furnace
5. Solidification

Regulatory Process

The treatment study proceeded from a carefully reviewed and approved work plan to conduct of technical evaluations, review of interim conclusions, preparation of a draft and final treatment assessment report and then preparation of a proposed decision document. Both the treatment assessment and proposed decision document was presented in public hearings, and subsequently a final decision document was issued. This process assured that all affected and interested agencies had ample opportunities to exert an influence on the remedial decision.

This process was complicated by the number of entities involved; in addition to the Army, Shell and the U.S. EPA, the Departments of Justice, Health and Human Services and Interior and the State of Colorado were participants. Each entity brought different interests to the process along with different styles of dealing with other agencies and the public. To accommodate the large number of interactions required by the participants in the regulatory process, the Army arranged for numerous briefings, progress meetings, special purpose committees and written materials to keep the parties up-to-date.

Community Relations Program

To assure that the community at large also had opportunities to exert an influence on the remedial decision, a community relations program was implemented. The program included informational elements, such as fact sheets and presentations, as well as participatory (consensus building) elements, such as workshops and hearings. The community relations program started at an early point, and the public was made a participant in the evaluation of technical material and the development of a remedial decision. To give the program more visibility and make it function more effectively, the Army established a community relations task force to plan and oversee all of the community relations activities.

CONSENSUS BUILDING

In 1988, the Army agreed to a 5-yr limit on temporary storage of Basin F liquid, yet any of the feasible remedial alternatives would take several years to implement. A delay in implementing the selected remedy could not be tolerated if the 5-yr storage limitation was to be observed. If there was general agreement in the community on the selection of a remedy, then the chances for a program delay due to public opposition would be reduced. Therefore, the Army set out to build consensus in the community for a remedy selection, using the community relations program to dis-

seminate technical information and receive inputs from members of the public. The main elements of this consensus-building initiative are discussed below.

Frequent informational meetings

The Army held several meetings to brief special interest groups and the public at large on the progress of the technical studies.

Workshop

The Army held a day-long public workshop on the technical studies, and gave members of the public the opportunity to have first-hand experience in evaluating the technical information. In one exercise, the detailed evaluation and ranking of the seven remedial alternatives was opened up to the public, and the participants had the opportunity to alter the ranking weights as they wished and see in real time the effect this had on the ranking scores and rank orders. This analysis showed the participants in the public meeting that the Army's selection of a particular alternative was the reasonable result of a logical process, and that under a broad spectrum of points of view, the same technology (submerged quench incinerator) would rank first. This builds consensus for the technical evaluation.

Well-planned media relations

The Denver area press were invited to all public meetings and were given special briefings. Based on the high level of information made available to the media, no single-issue special interest groups were able to divert media attention.

Letting the public make part of the decision

In the informational meetings and the workshop, numerous concerns were expressed and repeated by the public, mostly concerning the operational safety of whatever remediation was selected and the objectivity of the Army in monitoring the remedial action. At the workshop, the Army committed to address these concerns by converting these concerns into elements of the remedial decision. Thus, for example, concerns over products of incomplete combustion (PICs) were addressed by a decision to conduct a special predesign pilot test; concerns over operational safety under severe weather or upset condition were addressed by a decision to include operational controls in the design; concern over the objectivity of monitoring was addressed by agreement to have an independent third-party monitor on-site. In all, 12 discrete decision elements were added to the basic technological remedy selection; all of these elements were shown in the decision document to be directly derived from public concerns. While the Army reserved the responsibility to select the remedial technology, the public owned a significant part of the decision concerning how the selected technology would be operated.

Advance resolution of all sensitive issues

The Army used an "open-handed" approach, by bringing up and resolving sensitive public issues early in the process, before they became points of contention. These issues included on-site versus off-site remediation, health risk studies, the effects of incineration, etc.

Establishment of standards-setting and dispute resolution procedures

The Army included standards-setting and dispute resolution procedures in the ARARs section of the decision document to give form to the operating guidelines and lasting commitment to safety and community interaction by the Army.

CONCLUSION

When the Decision Document describing the selected remedy was issued in March 1990, there was no widespread public opposition to the selection of a submerged quench incinerator for the

Basin F Liquids at RMA. On the contrary, state officials commended the Army on its selection process and lent their weight to the decision. There has not been any organized opposition to this incinerator since the decision was announced. The incinerator is in the final stages of design at the moment, and construction is scheduled to begin in a few months. Some of the principal lessons learned in this remedy selection and consensus building process are:

- Among the benefits of intensive planning is early identification and resolution of sensitive technical issues;

- Formal risk analysis is a cost-effective screening and evaluation tool because it addresses the top concerns of the public and most agencies;

- Sensitivity analysis of a formal ranking method is insightful and useful for planning consensus building activities;

- Early involvement of the public is key to building support for the decision;

- Direct use of public input in the technical decision improves the quality of the decision and avoids downstream delays.

Interim Response Actions: An Approach to Short-Term Remediation (Ahead of the Record of Decision)

Bruce M. Huenefeld
Kathryn R. Cain
Rocky Mountain Arsenal
Commerce City, Colorado

ABSTRACT

The environmental restoration of Rocky Mountain Arsenal (RMA) in Denver, Colorado, is a nationally prominent CERCLA project. An outgrowth of the settlement between the Federal Government and Shell Oil Company is a unique Interim Response Action Program being implemented at the Arsenal by the U.S. Army with technical assistance from Shell under U.S. EPA oversight.

Interim Response Actions (IRAs) were identified in the RMA Federal Facility Agreement as beneficial measures that could be taken prior to the final ROD for the entire Arsenal. A specially structured process was developed for the IRA program that simplifies the U.S. EPA's standard RI/FS program guidance. The IRA process starts with the assumption of utilizing existing data which correlate with the RI/FS site characterization. The next IRA process step, assessment, is the functional equivalent of the RI/FS steps of development and screening of alternatives, treatability studies and detailed evaluation of alternatives. The IRA decision document step corresponds to the RI/FS ROD. The IRA process also adds an implementation/design document step prior to remediation.

The unique features of the IRA process include the range of measures possible, how the process is administered, the regulatory review involved and the community relations program intended to encourage public involvement. In addition to the organizations already mentioned, the Department of Interior, the U.S. Fish and Wildlife Service and the Colorado Department of Health are afforded a nearly equal participation in the IRA process.

In practice, the IRA process has been an unqualified success. Beneficial mitigation is being accomplished at 13 IRA sites. The IRAs range in scope from treating and disposing of 8.5 million gallons of liquid to groundwater treatment systems to in situ soils treatment. The most notable of the IRAs is the Basin F site — one example of how well the IRA process works. The Basin F IRA has involved two separate phases that entailed the removal and temporary storage of contaminated soils and liquids, followed by final remediation of the liquids. Final remediation of the soils will be accomplished through the ROD. The first phase of the Basin F IRA has been completed and the second phase has just passed the Decision Document step.

INTRODUCTION

The environmental restoration of Rocky Mountain Arsenal (RMA) in Denver, Colorado, is a nationally prominent Superfund project. Out of the litigation between the Federal Government and Shell Oil Company has risen a unique solution for accelerated remediation of certain sites at the Arsenal. The Interim Response Action (IRA) program is being implemented by the U.S. Army with technical assistance from Shell under U.S. EPA oversight.

Interim Response Actions were identified in the RMA Federal Facility Agreement (FFA) as beneficial measures that could be taken prior to the final ROD for the Arsenal. Because IRAs are near-term remediation projects, they must be consistent, to the maximum extent practicable, with the final remediation to be defined by the ROD. Through the FFA, a specially structured process was developed for the IRA program that simplifies the U.S. EPA's standard RI/FS program guidance.

HOW THE IRA PROCESS WORKS

The IRA process is similar, but not identical, to the CERCLA RI/FS process (Fig. 1). After utilizing existing data to characterize the site of the IRA, the IRA process begins with the preparation of an alternatives assessment. The assessment step is equivalent to the RI/FS steps of development and screening of alternatives, treatability studies and detailed evaluation of alternatives. The goal of the assessment is to evaluate alternatives that can achieve the objectives of the IRA. The evaluation of alternatives follows general CERCLA guidelines and may include factors such as effectiveness, protection of human health and the environment, mitigation of the threat to human health, the reasonableness of cost and timeliness. Concurrent with the assessment, a proposed applicable or relevant and appropriate requirement (ARAR) determination is developed and issued. The principal signatories of the RMA Federal Facility Agreement (FFA) (i.e., U.S. Army, U.S. EPA Region VIII, U.S. Department of Interior and Shell Oil Company), referred to as the Organizations, are given 30 days in which to comment on the draft assessment and proposed ARARs. Although not a signatory of the FFA, the State of Colorado is allowed the same review of and comment on IRA documents as the Organizations.

Once the assessment and ARARs are finalized, based on comments received, a Proposed Decision Document is prepared to provide the rationale for the selected alternative and the revised ARAR decision.

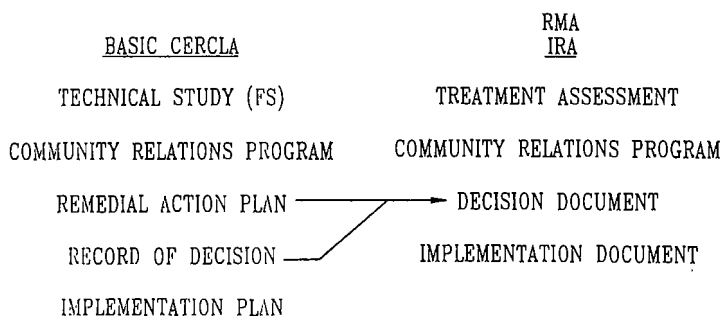
BASIC CERCLA	RMA IRA
TECHNICAL STUDY (FS)	TREATMENT ASSESSMENT
COMMUNITY RELATIONS PROGRAM	COMMUNITY RELATIONS PROGRAM
REMEDIAL ACTION PLAN	DECISION DOCUMENT
RECORD OF DECISION	IMPLEMENTATION DOCUMENT
IMPLEMENTATION PLAN	


Figure 1
IRA vs. CERCLA Remedy Selection Process

The Decision Document step is equivalent to the RI/FS ROD. The Organizations and State (OAS) and the public are given 30 days to comment on the Proposed Decision Document and ARARs. At least one public meeting is held during the comment period to inform the community in the vicinity of RMA.

Following receipt of comments on the Proposed Decision Document from the OAS and the public, a Draft Final Decision Document is prepared. The Organizations then have 20 days to review the Draft Final Decision Document and to raise any objections. If no dispute is raised, the Draft Final Decision Document automatically becomes the Final Decision Document.

The final step in the IRA process is the additional requirement of an Implementation Document, which includes the final drawings, specifications, design analysis, cost estimate for implementation and deadlines for completion. During design or implementation, an Organization may advise the others if it believes that the IRA is being designed or implemented in a way that will not meet the IRA objectives as set forth in the Final Decision Document.

Disagreements that may arise between the Organizations are resolved through a mechanism called dispute resolution. The dispute resolution process consists of review of the issue at progressively higher levels of corresponding management authority among the Organizations. The dispute resolution process continues as necessary until it culminates at the final review committee level, where the Administrator of the U.S. EPA makes a binding decision for the Federal Government. Shell may seek judicial review if still unsatisfied with the decision. To date, no dispute has been raised to the final review committee.

At any time prior to the ROD, any Organization may request consideration of the need for additional IRAs or modification of existing IRAs. Additional IRAs have been considered and may be implemented in the future at RMA.

SPECIFICS OF THE IRA PROGRAM

In practice, the IRA process has been an unqualified success. Beneficial mitigation is being accomplished at 13 IRA sites (Fig. 2). The IRAs range in scope from treating and disposing of 8.5 million gallons of liquid to groundwater treatment systems to in situ soils treatment.

The FFA identifies 13 cleanup areas for the IRA program:

- Groundwater Intercept and Treatment System North of the Arsenal
- Improvement of the North Boundary System and Evaluation of all Existing Boundary Systems
- Groundwater Intercept and Treatment System North of Basin F
- Closure of Abandoned Wells on the Arsenal
- Groundwater Intercept and Treatment System in the Basin A Neck Area
- Basin F Liquids, Sludge and Soils Remediation
- Building 1727 Sump Liquid
- Closure of the Hydrazine Facility
- Fugitive Dust Control
- Sewer Remediation
- Asbestos Removal
- Remediation of Other Contamination Sources
- Pretreatment of CERCLA Liquid Wastes

When the IRA program was formulated in 1987, a combination of proposed one-time and ongoing actions was considered. Thus, ongoing projects such as application of dust suppressant and removal of asbestos were exempted from the requirement of a Decision Document and a public meeting. Other projects such as the construction of recharge trenches at the North Boundary System and the closure of abandoned wells were exempted from the requirements of an assessment and public meeting.

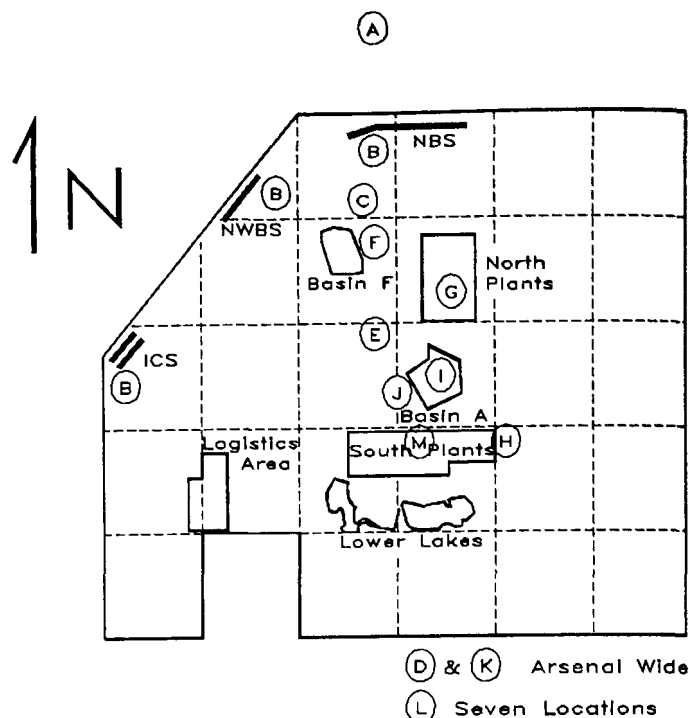
The IRA program can be broken into two broad cleanup areas. For example, IRAs A. B. C and E deal exclusively with the interception and treatment of groundwater contamination. All other IRAs can be grouped as removal or treatment actions.


Figure 2
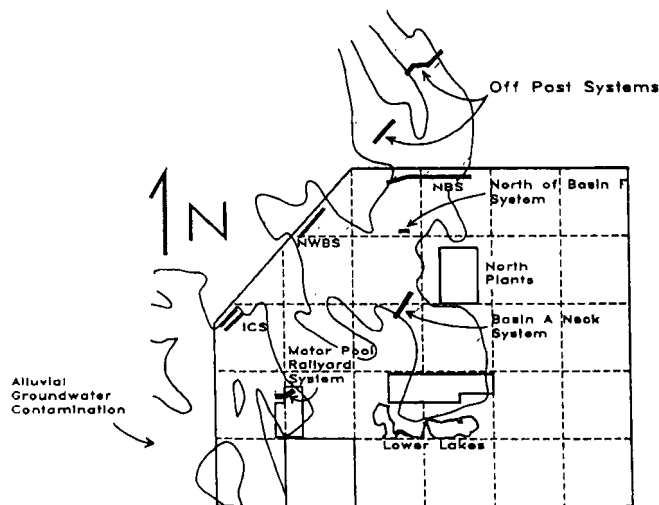
Approximate IRA Locations


Figure 3
Groundwater Intercept and Treatment IRAs

GROUNDWATER INTERCEPT IRAS

The IRA for Groundwater North of the Arsenal (IRA A) was initiated to clean up the area just north of the Arsenal where contaminated groundwater had migrated off the Arsenal before the North Boundary System was installed (Fig. 3). The groundwater presented a threat of further migration and so was considered important enough to assess the need to construct one or more pump-and-treat systems in the area. The design of two interconnected intercept systems has been completed and the implementation document was issued in October 1990. Construction is scheduled to begin in 1991.

IRA B, Improvement of the North Boundary System and Evaluation of all Existing Boundary Systems, consists of three parts: (1) assessment of the need for improvements (such as expansion) to the North Boundary System and assessment, selection and implementation of any

necessary improvements to the system; (2) assessment of the other two boundary systems (Irondale and Northwest) and assessment, selection and implementation of any necessary improvements; and (3) implementation of the groundwater recharge trenches to increase the rate of reinjection of treated groundwater at the North Boundary System. Currently, construction of improvements to the North Boundary System is underway and is expected to be complete in December 1990. Assessment of the Northwest Boundary will be complete in December 1990, as well. The groundwater recharge trenches at the North Boundary are complete and have been operating since June 1990. The three boundary systems treat all contaminated groundwater approaching the boundaries before it leaves the Arsenal.

The Groundwater Intercept and Treatment System North of Basin F (IRA C) and the Groundwater Intercept and Treatment System in the Basin A Neck Area (IRA E) were designed to intercept and treat contaminated groundwater flowing through small channels the Basin F and Basin A. These systems are interior to the Arsenal and will treat water before it reaches the boundary systems. Treating contaminated water in this way will significantly speed up the final remediation after the ROD. These two IRAs are relatively close in location, so the Basin A Neck treatment system of granular activated carbon (GAC), which was complete and online in July 1990, will treat the North of Basin F groundwater after it is treated by an air stripper. The North of Basin F intercept system was complete in September 1990.

OTHER IRAS

From June 1988 until February 1990, 352 old and deteriorating farm wells and unused Arsenal wells were located and closed under IRA D, Closure of Abandoned Wells. The success of this IRA in closing wells on the Arsenal that had the potential to spread shallow groundwater contamination to deeper aquifers has prompted U.S. EPA to suggest an expansion to areas off the Arsenal where Arsenal contaminants exist in the groundwater.

IRA G, Building 1727 Sump Liquid, was initiated in May 1987. The sump, which was a central collection sump for the North Plants manufacturing complex, was filled to capacity with contaminated run-off from the other buildings. A 5-gpm treatment system was installed during the assessment portion of the IRA to begin liquid treatment and to alleviate the potential for overflow. More than 350,000 gallons of wastewater were treated by an activated alumina (AA) and GAC process, which removed the principal contaminants of fluorine, arsenic and diisopropyl methylphosphonate (DIMP). Continued operation of the small temporary system was eventually determined to be the preferred solution and the implementation has included expansion of treatment capacity to 7.5 gpm. IRA G served to treat water that would have had to be stored until after the ROD was issued and that could have leaked into the groundwater.

An assessment of the Closure of the Hydrazine Facility (IRA H) was already underway when the FFA was finalized. The facility had been closed since 1982 when the blending operations ceased. Fuels were removed from their holding tanks, which were triple-rinsed. The rinsate is unlike any other on the Arsenal and requires a unique treatment process. The preferred option for treating the remaining 300,000 gallons of hydrazine-contaminated rinsate is an ultraviolet (UV)/chemical oxidation system. In addition, the facility is to be dismantled once the wastewater has been treated and disposed. Implementation is scheduled to begin in early 1991.

IRA I, Fugitive Dust Control, consists of a periodic application of dust suppressant in Basin A. The application is necessary because Basin A no longer is filled with liquid and consists of highly contaminated soil. This situation creates a risk of windblown dust contaminating other areas of RMA and possibly locations beyond the boundaries. One application has been made since the IRA was initiated in 1988 and a second is planned for 1991.

The sanitary sewer system at RMA was included as IRA J because of its deteriorating condition in the area of the South Plants manufacturing complex and its location within saturated, contaminated alluvium in the Basin A area during seasonal high groundwater levels. The preferred alternative was in-place abandonment of the sewer in the South Plants and Basin A area. Most of the South Plants area will be abandoned, but remaining activities in the vicinity of South Plants will likely be linked by a new line to the rest of the sewer system. The replacement line will be constructed first, followed by in-place abandonment as South Plants buildings are closed. This IRA is presently being implemented.

IRA K, Asbestos Removal, was an outgrowth of ongoing Arsenal programs to remove asbestos from occupied buildings. U.S. EPA has decided that the IRA will eventually address all buildings at RMA prior to demolition. Asbestos has been removed from 10 occupied structures. More than 1,000 structures may eventually have asbestos removed prior to demolition.

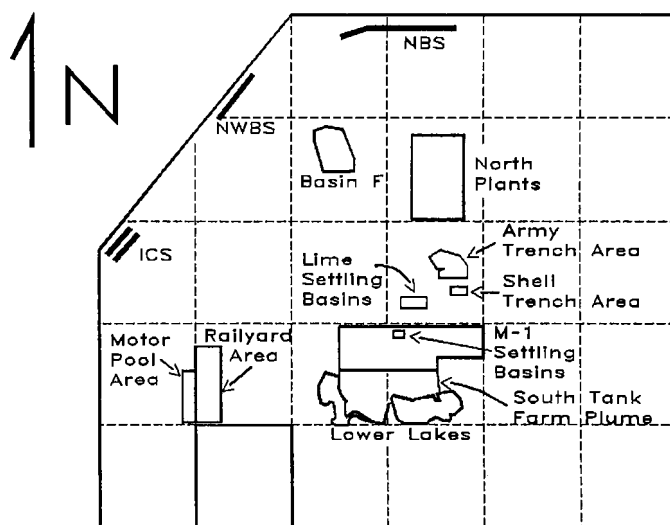
"Hot Spots" is the title often used for IRA L, Remediation of Other Contamination Sources. This IRA addresses as a group those sites of suspected contamination that on their own might not warrant inclusion as a separate IRA (Fig. 4). To date, seven sites have been assessed and Final Decision Documents have been issued for six of those. The selected treatments range from in situ vapor extraction and in situ vitrification to groundwater extraction and treatment to capping and/or groundwater monitoring. This IRA is unique in that it allows the inclusion of new sites within its procedural mechanism upon approval of the Organizations.


Figure 4
Locations of Other Contamination Sources IRA

The Pretreatment of CERCLA Liquid Wastes (IRA M) consists of the design, construction and operation of a wastewater treatment system to treat water generated by ongoing remedial investigation activities, feasibility study testing, laboratory wastes and other IRAs. This IRA is presently in design and completion of construction and startup will occur in the fall of 1991. The constructed treatment facility will continue treating wastewater as the final remediations are being implemented after the ROD.

Basin F IRA

Although the Basin F IRA is included in the "other" category, its extreme complexity and cost warrant a separate, detailed discussion. Basin F was built as a state-of-the-art, asphalt-lined evaporation pond in 1956 and was used as the primary disposal system for Army and Shell wastes until 1982. From its maximum capacity of 240 million gallons, it was estimated that approximately 4 million gallons of concentrated brine and waste remained by the summer of 1987. As the only remaining basin containing liquid, coupled with the wide variety of wastes it received and its lengthy operating history, Basin F represented one of the most complex cleanups at the Arsenal. It also represented a potential threat to wildlife, groundwater quality and air quality.

Two separate phases were recognized as necessary in remediating Basin F. In the first phase, conducted in 1988 and 1989, the liquid was removed from the basin and was stored and the most contaminated sludges and soils were consolidated into a double-lined, capped waste pile. Treatment of the liquid is to be carried out as a second phase within approximately 5 years from the time it was stored. The waste pile will be examined in the ROD.

Due to a heavy unexpected rainfall and the discovery of a false basin floor formed from crystalline condensate from the liquids stored there, a total of approximately 11 million gallons of liquid were removed from Basin F by September 1988. To accommodate this unexpected increase in liquid, an 8 million-gallon pond was constructed in addition to the originally planned 4 million-gallon tank storage capacity. By the time the pond was covered in May 1988, evaporation had reduced the total amount of stored liquid to approximately 8.5 million gallons. This amount has increased slightly over time due to the addition of leachate from the waste pile.

Approximately 500,000 yd^3 of contaminated material were placed in the waste pile. The material consisted of the Basin F walls, the liner, approximately 6 inches of material below the liner and the overburden of sludges above the liner (Fig. 5).

The second phase of this IRA was initiated in September 1988. Submerged Quench Incineration by the T-Thermal Sub-X Liquid Datur (TM) incinerator has been selected as the preferred treatment technology after an exhaustive review and assessment of treatment possibilities was conducted from 1979 through 1989. Design will be completed in December 1990, and installation on the site will begin in the spring of 1991. A trial burn has tentatively been scheduled for January 1992. Operations are expected to take place from May 1992 through the fall of 1993, thus completing liquid treatment within the 5-year limit.

LONG-TERM BENEFITS

By affording the Army and Shell an efficient regulatory process under which important actions can be accomplished prior to the ROD, the IRA program has played a significant role in the initial cleanup of RMA. Approximately $200 million in cleanup actions will have been completed by the time the ROD is issued (Fig. 6). Completion of the IRAs will simplify the eventual cleanup and, in the meantime, this approach will decrease the potential health threat of various sites on the Arsenal. Significantly, the cleanup of Basin F is now a greatly reduced cleanup action under the ROD simply because of the IRA. Only the waste pile soil, possible limited underlying soils and empty liquid storage facilities will remain after the IRA is complete.

ABSTRACT

The unique quality of wastewater and the stringent treatment requirements imposed by regulatory agencies can drastically impact the type of treatment selected for any site. Remediation options for treatment of 300,000 gallons of hydrazine-contaminated wastewater at Rocky Mountain Arsenal (RMA) in Denver, Colorado, are affected by the presence of hydrazine fuel compounds and n-nitrosodimethylamine (NDMA), a decomposition byproduct, as well as part per trillion (ppt) limits on NDMA in the effluent from the treatment system. Although ultraviolet (UV)/chemical oxidation treatment is a fairly common process for destruction of organic constituents in water, the treatment method has only recently been used to destroy more exotic chemicals such as the hydrazine fuel compounds and their by-products.

Steps taken in the development approach for the treatment system include a rigorous treatability testing and equipment selection program, the analytical method development and certification process for the hydrazine fuel compounds and NDMA, and development of the optimal treatment equipment configuration and operating parameters during design, construction and full-scale startup testing, all within significant time constraints set forth in the RMA Federal Facility Agreement (FFA).

INTRODUCTION

The Hydrazine Blending and Storage Facility (HBSF) at Rocky Mountain Arsenal (RMA) northwest of Denver, Colorado, was constructed in 1959 and operated for 23 years from 1959 to 1982. The 10-acre site (Figure 1) consists of two tank yards and a connecting pipeline and was used as a depot to receive, blend, store and distribute hydrazine fuel compounds. The primary operation was blending anhydrous hydrazine and unsymmetrical dimethyl hydrazine (UDMH) to produce Aerozine 50, a rocket propellant. The materials were manufactured elsewhere and were shipped to RMA for blending. Blending operations were not continuous and occurred in response to U.S. Air Force requests. Other operations at the HBSF included loading and unloading rail cars and tanker trucks, destroying off-specification Aerozine 50 and storing Aerozine 50, anhydrous hydrazine, monomethyl hydrazine (MMH), monopropellent hydrazine, hydrazine 70, UDMH and hydrazine.

Hydrazine and UDMH are unstable in the natural environment and rapidly decompose when exposed to the atmosphere. One decomposition byproduct of UDMH is NDMA, a suspected human carcinogen. In 1982, the U.S. Occupational Safety and Health Administration (OSHA) surveyed the HBSF and detected the presence of airborne NDMA within the facility. In May 1982, RMA ceased operations and closed the HBSF to all but safety-essential or emergency-response entries. In the process of closing the HBSF, piping and tanks were cleaned, and 300,000 gallons of decontamination water from these cleaning operations were generated. This wastewater is currently stored in three tanks (Figure 2). Each tank was sampled at four depths, and the ranges of concentrations of analytes found in the wastewater are summarized in Table 1. Analytes showing the highest concentrations include the hydrazine fuel compounds, NDMA, aniline and iron.
Figure 1
Location Map

In February 1989, a Federal Facility Agreement (FFA) was signed for cleanup of RMA, and a number of Interim Response Actions (IRAs) were initiated to alleviate certain concerns prior to the final remedial action. Before implementation of an IRA, the IRA process requires

completion of an Assessment Document, a Decision Document that includes applicable or relevant and appropriate requirements (ARARs), and a draft Implementation Document that includes design specifications. The Decision Document also specifies that the UV/chemical oxidation process is to be used to treat the hydrazine wastewater that currently is stored at the HBSF. The action levels for the contaminants of concern are shown in Table 2. NDMA's action level, also an ARAR, was derived from an overriding health-based goal of a 10^6 lifetime excess cancer risk. In an extremely conservative approach, discharge to ambient water immediately following treatment was assumed. Therefore, treating NDMA to the ultra-low level in the reactor was examined.

The decommissioning of the HBSF is to occur in two phases: (1) treatment of hydrazine wastewater and subsequent discharge of the wastewater to the RMA sanitary sewer system, and (2) decontamination of tanks and piping and demolition of all aboveground structures such as buildings, concrete, piping and support systems and storage tanks.

The objectives of the hydrazine wastewater treatment portion of the IRA include: (1) developing analytical methods and certifying the methods and laboratories that will perform the analyses under the Program Manager for Rocky Mountain Arsenal's (PMRMA) analytical certification program, (2) conducting a treatability test to determine whether qualified manufacturers can reduce the concentrations of

hydrazine fuel compounds present in the wastewater stored at the HBSF to concentrations near the action levels identified in the Decision Document, (3) selecting an appropriate UV/chemical oxidation treatment system and designing and constructing a full-scale treatment system to include one UV/chemical oxidation reactor, (4) conducting full-scale startup testing of the treatment system using approximately 10,000 gallons of hydrazine wastewater stored at the HBSF, (5) gathering sufficient process information from the full-scale testing to more specifically define operational treatment requirements, including kinetic data to predict treatment time necessary to achieve action levels identified in the Decision Document and (6) preparing an Implementation Document defining the step-by-step procedures for installation of a second treatment unit and treatment of the remaining hydrazine wastewater at the HBSF.

ANALYTICAL PROGRAM

Before any testing could be accurately conducted, methods for analyzing the hydrazine fuel compounds and NDMA had to be developed and certified in order to ensure that the ultra-low levels specified in the action levels could be reached in treatment. An analytical method for NDMA was previously certified under the U.S. Army Toxic and Hazardous Materials Agency (USATHAMA) certification program at a level of 200 ppt. Hydrazine, UDMH and MMH were not previously certified under the USATHAMA certification process because methods of analysis for these compounds had been shown to be unstable. Extensive research was conducted during the method development stages, and methods for NDMA and MMH were certified. The method for analysis of UDMH still is not certified because it remains unstable. Certified reporting limits are shown in Table 3.

One difficulty encountered in implementing this IRA is that analytical certification was not achieved at or below the action levels specified for this IRA. This can be seen by comparing the action levels in Table 2 with the reporting limits in Table 3.

TREATABILITY TESTING PROGRAM

Neither a literature review nor the manufacturers of UV/chemical oxidation equipment could provide much information regarding the treatment of hydrazine fuel compounds and NDMA by UV/chemical oxidation. Thus, the primary objectives of the treatability testing were to: (1) determine whether qualified manufacturers could reduce the concentrations of hydrazine fuel compounds and NDMA present in the wastewater stored at the HBSF to concentrations near the action levels; and (2) generate design and operational information for the full-scale treatment system. Bench-scale and pilot-scale testing were performed at the manufacturing facilities of three qualified vendors of UV/chemical oxidation equipment using representative wastewater collected from the largest tank in which hydrazine wastewater is stored at the HBSF. Peroxidation Systems, Inc., and ULTROX International performed bench-scale testing, while SolarChem Environmental Systems performed pilot-scale testing of their respective UV/chemical oxidation equipment. Analytical testing was performed by an independent laboratory. Hydrazine wastewater was collected, sampled and shipped in stainless steel drums to the three vendors. A sample of influent wastewater was analyzed for the hydrazine fuel compounds, NDMA, purgeable halocarbons and metals, and the results served as the influent baseline for all three vendors.

Visits were made to each vendor's manufacturing facility during the treatability testing to witness the testing and to assess the capabilities of each manufacturer. Effluent wastewater samples from the treatability testing were analyzed for NDMA and the hydrazine fuel compounds by developmental analytical methods not yet certified under the PMRMA program. Purgeable halocarbons and metals were analyzed using standard U.S. Environmental Protection Agency (EPA) methods.

Performance results from the treatability testing (Table 4) indicate that the hydrazine fuel compounds and NDMA were reduced by all three vendors to the respective detection limits of the developmental methods used for analysis. Purgeable halocarbons also were reduced to below detection limit levels. Thus, all three vendors met the objective of reducing the influent concentrations to action levels for the compounds of concern. Recommendations from the treatability testing for

full-scale operation were similar for all three vendors and included: (1) treatment in batch mode, (2) treatment time of between 8 and 16 hours using an ozone and/or hydrogen peroxide chemical oxidant concentration greater than the stoichiometric concentration, (3) maintaining a solution pH of between 3 and 5 throughout treatment and (4) use of a metal-based catalyst.

The selection of Peroxidation Systems, Inc., to provide the UV/chemical oxidation equipment was based in part on the analytical results from the bench- and pilot-scale testing program. Other evaluation criteria that were considered included capital and operating costs, potential for generation of off-gas, ease of installation and operation, experience, delivery time and anticipated response and support services. These other criteria were evaluated based upon information contained in the treatability testing reports and gained from visits to the vendor facilities during treatability testing.

DESIGN/CONSTRUCTION

Full-scale design criteria resulting from the treatability testing pro-

gram included: (1) UV-enhanced oxidation of the high-strength hydrazine wastewater should be performed in the batch treatment mode in order to maintain a reasonable reactor size; (2) the temperature of the wastewater should be maintained at 140 °F or less; and (3) the pH of the wastewater should be maintained between 3 and 5 for the most effective reduction of NDMA. Based on these and other criteria, a full-scale treatment system, incorporating the unit processes indicated in Figure 3, was designed and constructed within a 4-month period. The heart of the system includes the UV/chemical oxidation reactor, recycle tank and pump, and chiller (Figure 4). Other appurtenant unit processes include influent and effluent transfer and storage systems, bag filtration of the influent, hydrogen peroxide, concentrated sulfuric acid, liquid catalyst, caustic chemical storage and feed systems, a tank and reactor off-gas collection system, a hydropneumatic potable water system, air monitoring and safety subsystems. The off-gas collection system was included to collect and treat air displaced in the headspace of tanks and to treat any gases that might be generated in the reactor.

The treatment system is housed in a 40- by 60-foot insulated

preengineered metal building. All tanks and equipment are located within a secondary containment curbing; lined sumps are included to collect and remove any spilled liquids; and the floor of the facility is protected with a nonslip, chemical-compatible, protective coating system.

FULL-SCALE STARTUP TESTING

Once the treatment building was complete, full-scale startup testing of the hydrazine wastewater treatment system was conducted from January to May 1990, using nine batches of wastewater ranging in volume from 700 to 1,300 gallons. The purposes for startup testing were to: (1) address equipment and related startup concerns, (2) perform any necessary physical and operational modifications to the system and (3) gather process and analytical data to define the operational requirements for treatment of the approximately 300,000 gallons of hydrazine wastewater.

Wastewater was pumped via a submersible pump suspended at an intermediate depth in the largest tank, which the characterization data indicated has the highest concentration of the hydrazine fuel compounds and NDMA. During treatment of each batch, the operating parameters included pH, oxidation/reduction potential (ORP), temperature, hydrogen peroxide concentration, catalyst type, recycle rate, total treatment time and wastewater volume (Table 5). For those parameters that varied during treatment, both initial and final values are presented.

Pretreatment of all batches consisted of filtration through 50- and 5-micron pore-size bag filters arranged in series. Iron fouling of the quartz sheaths that surround the UV bulbs in the reactor during Batches 1 and 2 resulted in modifications to the system including adding a 1-micron pore-size bag filter in-line with the reactor and recycle tank, replacing the liquid ferrous sulfate catalyst with an in-line solid tungsten

Figure 4
UV/Chemical Oxidation Reactor, Recycle Tank and Chiller

rod reactor and attempting to oxidize and remove iron using hydrogen peroxide and polymer chemical addition, slow mixing and settling. Because the influent concentration of NDMA varied greatly between batches, the attempt to remove iron seemed to be oxidizing the UDMH and creating NDMA. Thus, pre-oxidation and polymer addition were discontinued for pretreatment of Batches 8 and 9.

Batch 1 was treated using the recommended operating parameters

from the bench-scale testing program. The literature suggests that hydrazine fuel compounds are destroyed best via an oxidation process at a pH above neutral, while destruction of NDMA is enhanced at a pH less than 4. Thus, for Batches 2, 3, 4, 8 and 9, the influent pH of between 7 and 9 was maintained at the beginning of each batch in an attempt to enhance the destruction of the hydrazine fuel compounds. The pH was later reduced in these runs to promote NDMA reduction. In an attempt to avoid the formation of NDMA by oxidation of UDMH, Batches 5, 6 and 7 were run at a pH of less than 2 units for the entire run time.

Three types of wastewater samples were collected during each batch: influent, process stream and effluent. Influent samples were collected after the pretreatment steps to obtain baseline water quality data. Process stream and effluent samples were collected from the same location downstream of the reactor. Process stream samples were collected at planned intervals throughout each batch and were analyzed to determine: (1) the concentration of NDMA and the hydrazine fuel compounds as a function of time, (2) reaction rate kinetics and (3) the time required to reach the lowest effluent NDMA and hydrazine fuel compound concentrations. Process stream samples were collected at 2-hour intervals during Batches 3 and 9 to develop reaction kinetics data.

Results from the nine batches treated during the full-scale startup testing period are shown in Tables 5 and 6 and in Figures 5 and 6. The results indicate the following:

- The UV/chemical oxidation process very successfully in reduced the levels of hydrazine fuel compounds, NDMA and other organics present in the hydrazine wastewater at RMA. In particular, the removal of the suspected carcinogen, NDMA, ranged from 99.785 to 99.999%. The hydrazine fuel compounds were consistently reduced to below detection limits in all batches. Where data are available, it appears that the hydrazine fuel compounds are destroyed in the initial 10 hours of treatment time. Other organic compounds also were reduced or destroyed in the process.
- Analytical method limitations do not allow measurement of NDMA to the ARAR (1.4 ppt) required for this IRA. Nevertheless, the detection limit for NDMA was not reached in any process stream or effluent sample through the full-scale testing program. It is therefore assumed that the limits of the UV/chemical oxidation technology, with respect to NDMA, were established during this testing.
- Iron fouling of the quartz sheaths that surround the UV bulbs occurred during Batches 1 and 2 and appeared to inhibit the treatment capability of the reactor.
- Pretreatment of hydrazine wastewater to remove iron appeared to enhance the formation of NDMA.
- A treatment scenario involving treatment at the initial pH of between 7 and 9 until the hydrazine fuel compounds are reduced to below detection limits, followed by reducing the pH to less than 4, appeared to provide the lowest effluent NDMA concentrations in the shortest treatment time. The data from Batch 9 suggest that effective reduction of the compounds of concern may be achieved in approximately 16 hours. Using this treatment scenario, it appears that the hydrazine fuel compounds may be reduced to below detection limits, while NDMA reduction to less than 2 ppb may be consistently achieved.
- Influent concentrations for the hydrazine fuel compounds and NDMA appear to vary significantly throughout Batches 1 through 9.
- Influent concentrations of NDMA and the hydrazine fuel compounds can vary greatly, even when taken from the same depth in the same tank.

RECOMMENDATION FOR FULL-SCALE TESTING

Based on the results from the full-scale startup testing, the following recommendations are made for treatment of the approximately 300,000 gallons of hydrazine wastewater stored at the HBSF:

- Each batch should be treated by not adjusting initial pH and by adding hydrogen peroxide in an amount exceeding the stoichiometric requirement. After the hydrazine fuel compounds are destroyed, which is indicated by a drop and subsequent leveling off of pH, the pH of the waste stream should be reduced to 2 for destruction of NDMA. Verification testing will be conducted during treatment of batches in the next phase of the IRA to determine whether the

Operating Results—Batch 9

recommended treatment scenario is effective.

- The treatment system should be modified to eliminate "dead spots" in the reactor, recycle tank and interconnecting piping.
- The reactor and associated steel piping should be modified such that all connecting parts are made of 316 stainless steel in order to reduce the "battery" effect caused by the high concentrations of acid in the reactor.
- Treatment time should be approximately 16 hours, but actual time should depend on the concentrations of hydrazine fuel compounds and NDMA in the influent.

CONCLUSION

The results of the treatability testing and the startup testing suggest that the UV/chemical oxidation reactor can successfully treat the wastewater; however, the limits of the reactor have been reached when treating the hydrazine-contaminated wastewater at the HBSF. Additional treatment time does not significantly reduce the concentration of NDMA below 1 to 2 ppb. Therefore, the exposure pathways must be examined to determine whether NDMA levels of 1 to 2 ppb may still achieve the overriding health-based goal of 10^{-6} lifetime excess cancer risk rate. If the health-based risk goal cannot be achieved, additional treatment with adsorption media or a solar evaporation pond must be performed. A risk assessment is being conducted, and the methods of additional treatment are currently being tested.

A Systematic Approach to Analytical Method Development to Meet Ultra-Low-Level-Based ARARs, Rocky Mountain Arsenal, Denver, Colorado

Commerce City, Colorado

ABSTRACT

In many cases, health-based action levels or applicable or relevant and appropriate requirements (ARARs) are established that require treatment of chemicals in environmental media to ultra-low levels that are often below currently available method analytical detection limits. For this reason, analytical method development must be undertaken to achieve the lowest level of detection possible to demonstrate that ultra-low-level ARARs can be met. Two approaches to method development include: (1) modification of currently available analytical methods to improve performance while not restricting the flexibility of the overall analytical approach and (2) methods development when published methods are not available for contaminants that are stipulated for regulation under a recently developed technology or health-based ARARs.

Modifying the current U.S. Environmental Protection Agency (EPA) Method 607 became necessary at Rocky Mountain Arsenal (RMA) for the analysis of N-nitrosodimethylamine (NDMA) in treated wastewater to evaluate the practicality of achieving an Ambient Water Quality Criteria (AWQC)-based ARAR of 0.0014 parts per billion (ppb) for NDMA. In conjunction with method modification for analysis of NDMA, method development for analyses of hydrazine (HYDZ), monomethylhydrazine (MMH) and unsymmetrical dimethylhydrazine or 1,1-dimethylhydrazine (UDMH) also was necessary because published methods were neither available nor adequate to meet program-stipulated ARARs. Methods are evaluated using a systematic approach and a rigorous quality assurance/quality control (QA/QC) program developed by the U.S. Army Toxic and Hazardous Materials Agency (USATHAMA) and adopted by the Program Manager for Rocky Mountain Arsenal (PMRMA). The PMRMA QA/QC program substantiates that modified method results or results generated using newly developed methods meet or exceed U.S. EPA or state agency requirements for analytical precision, accuracy, representativeness, completeness and comparability.

Conservative risk assessment-based ARARs may be analytically unachieveable, considering the current state of technology, and must be evaluated before signing the record of decision (ROD) to ensure the action levels selected are practicable and protective of human health. Well-documented method development programs will improve the understanding of the analytical constraints that must be considered when selecting final treatment levels.

INTRODUCTION

During 1989, the U.S. Army, U.S. EPA Region VIII, Shell Oil Company (Shell) and the Department of Interior (DOI) agreed on a plan for safe disposal of hydrazine-contaminated wastewater and for decommissioning of facilities previously used for blending of hydrazine rocket propellants at the Rocky Mountain Arsenal (RMA). The plan was defined by a Decision Document in which a preferred remedial alternative was recommended. Action levels were established for four compounds in the wastewater at the Hydrazine Blending and Storage Facility (HBSF): (1) NDMA at 0.0014 ppt, (2) HYDZ at 2.5 parts per billion (ppb), (3) MMH at 15 ppb and (4) UDMH at 25 ppb. The Interim Response Action (IRA) program for RMA defined by the Federal Facility Agreement (FFA) provides that "IRAs shall, to the maximum extent practicable, attain ARARs."

Development of the ARAR established for NDMA was based on a health-based standard because NDMA is not directly governed under any state or federal regulatory laws. At the time of signing the HBSF IRA Decision Document, the Ambient Water Quality Criteria (AWQC) was selected as the ARAR for NDMA. Because no health-based criteria are currently available, the action levels selected for the hydrazine fuel compounds (i.e., HYDZ, MMH and NDMH) were based on unpublished analytical method detection limits.

The AWQC for NDMA of 0.0014 ppb was developed pursuant to Section 304(a)(1) of the Clean Water Act, 33 U.S.C. 1314(a)(1). Under this section of the Clean Water Act, the U.S. EPA must periodically review and publish criteria for water quality that accurately reflect the latest scientific health and welfare knowledge. The NDMA ARAR of 0.0014 ppb represents a 1×10^{-6} cancer risk factor for an average person who consumes a total of 2 liters of NDMA-contaminated water per day during 70 years and an average 6.5 grams of NDMA-contaminated fish per day during the same 70-year lifetime. This AWQC was developed and published by the U.S. EPA during 1980 as guidance when establishing ARARs for site remediation. The ultimate utility of any such site-defined ARAR depends on two essential elements under the Superfund Amendments and Reauthorization Act (SARA). A new level of treatment can be redefined after an ARAR has been agreed upon only if: (1) the new level of treatment can be shown to be protective of human health or (2) the established ARAR can be shown to be unpracticable.

To show the levels to which ARARs are set are practical and achievable, two elements of any pilot-scale or bench-scale treatment program must be carefully examined: (1) efficiency of the treatment system to meet program ARARs and (2) the reliability of the analytical method when evaluating the treatment system efficiency.

Many methods currently are available for evaluating the efficiency of analytical methods. The U.S. EPA uses a statistical approach for calibration standards that evaluates method accuracy based on seven replicate analyses run during a single day. The approach is designed to evaluate instrument sensitivity and accuracy. However, this method of determining method detection limits does not consider sample preparation and extraction efficiencies, which generally control and dictate analytical method reliability.

During the early 1980s, USATHAMA introduced a statistical method to evaluate method detection limits that was designed to account for sample preparation and extraction efficiencies. This program requires that a series of calibration standards and investigative samples be prepared and analyzed over the entire estimated range of method performance. Four consecutive days of extraction and analysis are required to be evaluated using a series of standard statistical tests. The U.S. EPA method startup protocols, which prepare and analyze samples in quadruplicate during a single day and compare results to a national data base, are most comparable to the USATHAMA method design plan; however, the investigative samples prepared and analyzed under the U.S. EPA method startup protocol are run only at a single level of concentration and are analyzed during a single day.

Under a prime contract to perform several different studies at RMA, Harding Lawson Associates (HLA) designed and tested an ultraviolet (UV)/chemical oxidation treatment system for the HBSF wastewater. To accomplish this task, HLA researched and developed analytical methods to attempt to satisfy the program-stipulated ARARs set forth in the HBSF Decision Document.

CHEMICAL PROFILE OF NDMA

The major uses, sources and regulatory constraints on human exposure to NDMA are very important for understanding the nation-wide significance of the analytical technology available for analyzing the presence of NDMA.

Before April 1976, NDMA was used as an intermediate in the production of UDMH, a liquid rocket propellant believed to have contained up to 0.1% NDMA as an impurity. NDMA also forms from the chemical breakdown of UDMH. NDMA has been used as an industrial solvent; as an antioxidant; in lubricants and condensers to increase the dielectric constant; as a nematocide; as a softener for copolymers; as an inhibitor of nitrification in soil; and in active metal anode-electrolyte systems.[4]

Nitrosamines, including NDMA, are present in a wide variety of food as reported by Fine[5] and Scanlan.[6] Nitrosamines are found most commonly in cured meats (particularly cooked bacon); beer; Scotch whiskey; some cheeses (especially Gouda and Edam types); nonfat dry milk and buttermilk; and sometimes fish.[4] Levels of total volatile nitrosamines are generally less than 5 μg/kg in these foods. The average daily intake of volatile nitrosamines from food is estimated to be approximately 1 μg per person. NDMA is also found in rubber pacifiers, baby-bottle nipples and occasionally in cosmetics. Smokers are exposed to an estimated 6.5 nanograms (ng) of NDMA per cigarette from mainstream smoke; undiluted sidestream smoke may contain 20 to 100 times as much NDMA as mainstream smoke.[3]

NDMA does not appear to be common in drinking water or ambient air. Brodzinsky and Singh[7] compiled all available atmospheric monitoring data for a number of organic compounds, including NDMA, for 404 locations. In rural and remote areas the median concentration of NDMA was 0.018 μg/m^3; the median concentration in urban and suburban areas was 0.028 μg/m^3 and in source-dominated areas, 0.042 μg/m^3. Indoor levels of NDMA measured in restaurants and other public places have been between 0.01 and 0.24 μg/m^3 and are attributed primarily to tobacco smoke.

REGULATORY STATUS OF NDMA

The following is a brief summary of the March 1, 1989, nationwide regulatory status of NDMA. This summary is provided to inform the reader of manufacturing and other industrial situations that may result in the release of chemicals discussed in this paper. The regulatory environment is rapidly changing in relationship to NDMA and HYDZ, MMH and NHMH. A clear understanding of the state of current regulations governing these chemicals will provide the reader a better understanding of the potential effect that method development, such as that described in this paper, will have on the ultimate success or failure of any remedial action. Not only can the following discussion help to clarify the regulatory constraints currently applicable to the specific chemicals discussed in this paper, but it also can provide insight into how method development will affect remediation programs for

chemical compounds, other than those discussed in this study, for which legal constraints are not yet clearly defined.

Federal Programs

Clean Water Act (CWA)

NDMA is listed as a toxic pollutant, subject to general pretreatment regulations for new and existing sources and to effluent standards and guidelines. Effluent limitations specific to NDMA have been set in the following point source categories: electroplating, steam electric power generating and metal finishing. Limitations vary depending on the type of plant and industry.

Resource Conservation and Recovery Act (RCRA)

NDMA is listed as an acute hazardous waste and a hazardous waste constituent. This chemical is subject to land-disposal restrictions when its concentration as a hazardous constituent of certain wastewaters exceeds site-specified designated levels. NDMA is included on the U.S. EPA's groundwater monitoring list. The U.S. EPA requires that all hazardous waste treatment, storage and disposal facilities monitor their groundwater for chemicals on this list when suspected contamination is first detected and annually thereafter.

Comprehensive Environmental Response Compensation and Liability Act (CERCLA)

NDMA is designated a hazardous substance under CERCLA. It has a reportable quantity (RQ) limit of 0.454 kg. NDMA is designated an extremely hazardous substance under SARA Title III Section 302. Any facility at which this chemical is present in excess of its threshold planning quantity of 10 pounds must notify state and local emergency planning officials. If NDMA is released from a facility in excess of its RQ, local emergency planning officials must be notified.

Marine Protection Research and Sanctuaries Act (MPRSA)

Ocean dumping of organohalogen compounds as well as the dumping of known or suspected carcinogens, mutagens or teratogens is prohibited except when they are present as trace contaminants. Permit applicants are exempt from these regulations if they can demonstrate that such chemical constituents are nontoxic and nonbioaccumulative in the marine environment or are rapidly rendered harmless by physical, chemical or biological processes in the sea.

Occupational Safety and Health Act (OSHA)

Employee exposure to NDMA should be avoided. This chemical is designated an Occupational Safety and Health Administration (OSHA) carcinogen. Detailed regulations exist in 29 CFR 1910.1016 for areas where NDMA is manufactured, processed, used, packaged, released, handled or stored. These include requirements for reporting maintenance and decontamination.

Hazardous Materials Transportation Act (HMTA)

The U.S. Department of Transportation (DOT) has designated NDMA as a hazardous substance with an RQ of 0.454 kg, subject to requirements for packaging, labeling and transportation.

State Water Programs

All states have adopted the AWQC criteria as their promulgated state regulations, either by narrative reference or by relisting specific numeric criteria. The following states have promulgated additional or more stringent criteria:

- *Kansas* - Kansas has an action level of 0.0014 ng/L for NDMA in groundwater.
- *New York* - New York has a maximum contaminant level (MCL) of 50 μg/l in drinking water.
- *Oklahoma* - Oklahoma has set an enforceable Toxic Substance Goal of 0.8 ng/L for nitrosamines in surface waters classed for public and private water supplies.

Proposed Regulations

- *Federal Programs* - No proposed regulations are pending.

- *State Water Programs*

    Most States - Most states are in the process of revising their water programs and proposing changes in their regulations that will follow the U.S. EPA's changes when they become final. Changes are projected for 1989-90.

    Minnesota - Minnesota has proposed a Recommended Allowable Limit (RAL) of 0.007 µg/L for drinking water.

CHEMICAL PROFILE OF HYDRAZINE/HYDRAZINE FUELS

For the purpose of demonstrating the significance of the hydrazine fuel compounds to programs nationwide and in an attempt to not provide an exhaustive narrative, hydrazine is presented as an example of the industrial uses and regulatory environment surrounding hydrazine fuel compounds. Hydrazine is similar in chemical composition and in many of its industrial applications to UDMH and MMH. However, distinctly different industrial and regulatory constraints govern each of these compounds. For a more detailed discussion of these topics, the reader should contact a local regulatory agency for further guidance and reference materials.

Hydrazine is used in industry as a chemical intermediate in the manufacture of pharmaceuticals and plastic blowing agents and is used as an oxygen scavenger in boiler feed-water treatment and in fuel cells. It also is used as a missile propellant and in auxiliary power units of the space shuttle orbiter and solid rocket boosters. Each F-16 aircraft carries 6.5 gallons of a 70% hydrazine/30% water solution used in an emergency power unit to supply electrical and hydraulic power.

Information on sources of exposure to hydrazine is limited. The primary source of human exposure appears to be smoking, because hydrazine is a component of mainstream cigarette smoke. No data were found by HLA on its presence in the ambient environment. However, UDMH is a common breakdown product for the plant growth regulator Alar, applied to many fruits such as peaches and apples.

The following is a summary of the regulatory status for hydrazine as of March 1, 1989:

Federal Programs

Safe Drinking Water Act (SDWA)

In states with an approved Underground Injection Control program, a permit is required for the injection of hydrazine-containing wastes designated as hazardous under RCRA.

RCRA

Hydrazine is identified as a reactive, toxic hazardous waste and listed as a hazardous waste constituent.

CERCLA

Hydrazine is designated a hazardous substance under CERCLA. It has an RQ limit of 0.454 kg. Reportable quantities have also been issued for RCRA hazardous waste streams containing hydrazine, but these depend on the concentrations of the chemicals in the waste stream. Hydrazine is designated an extremely hazardous substance under SARA Title III Section 302. Any facility at which hydrazine is present in excess of its threshold planning quantity of 1000 pounds must notify state and local emergency planning officials annually. If hydrazine is released from the facility in excess of its RQ, local emergency planning officials must be notified. Under SARA Title III Section 313, manufacturers, processors, importers and users of hydrazine must report annually to the U.S. EPA and state officials their releases of this chemical to the environment.

MPRSA

Ocean dumping of organohalogen compounds as well as the dumping of known or suspected carcinogens, mutagens, or teratogens is prohibited except when they are present as trace contaminants.

Occupational Safety and Health Act

Employee exposure to hydrazine shall not exceed an 8-hour time-weighted average (TWA) of 0.1 ppm. Employee skin exposure to

hydrazine shall be prevented/reduced through the use of protective clothing and work practices.

HMTA

The DOT has designated hydrazine as a hazardous substance with an RQ of 0.454 kg, subject to requirements for packaging, labeling and transportation.

Food, Drug and Cosmetic Act (FDCA)

Hydrazine may not be used as a boiler-water additive in any amount in the preparation of steam that will contact food.

State Water Programs

All states have adopted U.S. EPA AWQC and National Discharge Permit Water Restrictions (NDPWRs) as their promulgated state regulations, either by narrative reference or by relisting the specific numeric criteria. The U.S. EPA has not currently published any AWQC for hydrazine. Only New York has promulgated additional or more stringent criteria:

New York has an ambient water quality standard for hydrazine of 5 µg/L at less than 50 ppm hardness and 10 µg/L at greater than or equal to 50 ppm hardness for Class A, A-S, AA, AA-S, B, and C surface waters. New York also has an ambient water quality standard for hydrazine of 50 µg/L at less than 50 ppm hardness and 100 µg/L at greater than or equal to 50 ppm hardness for Class D surface waters.

Proposed Regulation

- *Federal Programs* - No proposed regulations are pending.
- *State Water Programs* - No proposed regulations are pending. Most states are in the process of revising their water programs and proposing changes in their regulations that will follow the U.S. EPA's changes when they become final.

After review of the current state of regulations for compounds such as NDMA or hydrazine fuels, it is apparent that regulatory constraints will most likely be based, at least in part, on the level of detection achievable.

METHOD DEVELOPMENT FOR THE ANALYSIS OF NDMA IN WATER

U.S. EPA-approved methods for analysis of NDMA in aqueous samples include U.S. EPA Methods 607, 625 and 1625. The method detection limits published for these methods are 0.150 ppb or ug/l (Method 607) and 50 ppb (Method 1625). No detection limit for Method 625 is published. Because the AWQC-based ARAR for NDMA under the HBSF IRA program is 0.0014 ppb, none of these U.S. EPA methods, in their current state of development, were adequate to meet required objectives.

Some potentially applicable analytical work on the analysis of ultra-low levels of NDMA was reported by Jody[8] and others from the Illinois Institute of Technology Research Institute. In Jody's paper, "Ozonation of Hydrazine Fuels and Their Associated Impurities," he reported that levels of NDMA detection using a rotary-evaporation sample concentration technique coupled with a gas chromatograph and nitrogen phosphorus detection (GC/NPD) system were approximately 0.010 ppb. The IITRI method was essentially a modified U.S. EPA Method 607.

HLA contacted IITRI and requested they repeat their previous analytical work and subject it to the statistical programs utilized by PMRMA. The PMRMA certification program for systematically evaluating method performance involves a two-step process that ultimately yields a certified reporting limit (CRL) for the analyte(s). The initial step, or precertification, is used to evaluate instrument stability and linearity over the proposed testing range of concentration. The program involves preparing two separate sets of calibration standards and analyzing them in the sequence that will be used during daily calibration. IITRI's analytical results were found to satisfy all linearity and instrument sensitivity requirements. Table 1 shows that instrument sensitivity and reproducibility were acceptable down to the 0.020 ppb level of concentration. Instrument response to NDMA was evidenced

at the 0.0075 ppb level, but reproducibility was poor. Linearity of calibration checks was acceptable, as shown in Figure 1.

During the second step of method certification using the systematic approach used by PMRMA, four consecutive days of instrument calibration and spiked-sample extraction analysis were performed and subjected to statistical analysis. Table 2 shows the results for spiked samples analyzed using the IITRI, U.S. EPA Method 607 modification during 4 days of analysis. Recovery values were found to be erratic. Figure 2 shows the data were not linear and failed to meet linearity criteria. Thus, it became apparent that investigation into the development of better sample extraction procedures was required to analyze for the presence of NDMA at ppt levels.

0.010	0.014	140.00	0.031	308.00
Method Blank	0.000		0.000	

Published QC acceptance criteria listed in U.S. EPA Method 607 for NDMA-spiked samples at 20 ppb in water are 13 to 109 percent recovery. The reported method detection limit based on the analysis of seven replicate calibration standards is 0.150 ppb. This indicates that a sample with an NDMA concentration as high as 1.15 ppb could potentially be reported as not detected at the U.S. EPA Method 607 detection limit of 150 ppt if sample recovery were only 13%. This level of method performance was not acceptable using the PMRMA two-step certification process.

DataChem Laboratories in Salt Lake City, Utah, had previously successfully certified a method for the analysis of NDMA at 0.200 ppb. Precertification was rerun by Datachem for the analysis of NDMA using instrument conditions similar to those used by IITRI; the data were found to be comparable. In an attempt to improve spiked sample results, the florisil column cleanup recommended in U.S. EPA Method 607 was eliminated from the extraction procedure because it drastically reduced NDMA extraction efficiency. Separatory funnel extraction, used in U.S. EPA Method 607, was substituted with the use of liquid-liquid continuous extraction at a pH between 5 and 9.

After an 8-hour liquid-liquid continuous extraction using the extraction solvent methylene chloride (MECL2), sample concentration was found to be most efficient by adding 15 mLs of methanol (MeOH) to the 300 mLs of MECL2 extract and then concentrating the extract in a cool-water bath at 65 °C, using a Kuderna-Danish. When the extract reached a volume of 100 mLs, a hot-bath concentration step at 90 °C was used to reduce the sample to a volume of 5 to 8 mLs. A nitrogen blowdown step was then used in a cold-water bath at or below 30 °C. Numerous types of concentration methods were examined, such as condensers, turbo-evaporators and micro-snyder columns. In all cases, the preferred method that yielded at least 40% NDMA recovery was the one that utilized the Kuderna-Danish coupled with a nitrogen blowdown.

Table 3 shows the results of 4 days of spiked-sample extraction and analysis using the described modifications to U.S. EPA Method 607. The range of concentrations tested is a subset of the actual range over which the method was tested. The method was tested initially over a range of concentration from 0.010 ppb to 2 ppb. However, over this range the method was found to be not linear, so higher levels tested were eliminated and a selected low-end subset of the analytical results that

provided the lowest CRL possible was presented. From the analytical results in Table 3 and the graphical display of these data in Figure 3, it is obvious that some analytical variability exists even at the reported levels of spiked-sample concentrations listed. This resulted in a statistically determined CRL of 0.042 ppb and a working range that extended only to 0.150 ppb. Because the program objective was to obtain a CRL as close to 0.0014 ppb as possible, this limited range did not cause problems.

Table 3
DataChem Certification Sample Results for NDMA

Found Concentration vs. Target Concentration
DataChem Certification Sample Results of NDMA

However, in addition to strict analytical considerations of precision, accuracy, completeness and comparability, the representativeness of analytical results was also considered when attempting to evaluate the practicality of ultra-low-level- based ARARs such as that for NDMA in the HBSF IRA program. Table 4 shows a list of method blank results obtained during some of the analyses performed during Phase I of the HBSF IRA program. Table 4 shows that when attempting to analyze high-level samples, special considerations needed to be added to the method to eliminate cross-contamination. After analysis of method blank samples shown in Table 4, individual ventilation units were placed over each sample extraction vessel and concentration steps for low- and high-level samples were segregated. This, along with adopting additional cleaning procedures and eliminating a step using a pipetting apparatus, eliminated the previously observed cross-contamination.

METHOD DEVELOPMENT FOR THE ANALYSIS OF HYDRAZINE FUEL COMPOUNDS IN WATER

The hydrazine fuel compounds are not included among the U.S. EPA-designated priority pollutants, and a U.S. EPA-approved procedure for

the analysis of hydrazine fuel compounds is not currently available. However, one analytical method recommended for the analysis of azo compounds, hydrazines and derivatives involves derivatization and analysis by GC/NPD, mass spectrometer (MS) or a flame ionization detector. Numerous other methods for the analysis of hydrazine in air and soil have been published and were investigated during the method development process.

The only directly applicable method for analyzing hydrazines in water was developed by Environmental Science (ES) for the Facilities Management Division (ASD/PMDA), Headquarters Aeronautical Systems Division, Wright-Patterson Air Force Base, Ohio, and several other Air Force bases, and was published in February 1988. In this experimental method, derivitization using 2-furaldehyde, benzaldehyde, 2,4-pentanedione, methylethyl ketone and cinnamaldehyde was evaluated. The reaction of the target compounds with 2-furaldehyde produced the most successful results using an internal standard, nitrobenzene, for quantitation. No work was performed by ES concerning absolute recovery efficiencies. This method utilizes procedural standards whereby calibration standards and analytical samples are derivatized before analysis. Using such procedural standards, and standard U.S. EPA-type statistical methods for determination of method detection limits, the 2-furaldehyde method detection limit for hydrazine was 21 ppb, for MMH was 15 ppb, and for UDMH was 18 ppb.

Based on the QC results published by ES on their 2-furaldehyde method, Vista Laboratories, Wheat Ridge, Colorado, was asked to conduct method development and evaluation of the ES method utilizing the systematic program used by PMRMA.

The method development effort began with a review of the existing method developed by ES as well as other methods developed by NIOSH for monitoring hydrazine fuels in air. The existing methods did not meet the project objectives of obtaining a CRL of 2.5 ppb for hydrazine and 20 ppb for UDMH; however, the existing methods showed the promise of improvement to attain these goals.

The laboratory study began with the reaction of 2-furaldehyde (furfural) with the hydrazines to create hydrazone derivatives that would be of sufficient molecular weight to extract and of sufficient stability to chromatograph. Following the evaluation of the derivatives of their detector response, optimal GC conditions were developed for all three derivatives on the primary DB-1 and confirmatory DB-608 columns. Phenylhydrazine was investigated as a potential surrogate for the method and the phenylhydrazine derivative was successfully chromatographed. Two compounds, 2-picoline and nitrobenzene, were evaluated as potential internal standards for the method. Nitrobenzene was chosen because of retention time considerations.

Hydrazine derivatives were synthesized in ethyl acetate solutions. Because of the insolubility of furfural in hexane, the sample extract solvent of choice for nitrogen phosphorus detectors was ethyl acetate. Calibration standards were prepared in hexane. "Micro-extraction" techniques were evaluated for extraction of the derivatives from water samples. Sample aliquots of 100 mLs were extracted with 2 mLs of hexane, yielding recoveries of 1 to 10% for the hydrazones. MECL2 was evaluated as an extraction solvent followed by a solvent exchange with hexane. Initial tests of the concentration and solvent exchange revealed the hydrazine derivatives were stable through these steps, with recoveries ranging from 75 to 100%. One-liter samples were extracted with MECL2 and the extracts were concentrated and exchanged to hexane. Excess 2-furaldehyde was co-extracted and formed a nonmiscible layer with MECL2 during concentration. Recoveries of the hydrazones ranged from 10 to 40%; thus, it was decided to seek another extraction solvent.

Hexane extraction was again attempted on a "macro-extraction" scale. Aliquots of 100 mLs of hexane were concentrated to see if the hydrazones would survive the higher water-bath temperatures required to concentrate hexane versus MECL2. Recoveries from the concentration step ranged from 83 to 95%. One-liter samples were extracted with hexane, and the extracts were concentrated to 1 mL. Recoveries of the hydrazones ranged from 7 to 40%, indicating no improvement in using hexane over using MECL2.

Because ethyl acetate had been used in some of the existing methods, it was decided to evaluate it as an extraction solvent. Samples 100 mL in size were extracted with ethyl acetate and extracts concentrated. Recoveries ranged from 40 to 94%. Samples were prepared covering a range from 2.5 to 250 ppb, and recoveries ranged from 65 to 100% for hydrazine, 45 to 75% for UDMH and 2 to 10% for MMH. The 2-furaldehyde derivative of MMH yielded such a low response it was decided to use another derivatizing agent for this compound. A method using 2,4-pentanedione to derivatize MMH was evaluated with success.

The sensitivity of the GC system to the derivatives was then evaluated. Solutions of the hydrazones were prepared to place 10 ng (absolute) of the hydrazine fuel derivatives on column. Sufficient instrument response was observed to estimate that a 100-mL sample volume would be adequate to meet the target reporting limit concentrations.

The two methods were again evaluated over the previously established testing range. Sample aliquots of 100 mLs were derivatized with 2-furaldehyde for hydrazine and UDMH and 2,4-pentanedione for MMH and then extracted with ethyl acetate. Nitrobenzene proved to be a suitable internal standard; however, the hydrazone of UDMH either was not recovered or disappeared from the extract. The methods performed favorably for hydrazine and MMH.

The methods were then redrafted to include "preparatory" procedural standards rather than the "externally derivatized" standards used to this point. It was believed that any inefficiency in synthesis or extraction of the derivatives would be accounted for by preparing standards in a manner identical to sample preparation.

Precertification of the method for MMH was successful. Phenylhydrazine recoveries were very erratic; subsequently, this compound as a surrogate standard was abandoned. Precertification of the method for hydrazine and UDMH was attempted with very poor results. Very poor chromatography was observed for the hydrazine derivative at lower concentrations. The DB-608 column was replaced with a newer version of the DB-608 column and NPD detector perfor-

mance improved. A DB-17 column was installed and adopted as the confirmatory column.

Because of the variability and introduction of chromatographic interference from the ethyl acetate, it was decided to evaluate a different extraction solvent. Diethyl ether was chosen because of its similar polarity properties.

Diethyl ether was found to be a suitable extraction solvent. Precertification was attempted using ethyl acetate in addition to diethyl ether as a keeper during solvent concentration; however, retention time shifts were noted during GC analysis, which invalidated the precertification. Precertification was again attempted, and successful, using hexane as a keeper to remove the previously observed retention time shifts. Precertification for MMH was also attempted, and successful, using the diethyl ether/hexane solvents.

After precertification, approval was given to attempt certification of the methods. Certification was successful for MMH, yielding a CRL of 7.5 ppb, which was sufficiently below the program ARAR of 20 ppb. During the certification attempts it was revealed that the concept of initial calibration checks and daily single-point calibrations for hydrazine and UDMH would not be successful. Although any single calibration curve was reasonably linear, the slope of the curve varied from preparation to preparation. A scheme of daily five-point calibrations was, therefore, drafted and included in the method.

The second certification attempt proceeded and yielded CRLs of 9.9 ppb for hydrazine and 30 ppb for UDMH. Because these CRLs did not meet the ARAR targets of 2.5 ppb and 25 ppb respectively, a third certification attempt was scheduled.

During the third certification attempt, a problem with the disappearance of the UDMH derivative was observed, as it had been during previous analyses. The derivative appeared to be synthesized, but would rapidly disappear, from the derivatized extracts. Analyses of a single extract performed one-half hour apart indicated a loss of 50% or more of the UDMH hydrazone.

After experiencing the problems with UDMH disappearance, it was determined that the method would be recertified as a qualitative method at the level required by the ARAR. Recent developments have pointed to the possibility that the antioxidant L-ascorbic acid may provide some relief from the observed UDMH disappearance problem.

SELECTION OF PROTECTIVE AND TECHNOLOGICALLY FEASIBLE REGULATORY LIMITS

When establishing ARARs or cleanup goals at any hazardous waste site, careful consideration of the analytical constraints that govern the reliability of analytical data must be reviewed and compared to proposed health-based criteria. Analytical method development, using an exhaustive QA procedure similar to that used by PMRMA, is essential before establishing final cleanup goals for unregulated chemical constituents for which methods are not available.

Table 5 compares the oral carcinogenic potency factor, the 1×10^{-6} calculated cancer risk factor for two commonly known human carcinogens, benzene and vinyl chloride, to the SDWA-stipulated MCLs. The 10^{-6} cancer risk factor can be directly related to the cancer potency factor, provided the route of exposure is the same. Comparing the 10^{-6} cancer risk factor to the SDWA MCL, it is obvious that the MCLs for both benzene and vinyl chloride are significantly above the 10^{-6} cancer risk level of concentration. The 1×10^{-4} cancer risk factors (i.e., the generally accepted level of protectiveness by most regulatory agencies) for benzene and vinyl chloride (Table 5) are 100 and 1.5 ppb, respectively. The U.S. EPA has chosen the MCL for these two compounds by rounding the vinyl chloride 10^{-4} risk factor of 1.5 to 2.0 ppb (which is the generally accepted practical quantitation limit (PQL) for the U.S. EPA-accepted method for analysis of vinyl chloride) and has set the MCL for benzene on the U.S. EPA Method PQL alone.

The rationale used to establish cleanup goals is similar to that used to establish ARARs: (1) the selected cleanup goal should be protective of human health, or between the 10^{-4} and 10^{-6} estimated cancer risk level, and (2) the selected cleanup goal should be practically achievable given the current state of available analytical technology. Based on this

Table 5
Comparison of Health Risk versus
Analytical Quantitation Limits

Compound	EPA Classification	Oral Carcinogenic Potency Factor (mg/kg/day)$^{-1}$	One-in-one-Million Drinking Water Risk Concentration (ppb)	SDWA MCL (ppb)
NDMA	B2 Probable Human Carcinogen	51	1.4×10^{-3}	
Benzene	A Human Carcinogen	0.029	1	5
Vinyl chloride	A	2.3	0.015	2

line of reasoning, the analytical constraints on the detection of unregulated chemical compounds should play a critical role in the selection of final treatment objectives at any hazardous waste site.

SUMMARY AND CONCLUSIONS

In the case studies reviewed, it is apparent that a target treatment level of 0.0014 ppb for NDMA is realistically unachievable given the current state of analytical technology. However, the technology currently available can yield reliable data in the 10^{-4} to 10^{-6} cancer risk factor range between 0.140 ppb and 0.0014 ppb. In the case of hydrazine fuel compounds, it was discovered that currently available methods of analysis can verify treatment to higher levels of protection for the compound MMH, but the method for analysis of hydrazine is insufficiently reliable at the levels currently stipulated in the HBSF IRA Decision Document.

For UDMH significant analytical problems still exist that must be overcome before the reliable quantitation of UDMH can be performed, but program objectives can be satisfied through the use of a qualitative

approach until further method improvements can be implemented.

The role of analytical chemistry in the conscientious selection of ARARs and final treatment objectives is often over-shadowed by the desire to obtain a solely health-based protective solution to chemical contamination problems at hazardous waste sites. Provided that a level of cleanup is protective, it is critical that the analytical methods reliably portray the level of contamination or remediation that may be required by a program ARAR. Therefore, a careful selection and QA review of health-based and technology-based criteria must be performed before selecting final treatment or regulatory limits.

Timing—The Critical Element in a Successful Community Relations Program at the Rocky Mountain Arsenal The Basin F Liquids Story

ABSTRACT

Early community relations planning and implementation at controversial Superfund sites can enhance the quality of decisions made and help keep projects on schedule. A case study at the Rocky Mountain Arsenal in Denver, Colorado, demonstrates that at a site with complex technical issues and regulatory framework, where incineration is a likely decision and where the local populace is opposed to incineration, an aggressive community relations program can be a technical tool for achieving technical objectives. The project worked within a framework of a community relations task force, briefed a wide range of interested parties (including the governor's staff), offered a community workshop and responded to community concerns in the decision document or with written responses.

PREMISE:
COMMUNITY RELATIONS ENHANCES DECISIONS, SUPPORTS SCHEDULES

During confirmation hearings for U.S. EPA administrator William K. Reilly, the U.S. Senate asked for an evaluation of the Superfund program and how it could be improved. Reilly returned with a management review in 90 days with *A Management Review of the Superfund Program*, known internally as the "90-day Study." In the study, the U.S. EPA announced a new long-term strategy for the Superfund program. One element is to encourage full participation by communities in cleanup decisions. The 90-day Study made 50 recommendations for improving the Superfund program. Of the 50 recommendations, 10 deal with community involvement. One key recommendation was: "Strongly support increased public involvement in Superfund decisions and accept occasional delays as the result of greater public involvement."

While we applaud the increased emphasis on public involvement, it has been our experience that an active community relations program initiated early in the process actually helps avoid delays, rather than causing them. The case study that follows shows not only that citizen involvement can help us stay on schedule, but that it can improve the quality of Superfund decisions.

CASE STUDY:
THE ROCKY MOUNTAIN ARSENAL

In March 1990, the U.S. Army at Rocky Mountain Arsenal (RMA) announced it would act quickly to use on-site incineration to handle its most complex and controversial waste problem. This decision was endorsed and supported by the U.S. EPA, the State of Colorado, officials of the local affected community and several citizen interest groups.

The nature of this decision bears examination, because it was so widely accepted and yet it contains so many elements of controversy. Citizen involvement was not by itself the critical element in this

widespread acceptance. As this case study will show, it was the timing of that involvement that made a difference. In a nutshell, our challenge was to:

> "Site a moderately-sized hazardous waste incinerator near Denver, a large, environmentally conscious city, to treat 8,500,000 gallons of toxic liquid waste at the nation's worst military hazardous waste site under a tight, legally mandated deadline."

At first glance, these conditions might seem to define a hopeless situation. To reach a remedial decision, the Army required some relatively complicated technical studies. It also needed to build enough comprehension and confidence in the community to ensure citizens could comment knowledgeably and the U. S. Army would have time to respond. We believed if we could do this, the solution finally selected could be put in place on time without fostering opposition or creating discomfort among the people affected by the cleanup. How the Army faced this challenge is the subject of this paper.

HISTORY:
MUNITIONS AND CHEMICAL HANDLING AT RMA

The Rocky Mountain Arsenal was established in 1942 on more than 17,000 acres (27 mi^2) adjacent to Adams County, Colorado. The installation is located approximately 10 miles from downtown Denver just north of Stapleton International Airport. The Arsenal has been the site of the manufacture of chemical materials such as mustard gas, white phosphorous and napalm. In the 1950s, the Army produced GB nerve agent and continued munitions-filling operations until 1969. Later, the Army initiated a program to destroy chemical munitions, which continued until the 1970s. To offset operating costs at the end of World War II, Congress directed the Army to lease selected facilities, including the Arsenal, to private industrial chemical manufacturers. Shell Chemical Company (now Shell Oil Company), a major lessee, manufactured agricultural chemicals at the Arsenal from 1952 to 1982.

In 1956, Basin F, a state-of-the-art evaporation pond, was constructed by building a dike around a natural depression and lining it with a 0.75-inch asphalt membrane. A one-foot layer of earth was placed on top of the asphalt to protect it. The pond could hold approximately 243,000,000 gallons of wastewater. From August 1957 until its use was discontinued in early 1982, Basin F was the only lined evaporative disposal facility in service at the Arsenal.

In February 1989, two administrative agreements were signed to ensure the Rocky Mountain Arsenal cleanup program was carried out in a smooth and responsible manner. The Federal Facility Agreement (FFA) and the Settlement Agreement (SA) define how appropriate remedial actions will be determined and the technical and financial responsibilities for each party. The FFA also defines how the interim

response actions (IRAs) will be carried out, consistent with the NCP. The IRAs are designed to support and be consistent with the final ROD on how the Arsenal will be cleaned up. When this decision is made in late 1993, the IRAs will either be completed or be incorporated into the final cleanup actions.

STRATEGY AND ISSUES:
AGGRESSIVE COMMUNICATIONS IN
A NEGATIVE ATMOSPHERE

The remedial objective of the Basin F Liquids IRA is to destroy Basin F liquids or render them harmless by June 1993. For a number of reasons discussed below, this schedule is exceedingly restrictive. To help achieve this objective on time, the Army needed a community relations program that would do more than simply inform the public of a decision after all the technical assessment had already been completed, with hopes the public would support the decision—or, at a minimum, not be so opposed that there would be delays in the schedule. The Army needed the public's help and participation in framing a decision that responded to citizen concerns even as it was developed. The key to the Army's approach was designing the community relations program to be a technical tool that helped to shape the remedial decision and thereby built consensus. The design of the community relations program was, therefore, based on the following premises:

- It should accommodate the full range of issues and community concerns generated by the technologies under consideration for Basin F (as well as those technologies that were excluded).
- It should provide a means of active public participation in technical issues that would have impact on significant portions of the remedial decision (i.e., response to public concerns should form a part of the decision and thereby build consensus and active support for the decision);
- It should have a substantial outreach component to ensure that all appropriate constituencies and affected parties are informed and involved;
- It should strive to achieve a "win-win" result. Early citizen involvement should improve the quality of the decision and help the Army stay on schedule.

Within the framework of this approach, the community relations program was influenced by several issues that were either peculiar to RMA or inherent in the nature of the Basin F liquids problem and its potential solutions. These issues were:

Complex Technical Issues

Basin F liquids are unique and unusual and cannot be handled by most conventional treatment methods. The waste is corrosive to most treatment equipment, has high concentrations of ammonia and contains significant concentrations of metals and organic chemicals (as many as 80 species). Scores of experimental treatability tests have been done over a 10-year period and a number of commercial hazardous waste facilities have tried without success to treat Basin F liquids. A few innovative technologies still in developmental stages seemed to be potentially promising, but the limit on temporary storage of the wastes ruled out all but proven approaches, none of which had been tried on wastes exactly like Basin F liquid.

Generalized Aversion to Incineration

This issue is not local, but rather reflects a national fear and mistrust of hazardous waste incineration. The Army evaluated 40 different treatment technologies, but the final set of five feasible technologies included two incineration techniques and two quasi-incineration techniques. Hence, from an early point in the study, it was apparent that incineration was the major technology under active consideration. All the design and risk studies subsequently showed incineration to be the safest and most reliable alternative. Nevertheless, the public in general and some groups in particular, were predisposed against incineration and expressed fears about explosive hazards and deleterious health effects of incinerators that were taken to be common knowledge.

The Superiority of One Incineration Technology
Over All Other Alternatives

Perversely, the problem of dealing with the widespread aversion to incineration was made "worse" by the results of our remedy selection study; they showed that one type of incinerator was so much better in nearly every way than the other alternatives, that it was almost impossible to define a set of decision-making priorities where this incinerator would not be the preferred solution. Thus, not only did we think that incineration was the best solution while the public was predisposed to think it was the worst solution, but also our technical case for incineration was so strong that the public was likely to think that we had manipulated the data.

Local Aversion to Incineration

Colorado—and Denver in particular—is environmentally conscious and has a history of objecting to any type of disposal practices that might result in air emissions into the already polluted atmosphere. As a consequence, we knew the cumulative impact of any IRA alternative on air quality would be carefully scrutinized by the public. Incineration, often referred to by citizen activist groups as a "landfill in the sky," would undoubtedly be a target of Denver's concern if it were proposed as a preferred alternative.

Complex Regulatory Framework

The cleanup of RMA is a Superfund action, but a history of litigation, unapproved consent decrees and settlement agreements has shaped the content and procedures of the cleanup program. In 1989, a Federal Facility Agreement (FFA) was signed that defined the roles and responsibilities of the participating organizations, who are: (1) the U.S. Army; (2) the U.S. Environmental Protection Agency; (3) Shell Oil Company; (4) the State of Colorado (not a signatory); (5) the U. S. Department of Justice; (6) the U. S. Department of Interior; and (7) the Agency for Toxic Substances and Disease Registry.

Two committees have an active role in remedial oversight. The RMA Committee, which consists of representatives of all of the agencies listed above, oversees most investigation and remediation programs. The Technical Review Committee (TRC), which consists of representatives of a number of local health and utility agencies, at-large citizen representatives, local government and representatives of the Army, was established by the FFA. In addition, day-to-day decisions on the community relations program are subject to the guidance of the Community Relations Task Force, which includes representatives of the Army, U.S. EPA, Shell and their contractors.

The FFA states that community relations at RMA will be done in accordance with U.S. EPA regulations. Interim Response Actions, such as the Basin F Liquids IRA, are performed under the Superfund removal authority, for which the community relations requirements are not well defined and for which there is no formal guidance aside from the public hearing and comment period requirements. At RMA, the Community Relations Task Force can recommend to the RMA Committee, which approves the action, on the direction and content of community relations programs for IRAs.

The overall regulatory picture, then, consists of a complex legal history, a complicated interagency agreement, seven major players with widely differing agendas, committees making decisions and committees making committees and reliance on a law that gives no clear-cut directions for community relations programs for large-scale, removal-authority actions like the Basin F Liquids IRA.

Multiple Conflicting Interests

All parties to the FFA and the State of Colorado shared a common interest: destruction of Basin F liquids by mid-1993. Each party, however, had other interests that had to be considered in the planning and implementation of the community relations program.

For example, the Army and U.S. EPA, facing a multidecade cleanup program, are individually concerned about establishing precedents for the future and the adequacy of the public participation and decision-making process as well as the effectiveness of the selected IRA alter-

native. Shell urges caution in all matters that it believes might have a bearing on present or future litigation. DOJ is concerned that concepts and commitments are correctly presented and consistent with other declarations of the federal government. The State maintains that it should manage the Basin F cleanup as a RCRA action. The State usually takes the position that the Army is not in compliance with RCRA and is therefore in willful breach of the law. The State is concerned that its official position should be correctly stated as final approval authority on the project. The Department of Interior is charged with protecting Arsenal wildlife, including the endangered bald eagles and the threatened ferruginous hawks. All this is to say that, in addition to overcoming the complexity of technical and community issues in working with the public, we had to devote substantial energy to overcoming the complexity of the RMA Committee members' interests.

Community Sensitivities

In 1988, Basin F liquids were removed from the basin and the soils and sludges were scraped up and placed in secure storage. The process of moving these soils and sludges unexpectedly released strong ammonia-like odors to the atmosphere. The odors drifted into neighborhoods adjacent to the Arsenal and residents complained strenuously. Some neighbors said that the odors caused serious health problems, but the Army, the U.S. EPA and the Colorado Department of Health (CDH) were unable to document any problems or detect harmful concentrations of contaminants with ambient air monitors.

Nevertheless, the odor problem was covered closely in the press and lasted for several months. The memory of this problem, reinforced by periodic mention in the press, lingered. Many residents perceived that the Army and its contractors had not taken adequate precautions to prevent this hazard, that the hazard had adverse health effects and that the Army either failed to own up to its actions or had tried to cover up a serious community health problem. Thus, a general climate of bitter memories and mistrust of the Army prevailed as the Basin F Liquids IRA study began.

In short, this was a tough technical problem with many of unusual conditions. In spite of this situation, or perhaps because of it, we wanted residents to understand these technical issues so that they could participate effectively in the critical elements of our decision: selection of one remedy from a small group of feasible technologies and determination of how that technology would be operated to ensure that it would both be safe and achieve cleanup objectives.

Based on the nature of these issues and the tight schedule for implementation of a Basin F liquids remedy, Community Relations Task Force members recommended to the management of their respective organizations that an innovative approach be taken to informing the public of incineration's probable preferred alternative status. Instead of waiting for the Draft Decision Document to be released and then holding a public meeting to hear from the citizens, the Community Relations Task Force recommended that a public education and involvement process start earlier than required in the FFA. The Task Force recommended that the Army hold a series of briefings for elected officials, special interest groups, the media and the general public to inform them of what technologies were being investigated and the pros and cons of each technology.

The Army approved this approach and within a week after the Draft Treatment Assessment Report was released, more than 200 people received background information on the technologies being considered. During these briefings, the Army made it clear that incineration was the leading candidate. The approach was significant because it was the first time the Army had "gone public" with a Draft Treatment Assessment Report. This departure from the norm was not only a first, but as was demonstrated, was key to the Army's success in gaining community support for its eventual decision.

In addition to the briefings, the Army hosted an informal workshop and invited interested citizens to attend. The workshop was designed not only to provide more in-depth technical information to the public on all the technologies being studied, but more importantly, to also provide the Army with in-depth knowledge of the public's questions and concerns. Having learned of the public's concerns and questions, the Army was then in a position to demonstrate its sensitivity to the community by addressing its concerns orally at the workshop, at the formal public meeting held at the start of the comment period two months later and in the Army's Final Decision Document.

The effectiveness of the Task Force's community relations efforts can be measured by the overwhelming lack of negative reaction to the Army's decision. The community relations program and individual techniques that were employed are described below.

THE PROGRAM:
BUILDING CONSENSUS THROUGH INTERACTION

The two basic building blocks of our community relations program were the development of a community relations plan and strategy and the implementation of aggressive community relations activities. These activities were undertaken under the combined guidance and review of the Community Relations Task Force.

The Community Relations Task Force

The Task Force represented the diverse interests of the Army, the U.S. EPA and Shell Oil Company. The group met frequently and attendance at any given meeting included some or all of the following: the Army's technical, community relations and legal staff and consultants; Department of Justice attorneys; Shell's public relations and technical staff and consultants; and U.S. EPA's community relations coordinators. The purpose of this group was to discuss, coordinate and agree on community relations activities planned for the Arsenal.

The Community Relations Plan and Strategy

To provide a useful framework for understanding and responding to community concerns, Superfund guidance required development of a Community Relations Plan (CRP) tailored to the community that surrounds and is potentially affected by, the Arsenal. Using documents and information previously developed by Shell and the U.S. EPA as a basis, the Army conducted a community assessment that included telephone interviews with Arsenal neighbors and other interested parties. All of this information was then distilled into a CRP that provided background and guidance not only for the Basin F Liquids IRA, but also for the program as a whole.

Further, the Task Force developed a Communication Strategy targeted specifically to the vigorous public information effort launched in conjunction with release of the Draft Treatment Assessment Report. The document identified messages, audiences and a briefing schedule. Out of this overall planning process, we identified several categories of interested individuals, each with its own unique set of interests and concerns. While it might be natural to assume that we could take a single approach to the information needs of a particular group, we discovered through the community assessment that we had to differentiate the information needs and concerns even within categories. For example, in the case of key federal officials, members of Congress not only had different concerns from the U.S. EPA, but different concerns from one another. These varied audiences are described below:

- **Federal officials**, including both regulatory agencies and Members of Congress who have expressed continued and active interest in cleanup plans for the Arsenal. Members of Congress have most often expressed concern about the cleanup schedule and the long-term uses of Arsenal land. The U.S. EPA sought the highly technical information in our Treatment Assessment Report and was very sensitive to state and community acceptance of our alternative.
- **State officials**, including four different groups: the Governor's office, the Colorado Department of Health, the Attorney General and state legislators, who at any given time had divergent agendas for the Arsenal. For example, the Attorney General's office sought and reviewed information on the Basin F Liquids IRA with litigation issues as the foremost concern, while the Colorado Department of Health wanted detailed information about cleanup technologies and eventual uses of the land.
- **Local government**, including the affected counties, cities and water

district were most concerned about immediate and long-term health effects, long-term operation and maintenance costs and negative impacts on their communities and property values.

- **Arsenal neighbors**, including citizen groups such as Citizens Against Contamination that had organized to address Arsenal issues and had concrete, specific concerns and information needs about where, when and how cleanup technologies would be implemented.
- **Special interest groups**, such as Citizens' Intelligence Network, the National Toxics Campaign, the League of Women Voters, the Sierra Club and the Audubon Society, whose interests spanned the range of environmental issues.
- **The media**, including the major metropolitan print and electronic media, national media and two Commerce City newspapers, all of which covered Arsenal activities with great interest, cast doubt on the Army's credibility and commitment to cleanup and often sensationalized new developments at the Arsenal.

Even when everyone agreed on the importance of a specific issue, individual information needs were different. For example, almost everyone was concerned about cleanup standards, i.e., how clean is clean? For some audiences, this meant we had to speak in concentration units ppb; for others, in precedents set at other locations; and for others, in terms of the long-term uses of the land that the standards would allow. As a result, we knew not only that a single community relations technique would not suffice, but also that even individual techniques, such as briefings, would have to be tailored to individual audiences.

Community Relations Activities

Taking into account the varied audiences and the aforementioned issues that were impacting the Basin F Liquids IRA alternative selection process, we embarked on the community relations activities described below.

Official briefings

Over a period of a week after the release of the Draft Treatment Assessment Report, the Army presented tailored briefings to key target audiences described above. We devoted considerable effort to the briefings through the preparation of the following materials:

- A **slide show** to provide background for the Basin F Liquids Interim Response Action, the alternatives evaluated and the preferred alternative.
- **Information kits** that included the following information:
  — Five fact sheets describing the five alternatives we evaluated;
  — Fact sheets on the Federal Facility Agreement, Risk Assessment, Notes on Chemicals in Basin F Liquids and the Remedy Selection Process
  — A U.S. EPA fact sheet on Public Involvement in the Superfund Program
  — A Brief History of the Rocky Mountain Arsenal
  — A Background Paper on the Basin F Liquids Interim Response Action, including a detailed description of alternatives

Media briefings

After briefing key officials, we briefed the media, drawing upon and tailoring our repertoire of information and support materials.

Workshop

To help interested citizens understand the complex technologies and evaluation process, we invited them to a half-day workshop so that we could begin to address their questions and concerns in detail. The workshop was designed to accomplish the following objectives: (1) help residents understand the alternatives evaluated for Basin F liquids; (2) respond to concerns that had been expressed up to that point regarding the alternatives; (3) help residents understand the selection process and provide the opportunity to manipulate weighting of the selection criteria; and (4) provide responses to new questions that the workshop generated. Activities associated with each of these activities are described below.

Basin F liquids alternatives

For this presentation, we drew upon key portions of the basic slide show that had been used for the briefings and tailored the presentation to a lay audience of neighbors.

Response to previously expressed concerns

To make sense out of the high-tech information related to Basin F liquids, we took a low-tech, down-to-earth approach to answering persistent questions that had been generated previous to the workshop. For example, to help people understand the physical properties of Basin F liquids, we presented a one-liter graduated cylinder of simulated Basin F liquids (made with water, food coloring and coarse kosher salt) to demonstrate how a supersaturated brine (like that from Basin F) looks and behaves. We used this demonstration to show how difficult it is to pass the liquid through a normal pipe and to call attention to the corrosive nature of the liquid, both of which severely constrained the alternatives that could be considered.

Then we used half-pint (250 Ml) jars to demonstrate the quantity of waste that would remain after treatment with the various technologies we had evaluated: from one liter of actual Basin F liquid (the same volume as our demonstration model), we demonstrated, that either of the two incineration alternatives would leave 250 Ml (one jar) of residue. Either of the two quasi-incineration alternatives would leave 750 Ml (three jars) of residue and solidification, the fifth alternative, would leave 2,250 Ml (nine jars). To demonstrate the quantity of residual pesticides remaining in the off-gas production from incinerating the entire 8,500,000 gallons of Basin F liquid during the 18-month operation of the incinerator, we used a 0.5 oz vial, which could fit in the palm of our presenter's hand.

The selection process

For this discussion, we changed gears and brought the power of the computer to the workshop. We set up the raw technical scores against the selection criteria and then projected this matrix from a computer screen onto an overhead screen. After explaining and demonstrating how the selection process worked, we changed the weightings of any of the selection criteria to meet the preferences of members of the audience—live and on-screen.

It is worth noting that in preparing for the workshop, this portion of the agenda caused the most discussion and consternation. Some members of our Task Force said that putting this kind of information in the hands of ordinary people was similar to "handing them a gun." Others said that allowing people to manipulate the values themselves was essential in order to persuade people that the Army had not skewed the results to favor its own preferred alternative. Alternate proposals were set forth to provide hard copies of different scenarios or to demonstrate the selection technology on the overhead computer screen without allowing citizens to manipulate the values. Our Program Manager decided to use the full information approach that included manipulation of weightings.

New questions

To maximize opportunities for participants to ask questions, we divided into small, interactive groups moderated by neutral facilitators. While we committed ourselves to a flexible format for these meetings to allow group dynamics to drive the way they operated (which turned out to be rather differently from one another), in general we structured them to be moderated by a neutral, non-Army employee, with a resource person assigned to each group to assure that the group did not go off on a tangent based on factually inaccurate information. In general, the resource persons spoke only when spoken to; they also synthesized the public concerns and comments to feed back to the Army's technical policy staff for response by the end of the workshop. The questions generated also were recorded on large flip-charts. The U.S. EPA had an observer in each small group; but all Army and Shell staff left the room, in order to encourage the free flow of questions.

At the end of this part of the agenda, the groups categorized their questions and identified a representative to report to the full group.

When the group questions and concerns were reported, the Program Manager and his technical staff responded to questions that could be answered at that time. Other questions were deferred until more information was available. Some concerns were incorporated into the design of the final decision.

Public comment period and public meeting

We held a 30-day public comment period, during which we held a public meeting to receive comment.

Information repositories and information center

To make the full range of technical information available to the interested public, copies of the full technical documents were placed in the Arsenal's Joint Administrative Record and Document Facility (JARDF) and five libraries in the Denver area.

Tours

Tours of the Arsenal are an ongoing feature of the community relations program.

Mailing List

We compiled a mailing list from our own and the U.S. EPA's sources to create a combined list of key contacts to whom we could send information. We also used this list and a professional calling service to call interested citizens to invite them to the workshop and the public meeting.

THE IRA DECISION: THE PUBLIC MAKES A DIFFERENCE

Effects on Implementation and Operation Objectives

One of the comments the public most commonly make regarding the public involvement process for hazardous waste remediation is, "You, (the Army) say that you want public input to your decision. But I am sure that if we come to the end and you favor one remedy and the community favors another remedy, you are going to go with your preferred alternative."

Our experience at the Rocky Mountain Arsenal clearly demonstrated that, as public involvement experts, we must recast the "them-us" perception and the "thumbs up/thumbs down" approach to decision-making. Involving the community early in the process allows us to work together to develop a solution to the contamination. At the end of the studies, we should share some common understandings about the nature of the problems and the attendant complexities.

In the case of the Arsenal, we were able to refocus the discussion from "incineration/not-incineration" to consideration of the best ways to protect the public both from negative health effects and from worry about the technology that was most appropriate for the overall management of Basin F liquids.

We did this in one of two ways: (1) we incorporated public concerns into the decision document itself, and (2) we responded in writing to public concerns about incineration and other issues related to final disposal of Basin F liquids. Thirteen supplemental provisions for implementation and operation of a Submerged Quench Incineration treatment facility were added to the decision document as a result of public involvement. These supplemental provisions concern how the treatment system will be developed and operated, to assure that government agency and private citizen concerns for safety and environmental protection are met.

The concerns fel into seven general categories with one to six subtopics in each category. Each subtopic was addressed in one of the two ways mentioned above. To document how the Army addressed each of the concerns, the decision document included a matrix with a bullet-list of the concerns and how the Army responded to them (Table 1). The matrix was followed by a description of the decision elements listed in the matrix.

For example, under general concerns about incineration, the Army incorporated specific provisions in the decision document to respond to four of the six specific subtopical concerns. One of these, the concern about other uses of the incinerator after the Basin F IRA is completed, resulted in this commitment in the decision document: "Following completion of the Basin F Liquids IRA, the incinerator will be shut down, decontaminated, decommissioned and disassembled under the closure provisions described in Section 9.0." The other two concerns that were subtopics under the general category of incineration received written responses.

Table 1
Expressed Concerns and Form Response[1]

MAJOR TOPIC	SPECIFIC CONCERN	FORM OF RESPONSE*
Treatment Process in General	Odor	Written Response
	Operational controls re: weather, upset conditions	Decision Element (4,5)
	Location of facility	
	Off-site disposal of residuals or wastes	Decision Element (1)
	How the process works	Written Response
		Written Response
Incineration	Characteristics of submerged quench incinerator	Written Response
	Operational controls re: weather, upset conditions	
	Products of incomplete combustion (PICs)	Decision Elements (4,5,8)
	Safety of SQI technology	
	Use of incinerator after Basin F IRA	Decision Elements (2,8,11)
	Screening and selection of incinerators	Decision Elements (3,6)
		Decision Element (13)
		Written Response
Health Effects	Transportation risks	Decision Element (7)
	Treatment process risks	Decision Elements (4,5,8,9,11)
		Written Response
	Long-term effects	
Trust/Credibility	Objectivity and quality of monitoring	Decision Elements (8,9,10)
	Existence and enforceability of standards for many emission compounds of concern	Decision Elements (2,8,11)
	Army's commitment to safety	Decision Elements (3,4,5,7,8,9)
Ranking	Details on ranking	Written Response
	Constraints to study	Written Response
Public Involvement	Expand opportunities for interaction	Written Response
	Permanent hotline and response log	Decision Element (12)
Regulatory Process	Scope of IRA in relation to other cleanup activities	Written Response

* Written response to expressed concerns occurs in Appendix A to the Treatment Assessment Report. Concerns from the public workshop are grouped separately from other concerns and comments submitted by government agencies and parties to the federal facility agreement.

"Decision Element" means that the Army's response to the expressed concern has been made a part of the proposed decision described in Section 6.0 of this decision document. The decision element numbers (in parentheses) shown here correspond to the numbered "Implementation and Operating Objectives" presented in Section 6.2 of this document. [See below]

Public and State Response

Response to our approach was very positive. At the end of the workshop, for example, one person commented that for the first time, he understood what the problems at the Arsenal are and how the technology will help solve the problems. Another person said, "The workshop was important to communicating to the citizens of this area the concern of the Army."

There has been no groundswell of opposition to the final decision. In fact, when the National Toxics Campaign criticized the Army for its decision, the Colorado Attorney General's Office came to the Army's defense, noting that the Army had made extraordinary efforts to involve and respond to citizens regarding the Basin F Liquids IRA.

LESSONS LEARNED: BENEFITS OF PUBLIC INVOLVEMENT

In many Superfund programs, the community relations program is tangential to the more central attractions of the RI/FS. The common model is to use technical studies to reach decisions and the community relations program to inform the public of these decisions and answer any questions about the decisions. For the Basin F Liquids IRA, however, we moved the community relations effort to center stage and gave the program a substantive role in shaping the technical decision. The effectiveness of this approach provides us with several lessons for the future on how similar technical decisions can be made in a fair and timely fashion.

Involve the Public Early

Citizens expect to have a role in environmental decision-making and laws such as those that gave us the Superfund program guarantee them that right. Superfund requirements, however, do not compel the Army to provide for public input until the official comment period, which is held after the Army has developed a preferred alternative. Being asked to comment under these circumstances, however, invariably perturbs

the public and often results in opposition to a project based not so much on its merits, but rather on how the initial decision was made, i.e., with the public excluded. For the Basin F Liquids IRA, it was evident that involving the public at a predecisional stage met with wide approval amongst not only the public, but also the various state and federal agencies with oversight responsibilities. In other words, no one opposed the Army's decision on procedural grounds. Timing on this project was absolutely key.

Incorporate the Public's Input Into the Decision-making Process

It is not enough simply to listen and record the public's questions and concerns. These concerns must be addressed and considered in a meaningful way. Timing of the community relations program for the Basin F Liquids IRA demonstrated that it was possible to get the public's input early enough in the process that the remedial alternatives could be crafted to enhance adherence to Superfund provisions that require consideration of state and community acceptance.

Document Your Response to the Public's Input

Too often a federal agency gets no credit for the portion of the public's input that it does incorporate, only criticism for the input it apparently discounts. In its Final Decision Document for the Basin F Liquids IRA, however, the Army went to great lengths to document its full understanding of the community's concerns and addressed them in concrete terms through the addition of more than a dozen supplemental provisions. By developing the matrix of community concerns and Army responses (Table 1), the Army got credit for being responsive to the community and the community could clearly see that it had been included in the decision-making process.

Include Community Relations as a Technical Tool to Achieve Technical Objectives

Incorporating citizens' input was not designed simply to make them feel better about the process; it improved the quality of the decision itself. It is all too easy to be condescending in our attitudes toward public input, believing that because we are the experts, we have all the answers and could not possibly have overlooked anything. The addition of 13 supplemental technical provisions to the decision document based on public comments demonstrated that educating the public early helps residents contribute constructively to the decision-making process. The result is a technical solution that better addresses the safety and environmental protection objectives of the IRA.

For example, the Army responded to citizen concerns about products of incomplete combustion by agreeing to "...conduct a special predesign pilot test of the incinerator, planned specifically to collect and analyze data on products of incomplete combustion or PICs. Information from this test will be used both in design and in planning of operational controls... [and] will be presented to the Organizations and the State in a design review."

An Aggressive Community Relations Effort Speeds, Rather Than Delays, the Decision-making Process.

Working under the tight time frame that the Army had for implementing the Basin F Liquids IRA, it would have been easy to conclude that there "wasn't time" for up-front community relations. The experience for this IRA demonstrates clearly that the real potential for delays was not in involving the public, but in making a decision that would be challenged by the community and oversight agencies. Given the issues involved in the Basin F liquids problem, the Army knew that such challenges were not just possible, but probable. Timing of the Army's up-front community relations effort clearly demonstrated the potential for building consensus out of controversy.

If You Have a Pattern That Works, Use It Again.

As the Army embarks on evaluation of remaining IRAs, we expect to include community relations planning as an integral part of our technical work. In this process, we expect to identify community issues and concerns, respond to those concerns as we go and thereby work within our time constraints. We expect to foster the free flow of technical information and community concerns between the Army and the community and to build a decision tree that includes public input. Thus, we feel that by anticipating and responding to issues, we can not only stay on schedule, but also end up with better solutions to the Arsenal's contamination problems.

Remediation of a 115,000-Gallon Petroleum Pipeline Leak

Michael R. Noel
Kendrick A. Ebbott
Hydro-Search, Inc.
Brookfield, Wisconsin

ABSTRACT

A rupture in a buried petroleum pipeline released 115,000 gallons of diesel fuel, contaminating soil and groundwater at a site in Milwaukee, Wisconsin. Emergency and interim response actions resulted in the recovery of more than 70,000 gallons of product from the ground surface, a nearby creek and recovery trenches. Based on the results of a contamination assessment, an evaluation of remedial alternatives indicated that the most cost-effective and technically feasible remedial method included low temperature thermal desorption for treating the impacted soils and discharge of impacted groundwater via an automated interception trench to a sanitary sewer. The implementation of the thermal desorption process was the first application of its type in the State of Wisconsin.

Approximately 10,000 cubic yards of soil, with a total petroleum hydrocarbon (TPH) concentration of up to 24,000 parts per million (ppm), were treated at the site using the thermal desorption system. Using a feed rate of between 15 and 30 tons per hour, the impacted unconsolidated materials, varying in composition from gravelly sand to silty clay, were heated to between 400 and 500 °F in a propane-fired rotary kiln. The petroleum vaporized from the soils and was completely oxidized in an afterburner operating at 1450 °F. After processing, the soil was replaced in the excavation with a TPH concentration of less than 10 ppm.

Groundwater remediation continues at the site. Impacted groundwater is intercepted by a 225-foot long collection trench. An automated pumping system recovers impacted groundwater which is subsequently discharged to a sanitary sewer. Dissolved organic compounds total less than 5 ppm, therefore, no treatment is required prior to discharge to the sewer.

INTRODUCTION

On June 4, 1988, approximately 115,000-gallons of No. 2 diesel fuel leaked from a ruptured underground pipeline. The pipeline rupture occurred in a county park in a residential area of Wauwatosa, Wisconsin. Some of the product from the pipeline rupture gushed to the surface where it flowed downhill and into an adjacent creek. The leak was immediately discovered by pipeline pressure monitoring at which time the pipeline was shut down. All relevant authorities were immediately notified including the local police and fire departments, the Wisconsin Department of Natural Resources (WDNR) and the Department of Transportation (DOT).

Emergency response actions included controlling access to the site, excavation and replacement of the ruptured pipeline segment, and recovery of free product. Free product was recovered from the pipeline repair excavation and from the ground surface using vacuum trucks. Absorbent booms and pads were placed in the creek to contain and collect product from the surface water. During the week after the leak,

additional back-hoe pits were dug in the vicinity of the release to recover subsurface free product with vacuum trucks. These immediate response actions recovered approximately 70,000 gallons of free product.[1]

SITE INVESTIGATIONS

Site investigations were required to define the nature and extent of impacts to soil and groundwater. The investigations Hydro-Search, Inc. conducted included the installation of soil borings with soil sampling to characterize the geology and determine the lateral and vertical extent of impacted soils, and the installation and sampling of observation wells to characterize the rate and direction of groundwater flow and the extent of impacted groundwater. In addition, a site survey was performed locating all sampling locations as well as site features and utilities including overhead power lines, storm sewers, sanitary sewers, gas pipelines and petroleum pipelines.

Geology

Regional information regarding the geology at the spill site was obtained from 41 private well logs located within one-half mile of the site. Site-specific geologic information was obtained from more than 40 soil borings constructed during the site investigation.

Geologic materials at the site consist of unconsolidated glacial deposits underlain by dolomite bedrock. The thickness of the unconsolidated deposits vary regionally from less than 10 feet to several hundred feet.[2] The unconsolidated materials consist of intermixed silty clay, sand and gravel. Figure 1 shows an east-west regional geologic cross-section through the spill area. The cross-section information is based on private well logs located in the area. At the site, the thickness of the unconsolidated deposits is at least 30 feet. The unconsolidated material consists of approximately 0.5 to 1.0 feet of clayey silt topsoil, between 1 and 4 feet of silty sand and gravel fill material, occasionally a 1 to 2-foot thick buried black clayey silt soil horizon, and intermixed glacial silty sand, clay, and gravel.[3] Figure 2 presents a northeast to southwest geologic cross-section across the site.

Underlying the unconsolidated glacial deposits is the Niagara dolomite, a white to gray, fine to coarsely crystalline dolomite. The Niagara dolomite dips gently to the northeast into the Michigan Basin.

Hydrogeology

The water table at the site occurs in the unconsolidated glacial deposits approximately 5 to 7.5 feet below ground level. Based on water level measurements obtained on several occasions from seven monitoring wells and Underwood Creek, local groundwater flow across the spill site is west towards the local discharge point, Underwood Creek. Figure 3 shows a water table map which indicates the local flow direction.[1] Regional groundwater flow deeper within the bedrock aquifer is to the east towards Lake Michigan.[2]
Figure 1
Regional Geologic Cross-Section A-A'

The site hydraulic gradient is relatively gentle, averaging approximately 0.035 feet per foot. The hydraulic conductivity at the site ranges from approximately 1×10^{-3} cm/sec to 1×10^{-5} cm/sec. Assuming a porosity of 25%, the calculated range of flow velocities across the site varies depending upon the hydraulic conductivity from 0.4 ft/day (146 ft/year) to 0.004 ft/day (1.46 ft/year).

Local Groundwater Use

All homes in the vicinity of the site have a municipal water supply available for use. Records indicate 41 private wells are located near the site. With the exception of five deep wells, all the private wells were constructed prior to 1963. Because these homes are supplied with a source of municipal water, the private wells are no longer used for potable water. Therefore, the risk to local residential water users is low. Some of the private wells may be used for watering lawns. All the private wells are cased from the ground surface into the bedrock.[3]

Soil Impacts

The horizontal and vertical extent of soil impacted by the diesel fuel leak was investigated by installing 36 soil borings at the site. The boreholes were advanced using the continuous split spoon sampling technique.

All soil samples were screened for volatiles in the field during drilling using an HNu Model PI-101 photoionization detector (PID) with an 11.7 eV probe. Soil samples with elevated PID readings were submitted for laboratory analysis of total petroleum hydrocarbon (TPH). Two samples were submitted from several boreholes to determine the vertical extent of the petroleum impacts. In general, soil impacts ranged from non-detectible levels of less than 10 parts per million (ppm) TPH to 24,000 ppm TPH.[1]

In Wisconsin, there are no regulations governing the concentration of petroleum products in soils. However, the Wisconsin DNR uses a guideline of 10 ppm TPH as its cleanup standard.[4] Based on this standard, the lateral extent of impacted soil is shown in Figure 4. The impacted soils generally form a 25- to 50-foot halo around the surficially stained area where the spilled product initially pooled. The impacted soil area extends approximately 300 feet long by 100 to 260 feet wide and covers an area from east of the pipeline rupture to the edge of Underwood Creek. The lateral wicking of the product into the unsaturated soils was enhanced by the extremely dry condition of the soils at the time of the release due to drought conditions occurring in the area during the summer of 1988.

The vertical extent of soil impacts indicated elevated TPH concentrations to depths of 12 feet.[1] The impacts below the water table are attributed to the forced migration associated with the pressure of the release. Figure 2 shows the lateral and vertical extent of soil impacts
Figure 2
Local Geologic Cross-Section B-B'
with Extent of Impacted Soils

at the site along a southwest to northeast cross-section.

Groundwater Impacts

Groundwater quality was monitored by sampling groundwater observation wells which were installed around the perimeter of the impacted soil area. These wells were sampled on several occasions and analyzed for either benzene, ethylbenzene, toluene and xylene (BETX), or volatile organic compounds (VOCs) and base neutral/acid extractable compounds (BNAs). The laboratory results from all sampling events indicate no detections of any compounds in any of the monitoring wells.[5] Monitoring wells were not installed within the impacted area since they likely would be destroyed during soil remediation.

INTERIM ACTION

Based on the results of the site investigations, two recovery trenches were installed to prevent off-site migration of hydrocarbon compounds and to facilitate additional product recovery. In July 1988, two 150-foot long recovery trenches were installed across the impacted area (Figure 4). Each trench was excavated to a depth of 2 to 5 feet below the water table, backfilled with pea gravel, and capped with site soils. A 36-inch diameter steel slotted culvert was installed vertically in each trench to act as a sump for recovery of groundwater and free product. Groundwater was pumped from the base of each sump and discharged

under permit into the sanitary sewer system. The groundwater pumping removed impacted water and depressed the water table to expedite free product recovery. Free product was recovered using an oil skimmer and/or oil absorbent pads.

During the past 2 years of operation of this recovery system, approximately 7,300 gallons of free product have been recovered with approximately 85% of this total coming from Trench 2 which is located closest to the pipeline leak. During this period, approximately 2,000,000 gallons of water were discharged to the sanitary sewer. Monthly monitoring of this effluent indicates the water contains an average of less than 500 ppb of total organics consisting predominantly of benzene, ethylbenzene, toluene, xylene, naphthalene, hexachloroethane, bis(2-ethylhexyl) phthalate, fluorene, acenaphthene and 2,4-dinitrotoluene.[5]

EVALUATION OF SOIL REMEDIATION ALTERNATIVES

Due to the large amount of unrecovered product contained within the soils, the WDNR required remediation to the 10 ppm TPH level.[4] Several methods for remediation of impacted soils were evaluated by Hydro-Search, Inc. and included:

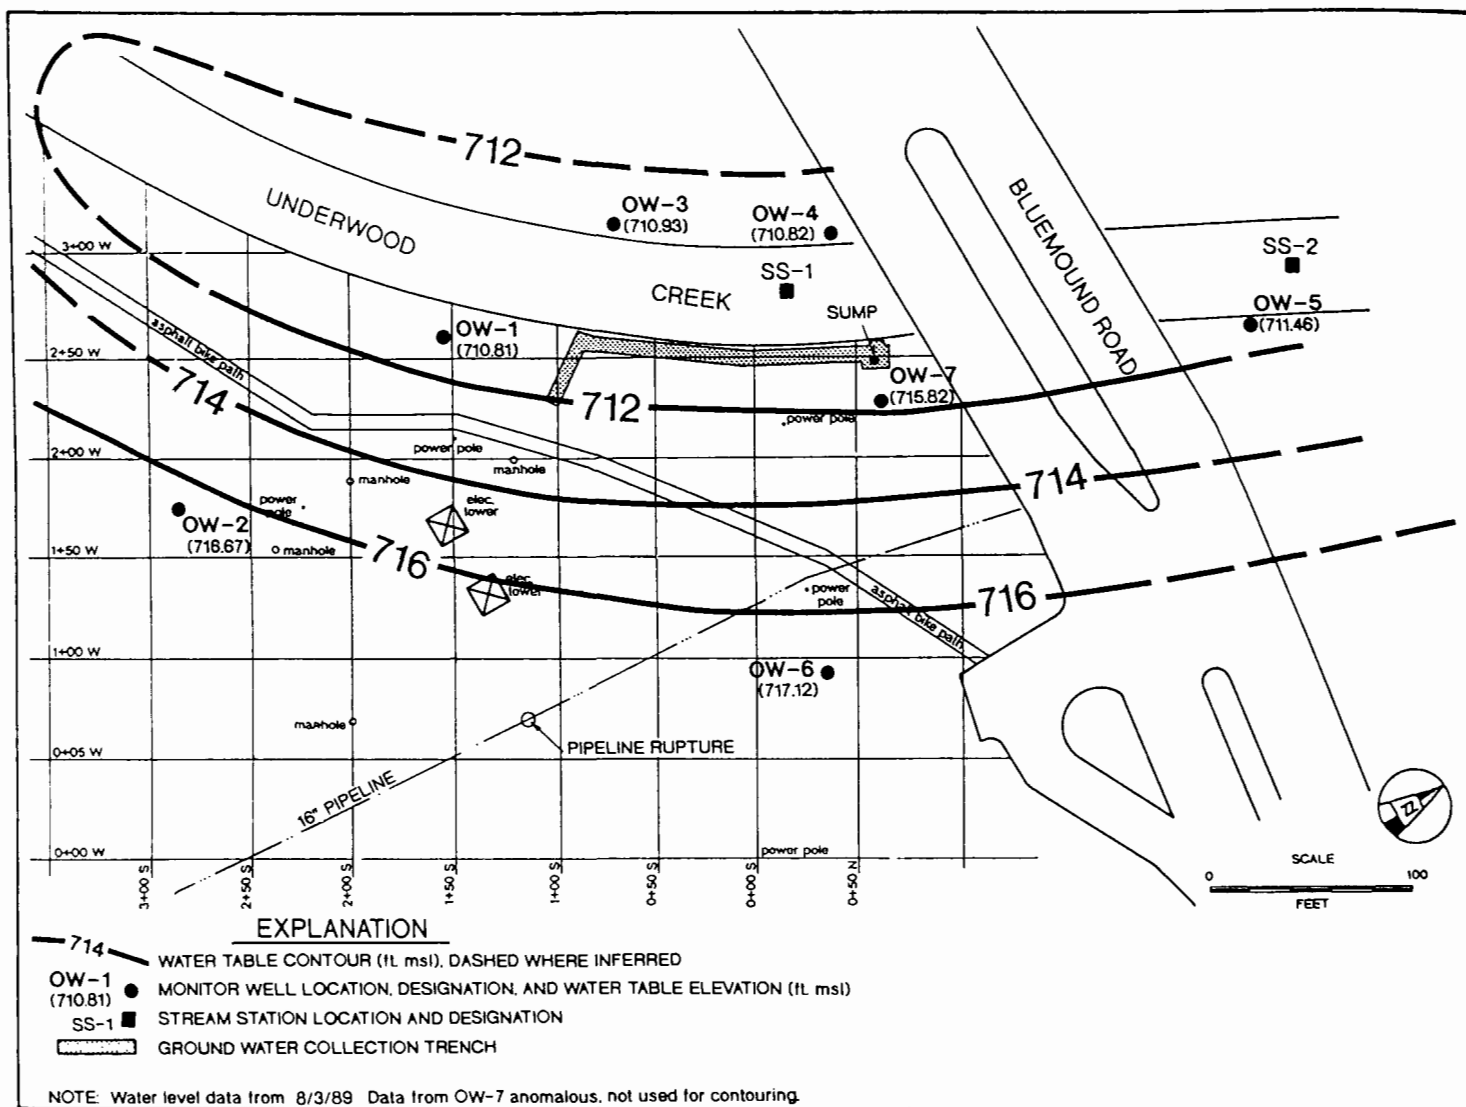
• Passive Remediation
• Excavation and Landfilling


Figure 3
Water Table Surface

- Landspreading
- Vapor Extraction
- Bioremediation
- Enhanced In Situ Bioremediation
- Thermal Evaporation

These alternatives were evaluated for technical implementability and environmental effectiveness; permitting and monitoring requirements; and cost and duration of project.

In order to evaluate various cleanup methods, the following assumptions were employed:

- The volume of impacted soils requiring remediation is 10,000 cubic yards. The approximate dimensions of the impacted area, as determined by laboratory TPH analysis of less than 10 ppm, are 200 feet by 250 feet by 7 feet deep.
- The worst case average TPH concentration in the impacted soils is 5,000 ppm. This conservative value is more than double the average laboratory TPH concentration detected in the impacted soil samples.
- Remedial alternatives involving excavation would not be required to excavate beneath the high tension electrical towers, behind or beneath the concrete panels lining the creek or below the water table which occurs at a depth of between 5 and 7.5 feet.

In August 1988, Hydro-Search, Inc. submitted the feasibility study to the WDNR. A summary of the evaluation of these alternatives is presented in Table 1. The WDNR review of the feasibility study concluded the following:

- Passive Remediation: determined to be inappropriate and rejected in favor of more environmentally responsible options.
- Excavation and Landfilling: determined to be an acceptable means for cleaning up the site because it provides for source removal, thus eliminating many long-term site management concerns.
- Landspreading: determined to present a number of permitting, operating and monitoring obstacles which limit the applicability of the method. In addition, landspreading was not recommended for diesel fuel contaminated soils.
- Vapor Extraction: determined to be not appropriate based on the low volatility of diesel fuel.
- Bioremediation: determined to be not acceptable because operational requirements for space preclude the use of the immediate vicinity of the spill site.
- Enhanced In Situ Bioremediation: determined to be unacceptable based on lack of approval by the Water Supply Section for a waiver for the use of injection wells.
- Thermal Evaporation: determined to be the most acceptable means of remediating the site because it contains a number of desirable aspects such as:

  — It eliminates the source of soil, air, surface water and ground-

water contamination.

— It does not require a source of clean fill.
— It does not take up valuable landfill space.
— It does not generate a high volume of truck traffic to and from the site.
— It does not involve the use of injection wells for supplying nutrients to microbial populations.[4]

Based on these comments, the comparable costs of landfilling and thermal evaporation, and the potential for continued liability with land-filling, it was decided to remediate the soils using the thermal evaporation process, which was the first application of that technology in the State of Wisconsin.

SOIL REMEDIATION

Contracting and Permitting

Bid specifications were prepared by Hydro-Search, Inc. in July 1989, and submitted to several contractors who provide thermal evaporation process services. The contractor selected for the job was Clean Soils, Inc. of Minneapolis, Minnesota. Clean Soils was selected based on their experience, cost and the fact that they already had the required permits from the Air Management Section of the WDNR.

A soil remedial action plan was prepared by Hydro-Search, Inc. and submitted for WDNR approval in December 1989.[6,7] The plan con-

sisted of five general elements which included:

* soil excavation
* confirmational testing of excavation
* soil treatment and stockpiling
* confirmational testing of treated soils
* backfilling and restoration

The sequencing of these elements is presented schematically in the flow chart shown in Figure 5.

Prior to startup, arrangements had to be made and permits obtained from county and local officials regarding operational procedures and site restrictions. These included:

* Milwaukee County Parks and Recreation Board: permit specifying hours of operation, fencing restrictions, security arrangements, noise and dust restrictions, restoration requirements, and insurance requirements
* City of Wauwatosa: temporary occupancy permit specifying hours of operation, fencing restrictions, and emergency response arrangements
* Wauwatosa Fire Department: approved use of 18,000-gallon propane tank for treatment unit as well as fencing and signage requirements
* City of Wauwatosa Water Department: approved use of fire hydrant for dust control

Table 1
Comparison of Remedial Alternatives

REMEDIAL ALTERNATIVE	TIME	COST ESTIMATE		REGULATORY REQUIREMENTS	CONTINUING LIABILITY	COMMENTS
Passive Remediation	4-10 years	Site Characterization and Risk Assessment Soil Sampling and Ground-Water Monitoring	$ 25,000 - $ 50,000 $ 40,000 - $ 100,000 TOTAL: $ 65,000 - $ 150,000	Subject to DNR Approval	Yes	Potential ground-water impacts.
Excavation/ Landfilling/ Refilling	20 days	Landfilling Excavation/Fill Continuous Field Screening and Supervision	$ 120,000 $ 250,000 $ 15,000 TOTAL: $ 385,000 $38.50/cu.yd	Landfill Acceptance Forms Potential Noise Restrictions	Yes	Excavate Omega Hills Landfill Contractor costs may vary substantially
Landspreading	3-6 months	Excavation/Fill Tilling and Field Screening	$ 250,000 $ 20,000 TOTAL: $ 270,000 $27.00/cu.yd	Potential Air Emission Permit	No	Excavate Move impacted soils to another site.
Thermal	75 days	Excavation and Treatment Weekly Field Screening and Project Management	$ 560,000 $ 15,000 TOTAL: $ 575,000 $57.50/cu.yd	Potential Air Emission Permit: 90-120 days start-up delay Potential Noise Restrictions	No	Excavate
Vapor Extraction	6-12 months	Set-up and Operation $400,000 - $ 600,000 Project Manager $ 20,000 TOTAL: $420,000 - $ 620,000 $42-$62/cu.yd		Potential Air Emission Permit: 90-120 days start-up delay Potential Noise Restrictions wells	No	In-situ Cost dependent on final clean-up criteria and number of required
Bioremediation	6-8 months	Excavation $ 200,000 Set-up and Operation $500,000 $ 800,000 Project Manager $ 15,000 TOTAL: $715,000 - $1,015,000 $71.50-$101.50/cu.yd		Potential air Emission Permit: 90-120 days start-up delay	No	Excavate Cost dependent on final clean-up criteria and bacteria, nutritional requirements
Enhanced In-Situ Bio-remediation	9 months 2 years	Set-up and Operation Project Management	$ 500,000 $ 20,000 TOTAL: $ 520,000 $52/cu.yd	Requires DNR waiver of injection well restriction	No	In-situ Provides soil and water treatment. Cost dependent on final clean-up criteria, bacteria, nutritional requirements and number of required wells.

Note: All cost and item estimates are approximate based upon 10,000 cubic yards of impacted soils. Landfilling and thermal remediation costs are more fully determined than the other methods due to the nature of the respective methods.

SOIL REMEDIATION PROCESS

The treatment of the soils was accomplished using the Clean Soils Thermal Desorber which was mobilized to the site in January 1990. A schematic of the system is shown in Figure 6.

Soils were excavated and transported to the processing unit using a back-hoe and front-end loader. The soils were first screened through two grates to remove rocks and debris larger than 2 inches in diameter and then fed by conveyor to the treatment unit. As the soils entered the treatment unit, they were cascaded by a 5-foot diameter rotating drum towards the main burner. Within the chamber, the soils were heated to approximately 450°F to vaporize the hydrocarbons. The resultant vapors were pulled through a baghouse to remove all dust-sized particulate matter. Combustion of the vapors occurred inside a propane-fired afterburner where the vapors were completely consumed by burning at temperatures of 1400 to 1470°F.

The treated soils exited the unit via a conveyor where they were stockpiled until confirmational analysis documented cleanup. Upon receipt of the laboratory analysis verifying that cleanup standards were met, the soils were backfilled into the excavation. Once the soil remediation was completed, the area was graded, covered with topsoil, seeded, landscaped and the bike path restored.

The soils were processed at a rate of between 15 and 30 tons per
Figure 6
Thermal Desorption Treatment Unit Layout

hour. Processing rates were influenced by soil moisture content, diesel fuel concentration and soil type. Fine-grained soils with a high silt and/or clay content were processed at a slower rate than sandy or gravelly soils. Wet and highly impacted soils were also processed slowly to maintain the proper fuel/oxygen mixture in the afterburner for the combustion of the vapors. Weather, site ground conditions and equipment breakdowns also affected the rate of soil processing.

Soil processing was carried out from January through May of 1990. Over the total project duration of 132 days, actual soil processing was performed on 93 days. Complete system shutdown related to equipment failure, maintenance or inclement weather occurred on 39 days. Over the life of the project, daily soil processing rates varied from less than 20 tons to more than 400 tons per day. A total of 13,989 tons of soil were processed (10,000 cubic yards) in 93 days of actual soil processing for a daily average of 150 tons.

Over the last 6 weeks of the project, most of the mechanical difficulties associated with the equipment had been corrected, and the thermal desorption unit processed an average of more than 200 tons of soil per day.

GROUNDWATER REMEDIATION

A groundwater remediation plan was prepared by Hydro-Search, Inc. and submitted to the WDNR in July 1990 for approval.[5] The objectives of the remediation plan were to clean up groundwater to meet NR140 (Wisconsin Administrative Code) preventive action limits and to prevent off-site migration of impacted groundwater. The plan[5] called for:

* The recovery of groundwater from Trench 1 along Underwood Creek (Trench 2 was destroyed during soil remediation)
* Discharge of groundwater to the MMSD sanitary sewer
* Free product recovery from the sump in Trench 1 as necessary
* Performance monitoring of the system
* Periodic reporting on the system progress

Continued use of Trench 1 to capture on-site impacted groundwater was proposed based on its successful performance over the past 2 years. Although the trench has only been pumped on a part-time basis (8 to 10 hours a day) for the past 2 years, impacted groundwater has not

migrated off-site. Automation of the system will provide full-time operation. Discharge of groundwater to the sanitary sewer is the most cost-effective and least disruptive alternative for treating impacted groundwater at the site.

To implement the plan requires modifications to the existing trench system which are anticipated to take place in fall of 1990, and which include extending the trench 75 feet to the south to ensure adequate capture, deepening the sump construction, automating the pumping system to reduce the manpower requirements and winterizing the system to allow year-round operation. A plan and schematic of the proposed system are shown in Figures 7 and 8.

Operation of the system will be controlled by float-activated switches to maintain a 1.5-foot drawdown in the trench. Groundwater will be discharged to a sanitary sewer with the volume monitored by an in-line totalizing flow-meter.

Free product that collects in the sump will be pumped out with an oil skimmer or oil absorbent pads on an as-needed basis. Manual operation was chosen because the diminishing product recovery in the trench over the last 2 years indicates not much additional product will be recovered. Automated product recovery and containment would have included construction of a building to house the recovered product. Therefore, providing automated product recovery was not considered cost-effective.

Performance of the system will be monitored by the observation wells shown in Figure 7. These wells will monitor both the hydraulic capture of the system and water quality to ensure impacts do not migrate off-site. The system will operate until the hydrocarbon compounds in the groundwater are below the NR140 preventive action limits.

CONCLUSIONS

Within 24 months of the 115,000-gallon release, nearly all free product has been recovered, impacted groundwater has been controlled to prevent off-site migration and impacted soils have been remediated. Groundwater remediation is expected to continue for another 2 to 4 years, or until hydrocarbon compounds meet WDNR water quality criteria.

The cleanup's success is attributed to the emergency response efforts that resulted in the recovery of approximately 70,000 gallons of product, the interim action of installing trenches to intercept impacted groundwater and recover an additional 7,300 gallons of free product and the application of new thermal desorption technology which was mobilized to the site during a harsh Wisconsin winter and used to remediate 10,000 cubic yards of impacted soil in less than 5 months.

These accomplishments would not have been possible without the environmental consciousness of the pipeline owner/operator, the dedication of the response crews and contractors, the cooperation of the local agencies and officials, the understanding of the surrounding residents and the progressive attitude of the WDNR to allow the use of new and innovative technologies.

Assessment of the Emergency Response Actions and Environmental Impact of the January 2, 1988 Diesel Oil Spill Into the Monongahela River

Roger L. Price, P.E.
Edgar Berkey, Ph.D.
Center For Hazardous Materials Research
The University of Pittsburgh Trust
Pittsburgh, Pennsylvania

INTRODUCTION

This paper presents an assessment of the overall adequacy of the emergency response to the January 2, 1988, Ashland Oil spill into the Monongahela River near Pittsburgh, Pennsylvania. Additionally, we present an assessment of the environmental impacts of the spill. Information for the assessment has been gathered from meetings with public and private emergency response officials, public hearing records and government reports. Many of the recommendations made by emergency response officials involved in the Ashland incident have been included in this paper.

The assessment of the overall adequacy of the emergency response portion of this paper was adapted from a chapter of a report entitled "Economic and Policy Implications of the January 1988 Ashland Oil Tank Collapse in Allegheny County, Pennsylvania," which was a collaborative effort involving the staffs of both the Center for Social and Urban Research and the Center for Hazardous Materials Research at the University of Pittsburgh. The report was prepared for the Allegheny County Planning Department and funded through a grant provided to Allegheny County from the Pennsylvania Department of Commerce.

DESCRIPTION OF EMERGENCY RESPONSE ACTIVITIES

Successful protection of the public health throughout the emergency resulted from the outstanding efforts and cooperation of hundreds of response personnel, including individuals from Ashland Oil Inc. and its contractors, 17 regional offices of seven federal agencies, 11 state agencies from four states and numerous local emergency response agencies, fire departments and water suppliers.

The Center for Hazardous Materials Research (CHMR) has identified a number of events that are key to understanding and assessing the on-site emergency response. A detailed minute-by-minute summary of these events and a map of the accident site are provided in the full report on the economic and policy implications of this incident.

Initial response efforts focused on the terminal site in order to: (1) establish access control; (2) stop the flow of diesel fuel on-site; (3) plug leaks found in a damaged tank holding 1,000,000 gallons of gasoline; and (4) conduct a thorough assessment of the extent of the spill. The initial on-site assessment was severely hampered by cold weather, darkness and concern over the potentially volatile mixture of gasoline and diesel fuel. Dangerous conditions on the river (rapid currents, cold weather and darkness), moreover, severely restricted any possible response action on the water.

As a result, estimates of the large volume of fuel released and the severity of the impact of the spill on the river system and downstream water suppliers was not fully realized until early the next morning, January 3. Preliminary reports suggested that water intakes were low enough to avoid the oil or that river water could be adequately treated by the water plants. The dispersion of oil throughout the water column was not recognized until at least 12 to 18 hours after the release.

On January 3, 1988, approximately 14 hours after the release, the U.S. EPA On-Scene Coordinator arrived on-site and advised Ashland that the U.S. EPA determined that the response actions taken by Ashland were appropriate and that federal supervision of Ashland Oil's cleanup was equivalent in every respect to what the federal government would have done under the same circumstances.

Considering the initially rapid rate of release, standard response time for off-site emergency responders and circumstances common to incidents of this type, it is unlikely that the quantity of release could have been substantially reduced in the crucial first 2 hours.

It is important to note that the on-site company personnel responded within minutes of the accident by closing a valve controlling the discharge of oil from the facility API separator. This action effectively stopped the discharge of oil from this source and contained millions of gallons of oil within the facility's spill containment system.

On January 2, 1988, the flowrate and velocity of the Monongahela River were high. As river water moved over each dam, it dropped many feet in height — a circumstance which adversely affected oil recovery efforts because it caused the oil, water and suspended sediment to become increasingly mixed as each dam was passed. This mixing action caused the oil to contact and coat sediment particles suspended throughout the water column, which prevented much of the oil from floating back to the surface.

Approximately 205,000 gallons of diesel fuel (29% of the total 705,000 gallons released to the river) were recovered through skimming operations. The oil which remained in the river became completely mixed and emulsified in the water by the time the spill passed the Dashields Lock and Dam, approximately 38 miles downstream from Floreffe on the Ohio River. No substantial recovery occurred below this point. The cleanup operations, which ultimately spanned 38 miles, were severely hampered by extremely cold weather conditions. The risk of hypothermia for cleanup crews led to the decision to remove all personnel from working on the river on the fourth day after the spill.

The morning following the accident, state and local authorities directed their efforts toward concerns over water quality and drinking water supplies. By noon on January 3rd, these efforts began to constitute a separate, significant response activity, which the state and county authorities managed.

A disaster emergency was declared for Allegheny, Beaver and Butler Counties by the governor. Temporary interconnects were installed to link the City of Pittsburgh and West Penn Water systems. Work was started on numerous new permanent interconnects and other, older interconnects were opened. Substantial efforts were made to bring in equipment in order to distribute drinking water to affected communities.

West Penn Water Company, with assistance from the Pennsylvania Department of Environmental Resources (PADER), developed and pilot-tested a treatment that successfully removed oil from water supplies. This process was used by downriver water suppliers, making it possible for them to open river intakes days before they otherwise would have been able to do so. Water supplies in four states — Pennsylvania, Ohio, West Virginia and Kentucky — were affected as the spill flowed downriver. By the time the spill passed Cincinnati, oil concentrations in the Ohio River had decreased to the point where immediate concern with regard to drinking water had subsided.

Over the short-term, the diesel oil spill produced a few small to moderate impacts on organisms dependent on the river system in limited regions of the first 185 miles down-river. Natural processes associated with the spill and river system combined to mitigate and significantly restrict the impacts, except in a few localized areas. Significant long-term effects on the river system as a whole from the spill are not expected.

CONCLUSIONS AND RECOMMENDATIONS

The oil spill incident had a significant impact on the water companies which depend on the Monongahela and Ohio Rivers for their source of supply. The spill created water supply shortages in some areas requiring customers to conserve water; the spill actually led to the loss of water supply in one service area. In spite of these hardships, the outstanding efforts of all responding agencies, groups, individuals and Ashland Oil Company resulted in the successful protection of the public health throughout the emergency. Extensive emergency response actions prevented any contamination of operating public water systems.

The goal of the following recommendations is to improve preparedness among emergency responders in confronting incidents similar to the Ashland Oil spill. The recommendations benefit from CHMR's experience in emergency management and preparedness as well as from observations and suggestions offered by emergency response officials in public hearing records and government reports on the Ashland Oil spill.

Organization and Speed of the Response

The following list provides a summary of CHMR's conclusions and recommendations regarding the overall organization and speed of the response. Five key findings can be highlighted.

- Ashland took appropriate initial response actions, which included notifying the National Response Center and calling the necessary emergency response contractors.
- Although downstream water users were quickly notified of the incident, the severity of the potential impact on the river system and downstream water supplies was not fully realized until 12 to 18 hours after the spill.
- The fact that the severity of the potential off-site impact was not realized, combined with concern over volatile conditions on-site, cold weather, darkness and dangerous conditions on the river, hampered initial response actions and caused the initial priority of the response to be directed on-site.
- Although initial problems with the overall organization of the response caused some operational difficulties for response personnel during the first 24 to 36 hours, it is unlikely that these difficulties adversely affected the overall adequacy of the emergency response for minimizing losses to property, businesses and individuals.
- It is also unlikely that any other organization of the emergency response would have resulted in more effective protection of the public health or further minimized losses caused by the accident.

The overall organization and speed of the response thus were adequate to fully protect public health and minimize losses to property, businesses and individuals under the circumstances of this incident. However, some lessons can be learned which may improve the efficiency of future responses.

- In the future, the On-Scene Coordinator should initiate coordination activities earlier and start assigning responsibilities sooner. The RRT team should be activated as soon as possible and a decision

made as to whether its members should be brought together on-site. An "RRT Coordinator" should be designated to assist the OSC by facilitating communications among responding agencies.

- A responsible party representative (in this case, someone from Ashland Oil) in RRT conferences should directly provide the RRT with factual details regarding the responsible party's activities and ability to comply with RRT recommendations to the OSC.
- Important environmental data were not collected during the first few hours of the incident because emergency response personnel were preoccupied with responding to the emergency at hand. Facility Preparedness Prevention Contingency plans should identify individuals of the responsible party or its contractors whose sole responsibility is the collection of environmental data.
- In the initial days of the spill, the coordination and communications of river monitoring data suffered because no lead agency was assigned to oversee these activities. A lead agency should be designated to focus the coordination and communication of monitoring data and to assure standardization in the analysis of these data.

Adequacy of Equipment & Materials

The lack of immediately available containment and monitoring equipment hindered the emergency response. The need to locate and transport essential equipment caused delays.

However, as a result of the unique circumstances of this incident (e.g., the rapid release and discharge of most of the oil into the river with the first two hours, darkness, cold weather, rapid river currents and dispersion of oil throughout the water column), it is unlikely that another response could have been any more effective in significantly reducing the total quantity of oil discharged to the river or increasing the total quantity of oil recovered from the river.

Nevertheless, additional lessons can be learned. The following 11 points summarize CHMR's conclusions and recommendations regarding the adequacy of available equipment and materials as well as the preparedness of personnel for future contingencies.

- Containment dikes are an essential first line of defense to prevent the release of oil and hazardous substances from leaking tanks. It is unlikely, however, that dikes can be constructed to provide complete containment of all possible incidents such as sudden massive tank ruptures.
- Facility Preparedness Prevention Contingency plans should "look beyond the dike" and be prepared to install a "second line of defense" in the event a spill escapes the containment area. All drainage ways near containment dikes should be identified in PPC plans, a strategy should be developed for intercepting releases in the drainage ways and secondary structures should be maintained.
- A computerized geographic information system with the capability for displaying maps of the physical infrastructure of Allegheny County should be implemented to provide emergency responders as quickly as possible with necessary information for rapid responses.
- Facility PPC plans should be current and include information on locations of hazardous and environmentally sensitive materials stored on-site. PPC plans should be provided or made readily available to local emergency responders. Consideration should be given to keeping a current copy of this plan in a highly visible "lock box" located on the perimeter of the site.
- Inventories of locally available equipment should be prepared to assist emergency responders in quickly locating necessary items. Such inventories could be developed and augmented where necessary through a cooperative arrangement between local industries and government.
- Methods to monitor the dispersion and concentration of airborne contaminants which could emanate from a spill should be considered in local contingency plans. The availability of air-monitoring equipment (local stationary installations and mobile units) capable of providing real-time data needed to estimate community exposures should be assured and included in inventory lists.
- State or local contingency plans should maintain a list of local laboratories certified to perform necessary testing in an emergency. Development of a mobile laboratory capability by the responding agencies should be considered.

- The Ashland incident could have been far more devastating if public water supplies had been contaminated or water shortages had become more severe. Emergency planning agencies and water suppliers should work toward improving the availability of contingency water supplies with consideration given to the installation of permanent interconnect grids among neighboring water suppliers and expanded storage capacities for both raw and treated water.
- The ability of facilities such as hospitals, nursing homes, medical clinics and schools to respond to and maintain operations should be strengthened.
- Emergency planning agencies should maintain a current list of available bulk water haulers, facilities with tankers that can be used in refill operations and sources of plumbing expertise and supplies for distribution hookups.
- Each water supplier should maintain a list of service and equipment companies that can provide replacement pumps, chlorination equipment and chemical feed equipment to add water treatment chemicals in the event of an emergency.

Adequacy of Communication Among Emergency Responders

Problems were encountered due to insufficient communications equipment at the command post to support the large number of response agencies. Problems were encountered contacting RRT members during off-duty hours, and numbers to installed or rented phones were not available in a timely manner.

- A list of 24-hour telephone numbers for RRT members should be regularly updated and made available. Electronic mail systems operated by various agencies can be efficient mechanisms for communication among RRT members. An RRT E-mail distribution system should be established, and each RRT member should be assigned an electronic mailbox.
- Adequate telephone lines must be immediately installed at command posts in addition to having ample numbers of cellular phones available. Telephone numbers of newly-installed or rented portable phones must be gathered early and disseminated more aggressively during an emergency.
- The Ohio River Valley Water Sanitation Commission's electronic bulletin board was widely used and worked well for distributing river monitoring data. Procedures could be developed to use such a resource even more effectively.

Adequacy of Communications Between Responders and the Public

The water suppliers' public communications activities were generally excellent during the Ashland emergency, but some lessons nonetheless can be learned from the experience. The following conclusions and recommendations regarding proper procedures for communicating with the public during emergencies are offered for consideration based on the lessons learned from how information was provided to the public during the Ashland episode.

- At one point, prior to receiving official notice from the state, a local agency suggested that the need for water conservation was lessening. Criteria and authority for lifting water conservation orders should be made clear by the party establishing such an order, so there is advance agreement on when conservation can be discontinued.
- Information should be given to the media consistently and on a regular basis during emergencies, preferably through one spokesperson at the facility.
- Special attention must be paid to ensure that the media continually notify the public if the problem is one of quantity and not of contamination. Suppliers must communicate to the public that the use of interconnections, changes in water flow patterns and varying pressures may lead to taste and odor problems that can be misinter-

preted as contamination.
- The need for predetermined health advisory threshold levels for releases of a wide variety of hazardous substances to surface waters and the atmosphere and a system to warn the public about health-threatening conditions continues to be a concern.

Educational Training and Information Resources

Although the response to the Ashland Oil spill was effective in protecting public health, it is evident that more timely health effects data on spilled hazardous substances were needed along with assistance in interpreting their significance.

Recent federal requirements under the SARA are generating significant new information on the specific locations of hazardous materials produced or used by particular industries. Firefighters and other emergency responders should be properly equipped to respond to any emergency which could occur in their respective service areas.

CHMR's conclusions and recommendations regarding training and information resources, based on lessons learned from the Ashland Oil spill, include the following items.

- The federal Agency for Toxic Substances and Disease Registry (ATSDR) as well as state health departments could be better utilized to provide more timely health effects data and data interpretation.
- More training for fire fighters and other responders is recommended. The training programs need to emphasize rapid identification of hazardous substances involved in an emergency. The significant volumes of new SARA information on specific locations of hazardous materials used by particular industries must be assimilated into training updates for local emergency responders.
- Consideration should be given to the creation of computerized data base capabilities for local emergency responders. An appropriate mobile command vehicle might have access to this system.
- Sampling and analysis protocols for emergency responders should be developed.

The "Petroleum Exclusion" Under CERCLA: A Defense To Liability

Lloyd W. Landreth
PRC Environmental Management, Inc.
Denver, Colorado

ABSTRACT

When CERCLA was originally passed in 1980, the petroleum industry lobbied successfully to exclude the term "petroleum" from the definition of a CERCLA §101 (14) hazardous substance. Under CERCLA § 101 (33), petroleum is also excluded from the definition of a "pollutant or contaminant." Exclusion from the designation as a defined hazardous substance has provided a defense to liability under CERCLA § 107 when the release of petroleum occurs.

The scope of the petroleum exclusion under CERCLA has been a critical and recurring issue arising in the context of Superfund response activities. Specifically, oil that is contaminated by hazardous substances during the refining process is considered "petroleum" under CERCLA and thus excluded from CERCLA response authority and liability unless specifically listed under RCRA or some other statute. The U.S. EPA position is that contaminants present in used oil, or any other petroleum substance, do not fall within the petroleum exclusion. "Contaminants," as discussed here, are substances not normally found in refined petroleum fractions or present at levels which exceed those normally found in such fractions. If these contaminants are CERCLA hazardous substances, they are subject to CERCLA response authority and liability.

This paper discusses the parameters of the CERCLA "Petroleum Exclusion." It briefly examines selected state laws, RCRA, the Clean Water Act (CWA) and the Safe Drinking Water Act (SDWA) for treatment of petroleum and petroleum products. And, finally, this paper discusses new legislation regarding oil pollution liability and compensation.

INTRODUCTION

Crude oil, and the commercially derived fractions therefrom, represent by quantity the largest volume of hazardous substances in our environment today. However, the CERCLA as amended by SARA specifically excludes oil and its fractions as defined hazardous substances. This exclusion limits Superfund expenditures on sites contaminated by such substances and denies claims based on the strong liability scheme of CERCLA/SARA.

The following sections discuss the current environmental legislation on oil, the liability scheme within this legislation and new legislation related to releases of oil in the environment.

RELEASE OF CRUDE OIL AND DERIVATIVES UNDER CERCLA/SARA

When the release[1] of a hazardous substance occurs in the environment, statutory authority to address such a release can be found in CERCLA/SARA and analogous state laws. In establishing liability under CERCLA/SARA, a key factual element is classification of the substance released as "hazardous." The term hazardous substance is defined in

CERCLA § 101 (14), 42 U.S.C. §9601(14)(1990) to mean:

(A) any substance designated pursuant to section 311(b)(2)(A) of the Federal Water Pollution Control Act, (B) any element, compound, mixture, solution, or substance designated pursuant to section 102 of this Act, (C) any hazardous waste having the characteristics identified under or listed pursuant to section 3001 of the Solid Waste Disposal Act (but not including any waste the regulation of which under the Solid Waste Disposal Act has been suspended by Act of Congress), (D) any toxic pollutant listed under section 307(a) of the Federal Water Pollution Control Act, (E) any hazardous air pollutant listed under section 112 of the Clean Air Act, and (F) any imminently hazardous chemical substance or mixture with respect to which the Administrator has taken action pursuant to section 7 of the Toxic Substances Control Act. The term does not include petroleum, including crude oil or any fraction thereof which is not otherwise specifically listed or designated as a hazardous substance under subparagraphs (A) through (F) of this paragraph, and the term does not include natural gas, natural gas liquids, liquefied natural gas, or synthetic gas usable for fuel (or mixtures of natural gas and such synthetic gas).

Liability can also be established under CERCLA/SARA to include release of those substances described as pollutants or contaminants under CERCLA §101(33), 42 +wS.C. §9601(33) and defined as follows:

...any element, substance, compound, or mixture, including disease-causing agents, which after release into the environment and upon exposure, ingestion, inhalation, or assimilation into any organism, either directly from the environment or indirectly by ingestion through food chains, will or may reasonably be anticipated to cause death, disease, behavioral abnormalities, cancer, genetic mutation, physiological malfunctions (including malfunctions in reproduction) or physical deformations, in such organisms or their offspring; except that the term "pollutant or contaminant" shall not include petroleum, including crude oil or any fraction thereof which is not otherwise specifically listed or designated as a hazardous substance under subparagraphs (A) through (F) of paragraph (14) and shall not include natural gas, liquefied natural gas, or synthetic gas of pipeline quality (or mixtures of natural gas and such synthetic gas).

If the substance being released into the environment does not come under the definition of "hazardous" or pollutant or contaminant, then CERCLA/SARA is not applicable. Note the last portion of each definition specifically excludes crude oil and derivatives therefrom as a defined hazardous substance pollutant or contaminant. With a few words, the U.S. Congress denied CERCLA liability to the most voluminous class of substances released in the environment today. And it did so with

poorly worked definitions which have resulted in a variety of attempts to describe the congressional "intent" of its exclusatory language.

In 1982, the U.S. EPA Office of General Counsel described the liability under CERCLA for diesel oil contamination of groundwater.[2] This memorandum discussion regarded classifying diesel oil as a hazardous substance due to the presence of hazardous substances such as benzene and toluene. General Counsel concluded that diesel oil and its hazardous constituents fall within the CERCLA petroleum exclusion, unless the constituents were found in elevated levels or added after the product was issued as diesel oil. This early memorandum helped define the question which recurs to this day, "When are crude oil and derivatives therefrom not subject to the CERCLA petroleum exclusion?"

In 1983, the General Counsel again issued an interpretive memorandum on the CERCLA petroleum exclusion.[3] This memorandum concerned releases of gasoline, which in its refined state always contains defined hazardous substances, pollutants or contaminants. The interpretation posed to the General Counsel was that only raw gasoline, without any additives, comes under the petroleum exclusion. The General Counsel determined that such an interpretation would enervate the intent of CERCLA. As with diesel oil, the conclusion was that blended gasoline, as it is issued in a refined state, comes within the petroleum exclusion. Again, the addition of hazardous substances, pollutants or contaminants to blended gasoline after refining may nullify the applicability of the petroleum exclusion.

Subsequent case law upheld the interpretation offered by the U.S. EPA General Counsel in the 1982 and 1983 memoranda. In the 1984 case *U.S. v Wade*,[4] the court held that fuel oil came within the petroleum exclusion, regardless of the hazardous components found to normally occur therein. A 1986 case, *Marmon Group, Inc. v. Rexnord, Inc.*,[5] came to a similar conclusion. In that case the substance at issue was "cutting oil." Based on the facts, the court held that this specific cutting oil came within the petroleum exclusion.

As an apparent result of receiving numerous interpretive inquiries on the petroleum exclusion from the U.S. EPA Regional Counsel, the General Counsel in 1987 issued yet another memorandum on the subject.[6] In this memorandum, the General Counsel gave a history of the U.S. EPA's position regarding the CERCLA petroleum exclusion. At issue was the applicability of the exclusion to "used oil." The General Counsel's conclusion was that oil, having been used and combined with hazardous substances, pollutants and contaminants, did not come under the petroleum exclusion.[7] The General Counsel further noted, "moreover, under this interpretation not all releases of used oil will be subject to CERCLA since used oil does not necessarily contain non-indigenous hazardous substances or hazardous substances in elevated levels. Although used oil is generally "contaminated" by definition, *see e.g.*, RCRA Section 1005 (36), the impurities added by use may not be CERCLA hazardous substances."

The 1987 the U.S. EPA memorandum was followed by a case whose facts were similar to the memorandum discussion. In *State of Washington v. Time Oil Co.*,[8] the defendant was held liable for the release of hazardous substances which contaminated groundwater supplies. In this opinion, the court discussed used oil that was present and stated,

". . .some of the contaminants found on the Time Oil property were found in amounts in excess of the amounts that would have occurred in petroleum during the oil refining process. Other substances found on the property would not have occurred due to the refining process. The "petroleum exclusion," CERCLA §104(a)(2), will not operate to exclude Time Oil from liability."

Time Oil at 687 F. Supp. 532.

The *Time Oil* case was followed by the most recent definitive opinion on the petroleum exclusion. In *Wilshire Westwood, Assoc. v. Atlantic Richfield*,[10] the Ninth Circuit court was asked to interpret the CERCLA petroleum exclusion as it applies to unrefined and refined gasoline. The facts of this case were similar in form to the 1983 U.S. EPA memorandum discussed above.[11] In this case, a number of CERCLA hazardous substances were found to exist in the gasoline that had been released into the environment. These hazardous substances were those normally occurring or added to gasoline in the refining process. In finding

that gasoline comes within the petroleum exclusion, the court concluded, "the petroleum exclusion in CERCLA does not apply to unrefined and refined gasoline even though certain of its indigenous components and certain additives during the refining process have themselves been designated as hazardous substances within the meaning of CERCLA."[12] The court, in this opinion, relied in part on the 1987 U.S. EPA memorandum discussed above.[13] It is unclear how the U.S. EPA interpretation could carry such great weight when the word "petroleum" is not defined in CERCLA.[14]

STATE CERCLA-TYPE STATUTES AND THE PETROLEUM EXCLUSION

Under the federal CERCLA statute, the petroleum exclusion covers not only crude oil, but also a large number of crude oil derivatives. While CERCLA is expansive in jurisdiction, this statute does not preclude several states from developing legislation wherein the release of petroleum and its derivatives is actionable.[15]

A list of states with CERCLA-type legislation where petroleum and its derivatives are classified as hazardous substances is beyond the scope of this paper. However, CERCLA-type statutes of Montana[16] and Washington[17] provide examples of state laws where petroleum is defined as an actionable substance.

PETROLEUM PRODUCTS SUBJECT TO REGULATION UNDER RCRA

While CERCLA may exclude petroleum products from the definition of hazardous substances, a recourse to liability for release of petroleum may be available under RCRA. As with CERCLA hazardous substances, petroleum or crude oil is not defined as a RCRA hazardous waste.[18]

If the constituents of the petroleum or oil product are considered a hazardous waste, then a release may be actionable under RCRA. And a finding that various components of petroleum may be considered a RCRA hazardous waste when combined with soil is more likely under the new Toxicity Leaching Characteristic Procedure.[19] For cleanup liability to be established under RCRA, the release must occur from a transportation, treatment, storage or disposal facility. The release is actionable both within and outside of the facility boundaries.[20]

Perhaps the greatest source of petroleum contamination comes from leaking underground storage tanks (USTs). In response to this obvious problem, Congress added Subtitle I to RCRA.[21] This subtitle provides requirements for new USTs, testing of in place USTs, and remedies for releases from USTs. To ensure that releases from USTs were remedied, Congress provided funds under SARA to assist in the financing of cleanup costs.[22] The scope of the term UST is defined in Subtitle I, as is the word "petroleum."[23]

RCRA UST legislation provides an avenue for cleanup liability when a release of petroleum or crude oil occurs from a regulated tank. While this legislation is a positive step in the direction of remediating all land-based releases of crude oil and petroleum, it is not as far reaching as CERCLA in its liability scheme.

PETROLEUM PRODUCTS SUBJECT TO REGULATION UNDER FWPCA

Should a release of crude oil or derivatives therefrom occur upon the navigable waters of the United States, then said release is actionable under the Federal Water Pollution Control Act (FWPCA).[24] The FWPCA has a specific section that details the scope of liability for releases of oil.[25]

PETROLEUM PRODUCTS SUBJECT TO REGULATION UNDER SDWA

The Safe Water Drinking Act (SDWA) has as its primary purpose the protection of public drinking water supplies from contamination.[26] For a substance to be actionable under the SDWA, it must exceed the Maximum Contaminant Level (MCL) for that substance. The SDWA does not identify an MCL for crude oil or petroleum. However, hazardous substances found in petroleum such as benzene or xylene have established MCLs.

The SDWA also established a permit program for the underground injection of wastes. The Underground Injection Control (UIC) Permit Program regulates those persons utilizing underground injection wells for waste disposal.[27] It appears injection of oil or petroleum wastes would be regulated or prohibited if such injection would endanger drinking water resources.

PETROLEUM PRODUCTS SUBJECT TO REGULATION UNDER THE OIL POLLUTION ACT OF 1990

At the time of submittal of this paper, proposed legislation entitled the "Oil Pollution Act of 1990" (OPA) had not become law. The most recent information available on this legislation was the conference committee report on the bill.[28] OPA concerns and coverage focuses on costal and marine environments. This legislation is obviously a reply to the recent oil spills in Alaska, the Gulf of Mexico, and along the east coast of the United States The term oil is defined as follows:[29]

"... "oil" means oil of any kind or in any form including, but not limited to, petroleum, fuel oil, sludge, oil refuse, and oil mixed with wastes other than dredged spoil, but does not include petroleum, including crude oil or any fraction thereof, which is specifically listed or designated as a hazardous substance under subparagraphs (A) through (F) of section 101(14) of the [CERCLA] (42 U.S.C. §9601(1990)) and which is subject to the provisions of that Act."

Liability for discharge of oil into the costal and marine environments covered by the OPA is the same as in the CWA.[30] One of the main distinctions of the OPA is the establishment of a fund for the removal costs incurred to cleanup the discharge.[31] The OPA appears in many ways to be a combination of CERCLA and the CWA. It does provide a true liability scheme for discharge of oil and derivatives therefrom. However, this liability is limited to those environs described by the OPA.

CONCLUSION

The petroleum exclusion is alive and well under CERCLA. When a defined hazardous substance exists within crude oil or petroleum in levels exceeding the norm, CERCLA's strong liability scheme is unavailable. There are a number of valid public policy arguments to support the petroleum exclusion, but public policy should not be allowed to interfere with our need for great care in exploration, transportation, use and disposal of crude oil and its derivatives. These substances are truly hazardous and any release should be immediately addressed and remediated by the person responsible parties.

It appears that petroleum and oil will be treated as other hazardous substances when discharged in our costal and marine environments. And under the new Toxic Characteristic Leaching Procedures (TCLP), RCRA corrective authority may be available for cleanup of a wider variety of oil and petroleum wastes. But there remain a number of land-based sites in the United States where releases of crude oil and petroleum are not actionable under federal law. On a number of these sites the responsible party will initiate cleanup. On those sites without a identifiable or financially viable responsible party, the Hazardous Substance Trust Fund is unavailable unless the release of a hazardous substance can be identified.

Public policy intends to represent the collective good of the population at large. It is incongruous that the public and private industry support the Hazardous Substance Trust Fund and yet a burdensome exclusion stands in the way of using this fund for its intended purpose: the cleanup of "hazardous substances" in our environment.

REFERENCES

1. Release is defined in CERCLA §101(22), 42 U.S.C. §9601(22) as:

... any spilling, leaking, pumping, pouring, emitting, emptying, discharging, injecting, escaping, leaching, dumping, or disposing into the environment (including the abandonment or discarding of barrels, containers, and other closed receptacles containing any hazardous substance or pollutant or contaminant), but excludes (A) any release which results in exposure to persons solely within a workplace with respect to a claim which such persons may assert against the employer of such persons, (B) emissions from the engine exhaust of a motor vehicle, rolling stock, aircraft, vessel, or pipeline pumping station engine, (C) release of source, byproduct, or special nuclear material from a nuclear incident, as those terms are defined in the Atomic Energy Act of 1954, if such release is subject to requirements with respect to financial protection established by the Nuclear Regulatory Commission under section 170 of such Act, or, for the purposes of section 104 of this title or any other response action, any release of source byproduct, or special nuclear material from any processing site designated under section 102(a)(1) or 302(a) of the Uranium Mill Tailings Radiation Control Act of 1978, and (D) the normal application of fertilizer.

ABSTRACT

A major objective of the U.S. EPA's Emergency Response Program is to evaluate and, if necessary, respond to releases of oil and hazardous substances that pose a threat or potential threat to public health and/or the environment. To manage this function appropriately, the U.S. EPA in coordination with other members of the emergency response community including the National Response Center (NRC) and the U.S. Coast Guard (USCG), developed a nationwide system to receive and process notifications of releases.

This nationwide system consists of notification data collection and reporting processes that meet the legislative and regulatory requirements of the Clean Water Act (CWA), section 311; CERCLA of 1980, sections 103 and 104; SARA; and the National Oil and Hazardous Substances Pollution Contingency Plan (NCP), sections 300.125, 300.300 and 300.405.

Central to collecting, processing and reporting release notifications among the NRC, U.S. EPA and USCG is a national computer data base called, the Emergency Response Notification System (ERNS). The data base is maintained by the Department of Transportation's Transportation Systems Center (TSC) through an interagency agreement with the U.S. EPA. The data base contains release notification data reported each time a call is made to the NRC, U.S. EPA or USCG.

This paper focuses on the process used in the development and advancement of ERNS and on the trends of oil and hazardous substance releases collected by ERNS for the past three years.

INTRODUCTION

The Emergency Response Notification System (ERNS) supports two U.S. EPA Emergency Response Program processes: release notification and release verification. The notification process involves receiving and capturing data on all reported notifications of a release. The verification process involves making an initial release assessment, a response evaluation and then, if necessary, planning a removal action for the release.

The U.S. EPA portion of ERNS represents release notification reports collected by each of the 10 U.S. EPA Regions using a Regional ERNS data base. The Regional ERNS is a stand-alone Personal Computer (PC)- or Local Area Network (LAN)-based system which standardizes the process of collecting, documenting and analyzing data on releases of oil and hazardous substances specific to each Region.

Each time a call is made to the U.S. EPA to report a release of oil or a hazardous substance, the data are put into the Regional ERNS data base as shown in Figure 1. Regional notification and verification data are sent electronically to the National ERNS data base on a weekly basis. At the same time, NRC notification reports, that are referred to the U.S. EPA via phone for verification and response evaluation, are also sent electronically to the respective Regional ERNS data base.

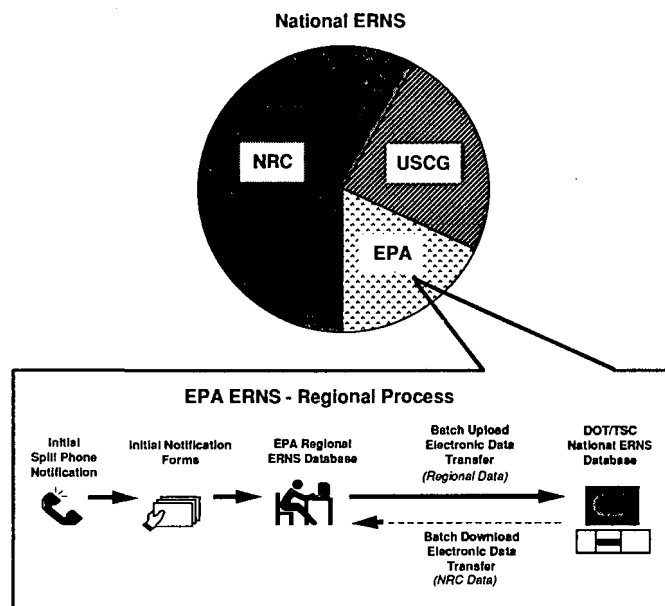
By standardizing the collection, processing and reporting of oil and hazardous substance release notifications through the use of ERNS, the emergency response community has achieved consistent data collection, reduced operational differences among entities receiving notifications and streamlined data sharing among the numerous and widely dispersed members of the response community. The objective of this paper is to describe the process used to develop ERNS and some of the factors that led to its successful implementation.


Figure 1
Emergency Response Notification System

ERNS DEVELOPMENTS
YESTERDAY, TODAY and TOMORROW

ERNS development began in 1986. The objective was to meet the functional and regulatory requirements for recording and maintaining data collected from the notifications of oil and hazardous substances. Since then, ERNS has expanded its objective to include the assessment of notification data for incident and program management analyses.

ERNS was developed and implemented in two phases as shown in

Figure 2: Phase I documented initial release notification information and Phase II expanded the focus of information flow to assessment and response.

PHASE I

Building ERNS Notification Data Collection Capabilities

Documented initial release notification data for:

* Initial incident evaluation
* Transmission to national ERNS
* Responding to information requests

PHASE II

Enhancing ERNS Capabilities To Support Release Verification

Focus information flow to assessment and response:

* Verifies initial information
* Characterizes incident sources/causes
* Documents incident disposition

PHASE II

Developing ERNS Into An Incident Analyses and Program Management Tool

Target initiatives on:

* Establishing program definitions for ERNS data
* Improving data quality through training and audit reports
* Expanding data access and usage

| 1986 | 1988 | 1990s |

Figure 2
ERNS Developments by Phase

A phased systems development approach was taken in order to: (1) provide ERNS users sufficient time to understand and test how ERNS capabilities would or would not meet specific data and work needs and (2) permit the ERNS development team to gain a thorough understanding of removal program data and operational requirements and produce results within a short time frame. The following paragraphs describe ERNS developments by phase.

Phase I: Building ERNS Notification Data Collection Capabilities in 1986

Prior to ERNS development, collection of notification data was a manual and paper-intensive process. At an April 1986 meeting with federal emergency response personnel including the NRC, USCG, TSC, U.S. EPA Emergency Response Division (ERD) Headquarters (HQ) personnel and U.S. EPA Regional On-Scene Coordinators (OSCs), 85 critical notification data elements were defined as the national data set. The U.S. EPA and TSC participants later became the U.S. EPA ERNS Work Group. The Work Group concept provided and continues to provide, a core team that ensures that ERNS user needs are addressed on all current and new system initiatives and that continual improvement is built into the operation and maintenance of the system.

To obtain the national data set for each notification, report forms were developed and completed by U.S. EPA Regions manually. A copy of the forms was sent to TSC for data entry into a National ERNS data base. While the pre-ERNS process met legislative and regulatory data collection requirements, data handling and processing problems were encountered. They included: (1) notification forms being completed and copied illegibly; (2) form contents varying by Region, thereby hampering data entry speed and causing inconsistent data collection and interpreta-

tion; (3) use of different abbreviations and acronyms which hampered data retrieval; and (4) poor notification reporting accountability for program planning and management.

To address several of these problems, ERNS Phase I development was initiated to automate the processes of capturing Regional notification data and sending the forms to TSC. The ERNS role in Phase I was to document notifications at the Regional level on standard notification report forms. Regional staff would then either mail a copy of the form to TSC or enter the data into ERNS which would transmit the data electronically to the National data base. In addition, Regions were requested to list Region-specific data elements. These data typically included data for response tracking and referral.

ERNS Phase I was developed for stand-alone PCs using dBASEIII and was pilot tested in U.S. EPA Regions II and VI. The pilot program served as a test for monitoring real-world performance of ERNS. Regional piloting also allowed direct system support by the ERNS development team. The ERNS development team concentrated on the two pilot Regions' systems to ensure smooth change integration and full system operability before implementation in the remaining Regions. ERNS Phase I became operational in October 1986.

Phase II: Enhancing ERNS Capabilities to Support Release Verification in 1988 and Developing ERNS Into An Incident Analyses and Program Management Tool in the 1990s

ERNS Phase II has focused and continues to focus, on improving the Emergency Response Program's ability to characterize actual incidents by providing information on the nature of the release for response evaluation. While basic notification data collected by ERNS Phase I helps an OSC decide whether a U.S. EPA response is warranted, Regions follow up on most, if not all, notifications to obtain more detailed information. This information is obtained by calling State/local contacts at the scene or by an OSC or an authorized contractor visiting the site. It is the information collected from these activities that provides the key data gaps during response determination.

In collecting after-the-fact or verification data, the emphasis is on collecting as much data as possible on the release and to ensure that the data are accurate and reliable enough to make a sound response determination. After-the-fact data provide a clearer, more complete picture of the accidental release. It provides key data that substantiate, verify or revise data collected during the initial release notification. It is this level of detail, accuracy and completeness that the U.S. EPA management needs in order to make sound planning and budgeting decisions and to report program activities accurately to Congress and the public.

ERNS Phase II focuses on enhancing system capabilities by collecting and modifying detailed after-the-fact data on a release and streamlining the NRC data transfer process. ERNS Phase II provides the capability to: (1) record additional data elements specific to verified incidents, along with the original notification data; (2) continually update the status of a verified incident; (3) receive notifications, originally received by the NRC, automatically through electronic transmissions from the National ERNS data base; (4) integrate user aids, such as chemical and location tables, in the data capture process; and (5) expand Regional access to ERNS by upgrading to a multiuser LAN environment.

Additional features such as password security, variable fiscal year data, cursor movements, restricted input fields, on-line help, popup screens, screen colors, archived spill records, free-form notepad, backup procedures and NRC data transfer are also included in ERNS. To ensure that ERNS Phase II features are appropriate for Regional ERNS operations, they are demonstrated at National ERNS conferences for maximum user suggestions and are tested in a pilot Region for real-world performance.

ERNS Phase II telecommunications enhancements and user aids reduce the data input workload in the U.S. EPA Regions significantly. The telecommunications enhancements enable each Region to keep their individual notification data base current with the National notification data base. ERNS Phase II ensures that the 10 distinct Regional systems operate in a parallel fashion with one another and merge effectively

with NRC and USCG data to create the centralized National ERNS data base. This merging of data bases saves resources and improves the completeness and quality of the data.

ERNS today encompasses all of these data capture and telecommunications capabilities. As ERNS users become increasingly skilled in using ERNS as a notification data collection tool, they also identify ways of applying ERNS data to response activities. ERNS' function is evolving from strictly an initial notification data collection system. ERNS is used increasingly to support incident and program management analysis, emergency preparedness and planning, U.S. EPA enforcement and responses to public and private information requests. To meet these dynamic needs, the U.S. EPA's ERD has begun several initiatives in fiscal year 1990 including: (1) establishing program definitions for ERNS data to ensure consistent interpretation and usage; (2) improving data quality for response determination; and (3) expanding data access for information queries and public use.

KEYS TO ERNS SUCCESS

ERNS success is attributed largely to the frequent and dynamic communication among the ERNS Work Group members and the close working relationships among the U.S. EPA, TSC, NRC and USCG. Regional communications cover topics such as assistance on ERNS operations and ad hoc reports; data quality assurance and data control issues; input and feedback on HQ activities; and working through and testing planned system enhancements and training activities. Communications with other federal agencies cover topics such as National ERNS data base integrity and data quality issues; information distribution to Congress and the public; and implications of other federal emergency response initiatives, such as the July 1990 promulgation of the final rule on "Reporting Continuous Release of Hazardous Substances."

This section describes the key factors that contributed to the successful development and implementation of ERNS. These factors include extensive user participation from the inception of ERNS; keeping ERNS simple and flexible; proactive development and implementation initiatives; and maintaining ERNS visibility to management and visibility to the emergency response community.

Extensive User Participation From The Inception Of ERNS

The ERNS Work Group established in 1986 has been and continues to be the round table discussion forum for addressing ERNS program requirements and user needs on all current and new initiatives. The Work Group consists of ERD HQ personnel, Regional OSCs and program staff who represent U.S. EPA Emergency Response Program users and the TSC and U.S. EPA ERNS development team who support the National and Regional ERNS data bases respectively. As illustrated in Figure 3, the ERNS Work Group is central to system management in addressing programmatic and system issues and coordinating and communicating ERNS activities within the U.S. EPA, with its federal counterparts, NRC and USCG and with the public.

A participatory development and implementation approach is used to ensure that ERNS contains usable and practical features for U.S. EPA Regional users. The overall approach consists of:

- Identifying requirements or improvement areas for ERNS
- Demonstrating a system improvement concept to the entire Work Group usually at the National ERNS conference
- Incorporating the new capability into ERNS if the feedback is favorable
- Conducting a Regional pilot test for real-world performance
- Refining the capability based on Regional pilot results
- Implementing the enhancements or improvements in the remaining Regions
- Operating, maintaining and monitoring the system.

All or parts of this approach have been used successfully for a variety of ERNS initiatives—from implementing system changes and improvements to developing training courses and procedural guidance.

Keeping ERNS Simple and Flexible

Many of ERNS users were and are first time PC users. The way ERNS

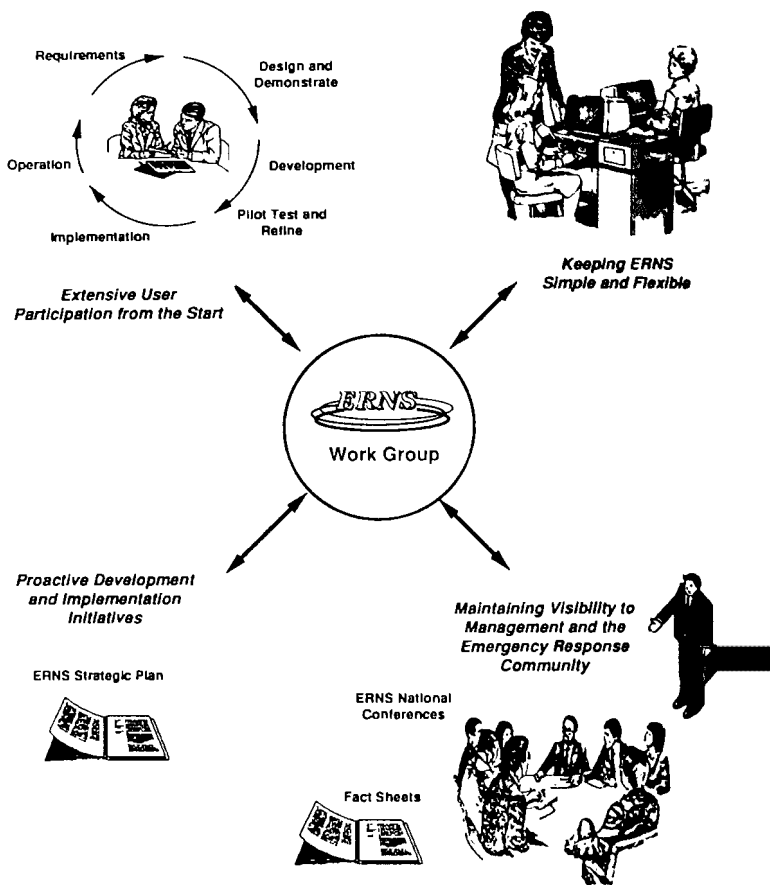
'looks and feels' is, therefore, important to its initial and continued use. With this in mind, ERNS was developed as a menu-driven system with tables which lead users through its operations. Additionally, the phased development approach and Regional pilot tests helped pace and tailor the introduction of new ERNS features and capabilities with users' knowledge and comfort with PCs and the system. The human/machine interactions also contributed to ERNS success. Human/machine interactions took into account how ERNS needed to 'look and feel' in order to ease any user discomforts with using a computer for the first time.


Figure 3
Keys to ERNS Success

Not only does ERNS need to be easy to use, but it also needs to be flexible to support evolving program and user needs and changes in PC technology. As users became more knowledgeable and confident in the system, ERNS usage began to grow and change. ERNS users grew to need more system capabilities as evidenced by the number of features added to ERNS in Phase II. ERNS maintains its simplicity to accommodate new users while providing expanded capabilities for more sophisticated users. In keeping with the Agency's direction in the use of PC LAN technology, ERNS was also upgraded from a single user system on a stand-alone PC to a multiuser system operating on a LAN. Today, ERNS initiatives include addressing an evolving and growing need by the Emergency Response Program and the public to use ERNS data for incident analysis in addition to the notification analysis performed today.

Proactive ERNS Development and Implementation Initiatives

Throughout development and implementation, ERNS Work Group members defined what ERNS should do and what ERNS needs to do. The ERNS development team designed and developed how ERNS would operate and worked closely with Regional OSCs and program staff in testing and refining ERNS operations and user interface.

Following ERNS Phase I implementation, the ERNS development team began providing technical support to ERNS Regional users. The Team provides user assistance more than the telephone; uses software which allows remote ERNS diagnostics, repair and assistance; and obtains user suggestions and feedback on ERNS operations and uses regularly. By having continual contact with Regional users, the ERNS development team has tracked recurring questions and problems and has suggested ERNS improvements based on first-hand knowledge of how ERNS is being used. This close working relationship keeps ERNS aligned with the emergency response support needed by the Regions.

Maintaining ERNS Visibility to Management and Visibility to the Emergency Response Community

Management support and ERNS visibility to the emergency response community were obtained through the U.S. EPA's Emergency Response Program management briefings, environmental conference presentations and public relations brochures. Fundamental to ERNS success is its well-established reputation and use by federal agencies and an increasing number of state and local agencies and commercial firms.

NOTIFICATION TRENDS IN OIL AND HAZARDOUS RELEASES

ERNS captures data on the initial notification of a release and on verified releases. With the 85 notification data elements, the following data are collected: the notification caller, the discharger and the released substance; the release location, date and time; the release source, medium and cause; the potential human health risks or imminent danger; and actions already underway to mitigate the reported release or release threat.

Since October 1986, more than 95,000 release notifications have been collected by ERNS, including 49,000 release notifications for oil releases. In the past two years, the total number of notifications has increased slightly with 29,874 reports in 1988 and 34,089 reports in 1989. Figure 4 shows the distribution of notifications received since 1987.
Figure 4
ERNS Trends: Total Oil, CERCLA, and Other
1986 Through 1989

As seen in Figure 4, the number of oil soil notifications in the last three years has remained stable, showing only an increase of 571 reports more than the three-year period. In contrast, reports of CERCLA substance releases have increased steadily with 2000 more reports in 1989 than in 1987. The increase in CERCLA substances release reports may be attributed to an actual increase in the number of releases, an increase in awareness of reporting requirements and/or compliance with

spill reporting requirements, as well as an improvement in data recording and record-keeping used by the federal government.

Since 1987, there have been more than 16,000 CERCLA release notifications. More than 75% of these reports identified the source of the reported release as a fixed facility-related incident. Highway and rail incidents comprise another 15% of the reported sources of CERCLA notifications. Figure 5 provides the complete distribution of reported release sources resulting in CERCLA notifications for the last three years.
Figure 5
CERCLA Release Notifications by Source From
1987 to 1989

The five CERCLA substances most frequently reported released, for each of the last three years are shown in Figure 6. These most released chemicals include PCBs, chlorine, sulfuric acid, sodium hydroxide and anhydrous ammonia. PCBs have remained the most frequently reported CERCLA hazardous substance for all three years. Figure 6 shows an increase of more than 100% in the number of anhydrous ammonia
Figure 6
"ERNS Top 5"
CERCLA Hazardous Substances

release notifications in 1988 more than 1987. Although there was a slight decrease in the number of anhydrous ammonia reports in 1989, anhydrous ammonia remained the second most frequently reported CERCLA substance for that year.

More than 47,000 oil release notifications have been received since 1987. Incidents related to fixed facilities, such as refineries and oil wells, account for 49% of the oil reports; 25% have been marine related. Figure 7 provides the complete distribution of CERCLA notifications since 1987.

The most frequent oil substances released in 1987, 1988 and 1989 are shown in Figure 8. As the graph shows, crude oil reports increased

more than 40% from 1988 to 1989 and surpassed the number of diesel oil reports. These data reverse the trend established in 1987 and 1988
Figure 7
Oil Release Notifications by Source
From 1987 to 1989

when diesel oil releases were the most reported oil releases. The graph also shows a significant drop in the number of waste oil reports from approximately 1,100 in 1987 and 1988 to 670 in 1989.

CONCLUSIONS

ERNS is a critical tool in streamlining and standardizing the collection and dissemination of information on notifications of oil and hazardous substance releases. Its success is largely a result of the frequent and dynamic communications among members of the emergency response community including the U.S. EPA, NRC and USCG.
Figure 8
ERNS Top 5" Oil 1987 Through 1989

With a solid data base of release notification information, ERNS is now being developed to support incident and program management analysis, emergency preparedness and planning, U.S. EPA enforcement and responses to public and private information requests.

The NLM/ATSDR ANSWER™ Work Station with the TOMES Plus™ CD-ROM Information System for HAZMAT Incident Response

ABSTRACT

The time-critical nature of emergencies involving hazardous materials demands a means of retrieving needed emergency response, medical, and toxicological information rapidly. Transportation-related hazardous materials emergencies often occur in locations where access to a telephone connection for on-line searching is unavailable and where surrounding terrain may complicate or preclude radio contact for dispatch-based information transfer.

The ANSWER™ Workstation was produced by the National Library of Medicine (NLM) in conjunction with the Agency for Toxic Substances and Disease Registry (ATSDR) to address these issues. This work station is based on an IBM-compatible portable computer with a compact disc drive and internal modem. If telephone access is available, a gateway program called MICRO-CSIN allows for simplified on-line access to a wide variety of remote data bases. Pro-Com provides access to real-time weather information from the National Weather Service. A hard-disk data base contains information collected during previous emergency response situations. Other ANSWER Workstation features are an air dispersion plume modeling package, word-processing and FAX transmission capabilities. The ANSWER Software will also run on a desktop IBM-AT or compatible PC.

The TOMES Plus™ Information System (Toxicology, Occupational Medicine and Environmental Series) is the CD-ROM (Compact Disc-Read Only Memory) portion of the ANSWER Workstation, allowing over 500 megabytes of information to be provided on-site on a single compact disc only 4-3/4 inches in diameter and weighing only 1/2 ounce. A menu-driven search software allows even novice users to quickly retrieve required information on over 100,000 individual chemicals, accessed by chemical name, synonym, CAS number, NIOSH/RTECS number, UN/NA number, STCC number, RCRA Hazardous Waste Number, etc.

The TOMES Plus system currently contains the following data bases of particular interest to hazardous materials incident responders: HAZARDTEXT™, DOT Emergency Response Guides, HSDB (the Hazardous Substances Data Bank produced by NLM), CHRIS (the Chemical Hazards Response Information System produced by the US Coast Guard), OHM/TADS (the Oil and Hazardous Materials/Technical Assistance Data System produced by the U.S. EPA) and RTECS (the Registry of Toxic Effects of Chemical Substances produced by NIOSH). Additional data bases on the TOMES Plus disc provide information on medical evaluation and treatment, risk assessment, toxicology and reproductive hazards. Under development in 1990 are SARATEXT™ for SARA Title III Extremely Hazardous Substances medical evaluation and treatment reporting and REPROTEXT™ with rating scales and monographs on the chronic toxicity and reproductive hazards of chemicals.

The ANSWER Workstation is currently being used by several State health departments and hazardous materials response agencies.

INTRODUCTION

Emergencies involving hazardous materials may occur anywhere and any time. Some crucial aspects of successful HAZMAT incident response involve rapid procurement of adequate data on hazards, toxicity and proper response actions; plotting the anticipated spread of released airborne contaminants to determine possible areas for evacuation; transmission of data and current incident status to other agencies or facilities that may become involved in the response; and collection of incident-specific data for later evaluation and utilization when similar situations occur in the future.

Because radio or telephone line communications may be difficult to achieve, particularly during the initial response phase, as much information as possible should be moved directly to the incident site. The concept of a portable work station, able to be carried on airplanes as hand baggage (fitting in overhead compartments or under a seat) and weighing less than 30 pounds, has been developed by the National Library of Medicine (NLM) in conjunction with the Agency for Toxic Substances and Disease Registry (ATSDR). The prototype product, the ANSWER™ Work station (ATSDR/NLM's Work station for Emergency Response), encompassing a variety of features required for HAZMAT incident response and including a CD-ROM data base (the TOMES Plus™ Information System from Micromedex, Inc.) is currently being beta-tested by a number of state health and HAZMAT response agencies.

ANSWER WORKSTATION FEATURES

The Event Description File (EDF) is a hard-disk data base enabling emergency response personnel to maintain and query a wide range of information on previous HAZMAT response events. HAZMAT responders can retrieve actual experience and results from either their own or a nationally collated and shared data base of the results of similar incident responses. Each individual HAZMAT response incident and the results of various interventions can be recorded in the EDF, retrieved by the responding organization and may also be shared nationally with other similar agencies. The EDF can also be used to prepare reports required for local, state or national agencies, or the National Fire Protection Association (NFPA).

Should information regarding a particular incident need to be shared on an urgent basis with other response agencies, the FAX feature of the ANSWER Workstation can be used to transmit hard copy and files to fire departments, hospitals, other governmental agencies, etc. Both transmission of information and review of FAX files received from remote sites can be accomplished. Hard copy can be printed on-site as required.

The Health/Hazard module of the ANSWER Workstation is the CD-ROM-based TOMES Plus™ Information System developed and provided by Micromedex, Inc. of Denver, Colorado. CD-ROM data bases which can be accessed through the ANSWER Workstation are described below. Any portion of the TOMES Plus Information System can be printed out in hard copy or sent to the hard disk for local editing or remote transmission with the ANSWER Workstation FAXing feature. After telephone line connection is established, the MICRO-CSIN feature of the ANSWER Workstation allows simple access to a very wide range of on-line data bases for retrieval of further information about hazardous substances. MICRO-CSIN is a gateway program which minimizes the training required to successfully query remote on-line data bases for retrieval of fact, numeric and chemical identification data from eight component vendor systems. TYMENET and Telenet can be used with MICRO-CSIN through the Communication Parameters feature. The menu-driven software package Grateful Med, which greatly simplifies searching NLM's MEDLARS data base, can also be used with the ANSWER Workstation.

The ANSWER Workstation WEATHER feature uses Pro-Com to obtain the most recent weather observations from 1,000 National Weather System reporting stations throughout the United States and Canada from the Weather Information System developed by the WSI Corporation. The most applicable plume modeling program for ANSWER Workstation users is currently being studied. As soon as a plume model is available, data such as current wind direction and speed, relative humidity, dew point, etc. can be retrieved with the WEATHER feature and used in the plume modeling program.

The ANSWER Workstation also incorporates word processing and management functions to allow information editing, development of local "call lists" of crucial personnel, inter- and intraagency locally-defined communications functions and more. ANSWER Workstation Project Information is available from Specialized Information Services at the National Library of Medicine, Bethesda, Maryland. User Support Staff are available at the Training & Management Systems Division of the Oak Ridge Associated Universities, Oak Ridge, Tennessee.

TOMES PLUS CD-ROM DATA BASES

The TOMES Plus™ Information System (Toxicology, Occupational Medicine and Environmental Series) developed and produced by Micromedex, Inc. of Denver, Colorado, is the CD-ROM (Compact Disc-Read Only Memory) portion of the ANSWER Workstation. The TOMES Plus system provides more than 500 megabytes of information available on-site on a single compact disc only 4-3/4 inches in diameter and weighing only 1/2, ounce and is accessible with either a half-height CD-ROM disc drive which can be internally mounted in certain portable personal computers, or an external CD-ROM disc drive connected to a desktop PC. The unique TOMES Plus system menu-driven search software allows even novice users to quickly retrieve required information on more than 100,000 individual chemicals, accessed by a wide variety of identifiers, including: chemical name, synonyms, CAS number, NIOSH/RTECS number, UN/NA number, STCC number, RCRA Hazardous Waste Number, etc. After initial query, a resident function allows retrieval of all NIOSH/RTECS (and other source) synonyms and identifiers to confirm that the correct chemical is being researched.

The TOMES Plus system currently contains a wide variety of data bases which are of particular utility for hazardous materials incident responders:

- HAZARDTEXT™ (produced by Micromedex, Inc.) containing a review of EMT-paramedic level clinical effects, patient evaluation

and treatment data, range of toxicity including pertinent workplace and environmental exposure standards and recommendations, a thorough review of common handbooks and other primary and secondary sources of information for fire control, hazards of combustion products, environmental hazards, chemical reactivities, physical and chemical properties and recommendations for the choice of chemical protective equipment

- Frequently-consulted DOT Emergency Response Guides (from the Department of Transportation); the entire HSDB (the Hazardous Substances Data Bank produced by NLM) with detailed information on the production, common uses, manufacturing, physical/chemical properties and hazard, environmental and potential health effects of more than 4,200 individual chemical substances
- CHRIS (the Chemical Hazards Response Information System produced by the US Coast Guard) with fire, health, environmental and other hazard data on over 1,200 chemicals
- OHM/TADS (the Oil and Hazardous Materials/Technical Assistance Data System produced by the U.S. EPA) with information on the environmental and health hazards of over 1,000 chemical substances and recommendations for cleanup or amelioration of spills or other releases
- RTECS (the Registry of Toxic Effects of Chemical Substances produced by NIOSH) containing information on the irritant, acute toxicity, genotoxicity, tumorigenicity and reproductive hazards of over 100,000 individual chemical substances

Additional data bases on the TOMES Plus disc:

- MEDITEXT™ (produced by Micromedex, Inc.), which provides physician-level detailed information on the medical evaluation and treatment of patients exposed to hazardous chemicals for use by both emergency responders and emergency department or other hospital-based medical personnel
- U.S. EPA's IRIS (Integrated Risk Information System) data base for performing risk assessments following releases into air or drinking water
- REPRORISK™ series of data bases for the assessment of potential chronic exposure and reproductive hazards of hazardous chemical exposure

New TOMES Plus data bases being developed by Micromedex, Inc. during 1990 are SARATEXT™ for SARA Title III Extremely Hazardous Substances medical evaluation and treatment reporting and REPROTEXT™ with rating scales and monographs on the chronic toxicity and reproductive hazards of chemicals.

BETA-TEST SITES

The ANSWER Workstation with the TOMES Plus Information System is currently undergoing beta-testing. Fifteen initial installation sites have been chosen, including five State health agencies, a city-county health department, three poison control centers, a county fire department, three locations of the ATSDR, the National Library of Medicine and the Oak Ridge Associated Universities (where training development is in progress).

CONCLUSION

Continuing development of both the informatics and utilities content and features of the ANSWER Workstation and the TOMES Plus Information System have promise to make this combination portable/remote HAZMAT incident response tool an indispensable information and communications resource for HAZMAT incident response, community planning and risk assessment.

1990 Exhibitors

**3M Environmental
Protection Products** 0905-0907
3M Center, Building 223-6S-04
St. Paul, MN 55144-1000
612/736-5335

3M Company - Environmental Protection Products - 3M Foams. 3M Foams have proven their suppression effectiveness during hazardous material clean-up that involves release of volatile organic compounds (VOCs), air toxics, odors, and dust. These water-based foams conform to the terrain and last hours, days, and even weeks, depending on the site requirements.

A.E.T.C. 2411/2413
Gold Mine Rd.
Flanders, NJ 07836
201/347-7111

A.E.T.C. has been providing fully integrated hazardous and chemical waste management services since 1976. A.E.T.C. specializes in the management of reactives and package laboratory chemicals, as well as production wastes, PCB destruction, household hazardous waste, and a full range of site remediation services from our thirteen locations.

**A.O. Smith Harvestore
Products, Inc.** 1903
345 Harvestore Dr.
DeKalb, IL 60115
815/756-1551

A.O. Smith Harvestore Products, Inc. will be exhibiting its Aquastore® Tank products line. These tanks, with capacities up to 2 million gallons, are factory coated with fused silica glass on the inside and outside for corrosion control. The tank is field-erected by bolting and the joints are sealed.

ABB Environmental Services Inc. 0223
261 Commercial St.
Portland, ME 04112
207/775-5401

Environmental Consulting, monitoring and

chemical analysis; hazardous waste site investigations, remedial design, construction and clean-up; thermal and non-thermal waste treatment systems.

AIM USA 0218
P.O. Box 720540
Houston, TX 77272-0540
713/240-5020

AIM develops and manufactures microcomputerized portable toxic/combustible/oxygen air monitoring instruments. AIM is able to quickly develop hardware and software solutions for many special gas detection needs. AIM instruments are used by over 70 USA military installations, environmental remediation firms, all types of industries and many major hazardous material response teams.

**ALCOA SEPARATIONS
TECHNOLOGY, INC.** 2008/2010
Subsidiary of Aluminum Company
of America
181 Thorn Hill Rd.
Warrendale, PA 15086-7527
412/772-0086

Innovative technologies for the recovery/treatment of groundwater and the treatment of sanitary and hazardous landfill leachates are on display by Alcoa Separations Technology, Inc., Subsidiary of Aluminum Company of America. Comprehensive treatment/recovery equipment, services and technologies are highlighted and information regarding the various treatment approaches are available.

ALL-PAK, INC. 1608
2260 Roswell Dr.
Pittsburgh, PA 15205
412/922-7525

U.N. Performance Tested/DOT Exempt Packaging, EPA Pre-cleaned Sample Bottles, Overpack Drums - metal/plastic, Lab Packs, Teflon-lined Caps, Safety Coated Bottles, Complete Line of Glass, Plastic and Metal Containers.

ARAMSCO 0320
1655 Imperial Way
Thorofare, NJ 08086
609/848-5330

ARAMSCO specializes in safety products for the hazardous environment, introducing the Blastrac - a portable shotblast cleaning system for emoving contaminants such as PCB, asbestos, radiation from concrete or metal floors.

AVS Video Productions 0613
8548 N. Dale Mabry, 2nd Floor
Tampa, FL 33614-1600
813/935-1898

Turnkey video production - scripting through duplication of finished programs; OSHA certified camera crews shoot broadcast quality footage of remedial investigations, Superfund cleanups, SITE demonstrations and experimental facilities; post production capabilities include state-of-the-art 3D animation to illustrate the operation of innovative equipment and chemical processes.

AWD Technologies, Inc. 2119
15200 Omega Dr.
Rockville, MD 20850
301/869-4800

AWD Technologies, Inc., a wholly owned subsidiary of The Dow Chemical Company, provides full-service groundwater, soil, and site remediation. Services include site investigation, planning and engineering design, construction, operation and maintenance, and overall project management.

Acres International Corporation 0501
140 John James Audubon Pkwy.
Amherst, NY 14228-1180
716/689-3737

Acres provides waste management expertise to a wide variety of industrial firms, utilities, and government agencies (federal, state and local). Site investigations, permitting and regulatory compliance evaluations, remedial investigations and feasibility studies, conceptual and detail de-

sign, and construction supervision are among the comprehensive services offered. Acres offers a multidisciplined and experienced team of geologists, hydrogeologists, chemists, biologists, geotechnical, chemical, civil and hydraulic engineers and support staff to successfully complete a variety of waste management projects.

Agency for Toxic Substances and Disease Registry 2407
1600 Clifton Rd., N.E. (MS F-38)
Atlanta, GA 30333
404/639-0708

The Agency for Toxic Substances and Disease Registry (ATSDR) is part of the Public Health Service and is based in Atlanta, Georgia. It was created by Congress to implement the health-related sections of laws that protect the public from hazardous substances.

Alliance Technologies Corporation 0301
213 Burlington Rd.
Bedford, MA 01730
617/275-9000

Alliance specializes on the investigative, diagnostic phases of environmental projects. The services we offer include: emission source characterization and quantification, health and ecological risk assessments, pollution control technology evaluation and design, site assessments and subsurface investigations, environmental audits for facilities, permitting and advanced modeling, health and safety plans, database design and management, and waste minimization and pollution prevention.

Alternative Systems, Inc. 2009
225 S. Cabrillo Hwy., Suite 124-C
Half Moon Bay, CA 94019
415/726-5700

TINIA is the most comprehensive hazardous materials liability management software designed for industry, State and Local, and Federal government. TINIA is written in a fourth generation language utilizing state of the art technology, integrated imaging, telephony, geographic information mapping, and systems integration. TINIA is platform independent. TINIA is a commitment to the environment.

American Colloid Company 2021
1500 West Shure Dr.
Arlington Heights, IL 60004
708/392-4600

American Colloid Company is the world's largest producer of bentonite clay and related products. ACC's Environmental Division manufactures Volclay bentonite for landfill lining, Bentomat seepage control liner and Sorbond waste solidification/fixation agents. The Water/Mineral Division will be showing the PureGold product line of Groundwater Monitoring products, which include environmentally safe bentonite grout, drilling fluid and tablets.

American Health & Safety, Inc. 0309
6250 Nesbitt Rd.
Madison, WI 53719
608/273-4000

American Health & Safety, Inc. is a nationwide

industrial safety supply house featuring a full line of on-the-job safety products. We have over 5,000 line items which are distributed throughout the safety industry, including asbestos, laboratory and food industries. American Health & Safety specializes in the hazardous materials and toxic waste disposal fields. We will be displaying gloves, respirators, coveralls, boots, safety glasses, tape, shovels, instrumentation and first aid used heavily in the hazardous materials industry.

American Industrial Marine Services 0224
1550 E. Patapsco Ave.
Baltimore, MD 21226
201/756-4200

American Industrial Marine Services LDC
1550 E. Patapsco Ave.
Baltimore, MD 21226
301/355-7600

American Industrial Marine Services specializes in Hazardous Waste Transportation, Tank Cleaning and Removal; Remedial Services; Emergency Spill Response; Decontamination Services; Industrial Maintenance, and Equipment and Materials Sales. Offices are located in NJ, MD, PA and NY. Call 1/800/762-4201 for more information.

American International Companies 0317
2005 Market St., Suite 2800
Philadelphia, PA 19103
215/981-7117

Meeting the insurance needs of industry by providing Environmental Impairment Liability, General Liability, Business Automobile Coverage, and Property Insurance, for companies in the environmental field, through experienced underwriting, comprehensive risk management, and dedicated claims handling.

American Laboratories & Research 0409
P.O. Box 15609
Hattiesburg, MS 39404
601/264-9320

Amoco Fabrics and Fibers Company 1710
900 Circle 75 Pkwy., Suite 300
Atlanta, GA 30339
404/956-9025

Amoco Fabrics and Fiber Company is the only manufacturer of both woven and nonwoven geotextiles. Nonwoven polypropylene fabrics ranging in weight from 3 to 20 ounces per square yard. Applications for geotextiles include geomembrane cushion, filtration, stabilization, erosion control, separation and reinforcement. Call (404) 984-4433 for information.

AnalytiKEM, Inc. 1008
28 Springdale Rd.
Cherry Hill, NJ 08003
609/751-1122

AnalytiKEM is a full services analytical laboratory network with facilities located in Cherry Hill, NJ, Rock Hill, SC, Houston, TX, and Wilmington, MA. AnalytiKEM's expertise includes environ-

mental analysis for NJ/ECRA and other real estate assessments, cleanup, Full RCRA characterization, NPDES permit compliance, groundwater monitoring and compatibility testing. AnalytiKEM utilizes state-of-the-art instrumentation including GC/MS and provides field sampling services.

Andco Environmental Processes, Inc. 0401
595 Commerce Dr.
Amherst, NY 14228
716/691-2100

Wastewater treatment systems to remove heavy metals, fluorides, phenol, and other organics from industrial wastewater, contaminated groundwater, and leachate. Also a portable heavy metal pilot unit.

Andersen Instruments, Inc. 0712
4801 Fulton Industrial Blvd.
Atlanta, GA 30336
404/691-1910

Andersen Instruments, Inc., is one of the world's foremost manufacturers of environmental monitoring and occupational health diagnostic instrumentation. Andersen equipment is known for protocol compliance, ease of use, and accuracy. Specifically featured will be EPA-approved remote air samplers, particulate impactors and ambient toxic gas analyzers. Call (800) 241-6898 for more information.

Aqua Tech Environmental Consultants, Inc. 2017/2019
181 South Main St., P.O. Box 436
Marion, OH 43302
800/783-5991

Aqua Tech Environmental Consultants, Inc. proves accurate and precise analytical data on a timely basis, at competitive prices, to industrial, governmental and private clients. Aqua Tech's services include complete capabilities for organic and inorganic analysis, bioassay/biomonitoring, sampling, and mobile laboratory analysis. Call (614) 382-5991 for more information.

Aqua-Chem, Inc. LDC
210 W. Capitol Dr., Box 421
Milwaukee, WI 53201
414/962-0100

Aquastream LDC
1115 North First St.
Garland, TX 75040
214/276-5690

Aquastream has recently expanded its innovative water well equipment product line to include a lab-certified pre-packed "Gravelwall Monitor Screen." The unique environmental well screen (available in stainless, PVC or Teflon), features a silica gravel-pack which is bonded directly to the screen itself, thus insuring uniform filtration with reduced drilling costs.

Art's Manufacturing & Supply 1112
105 Harrison at Oregon trail
American Falls, ID 83211
800/635-7330

AMS will be exhibiting their full line of soil

sampling equipment. AMS will be displaying for the first time, the new "PAT" dual valve liquid sampler. AMS will also be showing a video of the new AMS dual reel portable boom system for groundwater monitoring wells.

Associated Design & Manufacturing Co.   1114
814 N. Henry St.
Alexandria, VA 22314
703/549-5999

Associated Design provides suitable laboratory equipment for TCLP and liquid relase testing of solid waste. Featured products include the zero headspace extractor (ZHE) for collection of volatile contaminants, two bench-top filtration units, the new liquid relase test device, and large-capacity rotary agitators which hold bottles separatory funnels or ZHEs. Design and fabrication services are available. New products will be introduced at this conference.

ATLANTIC RESEARCH - ARC/ARCTECH   0110
1375 Piccard Dr.
Rockville, MD 20850
301/670-2000

ATLANTIC RESEACRH ARC/ARCTECH provides remedial technologies and consulting/ engineering services including: LARC Light Activated Reduction of Chemicals for PCB and Pesticide Destruction; OZO-DETOX - Ozonation for Destruction of Coal Tars and PAHs; COMPOSTING - Bioremediation of Organic Compounds and Explosives; INFORMATION/DATA MANAGEMENT; MONITORING/MODELING; SITE ASSESSMENT/SAFETY and TRAINING/EDUCATION.

B&V Waste Science and Technology Corp.   1505
4370 W. 109th St., Box 7960
Overland Park, KS 66211
913/339-2900

A Black & Veatch Company, BVWST provides complete hazardous waste management services, including RI/FS, design plans and specs, implementation oversight, RCRA services, regulatory and permit support, and litigation assistance. Other specialties include waste treatment, PCB transformer replacement, public health evaluations, facility closure services, environmental audits, and community right-to-know planning.

BAKER/TSA, Inc.   0808
420 Rouser Rd., Airport Office Dr., Bldg.3
Coraopolis, PA 15108
412/269-6000

Performance of: remedial investigation/feasibility studies; site assessments; risk assessments, remedial/closure design and management; RCRA permitting and compliance programs; industrial hygiene and asbestos management; economic analyses, waste utilization and market studies; tank management; waste minimization programs; water and wastewater treatment; environmental auditing; and air quality services.

BCM Engineers   2100
One Plymouth Meeting
Plymouth Meeting, PA 19462
215/825-3800

Quality engineering since 1890. Services include hazardous waste management and control; groundwater studies, geophysical surveys, remedial design engineering, Superfund site investigations, facility permitting, closure plans, real estate contamination assessments, asbestos surveys, and full-service laboratory.

BGI Incorporated   1811
58 Guinan St.
Waltham, MA 02154
617/891-9380

Manufacturer/distributor of air sampling equipment, negative air pressure monitors, and calibration equipment. Also available is a complete line of personal gas monitors, Draeger grab sampling/ dosimeter tubes and respiratory equipment. In addition, gas sampling bags of tedlar and teflon and gas bag filling pumps.

BNA Communications Inc.   LDC
9439 Key West Ave.
Rockville, MD 20850
301/948-0540

BNA Communications Inc. will display brochures on our new eight-module safety training program, WORKING IN THE HAZARD ZONE, plus brochures on our HANDLING HAZARDOUS WASTE program, and our safety catalog in the Literature Distribution Center.

BNA, INC.   2218/2220
1231 25th St., N.W.
Washington, DC 20037
202/452-4200

BNA Publishes regulatory, legal and working guides providing the latest information concerning the manufacture, transportation, safe handling and disposal of hazardous materials.

BOOZ, ALLEN & HAMILTON Inc.   1109
4330 East West Hwy.
Bethesda, MD 20814
301/951-2200

Booz, Allen & Hamilton Inc. is a leading technology and management consulting firm that has earned an outstanding reputation in environmental services through years of direct involvement developing and implementing key programs for government and industry world-wide. The firm has worked with the Superfund and RCRA programs since their inception and offers comprehensive mission and program-related expertise. Technology and management services include: risk management; audits and technical evaluations; regulatory enforcement and policy support; records management; information system development; and program planning, implementation, and evaluation.

Barnebey & Sutcliffe Corporation   0903
835 N. Cassady Ave.
Columbus, OH 43219
614/258-9501

We manufacture activated carbons made from coconut shell, coal and wood. Granular, pelletized and powder forms available. Carbon regeneration service is offered by our factory in Columbus, Ohio. We offer custom package systems for solvent recovery, VOC emission control and wastewater treatment applications.

Beazer Environmental Services, Inc.   LDC
436 Seventh Ave.
Pittsburgh, PA 15219
412/227-2198

Beazer Environmental Services, Inc., offers a full range of environmental construction and remediation services to customers on a world-wide basis. We can provide complete engineering and design, project management and construction services for groundwater and wastewater treatment plants, RCRA/CERCLA closures, and bioremediation projects.

Bergen Barrel & Drum Company   1815/1915
43-45 O'Brien St.
Kearny, NJ 07032
201/998-3500

An innovative line of polyethylene drums, both open and closed head, tanks and environmental products specifically designed for the hazardous waste industry. Various sized drums and tanks along with pallets, overpacks and other products will be displayed.

Betz Laboratories   1913
9669 Grogans Mill Rd.
The Woodlands, TX 77380
713/367-6201

Betz Analytical Services offers complete environmental testing. We provide accurate timely data using the latest, automated instrumentation. Our facilities located in Houston and Philadelphia follow strict QA/QC programs to meet your testing needs. We participate in the EPA Contract Laboratory Program (CLP).

Bioscience Management, Inc.   0319
1530 Valley Center Pkwy.
Bethlehem, PA 18017
215/974-9693

Your best single stop for bioremedial supplies and services for cleaning up soil, sludge, groundwater and wastewater. We manufacture and market automated laboratory treatability and waste characterization instruments, microbial cultures, packaged groundwater biotreatment units and biostimulation chemicals. We furnish treatability studies, process engineering, site monitoring and trouble shooting, and turnkey bioremedial programs.

Biospherics Incorporated   1512
12051 Indian Creek Ct.
Beltsville, MD 20705
301/369-3878

Biospherics Incorporated has serviced asbestos

related and industrial hygiene needs for years, therefore, knowledgeable of technical and operational requirements of such programs. Comprehensive services are provided including consulting, visual and physical inspections, bulk sampling, analysis, training, program management/development, risk assessment and abatement prioritization, lead paint and PCB investigation and remediation.

Brown and Caldwell Consultants   1124
3480 Buskirk Ave.
Pleasant Hill, CA 94523-4342
415/937-9010

Brown and Caldwell Consultants is a nationwide multidisciplinary environmental consulting firm, providing complete project services for hazardous waste, water, wastewater, and solid waste. Services include RI/FS, regulatory compliance, permitting, design, engineering, remediation, air and water quality, laboratory services, project and construction management.

Burlington Northern Railroad   LDC
3700 Continental Plaza, 777 Main St.
Fort Worth, TX 76102
817/878-2168

Burlington Northern Railroad Company operates the largest railroad system in the United States. Its main lines runs through 25 states and 2 Canadian Provinces. It moves raw materials and finished products to over 4,000 communities nationwide. In addition, it serves ports in the Pacific Northwest and the Gulf of Mexico.

**CALGON CARBON
CORPORATION**   1105
P.O. Box 717
Pittsburgh, PA 15230
412/787-6700

Calgon Carbon Corporation supplies activated carbon products, systems and services, and airstrippers to remove soluble and volatile organic chemical compounds from contaminated groundwater, surface water or wastewater.

**CDM/Federal Programs
Corporation**   2016
13135 Lee Jackson Memorial Hwy.
Suite 200
Fairfax, VA 22033
703/968-0900

CDM Federal Programs Corporation provides environmental consulting services to the federal government, including: environmental assessments, site investigations, sampling and analysis, feasibility studies, risk assessments, environmental impact statements, groundwater modeling, GIS and CADD computer modeling, health and safety plans, community relations planning, operations/maintenance and underground storage tank remediation services.

CEA Instruments, Inc.   0306
16 Chestnut St.
Emerson, NJ 07630
201/967-5660

CEA Instruments, a leading supplier of hazardous gas detection instrumentation since 1972, will be exhibiting a new portable Landfill Gas Analyzer

for CO_2 and CH_4, portable and wall mounted CO_2 analyzers, and other units for monitoring toxic gases, combustible gases and oxygen levels in portable, single and multichannel fixed systems.

**CEIMIC
CORPORATION**   2215/2217/2219
100 Dean Knauss Dr.
Narragansett, RI 02882
401/782-8900

Ceimic, an employee-owned full-service environmental laboratory, provides analytical support nationwide to both industry and government. Ceimic specializes in rapid turnaround services and our ability to produce quality data is evidenced by participation in EPA's Contract Laboratory Program (CLP), DOD's HAZWRAP and NEESA programs, and multi-state certifications. The laboratory facility and instrumentation are state-of-the-art and they are complemented by a staff of over 60 environmental professionals.

CH2M HILL, INC.   0510/0512
P.O. Box 4400
Reston, VA 22090
703/471-1441

CH2M HILL provides waste management services - including design, construction, investigation, and planning - to industry and government. We are the largest environmental engineering firm in the United States, with 4,500 employees in 60 offices worldwide. Over a third of our business is managing hazardous, radioactive, and solid waste.

The CHEMTOX^R System   2117
P.O. Box 1848
Brentwood, TN 37024-1848
615/373-5040

The CHEMTOX^R System provides software (The CHEMTOX Database, MSDS ACCESS^R, and DocuWaste™ for Hazardous Waste) for retrieval and documentation of chemical data needed for safety and health environmental, emergency response, and transportation decisions. It will produce needed management reports, record inventories, employee exposures, create material safety data sheets, departmental reports, and track chemical processes and waste through disposal. Updated quarterly, users are provided the most current chemical and physical data. All records are variable length and accept any alphanumeric character combination. CHEMTOX and MSDS ACCESS are registered in the U.S. Trademark & Patent Office. DocuWaste is a trademark of Resource Consultants, Inc.

**COMPUCHEM
LABORATORIES, INC.**   2110/2112
3308 Chapel Hill/Nelson Hwy.
Research Triangle Park, NC 27709
919/549-8263

CompuChem Laboratories, Inc., a full service organic and inorganic laboratory, specializes in CERCLA, RCRA, DIOXIN, PRIORITY POLLUTANT and WASTE CHARACTERIZATION ANALYSES following the new TCLP regulations. In 1990 CompuChem has expanded its analytical services to include low level RADIOLOGICAL and MIXED WASTE ANALYSES. CompuChem's Environmental Site Profile (ESP),

a proprietary data management system, provides on-line access to test results which can be downloaded to your personal computer. For forensic quality data and expedited turn-around times, visit the staff of CompuChem Laboratories at booths 2110 and 2112.

Camp Dresser & McKee, Inc.   2014
One Cambridge Center
Cambridge, MA 02142
617/621-8181

Camp Dresser & McKee, Inc., (CDM) provides environmental engineering and consulting services to government and industry for the management of hazardous and solid wastes, wastewater, and water resources. Waste management services include remedial design, site assessments, environmental audits, RCRA compliance, treatment facility design and operation, and groundwater modeling and restoration.

Canadian Hazardous Materials Mgmt.   LDC
12 Salem Ave., Suite 200
Toronto, Ontario, Canada M6H 3C2
416/536-5974

**Canonie Environmental
Services Corp.**   1017
800 Canonie Dr.
Porter, IN 46304
219/926-8651

Comprehensive design and construction services for the remediation of sites contaminated by hazardous wastes. Principal services include, but are not limited to, soil remediation (thermal treatment and in situ), groundwater restoration, landfill and lagoon closure, removal actions, slurry walls and facility decommissioning. Complimentary services include engineering design and analytical services.

Carbonair Services, Inc.   2419
8530 35th St., South
Minneapolis, MN 55343
612/935-1844

Carbonair Services, Inc. provides technology and treatment plants for the decontamination of water, soil and air. Services provided include carbon adsorption, airstripping, inorganic and biological pretreatment, soil venting, and other decontamination technologies. Carbonair can provide whatever level of assistance needed to complete the project. Systems may be purchased or rented.

Caswell, Eichler and Hill, Inc.   LDC
One Harbour Pl., Suite 300
Portsmouth, NH 03801
603/431-4899

CEH is a full-service hydrogeological consulting firm with extensive experience and capability in contaminated industrial site characterization and remediation and water supply development. We are a firm of professionals specializing in geology, hydrology, geophysics and remediation engineering, who provide expert consulting services to private industry, governmental agencies and large contractors. Our services focus on solving the complex problems associated with the use, protection, management and cleanup of ground and surface water resources.

ChemCycle Corporation 1311
129 South St.
Boston, MA 02111
617/451-0922

ChemCycle Corporation is an engineering and design consulting firm that specializes in solving industrial hazardous waste and environmental problems. We offer services in process engineering, environmental controls, waste minimization, site assessments, compliance audits, permitting, site remediation and construction management.

Chemfix Environmental Services 0106
2424 Edenborn Ave., Suite 620
Metairie, LA 70001
504/831-3600

Chemfix Environmental Services offers the patented Chemfix^R process for treatment of sludges and high solids wastes. Complete mobile services are offered, as well as fixed plant facilities. CES services include site assessment, waste stream characterization and permitting support.

Chemical Waste 2207/2209
Management, Inc. 2211/2213
3001 Butterfield Rd.
Oak Brook, IL 60521
708/218-1500

Chemical Waste Management, Inc., is America's complete Hazardous Waste Manager. Our full range of services includes: Water Reduction Services, Resource Recovery, Site Remediation, Treatment, Transportation, Disposal, Incineration, Secure Landfill, Asbestos Abatement and Advanced Technologies for On-Site Soil Remediation and Wastewater Treatment and Recovery. Call Toll-free: 1-800-843-3604 for more information.

Clark Boardman Company, Ltd. LDC
375 Hudson St.
New York, NY 10014
212/929-7500

Clark Boardman Company is proud to offer its acclaimed Environmental Law Library. Designed to save hours of research time for busy practitioners and industry professionals, the library provides detailed analysis of the law - and expert guidance. We understand that ensuring compliance with today's environmental laws is your first priority.

Clayton Environmental
Consultants, Inc. 0101
1252 Quarry Ln., P.O. Box 9019
Pleasanton, CA 94566
415/426-2600

Since 1954, a recognized leader in the field of environmental consulting with broad-based capabilities in the areas of environmental engineering, industrial hygiene, asbestos management, indoor air quality, and laboratory analysis. Clayton has 11 offices and six laboratories throughout the U.S., Canada and the United Kingdom. The Michigan facility is an EPA CLP laboratory.

Clean Air Engineering Inc. 1616-1617
500 West Wood St.
Palatine, IL 60067
708/991-3300

Clean Air Engineering: Clean Air Engineering is

a full service environmental consulting firm, offering its industrial and municipal clients a wide range of services. These include air quality monitoring (EPA Methods 1-25, Multi-metals, VOST/MM5), trial burn assistance, mobile analytical laboratory services, environmental audits, flow modeling, environmental software design, temporary environmental professionals, design engineering, instrumentation rental and training seminars. CAE Instrument Rental: The leader in portable HazMat instrumentation, including PIDs, FIDs, O$_2$/LELs, Sample Pumps, Aerosol Monitors, Met Equipment, PUFs, etc. All available for short or long term rental featuring our "10 Day Week." Introducing a new product this year, the ADC LFG 10 for landfill gas analysis. Those of you who know who you are, stop by and say hi. Those of you who don't, come on by and get acquainted.

Clean Sites, Inc. 0910
1199 North Fairfax St., #400
Alexandria, VA 22314
703/739-1209

Clean Sites is a non-profit organization founded in 1984 to accelerate hazardous waste cleanup. We help parties at sites with: cost allocation; dispute resolution; technical assistance; quality assurance; and managing site studies and cleanups. We also work with government agencies to develop effective hazardous waste programs and conduct independent policy analyses.

Clem Corporation
(James Clem Corp.) 0216
444 North Michigan Ave., Suite 1619
Chicago, IL 60611
312/321-6255

The James Clem Corporation manufactures CLAYMAX®, an impermeable clay liner made with the world's highest quality sodium bentonite. It combines the durability of a woven geotextile fabric with the impermeability of a pound per square foot of sodium bentonite. The liner can be used as a primary or secondary liner in landfills and landfill caps, tank farm secondary spill containment and various applications in the mining industry.

Consolidated Rail Corporation 2513
Room 919 - One Liberty Place
Philadelphia, PA 19103-7399
215/851-7281

Conrail is one of the largest freight railroad systems in the Northeast-Midwest quarter of the United States, operating over a network of approximately 13,100 route miles. Conrail is a licensed and registered transporter of hazardous waste and sixty percent of all Superfund sites are located within its territory. Conrail works closely with connecting rail carriers, trucking, and equipment companies to offer reliable transportation services.

Corroon & Black Env'l
Insurance Svs. 2221
6510 Grand Teton Place, #102
Madison, WI 53719
608/833-2887

Cousins Environmental Services 0414
1800 Matzinger Rd.
Toledo, OH 43612
419/726-1500

A complete environmental contractor. Specializing in contaminated site remediation, we have extensive experience in bioremediation of soil contaminated with both hazardous and non-hazardous materials. In addition, we have designed and operated biological systems for pretreatment of industrial waste. Cousins' staff of over 100 are experienced in UST removal, site assessments, and specialized waste treatment and removal.

Curtis & Tompkins, Ltd. 0710
2323 Fifth St.
Berkeley, CA 94710
415/486-0900

Curtis & Tompkins Laboratories. Analytical services since 1878. Environmental, Industrial Hygiene and Air Analyses. For analytical services, look to Curtis & Tomkins - the complete laboratory offering customized reports, data management, and electronic data transfer to ensure complete, accurate and timely results for your projects.

DartAmerica 1212
61 Railroad St.
P.O. Box 89
Canfield, OH 44406
216/533-9841

A group of companies dedicated to the transportation of hazardous waste and general commodities in 48 states utilizing dumps, roll-offs, vans, flatbeds, pneumatic and liquid tank equipment, and LTL van service.

DataChem Laboratories 2214
960 West LeVoy Dr.
Salt Lake City, UT 84123
801/266-7700

Serving the analytical chemistry support sectors since 1971, DataChem Laboratories is now one of North America's largest and most experienced providers of laboratory services. The highly specialized tests performed by DataChem Laboratories are designed to assist clients in the evaluation of industrial hygiene and environmental issues.

Davy Environmental 0503
2430 Camino Ramon
San Ramon, CA 94583
415/866-1166

Davy Environmental draws upon Davy's worldwide technologies and project execution capabilities to provide comprehensive consulting, engineering, design and construction management services. These services include: remedial investigations/feasibility studies; treatment systems design; remediation of contaminated soils, water and air; waste encapsulation, isolation and incineration; and facility closure monitoring.

Dexsil Corporation 0102
1 Hamden Park Dr.
Hamden, CT 06517
203/288-3509

Dexsil Corporation provides environmental field

testing kits that detect environmental contaminants. Dexsil's field test kits are quick, easy to use, and afford the user an economical advantage over costly and time-consuming laboratory services. Dexsil's test kits detect total halogens (chlorine) in waste oils, total organic halogens in oil/water mixtures, and PCBs in transformer oil and soil.

Donohue & Associates, Inc. 1513
4738 North 40th St.
Sheboygan, WI 53083
414/458-8711 x2222

Donohue is an ARCS contractor with a nationwide staff of over 1,000 and a 1990 ENR ranking of 72. Our environmental scientists and engineers are specialists in waste management, disposal and cleanup. Donohue's hazardous waste services include RCRA investigations and compliance monitoring, RI/FS studies, and engineering of remedial cleanup actions.

Du Pont Company 2104/2106
1007 Market St., EA, NA-228
Wilmington, DE 19898
302/774-7248

Du Pont Safety and Environmental Resources will exhibit its Environmental Remediation Service which provides the treatment of contaminated soil and groundwater. In addition, the Du Pont Waste Management offering will be exhibited, providing state-of-the-art, in-compliance treatment and disposal services and environmental consulting to industry.

Dunn Geoscience Corporation 1415
12 Metro Park Rd.
Albany, NY 12205
518/458-1313

Full Service Environmental Consultants: Complete staff of hydrogeologists, geologists, environmental specialists and engineers, toxicologists, and regulatory experts provides a range of services including RI/FS and RCRA Corrective Actions, Remedial Design and Construction Management, Toxicology/Public Health Assessments, Hazardous Waste Planning and Management, Hydrogeologic Investigatory Services and Property Transfer Environmental Site Assessments.

Dynamac Corporation 0812
Dynamac #2 Bldg.
11140 Rockville Pike, Third Floor
Rockville, MD 20852
301/230-6117

Dynamac is a full service environmental firm. We are specialists in integrating expertise in environmental regulations and technology with the latest in information management techniques. Our services include preliminary site and risk assessments, RI/FS and remedial design activities, management of removal and remedial action efforts, program management, as well as community relations and public outreach activities.

Dynamic Graphics 1501
7201 Wisconsin Ave., Suite 640
Bethesda, MD 20814
301/656-3060

Dynamic Graphics provides advanced software

tools for the modeling, analysis and display of 2-dimensional and 3-dimensional phenomena in the earth, water and air. Applications include plume modeling and monitoring, particle dispersion, site characterization and remedial evaluations. Geoscience disciplinary fields include geology, hydrology, geochemistry and meteorology.

EA Engineering, Science & Technology, Inc. 0612
11019 McCormick Rd.
Hunt Valley, MD 21031
301/584-7000

EA is a nationwide, multidisciplinary professional services consulting firm providing a wide range of engineering, scientific, analytical and remediation capabilities to address existing and potential threats to the environment and to human health and safety. EA develops solutions for waste management, energy conservation and emissions control, and indoor air quality.

EBASCO Environmental 0504/0506/0603/0605
160 Chubb Ave.
Lyndhurst, NJ 07071
212/839-2744

Ebasco Environmental, a division of Ebasco Services Incorporated, provides a wide range of environmental and waste remediation services to industry and government clients. Services include remedial assessments/investigations, feasibility studies, remedial designs and corrective actions; a broad range of environmental and risk assessment and remediation consulting services; design and construction of quality management and control systems; and comprehensive licensing and permitting services.

ECOFLO, Inc. 2208
8520-M Corridor Rd.
Savage, MD 20763
301/498-4550

ECOFLO provides answers to client-specific waste management needs from our extensive offering of services, including: Waste Characterization; Collection, Transportation and Treatment/Disposal of Most Wastes; Lab Pack Services; Remediation and Cleanup Services; Waste Minimization Advice. ECOFLO serves the Mid-Atlantic region from offices in Maryland and North Carolina.

ECOVA Corporation 2310
3820 159th Ave., N.E.
Redmond, WA 98052
206/883-1900

ECOVA solves hazardous waste problems with technologies for on-site remediation: Bioremediation, In Situ Treatment, Soil Washing, Incineration. ECOVA has cleaned up more than 800,000 cubic yards of soil and millions of gallons of water using bioremediation. Integrated science, technology, and engineering expertise provides successful technology dvelopment and field remediation.

EIMCO Process Equipment Co. 1804/1806/1808/1810
P.O. Box 300
Salt Lake City, UT 84110
801/526-2000

EIMCO supplies a complete line of liquid-solids separation and dewatering equipment, including cost-effective bioremediation for treating hazardous wastes. Bioremediation offers lower energy costs than conventional systems, and is able to biodegrade organic slurries of 30-50 WT. % solids concentration.

EMPIRE SOILS INVESTIGATIONS, INC. 1015
140 Telegraph Rd., P.O. Box 250
Middleport, NY 14105
716/735-3502

Empire Soils Investigations, Inc., along with its laboratory division, Huntington Analytical Services, and its wholly owned subsidiary, Asteco, Inc., provides the following services: contract drilling and installation of groundwater monitoring wells, geotechnical testing including contaminated soils, geotechnical engineering, chemical analytical testing, asbestos inspection and testing, and materials engineering and testing.

ENCYCLE/TEXAS, INC. 0802/0804
5500 Up River Rd.
Corpus Christi, TX 78407
512/289-0035

Encycle/Texas is a Part B permitted waste recycling facility with the capabilities of processing as well as recovering heavy metals from solids, liquids, sludges, waste streams. Also, we process acids, bases, sulfides and hexavalent chromium.

ENRECO, Inc. 1611-1613
P.O. Box 9838
Amarillo, TX 79105
806/379-6424

ENRECO, Inc. uses a combination of basic chemistry and specialized equipment to stabilize the hazardous constituents within a waste matrix. ENRECO consists of four operating groups; Laboratories, Engineering, Technologies, and Operations. The four groups provide a wealth of experience which is used to design innovative, yet economical, remedial plans, navigate through the regulatory maze, and complete the construction in a timely and proficient manner.

ENSCO, Inc. 0410-0412, 0509-0511
333 Executive Ct.
Little Rock, AR 72205
813/289-5600

ENSCO provides integrated hazardous waste management services to private industry, public utilities, and government entities. These services include chemical analysis, collection, transportation, processing, and incineration of hazardous waste.

ENTROPY Environmentalists, Inc. 1125
P.O. Box 12291
Research Triangle Park, NC 27709
919/781-3550

ENTROPY Environmentalists, Inc., provides the

most comprehensive air emissions testing services nation-wide. In business since 1972, ENTROPY is the specialist for Trial Burns, VOCs, RCRA/TSCA, SARA, CEM, Particulates, POHCs, and Criteria Pollutant testing. Call Pete Watson for further information at (919) 781-3550.

ENVIROCARE OF UTAH, INC.　　　LDC
215 South State, Suite 1160
Salt Lake City, UT 84111
801/532-1330

ENVIROCARE is the country's first licensed disposal facility for naturally occurring radioactive material (NORM). ENVIROCARE has recently received a permit to dispose of hazardous (RCRA) radioactive waste. Our facility location and design are the result of long-term environmental planning. Transportation options for shipment to ENVIROCARE include rail and highway.

ENVIRONMENT TODAY　　　0113
1905 Powers Ferry Rd. #120
Marietta, GA 30067
404/988-9558

ENVIRONMENT TODAY - the Newsmagazine of Environmental and Pollution Control.

Environmental Audit, Inc.　　　0701
717 Constitution Dr.
Hankin Bldg., Ste. 101
Exton, PA 19341
215/458-1122

Environmental Audit, Inc. is an environmental information and education company. EAI provides parties to real estate transactions and their consultants with EPA and state environmental agency records organized on a database for use with real estate assessments and audits. EAI also provides education and training for use of these records.

ENVIRONMENTAL PROTECTION Magazine　　　1809
225 N. New Rd.
Waco, TX 76710
817/776-9000

ENVIRONMENTAL PROTECTION magazine reaches more than 90,000 buyers of environmental and pollution control products and services. OCCUPATIONAL HEALTH & SAFETY reaches more than 80,000 buyers of occupational health, safety and hygiene products and services.

ENVIRONMENTAL PROTECTION SYSTEMS　　　1812
3800 Concorde Pkwy., Suite 2100
Chantilly, VA 22021
703/631-2411　　　.

Environmental Protection Systems (EPS) is a rapidly growing engineering, industrial hygiene and analytical firm that has been providing environmental consulting services to government and industry for over 17 years. With eight offices nationwide, EPA has developed an outstanding reputation for providing quality engineering in hazardous waste assessments and site investigations; RI/FS development; spill response planning and mitigation; real estate audits; facility permitting and design; asbestos management and abatement supervision and analytical services.

ERCE　　　1813
3211 Jermantown Rd.
Fairfax, VA 22030
703/246-0440

ERCE is a professional and technical services company that offers environmental, infrastructure and energy consulting and engineering services to industrial and commercial companies, electric utilities and governmental agencies. Engineering, design and environmental science services are supported by four EPA-accredited analytical laboratories strategically located throughout the U.S.

ERM Group, The　　　2018-2020
855 Springdale Dr.
Exton, PA 19341
215/524-3500 ˙

The ERM Group, a full-service environmental consulting firm with more than 50 offices worldwide, provides the following services: site remediation; hydrogeology; hazardous/solid waste management; management consulting; industrial/municipal water and wastewater treatment; underground tank management; environmental science; air pollution control; computer sciences; construction management; and health, safety and toxicology.

Eagle-Picher/Environmental Services　　　1119
36 B.J. Tunnell Blvd. East
Miami, OK 74354
918/540-1507

Precleaned and certified, glass and plastic sample containers to EPA specifications. Documentation of quality control and chain of custody with each container. Complete line of clear or amber glass and high density polyethylene in a variety of styles and sizes. Also offering various ampule preservatives. Free sample reference guide. For more information, call our toll-free number: 800-331-7425.

Earth Resources Consultants, Inc.　　　2417
1227 Marshall Farms Rd.
Ocoee, FL 34761
407/877-0877

Earth Resourses Consultants (ERC) is a full-service hazardous materials management firm specializing in the containment, treatment, and removal of all types of hazardous materials. ERC has a highly trained professional and technical staff experienced in the design and implementation of innovative solutions to today's waste problems. ERC's capabilities include but are not limited to soil, groundwater, facilities, containerized wastes and pressurized gas cylinders.

Earth Technology Corporation, The　　　1605/1607
100 W. Broadway, Ste. 5000
Long Beach, CA 90802
213/495-4449

As one of the nation's leading environmental, earth sciences and geotechnical consulting firms, The Earth Technology Corporation's primary business activities include: Waste Management and Environmental Services, Critical Facilities Siting, Related Advanced Technology and Testing Services, and Asbestos and Air Quality Management. Founded in 1970, our staff of 500 expert hydrogeologists, geologists, engineers, environ-

mental scientists, chemists and managers in 15 offices nationwide work to deliver superior technical solutions for government and private industry. Visit booths 1605 and 1607 for more specific capability information.

EcoTek LSI　　　2114
3342 International Park Dr.
Atlanta, GA 30316
404/244-0827

Full service environmental laboratory with multiple state certifications. EPA CLP participant. 8,000 ft^2 chemical laboratory, 16,000 ft^2 radiological laboratory. EcoTek LSI provides analyses of full organics and inorganics, and some R & D. EcoTek LSI's radiological laboratory provides analyses on hazardous wastes, mixed wastes, drinking water, solid wastes, and other toxic materials.

Ecology and Environment, Inc.　　　2103/2105
　　　2107/2109
Buffalo Corporate Center
368 Pleasantview Dr.
Lancaster, NY 14086
716/684-8060

Ecology and Environment, Inc., provides the complete range of scientific and engineering consulting services required by generators, storers, transporters, and disposers of hazardous, toxic, infectious, radioactive and solid wastes. The firm has offices from coast-to-coast and is represented around the globe. A broad spectrum of environmental assessment and pollution control services are also provided including emergency spill response, asbestos removal management, hazards and risks analysis, and analytical laboratory and testing services.

Ejector Systems, Inc.　　　0902/0904/0906/0908
910 National Ave.
Addision, IL 60101
708/543-2214

Ejector Systems, Inc., manufactures pumping and treatment systems for contaminated groundwater and leachate.

Engineering News-Record (ENR)　　　1711
1221 Avenue of the Americas
New York, NY 10020
212/512-3132

Engineering News-Record (ENR), McGraw-Hill's building and construction newsweekly, reports on every segment of the marketplace: buildings, transportation projects, water and power, the environment, and more. Over 416,000 decision-makers rely on ENR for the business and technical news they need to compete in the world's largest industry.

Engineering-Science　　　2204/2206
75 North Fair Oaks Ave.
Pasadena, CA 91103
818/440-6101

Engineering-Science (ES) is a full service, national and international environmental engineering firm providing complete services in hazardous waste management. With offices in 27 domestic locations, ES is active in supporting industrial and military clients in all phases of site/remedial investigations, feasibility studies, remedial action

plan preparation, site cleanup/closure and post-closure activities.

**Enviro-Tech Management
Consulting** 1713
7120 Wyoming N.E.
Albuquerque, NM 87109   505/828-9885

Enviro-Tech is a full service management consulting firm that specializes in acquisitions, mergers, source funding, certified business valuation and search & recruitment primarily for the environmental industry. Give us your requirements for a corporate candidate and let us put our highly qualified personnel to work. (Offices nationwide) For information call 1-800-873-4280.

The EnviroMed Companies, Inc. 0602
414 West California Ave.
Ruston, LA 71270
318/255-0060

The EnviroMed Companies, Inc. (EMC), is a multidisciplinary environmental engineering, consulting and testing firm founded in 1974. EMC Personnel include engineers, geologists, chemists, biologists, toxicologists and industrial hygienists who provide turnkey solutions to groundwater, hazardous waste, effluent discharge and industrial hygiene problems. EMS routinely designs and installs hazardous waste/groundwater remediation systems. EMC owns three full-service laboratories operating GC/MS, GC, ICP, AA, HPLC and other state-of-the-art instrumentation. Call NATIONWIDE 1-800-256-4362.

Environmental Careers 0311
760 Whalers Way, Suite 100-A
Fort Collins, CO 80525
303/229-0029

ENVIRONMENTAL CAREERS magazine is dedicated to the human resources needs of the environmental industry. Each issue features advertising for environmental employment opportunities and training programs, a professional education calendar, and timely career and training articles written by industry experts. Also on display are ENVIRONMENTAL LAB and ASBESTOS ISSUES magazines.

**Environmental Chemical
Associates, Inc.** 0226
5118 Highway 33 & 34
Farmingdale, NJ 07727
201/938-3010

Waste Management Services: Waste Characterization, Laboratory Analysis, Facility Approval, Transportation, Documentation, Disposal. Technologies available include Recycling, Fuels Blending, Incineration, Treatment, Stabilization, Secure Landfill. Services also include: Lab Packing, Site Remediation and Consulting.

**Environmental
Company, Inc., The** 1606
P.O. Box 5127
1230 Cedars Court, Suite 100
Charlottesville, VA 22905
804/295-4446

The Environmental Company (TEC) is a multi-disciplinary environmental consulting company providing services to DOD, civilian agencies, and private clients. TEC offers the full range of environmental disciplines: engineering, environmental, physical science, asbestos, health and safety, as well as construction management in support of environmental projects.

**Environmental Compliance
Services, Inc.** 0302
One East Uwchlan Ave., Suite 300
Exton, PA 19341
215/269-6731

ECS is an organization dedicated to assisting environmental companies with their insurance, safety, and compliance needs through the unique combination of in-house expertise in environmental regulation, risk management, and insurance underwriting. ECS is the only company in the country to provide an exclusive program of insurance for companies facing an environmental exposure.

Environmental Directory, The 2415
60 E. Chestnut, Suite 415
Chicago, IL 60611
708/671-5853

The Environmental Directory is a nationwide company which publishes Regional Environmental Directories. The Environmental Directory is a Single-source Directory of hundreds of companies offering a variety of Environmental Products and Services ranging from Air Consultants to Waste Minimization. Directories are currently available for the Midwest, Eastern Seaboard, Southern California, Northern California, Southwest, Pittsburgh, and the Pacific Northwest, with more to come.

**Environmental
Instruments, Inc.** 0313/0315
2170 Commerce Ave., Unit S
Concord, CA 94520
415/686-4474

Environmental Instruments Co. (EI) sells and rents equipment specifically designed to meet the needs of the environmental industry - specializing in innovative equipment for water, soil and air treatment, sampling and monitoring. We will be demonstrating our vapor extraction blower and vapor treatment system, a catalytic incinerator, new photo-ionization detector and new flame-ionization detector. For more information, call our toll-free number: (800) 648-9355.

**Environmental Science &
Engineering, Inc.** 2118/2120
P.O. Box 1703
Gainesville, FL 32602-1703
904/332-3318

ESE offers comprehensive in-house services in Toxic and Hazardous Materials Control; Environmental Engineering; Analytical Services; Industrial Hygiene/Safety; Geosciences; Surface and Groundwater Monitoring; Air Resources; Asbestos Management; Biosciences; Risk Assessment; Underground Storage Tank Management; Environmental Audits; Planning and Permitting; and Public/Community Relations.

Environmental Technology, Inc. 0608
3705 Saunders Ave.
Richmond, VA 23227
804/358-5400

HazWaste Industries Incorporated and its operating subsidies (Environmental Technology, Environmental Risk Sciences, Bionomics and HazLabs) provide a full range of environmental services: Site Investigations, Inspections and Audits; Risk Assessments; Feasibility and Treatability Studies; UST Closures; Facility Decontamination and On-Site Treatment; Site Remediation, Emergency Response and Removal; and Long-Term Monitoring. HazWaste provides complete, quality and cost-effective solutions to its clients' environmental problems.

Envirosafe Services, Inc. 2122/2123
P.O. Box 167571
Oregon, OH 43616-7571
419/255-5100

Envirosafe Services, Inc. provides cost effective, proven waste management services to generators of hazardous and industrial waste materials. Federal Part B awarded waste management facilities in Idaho and Ohio conveniently service the entire nation via truck or rail transportation. Envirosafe specializes in secure disposal, chemical stabilization and PCB management services. Envirosafe offers economical, environmentally sound waste management for a wide variety of hazardous and industrial waste materials.

Envirotrol, Inc. 0711
P.O. Box 61, 432 Green St.
Oregon, OH 43616-7571

Envirotrol is a nationwide full service activated carbon company. We provide carbon reactivation, and adsorption systems for wastewater, groundwater, air purification, solvent recovery, and process applications. We also offer virgin carbon, bulk transportation. We serve hazardous, non-hazardous, liquid, and vapor phase applications.

Exxon Chemical Company 1303
P.O. Box 4321
Houston, TX 77210-4321
713/460-6826

Exxon Chemical Company offers a complete line of products and application expertise specifically for waste-water treatment. Of particular interest are Diklor® chlorine dioxide products for organic contaminate destruction of phenols, mercaptans and sulfides.

Fenn-Vac, Inc. 2022
P.O. Box 62679
North Charleston, SC 29419-2679
803/552-8306

Fenn-Vac, Inc., offers Tank Cleaning and Decontamination; Tank Removal and Disposal; Lagoon Closure; Filter Press Dewatering Systems; Transfer, Transport and Disposal of Bulk Liquids/Sludge; Excavation and Removal of Waste Solids; Surface and Subsurface Product Recovery; Treatment of Contaminated Groundwater; Permitted

Hazardous Waste Transporter; Emergency Response Actions; Remediation of Hazardous Waste Sites; and Total Capability in Hazardous and Non-Hazardous Environments.

First Environmental Laboratories   0111
#2 Stewart Ct.
Denville, NJ 07834
201/328-3900

First Environmental Laboratories - complete analytical services for soil, air, water - NPDES, RCRA, drinking water, Superfund TLC - 19,000 square foot facility - state of the art instrumentation used by professional, experienced staff.

Fluor Daniel, Inc.   1014/1016
3333 Michelson Dr.
Irvine, CA 92730
714/975-6000

Fluor Daniel offers a broad range of environmental services including new facility support (permitting air emissions, wastewater treatment), regulatory compliance (audits, UST), and remediation services (RI/FS, Remedial Design, Remedial Action), which is backed by full engineering, construction, project management and maintenance experience.

Forestry Suppliers, Inc.   1315
P.O. Box 8397
Jackson, MS 39284-8397
601/354-3565

Environmental equipment catalog company displaying soil recovery augers and probes, groundwater/surface water sampling and testing equipment, safety wear for workers exposed to hazardous wastes, surveying/engineering instruments and supplies - and more! Sign up for our free 420-page catalog.

**Foster Wheeler
Enviresponse, Inc.**   2203-2205
8 Peach Tree Hill Rd.
Livingston, NJ 07039
201/535-2378

Foster Wheeler Enviresponse, Inc. is a full services environmental engineering, consulting, and remediation company. Principal services include regulatory compliance know-how, environmental technical assistance, remedial design capabilities and remedial action. The company has an outstanding and well-trained professional staff experienced in site investigations, environmental audits, permitting, risk assessments, remedial investigations, feasibility studies, technology evaluations, sampling, closure plans, wastewater treatment, air pollution control, and remedial designs as well as site cleanups.

**Four Seasons Industrial
Services, Inc.**   2509/2511
4920 Old Pineville Rd.
Charlotte, NC 28217
704/527-1293

Full service environmental construction company with capabilities in industrial services, tank services, on-site treatment systems, emergency re-

sponse, remedial services and transport tanker cleaning. To offer these capabilities, the company has developed the following technologies: groundwater treatment utilizing air strippers; contaminated soil treatment using vacuum extraction; bio-remediation; stabilization; design and construction of secondary tank containment systems and thermal volatilization and destruction of VOC-contaminated non-hazardous soils.

The Foxboro Company   2404/2406
Foxboro, MA 02035
508/543-8750

Instrumentation for providing quantitative and qualitative information on hazardous waste and spill site contaminants. The Foxboro CENTURY Organic Vapor Analyzer (OVA) can be used to detect areas of high vapor concentration, identify and determine concentration levels of various organic compounds and provide rapid, reliable screening/analysis of volatile hydrocarbons in groundwater samples. The newest Foxboro MIRAN portable Gas Analyzer, the MIRAN 203, is an economical choice for applications where only one gas is being detected and measured. This new lightweight analyzer permits the user to measure any number of gases by simply inserting a different calibration set.

FRANKLIN MILLER INC.   LDC
60 Okner Pkwy.
Livingston, NJ 07039
201/535-9200

**GREENHORNE &
O'MARA, INC.**   2500
9001 Edmonston Rd.
Greenbelt, MD 20770
301/982-2800 x442

Greenhorne & O'Mara, Inc. provides hazardous waste management services to industry and government. Our experienced staff (most OSHA/ AHERA-certified) know the requirements of RCRA, CERCLA, SARA, TOSCA, NEPA, CWA, and CAA. Services include site characterization, property transfer assessments, asbestos management, groundwater assessments, facility audits, RI/FSs, remedial design, waste minimization, and surveying.

Galaher Settlements Company   1209
260 Franklin St., Ste. 1510
Boston, MA 02110
617/439-6260

Pioneering the use of structured settlements in environmental cases, Galaher Settlements reinforces its position as a leading national firm specializing in the development of creative periodic payment programs individually tailored to the present and future needs of all parties. Contact our specialists today - there is no charge for our service.

Galson Remediation   0115-0117
6627 Joy Rd.
East Syracuse, NY 13057
315/463-5160

Gaslon Remediation Corporation (GRC) specializes in the development and application of chemical destruction of PCB's, dioxins, PCP, pesticides,

and other hazardous wastes in soils and sludges. Processes for cleaning soils and sludges are now at full scale commercial operation levels. Gaslon Laboratories offers complete and professional analytical services for the full range of environmental samples, including hazardous wastes, priority pollutants, toxic metals and organics in soil, groundwater and wastewater, air toxics, leachates, drinking water, and emission samples. Gaslon Laboratories has extensive analytical experience under environmental regulations such as RCRA, CERCLA, the Clean Air Act, and the Clean Water Act. We perform all pertinent analyses according to the EPA Contract Lab Program (CLP) protocols as a standard service.

Gartner Lee, Inc.   1302
105 Main St.
Niagara Falls, NY 14303
716/285-5448

Environmental consulting - offering services in environmental and engineering geophysics, packer testing and contaminant hydrogeology. Geophysical services include high resolution EM, magnetics, radar, borehole geophysics, seismic refraction and reflection. Hydrogeology services include site investigations, geochemistry, modeling, monitoring and water supply. Perform RI/FS, ECRA studies, Phase I and II surveys.

General Physics Corporation   0209
6700 Alexander Bell Dr.
Columbia, MD 21046
301/290-2300

General Physics Environmental Services offers laboratory and pilot treatability testing for many industrial waste and remediation technologies. GP combines the resources of environmental engineering with our in-house EPA CLP testing. GP provides a full range of industrial hygiene services. GP provides innovative, value-driven services that accurately address the needs of our customers.

Geo-Con, Inc.   0204/0206
P.O. Box 17380
Pittsburgh, PA 15235
412/856-7700

Geo-Con, Inc. is a national remedial construction company specializing in on-site hazardous waste treatment. Capabilities of the company include: Turn-key project execution; In-situ solidification and stabilization; Containment systems such as vertical barriers, capping and liners; RCRA landfill construction and retrofit; Deep soil and Shallow soil mixing; Groundwater collection and treatment; VOC removal from soil; Bioremediation; Plant decontamination and Decommissioning and construction Management.

GeoGroup, Inc.   1106-1108
9029 Shady Grove Ct.
Gaithersburg, MD 20877
301/258-7491

Geo Group, Inc. provides a range of quality soil, rock and environmental monitoring services. Part of our range includes Water Level Indicators, Bailer Samples and Temperature Meters. We also provide innovative Data Logging Systems and Portable Readout Units using infra red techniques to monitor gas emissions from landfill sites.

Geophysical Survey Systems, Inc.　0601
13 Klein Dr.
P.O. Box 97
North Salem, NH 03073-0097
603/893-1109

Radar: Ground penetrating, subsurface interface radar (SIR) systems used to non-destructively scan the subsurface for buried tanks, pipes, and drums; locate and delineate landfills and trenches; and identify water table, bedrock and other geological features.

Geoprobe Systems　2420
607 Barney St.
Salina, KS 67401
913/825-1842

Geoprobe Systems manufactures innovative equipment for soil gas, soil core, and shallow groundwater sampling using small diameter driven probes. This equipment includes the hydraulically powered Geoprobe 8-M probe machine which has found extensive use in site investigation work. Geoprobe manufactures a complete line of probing tools.

Geosafe Corporation　2102
303 Parkplace, Suite 126
Kirkland, WA 98033
206/822-4000

Geosafe Corporation offers in situ vitrification (ISV) services for remediation of contaminated soil and sludge sites. The ISV process destroys hazardous organics through pyrolysis and simultaneously immobilizes hazardous inorganics in a delistable, vitrified residual. This cost-effective process offers significant advantages over conventional soil treatment processes.

Geoscience Consultants, Ltd.　1914
500 Copper N.W., Suite 200
Albuquerque, NM 87102
505/842-0001

Geoscience Consultants, Ltd. (GCL) is a minority-owned small business (8(a) Certified) and is a full-service environmental design and engineering consulting firm. GCL provides the following services: UST Management; Air Quality Assessment or Permitting; Remedial Engineering, Investigations, and Actions; Waste Minimization and Compliance Reviews; Groundwater Remediation; Regulatory Negotiation; Risk Assessments; and Health and Safety Training.

**GILARDE ENVIRONMENTAL
OF FLORIDA, INC.**　LDC
1201 U.S. Hwy. One, Suite 435
North Palm Beach, FL 33408
407/624-9770

GILARDE ENVIRONMENTAL OF FLORIDA, INC. offers full service environmental management to private industry, utilities and governmental entities. GILARDE specializes in: project management, remedial action, hazardous waste transportation/disposal, biohazardous/medical waste removal/destruction, emergency response management and landfill construction/closure, utilizing its own fleet of heavy equipment and trained operators.

Golder Associates, Inc.　LDC
3730 Chamblee Tucker Rd.
Atlanta, GA 30340
404/496-1893

Golder Associates is an international group of employee-owned consulting engineering companies providing regular support to clients in the fields of hazardous, solid, nuclear and mixed waste management, transportation, power generation, water resources management, mining, and commercial development. The group of companies currently maintains 37 offices in the United States, Canada, the United Kingdom, Sweden, Australia, Germany and Italy. The worldwide staff consists of over 950 personnel including more than 600 professional engineers and geologists.

Griffin Remediation Services, Inc.　0610
500 Winding Brook Dr.
Glastonbury, CT 06033
203/657-4277

Griffin Remediation Services, Inc. (GRS) is a full-service remediation company with specialty expertise in the design and implementation of comprehensive solutions to groundwater-oriented environmental problems. An affiliate of Griffin Dewatering Corp., GRS utilizes over 50 years of groundwater control experience. From their 21 locations throughout North America, Griffin employs innovative technologies focused on the containment, recovery, treatment and/or disposal of hazardous and nonhazardous groundwater pollutants. Services include: remedial dewatering; trenching; slurry, bio-polymer, interceptor, leachate collection; landfill gas vents; deepwells; wellpoints; monitoring wells; soil vents; air stripping; and pump sale/rentals.

Groundwater Technology Inc.　1001
220 Norwood Park South
Norwood, MA 02062
617/769-7600

A full service environmental company specializing in petroleum hydrocarbon site investigation and remediation including in situ and aboveground bioremediation, vapor extraction, chemical neutralization, soil gas surveys, air quality monitoring, well drilling, real estate audits, risk assessments, GTEL Analytical Laboratories, and ORS Environmental Equipment including Thermal and Catalytic Scavenger Vapor Abatement Systems, product recovery pumps, bioreactors, and airstripping towers.

**GRUNDFOS PUMPS
CORPORATION**　0211
2555 Clovis Ave.
Clovis, CA 93612
209/292-8000

GRUNDFOS PUMPS CORPORATION is the manufacturer of the REDI-FLO ENVIRONMENTAL PUMP. The REDI-FLO is constructed of stainless steel and Teflon and is designed to pump contaminated groundwater from a 4-inch well or larger. REDI-FLO pumps can provide flow rates up to 32 gallons per minute and to heads of 680 feet. For more information, contact GRUNDFOS at (209) 292-8000.

Gundle Lining Systems, Inc.　0505
19103 Gundle Rd.
Houston, TX 77073
713/443-8564

Gundle Lining Systems, Inc. Houston, Texas, is recognized as the world leader in the manufacture and installation of high density polyethylene lining systems. Gundle manufactures HDPE (Gundline HD) synthetic liner in over 34 ft. seamless widths from 30 to 140 mils thick. The company offers a full product range that can be adapted to any operational need. In addition, Gundle illustrates its commitment to excellence with innovations such as the patented extrusion welding machine and the new automatic wedge welder. Product innovations from Gundle include: Gundnet, drainage net; Gundline HDT, a textured HDPE liner; and Hyperlastic, a very low density polyethylene liner.

H2M Group　1908
575 Broad Hollow Rd.
Melville, NY 11747
516/756-8000

H2M is a multi-disciplined consulting firm. With over 57 years of experience, H2M specializes in civil, environmental and structural engineering, architecture, planning and environmental science. The firm's full scope of professional services encompasses wastewater pollution control, civil/site engineering, community planning, water supply/resources management, solid and hazardous waste management, environmental impact analysis, as well as environmental laboratory services.

**HARDING LAWSON
ASSOCIATES**　0413/0415
1155 Connecticut Ave., N.W., #500
Washington, DC 20036
202/429-6675

HARDING LAWSON ASSOCIATES (HLA) provides engineering, environmental, and construction services for hazardous and solid waste management. Ranked 59th in top 500 design firms and 12th in hazardous waste by Engineering News Record; ranked one of nation's best small companies by Business Week and Forbes; and awarded two national and one State engineering excellence awards for innovative site remediation.

**HAZCO
Services, Inc.**　2303-2307 & 2304-2308
2006 Springboro West Rd.
Dayton, OH 45439
513/293-2700

Personal protective equipment, instrumentation rental and repair services, sampling equipment, decontamination trailers and software solutions for the hazardous waste cleanup market.

**HAZMAT Training, Information
and Services, Inc.**　1006
(Hazmat TISI)
6480 Dobbin Rd.
Columbia, MD 21045
301/964-0940

HAZMAT Training, Information and Services, Inc. (Hazmat TISI), is a training company whose offerings include the development and delivery of

courses that meet the hazardous waste operations and emergency response training requirments of 29 CFR 1910.120 and/or NFPA Standard 472, etc. In addition to open-enrollment courses offered at their Columbia, Maryland, location, they deliver tailored, on-site programs. For more information, call our toll-free number: (800) 777-TISI (8474).

HMCRI 2011
9300 Columbia Blvd.
Silver Spring, MD 20910-1702
301-587-9390

Hazardous Materials Control Research Institute (HMCRI) is a public, nonprofit membership organization. Its mission is to promote the establishment and maintenance of a reasonable balance between expanding industrial productivity and an acceptable environment. This major goal is being met by providing national and regional conferences, numerous publications and texts, seminars, advanced degree possibilities, exhibitions on a large scale showing equipment and products, and many other informational dissemination programs. HMCRI's membership program, unique to the industry, now exceeds 5,000 active participants. A definite and distinctive forum is now available for these individuals and future members to exchange information and experiences dealing with hazardous waste and the protection of the environment. JOIN HMCRI TODAY! Become active in the ONLY hazardous waste membership organization.

HMM Associates, Inc. 2201
196 Baker Ave.
Concord, MA 01742
508/371-4000

HMM Associates is an environmental engineering, consulting and planning firm with headquarters in Concord, Massachusetts. HMM provides a full range of hazardous waste/materials services including: Superfund RI/FSs, remedial design and construction oversight; personnel protection and safety training; and environmental compliance audits and management. HMM is a Summit Environmental Group company.

HNU Systems, Inc. 2421/2422/2423
160 Charlemont St.
Newton Highlands, MA 02161
617/964-6690

Model HW101 Hazardous Waste Analyzer; IS101 - Intrinsically Safe Analyzer; PI101 - Photoionization Analyzer (and portables); 301DP - Dedicated Programmable Gas Chromatograph; 311 - Portable Gas Chromatograph; 321 - Compact temperature programmed gc; 331 - Compact dedicated capillary gc; SEFA-P - Portable x-ray fluorescence analyzer; 75 Meter - Portable ph/mv temperature meter; 76 Meter - Microprocessor ph/ion meter; ISE - Ion Selective Electrodes.

HWAC 0514
1015 Fifteenth St., N.W., #802
Washington, D.C. 20005
202/347-7474

HWAC - An Association of Engineering and Science Firms Practicing in Hazardous Waste Management (formerly the Hazardous Waste Action Coalition) is a national trade association representing engineering and science firms involved in

hazardous waste management. HWAC represents more than 115 member firms who employ 60,000 people across the nation who are responsible for approximately 90 percent of the available consulting capacity of cleanup of hazardous waste sites in the United States. Since its formation in 1985, HWAC has worked to improve business and professional conditions for engineering and science firms.

HYDRO-SEARCH, INC. 0615
175 N. Corporate Dr., Suite 100
Brookfield, WI 53045
414/792-1282

Services in Hydrogeology, Engineering, and Project Management for: Remedial Investigations/Feasibility Studies (RI/FS); Preparation of Work Plans; Managing On-Site Activities; Designing and Implementing Remedial Action Programs; Technical Guidance for Responsible Parties; Oversee EPA Contractors; Review Groundwater Monitoring Plans and Reports; Underground Storage Tank Management; Landfill Siting and Design; Water Resource Management; Mine Tailings and Water Management.

Hanson Engineers Incorporated 1405
1525 S. 6th St.
Springfield, IL 62703
217/788-2450

Hanson Engineers, Inc., provides a full range of environmental-waste management services nationally to industry, government and consultants. Services include: site assessment; RI/FS; design/oversight of remedial action; hydrogeologic/geophysical services; UST management; property audits; RCRA permitting; site characterization for hazardous, mixed and LL nuclear waste; soil gas surveys; geotechnical laboratory for contaminated soils.

Hart Crowser, Inc. LDC
1910 Fairview Ave., E.
Seattle, WA 98102
206/324-9530

Hayward Baker Inc. 1021
1875 Mayfield Rd.
Odenton, MD 21113
301/566-6110

Hayward Baker Environmental, a national specialty contractor, provides a range of solutions including: Containment Barriers; Contaminated Groundwater Collection; Sludge Solidification and Stabilization; Landfill Closures and Stabilization; and other On Site Remediation Services. With over 40 years of experience, we have the resources to meet time, quality control and safety constraints.

HazMat Environmental Group, Inc. 1401
60 Commerce Dr.
Buffalo, NY 14218
716/827-7200

HazMat Environmental Group, Inc., is a firm specializing in hazardous waste/hazardous materials management. Our services are offered throughout the United States. The services we offer include transportation, technical consulting, and personnel training. HazMat operates offices in Buffalo, NY and Cincinnati, OH.

HazMat World Magazine 0411
800 Roosevelt Rd., Bldg. C, #206
Glenellyn, IL 60137
708/858-1888

A publication edited for individuals responsible for specifying and purchasing products, systems, equipment and services used for hazardous materials and waste management from generation through packaging, handling, transportation, processing or ultimate disposal. Information and forms for free subscriptions will be available for qualified individuals.

Hazen Research, Inc. 1004
4601 Indiana St.
Golden, CO 80403
303/279-4501

Hazen Research, Inc. provides a full range of waste treatment services including characterization, reduction, remediation and minimization, treatability studies, leaching and extraction processes, soil washing, and thermal processes. Specializing in treatment of metal-bearing wastes, Hazen's other services include custom engineering, pilot plant services, process development, analytical services, and market/feasibility studies.

Heritage Environmental Services Inc. 2401/2402
2728 Colonial Ave., #100
Roanoke, VA 24015
703/344-1750

Heritage is a full-service environmental company with national service. Some of the services provided include complete laboratory services, treatment and disposal, transportation, remediation and engineering, and lab pack.

Hewlett-Packard 1011-1013
Route 41, Box 1100
Avondale, PA 19311-1100

Hewlett-Packard will display systems for EPA environmental analysis and methods. They include: a GC/MS system for hazardous waste analysis, an HPLC-based Pesticide Analysis System, and a Supercritical Fluid Extractor for sample preparation. All feature automation and instrument control.

Hill International, Inc. 2502/2504
One Levitt Parkway
Willingboro, NJ 08046
609/871-5800

Hill International, the world's leader in construction claims and construction consulting, will be introducing the ENVIRONMENTAL CLAIMS CENTER. The Center is a professional services organization combining the skills of attorneys, engineers, and environmental specialists along with contracts and construction experts. The Center assists clients with Superfund enforcement actions and cost recovery.

Howard Smith Screen Company 1709
P.O. Box 666
Houston, TX 77001
713/869-5771

Howard Smith Screen Company is a manufacturer of well screens and accessories for the environmental, water well and oil industries.

Hoyt Corporation   0303
251 Forge Rd.
Westport, MA 02790
508/636-8811

Hoyt Corporation of Westport, MA will be displaying their full line of Solvent Vapor Recovery/ Air Pollution Control Equipment, Distillation Equipment, Odor Control Equipment, and Liquid Purification Equipment.

Hydro Group, Inc.   1118
97 Chimney Rock Rd.
Bridgewater, NJ 08807
201/563-1400

Hydro Group, Inc. is a unique full-service company that can combine engineering and construction capabilities for all phases of groundwater remediation from groundwater exploration through well installation and treatment systems to startup. Treatment equipment manufactured by Hydro Group, Inc. includes air stripping towers, clarifiers, pressure filters, aerators and GAC units.

Hygienetics, Inc.   0807
150 Causeway St.
Boston, MA 02114
617/723-4664

Hygienetics, Inc. is an industrial hygiene and environmental consulting firm specializing in asbestos management, hazardous materials management, and indoor air quality assessment. Our worldwide offices - in Boston (Headquarters); Hartford, New York City, Washington, D.C., Chicago, Los Angeles, San Francisco, Honolulu and Frankfurt, West Germany - assure quick and cost-effective service.

I-Chem Research   1703-1705
23787-F Eichler St.
Hayward, CA 94545
415/782-3905

A complete line of glass and polyethylene sample bottles, jars and vials supplied with Teflon-lined closures attached and available chemically precleaned and laboratory-certified to meet EPA specifications. Also available are: custom cleaned sample containers, protective shipping materials, convenient sampling kits, and preservatives in ampules.

ICF Kaiser Engineers   1214
1800 Harrison St.
Oakland, CA 94612
415/268-6000

ICF Kaiser Engineers provides engineering and construction services to clients involved with environmental, transportation, industrial, advanced technology, energy, and other infrastructure projects around the world. ICF Kaiser Engineers' 1600 professionals work on hundreds of projects including planning and managing the cleanup of Boston Harbor. We are one of the nation's top five companies in hazardous waste engineering.

ICM Laboratories   0416
1152 Route 10
Randolph, NJ 07869
201/584-0330

Full service laboratory specializing in environmental analysis. Laboratory services include

analysis for compliance with ECRA, RCRA, NJDES, hazardous waste classification, CERCLA and TCLP. Monitoring well sampling also available.

In-Situ, Inc.   1002
P.O. Box I, 210 South 3rd St.
Laramie, WY 82070
307/742-8213

In-Situ's HERMIT Data Logging Systems provide reliable field instrumentation for water resource evaluations, including aquifer testing and short- and long-term monitoring in many types of water bodies. The instrumentation is widely respected for its ability to operate unattended in extreme weather conditions over extended periods of time without compromising accuracy. In-Situ also offers a number of Hydrologic Software programs for both PC and mainframe computers. In-Situ's Leak Detection Systems use a patented sensing technology for monitoring underground storage tank installations that provides intrinsically safe and reliable leak detection. Three different models are available.

Industrial & Environmental Analysts, Inc.   0310
3000 Weston Pkwy.
Cary, NC 27513
919/677-0090

IEA, Inc. is an environmental testing and sampling corporation. IEA offers unparalleled performance under the EPA Contract Laboratory Program (CLP). Analytical services include TCL/ TAL, TPH by GC and IR, TCLP, asbestos by TEM, metals by AA, ICP and ICP/MS, SEM and full wet chemistry. In addition, IEA offers sampling services in groundwater, air, wastewater and soils, adhering to strict EPA protocols.

Inquip Associates   0713
1300 Old Chainbridge Rd., #3
McLean, VA 22101
703/442-0142

Inquip Associates, Inc. is a geotechnical contractor whose history dates back to the 1950's. Inquip's main activity has related to the installation of soil-bentonite cutoff barriers and liners. Recently, it has expanded to include other geotechnical techniques, especially environmental projects, using the latest technical advances in the field.

Institute of Gas Technology   1706/1708
3424 South State St.
Chicago, IL 60616
312/567-3794

IGT is a not-for-profit educational, energy and environmental research and development organization established in Chicago, Illinois in 1941. IGT's environmental capabilities include waste incineration and detoxification, and catalytic and biological decontamination of hazardous and industrial waste, soils and sludges, and groundwater. IGT programs range from fundamental investigations through bench-scale and pilot plant process development to field testing.

Integrated Chemistries, Incorporated   1609
1970 Oakcrest Ave. Suite 215
St. Paul, MN 55113
612/636-2380

An environmental specialty chemical company that develops and markets chemical processes that create more effective ways to remediate and analyze hazardous waste. Our CAPSUR system has effectively remediated nonporous surfaces contaminated with Polychlorinated Biphenyls and Pentachlorophenol. The CAPSUR system is cost-effective and offers significant advances over conventional surface cleaning methods.

Intergraph Corporation   1123
2051 Mercator Dr.
Reston, VA 22091
703/264-5600

Intergraph Corporation is the largest CAD/CAM/ CAE systems vendor in North America and the leading supplier of interactive computer graphics systems to the federal government. A Fortune 500 company, Intergraph provides UNIX workstations and servers as well as fully integrated software in environmentally oriented applications such as mapping/GIS, AEC and facilities management.

International Technology Corporation   0203
23456 Hawthorne Blvd.
Torrance, CA 90505
213/378-9933

International Technology Corporation (IT) is an environmental management company with multiple technologies and human resources to solve a wide variety of problems involving hazardous chemical and nuclear materials. The Company provides a comprehensive range of services and products to industry and governmental agencies in four business areas: Environmental Engineering and Services, Analytical Services, Remediation Projects and Services and Pollution Control Systems.

Interox America   0225
3333 Richmond Ave.
Houston, TX 77098
713/522-4155

Hydrogen peroxide and FB^R Sodium Percarbonate - the oxidants of choice for wastewater treatment. Control odors and oxidize organic compounds, cyanides, chlorine and reduced sulfur compounds without toxic by-products.

J.J. Keller & Associates, Inc.   2418/LDC
8361 U.S. Highway 45
Neenah, WI 54957-0368
414/722-2848

J.J. Keller & Associates, Inc. currently researches, writes, edits, and prints over 60 technical publications serving the CPI and transportation industry. Keller also offers chemical handling and regulatory training kits, videos, and handbooks as well as hazardous materials management software. Featured at Superfund '90 will be Keller's Hazardous Waste Management Guide; Chemical Regulatory CrossReference; HAZWOPER Manual and Training Kits; OSHA Compliance Man-

ual; Chemical Training Booklets; Hazardous Materials Guide; Chemical Crisis Management Guide; Haz Mat II Software, and Reg-A-Dex Software.

Jacobs Engineering Group Inc. 2108
251 South Lake Ave.
Pasadena, CA 91101
818/449-2171

Jacobs is one of the largest professional service firms in the U.S. providing engineering, design and consulting services; construction and construction management; and process plant maintenance. The Company provides its services nationwide and internationally for selected industries including environmental and hazardous waste; facilities for aerospace, high technology and other applications; and process plants for chemical, petrochemical and pharmaceutical industries, the energy and refining industries, and the mineral and fertilizer industries.

James T. Warring Sons, Inc. 2212
4545 S St.
Capitol Heights, MD 20743
301/322-5400

All types and sizes of containers - new and reconditioned - fiber, steel, plastic. Our hazardous waste containers are DOT approved and range in size from 5 to 110 gallons. We accept orders from one to truck loads and we ship anywhere. You order a container - we don't have it - it's special - we will get it for you. No order is too small for James T. Warring Sons, Inc. Let us help you contain your hazardous waste. Also provided is empty drum removal with custom shredding and crushing done on your site.

KV Associates 1414
281 Main St.
Falmouth, MA 02541-9811
508/540-0561

KV Associates is a manufacturer of investigation products for soil, gas and water; and soil sampling of remediation products for soil venting and volatile destruction using shield screens and catalitic converter systems and flowmeters for determining rate and direction of groundwater flow.

Kimmins Thermal Corporation 0806
256 Third St.
Niagara Falls, NY 14303
716/282-7252

Kimmins Thermal Corporation, a Subsidiary of Kimmins Environmental Service Corporation (NYSE:KVN), provides full-service hazardous waste remediation contracting. Services range from packaging, transportation, and disposal services to on-site incineration. Disposal services include: radioactive and mixed wastes, gas cylinders, and explosive/shock sensitive materials. Services available nationally.

LTC International, Inc. 0912
101-G Executive Dr.
Sterling, VA 22170
800/822-2332

LTC International offers a full line of dust-free, high production vacuum blasting machines. This equipment is suitable for removal of many toxic substances, such as lead paint, while reducing waste generated by 95% over conventional open blasting!

LWD, Inc. 1010
P.O. Box 327
Calvert City, KY 42029
502/395-8313

LWD, Inc. is a full service waste management company specializing in the rotary kiln incineration of hazardous and non-hazardous materials. We are a licensed transporter of such materials and operate a HDPE non-hazardous industrial waste "special" landfill. A field service division performs site remediation and industrial cleaning to customer specifications.

Laboratory Resources 2416
363 Old Hook Rd.
Westwood, NJ 07675   201/666-6644

Laboratory Resources is a full service analytical testing laboratory capable of analyzing air, water, soil, hazardous waste, asbestos, industrial hygiene and a host of other matrices. The distinguishing nature of the company includes responsiveness to the customer, fast turnaround and unparalleled quality service. Call (800) 729-1397 for more information.

**Laborers-AGC Education
& Training Fund** 2116
P.O. Box 37, Rte. 97 & Murdock Rd.
Pomfret Center, CT 06259
203/974-0800

The Laborers-AGC Education and Training Fund is a labor/management trusteed organization that develops and implements training programs for over 70 training centers located throughout the United States and Canada (32). Courses offered include: Line Foreman Safety Training, Pipe Laying, Blasting, Laser Beams, Asbestos Abatement, and Hazardous Waste Worker Training.

Laidlaw Environmental   0215/0217
Services, Inc.   0219/0221
P.O. Box 210799
Columbia, SC 29221
803/798-2993

Laidlaw Environmental Services is the new name for GSX Chemical Services, Tricil and their affiliated companies. From more than 50 locations throughout the U.S. and Canada, Laidlaw Environmental Services offers a longstanding record of performance, financial stability, and the organizational flexibility to tailor service solutions to your specific environmental concerns. Combined strengths. Combined resources. Laidlaw Environmental Services...the ONLY name you need to know to manage your industrial and hazardous wastes.

Lancaster Laboratories, Inc. 1005
2425 New Holland Pike
Lancaster, PA 17601
717/656-2301

An independently owned and operated testing laboratory located in Lancaster, Pennsylvania. With a staff of more than 370 scientists, technicians, and support personnel housed in a 78,000

sq. ft. facility, we provide a wide range of environmental, industrial hygiene, food, and pharamaceutical testing services. We also provide ExpressLAB and sample pickup services.

Law Environmental, Inc. 2503/2505
114 Town Park Dr.
Kennesaw, GA 30144
404/590-4605

With more than fifty years of experience in the environmental consulting field, Law focuses on giving you creative and proactive solutions to environmental regulatory compliance issues. We offer you services in the following areas: Underground Storage Tanks; RCRA Hazardous Wastes; CERCLA/SARA Superfund; Solid Waste Management; Hydrology/Water Resources; Commercial Property Transfers; Industrial Property Transfers; Air Quality; Wetlands.

**Layne-Western
Company, Inc.** 2004/2006
1900 Shawnee Mission Pkwy.
Mission Woods, KS 66205
913/362-0510

Layne-Western Company, Inc. brings technical knowledge and practical experience to the specialized fields of investigative drilling, remedial action and environmental monitoring. From offices located coast-to-coast, Layne provides clients with a pool of talented professionals and a high commitment to professionalism, safety and quality.

**Lockheed Analytical
Laboratory** 2517/2519
1050 E. Flamingo Rd.
Las Vegas, NV 89119
702/734-3303

Built to meet the environmental chemistry needs of industry and government, Lockheed's world-class laboratory in Las Vegas, Nevada, offers a broad range of superior analytical chemistry services...services that ensure the success of even your most difficult environmental projects.

Lopat Enterprises Inc. 2101
1750 Bloomsbury Ave.
Wanamassa, NJ 07712
908/922-6600

Lopat's K-20/LSC is used in the control and remediation of all hazardous leachable toxic metals mandated by the USEPA, state and local authorities in incinerator ash, soil, soil-like solids or semi-solid wastes. K-20/LSC treated wastes will meet TCLP, CAM WET, MEP or EP TOX requirements. K-20/TCC is used in the control of PCB's and other chlorinated and organic compounds in soil-like particulate matter and on various cementitious surfaces.

**Los Alamos Technical
Associates, Inc.** 1507
6501 Americas Parkway NE, Suite 900
Albuquerque, NM 87110
505/884-3800

Los Alamos Technical Associates, Inc. (LATA), provides engineering and scientific services to government and industry in the areas of waste

management (hazardous, radioactive, mixed-waste); NEPA compliance planning and documentation; and nuclear process equipment and facility design. Over 300 personnel representing 40 technical disciplines. Most staff hold DOE Q clearances.

MAC Corporation/
Saturn Shredders 1117
201 East Shady Grove Rd.
Grand Prairie, TX 75050
214/790-7800

Manufacturers, designers, and fabricators of reduction systems to address the needs of PCB, haz-waste, low-rad waste, and steel-drummed chem-waste processors. If incineration or other treatment requires preparing the infeed through shredding, opening, separating, disengaging or reducing the size of same, our expertise will positively contribute to your decision-making process.

MICROMEDEX, Inc. 1306
600 Grant St. 6th Floor
Denver, CO 80203-3527
303/831-1400

Referenced source on medical and hazard information regarding thousands of chemicals used in the industrial setting; in-depth coverage of clinical effects, range of toxicity, workplace standards, and response to hazardous incidents. Designed for use by health and safety directors, occupational medicine professionals, and industrial hygienists.

MPC Environmental 2015
8631 W. Jefferson
Detroit, MI 48209
313/849-2333

MPC Environmental is a full service Environmental Contractor. Services include: 24 hour Emergency Response Capability, High Capacity Portable Pumping Systems (3,000 GPM), Site Cleanups, PCB Decontamination/Removal/Transportation, Hazardous Materials Cleanup/Transportation and Groundwater Remediation Services. GET TO KNOW US BEFORE ALL HELL BREAKS LOOSE!

MSA (Mine Safety
Appliances Co.) 0304
P.O. Box 426
Pittsburgh, PA 15230
412/967-3000

MSA will display a full line of personal protective equipment including products for respiratory protection and environmental monitoring.

MSP Technical Services, Inc. 1313
110 James Drive West, Suite 218
St. Rose, LA 70087
504/465-3300

To provide technically advanced, innovative products and services for the Waste Management Industry, while achieving the highest level of customer-driven, quality service at the lowest possible cost with an organization of highly trained people committed to health, safety and the environment for its employees and the community.

MWR, Inc. 2121
615 W. Shepherd St., POB 10
Charlotte, MI 48813
517/543-8155

Remedial services emphasizing a patented soil vapor extraction process.

Map Express LDC
P.O. Box 280445
Lakewood, CO 80228
800/627-0039

Map Express provides the full-service link between you, the professional community, and the resources of the U.S. Geological Survey and other agencies, supplying the map products your company needs today. Overnight shipping, toll-free 24-hour order line, personalized customer service, corporate deposit accounts, and a special research department are among the services we offer.

Marcel Dekker, Inc. LDC
270 Madison Ave.
New York, NY 10016
212/696-9000

Publishing firm of all types of Hazardous Waste texts, reference books and manuals.

Maxwell Laboratories,
S-CUBED Division 1402
P.O. Box 1620
La Jolla, CA 92038
619/453-0060

Chemical Analysis Services: CLP Organic Analyses; RCRA Analyses; Methods 1618, 1624, 1625 Analyses for OWRS Samples; Inorganic Analytes. Quality Assurance Support - BDAT, SITE, OPP Projects: QA Project Plan Reviews; Final Report Reviews; Field Audits; QA Training. Analytical Methods Development and Research. Environmental Engineering: Site Investigation/ Field Sampling and Monitoring; Treatability Studies; Solidification/Stabilization.

Medlab Environmental
Testing, Inc. 0402
P.O. Box 2045
Wilmington, DE 19899
302/655-5227

Medlab offers: full service environmental testing laboratory; free courier service; sampling; and analysis for hazardous waste, asbestos, wastewater and soils, drinking water and radon, and industrial hygiene; multi-state certifications. NVLAP accredited, NIOSH PAT participant.

Metcalf & Eddy 1126/1128
30 Harvard Mill Square
Wakefield, MA 01880
617/246-5200

Metcalf & Eddy protects the environment. Using a complete range of environmental services and capabilities, we assure that the nation's water resources and waste-generating activities are properly managed. Unique in the environmental field, Metcalf & Eddy offers you a single source for the development, design, construction management, and operation of water, wastewater,

sludge, hazardous and solid waste management systems. Few other firms offer their clients financial planning and management alternatives, such as total project delivery, contract operations, and program management. Industries, municipalities, and governmental agencies around the world have benefitted from Metcalf & Eddy's unique blend of technical, operation, and management expertise provided by a highly experienced staff of 2,200 technical and management specialists. Licensed, highly skilled personnel use a large and specialized assembly of equipment to clean up and transport hazardous waste.

Michigan Waste Report, Inc. LDC
400 Ann Street, N.W., Suite 204
Grand Rapids, MI 49504-2054
616/363-3262

Publishers for: MICHIGAN WASTE REPORT - Bi-weekly Newsletter, 21 Issues plus Directories, $325/yr. 3 SPECIAL ANNUAL DIRECTORIES REPORTS (sold separately) Haz. Waste, Env. Mgt., Solid Waste, $43.60 each. ACT 64 LEGAL MGT. SYSTEM MANUAL, MI Haz. Waste Laws & Regulations, $395. RESOURCE EXCHANGE & NEWS MAGAZINE Waste Exchange & Recycled Material Markets, 6 Issues, $48/yr. ENVI-ROX ON-LINE COMPUTER SERVICE Environmental Information & Waste Exchange Listings.

Millipore Corporation 0202
80 Ashby Rd.
Bedford, MA 01730
617/275-9200 x2337

Millipore will exhibit its line of products for the analysis of hazardous materials including the Zero Head Space Extractor designed specifically for evaluating waste according to the TLCP. Millipore also offers a Rotary Agitator, dispensing pressure vessels and a complete line of membrane filters.

Morrison Knudsen Corporation 1101
P.O. Box 73
Boise, ID 83729
208/386-6172

"One Sea, One Sky, One World Environment, One Company: MORRISON KNUDSEN" - serving private- and public-sector clients worldwide through site investigation, feasibility studies, engineering, and construction for: Industrial waste treatment and pollution control; Municipal waste management; High- and low-level radioactive waste disposal; Waste treatment, storage, and disposal (TSD) facilities.

NUS Corporation 2322-2323
Park West 2, Cliff Mine Rd.
Pittsburgh, PA 15275
412/788-1080

For 30 years, NUS Corporation has provided the environmental and engineering expertise to solve industry and government waste problems with cost-effective solutions. Our staff of 1950 multidisciplinary professionals offers a full range of services including environmental assessment, environmental engineering, remedial design engineering, hydrogeologic and geologic services,

risk assessment, regulatory assistance, environmental health and safety and analytical services.

Nappi Trucking Corporation 1514
P.O. Box 510, Hwy. #34
Matawan, NJ 07747
201/566-3000

Transportation and storage of Hazardous and Non-Hazardous Waste.

National Academy Press LDC
2101 Constitution Ave., N.W.
Washington, DC 20418
202/334-3313

The National Academy Press was created by the National Academy of Sciences to publish the reports issued by the Academy and by the National Academy of Engineering, the Institute of Medicine, and the National Research Council, all operating under the charter granted to the National Academy of Sciences by the Congress of the United States.

Nat'l Env'l Tech. Appl. Corp.
(NETAC) 0213
615 William Pitt Way
Pittsburgh, Pa 15238
412/826-5511

The National Environmental Technology Applications Corporation (NETAC) facilitates commercialization of promising environmental technologies. NETAC services include technical and commercial assessments; technology development assistance; testing and demonstration, market analysis and business development; permitting and regulatory assistance; identification of financial sources. NETAC was created in 1988 through cooperative between the U.S. Environmental Protection Agency and the University of Pittsburgh to help move environmental technology to the marketplace.

National Draeger, Inc. 2507
101 Technology Dr.
Pittsburgh, PA 15275
412/787-8383

National Draeger offers a wide range of products within the respiratory, instrumentation, and detector tube lines. The Model 190 Datalogger is the most advanced portable gas monitor available for industrial hygiene and safety professionals. It detects toxic gas and alarms independent of the microprocessor function. National Draeger's air-purifying respirators include cartridges for organic vapors, and gases and ammonia, as well as high efficiency particulate filters for dust, fumes, mists, radionuclides, and asbestos.

National Environmental Products 2521
Greenwood Ave., P.O. Box 38
Newfield, NJ 08344
609/697-1066

"Drum Stix" environmental sampling tools for liquids, solids and sludge. Call out toll-free number for more information: 1-800-542-6816.

National Environmental
Testing, Inc. 1312/1314
220 Lake Drive East
Cherry Hill, NJ 08002
609/779-3373

A growing nationwide network of environmental

testing laboratories, dedicated to providing high quality analytical services backed by a comprehensive field services which include field sampling, stack testing and industrial hygiene services.

National Express
Laboratories, Inc. 1712
6801 Press Dr., East Building
New Orleans, LA 70126
504/283-4223

NatEx is a network of environmental laboratories located in strategic regions of the country serving industry, engineering/consulting firms and governmental agencies. Each network laboratory is a participant in the EPA Contract Laboratory Program and has expertise in analytical methodologies in support of RCRA, CERCLA, SARA and CAA regulations. At NatEx, we emphasize responsive client services and meeting committed turnaround times, in addition to high quality analytical services.

National Library of Medicine 1612
8600 Rockville Pike, Building 38A, 3S308
Bethesda, MD 20894
301/496-6531

The National Library of Medicine plans to exhibit Environmental Protection Agency's (EPA's) Toxic Chemical Release Inventory (TRI87, TRI88) databases on NLM's Toxicology Data Network (TOXNET) System. TRI databases contain information on the annual estimated releases of toxic chemicals to the environment. It is mandated by Title III of the Superfund Amendments and Reauthorization Act (SARA) of 1986. The Inventory contains provisions for the reporting, by industry, on the releases of over 300 toxic chemicals into the air, water and land. NLM also will perform on-line demonstrations of searching the other files of TOXNET System such as HSDB, RTECS, CORIS, IRIS, DART, ETICBACK, EMICBACK and DBIR.

National Lime Association 2414
3601 North Fairfax Dr.
Arlington, VA 22201
703/243-5463

Lime - Calcium Magnesium Oxides and Calcium Magnesium Hydroxides - *Man's Oldest and Most Versatile Chemical*. Nature's gift for the stewardship of our planet. It almost does it all: neutralization, chemical fixation, stabilization and solidification of toxic and hazardous materials. Lime may be the natural, cost-effective solution to your hazardous waste problems.

National Seal Company 0318
1245 Corporate Blvd., #300
Aurora, IL 60504
708/898-1161

National Seal Company manufactures and installs flexible membrane liners, drainage netting and geotextiles for landfills, hazardous waste storage, leach pads and reservoirs. Computerized manufacturing system produces competitively priced liners that are twice as good as industry standards. NSC's unique seaming procedure enhances liner strength and leakage resistance.

National Solid Wastes
Management Association 1714
1730 Rhode Island Ave., N.W., Suite 1000
Washington, DC 20036
202/659-4613

CWTI (Chemical Waste Transporters Institute), ICWM (Hazardous Waste Treatment and Disposal Institute) and RCI (Remedial Contractors Institute) are components of National Solid Wastes Management Association to promote safe transport and cleanup of hazardous waste sites. NSWMA is the only association representing these interests for Superfund and other state cleanups.

Normandeau Associates, Inc. 2005
25 Nashua Rd.
Bedford, NH 03102
603/472-5191

Normandeau Associates, Inc., has been providing specialty environmental consulting services since 1970. These specialty services include ecological risk assessment, aquatic toxicology, analytical laboratory services, wetland mitigation, water quality studies, and a full range of environmental specialists at over 12 locations throughout the eastern U.S.

Northeast Research
Institute, Inc. 1121
309 Farmington Ave., Ste. A-100
Farmington, CT 06032
203/677-9666

NERI provides Petrex soil gas surveys, and Industrial Hygiene and Analytical Lab Services. Technical representatives will discuss how the Petrex soil gas method is used for site assessments, LUSTs, property transfers, etc. Custom analyses of Petrex samplers can now be achieved by GC/MS to meet sophisticated survey objectives.

Northeastern Analytical
Corporation 1307/1309
4 East Stow Road
Marlton, NJ 08053
609/985-8000

Environmental Services: Complete Environmental Field Sampling, In-house Gas Chromatography/Mass Spectrometry (GS/MS) Laboratory Analysis, Hazardous Site Training (40 Hours), Asbestos Inspection & Management & Abatement Monitoring Services, Asbestos Analysis by Transmission Electron & Optical Microscopy, Underground Storage Tank Testing, Excavation, Removal and Installation, Stack Emission and Ambient Air Testing.

OHM Corporation 0403/0405
16406 U.S. Route 224 East
Findlay, OH 45840
800/537-9540

OHM's subsidiaries provide the following environmental services: Environmental Testing and Certification Corp. (5 laboratories) - analysis and management; OHM Remediation Services Corp. (21 response centers) - assessment, engineering, design, on-site remediation for soil, groundwater, lagoons, facilities, waste sites; OHM Resource

Recovery Corp. (Part B facility): Waste treatment and disposal.

OLDOVER CORPORATION 1909
P.O. Box 228
Ashland, VA 23005
804/798-7981

Oldover Corporation provides comprehensive waste management services including transportation, fuel blending, thermal destruction, recycling and drum recovery. State-of-the-art equipment and multiple locations assure prompt, dependable service. A 17-year no-lost-time accident record demonstrates Oldover's commitment to the safe handling of hazardous wastes.

**OSCO Environmental
Management** 0308
618 Grassmere Park Dr., #7
Nashville, TN 37211
615/832-0081

The new treatment facility in Nashville, Tennessee, processes all types of liquid and solid wastes including waters, oils, sludges, acids, bases and cyanides. Solids stabilization is offered in bulk. Waste is received in bulk and drums by truck or rail. Transportation is available in 42 states. Remediation and professional consulting services are offered nationwide.

**OCCUPATIONAL HAZARDS
Magazine** 1412
1100 Superior Ave.
Cleveland, OH 44114
216/696-7000

OCCUPATIONAL HAZARDS Magazine is edited for management officials who are responsible for workplace safety, health and environmental compliance. Editorial material includes coverage of major legislative, regulatory, scientific and other developments affecting the field, as well as practical "how-to" articles.

**Ogden Environmental
Services, Inc.** 1308/1310
3550 General Atomics Ct.
San Diego, CA 92121-1194
800/876-4336

Turnkey site remediation services and in-plant destruction solutions. Ogden's transportable incinerator provides cost effective, environmentally safe, remediation alternatives.

**On-Site Instruments/
EnviroRENTAL** 0704/0706/0708
689 North James Rd.
Columbus, OH 43219
1/800/766-7483

On-Site Instruments/EnviroRENTAL sells, rents and services a complete line of industrial hygiene, laboratory and environmental monitoring instruments and equipment. Rent-to-own and leasing options are also available. Our service department provides technical and applications assistance, while our distribution center handles all accessory orders. On-Site also offers training classes at our Columbus, Ohio, facility. Call 1-800-7-On-Site for more information.

**P.E. LaMoreaux &
Associates, Inc. (PELA)** LDC
P.O. Box 2310
Tuscaloosa, AL 35403
205/752-5543

P.E. LaMoreaux and Associates, Inc. (PELA), consulting hydrologists, geologists, engineers and environmental scientists, offers hydrological, geological, environmental and hazardous waste consultation services. Other services provided include sampling, laboratory analysis, development of monitoring programs and installation of wells, reclamation, permitting, court testimony, and graphics and communications programs.

PACE Incorporated 0702-0801
1710 Douglas Dr. North
Minneapolis, MN 55422
612/544-5543

PACE is a national environmental laboratory and consulting firm serving all regions of the United States. Services are provided through a national network of 10 facilities. Services offered include: field sampling, organic and inorganic laboratory analyses for water, soil, and air; bioassay toxicity testing; and, asbestos, industrial hygiene, air pollution and risk assessment consulting services.

**POLLUTION EQUIPMENT NEWS/Rimbach
Publishing Inc.** 1023
8650 Babcock Blvd.
Pittsburgh, PA 15237
412/364-5366

POLLUTION EQUIPMENT NEWS, published bi-monthly, provides product information to the person responsible for air, water, wastewater and hazardous waste. An annual CATALOG & BUYER'S GUIDE provides buying source information. INDUSTRIAL HYGIENE NEWS, published bi-monthly, provides information on products and services for measuring and controlling health hazards in the work environment.

**PRC Environmental
Management, Inc.** 1510
303 East Wacker Dr., Suite 500
Chicago, IL 60601
312/856-8700

PRC EMI provides environmental services to both government and industry. Headquartered in Chicago, Illinois, PRC EMI maintains major offices in McLean, Virginia, San Francisco, and Denver as well as 13 other offices throughout the country. Specialties include remedial investigations/feasibility studies, endangerment assessments, remedial design and implementation, compliance audits, permitting support, waste reduction audits, risk management support, environmental and systems engineering, policy and regulatory analysis, economic analysis, and program management support.

PacTec, Inc. 0915
28701 Allen Rd.
Clinton, LA 70722 800/272-2832

PacTec, Inc., offers polyethylene liners utilized in dump trucks, roll-off assemblies and rail gondolas for transporting bulk solids and sludges. These liners reduce the risk of leaking, help eliminate washout costs and increase container longevity.

Pacific Analytical, Inc. 1610
1989-B Palomar Oaks Way
Carlsbad, CA 92009
619/931-1766

Pacific Analytical (PA) is an innovative, high technology environmental analysis laboratory oriented toward work with unusually complex samples. PA specializes in providing high quality analysis results for volatile and semivolatile organics, and pesticides using 500 series, 600 series, 1600 series and SW-846 methods; dioxins by 8280 (LRMS), 8290 and 1613 (HRMS); and metals by 6020 and 200.8.

Pennsylvania Drilling Company 0214
500 Thompson Ave.
McKees Rocks, PA 15136
412/771-2110

Pennsylvania Drilling Company will be demonstrating capabilities for installing monitoring wells on a variety of sites under a variety of conditions. In addition, they will be displaying drilling tools and monitoring well equipment made in their new shop in McKees Rocks near Pittsburgh, Pennsylvania.

Peoria Disposal Company 2515
4700 N. Sterling Ave.
Peoria, IL 61615
309/688-0760

RCRA Treatment, Disposal Facility, Analytical Services, Transportation, Remediation, Consulting and Engineering Services.

PermAlert ESP, Inc. 1912
7720 Lehigh Ave.
Niles, IL 60648
708/966-2190

Manufacturers of the Double-Pipe™ secondary contained piping systems. PAL-AT™ cable type leak detection and location system, and TankWatch™ leak detection system. DOUBLE-PIPE is a preengineered and prefabricated system available in steel, fiberglass and thermoplastics. The PAL-AT leak detection system is microprocessor based, UL listed and intrinsically safe for Class 1, Groups C & D, Div. 1.

Peroxidation Systems 0205/0207
4400 E. Broadway, Suite 602
Tucson, AZ 85711
602/327-0277

Peroxidation Systems supplies services and equipment for UV/hydrogen peroxide chemical oxidation of organic materials in water or wastewater.

**Photovac International
Incorporated** 2410/2412
25-B Jefryn Blvd. West
Deer Park, NY 11729
516/254-4199

Photovac will display portable instruments for environmental toxic monitoring in groundwater, soil, and ambient air: TIP™, a hand held Total Organics analyzer; the 10S Series Portable Gas Chromatographs; and MicroTIP™, a hand held analyzer which incorporates advanced microprocessor technology for real time digital or graphic assessment of toxic gases and vapors.

Poly-John Trailer Division 2514/2516/2518
P.O. Box 1037, Old U.S. 31 South
Rochester, IN 46975
219/223-6566

Poly-John Trailer Division's Decontamination Units are state of the art design and construction. Special attention is given to every detail insuring users of comfort and safety with a functional and practical floorplan. Any industry dealing with contaminated materials must take every precaution possible for the safety of its employees and the environment. Poly-John has created these units to meet these strict requirements and to put your mind at ease.

Polyfelt, Inc. 0109
1000 Abernathy Rd., Suite 1520
Atlanta, GA 30328
404/668-2119

Polyfelt, Inc. is a worldwide manufacturer of spunbonded, continuous filament, needlepunched geotextiles with a major focus in the Waste Containment industry. Our product lines range from 2.7 - 22 oz/sy. We provide technical support, geotechnical design guidelines and data, QC/QA certifications, and a worldwide distributor network.

**Princeton Testing
Laboratory, Inc.** 1116
P.O. Box 3108
Princeton, NJ 08543
609/452-9050

Environmental Analysis; Industrial Hygiene; RCRA/ECRA; industrial wastewater; NPDES; groundwater; OSHA workplace surveys; asbestos monitoring & evaluation; complete NIOSH laboratory methodology; asbestos & HAZ-MAT training courses; Right to Know compliance; Microbiology; Bioassay; Underground Storage Tank testing; AIHA accredited. Certified for:NJ DEP; NYDOH; PA DER; CT; RI; & DE.

Project Time & Cost, Inc. 0810
3390 Peachtree St., NE, 16th Floor
Lenox Tower South
Atlanta, GA 30326-1108
404/239-0220

Skillful management of cost, time and quality is essential to the successful completion of any project plan, especially in today's environmental arena. Project Time & Cost, a full-service cost engineering and project management consulting firm, possesses the experience and resources required to provide these essentials to both governmental and private sector clients.

QED Environmental Systems, Inc. 1025-1027
P.O. Box 3726
Ann Arbor, MI 48106
313/995-2547

Well Wizard® Dedicated Sampling Systems; Sample Pro® Groundwater Sampling Supplies; Pulse Pump® Recovery Pumping Systems; Hydro-Punch® Groundwater Sampling Without Wells.

QUALTEC, Inc. 0803-0805
11300 U.S. Highway One, Suite 600
Palm Beach Gardens, FL 33408
407/775-8395

QUALTEC, Inc., specializes in on-site remedia-

tion utilizing stabilization via fixation/solidification. QUALTEC also provides construction/closure of landfills and RCRA caps; treatability studies; pilot studies; site restoration; groundwater remediation; construction management; and fixation equipment and personnel leasing. QUALTEC's state-of-the-art cementitious fixation process has been utilized at Superfund sites across the nation.

Quantum Analytics, Inc. 0201
363-D Vintage Park Dr.
Foster City, CA 94404
415/570-5656

Quantum Analytics rents state-of-the-art analytical instruments and portable GCs. Products include GC, LC, AA, IR, UV, FL, TOC, and TOX.

R & G Sloane 1907
7660 N. Clybourn Ave.
Sun Valley, CA 91352
818/767-4726

ContainIt - secondary containment piping system fits over virtually any piping system. It is available with either split or solid pipe and split fittings, making it ideal for both retrofit and new system installations. The ContainIt systems injection bonding method allows it to be pressure rated up to 75 psi.

R.E. Wright Associates, Inc. 1305
Environmental Restoration Systems
3240 Schoolhouse Rd.
Middletown, PA 17057

REWAI designs and manufactures groundwater treatment and subsurface towers, pneumatic pumps and the Auto-Skimmer. REWAI provides turnkey systems - pre- and/or post-treatment, off-gas treatment and installation and maintenance contracts.

R.J. Lee Group, Inc. 1003
350 Hochberg Rd.
Monroeville, PA 15146
412/325-1776

RJ Lee Group provides analytical and consulting services in materials characterization. A wide variety of analytical equipment is used with emphasis on optical, scanning and electron microscopy. Materials investigated include metals, ceramics, powders, air particulates, semi-conductors and bio materials. Complete in-house chemical laboratory. Products include Zeppelin microimaging and MICROSURE® OPTICAL FIBER COUNTING COMPUTER systems.

**RMC Environmental
Services, Inc.** 1113
R.D. #1, Fricks Lock Rd.
Pottstown, PA 19464
215/326-9662

Environmental Consulting, Engineering and Analytical Services; including hazardous waste site investigations, hydrogeological investigations, aquatic and terrestrial ecological studies, wetland studies, natural resource damage assessments, regulatory compliance audits, hazardous waste volume and toxicity reduction, permit assistance, underground storage tank systems assis-

tance, waste treatment system engineering, and environmental chemistry laboratory services.

Radian Corporation 2403
8501 MoPac Blvd., P.O. 201088
Austin, TX 78720-1088
512/454-4797

RADIAN CORPORATION PROVIDES A FULL RANGE OF PROCESS, SOLID, AND HAZARDOUS WASTE ENGINEERING SERVICES...including site assessment to remediation design and construction, waste minimization to the design of waste treament or disposal systems, and preparing permit applications to responding to consent orders. In addition, the company has three full-service laboratories providing complete characterization and classification of soils, groundwater, run off, leachates, air emissions, soil vapors, and virtually any other substance or material for which measurements are required. RADIAN also has the unique ability to perform remedial pilot studies on site. This is accomplished through our transportable treatment systems. The unit physical-chemical operations incorporated into these systems can be configured to treat most contaminated waste streams. These systems have sufficient capacity to provide full-scale groundwater remediation.

Recra Environmental, Inc. 1410
10 Hazelwood Dr.
Amherst, NY 14228
716/691-2600

Recra Environmental, Inc. is an independently owned and operated corporation providing a wide range of organic and inorganic analyses on waters, soils and waste matrices. Recra is a U.S. EPA CLP laboratory with laboratories in Amherst, NY, Columbia, MD, Cleveland, OH and Detroit, MI. Data management, electronic transfer, individualized programs are provided with rapid, professional, high quality analytical services.

Remcor, Inc. 1506/1508
701 Alpha Dr.
Pittsburgh, PA 15238
412/963-1106

Remcor, Inc., provides the full spectrum of hazardous waste consulting and remediation services. By uniquely integrating expertise in engineering, construction, and environmental field services, Remcor performs projects ranging from investigations and assessments through actual remediation. As a turnkey contractor, Remcor has completed numerous projects including building decontaminations, surface impoundment and landfill closures, storage tank management, asbestos removals, groundwater remediation and mixed waste cleanups.

**Remediation Technologies,
Inc. (ReTeC)** 0614
22419 - 72nd Avenue South
Kent, Washington, 98032
206/872-0247

Remediation Technologies, Inc. (ReTeC), is a field services and engineering company specializing in on-site remediation of contaminants associated with organic wastes at industrial sites. ReTeC provides turnkey services from investigation

through final remediation/closure. ReTeC has designed and implemented bioremediation programs, groundwater treatment systems and thermal treatment systems for numerous RCRA and CERCLA sites.

Research Alternatives, Inc. 0105
966 Hungerford Dr., Suite #1
Rockville, MD 20850
301/424-2803

Research Alternatives, Inc., will be demonstrating the Emergency Information System (EIS) software used for environmental and emergency planning, response, and recovery for natural and technological disasters. This PC-based software combines 19 emergency and regulatory compliance databases with georelational digitized maps and data communication capabilities to provide immediate access to critical information.

Resource Analysts, Incorporated 0314/0316
P.O. Box 778, One Lafayette Rd.
Hampton, NH 03842
800/992-0724   603/926-7777 in NH

Resource Analysts, Inc., is dedicated to complete customer satisfaction in the area of analytical testing, field sampling, bioassay, bioaccumulation, product registration, FIFRA, TSCA, RCRA, CLP (ino/org) aquatic research organism supplier. Maintains certifications/approval status in numerous states, EPA regions, DOD, ACOE, and regulatory agencies.

Response Rentals 0502
1460 Ridge Rd. East
Rochester, NY 14612
800/242-3910

Response Rentals provides rental instrumentation for remedial investigation studies, compliance surveys and substance emergencies. The instrumentation is easy to operate, reliable and represents the best names in the industry. Broad product line meets virtually every application need and includes, X-Met, OVA's, CGI's, PID's Isothermal GC's, ELF Radiation and more.

Riedel Environmental Services, Inc. 0307
4611 N. Channel Ave.
Portland, OR 97217
503/286-4656

Riedel Environmental Services, Inc., provides to its governmental and private clients turnkey environmental services which include site investigations, real estate audits, environmental engineering and design, groundwater assessment, design and operation of vapor and liquid recovery systems, remedial cleanup utilizing alternative cleanup technologies, underground storage tank management, 24 hour emergency response to hazardous material incidents and operation of treatment, storage and disposal facilities.

Robertson's Barrier Systems Corporation 0901
580 Hornby St., Suite 800
Vancouver, BC Canada V6C3B6

Robertson Barrier Systems - Testable, High Security Geomembrane Liner Systems. The Robertson

Barrier Liner is a unique patented liner geomembrane system specifically designed for the safe containment of hazardous, toxic or valuable materials or wastes. Unique because it allows testing for the presence of potential leaks at any time without letting any of the contained liquid escape. It can be used for ponds and surface impoundments, landfills, underground storage tanks and as secondary spill containment. You can: Test for leaks both during construction and operation; Detect the onset and location of leaks; Control and isolate potential leaks. All this means reduced risk and liability for the owner, operator and the public.

Rocky Mountain Arsenal 0707
Public Affairs Office
Commerce City, CO 80022-2180
303/289-0250

Rocky Mountain Arsenal is an inactive installation conducting environmental cleanup, a result of past production practices. Environmental Remediation costs are expected to meet or exceed $1 billion. Because of its complex hazardous waste streams and contamination, RMA has been on the leading edge of technology with innovative techniques for sampling soil, groundwater and buildings.

Rollins Environmental Services, Inc. 0517-0518
P.O. Box 2349 One Rollins Plaza
Wilmington, DE 19899
302/479-3164

The Rollins Environmental Services family of companies provides unparalleled liability protection in hazardous waste management and disposal services which include multiple incineration facilities, laboratory analyses, small quantity waste and lab pack services, PCB removal, transportation, secure land disposal, encapsulation and deepwell injection. In Delaware, phone 302/479-2968 for more information.

Rose-Tillmann Inc. 1601
One Mark Twain Plaza
Suite 200
Edwardsville, IL 62025
800/228-3328

Rose-Tillmann Incorporated is a bonding and insurance brokerage specializing in providing programs nationwide for all types of environmental and pollution cleanup contractors. Specializes in providing hard-to-place programs for hazardous waste, asbestos abatement, underground storage tank removal and toxic and hazardous material transportation.

Rosemount Analytical/ Dohrmann Div. 0312
3240 Scott Blvd.
Santa Clara, CA 95052
408/727-6000

Dohrmann designs and manufactures trace element analyzers for water chemicals and petroleum products; Total Organic Carbon Analyzers, Total Organics Halide Analyzers, and Organic Halide Analyzers, plus analyzers for sulfur, chlorine and nitrogen in oil. Primarily used in product quality control and in pollution prevention and monitoring.

Roy F. Weston, Inc. 1102/1104
Weston Way
West Chester, PA 19380
215/430-3025

WESTON is a full-service environmental engineering firm specializing in analytical laboratory services, consulting and engineering, remediation, facility construction and operations, technical information management and the management of major programs. WESTON employs more than 2,500 people from various disciplines, wholly owns 8 subsidiaries and now has 42 offices nationwide.

S.S. Papadopulos & Associates, Inc. LDC
12250 Rockville Pike, Suite 290
Rockville, MD 20852
301/468-5760

S.S. Papadopulos & Associates, Inc. (SSP&A), is an internationally recognized firm providing specialized services in groundwater. SSP&A offers expert technical assistance in all areas involving water and contamination in the subsurface environment - including groundwater and soil contamination investigations and remediation, computer modeling of hydrogeologic systems and hydrochemical investigations.

SCS Engineers 0611
11260 Roger Bacon Dr.
Reston, VA 22090
703/471-6150

SCS, founded in 1970, provides hazardous and solid waste engineering to state and local governments, the federal government, industries, corporations and developers. Hazardous waste services include: Remedial Investigations, feasibility studies, and remedial designs for CERCLA and RCRA facilities; hazardous waste storage facility design; real estate contamination assessments; underground storage tanks; and wetland studies.

SENTEX SENSING TECHNOLOGY, INC. 1509
553 Broad Ave.
Ridgefield, NJ 07657
201/945-3694

Computerized, self-contained gas chromatographs to provide laboratory analysis, on-site, for emergency response, site evaluation, soil gas analysis and other applications. NEW ITEMS INCLUDE: A portable hand-held Flame Ionization Detector featuring "Point and Shoot" operation for total hydrocarbon detection; a portable Gas Chromatograph/Total Hydrocarbon Analyzer; and a portable Purge and Trap Gas Chromatograph System designed for on-site analysis of drinking, ground and wastewater.

SERROT CORPORATION 1012
5401 Argosy
Huntington Beach, CA 92648
714/895-3010

Specializing in the fabrication and installation of geomembrane liners and floating covers. We can provide backup engineering experience and support to ensure successful installations in a broad span of applications from hazardous waste liners, sewer treatment plants, chemical cell liners and

landfills. In addition we have a large prefabrication facility that makes liners for specialty applications.

SLT North America, Inc.   2506
16945 Northchase
Houston, TX 77060
713/874-2150

SLT the world's originator of High Density Poly-ethylene Lining Systems; manufactures & installs its own patented lining innovation FrictionFlex, from 60-240 mils. SLT also manufactures & installs HyperFlex, UltraFlex & PolyLock for landfills, tunnels, floating covers, primary & secondary containments, leach pads & potable water containments.

**SMC Environmental
Services Group**   2113-2115
Box 859
Valley Forge, PA 19482
215/265-2700

For more than 35 years, SMC Environmental Services Group's Scientists and Engineers have been providing environmental, engineering and consulting support to industry, bankers, lawyers, developers, and government agencies. Areas of expertise include: solid and hazardous waste, industrial hygiene and occupational safety and health, water and wastewater treatment systems, land planning, environmental property and facility audits, wetlands assessments/delineations, and a range of engineering specialties.

SSI Shredding Systems   1019
28655 S.W. Boones Ferry Rd., P.O. 707
Wilsonville, OR 97070
503/682-3633

SSI Shredding Systems provides on-site volume reduction and material processing of solid hazardous waste prior to material treatment. Specific services include pre-processing, feedstock preparation and volume reduction of solid hazardous waste utilizing mobile, low-speed rotary shear shredders. This low RPM equipment is easy to trailer mount and once on-site, is operational within hours. OSHA certified operators are provided. Other services include solvent recovery and volume reduction/blending for stabilization.

**SURETEK: Surety
Teknicians, Inc.**   2512
4830 W. Kennedy Blvd., Suite 600
Tampa, FL 33609
813/281-2550

SURETEK is a National Bond-only agency specializing in all types of Environmental Bonds, including: Remedial Action; Superfund; Lining Systems; Landfill Closure; Contractors; Underground Storage Tanks; Analytical/Laboratory; Monitoring & Detection; Transport; and Consultants/Engineers. We handle Contractors of all sizes, from those needing Small Bonds to Multi-National Public Companies.

Safety Storage, Inc.   LDC
2380 South Bascom Ave.
Campbell, CA 95008
408/559-3901

Sanderson Equipment Inc.   1603
P.O. Box 1066
Princeton, NC 27569
919/936-2042

Sanderson Equipment, Inc., is the USA distributor for the R-B VC Series of Long Reach Excavators. Utilizing a moving counterweight, the VC reaches up to 65' with a one cubic yard bucket which can be placed precisely where needed for a high degree of productivity and safety.

**Science Applications
Internat'l Corp.**   0811
1710 Goodridge Dr.
McLean, VA 22102
703/734-4302

**Scientific Specialties
Service, Inc.**   1107
4030 Benson Ave.
Baltimore, MD 21227
301/644-6200

Scientific Specialties Service, Inc., is showing its line of environmental sampling supplies. Including precleaned and regular vials, bottles, and jars in both glass (which is also available Safety-Coated, if desired) and plastic. They are also showing their Teflon® Capliners and Teflon®/Silicone septa and their line of Teflon® Sealing tapes and Teflon® tubing in an extensive range of sizes.

**Sevenson Environmental
Services, Inc.**   1406/1408
2749 Lockport Rd.
Niagara Falls, NY 14302
716/284-0431

Sevenson Environmental Services, Inc., provides remedial construction services to government and industry in site restoration; excavation, characterization, transportation, and disposal of bulk and drummed wastes; secure landfill and lagoon construction/closure; slurry wall construction; sludge solidification; recovery and treatment systems installations for groundwater, soils and air; leachate collection and treatment systems construction; on-site incineration; biological remediation; facilities decontamination and demolition; dewatering; and storage tank removal/remediation.

**Shields Manufacturing/
Unified Safety Corp.**   0604-0606
624 Maulhardt Ave.
Oxnard, CA 93030
805/988-1055

Environmental Compliance Products, HazMat Storage Facilities, Secondary Containment Systems, Fire Rated and Non-Fire Rated, **First** and **Only** Non-combustible Fire Rated, Factory Mutual Approved Units in the U.S.A.

**Shimadzu Scientific
Instruments, Inc.**   1707
7102 Riverwood Dr.
Columbia, MD 21046
301/381-1227

Shimadzu is among the three largest scientific instrument companies in the world. The broad product line includes gas & liquid chromatographs, spectrophotometers, TOC and thermal analyzers, oil content meters, and balances, turn key

and/or special application instruments such as Environmental GC, TOGAS, and Carbamate analyzers are also available.

Site Reclamation Systems, Inc.   0516
P.O. Box 11
Howey-in-the-Hills, FL 34737
904/324-3651

Manufacturing, Remediation: Mobile Rotary Kiln/Afterburner System designed to treat soils contaminated by light petroleum products such as gasoline, aviation gas and diesel fuel.

Skolnik Industries, Inc.   2510
4900 South Kilbourn Ave.
Chicago, IL 60632
312/735-0700

New steel containers (carbon, composite and stainless), SALVAGE DRUMS and OVERPACKS, drum tools and accessories, heavy-duty dolly, utility carts, components and drum replacement parts, drum liners and hoist paks.

**Solarchem Environmental
Systems**   1814
40 West Wilmot St., Unit #5
Richmond Hill, Ontario L4B 1H8
416/764-9666

SOLARCHEM ENVIRONMENTAL SYSTEMS is the manufacturer of RAYOX®, a second generation enhanced oxidation process for the destruction of toxic and hazardous organic contaminants in industrial process wastewater and contaminated groundwater. RAYOX® has also been applied to contaminated water from Superfund sites.

Soils Magazine   LDC
10229 E. Independence Ave.
Independence, MO 64053
816/254-8735

Solinst Canada Ltd.   2400
The Williams Mill, 515 Main St.
Glen Williams, Ontario, Canada L7G 3S9
416/873-2255

Manufacturers of high quality groundwater monitoring instrumentation, known for the Waterloo Multilevel System and reliable water level indicators. New this year are: a Water Level Meter tape marked each 1/50 ft. and improved environmental probe. Also an Interface Meter which measures the level and thickness of both floating and sinking hydrocarbons.

Solmar Corporation   0813
625 West Katella Ave. Suite 5
Orange, CA 92667
714/538-0881

Advanced Bio Cultures - Formulated bacterial products for the remediation of hazardous waste, containment soils and groundwater, and industrial and municipal wastewater. Solmar is a customer-oriented service company providing excellent support for our products, with years of experience in bioremediation.

Southdown Environmental   1206
Systems, Inc.   1208/1210
1200 Smith St., Suite 2400
Houston, TX 77002
713/653-8043

Advanced Organics-Processing Technologies.

997

**Southern Bonding and
Insurance Brokers, Inc.** 2321
2540 Professional Rd., Suite 8
Richmond, VA 23235
804/320-8390

Southern Bonding and Insurance Brokers is an
agency established to service the needs of contractors and consultants working in the environmental
field. Unique experience and knowledge of the
specialized area of environmental liability and
risk management, provide our clients the opportunity to choose the product best suited to their
needs. Call (703) 525-8060 for more information.

**Southwest Laboratory
of Oklahoma** 0417
1700 West Albany - Ste. C
Broken Arrow, OK 74012
918/251-2858

Quality and service oriented laboratory offering:
CERCLA, SARA, RCRA, Priority Pollutants,
Dioxins/Furnas, Appendix IX, Explosives and
TCLP. SWLO is a full participant, in good standing, in the CLP program with contracts for organics, inorganics, and high concentration organics.
Also, certified by Corps of Engineers for explosives and DERA PROJECTS.

Southwest Research Institute 1615
6220 Culebra Rd.
San Antonio, TX 78228-0510
512/522-2687

Southwest Research Institute provides commercial leak location surveys of geomembrane liners
for landfills, impoundments, and lined tanks to
accurately locate leaks in the material and seams.
Analytical laboratory systems and techniques will
be presented for both the sampling and analysis of
environmental pollutants. Bio-degradation techniques will also be discussed.

**Specialized Environmental
Equipment, Inc.** 0809
311 Three & Twenty School Rd.
Easley, SC 29642
803/859-8277

Mobile Laboratories: Chemical Analysis Units,
Water Pollution Analysis Units, Decontamination
Units. Special Service Units: Emergency Preparedness Trailers. Flow-Thru Proportional Bioassay
Dilutor Systems; Dual Purpose Pumps; Water
Baths; Reactors; and Oxygen Demand Apparatus.

Staff Liners Industries 1417
240 Chene St.
Detroit, MI 48207
313/259-1818

Liners and Caps fabricated and installed worldwide for hazardous and non-hazardous sites.
RCRA and all Agency compliance. Forty (40)
hour OSHA trained and medical'd crews with
immediate response capability. 1910.120,134 All
materials - PVC, CPE, CSPE (Hypalon®, EIA (XR-5®), LDPE and HDPE. References. Call (800) 526-1368 or (303) 259-1820 for more information.
Our FAX number is (313) 259-0631.

Stearns and Wheler 1407
1 Remington Park Dr.
Cazenovia, NY 13035
315/655-8161

Stearns & Wheler is an environmental engineering and scientific consulting firm. With nearly 200
professionals and support personnel, the firm
offers services in property audits, petroleum engineering, hydrogeologic investigations, remedial
investigation/feasibility studies, remedial designs, industrial hygiene, and risk assessments.
Headquartered in Cazenovia, New York, the
branches are in Tampa, Florida, Darien, Connecticut, and Bedford, New Hampshire.

Stout Environmental, Inc. 1120/1122
101 Jessup Rd.
Thorofare, NJ 08086
609/384-8000

Stout Environmental, Inc., is a full service environmental management company providing treatment and disposal of hazardous, industrial, and
municipal wastes, along with a broad range of
specialized support services. Our 15 service divisions enable us to offer a turnkey approach to
environmental problems providing timely and
cost-effective solutions.

Sverdrup Corporation LDC
801 North Eleventh
St. Louis, MO 63101
314/436-7600

With over 60 years of providing total project management, Sverdrup Corporation continues to
maintain its status as one of the most diversified
companies in the industry. Our Environmental
Divisions continue to provide a growing list of
clientele with engineering services in the areas of
hazardous waste, wastewater treatment, ultrapure
water, and air quality control.

**Sybron Chemicals, Inc./
Biochemical Div.** 2007
P.O. Box 66
Birmingham Rd.
Birmingham, NJ 08011
609/893-1100

Leaders in the application of Augmented Bioreclamation (ABR) for the treatment of contaminated soil and groundwater. Capabilities include
biosystems engineering services and supply of
selectively adapted organisms for specific containments. Technology useful for cleanup of
chemicals from leaking storage tanks, pipeline
spills, train derailments, etc. Advantages are ultimate disposal technology and low cost.

TCT-St.Louis 2408
1908 Innerbelt Business Center Dr.
St. Louis, MO 63114
314/426-0880

TCT-St. Louis (formerly Envirodyne Engineers,
Inc.) is a consulting engineering firm and an analytical laboratory. Our certified laboratory offers
full service capabilities including: radioactive
waste analyses, dioxins/furans, explosives, Appendix VIII/IX, EP Toxicity, TCLP, Priority Pollutants, herbicides, and all conventional inorganic
parameters in wastewater, potable water, soil, air,
and biological matrices. Our engineering services
include site assessments, UST, treatability studies,

groundwater monitoring, RI/FS, design and construction oversight.

TERRA VAC LDC
P.O. Box 2199
Princeton, NJ 08543-2199
609/530-0003

Terra Vac is a subsurface remediation company
providing the full range of technologies, technical
expertise and construction services required for
the resolution of soil and groundwater contamination problems. Terra Vac's services are focused
on the definition and implementation of remedial
programs which utilize on-site technologies to
address subsurface contamination in situ.

TETRA TECH, INC. 1409
630 N. Rosemead Blvd.
Pasadena, CA 91107
818/449-6400

Tetra Tech is a consulting engineering firm with
expertise in designing and implementing environmental engineering projects for private industry
and government. Lines of business include environmental contamination assessment and
cleanup, and innovative engineering solutions for
facilities design, process automation, and waste
management. Current clients represent all sectors
of business and industry as well as federal, state,
and municipal government agencies.

TMS Analytical Services, Inc. 0104
7726 Moller Rd.
Indianapolis, IN 46268
317/875-5894

While specializing in Dioxin/Furan analysis, TMS
offers a full complement of environmental testing,
including those specified by EPA for drinking and
waste waters, air, and solid waste. State of the art
instrumentation includes GC, GC/MS, GC/MS/
MS, GC/HRMS, HPLC, AA, ICP, and IR with
computer interfaces.

**TMS, Inc.
c/o U.S. Department of Energy** LDC
20201 Century Blvd.
Germantown, MD 20874
301/353-0102

TechLaw, Inc. 1201
14500 Avion Parkway, Suite 300
Chantilly, VA 22021-1101
703/818-1000

TechLaw, an environmental consulting firm experienced in the application of legal and technical
principles to tasks in support of RCRA and CERCLA enforcement activities, provides services including: PRP searches, image based case management, computer tracking systems, evidence
audits, documentary inventory systems, legal research, full text databases, transactional data validation, environmental site assessments and compliance audits.

Technical Minerals, Inc. 1910
P.O. Drawer 23028
Jackson, MS 39225-3028
601/944-4758

Technical Minerals, Inc. (TMI) products are the
culmination of a technical approach to problem

solving which involves a unique mixture of proprietary processes and materials. Surface modified minerals from TMI have been specially designed for a broad line of environmental and industrial application.

Tekmar Company 1614
P.O. Box 371856
Cincinnati, OH 45222-1856
513/761-0633

(1) LSC 2000 Series of Purge and Trap/Dynamic Headspace Concentrator; (2) the Automatic Process Sampler samples up to six aqueous streams which may be monitored either sequentially or on a timed basis using an internal real time clock; and (3) Static Headspace System: the SHS 7000 offers an unprecedented approach to static headspace analysis that significantly increases throughput and reproducibility; whether using static headspace for screening or direct analysis, sample integrity is assured by Tekmar's superior product performance.

Thermo Analytical, Inc. 2003
5635 Jefferson Blvd., N.E.
Albuquerque, NM 87109
505/345-9931

Thermo Analytical Inc.'s (TMA's) network of laboratories provides a full range of analyses of environmental contaminants and radioactive materials in soil, water, air, industrial waste and other matrices. TMA laboratories have analytical capabilities for the detection of pesticides, herbicides, industrial solvents, PCBs, dioxins, asbestos, trace metals, and over 200 radionuclides.

**Thermo Environmental
Instruments, Inc.** 0609
8 West Forge Parkway
Franklin, MA 02038
508/520-0430

Thermo Environmental Instruments will display a complete line of portable instruments for the field measurement of toxic vapors and liquids, including the new Model 580B Portable Organic Vapor Meter (OVM).

Tigg Corporation 1205-1207
P.O. Box 11661
Pittsburgh, PA 15228
412/563-4300

Manufacturers of modular adsorbers designed for the remediation of vapor and water pollution. The combination of over 30 years of experience with adsorbents and systems provides unique capabilities of technical expertise and product availability to address specific remedial problems with the most appropriate technology.

Toney Drilling Supplies, Inc. 1301
14060 NW 19 Ave.
Miami, FL 33054
305/685-2453

Complete line of drilling equipment: New/used drill rigs, drill rods, subs and bits. Diamond bits, core barrels, mud and additives; augers, casing and plugs; stainless steel screens, PVC screens, points and pcaps; monitoring and sampling devices; safety clothing, masks, gloves and boots. Consultation and instruction are also available.

Tracer Research Corporation 1602
3855 North Business Center Dr.
Tucson, AZ 85705
602/888-9400

Tracer Research Corporation specializes in leak detection for underground storage tanks, bulk storage, above ground tanks and pipelines; Tracer technology for groundwater monitoring and landfill liner tightness testing; on-site detection of subsurface volatile organic contaminants (Soil Gas Analysis); full-service organic analysis laboratory services.

TreaTek, Inc. 1316
2801 Long Rd.
Grand Island, NY 14072
716/773-8661 or 800/833-3335

TreaTek is an environmental service subsidiary of Occidental Chemical Corporation, and has as its commercial objective the application of advanced microbial and chemical treatment technologies to the remediation of waste streams and containment soil. TreaTek can provide remedial consultation, laboratory treatability studies (biological, chemical & physical), analytical support, system design & specifications and turnkey project management.

Triangle Laboratories, Inc. 0212
801-10 Capitola Dr.
Research Triangle Park, NC 27713
919/544-5729

Triangle Laboratories, Inc. includes two employee-owned contract laboratories specializing in the analysis of organic compounds. Both laboratories offer high quality environmental analysis using EPA approved methods guaranteed by experienced scientists. The Research Triangle Park (NC) facility is nationally recognized for low detection analysis for polychlorinated dibenzo-p-dioxins and dibenzofurans.

**Trinity Environmental
Technologies, Inc.** 0103
6405 Metcalf, Suite 313
Overland Park, KS 66202
913/831-2290

EPA-approved destruction of PCBs in mineral oil dielectric fluid less than 18,000 ppm; EPA-approved destruction of PCBs in other oils less than 500 ppm (fuel, #2, and hydraulic oils); Disposal of PCB-contaminated water; Laboratory analysis for PCBs in oil, water, solids, surface wipes and air monitoring cartridges with fax reporting from our laboratory within 48-hours at no extra charge; PCB sampler/mailer kits for oil, water, solids and surface wipes.

**Troxler Electronic
Laboratories, Inc.** 0709
P.O. Box 12057
Research Triangle Park, NC 27709
919/549-8661

Troxler, the World's leader in depth moisture, surface moisture/density and sediment density technology, has developed a full line of gauges for the hazardous materials industry. Introducing this year, the Sentry 200. A permanently installed,

non-nuclear moisture gauge with the accuracy of our State-of-the-Art Neutron Probe.

U.S. Analytical Instruments 1416
1511 Industrial Rd.
San Carlos, CA 94070
415/595-8200

Available for rent and immediate delivery - HNU model 101s, Foxboro OVA 128GCs, and Photovac MicroTips from U.S. Analytical Instruments. In addition, USAI offers for rent or lease GC, HPLC, Fluorescence, UV/VIS, AA and ICP, IR and FTIR instrumentation from major manufacturers such as Hewlett-Packard, Perkin Elmer, Varian, Foxboro, and Waters. We offer flexible rental and purchase option plans designed to meet your financial and instrumentation needs.

U.S. Army Corps of Engineers 0407
P.O. Box 103, Downtown Station
Omaha, NE 68101
402/691-4532

The U.S. Army Corps of Engineers and the U.S. EPA have joined forces to clean up Federal lead hazardous waste sites under the Superfund program. The booth will be manned by Corps personnel to assist architect-engineer firms and construction contractors take advantage of work available to them through the Corps of Engineers.

**U.S. Army Toxic & Haz.
Mat. Agency** 2202
Bldg. E4460, Attn: CETHA-PA
Aberdeen Proving Ground, MD 21010-5401
301/671-2556

U.S. Bureau of Mines 1026/1028
2401 E Street NW, MS 6201
Washington, DC 6201
202/634-1224

The U.S. Bureau of Mines conducts research to help managers, consultants, and engineers better handle mining and minerals processing wastes. In addition, experts at the Bureau analyze the impact of existing and proposed regulations on sectors of the industry. Results of these efforts will be available through free technical publications and the Bureau's exhibit at Superfund '90.

U.S. Bureau of Reclamation 1018
Mail Code D-3800
P.O. Box 25007
Denver, CO 80225
303/236-8646

The U.S. Bureau of Reclamation provides Total Project Management in hazardous waste site cleanup-PA/SI, RI/FS, RD, RA, and O&M. Work may be completed for other government agencies in planning, designs, construction, construction oversight, reviews or research. Work has been completed under RCRA, Superfund, and Federal Facilities section of CERCLA.

U.S. DOE Five-Year Plan 2405
EM-2
1000 Independence Ave., S.W.
Washington, DC 20024
202/586-4373

This five-panel exhibit described the U.S. Department of Energy's Office of Environmental Resto-

ration and Waste Management's Five Year Plan. This plan was developed to set DOE's strategy and activities for cleaning up and restoring its nuclear research and production sites.

U.S. Environmental 2311-2320
Protection Agency 2311-2319
26 W. M.L. King Dr. & 2312-2320
Cincinnati, OH 45268
513/569-7522

The U.S. Environmental Protection Agency is responsible for developing regulations, implementing programs, and conducting research to carry out its mandate established in the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA/Superfund) and other Hazardous Waste Management statutes.

U.S. Envirosearch, Inc. LDC
445 Union Blvd., Suite 225
Lakewood, CO 80228
303/980-6600

A nationwide recruiting firm based in Denver, Colorado, specializing in the recruitment of hazardous waste, environmental and incineration personnel. U.S. Envirosearch represents client companies in the areas of: hazardous waste disposal, site remediation, environmental engineering, analytical laboratories, environmental law, air quality, solvent recycling, PCB disposal, industrial cleaning and generators.

U.S. Geological Survey 1020-1024
12201 Sunrise Valley Dr. MS 790
Reston, VA 22092
703/648-4377

Panels depicting research and products of the U.S. Geological Survey dealing with earth sciences.

ULTROX INTERNATIONAL 2200
2435 S. Anne St.
Santa Ana, CA 92704
714/545-5557

The innovative ULTROX® process utilizes ultraviolet light with ozone and/or hydrogen peroxide to destroy toxic organic contaminants in groundwater, surface waters, wastewaters and leachate, on site. No sludges or wastes are generated requiring regeneration, disposal or incineration. UNTROX® is used as a stand alone treatment system and with other technologies.

URS Consultants, Inc. 1511
One Penn Plaza, Ste. 600
New York, NY 10119
212/736-4444

URS' multidisciplinary staff of engineers and scientists provides a full range of hazardous waste management services to governmental and private entities through its 25 offices nationally. Services include remedial investigations, feasibility studies, design of remedial actions, treatment system design, implementation of remedial actions, RCRA services, regulatory and permit support and litigation assistance.

USPCI, Inc. 0703/0705
515 West Greens Rd., Suite 500
Houston, TX 77067
713/775-7800

A full-service hazardous waste management

company. Services include laboratory analysis, transportation, treatment, remediation and disposal.

Union Carbide Industrial
Gases, Inc. 2216
39 Old Ridgebury Rd.
Danbury, CT 06817
203/794-5601

America's leading producer of industrial gases, including oxygen and nitrogen. The LINDE Oxygen Combustion System can safely double the capacity of your incinerator reducing CO excursions and auxiliary fuel consumption. See us to learn about recent Superfund installations.

University of Findlay LDC
1000 N. Main
Findlay, OH 45840
419/424-4540

Training and education provided in the areas of hazardous materials/waste, emergency response, spill response, confined space entry, asbestos removal, 40 hour OSHA, 8 hour OSHA and OSHA site supervisor training. Hands-on training facility. On-site training available upon arrangement.

VFL Technology Corporation 1007
42 Lloyd Ave.
Malvern, PA 19355
215/296-2233

VFL Technology Corporation is a civil/geotechnical construction firm specializing in the design and implementation of solutions to a variety of waste management problems. Services include soil/sludge solidification and stabilization, lagoon/landfill closures, hazardous site remediation, groundwater recovery and treatment, on-site treatment systems, excavation, treatment and disposal of contaminated materials on-site or off-site.

Vapex Environmental
Technologies, Inc. 1716
480 Neponset St.
Canton, MA 02021
617/821-5560

Vapex designs, installs, and operates high technology remediation systems for the cleanup of soil and groundwater. SOIL VAPOR EXTRACTION SYSTEMS FOR VOC SOIL TREATMENT: bench scale and field treatability testing; proprietary 3-D air flow modeling; chemical transport modeling; AIR SPARGING: for groundwater treatment; BIOVENTING: for treatment of semi-volatiles.

Versar Laboratories, Inc. 1213
6850 Versar Center, P.O. Box 1549
Springfield, VA 22151
703/750-3000

Versar Laboratories, Inc. provides comprehensive environmental analytical chemistry services. Capabilities include GC/MS, GC, AA, ICP, HPLC, Bioassay and various general chemistry techniques. Certified by USCOE-MRD, MMES and seven states.

Vesta Technology, Ltd. 0112
1670 West McNab Rd.
Fort Lauderdale, FL 33309
305/978-1300

Mobile On-Site Incineration Service.

Viar and Company, Inc. 1715
300 N. Lee St.
Alexandria, VA 22314
703/684-5678

Viar is an environmental sciences and systems development consulting firm of 250 providing program management and technical support to federal clients. Our services include: QA design/monitoring, data interpretation/validation; program budget, administrative and technical analyses; and all aspects of scientific, financial, and management information systems technology evaluations, design and development, and operational support services.

Vortec Corporation 1807
3770 Ridge Pike
Collegeville, PA 19426
215/489-2255

Vortec brings to the market a revolutionary new approach to solving hazardous waste disposal problems with its Advanced Vitrification/Incineration Process (AVIP). This system offers a new, modern alternative to standard and costly landfilling (in hazardous landfills) which is the current solution for disposal of most solid hazardous wastes.

WATERSAVER
COMPANY, INC. 1211
P.O. Box 16465
Denver, CO 80216
303/289-1818

Watersaver provides the world's most reliable membrane lining systems. Meet all state and federal regulations with Watersaver. Liners and closure caps for a wide variety of applications. Custom fabrication and installation of CSPE, CPER, PVC, XR-5, and others. Continuous service for over 30 years.

WSOS Community Action
Commission, Inc. LDC
P.O. Box 590, 109 South Front St.
Fremont, OH 43420
419/334-8911

WSOS provides head start programs, services for senior citizens, housing and energy programs, food services, outreach services, economic and community development, employment and training programs and environmental programs.

Wadsworth/ALERT
Laboratories, Inc. 1111
4101 Shuffel Dr. N.W.
North Canton, OH 44720
216/497-9396

Laboratory services for environmental and industrial hygiene markets. Analysis of soil/sediment, sludge/waste, and water and air, using state of the

art equipment, including GC/MS, GC, HPLC, AA, ICP, TOX, TOC and IR. Facilities include fixed location and mobile laboratories.

**Waste Abatement
Technology, Inc. (WATEC)**   0513
1300 Williams Dr.
Marietta, GA 30066
404/427-1947

Waste Abatement Technology, Inc. (WATEC), provides a full range of remediation services including: excavation of contaminated soils, waste deposits and drums; drum handling, characterization and removal; industrial UST remediation; surface impoundment closure-in-place stabilization, sludge removal and dewatering; water treatment (process, surface and groundwater); building decontamination; on-site treatment - physical, chemical, biological; transportation and disposal. WATEC, in both the public and private sector, has consistently demonstrated its ability to compete for and then carry projects to successful completion. This success is attributed to our staff of professionals and technicians who are well respected in the hazardous waste cleanup industry and our corporate commitment of placing senior level professionals in charge of site operations. These individuals, combined with our desire to excel in project execution, form the foundation for our record of innovative and successful project completion. WATEC's Marietta, Georgia, location can service sites nationwide. Additionally, we augment our capabilities through staff and services provided to us by our sister company, ATEC Associates, Inc., and its 45 offices.

Waste-Tech Services, Inc.   2409
800 Jefferson County Pkwy.
Golden, CO 80401
303/279-9712

Waste-Tech Services, Inc. (WTS), an affiliate of Amoco Oil Company, is "Making a Difference" in hazardous waste management through the application of proven and innovative technologies in the areas of thermal destruction and waste minimization. WTS offers services from design through operations. Let WTS make your difference!

Water Pollution Control Federation   LDC
601 Wythe St.
Alexandria, VA 22314-1994
703/684-2400

The Water Pollution Control Federation is a technical, professional organization of 36,000 members from Member Associations and affiliated associations throughout the world. Dedicated to "preserving and enhancing water quality worldwide," the WPCF offers more than 80 publications, 8 periodicals, educational training materials, a water curriculum program for schoolchildren, public education materials, career information, safety & health videos, and technical services.

Wayne Associates, Inc.   2001
2628 Barrett St.
Virginia Beach, VA 23452
804/340-0555

We are one of the oldest and largest specialized

recruiting firms serving the hazardous waste industry (since 1978). Our services include both retained contract and contingency search and our expertise covers all areas of the Hazwaste & Environmental market. We effectively service a nationwide client base. Stop by booth 2001 to discuss to discuss your company's needs or to investigate career alternatives.

Well Safe, Inc.   0913-0914
10223 FM 1464
Richmond, TX 77469
713/277-2530

Hazardous Waste, Petro-Chemical Industry and Oil & Gas Drilling and Production Safety Services. Specializing in on-site breathing air, breathing apparatus, instrumentation, on-site safety supervisors and decontamination services.

Westates Carbon, Inc.   0108
2130 Leo Ave.
Los Angeles, CA 90040
213/722-7500

Westates specializes in activated carbons, water and air pollution control equipment, solvent recovery, odor and corrosion control, precious metal recovery and custom engineered systems. Westates maintains a complete in-house laboratory for quality assurance, carbon testing and evaluation. Sales and service offices in Los Angeles, Oakland, Cincinnati, Houston and New York.

Westbay Instruments Inc.   0305
507 E. Third St.
North Vancouver, BC V7L 1G4
604/984-4215

Westbay manufactures and markets the MP System which allows multi-level groundwater monitoring in a single drillhole. This system reduces project costs and time related to drilling while improving filed quality control. In addition, water sampling with the MP System is achieved without repeated purging, thereby reducing operating costs. For more information, dial (800) 663-8770 (in U.S.).

**Westinghouse Environmental
Systems and Services**   1411/1413
875 Greentree Rd., Bldg. 5, 1st Floor
Pittsburgh, PA 15220
412/937-4061

Westinghouse offers a full range of environmental assessment and engineering approaches, environmental remediation, and hazardous waste treatment, storage and disposal services. Employing the best available technologies at TSD facilities in Minnesota, Kansas and Utah, Westinghouse helps clients deal effectively with stringent environmental requirements for disposing of wastes regulated under TSCA, RCRA and CERCLA.

**Williams Environmental
Services, Inc.**   LDC
1530 Alabama St.
Auburn, AL 36830
205/821-9250

Williams Environmental Services, Inc., does on-

site remediation using mobile equipment, primarily thermal processing, volume reduction and stabilization of hazardous waste.

Wilson Laboratories   0208
525 N. 8th St.
Salina, KS 67401
913/825-7186

Wilson Laboratories provides accurate and timely analytical services to industry, governmental agencies, municipalities and private consultants. Our services include: groundwater, waste water, and drinking water analysis; toxic and hazardous waste analysis for inorganics, organics and PCBs in various matrices.

Woodward-Clyde Consultants   1911
4582 S. Ulster St., Ste. 600
Denver, CO 80237
303/740-2600

Woodward-Clyde Consultants is a professional services firm with over 30 years of experience in geotechnical engineering, environmental, and social sciences. In hazardous waste, we offer total management solutions, from evaluation, permitting and initial investigation through design, construction, and remedial action. Our scientists and engineers represent all disciplines necessary to provide complete services - the earth, physical, and natural sciences as well as environmental, chemical and geotechnical engineering. With offices in 45 cities, we are staffed and positioned to offer nationwide management programs that are both comprehensive and responsive.

Worne Biotechnology, Inc.   0107
1507 U.S. Route 206
Mt. Holly, NJ 08060
609/261-5550

Worne Biotechnology, Inc., is a biotechnology company providing professional environmental and biological consulting services to both government and industry for the biological detoxification of hazardous and toxic organic wastes throughout North America, South America and Asia. WBI uses laboratory remediation studies coupled with environmental analysis, hydrology and feasibility evaluation to define environmental projects and integrates biotechnology with regulatory requirements to solve enviromental problems. WBI high rate biological reactors for industrial wastewater treatment and develops highly effective microbial ecosystems for these reactors to remove recalcitrant halogenated and non-halogenated organic wastes from municipal, agricultural and industrial waste streams.

**Youngstown Barrel &
Drum Company**   LDC
1043 Marble St.
Youngstown, OH 44502
216/746-3277

Youngstown Barrel & Drum Company is your one-stop container source specializing in a full line of standard and specialty pails, drums, overpacks, components and accessories made of steel, stainless, plastic, fibre or composites, from 2 gallon to 110 gallon capacity. In full compliance with all applicable DOT and/or U.N. specifications.

Containers are in stock and ready to ship in any combination of sizes, types, styles and quantities. There is no minimum. Reconditioned containers are also available. Call 1-800-359-DRUM for more information.

Zimpro/Passavant   2222/2223
301 W. Military Rd.
Rothschild, WI 54474
715/359-7211

Zimpro/Passavant is the developer of the PACT® wastewater treatment system, and wet air oxidation. Used in tandem, or singly, they are effective technologies for treating hazardous wastewaters and sludges, including process discharges, contaminated groundwater of surface runoff, landfill leachates. Portable units, factory-built skid-mounted plants, field-erected systems. Treatability studies and complete analytical laboratory capabilities.
