**A Report of the  
Chesapeake Bay Liaison Office**

**August 1988**

## Acknowledgements

---

The Point Source Atlas was written by Joseph Macknis, Environmental Protection Agency/Chesapeake Bay Program. The Atlas could not have been completed without support from state staff, particularly Jeff Rein, John Veil and Arcaido Sincero of Maryland; Al Pollock, John Kennedy and Richard Ayers of Virginia; and Cedric Harper and Lou Bercheni of Pennsylvania.

EPA Chesapeake Bay Program staff also contributed to the manuscript. David Clements, Computer Sciences Corporation/Chesapeake Bay Program, was responsible for data management. Tami Gill and Nina Fisher, Computer Sciences Corporation/ Chesapeake Bay Program, created the graphics and Will Neville, CSC, created the maps. Nina Fisher also provided technical editing and designed the format.

## Introduction

---

A computerized data base of Chesapeake Bay point source dischargers has been developed to document information on point source pollutant input to the Bay. Installed on the Chesapeake Bay Program computer and available to registered users, the Chesapeake Bay point source data base (Atlas 85) provides a central repository for locational and administrative data on almost 6,000 point source dischargers located in the commonwealths of Virginia and Pennsylvania, the states of Maryland, New York, West Virginia and Delaware, and the District of Columbia.

Point sources of pollution are defined as municipal and industrial plants that discharge waste to a water body from a discrete pipe or ditch. Municipal point sources are wastewater treatment plants that receive and treat both domestic wastewater and wastewater generated by local commercial and industrial activities. These wastewaters contain large amounts of organic matter, including nutrients such as phosphorus and nitrogen, that may cause significant depletion of dissolved oxygen (DO) in the receiving stream. Heavy metals, chlorinated hydrocarbons and other toxic substances may also be present.

Industrial point sources are commercial and industrial plants that carry out diverse and complex manufacturing processes which require solvents, catalysts, and other chemicals that contaminate discharged wastewater. These wastewaters may also contain large amounts of oxygen demanding substances. In the Bay watershed, there are 461 different types of industrial activity, including coal mining, iron and steel production, electric power generation, seafood processing, inorganic and organic chemical manufacturing, concrete manufacturing, and petroleum refining.

The point source data base contains information on 1345 municipal dischargers and 4651 industrial dischargers. Of these, 205 municipal and 192 industrial dischargers have been designated as major dischargers. The location and distribution of major dischargers are displayed in Figure 1. It is important to note that this point source map shows only the general location of sources and is intended primarily to illustrate the number and geographic distribution of selected categories of point sources.

The point source data base provides 1985 wastewater characteristics for more than 500 municipal dischargers and estimates nutrient and toxicant wastewater concentrations for 93 different types of industrial activities with the potential to generate and discharge these pollutants.

The information in the point source data base was initially compiled from federal data bases such as the Environmental Protection Agency (EPA) Needs Survey and Permit Compliance System; it was then refined and expanded with state and facility data. A more complete description of data sources may be found in the data base documentation file available from the Chesapeake Bay Liaison Office.

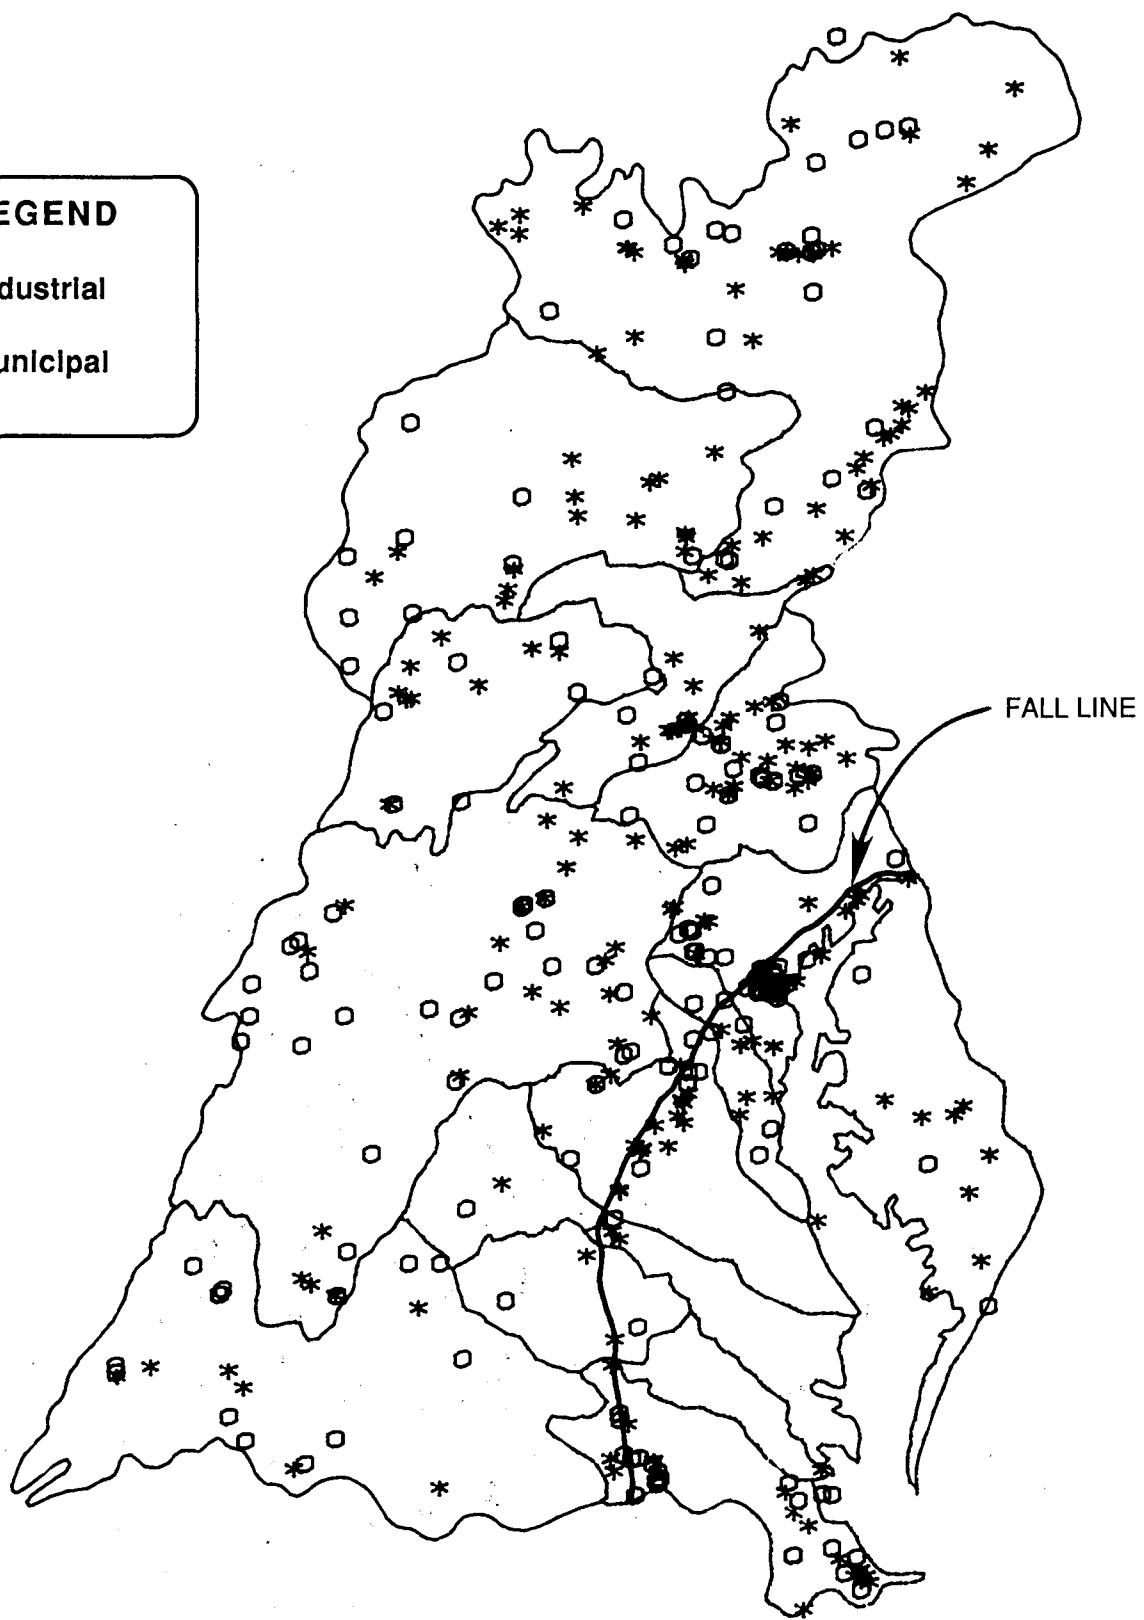

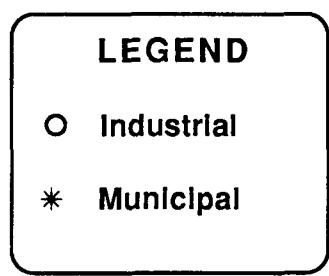

All effluent data are annual averages for the calendar year 1985. As such, the information in the data base serves as the baseline from which progress towards meeting the Bay Agreement commitment to reduce nutrient loads, reduce toxic discharges and control conventional pollutants can be measured. Importantly, municipal wastewater characteristics and industrial nutrient loads are consistent with state estimates presented in state nutrient reduction strategies (April 1988). These estimates include industrial nutrient sources not available during preparation of the report, "A Commitment Renewed" (Implementation Committee, February

1988). As a result, industrial nutrient loads (and percentages of point source total) are slightly higher than those cited in the earlier report.

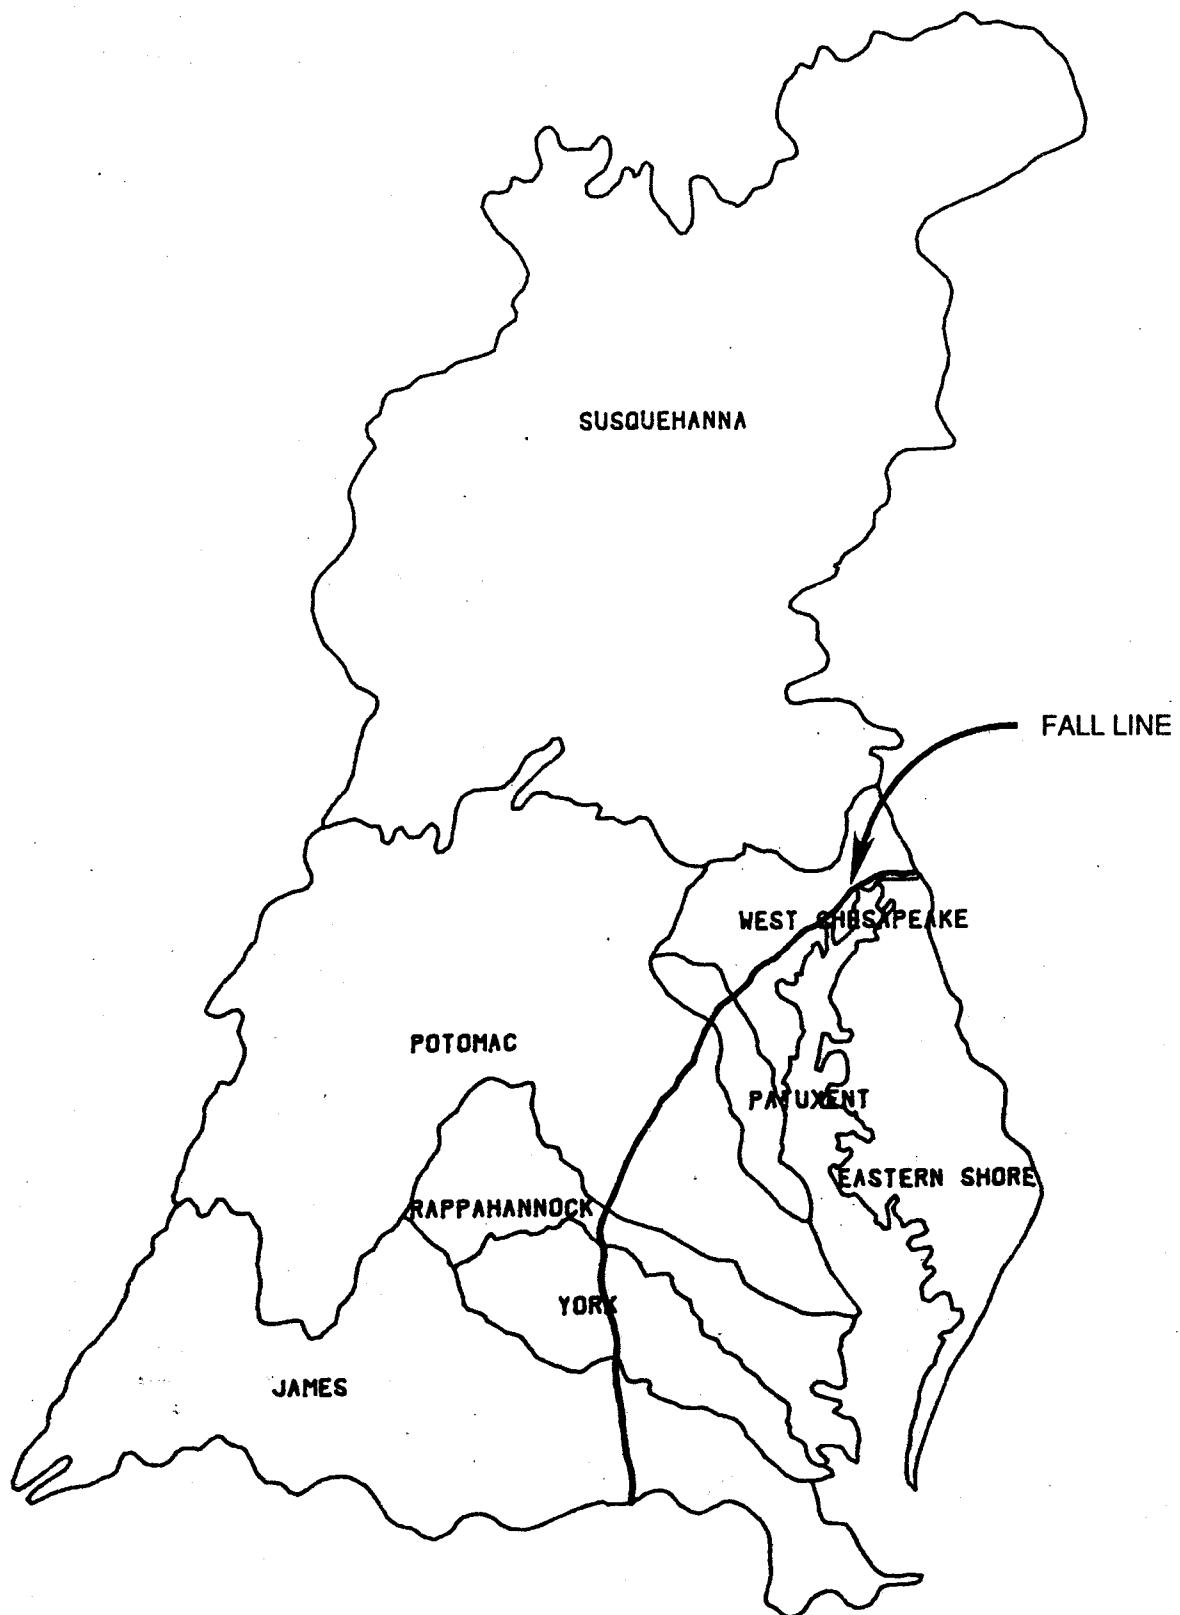

Other applications of the data base include evaluation of point source management alternatives, tracking program implementation, model input and loading calculations. Descriptive statistics and analyses derived from the data base are presented in the following discussions. The final section contains a data dictionary and describes how the data base may be accessed and used for other analyses.

The point source loadings presented are discharged pollutant loads. Discharged pollutant loads are "end of pipe" loads and do not reflect natural physical and chemical decay processes that occur as the loads are transported from the upper watershed to the Chesapeake Bay. The fall line (defined as the point on the Bay tributaries, usually marked by a waterfall, which signalizes the boundary between the resistant crystalline rocks of the Piedmont Plateau and the less resistant sediments of the Atlantic Coastal Plain) creates a natural divide to characterize nutrient input to the Bay basin. Above the fall line (AFL) pollutant loads are greatly influenced by decay processes, dependent upon their distance from the Bay; below the fall line (BFL) pollutant loads are not generally considered to be reduced by these processes because of their proximity to the Bay. The fall line and the eight major drainage basins in the Chesapeake Bay watershed are illustrated in Figure 2. Loads are calculated in million of pounds per year from flow and effluent concentration data contained in the point source data base. Nutrient and conventional pollutants information is presented, followed by information on toxic pollutants.

## The Pollutants: Nutrients

---

Municipal facilities are the major point source of nutrients to the Bay, discharging 94.0 percent of the total phosphorus and 88.3 percent of the total nitrogen loads (Table 1). Municipal and industrial nutrient loads presented in Table 1 are illustrated in Figures 3 and 4. The table and figures show that municipal sources BFL are the major source of nitrogen; municipal sources AFL are the major source of phosphorus. Table 1 shows that these sources discharge 59.6 percent of the nitrogen and 52.0 percent of the phosphorus loads respectively.

**Table 1**  
**Point Source Nutrient Loads**

POINT SOURCE	PHOSPHORUS Load	%	NITROGEN Load	%
<b>Municipal</b>				
AFL	7.3	52.0	26.2	28.7
BFL	5.9	42.0	54.4	59.6
Total Municipal	13.2	94.0	80.6	88.3
<b>Industrial</b>				
AFL	0.39	2.8	2.1	2.3
BFL	0.45	3.2	8.5	9.4
Total Industrial	0.84	6.0	10.6	11.7
<b>Municipal and Industrial</b>

BFL	6.35	45.2	62.9	69.0
Total Point Source	14.04	100.0	91.2	100.0

Municipal load in millions of pounds per year based on 365 operating days

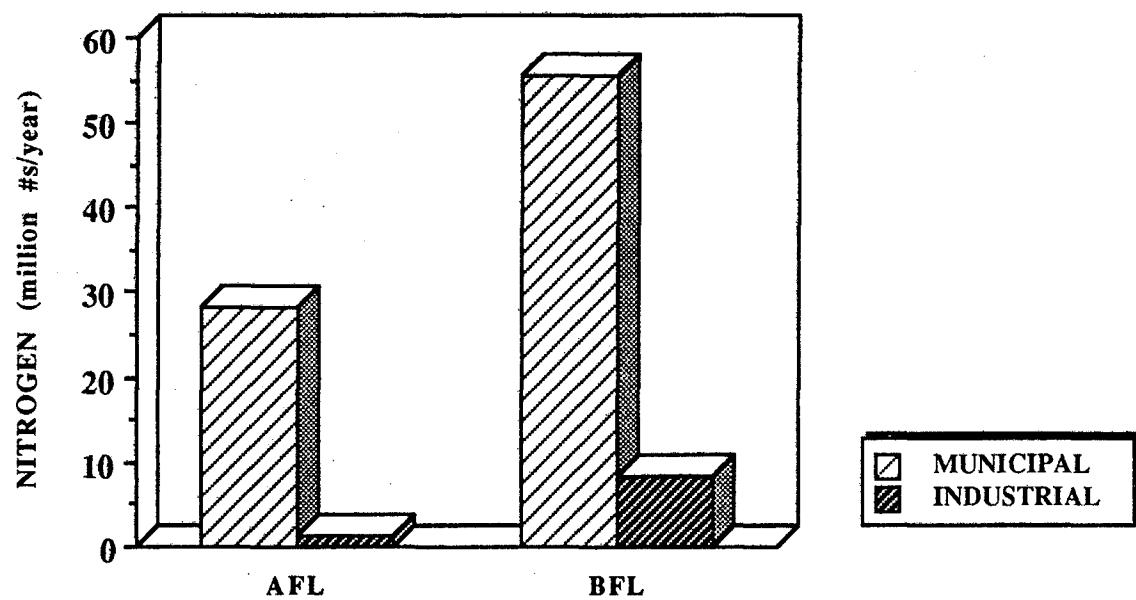

Industrial load in millions of pounds per year based on 250 operating days

% = Percent relative to total point source load.

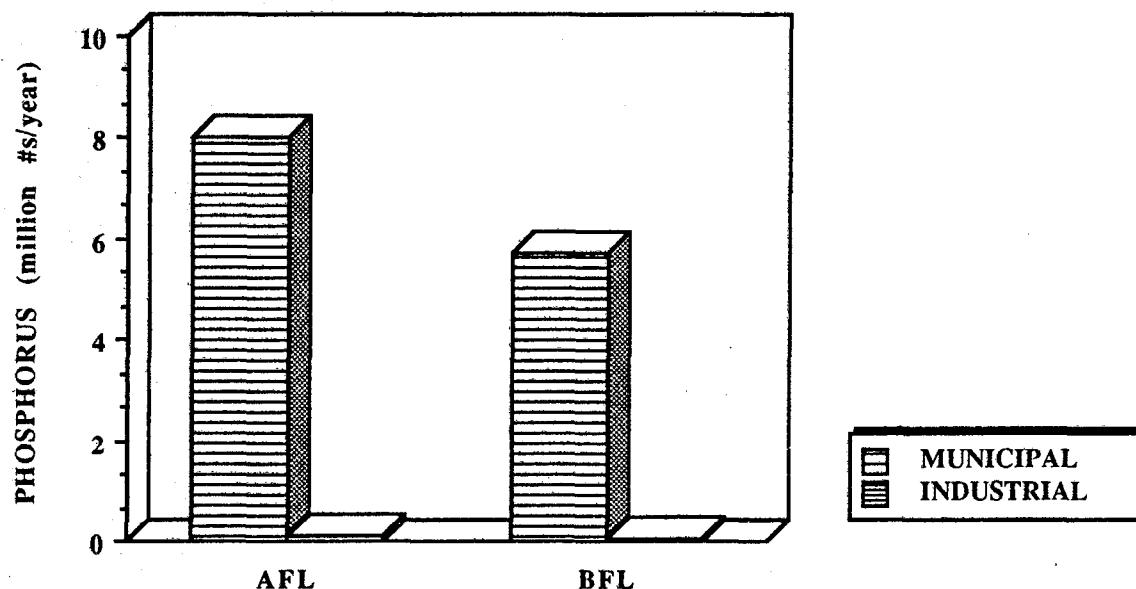

### MUNICIPAL NUTRIENTS

Municipal flows and nutrient loads are presented by basin in Table 2. Flows and nutrient loads for the four largest basins are illustrated in Figure 5. The largest municipal flows are discharged within the Potomac (521.3 million gallons/day (mgd)) and Susquehanna (336.2 mgd) basins. The largest nitrogen loads are also discharged within the Potomac (24.4 million pounds/year) and Susquehanna (18.6 million pounds/year) basins. The largest phosphorus loads are discharged within the Susquehanna (5.0 million pounds/year) and James (3.6 million pounds/year) basins.

**Figure 3**  
**Point Source Nitrogen Loads**

York	11.9	0.2	0.6	0.4	0.5
James	250.5	3.6	18.0	22.7	17.3

Flow in millions of gallons per day

Load in millions of pounds per year

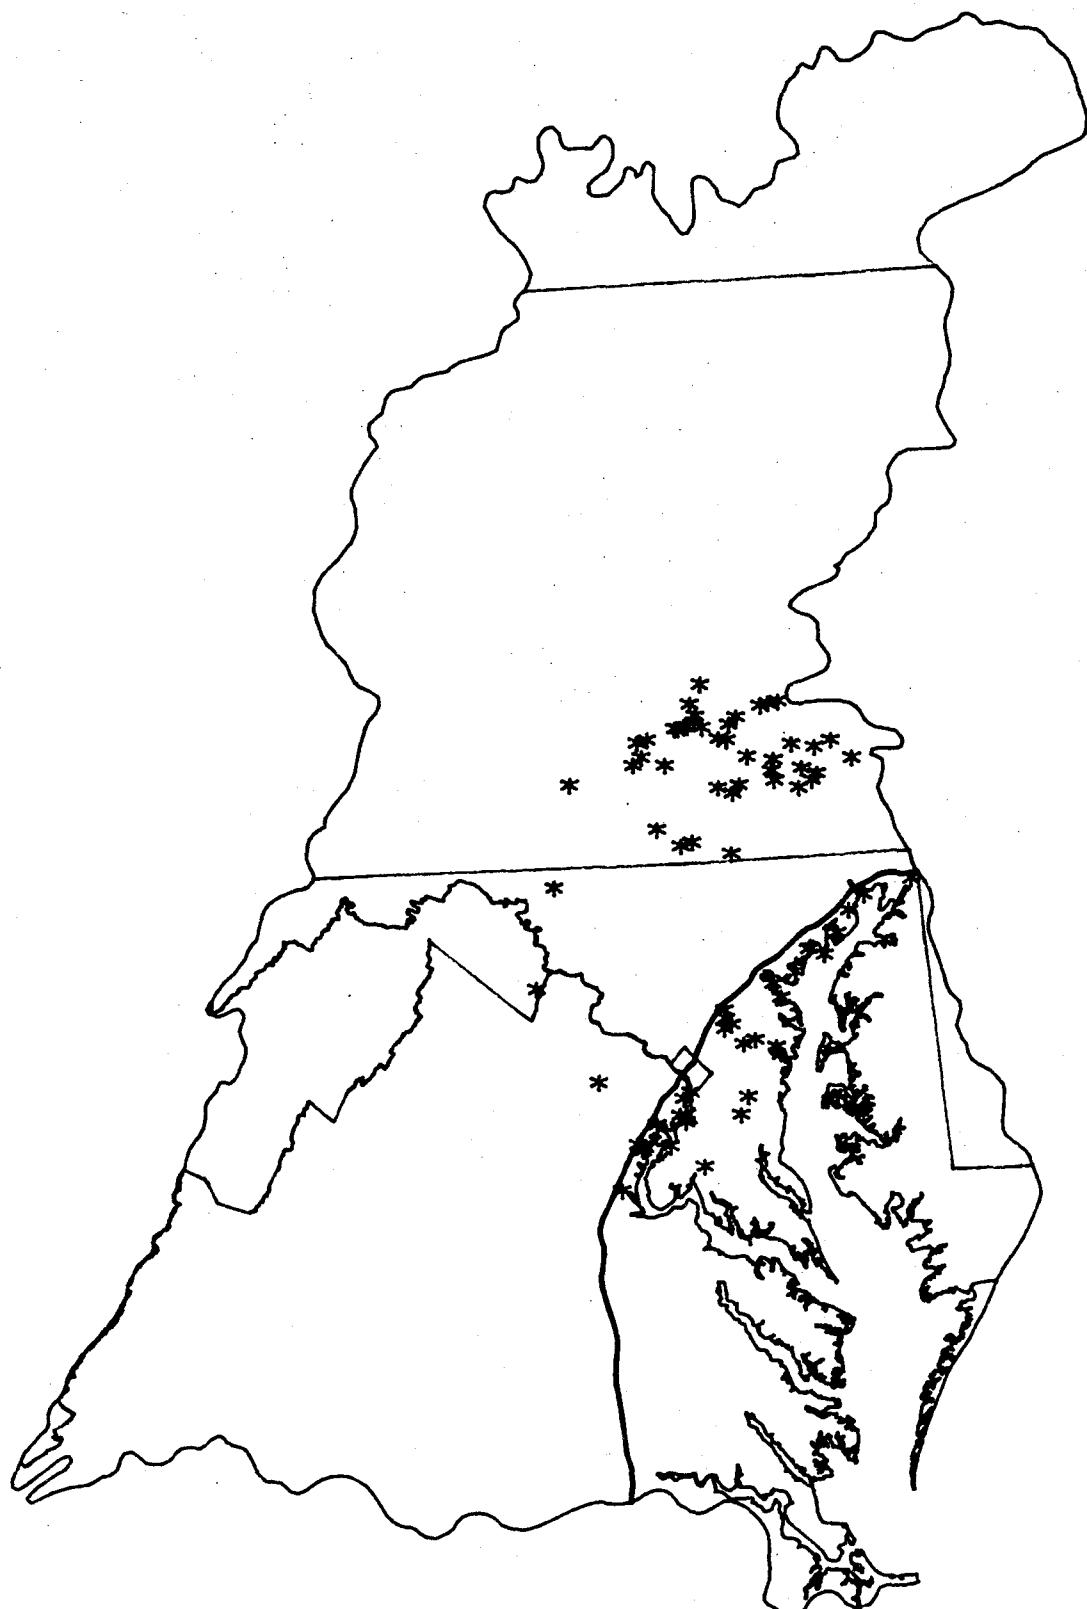

Includes all municipal dischargers in MD, VA, PA, NY, WV, DE and Washington DC

**Figure 5**  
**Municipal Flow and Nutrient Loads**

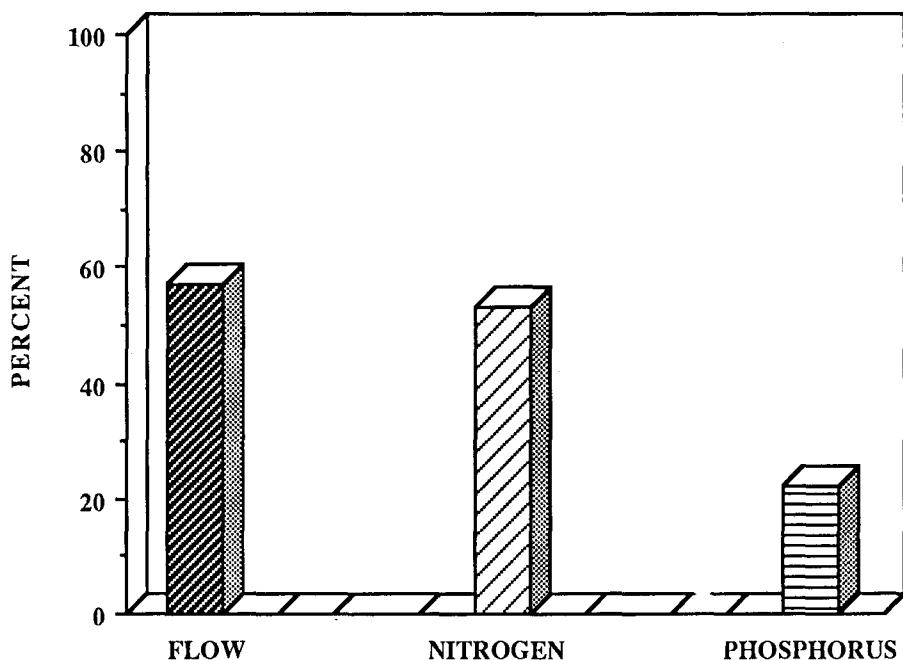

Maryland, Pennsylvania, Virginia and the District of Columbia have developed and implemented regional policies to control phosphorus. Only Maryland's Nutrient Control Strategy for the Patuxent River basin requires nitrogen control at selected dischargers, but, the strategy had not yet been implemented in 1985. Phosphorus control policies affect dischargers in the lower Susquehanna, West Chesapeake, Patuxent and upper Potomac river basins. Locations of dischargers subject to the policies are shown in Figure 6. Specific facilities subject to nutrient

**Figure 6**  
**Location of Municipal Dischargers Subject to  
Regional Nutrient Control Policies**

**Figure 7**  
**Percentage of Flow and Nutrient Loadings**  
**Basin-wide from Plants Subject to**  
**Regional Phosphorus Control Policies**

control policies, policy requirements, and 1985 operational data are listed in Table 3. Figure 7 summarizes basin level data and shows, basin-wide, the phosphorus controlled plants account for 57 percent of the total flow, and 53 percent of the total nitrogen, but only 22 percent of the total phosphorus load. A more complete description of the regional nutrient control policies may be found in Chapter 3 of the report "A Commitment Renewed."

Flow-weighted mean nutrient concentrations from municipal discharges are shown in Table 4. Mean nitrogen concentrations range from 15.6 to 24.0 mg/l. Phosphorus concentrations range from 1.1 to 6.7 mg/l with the lowest mean effluent concentration occurring in the Potomac River. The Potomac has the largest flow subject to a phosphorus policy (440 mgd) and the most stringent phosphorus discharge limits (0.18 mg/l).

Facilities with operational flows less than 0.5 mgd account for 83 percent of the total number of municipal plants. However, they account for only a little more than 3 percent of the total flow, 3 percent of the total nitrogen load and about 7 percent of the total phosphorus load discharged by municipal plants (Tables 5 and 6). Because of the large number of these plants and the small percentage of the nutrient load they contribute, most data gathering and analysis focuses on discharges with flows greater than 0.5 mgd.

The distinction between municipal loads discharged AFL and BFL is important because AFL loads are likely to be decreased by physical and chemical processes as they are transported to the Bay. As stated earlier, however, this discussion deals with discharged loads and does not account for decay processes which are difficult to quantify. Quantification of the decay processes is the domain of the watershed model. Municipal loadings AFL and BFL for each basin are presented in Tables 7 and 8. Municipal flow discharged AFL and BFL is illustrated

in Figure 8, with BFL facilities discharging 66 percent of the total flow. Figure 9 shows municipal flow and nitrogen loads from AFL and BFL. The nitrogen load is directly proportional to the volume of wastewater discharged. Figure 10 shows municipal flow and phosphorus loads from AFL and BFL. The phosphorus load is not proportional to the flow as was the nitrogen load providing further evidence of the impact of phosphorus control policies.

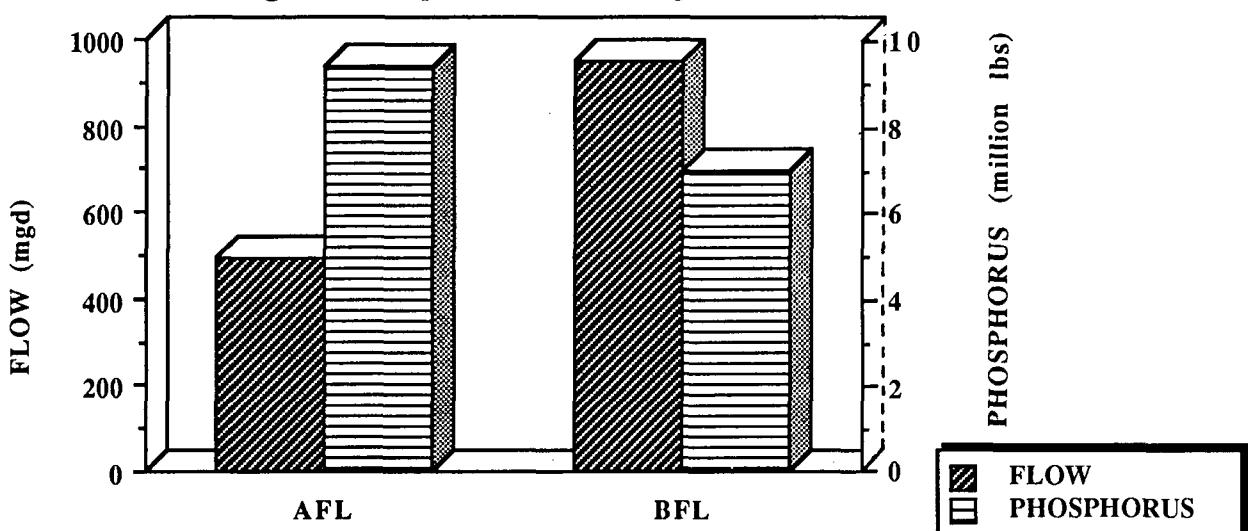

**Figure 8**  
**Total Municipal Flow Discharge AFL and BFL**

**Figure 9**  
Discharged Municipal Flow and Nitrogen Loads

**Figure 10**  
Discharged Municipal Flow and Phosphorus Loads

In the 1987 Chesapeake Bay Agreement, Maryland, Pennsylvania, Virginia and the District of Columbia agreed to the reduction of nutrient loads and control of conventional pollutant loads. Each state's municipal flow and discharged pollutant loads are presented in Table 9 and illustrated in Figure 10.

The largest flow and nutrient loads are discharged in Virginia. Maryland discharges the second highest volume of wastewater and pounds of nitrogen. Pennsylvania discharges the second highest phosphorus load. The most striking feature of Figure 11 is the large flow discharged by the District of Columbia and the very small phosphorus load, which is achieved through the use of the most advanced treatment technology available.

The District of Columbia's Blue Plains sewage treatment plant is a large regional plant serving the Washington Metropolitan area and adjacent high density residential areas in

Maryland and Virginia. These areas contribute 46 percent (138 mgd) of the total flow (309 mgd) at Blue Plains. Under a regional policy that provides for financial participation as well as compatible treatment in nearby plants, these areas contribute financially to the operation of Blue Plains.

Each state's municipal flow and pollutant loads discharged AFL and BFL are presented in Tables 10 and 11. The flow and loads from the District of Columbia include its contribution as well as both Maryland and Virginia's contribution to Blue Plains. Municipal wastewater treatment plants in Pennsylvania are the major source of nutrients discharged AFL and municipal wastewater treatment plants in Virginia are the major source BFL.

Table 12 presents design flow capacity and estimates of year 2000 flows by Maryland, Virginia and the District of Columbia. In any event, the incremental nutrient load increases occurring between 1985 and 2000 must be controlled to meet Bay Agreement commitments. Higher projected flows provide a safety margin in calculating needed reductions.

#### INDUSTRIAL NUTRIENTS

Categories of dischargers with the potential to discharge industrial nutrients and estimated concentrations are listed in Table 13. Developed by the EPA Effluent Guidelines Division, these default values can be used to target categories of dischargers as potential sources of nutrients. Effluent monitoring, however, is required to quantify loadings. Estimates of industrial nutrient loads discharged by basin AFL and BFL are presented in Table 14.

# The Pollutants: Toxicants

---

## MUNICIPAL TOXICANTS

Municipal point sources may discharge toxic substances received from industrial sources or produced by in-plant treatment during chlorine disinfection or decomposition of nitrogenous organic matter. Many industries use local municipal facilities to process their wastes instead of having their own treatment facilities. Industrial wastes, however, often contain heavy metals and toxic substances that are incompatible with normal sewage treatment processes and may interfere with treatment operations, pass through untreated, or contaminate sludge. Consequently, municipal plants that treat significant amounts of industrial wastewater or are larger than 5.0 mgd, are required to implement pretreatment programs.

There are 105 facilities identified in the point source data base required to develop and implement pretreatment programs. Listed in Table 15, their pretreatment programs have been approved by EPA or the delegated state and the municipalities are currently in the process of implementing these plans. Figure 12 shows the location of municipal plants with pretreatment programs. Other information provided in Table 15 includes design flows, industrial input flows, BOD 5 and TSS effluent concentrations.

Municipal plants may produce chlorinated hydrocarbons during chlorine disinfection. Discharge of these and other chlorinated by-products are extremely toxic to aquatic life. Both Virginia and Maryland have undertaken significant efforts to control chlorine toxicity. Virginia has established a chlorine water quality standard based on EPA water quality criteria that requires strict control or total elimination of chlorine from discharged effluent. This standard is being applied to municipal dischargers to determine permit limits as NPDES permits are reissued or reopened.

In Maryland, state water quality standards prohibit the use of chlorine or chlorine compounds in the treatment of wastewaters discharged to waters classified as natural trout waters and require dechlorination for wastewaters discharged to waters classified as shellfish harvesting. Table 16 lists Virginia and Maryland municipal dischargers, 1985 chlorine concentrations and status of current (1988) chlorine control. Only Maryland dischargers currently not providing chlorine control are listed.

Ammonia is another toxic substance discharged by municipal plants. It is produced during the decomposition of nitrogenous organic matter in the treatment process and may have a toxic effect on aquatic life depending upon the pH, dissolved oxygen level and total ammonia concentration of the receiving water. Municipal dischargers with ammonia or total Kjeldahl nitrogen (TKN) limits are listed in Table 17. Some dischargers such as Back River, Western Branch and Parkway do not currently meet these limits but are planning upgrades to provide the required nitrogen control that will be critical in the states' plans to meet nutrient loads reductions.

An effective means of evaluating the toxic potential of discharged effluent is through bio-monitoring. Biomonitoring is the measurement of the acute and chronic toxic effects of discharges on living organisms in a controlled experiment. When toxicity is confirmed, the discharger may be required to conduct a toxicity reduction evaluation (TRE). The overall objective of the TRE is to identify the source(s) of toxicity and develop acceptable control

NPDES Permit Requirements**

methods. Municipal point sources where biomonitoring tests have been conducted and TREs are underway or planned are identified in Table 18. The distribution of these facilities is shown in Figure 13. The point source data base is currently the only system available to record and track these data. Table 19 provides additional information on the TRE status of municipal dischargers in Maryland and Virginia.

**Table 19**

Patapsco	MD	Notified	Evaluating Test Results

### INDUSTRIAL TOXICANTS

Industrial manufacturing is a complex process that requires the use of many raw materials, catalysts, solvents and other chemicals that are extremely hazardous. Process or cooling wastewater contaminated by these substances may be toxic unless properly treated. Industrial categories with the potential to discharge heavy metals and/or priority pollutants are identified in Table 20. These values are default values developed by the EPA Effluent Guidelines Division and can be used to target categories of industrial dischargers as potential sources of toxicants. Effluent monitoring, however, is required to quantify loadings.

Industrial dischargers may also be required to biomonitor their effluent if toxicity is suspected. Industrial dischargers with biomonitoring or TRE requirements are listed in Table 21. Their locations are shown in Figure 14. Table 22 provides additional information on the TRE status of industrial dischargers in Maryland and Virginia.

### Federal Dischargers

The Chesapeake Bay Agreement specifically calls for the control and reduction of pollutant loads from federal facilities. The point source data base contains an inventory of 181 wastewater treatment facilities owned by the federal government. This inventory is being used to track progress in meeting this Bay Agreement commitment. Major federal facilities and their pollutant loads are presented in Table 23.

SIC = Standard industrial classification code; classifies commercial and industrial dischargers by the type of activity in which they are engaged.

# = Number of dischargers in category

As = arsenic, Cd = cadmium, Cr = chromium, Cu= copper, Pb = lead, Mg = mercury, Ni = nickel, and Zn = zinc

Concentrations are in micrograms per liter

Inorg = inorganic priority pollutants, organic = organic priority pollutants, I+O = total inorganic and organic priority pollutants; Concentrations are in pounds per day

Source: "Summary of Effluent Characteristics and Guidelines for Selected Industrial Point Source Categories: Industry Status Sheets", Revised February 28, 1986, EPA.

Chemetals	MD	Confirmed	TRE Completed and Cause of
Foremans Corner			Toxicity Identified
W.D. Byron	MD	Confirmed	TRE Study Underway
Williamsport			
SCM	MD	Confirmed	TRE Study Plan Completed
Baltimore			

Confirmed Toxicity indicates that toxicity initially determined to be present under state compliance programs or as a requirement of discharge permits was also found in subsequent facility sponsored biological testing.

## Data Availability

The preceding discussions and data were presented as an introduction to the type of data available in the point source data base and how it might be used. A complete listing of the variables contained in the data base and their definitions may be found in the Data Dictionary (see page 40). The data base may be accessed through CHESSEE, an information retrieval system available to authorized users. The reader is encouraged to access the data base and conduct specific analyses of interest. Over time, the data base will be expanded and improved. Questions on accessing the data base or suggestions to improve the accuracy or applicability of the data base should be directed to the Chesapeake Bay Liaison Office, attention Dave Clements (301-266-6873).
