The trend toward larger numbers of animals in feedlots has resulted in the concentration of their wastes. Consequently waste management has become a major problem. The general objective of this investigation was to explore the pollution characteristics of runoff from two feedlots in eastern South Dakota. The specific objectives were: (1) To determine the quantity and quality of feedlot runoff from the Animal Nutrition unit and the Dairy Research and Production unit at South Dakota State University, (2) To investigate the spring feedlot runoff resulting from snowmelt as well as the runoff produced by spring rainfall, (3) To determine the pollutional characteristics attributable to the suspended matter in the feedlot runoff in order to assess the effectiveness of settling in reducing the waste concentrations in feedlot runoff. It was concluded from the investigation that: (1) High concentrations of total and suspended solids, nitrogen, phosphorus, and oxygen-demanding material were present in the feedlot runoff, (2) The snow removal operation in the beef pens and the dairy confinement lot reduced the volume of snowmelt runoff from each unit, (3) Population equivalent values of the total animal waste load produced on the two feedlots were not a valid assessment of the actual pollution attributable to the runoff from these units, (4) The water pollution resulting from the feedlot runoff from the two units was probably negligible during this investigation, (5) The centrifuging procedure was effective in reducing the waste concentrations of the runoff samples, (6) Diversion of feedlot runoff onto cropland may be a satisfactory means of handling feedlot runoff in some situations. LAND SPREADING OF MANURE FROM ANIMAL PRODUCTION UNITS,

Department of Agricultural Engineering, The University of Newcastle upon Tyne
J. R. O'Callaghan, K. A. Pollock, and V. A. Dodd
Journal of Agricultural Engineering Research, Vol. 16, No. 3, p. 280-300, September, 1971. 6 fig, 13 tab, 22 ref.

Descriptors: Computer models, Waste disposal, Fertilizers, Cattle, Water pollution.
Identifiers: Land disposal, Loading rates, Manure, Swine, Hydraulic loading, Chemical loading.

A computer simulation model has been developed to determine manure output for a group of pigs as a function of diet. The results of this model are incorporated into a second model designed to simulate land spreading of the manure. One of the factors to be considered in land spreading is the hydraulic loading of the soil; this is assessed by comparing actual evapotranspiration with historical rainfall figures and allowing the manure to make up any soil moisture deficiency. Chemical loading is determined by assessing the levels of nitrogen, potassium, and phosphorus that will be removed by the crop or fixed in the soil. Any excess applied over this figure will result in groundwater or runoff contamination. Because of increased soil saturation and decreased organic activity in cold weather, spreading during winter months is not advisable. The farmer should never apply more slurry to the soil than can be immediately absorbed. Crops also affect the maximum permissible chemical loading; intensive grass production permits the maximum loading. To plan a waste disposal system, levels of manure output and its chemical composition must be established. The hydraulic and chemical loading maximums for each field and each crop will allow the minimum acreage required for waste disposal to be calculated. By avoiding the need to purchase fertilizer, the farmer can realize cash value from his manure. For example, if a farmer fattens 5,000 hogs per year, the total cash value of the nitrogen, potassium, and phosphorus content of the manure would be 5000 pounds sterling, with spreading costs of about 1,700 pounds sterling. MANURE-HANDLING CAPACITY OF SOILS FROM A MICROBIOLOGICAL POINT OF VIEW,

Department of Environmental Biology, Guelph University, Guelph, Ontario

J. B. Robinson
Presented at Canadian Society of Agricultural Engineers Conference, Charlottetown P.E.I., June 27, 1972, Paper No. 72-210, 18 p. 4 fig, 18 ref.

Descriptors: Soils, Microbial degradation, Nutrients, Phosphorus, Nitrogen, Pathogens.
Identifiers: Manure.

The criterion for handling capacity of a soil may be taken to be "the ability of the soil microflora to assimilate waste without permitting excessive leakage of nutrients and other undesirable components from the system." This ability is affected by temperature, moisture content, degree of aeration, pH, and initial microbial population. The components of most concern are carbon, phosphorus, nitrogen, and pathogenic organisms. Of these, nitrogen is usually the most critical. Due to the complexities of microbial conversions of nitrogen in mineralization, nitrification, and denitrification, generalizations are frequently erroneous and many contradictory results have been reported in the literature. (Whetstone, Parker, Wells-Texas Tech University)

REGIONAL MANAGEMENT OF ANIMAL MANURES–A MODEL FOR COLLECTION, STORAGE LOCATION AND DISTRIBUTION,

Agricultural Institute, Dublin
V. A. Dodd, D. F. Lyons, and J. R. O'Callaghan
Journal of Agricultural Engineering Research, Vol. 19, p. 233-244, 1974. 1 fig, 2 tab, 4 ref.

Descriptors: Mathematical models, Waste storage, Economics, Systems analysis, Poultry.
Identifiers: Land spreading, Swine, Collection.

It is proposed that a centralized storage facility should be provided for a group of pig and/or poultry units. The manure that is collected and brought to the central store can be disposed of by spreading on land in a separate operation. A mathematical, analytical model is constructed to determine the best place to locate the central store, and to determine the number of tanker wagons needed to collect and spread the manure. The model was applied to a specific region containing 58 pig fattening units. Results showed that the system may be economically attractive, having as additional advantages the minimization of pollutional hazards and the relieving of the pig or poultry farmer of the task of manure management. AGRICULTURAL WASTES--AN ENERGY RESOURCE OF THE SEVENTIES,

Bureau of Mines, U.S. Department of the Interior, Washington, D. C.
William L. Crentz
Presented at the World Farm Foundation Symposium, Anaheim, California, December, 1971, 25 p. 2 fig, 8 tab, 15 ref.

Descriptors: Recycling, Energy, Fuels, Gases, Oils, Autoclaves, Costs, Cellulose.
Identifiers: Pyrolysis.

The Department of Interior's Bureau of Mines has developed two processes for utilizing the cellulose from farm and urban wastes: pyrolysis and autoclaving. In the pyrolysis process, wastes are passed through a high temperature (200-900 degree C) retort system. A recovery train removes tar and heavy oils, a lighter oil, an aqueous product and tar fog and vapor mists. The remaining gases pass through scrubbers, an acid tower, and an alkali wash before emerging as a usable product. Pollution from the plant is negligible. For a large plant, the costs of pyrolysis are much less than the costs presently being paid by cities for incineration ($8 to $12 per ton) or landfill ($6 to $8 per ton). In the autoclaving process, the wastes are converted to low-sulfur oils by treatment with carbon monoxide and water under high pressures and temperatures. The most likely end use of this fuel oil would be for generation of electricity. (Cannon-East Central)

TREATMENT AND DISPOSAL OF ANIMAL WASTES,

Cornell University, Ithaca, New York
R. C. Loehr
Industrial Water Engineering, Vol. 7, No. 11, p. 14-18, November 1970. 3 fig.

Descriptors: Waste treatment, Waste disposal, Animal wastes, Aerobic treatment, Anaerobic conditions, Drying, Agricultural runoff, Nitrification-denitrification.
Identifiers: Oxidation ditch, Holding tank, Composting.

Intensive livestock production methods are becoming big pollution problems. Nine animal waste treatment and disposal methods are discussed. System one is daily disposal on the land without a holding tank and is common with many dairy operations. An aerobic unit is substituted for the holding tank in System two. In an attempt to reduce the size of the aerobic unit, System three incorporates an anaerobic unit which can act as a surge tank and a repository for the heavier solids. Systems four and five are in-house ditches. System number four, an in-house oxidation ditch system, offers the advantage of inexpensive construction since it is a part of the confinement building. System five incorporates a non-aerobic in-house system. System six separates the semi-solid wastes from the washwaters at the source. Systems seven-nine are based on the drying and composting of animal wastes but require a market for the product. These markets are not yet available on a general basis. The above systems will remove most of the organic-oxygen-demanding material but not the inorganic nutrients. Two engineering techniques are available to reduce the quantity of nitrogen in the wastes at the production site. These are nitrification-denitrification and ammonia release. Systems to handle runoff are discussed. (Kehl-East Central)

WINTER HIGH RATE COMPOSTING OF BROILER MANURE,

Department of Environmental Biology, University of Guelph, Guelph, Ontario
Bell, R. G. and Pos, J.
Canadian Agricultural Engineering, Vol. 13, No. 2, p. 60-64, December, 1971. 10 fig, 2 tab, 5 ref.

Descriptors: Winter, Farm wastes, Waste treatment, Poultry, Aeration, Temperature, Weather, Nitrogen, Carbon.
Identifiers: Composting, Manure, Broilers.

An aerated horizontal silo type composter was constructed to test the feasibility of high rate composting of broiler manure during the winter months. It was concluded that high rate composting is possible outside during the winter when supplementary heating equipment is used. It was hampered by snow buildups and freezing rain which necessitates a roof for maximum efficiency. A forced aeration system proved to be necessary for high rate composting, and ideally the composter should be loaded daily. The use of ground garbage will increase the carbon to nitrogen ratio and produce a better compost. The compost itself proved to be reasonably consistent, but several modifications and adjustments are necessary before the high rate composter could be considered successful. (Russell-East Central)

2788-B3, D3

THE FLOW OF SOLID WASTES IN PIPELINES,

Compost Science, Vol. 8, No. 2, p. 11, Autumn 1967-Winter 1968. 1 tab.

Descriptors: Solid wastes, Hydraulic transportation, Pipelines, Municipal wastes.
Identifiers: Feedlot wastes, Composting.

Among the research projects now being supported under the Solid Waste Program of the Public Health Service is a study by Dr. Iraj Zandi of the University of Pennsylvania who is exploring the pipeline collection and transportation of solid wastes. Despite the potential of solid pipeline systems, the inability to predict accurately the headlosses that will occur under an assumed condition has been one of the factors impeding the development and widespread use of hydraulic transportation. Experiments have shown that ground-up municipal refuse could be mixed with a small amount of water from the city sewer system and pumped out of the city. Pipelines would only have to be 2-in. in diameter to carry the wastes of a town with a population of 10,000 to 15,000. In the future, magnetic and centrifugal sorting devices may be used to separate metals, glass and plastics for salvage. The remaining organic material could be mixed with sludge from sewage treatment plants and manure from feedlots, and the entire mixture composted. A slurry of 40 per cent solid wastes may be a good input to a composting system. Industrial installations of pipeline transportation in the U.S. and Europe are listed. EFFLUENT SPRAY DISEASE RISK,

Senior Research Officer (Pollution), and Scientific Liaison Officer, of the Meat Industry Research Institute, Hamilton, New Zealand
C. F. Denmead and G. R. Bentley
New Zealand Journal of Agriculture, Vol. 125, No. 4, p. 23, October, 1972. 1 fig.

Descriptors: Health, Diseases, Salmonella
Identifiers: Spray irrigation, Cattle manure, New Zealand.

This article discusses the potential health hazards involved in spraying microorganisms from cattle dung around pastures. Salmonella is one of the dangerous organisms which can be found in cattle dung. In the case of spray irrigation this material is diluted and sprayed thinly over a large area. Whether or not an animal becomes infected depends on the number of live organisms ingested. In the case of a milk infection, milk production can be reduced. A serious infection could mean complete loss of production or the death of the animal. The following measures will assist in stopping the spread of infection: irrigating on ploughed ground; minimizing spray drift; and waiting a few months before using a sprayed pasture. By careful management of cowshed waste disposal, farmers can reduce the spread of cattle diseases. (Solid Waste Information Retrieval System)

TOXICITY OF NITRITE TO CHANNEL CATFISH,

Fisheries Research Laboratory and Department of Zoology, Southern Illinois, University, Carbondale.
M. Konikoff
The Progressive Fish-Culturist, Vol. 37, No. 2, p. 96-98, April, 1975. 1 fig, 3 tab, 13 ref.

Descriptors: Catfishes, Nitrites, Ammonia, Toxicity.

A study concerning the toxicity of nitrite, an intermediate compound formed during the biological oxidation (or nitrification) of ammonia (a major waste product of fishes), is reported in terms of toxic effects on channel catfish. Channel catfish, which had been held for at least four weeks in raceways, were added to five aquariums filled with 40 liters each of dechlorinated tapwater. The fish were added at an average density of 264 grams per aquarium Average fish weight was 40 grams. The fish were acclimated for 24 hours. Then appropriate amounts of sodium nitrite solution were added slowly to the aquariums. Groups of 6-10 fish were exposed to concentrations of 15, 20, 25, 30, and 35 mg/l of NO_2 for 4 days. This was repeated until 28 fish had been exposed to each concentration. Other groups of fish were exposed to 5, 10, 40 and 45 mg/l of NO_2 with fewer replications. Dead fish were removed at 24, 48, 72, and 96 hours. Temperature, dissolved oxygen and pH were measured. The median tolerance limit for each time period was calculated from a regression equation which was determined for the log of the nitrite concentration and the per cent fish surviving. The easiest method of confirming nitrite toxicity is to inspect the color of the fish's blood, which will become chocolate-brown under toxic conditions. The wide range of tolerances exhibited by fishes to nitrite poisoning indicates that nitrite might be used as a selective fish toxin. (Merryman-East Central)

THE TREATMENT OF PIGGERY WASTES,

L. Littlejohn (ed)
The Treatment of Piggery Wastes, Scottish Farm Buildings Investigation Unit, North of Scotland College of Agriculture, June, 1975, 66 p. 28 fig, 15 tab, 21 ref.

Descriptors: Waste treatment, Waste disposal, Anaerobic lagoon, Anaerobic digestion.
Identifiers: Swine, Scotland, Below-house oxidation ditch, Surface aerator, Oxidation ditch.

Treatment and disposal of piggery wastes in Scotland is not without problems. The ideal method of animal wastes disposal is to recycle them by application to the land. But because of the complexities of modern agricultural production and pressures from non-agricultural sectors of the community there are increasing numbers of situations arising in which it may be desirable to put animal wastes through some form of treatment before disposal, whether to the land or elsewhere. The objectives of such treatment may range from simple deodorization to the production of a final product acceptable by sewage authorities or river boards. This publication describes the problems that piggery wastes present. A description of the physical, chemical and biological properties of piggery wastes is given. Field scale experimentations with (1) Below-house oxidation ditch, (2) Surface aerator, (3) Anaerobic lagoon, (4) Independent oxidation ditch, and (5) Anaerobic digester are presented. Results of development work utilizing these treatment systems is reported. (Merryman-East Central)

THE EFFECT OF INCORPORATED ANIMAL MANURE AND pH ON THE SOLUBILITY OF SOIL MANGANESE,

T. M. Taukobong
MS Thesis, Tuskegee Institute, May, 1973, 79 p. 26 fig, 14 tab, 73 ref.

Descriptors: Manganese, pH, Plant response, Toxicity, Soil analysis, Lime.
Identifiers: Manure, Land disposal, Rye, Millet.

An investigation was conducted to study the relationship of pH and animal manure to the solubility of manganese in the soil, and to determine if high application rates of manure to the soil would result in manganese toxicity in plants. Several studies were conducted. In one such study, lime was added to soil samples to give pH values from 4.2 to 6.0 and in a second study, manure of 0 to 120 tons per acre were added to the soil. The soils were incubated, sampled, and analyzed for soluble, exchangeable and easily reducible manganese. In another study, the solubility of manganese was studied as indicated by its uptake in rye and millet. The following conclusions were drawn from these studies: (1) Manure addition to soil results in drastic change of soil pH. (2) The action of manure in causing manganese retention may be two-fold; partly due to the increase in pH and partly due to the complexing of the metal. (3) Exchangeable manganese, and to a lesser extent water soluble manganese, seems to be the fraction of soil manganese most susceptible to changes in pH and the amount of manure in the soil, while the easily reducible manganese does not readily respond to these changes. (4) When added to the soil in conjunction with lime, manure tends to reduce the drastic effect of lime on soil manganese. (5) There is no evidence that addition of manure could result in production of toxic amounts of manganese in the soil. (Sanders-East Central)

CHICKEN LITTER COW FEED,

R. Carmody
The Farm Quarterly, Vol. 19, p. 52-53, 92, 94, Fall, 1964. 1 fig.

Descriptors: Feeds, Litters, Poultry, Cattle, Maine, Performance, Costs, Economics, Legal aspects, Scours.
Identifiers: Refeeding.

Under drastic cost conditions, Maine farmers are forced to find a cheap feed so they can stay in production. Some think that chicken litter may be the answer. Results have revealed that by incorporating chicken litter into cattle feed, birth weights may be increased and calf scours may be reduced. However, care must be taken to keep the feed dry, as it becomes extremely unpalatable when wet. Dr. Brugman of the University of Maine is conducting tests on the utilization of poultry litter in cow feed. Although he isn't ready to release the data on his digestion trials, he did state that digestibility of the material was remarkably high. Feed samples made from laying-house litter have lignin content slightly under the 4 per cent figure. The doctor also stated that two things are important in the use of the litter and they are: (1) energy must be added to the ration, and (2) thorough mixing is essential. He further stated that although research data is still needed on the subject, chicken litter shows real promise as a feed for beef cow herds and for dairy replacements. Some conflict with Maine law may arise in feeding litter to producing dairy cows so its best use may be in raising replacement stock. One other problem was noted and that was the removal of metal trapped in the litter. One study showed that the primary cost in going to this feed was the purchase of a Gehl protable hammer mill and mixer in which the feed may be thoroughly mixed, and which can be hauled to the field and unloaded into the big feeders. (Penrod-East Central)

SOLIDIFICATION OF SLUDGES WITH PORTLAND CEMENT,

Department of Civil Engineering, Clarkson College of Technology, Potsdam, New York
E. A. Cassell and T. W. Walker
Journal of Sanitary Engineering Division, Proceedings of the American Society of Civil Engineers, Vol. 96 (SA1), p. 15-26, February, 1970. 7 fig, 7 tab, 13 ref.

Descriptors: Poultry, Portland cements, Fly ash, Leaching, Phosphates.
Identifiers: Sewage sludge, Solidification, Soil conditioners.

A report was made on research to investigate the solidification of sewage sludge and chicken manure in a matrix of Portland cement and fly ash. It was suggested that the solidified matrix could serve as a controlled nutrient release soil conditioner. The rate of phosphate leaching from the matrix, the compressive strength of the matrix, and the time required for the mix to set were influenced by the fly ash to cement ratio, the sludge (or manure) to cement ratio, and the water to cement ratio. (McQuitty and Barber-University of Alberta)

THE DISPOSAL OF COPPER-ENRICHED PIG-MANURE SLURRY ON GRASSLAND,

Department of Soil Science, University of Aberdeen
T. Batey, G. Berryman and C. Line
Journal of the British Grassland Society, Vol. 27, No. 3, p. 139-143, 1972. 8 tab, 16 ref.

Descriptors: Copper, Slurries, Toxicity, Soils, pH.
Identifiers: Swine, Herbage.

Manure slurry from swine that have been fed copper-enriched diets was applied to land located at the National Institute of Research in Dairying at Shinfield. The slurry was applied in May, June, and July of 1966 at rates of 5000 gal slurry ac and 10,000 gal slurry ac. The soil in the slurry disposal area, as well as the herbage grown there, was analyzed for possible effects. Although copper levels increased in the soil, the levels varied in herbage and appeared to be affected by the rate of grass growth. It appears that there is little risk of copper toxicity following copper-enriched slurry applications; however, to avoid possible hazards from copper buildups in the soil, a maximum annual application of 8.5 lb/ac copper is recommended until more is known about the availability of copper in slurry to crops and grass. (Penrod-East Central)

MANAGEMENT AND CONTROL OF BEEF FEEDLOT WASTE,

Agricultural Research Service, U.S. Department of Agriculture.
O. E. Cross, and C. B. Gilbertson
Farm, Ranch, and Home Quarterly, Nebraska Agricultural Experiment Station, Lincoln, p. 20-21, Winter, 1969. 2 fig.

Descriptors: Feedlots, Cattle, Nebraska, Regulations, Agricultural runoff, Water pollution.
Identifiers: Detention ponds, Rainfall.

Feedlot owners are being given the legal responsibility for insuring that their operation does not contaminate Nebraska's water. The Water Pollution Control Council of the Nebraska State Department of Health has been charged with setting up regulations to maintain Nebraska's water quality. Since information on the most effective ways to dispose of feedlot waste was not available, the Nebraska Livestock Feeders Association and its Pollution Control Committee were given two years to research and develop information on which regulations could be based. Several projects are underway to determine the efficiency of several different systems of waste management. Four systems are discussed which examine several different aspects of feedlot waste management. These systems cover runoff collection and treatment, movement of solids on dirt lots, and various methods of loader cleaning. Rainfall, its duration and intensity is recorded for use in the analysis. EFFECT OF NITROGEN AND FARM YARD MANURE ON FINGER MILLET <u>ELEUSINE CORACANA</u> (L) <u>GAERTN</u>,

Department of Botany, Tamil Nadu Agricultural University, Coimbatore-641003, INDIA
P. Rangaswamy
Madras Agricultural Journal, Vol. 60, No. 8, p. 949-952, August, 1973. 2 fig, 3 tab, 6 ref.

Descriptors: Nitrogen, Farm wastes, Crop response.
Identifiers: Land disposal, Millet, India.

This study discusses the response of early (95 days and below) and short (95-115 days) duration finger millet varieties to the application of graded doses of nitrogen and farm yard manure. The trial was conducted at Millets Breeding Station, Agricultural College and Research Institute, Coimbatore during 1965-1968. The manurial trial was a failure during the 1967 monsoon season due to severe drought and incidence of pests and diseases. Among the millet varieties viz., CO.8, AKP.2, CO.10, and EC.4841, the strain CO. 10 and selection EC.4841 recorded 35.3 and 50.3 per cent higher yield than the standard strain CO.8. Early duration varieties recorded 24.1 per cent higher grain yield at 67.5 kg nitrogen level; beyond that there was a decline in yield. For the early duration finger millet varieties, the yield differences due to the application of farm yard manure were significant during the year 1968. Application of farm yard manure at 25 tonnes-ha caused a 9.1 per cent increase in grain yield over no farm yard manure treatment. The short duration varieties responded well to the application of graded levels of nitrogen even up to 112.5 kg nitrogen-ha. Interactions between different levels of nitrogen and farm yard manure and varieties were not significant in all the years and in combined analysis. (Penrod-East Central)

RETORTING FEEDLOT WASTES,

Science News, Vol. 102, No. 10, p. 153, September, 1972.

Descriptors: Feedlots, Organic wastes, Carbon, Fuels, Water pollution, Air pollution.
Identifiers: Retort system, Pyrolysis, Inert ash, Char, Water clarification, Soil conditioner, Texas Technological University.

A particularly serious problem in the area of water and air pollution is feedlot waste. Each steer produces 16 times the organic waste produced by a human being. If organic wastes enter waterways, they cause high biological oxygen demand; if they are incinerated, they cause air pollution. Researchers at Texas Technological University have developed a retort system which dries feedlot waste, then pyrolyzes it. The product is char, carbon and inert ash which can be used for water clarification, as fuel, or as a soil conditioner. If the system is scaled up to commercial size and automated, it would require only one or two men to operate. (Solid Waste Information Retrieval System)

FUTURE ENERGY SOURCES FOR TRANSPORTATION,

College of Engineering, Drexel University, Philadelphia, Pennsylvania
C. W. Savery
Traffic Quarterly, Vol. 26, No. 4, p. 485-499, October, 1972. 7 tab.

Descriptors: Energy, Recycling, Animal wastes, Municipal wastes, Hydrogen, Ammonia, Sludge digestion, Fermentation, Anaerobic digestion, Methane, Carbon dioxide, Alcohols.
Identifiers: Transportation fuels, Agricultural wastes, Pyrolysis, Hydrocarbons.

Natural energy resources are being consumed at a terrific rate. In 1960, approximately 20 per cent of the total energy consumed in the United States was consumed in transportation—126,000 Btu per capita per day. On one hand transportation fuel sources must be conserved and synthetic fuels produced. Two of these fuels would be hydrogen and ammonia. The third type of fuel would be produced by recycling waste trash, animal wastes, and crop residues. The pyrolysis of municipal refuse offers a possibility of producing fuels. It is estimated that 500 to 700 Btu per capita per day would be produced by recovering gas from the sludge digestion process in the United States. Another source of hydrocarbon fuels is the digestion of animal wastes. About 50,000 Btu per capita per day could be produced from the annual total of animal waste production. Another category of recycling waste is agricultural crop residues. Two processes are possible—fermentation to make alcohol and anaerobic digestion to produce a combustible mixture of methane and carbon dioxide. About 25,000 Btu per capita per day could be produced. By altering the energy mix, recycling could thus produce 80,000 Btu per capita per day or about two-thirds of the amount of the transportation energy consumed in 1960. (Solid Waste Information Retrieval System)

GOBAR-GAS PLANTS PROMISES AND PROBLEMS,

Assistant Director, G. G. S. Khadi and Village Industries Commission, 3, Irla Road, Vile Parle (West), Bombay
H. R. Srinivasan
Indian Farming, Vol. 23, No. 11, p. 29, 31, 33, February, 1974.

Descriptors: Fuels, Anaerobic digester, Organic wastes, Fertilizers, Fermentation, Economics, Methane, Carbon dioxide, Nitrogen, Nutrients, Environmental sanitation.
Identifiers: India, Gobar-gas plant, Gas production.

Because of the present shortage of fertilizer, kerosene and petrol in India, it appears that gobar-gas plants can play a major role in preventing the draining away of valuable foreign exchange used for chemical fertilizer and crude oil imports. The gobar-gas plant is an anaerobic digester used for fermenting organic wastes. The digestion is carried out submerged in water. The end products of the anaerobic digestion are (1) Gobar-gas (a mixture of methane, carbon dioxide and minute quantities of H_2S and other gases) and (2) a blackish, odorless, readily drainable, innocuous substance rich in nitrogen and humus. While it is hoped that the gobar-gas can become an accepted source of fuel, there are still problems to be worked out. Since cattle-dung is a very slow fermentor, probably because it is poor in nutrients, some way is needed to collect the cattle urine as well. Also, as day temperatures go down, the gas production falls. The manure presents storage problems. Social adjustment to this new fuel source has posed a problem. It is hoped, however that these problems can be worked out. It is felt that the gobar-gas plant offers a markedly increased income from the farm due to more and better manure, coupled with better living conditions. The gobar-gas manure has given better yields in all crops when compared to farm-yard manure made from the same quantity of cattle dung. (Penrod-East Central)

FEEDLOT POLLUTION: A SOLVABLE PROBLEM?,

South Dakota Farm & Home Research, Vol. 21, No. 2, p. 30-31, Spring, 1970.

Descriptors: Agricultural runoff, Water pollution, South Dakota, Feedlots, Land management, Precipitation (atmospheric)
Identifiers: Retention ponds.

While he was a civil engineering graduate student at South Dakota State University, Paul Thormodsgard did research on snow and rainfall runoff from certain feedlots. He deducted that good land management could be a more feasible answer to feedlot pollution than expensive waste treatment. He found that a large ditch and a plowed field between the feedlot and a stream diminished the waste runoff. He also suggested that waste introduced into a stream in times of flood may be diluted by the large amounts of water. Thormodsgard pointed out that feedlot runoff is related to type of precipitation and could be held in retention ponds or possibly in a plowed field until conditions are right for its release. (Sanders-East Central)

FEEDLOT WASTE USABLE,

Poultry Meat, Vol. 23, p. 16, October, 1972.

Descriptors: Feedlots, Recycling, Feeds, Performance.
Identifiers: Fractionation, Building materials.

A two-step fractionation process for feedlot waste developed by the Agricultural Research Service, USDA obtains a fibrous residue, fifty per cent of the waste, which can be pressed into board or used as a nutrient for fungus that produces a fiber-digesting enzyme. Chicken feed treated with the enzyme has improved digestibility. The fungus itself is almost half protein. (Whetstone, Parker and Wells-Texas Tech)

AN ECOLOGICAL BLUEPRINT FOR TODAY,

Journal of Environmental Health, Vol. 34, No. 1, p. 30-39, July-August, 1971. 6 fig, 3 tab, 3 ref.

Descriptors: Waste disposal, Sampling, Chemical properties, Physical properties.
Identifiers: Land disposal, Spray irrigation, Application rates.

The recycling of human effluent and animal waste by spray irrigation was discussed. Ten acres of cropland and 12 acres of woodland were spray irrigated. Disposal of liquid manure was at the rate of 2 in. per week over a 10-acre tract of cropland which is equivalent to 20 acre-in. or 544,000 gal. Weekly sampling and testing from 32 stations in the spray irrigation area were performed for the presence of turbidity, temperature, dissolved oxygen, phosphates, nitrates, nitrites, pH, ABS, and chlorides. It was found that by taking effluent from agricultural wastes of 200 cows and spray irrigating the crops with this effluent, production was tremendously improved. By utilization of the nutrients and the water, tonnage per acre increased. It was found that animals prefer nutrient-irrigated crops, as the plants are more succulent and contain more phosphorus and other minerals than crops that are just watered. The establishment of a community using spray irrigation for handling sewage waste was also described. Results so far indicate that spray irrigation is an effective system. The waste is applied to croplands and woodlands instead of dumping it into streams and lakes. (Solid Waste Information Retrieval System)

INCREASED PRODUCTION OF BIOGAS FROM COWDUNG BY ADDING OTHER AGRICULTURAL WASTE MATERIALS,

Division of Soil Science and Agricultural Chemistry, Indian Agricultural Research Institute, New Delhi, India.
R. D. Laura and M. A. Adnani
Journal of Scientific Food Agriculture, Vol. 22, p. 164-167, April, 1971. 3 fig, 4 tab, 8 ref.

Descriptors: Gases, Methane, Fermentation, Anaerobic conditions, Chemical properties.
Identifiers: Production rates, Agricultural wastes, India.

"It was found that the addition of nitrogenous materials, such as casein, urea or urine, increased the extent of decomposition of cowdung, resulting in higher gas production. The effect appears to be to the maintenance of pH 7 during fermentation. With the addition of urea of $CaCO_3$, materials such as dry leaves and cane sugar have yielded high proportions of methane in the gas mixtures and three additions also increased the rate of gas production by promoting anaerobic conditions in the medium. Addition of cellulose also increased the rate but the gas mixture obtained had a lower methane content." (McQuitty and Barber-University of Alberta)

ABORTION IN CATTLE ASSOCIATED WITH THE FEEDING OF POULTRY LITTER,

Departments of Veterinary Science and Biology, Pennsylvania State University, University Park
L. C. Griel, Jr., D. C. Kradel, and E. W. Wickersham
The Cornell Veterinarian, Vol. 59, No. 2, p. 226-235, 1969. 3 tab, 7 ref.

Descriptors: Litter, Cattle.
Identifiers: Refeeding, Abortion, Dienestrol-treated feed, Estrogenic activity, Hormonal imbalance.

A study was made to determine the relationship between the feeding of poultry litter obtained from birds that had received dienestrol-treated feed and a series of abortions in a breeding herd of beef cattle. During the period in which the herd was receiving poultry litter, all animals exhibited a great deal of estrual behavior. Upon cessation of the feeding of the litter, this behavior completely disappeared, abortions ceased, and the remainder of the herd subsequently calved normally. While the exact biochemical mechanisms involved in the etiology of the abortions remain unsolved, the evidence indicated that some manner of hormonal imbalance may have been involved. Further work is needed to determine the interactions of all the factors present in this case in causing abortion in cattle. (Penrod-East Central)

LIVESTOCK WASTE: WHY WASTE IT?,

Agricultural Situation, October, 1971, p. 2-4.

Descriptors: Waste disposal, Livestock Economics, Lagoons, Dehydration.
Identifiers: Land disposal, Composting, Refeeding.

Methods of utilization or disposal of manure currently used or under investigation are described briefly. These include land disposal, lagoons, the Pasveer oxidation ditch, composting, dehydration, and animal feeding. (Whetstone, Parker, and Wells-Texas Tech)

2811-A3,A5,A6,C1,C2,E2

THE USE OF ANIMAL WASTES ON FERTILIZER,

Armstrong, D.W.
Journal of Agriculture (South Australia), Vol. 75, p. 178-184, 1972.

Descriptors: Fertilizers, Irrigation, Animal wastes, Nutrients, Feedlots, Chemical properties, Physical properties, Nitrogen, Odor, Agricultural runoff, Groundwater pollution.
Identifiers: Land disposal, Application rates, Australia.

The amounts of manure produced and its composition are discussed. Application rates should not exceed 300 lb of nitrogen per acre to avoid groundwater contamination and other detrimental effects. Application of more than 100 lb per acre is useless. If manure is used for irrigation it should be diluted with water. Odor and runoff can create difficulties. (Whetstone, Parker, and Wells-Texas Tech)

PHOSPHORUS IN PERCOLATES FROM MANURED LYSIMETERS,

Department of Land Resource Science, University of Guelph, Guelph, Ontario, CANADA
D. G. Bielby, D. A. Tel, and L. R. Webber
Canadian Journal of Soil Science, Vol. 53, No. 3, p. 343-346, August, 1973. 3 tab.

Descriptors: Phosphorus, Percolation, Lysimeters.
Identifiers: Liquid poultry manure.

The objective of this report was to determine if phosphorus from heavy surface applications of liquid poultry manure would be retained by the soil or would occur in the percolates. Over the 3-year study period, the phosphorus added in the treatments was equivalent to 50, 408, and 1,240 and 1,590 kg/ha. During this period, the percolates contained the equivalent of 0.35, 0.65, 0.38, and 0.35 kg of P/ha for the four treatments respectively. The corresponding concentrations of phosphorus in the percolates were 0.029, 0.057, 0.033, and 0.034 mg/l. Although abnormally large amounts of phosphorus were added, the amounts found in the percolates were not correspondingly large. The study confirms the general observation that applied phosphorus tends to remain immobile in the soil. As the water moves through the subsoil, phosphorus attenuation occurs. (Penrod-East Central)

CORN RESPONSE AND SOIL NITROGEN TRANSFORMATIONS FOLLOWING VARIED APPLICATION OF POULTRY MANURE TREATED TO MINIMIZE ODOR,

Research Station, Research Branch, Agriculture Canada, St. Jean, Quebec J3B 6Z8
K. A. MacMillan, T. W. Scott, and T. W. Bateman
Canadian Journal of Soil Science, Vol. 55, No. 1, p. 29-34, February, 1975. 4 fig, 3 tab, 14 ref.

Descriptors: Crop response, Corn, Poultry, Waste treatment, pH, Nitrification, Ammonification.
Identifiers: Land disposal, Nitrogen transformations.

The objective of this study was to examine the interrelationship between soil nitrogen transformations and corn response, following soil application of manure previously treated to minimize odor. Maximum above-ground yields obtained on Mardin and Honeoye silt loam were 54 and 23 g, respectively, whereas check yields were 9 and 8 g, suggesting that N additions had a greater influence on yield response under acid pH conditions. There were no visible signs of nutrient deficiency in plants from either soil, suggesting that nutrient supply was adequate. As a result of more favorable conditions for nitrification and NH_3 volatilization at the higher pH (Honeoye) as opposed to the acid pH (Mardin), there were differences in NH_4 plus concentrations between the two soils. The overall increases in NO_3—(Honeoye) and NH_4 plus concentrations during the course of the experiment indicated that the high N loading rates used were not toxic to the soil microorganisms at each pH value. On consideration of yield response as it related to measured soil N fractions, it was observed that NH positive and NO negative were the major N fractions used by the plants in the acid and neutral soil, respectively. Concentration of NO_2- toxic to corn was attributed as causing the substantial yield decreases with the higher rates of OD on the Honeoye soil. The study concluded that the major factor thought responsible for different N concentrations and ultimate corn yield response in each soil was soil reaction. (Penrod-East Central)

2814-B1,D1,D2,E3,F1,F5 F6
CONVERSION OF SWINE MANURE TO PROTEIN,

Department of Soil Science, Oregon State University, Corvallis, Oregon
Larry Boersma
Feedstuffs, Vol. 47, No. 39, p. 20-21, September 22, 1975. 1 fig, 3 tab.

Descriptors: Recycling, Algae, Proteins, Feeds, Economics, Energy, Methane.
Identifiers: Swine.

Oregon State University is experimenting with the use of swine manure as a substrate for growing algae, which may then be used as feed. The economics of such recycling is dependent upon such variables as water temperature, light intensity, depth of culture and retention time. Two harvesting methods were employed: (1) centrifugation and (2) precipitating the material with alum. The algal material obtained by centrifugation was a good source of protein. Alum precipitated algae did not give good results, strongly suggesting that harvesting should be done by centrifugation, air flotation, or some other method which does not add toxic materials. The development of an inexpensive method for harvesting algae has been a major deterrent to the development of commercial algal production. Centrifugation is expensive and energy intensive. It is hoped that methane, which is produced in the initial digestion of the manure, may be used as the energy source. Current experimentation at Oregon State is focused on determining optimum management techniques. (Cannon-East Central)

LIVESTOCK FARMING AND ENVIRONMENTAL PROTECTION,

U. Riemann
Landtechnik, Vol. 28, No. 5, p. 149-153, March, 1973. 9 fig.

Descriptors: Livestock, Waste treatment, Economics, Aerobic conditions, Anaerobic conditions.
Identifiers: Germany.

The livestock industry is confronted more and more with problems of environmental protection linked to costs threatening its competitiveness. The aims of manure treatment regarding odors, pathogens and volume reduction by clarification are considered. Agricultural use of manure appears to be the most economical method. For biological degradation of manure, two techniques are presented. Anaerobic decomposition yields strong smelling decay products and depends mostly on outside temperatures. In aerobic decomposition, few or no offensive smells are created because of the aerobic bacteria. Aerobic degradation is suitable for different types of manure, proceeds quickly and develops its own heat. The aerobic operations of oxidation ditches, oxidation silos, forced-air systems, and their possible improvement are discussed. Composting also involves aerobic biological degradation and is more desirable hygienically. However its marketability is limited by lack of effective cost defrayments. TECHNIQUE OF CONVENTIONAL DUNG DISPOSAL,

E. E. Schilling
Landtechnik, Vol. 28, No. 4, p. 103-106, 1973. 1 fig, 7 tab, 6 ref.

Descriptors: Waste disposal, Transportation, Equipment.
Identifiers: Land spreading.

Dung from conventional farms usually consists for the greatest part of solid substances while dung from mass stock keeping contains mainly liquid matter. The technique of dung disposal is characterized by transportation, dosing and distribution of the dung. Vehicles for the transportation of the dung must be adapted for unpaved roads and usually have one or two axles. Dosing of the dung is effected through a spreading device. According to the velocity with which the dung is led into the spreading device the quantities to be spread amount to from 50 to 400 double quintals per hectare. The situation of the spreading device on the side or back walls of the vehicle determines the distribution of the dung in a small or large range. REMOVAL OF LIQUID DUNG,

U. Riemann and H. Traulsen
Landtechnik, Vol. 27, No. 1/2, p. 12-16, January, 1972. 9 fig, 7 ref.

Descriptors: Liquid wastes, Waste disposal, Lagoons, Aeration, Ventilation.
Identifiers: Oxidation pits.

Various methods to remove liquid manure have been tested. The most economic one is the distribution of the manure on agricultural areas, costs of which will amount to 0.25 to 3.00 DM per cu m of manure. In the USA the disposal of the manure in lagoons is very popular. The dung is led into pools of 2-to-3-m depth where the organic substance is degraded and part of the moisture vaporizes. However, in winter no degradation takes place. Another disadvantage of this method is the development of bad odors and vermin. Some disadvantages of the agricultural utilization of manure can be eliminated by ventilation. The revolving ventilator favors the biological degradation processes. The amount of oxygen added by this type of ventilator is small; thus the developing heat in the manure is not cooled down by too much air. For this reason the surface gyroscope is not adapted for ventilating manure as it adds too much oxygen. The classic method is the oxidation pit where a roll revolves the manure in the pit. Several other methods are still in state of experiment so that exact results as to the advantages and disadvantages cannot be given. (Text in German) (Solid Waste Information Retrieval System)

LIQUID MANURE AND ENVIRONMENT PROTECTION,

K. Forster
Landtechnik, Vol. 27, No. 8, p. 166-168, April, 1972. 5 fig.

Descriptors: Liquid wastes, Odor, Regulation, Transportation.
Identifiers: Field spreading, Sweden, Switzerland.

A great number of farmers use liquid dung as manure on their fields because transportation costs for this method can be reduced by 30-40 percent. Several European countries provide for special environment protection measures to be applied in this case. Similar to the regulations for the storing of oils and chemical agents, those for storing and utilizing liquid manure will depend on whether the drinking water in the various regions is endangered by the liquid dung. In Sweden and Switzerland, storing liquid dung for 4-9 months is obligatory because after this time a great number of pathogenic microorganisms are destroyed and risk is considerably reduced. Another reason is that during special periods such as holidays or in high pressure areas, spraying liquid dung onto the fields is not allowed in order to prevent the formation of bad odors. Large farms will have to provide for dung deodorization in the future in order to avoid the present disadvantages of dung utilization. Dung deodorization can be effected mechanically, thermally, chemically, or biologically; the latter seems to be the most perfect and economical method. The biological treatment can be effective in a cold, warm or hot way; however, the cold method is the least advantageous since the fertilizing value in its liquid phase is extremely low. Dung treated in this manner can be distributed by means of a spraying device without causing difficulties, however, it will be economical only for farms with an annual dung production of more than 8,000 cu m of liquid dung. Smaller farms should use the new glass-fiber truck-mounted tanks of a volume of 8,000 liters. (Text in German) (Solid Waste Information Retrieval System)

FIELDS OF USE AND APPLICATION OF MANURE AND MANURE DISPOSAL,

V. G. Blanken
Landtechnik, Vol. 25, No. 21, p. 674-676, November, 1970.

Descriptors: Fertilizers, Waste treatment, Waste disposal, Incineration, Drying, Economics, Groundwater
Identifiers: Dumping, Land spreading

Manure can be used for fertilizing agricultural areas, it can be dumped, destroyed by chemicals, biologically decomposed or incinerated. Its use as fertilizer is still the most economic method for disposal of manure, provided that there is agriculture in the area. If not, one of the other methods must be selected. Drying has proved to be economical only in the case of chicken manure. Drying costs for the manure of about 40,000 chickens run at DM 7.00. Conversion into humus is justified only if there is a sufficiently large market for the product. Costs are DM 10.75 for 8,000 chickens. In the absence of a market for manure, it seems to be best to subject it to biological decomposition. There is, however, the problem of disposal of the residual matter. Incineration would be the best method from a sanitary point of view, but it is too expensive. Dumping is too dangerous for the environment. Pollution of the environment by larvae and worm eggs can be avoided, by storing the manure in large containers for long periods of time. For protection of the groundwater small amounts of manure ought to be spread over the fields at one time, and used on flat acres only. (Text in German).(Solid Waste Information Retrieval System)

UTILIZATION AND DISPOSAL OF LIQUID MANURE AT SMALL AVAILABLE SPACE,

V. H. Traulsen
Landtechnik, Vol. 25, No. 21, p. 665-668, November, 1970. 7 fig, 7 ref.

Descriptors: Liquid wastes, Waste treatment, Waste disposal, Economics, Odor, Groundwater pollution, Pathogens, Incineration, Drying
Identifiers: Land spreading, Spraying, Composting, Oxidation tanks, Germany

Of the manure disposal and utilization methods, spraying of liquid manure over crops is the least expensive one. Generally 40-60 cbm liquid manure can be applied per hectare and year. Some plants such as corn are able to consume up to 100 cbm per hectare and year, asparagus as much as 200 cbm. Pathogenic germs are not killed by this method. In the German Democratic Republic, it is required to store manure for 21 days before it is applied to the fields. Studies have shown that salmonellas survive almost one year in liquid manure. Other drawbacks of this method are that the manure cannot be applied to the fields at each season since it causes annoying odors and pollutes groundwater. Spreading over areas which are then withdrawn from agricultural use for one or more years bears the same disadvantages. Composting by mixing with lime, peat, and styropor has not been done yet with any manure other than chicken manure. Decomposing in lagoons does not kill all pathogenic germs either. Anaerobic decomposition is too expensive. Incineration is the most hygienic method but it involves high investment and operating costs. Composting and drying and oxidation tanks are the most economical methods available at the moment. (Text in German) (Solid Waste Information Retrieval System)

MANURE REMOVAL AND STORAGE OF SOLID MANURE,

V. H. Schulz, L. Krinner, and K. Wissmuller
Landtechnik, Vol. 25, No. 21, p. 657-665, November, 1970. 11 fig, 3 tab.

Descriptors: Solid wastes, Waste storage, Equipment.
Identifiers: Mechanical scraper.

Removal of manure in a solid state is frequently preferred over the liquid manure removal system since straw can be used here in the sheds for insulation against the cold concrete floor and reduction of odor. For solid manure removal, the cow sheds are usually divided into small boxes with a feeding table for the animals outside them. In the rear the manure is removed either by various types of scrapers, of which the two-winged flat arrowhead scraper is gaining increasing importance, or by tractors. The latter are quite versatile and can be used for other purposes, too. Front loaders require, however, at least 8 m of free space in the front of the shed, a door opening of 1.6 to 2.0 m wide and 2.5 to 3.0 m high and a manure track which is at least 1.7 to 1.9 m broad. More recently a number of smaller more mobile manure removal tractors have been introduced. One is a mini bucket-wheel-loader similar to the one used by construction workers for soil removal. It is driven by two starter batteries each with 12 volts and two dc motors. The electrically-hydraulically operated front loader carries a moveable shovel which can be equipped with prongs. Another such unit driven by a 12 HP single cylinder diesel engine consists of a three-wheeled chassis. It carries various shovels and rakes in addition to the loader. MANURE REMOVAL AND STORAGE OF LIQUID MANURE,

V. K. Grimm
Landtechnik, Vol. 25, No. 21, p. 645-649, November, 1970.

Descriptors: Waste storage, Equipment.
Identifiers: Mechanical scrapers.

If an automatic manure drain-off system is used in sheds, no fodder or straw can be placed in the animal resting place since it tends to clog the drainage pipes. If a straw-bed is to be provided for the animals it is advisable to use mechanical scrapers for removal of the manure. The arrowhead scraper is increasingly used for this purpose; it consists of two wings which are movably joined together in the form of an arrowhead. They are drawn by a chain which runs in a central guide rail. For storage of manure multi-chamber containers, dug-in containers open on top, and containers partly submerged in the ground are available. They can be made of wood, concrete, steel or plastic material. (Text in German) (Solid Waste Information Retrieval System)

THE PROBLEM OF MANURE UTILIZATION IN LARGE ANIMAL HUSBANDRIES,

V. G. Blanken
Landtechnik, Vol. 25, No. 21, p. 642-644, November, 1970. 2 fig, 4 tab.

Descriptors: Livestock, Poultry, Incineration, Waste disposal, Crop response, Groundwater pollution, Odor
Identifiers: Land spreading, Germany

In animal husbandries of the Federal Republic of Germany, 135 million tons of manure accumulate per year. Considering that the agriculturally useable area spans 13.9 million hectares, this amount of manure does not seem so high. Uniform distribution of the manure over the entire acreage would bring 10 tons of manure to one hectare. Unfortunately, however, animal husbandries tend to concentrate in one area so that distribution of manure over all agriculturally useable areas would mean transportation over long, distances involving additional cost. Other ways and means for disposal of manure must be found. Incineration seems the most aesthetic solution since it yields a sterile end product. It is also the most hygienic solution since it renders the end product free of any pathogenic germs, worm eggs or larvae. One chicken produces about 0.175 kg manure per day, a cow produces about 40 or 50 liters of liquid manure (including urine). Distribution of all manure onto the nearby fields is too much of a burden to the soil and as a consequence the crop yield drops. It is also an additional burden to the digesters but not as much to the groundwater. The odor annoyance must be considered too. All of this, plus the fact that artificial fertilizers are preferred over manure, leads to the conclusion that some other method of disposal must be found in addition to incineration which is simpler and less expensive. (Text in German) (Solid Waste Information Retrieval System)

LIVESTOCK WASTE MANAGEMENT WITH POLLUTION CONTROL,

Oregon State University, Corvallis
J. R. Miner and R. J. Smith, eds.
North Central Regional Research Publication 222, Midwest Plan Service, June, 1975, 89 p. 45 fig, 58 tab, 277 ref.

Descriptors: Farm wastes, Feedlots, Biological properties, Chemical properties, Physical properties, Separation techniques, Waste treatment, Byproducts, Transportation, Odor, Dusts, Agricultural runoff, Aerobic treatment, Anaerobic treatment, Recycling.
Identifiers: Waste management, Land application, Refeeding, North Central U.S., Housing.

The aspects of livestock waste management described in this report reflect the variations encountered across the 13 states of the North Central Region. The main objective of this report is to present information on waste management that will free a livestock producer from unnecessary labor, yet, at the same time, will allow him to operate within the confines of current environmental legislation. The NC-93 committee recognizes that such an objective alone is inadequate; hence, there are large sections of the report devoted to by-product recovery. The report summarizes the necessary features of any livestock-waste-management system and presents basic information on manure production and content. The effect of housing on livestock-waste management is discussed in terms of roofed facilities and unroofed facilities. Air pollution by gases and dust is regarded of such importance that one whole section is devoted to this topic. Conventional biological waste stabilization is discussed in two sections on aerobic and anaerobic treatment. The section on utilization attempts to analyze manure-processing technology for harvesting useful by-products. Some of the topics discussed include land application with crop production, hydroponics, composting, production of livestock feed supplements, and pyrolysis. The report culminates with two sections on information retrieval and technical terms encountered in livestock waste management. (Miner & Smith-Oregon State University, Merryman, ed.) R. E. Train, R. L. Sansom, A. Cywin, J. D. Denit

Environmental Protection Agency Report Number EPA-440-1-74-004-a, January, 1974, 319 p. 68 fig, 41 tab. 257 ref.

Descriptors: Effluent, Waste water disposal, Regulation, Feedlots, Livestock, Poultry
Identifiers: Guidelines, Environmental Protection Agency, Federal Water Pollution Control Act Amendments of 1972

This document presents the findings of an extensive study of the feedlot industry for the purpose of developing proposed regulation; providing guidelines for effluent limitations and Federal standards of performance for the industry to implement sections 304 and 306 of the Federal Water Pollution Control Act mal types were considered in this study: beef cattle, dairy cattle, swine, chickens, turkeys, sheep, ducks and horses. Guidelines are set forth for effluent reduction attainable through the application of the "Best Practicable Control Technology Currently Available," the "Best Available Technology Economically Achievable" and for New Source Performance Standards. The proposed recommendations require no discharge of process wastewaters to navigable water bodies by July 1, 1977 except for precipitation event(s) in excess of the 10 year, 24 hour storm for the location of the point source for all animal types except ducks. Duck growing operations will be required to meet a limitation on BOD and bacterial pollutants using biological treatment (e.g. 2.0 pounds of BOD per 1000 ducks). By 1983, the no discharge limitation will apply to all animal types except for precipitation event(s) in excess of the 25 year, 24 hour rainfall. The latter limitation also applies to all new sources. Supportive data and rationale for development of the proposed guidelines for effluent limitations are presented. (Train, et.al. EPA)

CONTROL OF POLLUTION FROM ANIMAL FEEDLOTS,

U. S. Committee on Government Operations
Hearings before a Subcommittee of the Committee on Government Operations, House of Representatives. Ninety-third Congress, First Session, November 29 and 30, 1973.

Descriptors: Feedlots, Water pollution, Regulation.
Identifiers: Pollution control, Manure, Subcommittee on Conservation and Natural Resources.

The Subcommittee on Conservation and Natural Resources held hearings on November 29 and 30, 1973 for the inauguration of an in depth study of manure. Attempts were made in these hearings to ascertain whether Federal pollution control laws are administered efficiently, economically, and so implemented as to control pollution from point sources such as animal feedlots. Testimonies were given from representatives of EPA and other Federal agencies and interested parties to determine the agencies' role in controlling pollution from animal feedlots. This 1268 page publication may be obtained from the Committee on Government Operations, 2157 Rayburn Bldg., Washington, DC 20515. (Cameron-East Central)

CHARACTERISTICS AND SOIL TREATMENT OF BIOLOGICALLY TREATED SWINE WASTES, VOL. I, CH. 1 through 3,

Water Resources Institute, Kansas University, Lawrence
C. E. Burkhead and M. Trnovsky
Kansas Water Resources Research Institute Contribution No. 132, February, 1974, 118 p. 6 fig, 23 tab.

Descriptors: Soil treatment, Oxidation Lagoons, Biological treatment, Farm wastes, Waste water treatment, Kansas, Hydraulic conductivity, Feasibility studies, Waste identification, Waste disposal, Water reuse, Soil types, Infiltration, Path of pollutants.
Identifiers: Swine wastewater, Land disposal, Waste characterization, Holding ponds, Percolate characteristics, Soil columns, Loading and resting cycles.

Feasibility of treatment and disposal by land application of a holding pond supernatant receiving effluents from oxidation ditches treating swine waste generated in a confined hog growing operation was investigated. The performance of the three oxidation ditches and the holding pond was evaluated. The evaluation was based on statistical analyses of physical and chemical characteristics of the oxidation ditch effluents and the holding pond supernatant. The wastewater was analyzed from data collected from ten random samples for each of the following sampling locations: effluents from the oxidation ditches, the holding pond supernatant, and well water. In addition, data on water consumption, number of hogs in the buildings, and rainfall data were collected. Suitability of five typical Kansas soils for treatment and disposal of the holding pond supernatant was investigated in fifteen indoor soil columns. The columns contained disturbed soil samples representing the following textural classes: sand, sandy loam, silt loam and clay. The wastewater was applied to the column in alternate loading-resting cycles. Infiltration rates and quality changes of the percolate were monitored. Changes in the soil's chemical characteristics as brought about by the application of the supernatant were determined on ten soil columns' increments upon termination of testing. Variation among the physical and chemical characteristics of the oxidation ditch effluents and the holding pond supernatant provided evidence of unsatisfactory in-building management, causing overloading of the oxidation ditches and accumulation of biodegradable pollutants in the oxidation ditch mixed liquor as well as in the holding pond supernatant. Application of the supernatant to the selected soils demonstrated that the soil's retention capacity for the supernatant constituents is definitely limited. The soil's retention capacity increased with the clay content of the soil and decreased with the wastewater volume applied. In the course of testing, the quantity of the supernatant soluble organics, salts, alkalinity, and cations in the columns' effluents increased appreciably with an increase in quantity applied. Basic relationships controlling the transformation of the major wastewater constituents are described. (Burkhead-Kansas Water Resources Research Institute).

WATER MANAGEMENT IN LIVESTOCK WASTE HANDLING SYSTEMS,

Clemson University
Clemson, South Carolina 29631
C. L. Barth and J. H. Bond
Report No. 51, South Carolina Water Resources Research Institute, January, 1975, 87 p. 35 fig, 11 tab, 23 ref.

Descriptors: Wastewater treatment, Water management (applied), Farm wastes, Farm lagoons, Aerobic conditions, Hogs, Salmonella, Mathematical models, Water reuse, Liquid wastes, Water conservation, Waste storage, Waste Treatment.

The potential for minimizing the use of water in several animal waste treatment and storage procedures were evaluated. Laboratory units simulated the operation of aerobic lagoons, anaerobic lagoons, and storage for diluted swine feeding floor waste under conditions of controlled temperature, lighting, loading rate and detention time. Reduction of volatile solids (VS) content under conditions similar to those of aerobic lagoons was limited due to algae production. Anaerobic lagoon simulators achieved volatile solids reduction rates of 75.8 percent at 24 C and 200 days detention time and as little as 22.1 percent at 10 C and 100 days detention time. Degradation of VS was generally high in the loading rate range of 50 to 400 g vs/day-m³ and sludge storage efficiency was also high in that range. Liquefaction was a significant factor in the storage simulators with reductions of total solids by as much as 69 percent. Survival of the swine pathogens Salmonella cholerae-suis and Salmonella typhimurium in laboratory simulators of swine manure lagoons was determined and compared with the survival of the indicator organisms Escherichia coli and fecal coliforms. The heaviest populations of the pathogens died off in 33 days. A cause for Salmonella die-off was proposed. A mathematical model was developed to describe the operation of the anaerobic animal waste lagoon and compared with relevant data which characterized the lagoon simulators. The symbiotic relationship of the acid formers (facultative heterotrophs) and methane formers (obligate anaerobes) was emphasized along with the possible inhibition of both cultures by high concentrations of volatile organic acids. (Barth-Clemson University)

COMPOSITION AND DIGESTIBILITY OF CATTLE FECAL WASTE,

Virginia Polytechnic Institute and State University
Blacksburg
D. M. Lucas, J. P. Fontenot, and K.E. Webb Jr.
Journal of Animal Science, Vol. 41, No. 5, p. 1480-1486, November, 1975. 1 fig, 6 tab, 29 ref.

Descriptors: Feeds, Cattle, Sampling, Chemical properties
Identifiers: Digestibility, Dried feces, In vitro studies

Recently three tests were made with six steers to study the digestibility of fecal waste. In Test 1, steers were fed 50 percent roughage containing high protein and TDN levels. Fecal samples were taken and the remaining feces were dried for 24 hours in a forced drafted oven at 120 degrees C and then ground. The chemical composition of the feces was 13.2 percent crude protein, 31.4 percent crude fiber, 2.8 percent ether extract, 5.4 percent ash, 47.2 percent NFE, 70.9 percent cell walls and 44.8 percent ADF, dry basis. In Tests 2 and 3, the animals were fed 80 percent basal ration and 20 percent dried feces. Results from Test 1 showed 68.2 percent digestiblity for dry matter, compared with 57.4 percent for the ration containing 20 percent dried feces. The digestibility of crude protein was 69.4 percent in Test 1 and 61.3 percent for the 20 percent dried feces ration. The in vitro method of study used in this experiment seems to be a useful means of determining relative digestibilities of waste materials. (Cannon-East Central)

EPA'S NEW FEEDLOT DISPOSAL PLAN,

Calf News, Vol. 9, p. 49, 62, August, 1971.

Descriptors: Feedlots, Agricultural runoff, Waste treatment, Phosphates, Nitrogen
Identifiers: Biological filter, Retention ponds

The Robert S. Kerr Water Research Center in Ada, Oklahoma, is attempting to perfect a process wherein a colony of micro-organisms will purify the effluent from a 12,000-head feedlot on 8 to 10 acres of grassy slope. Using a 2-to-6 percent slope, with terraces, on soil too heavy to irrigate, the process removes better than 80 percent of the phosphate and about 95 percent of the nitrogen. A two-pond system is used with effluent being pumped from the second pond after 2 or 3 days retention. Start-up requires about six weeks to allow the colony to establish itself. The water supply must be nearly continuous. (Whetstone, Parker, & Wells-Texas Tech)

THE PIG'S AIR ENVIRONMENT,

Associate Professor of Environmental Physiology, Department of Animal Science
Illinois University
Urbana-Champaign

S. E. Curtis
Reports of the Sixteenth Annual Swine Day, Special Report 426, Agricultural Experiment Station, Oregon State University, Corvallis, December, 1974, p. 7-9.

Descriptors: Air pollution, Health, Performance, Odor, Gases, Dusts, Microorganisms, Confinement pens
Identifiers: Swine

There is a trend in the pork industry toward more-or-less enclosed confinement and year-round production. The air in enclosed swine houses is polluted with dust, microbes, gases, and odorous compounds that arise from feed, wastes, and the pigs themselves. Eight questions concerning the pig's air environment are posed and answered. The questions and answers (based on experiments described in the paper) are: (1) How much dust is there in swine-house air?—an average of 1,326 µg per cubic meter, (2) What is the bacterial level in swine house air?—an average of 102,920 bacterial-colony-forming particles per cubic meter, (3) Do aerial dust and bacterial levels in swine houses change with time?—Air pollution in swine houses tends to be higher in winter than in summer, probably because ventilation rate is usually reduced in winter, (4) Are dust and bacterial levels in swine-house air related?—yes, (5) What kinds of bacteria occur in swine house air?—The ratio of the bacterial-colony-forming particle count on the special medium for staphylococci to that on the general medium was 0.36; on the special medium for fecal streptococci compared to the general medium was 0.13; and on the special medium for coliforms compared to the general medium was 0.01, (6) What sizes are aerial bacterial-colony-forming particles in swine-house air?—21 percent of the staphylococcal and streptococcal-colony-forming particles, respectively, and 9 percent of the coliform-colony-forming particles, were less than 4.7 μm in aerodynamic diameter. (7) Do atmospheric ammonia, hydrogen sulfide or dust reduce the rate of gain in healthy pigs?—No, not in the amount commonly found. (8) Does atmospheric ammonia reduce the ability of the pig's lungs to resist bacterial infection?—Yes, it appears to. (Merryman—East Central)

NEW CONCERNS IN SWINE WASTE MANAGEMENT,

Associate Professor, Department of Agricultural Engineering, Oregon State University, Corvallis
J. R. Miner and L. Boersma
Reports of the Sixteenth Annual Swine Day, Special Report 426, Agricultural Experiment Station, Oregon State University, Corvallis, December 1974, p. 16-21. 2 fig.

Descriptors: Recycling, Design, Anaerobic digestion, Algae, Separation techniques, Feeds.
Identifiers: Swine, By product recovery

A waste management system is being tested in Oregon State University in which swine manure from a confinement operation and waste heat from a thermal electric generating plant may be combined for growing algae. A flushing gutter in the swine confinement building carries the slurry to a sump, from which the slurry is pumped to a liquid-solid separator. The liquid-solid separator is mounted over an anaerobic digester so that the solids may be introduced into the digester without further handling difficulties. The digester contents are agitated and heated to maintain a 95 degrees F temperature. In a full-scale operating system, the heating would be done with waste heat from power plant cooling water. Effluent from the anaerobic digester is combined with discharge from the liquid-solid separator and the 2 liquids are used as input feed to a series of algae-growing basins. Effluent from the algae-growing basins is discharged into a storage tank from which accumulated liquid will be pumped to a centrifuge which will separate the water from the algal cells so that the water may be returned to the flush tanks for re-use in manure transport. The harvested algae is to be evaluated as a potential swine feed ingredient by chemical analysis and eventual feeding to experimental animals. The gas produced by the anaerobic digester, which in a full-scale operating system might be used as fuel, is discharged into a soil absorption field designed to deodorize the gas. Experimental results are not yet available. (Merryman-East Central)

MANURE MANAGEMENT TO CONTROL FLIES,

J. Falter
Poultry Digest, Vol. 34, No. 403, p. 375, September, 1975.

Descriptors: Poultry.
Identifiers: Fly control, Coning, Waste management.

While a poultry producer may already have a firmly established fly control system, there are still things that might be done to improve that system. In a dry-system with infrequent clean-out, it is recommended that under cage cleaning be done early enough to allow a pad of manure and some coning to start before fly season arrives. Proper grading, adequate roof overhang and proper construction and maintenance of watering devices will eliminate much moisture accumulation. Also, eggs should not be thrown into the manure. Weeds should be removed from around the poultry houses to improve air circulation and sun penetration. Built-up manure systems have the added advantage of maximizing development of biological control agents like predaceous and parasitic insects and mites which destroy eggs, larvae and adult flies. In a dry-system with frequent cleanout, weekly or twice weekly removal of droppings followed by proper disposal successfully breaks the fly life cycle, but clean-out must be thorough. Liquid systems are usually excellent for fly control, but odor may become a problem. (Merryman-East Central)

COLORADO ADOPTS PROCESSED WASTE FEEDING RULES,

Feedstuffs, Vol. 47, No. 49, p. 5, 38, December 1, 1975.

Descriptors: Colorado, Regulation, Feeds, Chemical properties, Physical properties
Identifiers: Refeeding

Rules adopted by the Colorado Department of Agriculture concerning the use of processed animal waste products became effective on October 15, 1975. These regulations allow state registration and intrastate sale of processed animal waste products which meet the following specified requirements: (1) No processed animal waste shall contain such extraneous materials as metal, glass, wire, nails, etc. (2) Dried Poultry Waste shall not contain (a) less than 20 percent crude protein, (b) more than 15 percent crude fiber, (c) more than 30 percent ash, (d) more than 1 percent feathers, (e) more than 12 percent moisture, or (f) more than 20 precent litter. (3) Dried Poultry Litter shall not contain (a) less than 18 percent crude protein, (b) more than 40 percent crude fiber, (c) more than 30 percent ash, (d) more than 5 percent feathers, or (e) more than 12 percent moisture. (4) Dried Ruminant Waste shall not contain (a) less than 12 percent crude protein, (b) more than 30 percent crude fiber, (c) more than 30 percent ash, or (d) more than 40 percent straw, wood, wood shavings, litter, dirt, sand, rocks or other similar extraneous materials, or (e) more than 12 percent moisture. (5) Undried Processed Animal Waste Products shall not contain more than 40 percent straw, wood, wood shavings, litter, dirt, sand, rocks or other extraneous materials. (6) Any product labeled as or containing dried animal waste products shall be 12 percent moisture or less to aid in maintaining microbiological quality. (Merryman-East Central)

2836-C2, D2, D3, F6
ANAEROBIC DIGESTION OF BEEF MANURE AND CORN STOVER,

Agricultural Engineering Department, Iowa State University, Ames
M. E. Hein, R. J. Smith, and R. L. Vetter
Presented at the 1975 Winter Meeting, American Society of Agricultural Engineers, Chicago, Illinois, December 15-18, 1975, Paper No. 75-4542, 18 p. 6 fig, 2 tab, 11 ref.

Descriptors: Anaerobic digestion, Equipment, Energy, Chemical properties, Chemical oxygen demand.
Identifiers: Gas production, Cattle manure, Iowa State University, Loading rate.

An experimental digester of about 100 gal (379 dm^3) was established at Iowa State University in order to: (1) examine gas recirculation mixing with regard to lowest energy input that would not lead to biological failure, (2) examine the operating variables of loading rate and detention time, and (3) monitor changes in chemical composition of manure as it passes through the digester and to correlate the COD with gas production. Operating experiences are reviewed. It was determined that: (1) Satisfactory mixing of a 100 gal (379 dm^3) digester requires a gas-recirculation rate of at least 3 cfm/10^3 gal (3.7×10^{-4} m^3/sec m^3) and more than 5 cfm/10^3 gal (6.2×10^{-4} m^3/sec m^3) would be preferable, (2) Inadequate mixing results in temperature gradients that cause lower gas production, (3) Adequate mixing will control scum-layer formation, (4) Approximately 45 percent reduction in COD can be expected at a detention time of 9 days, (5) Specific production corrected to 20 degrees C was about 13.7 ft^3/lb COD destroyed (0.86 m^3/kg COD), (6) During warm weather, mixing energy is about 20 percent of the total energy input required. The remaining 80 percent is required for heating, and (7) At the loading rate and detention times used (0.45 lb vs/day ft^3, 7.2 kg vs/day m^3; detention time 9 days), inhibition from high ammonia concentrations was not observed. (Merryman-East Central)

POLLUTION ABATEMENT FROM CATTLE FEEDLOTS IN NORTHEASTERN COLORADO AND NEBRASKA,

Agricultural Research Service, United States Department of Agriculture, P. O. Box E, Fort Collins, Colorado
L. K. Porter, F. G. Viets, Jr., T. M. McCalla, L. F. Elliott, F. A. Norstadt, et. al.
Environmental Protection Agency Report, EPA-660/2-75-015, June, 1975, 120 p. 27 fig. 34 tab, 112 ref.

Descriptors: Pollution abatement, Feedlots, Colorado, Nebraska, Cattle, Livestock, Waste disposal.
Identifiers: Rainfall runoff, Land application, Water pollution potentials, Waste characteristics.

Climatic factors, feedlot runoff, and organic material in the runoff were evaluated in experimental and commercial feedlots. The effects of slope, stocking rates, terraces, basins, and holding ponds were evaluated to obtain the best controls for containing runoff. In eastern Nebraska, 70 cm annual precipitation produces 23 cm of runoff; whereas, in northeastern Colorado, 37 cm annual precipitation gives only 5.5 cm of runoff. Large applications of runoff liquid, up to 91 cm on grass-Ladino and 76 cm on corn, in Nebraska did not decrease yields; however, in northeastern Colorado, the concentrated high-salt runoff required dilution before direct application to crops. The organic manure-soil interface severely restricts the movement of water, nitrates, organic substances, and air into the soil beneath feedlots. The amounts of NO_3-N in soil cores taken from Nebraska feedlots and croplands ranked as follows: abandoned feedlots greater than feedlot cropland greater than upland feedlots greater than river valley feedlots greater than manure mounds greater than alfalfa greater than grassland. Feedlots contribute NH_3, amines, carbonyl sulfide, H_2S, and other unidentified substances to the atmosphere. Ammonia and amine can be scavenged from the air by green plants and water bodies. Anaerobic conditions in feedlots are conducive to the production of carbonyl sulfide, H_2S, and amines. Management practices, such as good drainage, that enhance aeration will decrease the evolution of these compounds. (Porter, et. al.-USDA)

METHOPRENE AS A FEED ADDITIVE FOR CONTROL OF THE HOUSE FLY BREEDING IN CHICKEN MANURE,

Department of Entomology, Virginia Polytechnic Institute and State University, Blacksburg
G. C. Breeden, E. C. Turner, Jr. and W. L. Beane
Journal of Economic Entomology, Vol. 68, No. 4, p. 451-452, 1975.

Descriptors: Feeds, Additives, Poultry.
Identifiers: Methoprene, Fly control.

An experiment was conducted utilizing methoprene in 2 forms for control of house fly breeding in chicken manure. An 86.9 percent technical formulation (acetone solution sprayed on feed) and an incapsulated 7 percent dry premix formulation (blended with feed by mixer) were used as treatment additives. White Rock hens were fed and watered in groups of five. Three replicates of each group were used for each treatment rate. Hens receiving the technical formulation received treated feed at rates of 0, 25, 50, and 100 ppm for 7 days and untreated feed for the following 7 days. Hens receiving the dry pre-mix formulation received the treated feed at rates of 0, 25, 5, and 10 ppm for 10 days and untreated feed for the following 4 days. Bioassay data from the technical formulation treatments indicate that good consistent inhibition of housefly emergence began on the third day for the 50 ppm rate and on the first day for the 100 ppm rate. Posttreatment data indicate that the time required for all the unmetabolized methoprene to leave the chicken increased with treatment rate. Bioassay data from the encapsulated dry premix formulation indicate that good consistent inhibition of house fly emergence began on the eighth day for the 5 ppm rate and the first day for the 10 ppm rate. Posttreatment data indicate no difference between treatment rates in the amount of time required for all the unmetabolized methoprene to leave the chicken. While methoprene shows promise as a feed additive for the control of house flies breeding in chicken manure, the encapsulated formulation was definitely superior to the technical formulation. Ten times less encapsulated formulation achieved the same level of control as the technical formulation. (Cocon-East Central)

POLLUTION POTENTIAL OF RUNOFF FROM LIVESTOCK FEEDING OPERATIONS,

Instructor in Agricultural Engineering, Water Resources Institute, South Dakota State University, Brookings
J. M. Madden and J. N. Dornbush
Presented at 1971 Annual Meeting, American Society of Agricultural Engineers, Washington State University, Pullman, June 27-30, 1971, Paper No. 71-212, 15 p. 5 tab. 3 ref.

Descriptors: Agricultural runoff, Pollution, South Dakota, Feedlots, Livestock, Precipitation (atmospheric).
Identifiers: Statistical analysis.

A 2-year study was conducted to determine the quantity and quality of runoff from production feedlots in eastern South Dakota. A statistical analysis was used in evaluating the relationship between runoff volume, precipitation amounts, and animal concentration and the pollutional constituents associated with runoff. The following conclusions were drawn: (1) Estimation equations using feedlot characteristics and design runoff volumes can be applied to determine the total and suspended solids, plant nutrients, and oxygen demanding material in feedlot runoff. (2) Conventional methods of determining runoff from rainfall may not give accurate estimates of runoff from livestock feedlots. (3) Although the annual losses of animal waste from feedlots by runoff represent a small percentage of the total waste produced, the quantities are sufficient that control measures must be provided on feedlots whose runoff reaches lakes and streams. Further study is needed. (Merryman-East Central)

RECYCLED MODIFIED SWINE WASTES,

Feedstuffs Vol. 27, No. 52, p. 26, December 22, 1975.

Descriptors: Diets, Fermentation, Sterilization
Identifiers: Refeeding, Swine

A model system was built for the collection of raw swine wastes for aerobic fermentation, concentration, sterilization and refeeding as a supplement to growing-finishing pigs. The fermented liquid product was substituted for drinking water and used as a supplement to meal diets deficient in mineral, protein, and vitamins. Fifty pigs were used in this 6-week study. Pigs offered the waste as a supplement to a low mineral diet performed much the same as pigs on the low mineral diet, but not as well as pigs fed a complete diet. When a low mineral, low protein, low B-complex vitamin diet was supplemented with "waste", there was further reduction in feed intake and gains. The conversion of non-protein nitrogen to protein nitrogen was not an efficient process. Further study is needed. (Merryman-East Central)

PLASTIC FROM MANURE,

Hoard's Dairyman, Vol. 120, No. 20, p. 1195, October 25, 1975.

Descriptors: Recycling, Byproducts, Plastics, Methane, Fertilizer.
Identifiers: Ethylene, Anhydrous ammonia, Ethane.

Texas Tech researchers have discovered that beef cattle manure can yield significant amounts of ethylene—"the backbone of the plastics industry." Research was conducted with the intention of showing that feedlot waste could be converted into synthetic gas used for the production of anhydrous ammonia fertilizer. But it was discovered that methane, ethane, and ethylene were produced as well. Assuming a realistic value of 10 cents per pound for ethylene, a conservative estimate of the value of the ethylene production from manure produced from a 100,000-head feedlot in the Texas high plains is around $1.8 million per year. Research is continuing with the objective of improving the process in order to increase the ethylene production. (Merryman-East Central)

BORROWING HUMUS FROM THE "BANK OF ORGANIC WASTES"

Compost Science editor
J. Goldstein
Compost Science, Vol. 16, No. 5, p. 2-3, Autumn, 1975

Descriptors: Organic wastes, Fertilizers, Costs, Energy, Microorganisms.
Identifiers: Composting.

Several studies are cited which support the premise that use of organic matter as fertilizer is equal to or superior to the use of chemical fertilizers. According to a 1975 chemical fertilizer vs. organic fertilizer comparison study sponsored by the National Science Foundation, organic farmers can produce about as much food per acre with about one-third the energy. While conventional farmers spent an average of $17.33 per acre on fertilizers, organic farmers spent only $6.17. T. M. McCalla, USDA microbiologist at the University of Nebraska, is credited with projecting the importance of the interrelationship between organic wastes applied to the soil, and the microorganisms which decompose them. Dr. McCalla emphasizes that "...it is absolutely essential that we have this microbial transformation in order for man to survive." The editors of Compost Science feel that studies concerning the composting of organic wastes are not being pushed enough. They state that "while it takes a long time to give more than lip service to the value of organic matter in soil and to using organic wastes from cities and farms efficiently in crop production, there's little doubt that we are moving in that direction." (Merryman-East Central)

ROUNDING UP RUNOFF: REFLECTIONS IN WASTE HANDLING SYSTEMS,

Staff editor
M. Lane
Feedlot Management, Vol. 17, No. 12, p. 13-15, December, 1975. 3 fig.

Descriptors: Feedlots, Planning, Design, Agricultural runoff, Cost sharing
Identifiers: Soil Conservation Service, Runoff control

In order to participate in Soil Conservation Service programs, a feedlot owner must sign an agreement as a cooperator in the local soil conservation district or must be receiving Agricultural Stabilization and Conservation Service cost-sharing funds. Once one of these qualifications is met, expert planning assistance is at the feedlot owner's disposal through consultation with the SCS. SCS usually assists in small projects such as construction of farm ponds or terracing to prevent erosion, but it may also be called upon to assist in planning a whole feedlot design, giving guidance concerning runoff control measures. The design of all runoff control systems contains 3 basic elements—a lagoon; a diversion around the feedlot to direct water falling inside the lot into the lagoon; and a clean water diversion, which keeps water running into the feedlot from becoming polluted. Several specific instances of SCS assistance and planning are cited to illustrate how specific feedlot problems were overcome. Over the years, SCS has built up a knowledge of soils and drainage and altering water pathways. This places SCS in a better position than most to help control runoff from feedlots. (Merryman—East Central)

RULES AND REGULATIONS REGARDING PROCESSED ANIMAL WASTE PRODUCTS,

Colorado Department of Agriculture
Rules and Regulations Regarding Processed Animal Waste Products, Colorado Department of Agriculture, Division of Inspection and Consumer Services, Feed Section, 1973, 6 p.

Descriptors: Regulation, Legal aspects, Colorado.
Identifiers: Processed animal waste products.

These are the rules and regulations regarding processed animal wastes products. Legal-authority for these regulations is found in Title 35, Article 60, Section 107, Colorado Revised Statutes 1973, as amended. Definitions are given for: (1) animal waste, (2) processed animal waste, (3) processed, (4) dried poultry waste, (5) dried poultry litter, (6) dried ruminant waste, (7) undried processed animal waste product, (8) processed animal waste derivative, (9) person, and (10) references to statutes of agency rules or regulations. The following matters are outlined: (1) Registration Required, (2) Registration Procedure, (3) Registration Refused, (4) Quality Standards, (5) Labeling Requirements, (6) Testing Required, (7) Records Required, (8) Registration Revocation, Suspension, Annulment, Limitation or Modification, (9) Deviation from rules, (10) License and Bond Requirements, (11) Liability and Penalties, and (12) Effective Date and Duration of Regulation. These rules became effective on November 19, 1975. (Merryman-East Central)

VALUE OF POULTRY WASTE AS FEED, FERTILIZER DISCUSSED,

Feedstuffs editor
G. Emerson
Feedstuffs, Vol. 47, No. 41, p. 22, October 6, 1975.

Descriptors: Feeds, Fertilizers, Poultry, Proteins, Nutrients, Nitrogen, Potassium, Phosphorus.
Identifiers: Dried poultry waste, Dried layer waste, Dried poultry litter, Refeeding.

A workshop recently held in Corona, California, considered the pros and cons of poultry waste utilization as feed or fertilizer. Among the points made were the following: (1) While manure was once low in phosphorus, improved rations have now made phosphorus one of manure's most valuable ingredients. (2) Fresh or dried poultry manure is a good source of nitrogen, but animal manures and composted or stockpiled chicken manures are not. (3) Manure can best be utilized where nitrogen, phosphorus and potassium are needed—such as potassium and phosphorus-deficient areas planted in cotton or potatoes or in phosphorus-deficient areas in small grain or range production. Chemical nitrogen would still need to be added. (4) Limitations of dried poultry manure as fertilizer include the following: (a) Excessive application rates must be utilized to combat the problem of irregular distribution; (b) As a nitrogen source, dried poultry manure does not release nitrogen quickly enough for some crops; (c) Dried poultry manure supplies too much nitrogen for some crops and not enough for others. (5) Dried layer waste and dried poultry litter have nutrient values of $97 and $80 per ton, respectively, and have shown themselves to be satisfactory food supplements for ruminant animals. (6) Crude protein values are fairly high in DPW but much of the nitrogen is non-protein and of fairly limited use to non-ruminant animals such as poultry and swine. However, experimental results have suggested that levels of up to 10-12 percent DPW can be used in layer rations without significant effect on production, feed efficiency or egg size. (Merryman-East Central)

WHAT'S THE REAL VALUE OF LIQUID DAIRY MANURE?,

Illinois University
D. H. Vanderholm
Hoard's Dairyman, Vol. 120, No. 7, p. 505, April 10, 1975.

Descriptors: Dairy industry, Nutrients, Fertilizers.
Identifiers: Liquid dairy manure.

Fertilizer nutrient content and fertilizer value of liquid dairy manure are estimated in relation to current fertilizer prices. One gallon of liquid dairy manure contains about 0.024 lb N, 0.014 lb P_2O, and 0.025 lb K_2O, respectively. The value of these major nutrients in one gallon of liquid dairy manure is 1 cent per gallon. Because nutrient content of manure varies and because fertilizer prices may go up, dairy owners must have their own dairy manure analyzed and compared against current fertilizer prices to get a true estimate for themselves. (Merryman-East Central)

WASTE REFEEDING SEEN AS COST OFFSETTER.

Feedstuffs Southeastern Correspondent
R. H. Brown
Feedstuffs, Volume 47, No. 50, p. 5, 45, December 8, 1975.

Descriptors: Costs, Performance, Cattle, Poultry
Identifiers: Refeeding, Crop residues, Animal wastes

Speaking at a conference concerned with utilization of plant and animal waste in livestock feeding, Dr. R. L. Vetter of Iowa State University proclaimed crop residues and animal waste to be valuable feed sources. He described tests at Iowa State University in which cattle wastes were scraped twice weekly from a confinement building; mixed with weighted amounts of ground cobs, ground corn and molasses in a silage wagon; and blown into a silo for ensiling. Ingredients percentages were: excreta, 42; stover and cobs, 42; and ground corn and-or molasses, 15. Cattle fed the excreta-stover silage in a 100-day feeding test gained 197 lb, compared to 31 lb for cattle fed a balanced control ration of ground hay, cobs, and molasses estimated to provide 10.3 lb of total digestible nutrients per cow daily. Those head on excreta-stover silage consumed 28 to 30 lb of dry matter per day with free-choice feeding. No health problems were observed during the 5½ months tested. At this same meeting, Edward McCaugh of Morton, Mississippi, reported an experiment in which he fed his calves a mixture containing 12-15 percent corn, 60 percent poultry waste and 25-30 percent soybean stalks that had been run through a hammermill. No-till corn is also being looked at as both a cattle feed and a soil conservation practice. (Merryman—East Central)

WATER QUALITY IN A RECIRCULATING RACEWAY SYSTEM FOR FISH CULTURE,

Fisheries Biologist, Entomology and Fisheries Department, Coastal Plain Experiment Station, Tifton, Georgia
Descriptors: Fish farming, Water quality, Recirculated water, Parasites, Rainbow trout
Identifiers: Channel catfish.
T. K. Hill and J. L. Chesness
Presented at 1973 Winter Meeting, American Society of Agricultural Engineers, Chicago, Illinois, December 11-14, 1973, Paper No. 73-5508, 14 p. 2 fig, 5 tab., 4 ref.

Four seasons of fish production in an 8-segment recirculating earthen raceway system at the Coastal Plain Experiment Station, Tifton, Georgia, are discussed. Rainbow trout were raised during the winter and Channel Catfish were raised during the summer. Purina Trout Chow was fed twice daily to trout at rates of 2-2½ percent body weight and once daily to Channel Catfish at rates of 1-3 percent body weight. Catfish were parasitically infested by Cleidodiscus, Scyphidia, and Trichodina during the studies. Trout were infested by Gyrodactylas and Trichodina. All conditions were effectively treated with 30 ppm of formalin. Raceway water was periodically sampled and dissolved oxygen, total hardness, pH, CO_2, ammonia, turbidity, and visibility were measured. The fish were harvested at the end of each season. Experimental results indicate that recirculating raceways provide an easily manageable (treatment, feeding, and harvesting) production system for fish culture. Year-round fish production in a temperate climate can be accomplished by alternately growing Rainbow Trout and Channel Catfish as described. Eight inch long fingerlings should be stocked so that marketable size fish can be attained in the double-crop system. Maximum fish production capacity was not reached during the two-year study. Water quality was still good by the end of the study. It was felt that natural restorative capacity of the system combined with man-made systems (physical, chemical, biological) should provide water quality suitable for significantly increasing fish production. WATER QUALITY AND MANAGEMENT CHARACTERISTICS OF FEEDLOT RUNOFF HOLDING PONDS,

Agricultural Engineering Department, Illinois University, Urbana-Champaign
E. C. Dickey and D. H. Vanderholm
Presented at the 1975 Winter Meeting, American Society of Agricultural Engineers, Chicago, Illinois, December 15-18, 1975, Paper No. 75-4568, 12 p. 6 fig, 3 tab, 8 ref.

Descriptors: Water quality, Feedlots, Agricultural runoff, Illinois, Rainfall-runoff relationships, Nitrogen, Phosphorus, Potassium.
Identifiers: Holding ponds, Land application.

A study was initiated in 1974 to evaluate installed runoff control facilities in terms of their management requirements, operator acceptability, and their effectiveness in preventing water pollution. Six commercial livestock operations in central and northern Illinois—beef, dairy, and swine facilities—were monitored for two years. This paper reports the findings directly related to characteristics and management of the holding ponds. Each runoff control system consisted of a concrete settling basin with a gravity-drain or a pumped outlet, holding pond, and pumping equipment for holding-pond dewatering. Rainfall and runoff data were collected at all the locations. Five holding ponds were sampled monthly; the sixth was sampled weekly. It was found that the quality of holding-pond water is highly variable. Large variations in nitrogen, phosphorus, and potassium concentrations in the water were observed. Nitrogen concentration exhibited a definite seasonal trend: low concentrations during the summer months, increasing in late fall and winter, reaching a peak in late winter, and decreasing in the spring. It was concluded that major factors affecting holding pond water quality are the management of the lot surface, the number of animals in the system, and changes in annual rainfall patterns. In order to gain optimum nutrient benefits, dewatering of the holding pond should occur in the spring. However, dewatering in the fall is still recommended in most situations to provide capacity for winter runoff storage. (Cameron-East Central)

PLANT AND SOIL EFFECTS OF SWINE LAGOON EFFLUENT APPLIED TO COASTAL BERMUDAGRASS,

Soil Science Department
North Carolina State University
Raleigh
G. A. Cummings, J. C. Burns, R. E. Sneed, M. Overcash, and F. J. Humenik
Paper Number 4649, Journal Series of the North Carolina Agricultural Experiment Station, Raleigh, North Carolina, 17 p. 7 tab, 3 ref.

Descriptors: Effluents, Lagoons, Coastal Bermudagrass, Soil contamination, Agricultural runoff, Seepage, Leaching, Nutrients
Identifiers: Land application, Swine, Plant response

A study was done to (a) determine maximum permissible loading rate of anaerobic swine lagoon effluent upon Coastal bermudagrass grown on a Norfolk sandy loam, and (b) determine the fate of possible pollutants added to soils including crop utilization, soil absorption, and losses due to runoff, seepage, and leaching. In May, 1972, Coastal bermudagrass was established by sprigging on a Norfolk sandy loam, 0 to 3 percent slope after fumigation with methyl bromide to kill all existing vegetation. Weekly application rates of 5, 10 and 20 inches of effluent supplied 300, 600, and 1200 lbs of N respectively. Samples of effluent applied to plots were collected by placing 400 ml beakers within the plot during effluent application. Effluent, runoff, soils, forage, and solution samples from porous cups were all analyzed for total N, P, K, Ca, Mg, Na, Cl, and Cu. Independent analyses were made for other chemical properties as well. It was concluded that application of 24 inches of swine lagoon effluent, supplying over 1400 lbs each of N and K per acre annually, was not detrimental to yield or mineral content of Coastal bermudagrass in 1974. Total amounts of exchangeable P, K, and Mg increased in the soil profile as rate was increased. Changes in total N in the soil induced by treatments were not detected over the two year period. However, nitrate levels were high, up to 28 ppm, in the lower portion of the profile the second year. Although effluent rates increased soil reserves of several elements, no detrimental effects of effluent applications upon plants or soils were noted. More years of application are needed to evaluate long term effects. (Cameron-East Central)

HOW TAIWAN HOMESTEAD FARMERS MAKE METHANE WORK FOR THEM,

G. Logsdon
Compost Science, Vol. 16, No. 5, p. 30, Autumn, 1975. 1 fig.

Descriptors: Recycling, Methane, Fertilizers, Nitrogen, Economics.
Identifiers: Swine, Taiwan.

The Taiwanese farmer is turning to methane production in order to improve and preserve the fertilizer value of manure. Methane production reduces manure bulk, making it easier to handle. The protein-rich residue contains slightly less nitrogen than the original manure and the manure nutrients are more stabilized, making them far less likely to leach or volatilize in storage or in land spreading. With this approach, the cost of making methane is balanced against the nitrogen saved. A rural development specialist named Chung Po describes simple home methane generators which cost only about $300 to build. The generators run off the digested wastes of 10-15 pigs. Gas production is continuous. The gas contains 63-67 percent methane, 27-33 percent CO_2, and 1.7 percent hydrogen sulfide. In hot weather, about 3,000 liters of gas are produced a day—enough for cooking 3 meals a day or to run a 2 kw generator 3 hours a day. (Merryman-East Central)

RECYCLED MODIFIED SWINE WASTES AS A SOURCE OF PROTEIN, VITAMINS AND MINERALS FOR SWINE,

Animal Science Department, Florida University, Gainesville
H. D. Wallace, N. D. Thanh, G. E. Combs, and R. A. Nordstedt
Research Report AL-1975-4, Florida Agricultural Experiment Station, Gainesville, May, 1975, 6 p. 1 fig, 4 tab, 2 ref.

Descriptors: Performance, Diets, Nutrition.
Identifiers: Refeeding, Swine, Fermented Concentrated Sterilized Wastes.

A small model system was developed at the University of Florida which was capable of converting raw swine wastes into a feed suitable for refeeding to growing-finishing swine. Utilizing this system, swine wastes were fermented, concentrated and sterilized. The fermented liquid product was then substituted for drinking water and used as a supplement to meal diets deficient in mineral, protein, and vitamins. A total of 50 pigs were involved in this feed trial which lasted 6 weeks. The model system was successfully developed to a stage where the raw wastes were recycled through a workable system. However, treatment technique, volume control, changes in mineral concentration and other factors affecting the production of a consistently wholesome product of meaningful nutritional value were not adequately mastered. Pigs offered the fermented concentrated sterilized waste (FCSW) as a supplement to a low mineral diet performed similarly to control pigs on the low mineral diet but not as well as pigs fed a complete diet. The FCSW also failed to improve performance of pigs fed a low mineral, low protein (8 percent) diet. When a low mineral, low protein, low B-complex vitamin diet was supplemented with FCSW, further reduction in feed intake and gains resulted. The conversion of non-protein nitrogen to protein nitrogen was not an efficient process. Procedural changes are needed to improve the conversion. (Merryman-East Central)

COLD SLATTED FLOOR BARNS...WORK WELL IN SOUTHERN MINNESOTA,
D. W. Bates
Hoard's Dairyman, Vol. 120, No. 23, p. 1340, 1350, December 10 and 25, 1975. 1 fig, 3 tab.

Descriptors: Minnesota, Housing, Design, Dairy industry
Identifiers: Cold slatted-floor free-stall barns, Floors, Frozen manure

The performance of three cold slatted-floor free-stall barns is compared. One barn was at the University of Minnesota and two were independently owned by Minnesota dairy men. All were put to use in 1973 and performed during an extremely cold winter. Though problems arose, results indicated that such systems could be successfully utilized and that problems with frozen manure could be handled with good management. The following advice is given to dairymen considering such a system. (1) Provide a clear opening in the ridge that is a minimum of 6 inches wide. For buildings over 40 feet wide, add 2 inches for each additional 10 feet of building width. (2) Supply either adjustable, trackmounted ventilation doors about 3 feet high and 8 feet long, or tilt-type openings which pivot on a horizontal center support at regular intervals in both long walls. Regulate these openings according to weather conditions. (3) Limit alley width to concentrate animal traffic for effective movement of manure through the floor openings. Alleys between two rows of stalls may be as narrow as 6 feet. Use a width of 9-10 feet for alleys between a feed bunk and row of stalls. (4) Possibly remove manure from immediately behind the stalls by hand or scraper if freezing starts. (5) Follow good management practices essential to the success of any free stall system. (Merryman—East Central)

COLORADO OKAYS USE OF DPW,
Egg Industry, Vol. 8, No. 12, p. 13-14, December, 1972.

Descriptors: Colorado, Regulation, Chemical properties, Physical properties.
Identifiers: Dried poultry wastes, Processed wastes.

Colorado rules and regulations regarding use of processed animal wastes as feed products became official on October 15, 1975. The rules established that all products, whether dried poultry waste from poultry, litter, dried ruminant waste or processed waste derivative, such as yeast, algae, or other organisms produced from wastes, must not contain more than 12 percent moisture. It must be pathogen-free and must not exceed FDA standards for drug and pesticide residues or other "deleterious" substances. The product must not contain more than 500 ppm as mercury, lead, bismuth, copper, cadmium, arsenic, antimony or tin or in excess of 20 ppb of aflatoxins. DPW must not contain less than 20 percent crude protein or more than 15 percent crude fiber; 30 percent ash; 1 percent feathers, 12 percent moisture or 20 percent litter. Dried poultry litter shall contain no less than 18 percent crude protein or in excess of 40 percent crude fiber or 30 percent ash or 5 percent feathers or 12 percent moisture. Dried ruminant waste must contain no less than 12 percent crude protein or no more than 30 percent crude fiber, or 30 percent ash, or in excess of 40 percent straw, wood, wood shavings, litter, dirt, sand, rocks or other extraneous material, or in excess of 12 percent moisture. Copies of these regulations are available from: Division of Inspection & Consumer Services, Colorado Department of Agriculture, 406 State Services Bldg., 1525 Sherman St., Denver, Colorado 80203. ENERGY SOURCES FOR BIOLOGICAL DENITRIFICATION OF ANIMAL WASTES,
Agricultural Engineering Department
Delaware University
Newark
W. F. Ritter and R. P. Eastburn
Presented at 1975 Annual Meeting, American Society of Agricultural Engineers, University of California, Davis, June 22-25, 1975, Paper No. 75-4041, 6 p. 5 tab, 7 ref.

Descriptors: Denitrification, Animal wastes
Identifiers: Energy sources, Methanol, Molasses, Composted solid waste, Barriered landscape water renovation system

A 5-month laboratory experiment was conducted to evaluate methanol, molasses, and composted solid waste as energy sources for denitrification of animal wastes when applied to a barriered landscape water renovation system. Soil columns from acrylic plastic pipe were constructed with a length of 183 cm and 10.2 cm in diameter. Prior to applying waste to the soil columns, each column was leached with 3 liters of distilled water. All of the effluent from each column was collected and analyzed for COD, organic nitrogen, ammonia, and nitrate-nitrite nitrogen. Conclusions drawn were: (1) Molasses was the most suitable of the energy sources tested. (2) Composted solid waste would not make a suitable energy source for a BLWRS because of the organic matter and nitrogen that may be leached from it. (3)Molasses is more economical than methanol as an energy source for a BLWRS. (Cameron—East Central)

INTACT MANURE PACKS HALT SEEPAGE,
Hoard's Dairyman, Vol. 120, No. 18, p. 1087, September 25, 1975.

Descriptors: Feedlots, Odors, Cattle, Seepage control, Rainfall.
Identifiers: Soil pollution, Groundwater pollution, Manure packs.

A four-year research project has shown that cattle feedlots do not pollute soil and groundwater if they have an intact manure pack and about one animal per 200 square feet. Scientists of USDA's Agricultural Research Service have found that an intact manure pack eliminates water infiltration and movement of contaminants through the soil to the groundwater. Fred A. Norstadt and Harold R. Duke conducted a study utilizing commercial and experimental feedlots without concrete floors. To gather data on water content and chemical movement, the researchers installed three cased dry wells in one of the feedlots and a similar well in a nearby alfalfa field. Nitrate nitrogen concentration was found to be highest near the manure-soil interface. This nitrogen concentration decreased markedly with depth. Nitrate nitrogen content in the water table under each well fell into the same range as had been determined in 1912 before feeding operations were established. In relation to odor, Norstadt theorizes that odors produced by feedlots can be reduced and partially controlled by such improved management practices as using sawdust and wood chips for bedding and stirring the manure pack. A special feedlot was built at CSU's Animal Science Research Center to test what effect such practices would have on water, salt and nitrogen movement beneath a feedlot. One year of testing has shown that proper management results in no pollution hazard to soil or water beneath the feedlot. (Cameron-East Central)

FLORIDA RESEARCH FINDS MILK PRODUCTION UNAFFECTED BY 10 PERCENT DPW IN COW'S RATIONS,
Feedstuffs Southeastern correspondent
R. H. Brown
Feedstuffs, Vol. 47, No. 46, p. 4, 52, November 10, 1975. 1 tab.

Descriptors: Florida, Dairy industry, Performance, Calcium, Phosphorus.
Identifiers: Dried poultry wastes, Refeeding, Swine, Oxidation ditch-mixed liquor.

In University of Florida feeding trials, excreta obtained from 50,000 laying hens was dehydrated to a product of ten percent moisture or less. Four rations consisting of 0, 10, 20, and 30 percent DPW were substituted for citrus pulp and fed to 24 lactating cows, using a fixed amount of 30 percent cottonseed hulls as the main crude fiber plus small amounts of urea to balance the protein content. The waste was the only source of calcium and phosphorus supplementation in the 10, 20 and 30 percent DPW rations. Concentrate mixtures were balanced to 13 percent crude protein on an air-dry basis. It was found that DPW levels of up to 10 percent could be used by the cattle with little or no reduction in feed intake and milk production. The DPW can also serve as a source of calcium and phosphorus. A reduction in fat percent for the 10 percent DPW appeared to be the result of citrus pulp reduction. Dr. J. P. Fontenot, reporting on other studies, made the following observations: (1) Limited work indicates that layer waste ensiled with a dry feed such as grass hay will produce a nutritious feed. (2) Limited research has revealed that good performance may be obtained in swine which are fed oxidation ditch-mixed liquor from swine manure when compared with tap water. (3) While high heat processing of cattle waste appears to lower digestibility, addition of such chemicals as sodium hydroxide, improves digestibility. (4) Level of waste to be used in the ration depends on the level of production of the animals. Those in low production, such as pregnant beef cows, could be possibly fed close to 100 percent DPW whereas for fattening cattle the level would likely be 10-25 percent of the total ration. (5) The high protein and phosphorus content of poultry wastes would make them valuable as range supplement for cows and stocker cattle. (6) Waste recycling could save at least 40 million tons of grain annually. (Merryman-East Central)

EXCESSIVE MANURE CAN AFFECT POTABLE WATER,

Hoard's Dairyman, Vol. 120, No. 13, p. 799, July 10, 1975
Descriptors: Groundwater pollution, Pennsylvania, Regulation, Dairy industry
Identifiers: Land application, Application rates

Five years of experiments were made to determine what happens under Pennsylvania soil and crop conditions when concentrated operations use the land for manure disposal. Dairy manure slurry was injected under orchard grass sod at rates of 120-600 tons per acre yearly for three years. The lowest rate supplied 700 lbs of nitrogen per acre per year. Two years after the applications were discontinued, Penn State researchers still found nitrate nitrogen in the soil water in excess of 10 milligrams per liter, the potable water standard. This was found at 4 feet, where the lowest rate had been applied. Fifty to eighty tons of slurry per acre, supplying 300-500 lbs of nitrogen per acre, were injected in November, 1973, and in April, 1974, to compare fall and spring applications of more moderate applications. Nitrate nitrogen from the fall application had moved down four feet in soil water by June of 1974 but remained near the potable standard of 10 milligrams per liter after July. The nitrate nitrogen from the spring-applied manure never exceeded 10 milligrams per liter during the growing season. (Merryman-East Central)

DPW SHOWS WIDE VARIATION IN COMPOSITION,

Poultry Digest, Vol. 34, No. 405, p. 437-438, November, 1975. 2 tab.

Descriptors: California, Regulation, Microorganisms, Heavy metals.
Identifiers: Dried poultry wastes, Refeeding, Drugs.

While the state of California has passed regulations permitting the refeeding of dried poultry wastes (DPW), there may still be a basis of concern for allowing such refeeding. Bruce Boyer of the California Department of Food and Agriculture has revealed that there are two categories of control that may not meet tolerances—microbial count and heavy metals. Boyer has stated that when manure is properly pasteurized, there do not appear to be any pathogenic organisms or parasites, but there is a great variation in the microbiological plate count, ranging from 600 to 8,500,000 organisms per gram. The maximum allowed is 20,000. The great variation in metals is also a cause for concern. Against a maximum allowance of 0.1 ppm, selenium has ranged from .62 to 2.6 ppm. The levels of zinc, iron and mercury found in dried poultry wastes are now coming under scrutiny. (Cocon-East Central)

COSTS OF MANURE DISPOSAL ON DAIRY FARMS IN TENNESSEE,

Agricultural Experiment Station, Tennessee University, Knoxville
H. A. Henderson and L. L. Bauer
Bulletin 514, Agricultural Experiment Station, Tennessee University, May, 1973, 18 p. 11 tab, 16 ref.

Descriptors: Costs, Waste disposal, Dairy industry, Tennessee, Lagoons, Irrigation
Identifiers: Manure, Liquid system

The objective of this study was to estimate the initial investment requirements, annual variable or operating costs, and labor requirements of the 4 systems of manure disposal most often used on Tennessee dairy farms — lagoon, liquid, conventional, and irrigation systems. Throughout the analysis, manure was considered as only a nuisance with no value as a fertilizer. The initial investment requirements per cow were found to be $21.86 for the conventional system, $60.50 for the liquid with 15 days storage, $77.15 for the irrigation system, $86.00 for the liquid with 30 days storage, $97.59 for the lagoon, and $111.50, $137.00, $162.50, and $188.00 for the liquid systems with 45, 60, 75, and 90 days storage. The annual costs per cow were estimated as $9.54 for the conventional, $14.11 and $16.15 for the liquid systems with 15 or 30 days storage, $17.82 for the lagoon, $18.19 for the liquid with 45 days storage, $18.42 for the irrigation system, and $20.33, $22.27, and $24.31 for the liquid systems with 60, 75, and 90 days-storage. If it is desired that the manure be treated as having some fertilizer value, the cost figures can be reduced by $14.25 per cow per year for the conventional, irrigation, and liquid systems. However, the costs for these systems will also be increased due to the necessity of spreading manure over a wider area. Labor requirements for the lagoon system were lowest since no labor was required beyond scraping. Labor requirements for the other systems were essentially the same. Selection of a system to use depends on the particular situation, but should take into account the relative availability of resources, particularly capital and labor. (Cameron-East Central)

RUNOFF CHARACTERISTICS FROM MANURED FIELDS,

Department of Agricultural Engineering, Cornell University, Ithaca, New York 14853
R. E. Muck, A. G. Hashimoto, D. C. Ludington, and R. D. Black
Presented at the 1975 Winter Meeting, American Society of Agricultural Engineers, Chicago, Illinois, December 15-18, 1975, Paper No. 75-2560, 24 p. 8 fig, 4 tab, 15 ref.

Descriptors: Agricultural runoff, Chemical properties, Ammonia, Nitrates, Flow rates, Phosphates.
Identifiers: Field spreading, Poultry manure, Nitrogen.

The effect of flow rate on the concentrations of ammonia, organic nitrogen, nitrate and soluble phosphate found in the runoff from land to which partially dried poultry manure had been surface applied was investigated. The five experimental plots studied were Langford channery silt loam soil, having a fragipan at a depth of 0.5 to 1 m. Chicken manure taken from a high rise house, egg-laying operation was applied to four plots, while the fifth plot was given no manure or fertilizer. Surface runoff was collected in a plastic lined channel located above a tile drain. Water from the surface channel and tile drain entered a gauge house where flow rates were measured. For each major event, the concentration of a particular parameter from a sample was plotted versus the corresponding flow rate. None of the parameter concentrations showed any correlation with flow rate. (Cameron-East Central)

DRYING CHARACTERISTICS OF BROILER AND CAGED LAYER WASTE ON A HEATED CONCRETE SLAB,

Environmental Engineer, Environmental Protection Division, Georgia Department of Natural Resources, Atlanta
H. C. Gillespie and B. D. McLendon
Presented at the 1975 Winter Meeting, American Society of Agricultural Engineers, Chicago, Illinois, December 15-18, 1975, Paper No. 75-4564, 22 p. 7 fig, 3 tab, 6 ref.

Descriptors: Air temperature, Moisture content, Georgia
Identifiers: Drying characteristics, Broiler waste, Floor temperature, Relative humidity, Poultry waste,

An examination was made of the drying characteristics of broiler waste under controlled environmental conditions existing in an experimental broiler house. Research was conducted to: (1) determine the average vapor diffusion coefficient of poultry waste, (2) determine the effect that the floor temperature, air temperature and air humidity has upon the drying rate of poultry waste material on a heated concrete floor, (3) present an equation to predict the moisture content of poultry waste at a given time during the drying process, and (4) present guidelines for drying poultry waste material in an environmentally controlled poultry house. Experimental procedures are described. It was concluded that (1) the diffusion coefficient for the broiler waste is dependent upon its temperature, (2) the drying process for broiler waste cannot be adequately described by the equation $Y2 = A + B \text{ Log } X$ (Y-Moisture content; X-Time; A,B-Constants), (3) the equation $MC = AT^{b}$ (MC-Moisture content; A,B-Constants, T-Time) adequately describes the drying process, with the appropriate coefficients, (4) equilibrium moisture is an important factor in the drying of broiler waste, and (5) stirring of the broiler waste material can significantly decrease the time required for drying of the material to a satisfactory moisture content. (Cameron-East Central)

PHYSICAL AND CHEMICAL PROPERTIES OF OUTDOOR BEEF CATTLE FEEDLOT RUNOFF,

Agricultural Engineer, U. S. Department of Agriculture, Nebraska University, Lincoln
C. B. Gilbertson, J. R. Ellis, J. A. Nienaber, T. M. McCalla, and T. J. Klopfenstein
Research Bulletin 271, Agricultural Experiment Station, University of Nebraska, Lincoln, August, 1975, 16 p. 2 fig, 11 tab, 16 ref.

Descriptors: Physical properties, Chemical properties, Feedlots, Agricultural runoff, Nebraska, Design criteria.

In August, 1968-December, 1972, systems were constructed at the University of Nebraska Field Laboratory to study feedlot runoff and its control. Continuous flow systems, a batch system, and pairs of feedlots with a buffer strip between each pair were established. Automatic samplers were installed at all locations to obtain composite samples of runoff from each feedlot and of effluent discharged from each debris basin. Physical and chemical analyses were performed. Total, fixed, and volatile solids transported in rainfall runoff averaged 1.52, 0.84, and 0.68 (percent w.b.) respectively. Solids transported in rainfall runoff were 28 percent filtrable solids. The volatile solids portion decreased with a decrease in particle size while the particle density increased. The unit weight of runoff was 63.02 lb per cu ft. Settleable solids transported in runoff and discharged from the debris basin to the holding pond averaged 217 and 63 cu ft per acre-inch (60, 760, and 17,640 ppm) respectively. Bulk density of the settleable solids in runoff and discharged from the debris basin to the holding pond averaged 10.72 and 8.03 lb per cu ft respectively. Seventy-one percent (by weight) of the settleable solids settled within the first 15 minutes under static conditions. Runoff COD ranged from 14,100 to 77,100 mg/l in snowmelt runoff and 1300 to 8200 mg/l for rainfall runoff. Total N and P concentration in rainfall runoff averaged 916 and 361 ppm, respectively. Average values were 2105 and 292 ppm for snowmelt runoff. Solids transport and settling characteristics data may be valuable in calculating detention times and storage capacities for solids settling facility design. Results can also be used to calculate solids accumulations in holding ponds to estimate maintenance requirements. Feedlot runoff should be restricted from freely flowing into streams. (Merryman-East Central)

EPA PROPOSES NEW FEEDLOT REGULATIONS,

Wallaces Farmer, Vol. 100, No. 23, p. 9, December, 1975.

Descriptors: Regulation, Legal aspects, Feedlots, Animal wastes, Water pollution.
Identifiers: Environmental Protection Agency.

EPA proposals for new regulations for feedlot permits are advanced for scrutiny. Under the proposals, a feedlot operator will need a waste water discharge permit if: (1) Measurable wastes are discharged directly into any navigable waters that cross the feedlot. (2) Measurable wastes are discharged into navigable waters through a manmade drainage structure. (3) His operation includes more than: 1000 slaughter and feeder cattle, 700 mature dairy cattle, milking or dry, 4500 slaughter hogs, 350,000 feeder pigs, 12,000 sheep or lambs, 55,000 turkeys, 180,000 laying hens, 290,000 broiler chickens. (4) The operation is designated as a significant pollution source by EPA or state water pollution control agencies. If a feeding operation includes a waste control system that keeps wastes from discharging into navigable waters, such as a pit or lagoon, a permit probably won't be needed. (Merryman-East Central)

2865 - B2, C2
FERTILITY CONTENT OF FLUID MANURE FROM MAINE DAIRY FARMS,

Department of Plant and Soil Sciences, Maine University, Orono
J. R. McKenna, C. S. Brown, and P. N. Carpenter
Bulletin 703, Life Sciences and Agricultural Experiment Station, University of Maine, January 1973, 16 p. 1 fig, 10 tab, 20 ref.

Descriptors: Dairy industry, Maine, Fertility, Chemical properties, Nutrients.
Identifiers: Liquid dairy manure.

Studies were conducted to determine the fertility content of fluid manure from tanks in continuous use on three dairy farms. Samples were collected for chemical analyses at intervals over a period of one year (1968-1969). Macronutrient (N, P, K) data were obtained for a total of 33 samplings, and micronutrient data from 8 of these. The following conclusions were made: (1) Nitrogen content on a dry matter basis ranged from 1.42 to 2.91 percent, with an overall mean of 2.06. (2) Phosphorus content of manure dry matter ranged from 0.29 to 1.02 percent, with a mean of 0.52. (3) Potassium content ranged from 1.36 to 3.67 percent, with a mean of 2.50. (4) Mean values for secondary nutrients in manure dry matter were 0.64 percent calcium and 0.31 percent magnesium. (5) Mean values for five micronutrients on a dry matter basis were: manganese 144 ppm, zinc 100 ppm, copper 43 ppm, boron 24 ppm, and molybdenum 4 ppm. (6) The dry matter percentage of fluid manure fluctuated widely, ranging from 6.2 to 12.9 percent, with a mean of 9.5. (7) Nutrient content on a volume basis proved especially variable, considering the extremes in dry matter percentage and the nutrient level of dry matter. Nitrogen (N) may range from 7 to 28 lbs. per 1,000 gallons, phosphorus (P) from 1 to 10 lbs., and potassium (K) from 7 to 36. Mean values were 16 lbs. N, 4 lbs. P. and 19 lbs. K (McKenna-Maine University)

PREVENTING WATER POLLUTION FROM TURKEY OPERATIONS,

University of California Area Farm Advisor-Turkeys, Parlier, California
J. P. Schroeder
Poultry Digest, Vol. 34, No. 400, p. 240-241, June, 1975. 3 fig.

Descriptors: Water pollution, Poultry, Design criteria, Construction, California, Regulation.
Identifiers: Turkeys.

The California Regional Water Quality Control Board has prepared a survey of the turkey industry in the state to determine its status in relation to state and federal water quality regulations. Questionnaires are going to the turkey growing firms, the contractors, and they are responsible for getting the forms filled out for each of their growers. Sample questions are cited. The California regulations require turkey growers and poultry men to keep water runoff or excess water from their turkey and poultry operations on their farms or to dispose of it in such a manner as not to contaminate the subsurface water or the surface water of their neighbors and create a hazard to public health. For a number of years, turkey growers in central California have been building new facilities or remodeling old ones to conform to the requirements to prevent pollution of public waters. Growers have replaced older narrow shelters of the shed roof type with gabled-roof buildings, which have more height and width. Most of the construction has steel framing. (Cameron-East Central)

AN ANALYSIS OF DAIRY WASTE MANAGEMENT ALTERNATIVES FOR SOUTHERN CALIFORNIA DAIRYMEN,

Farm Advisor, Los Angeles and Orange Counties, California
F. F. Smith, S. E. Bishop, W. W. Wood, Jr., J. C. Oliver, W. C. Fairbank, and C. L. Senn
Agricultural Extension Service Publication, University of California at Riverside, November, 1973, 14 p. 5 fig, 2 tab.

Descriptors: Dairy industry, Costs, Animal wastes, Water pollution, Density
Identifiers: Waste management, Southern California, Porter-Cologne Water Quality Act

This publication analyzes the impact of the Porter-Cologne Water Quality Act, and suggests the conditions under which the Southern California dairy industry can remain and be competitive with other dairy regions capable of supplying the market. Regulations designed to prevent pollution of surface and underground waters will require new management decisions for most Southern California dairymen. The requirements of compliance are: (1) contain and dispose of all polluted water on land owned or controlled by dairymen, and (2) limit the application of dairy wastes to each acre ot cropland to that produced by 1.5 to 5 cows. Alternatives to each of these requirements are also listed. Eight factors which bear on the selection of these alternatives are (1) land values, (2) taxes on land, (3) cow density (or manure application) limitations imposed by water quality control agencies, (4) cow density limitation imposed by local governmental planning authorities, (5) production responses attributable to geographical region, (6) production responses attributable to the side effects of waste management facilities (heat, cold, mud, rain, injury, insects, disease), (7) operating costs attributable to various waste management systems, (8) net revenue realized from cropland used for waste disposal. A method of assessing the effects of these many variables is presented. (Cameron-East Central)

MANURE IS NOT A DIRTY WORD,

Calf News, Vol. 13, No. 10, p. 30-31, 46, October, 1975. 5 fig.

Descriptors: Recycling, Cattle, Feedlots, Byproducts, Colorado, California.
Identifiers: Refeeding, Soil conditioner, Fuel, France, Mexico.

In Sterling, Colorado, Ceres Ecology Corporation, is recycling cattle manure by breaking it down into four by-products. Much of this work is accomplished by use of the Gaynor separator. The separator completely separates a 70 percent manure slurry into solid and liquid fractions. This eliminates expensive dehydration of manure. The first product recovered in this recycling process is Cereco 1, a silage material of mostly fiber and grain particles. Cereco 1 is fermented and fed daily to steers in 2-pound portions. The second by-product, Cereco 2, is a protein supplement pelleted in ¼ inch diameter pellets. Minerals, vitamins, and antibiotics are added to complete the supplement. Cereco 2 is fed to chickens, trout, and cattle. Cereco 3, the third by-product, is a soil conditioner which may be used as a replacement for peat-moss. Cereco 4, the final product, is a fuel. It is rated at about 7000 BTU's per pound, about the same as low-grade coal or wood. It is low in sulfur and leaves very little ash. Ceres will begin a chicken-manure recycling plant very soon. Ceres also has a feedlot and recycling plant in Toulouse, France, and Ceres is building a recycling plant in Mexico. (Cannon-East Central)

QUALITY VARIATION OF FEEDLOT RUNOFF IN STORAGE,

U.S. Department of Agriculture, Agricultural Research Service, Lincoln, Nebraska
C. L. Linderman and J. R. Ellis
Presented at the 1975 Winter Meeting, American Society of Agricultural Engineers, Chicago, Illinois, December 15-18, 1975, Paper No. 75-2563, 16 p. 9 fig, 2 tab, 10 ref.

Descriptors: Feedlots, Agricultural runoff, Waste storage, Water quality, Nutrients, Chemical properties.
Identifiers: Holding ponds, Land disposal.

Studies of the Agricultural Research Service, in cooperation with the Nebraska Agricultural Experiment Station, Lincoln, were performed to determine the effluent changes of runoff stored in holding ponds. Feedlot runoff effluent stored in holding ponds may vary in composition due to solids settling, microbial activity, evaporation, and dilution by direct rainfall. These factors had the greatest effect on runoff which was stored with no additions of new runoff. Solids, nitrogen, phosphorus, and salts varied twofold to threefold. When no new runoff was added, NH -N varied sevenfold and electrical conductivity varied ninefold. If it is desired to efficiently utilize the nutrients in feedlot runoff in land disposal, chemical analyses should be performed periodically. This should foster better utilization of nutrients and should arm the feedlot operator in controlling soil salinity. (Merryman-East Central)

NUTRIENT AVAILABILITY FROM SWINE WASTES COMPARED,

J. D. Kendall, (ed)
Feedstuffs, Vol. 47, No. 45, p. 12-14, November 3, 1975.

Descriptors: Nutrients, Diets, Absorption, Retention, Proteins, Antibiotics, Energy.
Identifiers: Dried swine feces, Oxidation ditch liquor.

At Michigan State University, tests were conducted on absorption and retention of critical elements by dried swine feces and oxidation ditch liquor (ODL). Dietary protein and energy values of the diets were also measured. Pigs consuming either form of waste had increased fecal output. Nutrient absorption and retention from dried swine feces were less than that from fortified corn-soybean meal rations. Digestible protein and energy values of the dried swine feces were low, which limited their use in pig rations. ODL did not influence apparent absorption and retention of nutrients from the ration as much as dried swine feces did. Nutrient availability in the ODL diet, with the exception of calcium, phosphorus, and zinc, appeared to be adequate for finishing pigs. Availability of nutrients from ODL seemed to be better than that from dried swine feces, but less than that of most nutrients in fortified corn-soybean meal finishing rations. No pigs consuming recycled wastewater showed signs of respiratory or gastroenteric problems, however, there was evidence of greater infestation with p. sites. One trial tested the influence of dietary antibiotics (Chlortetracycline, sulfamethazine, and penicillin) on growing or finishing pigs receiving only fresh or recycled waste as drinking water. The drugs did not stimulate food intake, but did improve efficiency of gain. Overall, when using only recycled waste as drinking water, feed protein levels could not be reduced. Vitamin levels should not be reduced, but mineral levels could be. Feeding of antibiotics resulted in growth stimulation similar to the stimulation of pigs receiving fresh water. (Cannon-East Central)

SAMPLERS FOR MONITORING RUNOFF WATERS,

Department of Agricultural Engineering, Kansas State University, Manhattan
H. L. Manges and C.C. Nixon

Presented at the 1975 Winter Meeting, American Society of Agricultural Engineers, Chicago, Illinois, December 15-18, 1975, Paper No. 75-2562, 10 p. 4 fig, 9 ref.

Descriptors: Agricultural runoff, Sampling, Equipment, Design, Performance

A proportional sampler using short tubes to divide runoff flow was designed, built and tested at Kansas State University. In laboratory tests, sampling ratio became constant after decreasing with increasing flow rates for unsubmerged flow and was constant for submerged flow. Sampling ratio was quite variable during field testing due to debris clogging the reservoir below the short tubes. A sampler using orifices surrounded by short tubes in place of the short tubes alone for dividing flow had a slightly better sampling ratio for unsubmerged flow and a constant sampling ratio for submerged flow. Additional research and development is needed to perfect the design and construction of the proportional sampler. However, it has the potential for wide use in runoff monitoring when perfected. RESPONSE OF ORCHARDGRASS TO BROILER LITTER AND COMMERCIAL FERTILIZER,

Agronomy Department, Agricultural Experiment Station, Division of Agriculture, University of Arkansas, Fayetteville
L. H. Hileman
Report Series 207, Agricultural Experiment Station, University of Arkansas, Fayetteville, April 1973, 18 p. 4 fig, 9 tab. 13 ref.

Descriptors: Orchardgrass, Fertilizers, Nutrients, Arkansas, Application rates, pH.
Identifiers: Broiler litter, Forage response.

The objective of this study was to determine the effectiveness of broiler litter relative to commercial fertilizer as measured by the yield and chemical composition of orchardgrass forage, and the effect on the chemical properties of the fertilized soil. Broiler litter at rates of 0, 2, 4, 6, and 8 tons per acre and equivalent amounts of N-P-K fertilizers were applied annually to the experimental site located in Benton County in the Ozark Highlands of Northwest Arkansas. Soil tests made at the end of the three years of litter application showed a depression of soil pH and available calcium. Soil tests should be used to determine time and rate of lime applications needed to adjust soil pH and calcium levels. The 2- and 4-ton rates of broiler litter supplied adequate plant nutrients for high forage yields and increased the levels of soil phosphorus and potassium. (Cameron-East Central)

PATHOCIDE SYSTEM TREATS RECYCLED MANURE,

Calf News, Vol. 13, No. 11, p. 16, 42, November, 1975.

Descriptors: Chlorine, Potassium, Phosphorus, Fertilizers
Identifiers: Processed bovine waste, Pathocide unit, Pathocide chemical

Corral Industries of Phoenix, Arizona, has developed a Pathocide Unit which destroys pathogens and stabilizes processed bovine waste (PBW). This unit, fully automatic, meters food process grade chemicals into the PBW. The unit also jointly meters chlorine and pathocide chemicals into the solids. Chlorine provides initial fast pathogen kill and the pathocide chemical provides residual kill, thus stabilizing the solids so they can be stored without composting or heating. John Merten, of Merten Land and Cattle Co., Holtville, California, has recently installed one of these pathocide units. Merten feeds his cattle a high percentage of chopped hay and hay cubes. This high roughage increases PBW recovery by approximately 15 percent. The 3500 head of cattle at his lot produce 21 tons of PBW (solids) for refeeding with a moisture content of 70 percent. The projected value of the PBW is $114,975 annually, based on the value of PBW at $15 per ton. The liquid recovered from the PBW in the dewatering process is very valuable as a fertilizer. Merten stores the liquid in ponds and pumps it directly into his irrigation ditches. The estimated value of nitrogen and phosphorus is $146,000. In areas where the soil is low in potassium, the value of all three elements could rise to $250,000. The projections are based on actual production data from Merten and on estimates based on research findings by Corral and others. (Cannon-East Central)

UTILIZATION OF ANIMAL WASTE AS FERTILIZER,

Animal Sciences Department, Purdue University, West Lafayette, Indiana
A. L. Sutton, J. V. Mannering, D. H. Bache, J. F. Marten, and D. D. Jones
Publication ID-101, Cooperative Extension Service, Purdue University, West Lafayette, Indiana, 1975. 10 p. 3 fig, 6 tab.

Descriptors: Fertilizers, Crop response.
Identifiers: Land application, Application rates, Waste management.

The purpose of this publication is to provide the livestock producer with pertinent information concerning handling, storage, and use of animal waste as a fertilizer source. The following are discussed: (1) factors which affect the nutrient value of waste, (2) nutrient use by various types of crops, (3) how to determine waste application rates and the need for supplementary fertilizer, (4) how to obtain an animal waste analysis, (5) how to estimate the fertilizer potential of waste from a particular enterprise, and (6) suggestions for proper land application. MANAGEMENT PRACTICES TO PREVENT ANIMAL HEALTH PROBLEMS ON FESCUE PASTURES HEAVILY FERTILIZED WITH POULTRY LITTER,

Associate Professor of Medicine and Surgery, College of Veterinary Medicine, Georgia University, Athens
D. J. Williams, J. A. Stuedemann, and S. R. Wilkinson
Contribution from the Southern Branch, Soil and Water Conservation Research Division, Agricultural Research Service, U. S. Department of Agriculture, February, 1972, 14 p.

Descriptors: Land disposal, Poultry, Litters, Management.
Identifiers: Grass tetany, Fescue toxicity, Agalactia, Fat necrosis, Nitrate toxicity.

This report presents current recommended management practices for prevention of various problems associated with fertilization of fescue pastures with manure litter. The animal health problems discussed are essentially those associated with intensively managed pastures. The problems discussed are: grass tetany, fescue toxicity, agalactia (absence of milk), fat necrosis, and nitrate toxicity. Prevention techniques are outlined as follows: 1. Grass tetany—(a) Apply no more than 4 tons of poultry litter per acre per year. (b) Increase cow consumption of magnesium. (c) Correct soil deficiencies. (d) Avoid animal stress. 2. Fescue toxicity—(a) Apply no more than 4 tons of poultry litter per acre per year. (b) Change pastures. (c) Use other grasses or legumes. (d) Prevent accumulation of dead fescue. 3. Agalactia—(a) Remove cows from pasture. (b) Supplement grazing with grain and hay daily 4-6 weeks before calving date. 4. Fat necrosis—(a) Apply no more than 4 tons of poultry litter per acre per year. (b) Provide balanced source of minerals. (c) Use other grasses and or legumes. 5. Nitrate toxicity—(a) Use no more than 4 tons of poultry litter per acre per year. (b) Delay use of suspected forage. (c) Use vitamin and mineral supplements. (d) Avoid animal stress. ODORS FROM LIVESTOCK MANURES,

Department of Agricultural Engineering, New York State College of Agriculture and Life Sciences, Cornell University, Ithaca
A. T. Sobel
Information Bulletin 31, New York State College of Agriculture and Life Sciences, October, 1973, 4 p. 4 fig.

Descriptors: Odor, Air pollution, New York, Livestock.
Identifiers: Odor control.

Population expansion into non-urban areas has caused the farmer to concern himself with odor problems resulting from animal wastes. The two general categories of odor are: (1) source odors—odors at the point of origin and (2) ambient odors—odors distributed in the atmosphere. Animal waste odors arise from bacterially produced gases such as ammonia and hydrogen sulfide and from volatile organic compounds. Methods of controlling these odors include ventilation, combustion, absorption, adsorption, masking, and use of additives. Odor control by elimination of the source itself involves providing conditions in the manure unfavorable to the production of odorous compounds. Such control methods include aeration, moisture removal, and good housekeeping techniques. Each of the odor control methods is described in detail. (Cameron-East Central)

WASTE FEEDING FUTURE MAY DEPEND ON TYPE OF PROCESS,

J. E. Dendall, ed.
Feedstuffs, Vol. 47, No. 43, p. 14, October 20, 1975.

Descriptors: Cattle
Identifiers: Refeeding

According to Dr. L. M. Schake, Texas A&M University animal scientist, research has confirmed that cattle wastes may be refed with success. Fresh waste should be obtained for maximum nutrient availability. Furthermore, combination of fresh waste with other feedstuffs to accomplish reconstitution, controlled fermentation or chemical treatment generally enhances nutrient availability and provides an opportunity to safeguard public health. The following factors must be kept in mind when considering refeeding animal wastes: (1) Composition and contaminants are highly variable, (2) High moisture and-or low nutrient-containing wastes do not generally lend themselves to commercial milling and transportation systems, (3) The Food and Drug Administration does not today sanction waste refeeding, (4) Consumer acceptance of beef produced by waste refeeding may be counterproductive to industry goals, (5) Economical systems-handling and milling equipment for cattle waste must be available, and (6) No closed system of total waste refeeding has been developed allowing all waste produced and harvested to be refed to an equal number and type of cattle. (Merryman-East Central)

DESIGN CRITERIA FOR TURBINE AIR AERATION OF POULTRY WASTES,

Agricultural Research Service, U.S. Department of Agriculture, Department of Agricultural Engineering, Cornell University, Ithaca, New York 14853
A. G. Hashimoto and Y. R. Chen
Presented at the 1975 Winter Meeting, American Society of Agricultural Engineers, Chicago, Illinois, December 15-18, 1975, Paper No. 75-4565, 25 p. 6 fig, 3 tab, 21 ref.

Descriptors: Design, Equipment, Aeration, Poultry, Carbon, Nitrogen, Costs.
Identifiers: Turbine-air aeration system.

The most serious problem with currently available aeration systems is their high energy requirements.

Because the turbine-air aeration system (TAAS) has about twice the oxygen transfer efficiency of oxidation ditches, researchers decided to investigate the applicability of TAAS to commercial livestock operations. Design criteria for TAAS were determined for a 40,000 hen, egg-laying operation. It was found that aeration systems should be designed to provide sufficient oxygen to satisfy the carbonaceous and nitrogenous demand. Systems providing 125-150 percent were found desirable to minimize tank costs and nitrogen losses. Solids retention time of 5 days was an ideal compromise between management, treatment and economic constraints. Optimum mixed liquor total solids concentrations were found to range between 2-3 percent. Annual cost for operating a turbine-air system was about 2/3 that of a comparable oxidation ditch system. Research still needs to be done to find a means for eliminating high water requirements and foaming problems. (Cannon-East Central)

A NOTE ON THE APPARENT DIGESTIBILITY OF ENERGY AND PROTEIN IN DRIED POULTRY EXCRETA,

School of Agriculture
West Mains Road
Edinburgh, EH9 3JG
B. G. Lowman and D. W. Knight
Animal Production, Vol. 12, p. 525-528, 1970, 4 ref. 4 tab.

Descriptors: Energy, Proteins,Nutrition, Copper, Nitrogen
Indentifiers: Dried poultry excreta, Digestibility, Refeeding

The apparent digestibility of dry matter, organic matter, nitrogen, energy and copper in 5 diets containing 0-100 percent dried poultry excreta was determined in order to gauge the wastes nutritional value. Each diet was fed to 4 wether sheep in a trial of randomized block design. The dried poultry excreta supplied 20·21 percent apparently digestible crude protein and approximately 1·57 or 1·74 Mcal of metabolizable energy per kg dry matter. While the copper content was found to be almost double that of barley, it was concluded that (as far as copper levels was concerned) dried poultry excreta was safe for ruminants and a cheap source of protein. More work is needed to ascertain accurately the metabolizable energy of the material. (Merryman-East Central)

FEEDING TH 6040 TO CHICKENS: EFFECT ON LARVAL HOUSE FLIES IN MANURE AND DETERMINATION OF RESIDUES IN EGGS,

Chemical and Biophysical Control Lab., Agricultural Environmental Quality Institute, Agricultural Research Service, Beltsville, Maryland 20705
R. W. Miller, C. Corley, and K. R. Hill.
Journal of Economic Entomology, Vol. 68, No. 2, p. 181-182, April 15, 1975. 2 tab, 6 ref.

Descriptors: Feeds, Insecticides, Poultry
Identifiers: Fly control, Thompson-Hayward 6040, Residues, Harmful effects

Studies were conducted utilizing Thompson-Hayward (TH) 6040 to determine its effects on house fly larvae in manure and its retention in chicken tissues and eggs. Fourteen laying hens were fed commercial type rations for 18 weeks. TH 6040 was added to the ration at a level of 50 ppm for 3 weeks. Amounts of TH 6040 were halved each succeeding 3 weeks so that in the final 3 weeks the chickens received only 1.6 ppm. Composite manure samples were taken from treated chickens and from a control group on Monday, Wednesday and Friday of each week. Both samples were put into four 200-g cups and seeded with 25 laboratory house fly larvae. Also, during the third week of each period, eggs were collected from the treated chickens for residue analysis. Eggs were separated by shell color. Minimum concentrations of TH 6040 needed to completely kill houseflies fell between 12.5 and 6.2 ppm. At 12.5 and 6.2 ppm treatment levels, .30 and .23 ppm of TH 6040, respectively, were retained in the brown eggs and 1.0 and .55 ppm, respectively, were retained in white eggs. At each feeding level, concentrations in white eggs were about twice as high as those in brown eggs, probably due to differences in feed intake, egg production, or metabolism of the 2 breeds of chickens tested. The use of TH 6040 as a feed additive depends on finding formulas that will cause a greater portion of it to pass out of the chicken without being absorbed. (Cannon-East Central)

EFFECT OF INCUBATION AND CONTACT WITH SOIL ON MICROBIAL AND NITROGEN CHANGES IN POULTRY MANURE,

Department of Agronomy, Georgia University Athens 30602
J. Giddens and A. M. Rao
Journal of Environmental Quality, Vol. 4, No. 2, p. 275-278, 1975. 1 fig, 8 tab, 10 ref.

Descriptors: Incubation, Coliforms, Bacteria, Fungi, Nitrogen, Environmental effects.
Identifiers: Land application, Poultry litter, Ammonia volatilization.

Contamination of the environment from poultry manure is often related to the changes that occur in the material during handling. This study involves some of the microbial and chemical changes in poultry manure, especially nitrogen, that may result from methods of handling. The following laboratory treatments were used to determine microbial changes in manure: 40 g poultry litter; 30 g soil plus 10 g poultry litter; 40 g fresh poultry droppings; 30 g soil plus 10 g fresh poultry droppings; and 40 g soil alone. The materials were either mixed with or surface applied to soil. Moisture was added to approximate field capacity. The "mixed" treatments were incubated at 28°C for 3, 7, 14, 21, and 28 days. It was concluded from these experiments that: (1) Ammonia formed in poultry manure has a drastic effect on reducing the relative numbers of micro-organisms present, including total coliforms, (2) Less nitrates may be formed in soil by frequent manure applications than less frequent applications at the same total rate, (3) surface application of manure results in NH_3 volatilization and hence formation of less soil NO_3 than when incorporated, and (4) Rapid drying of poultry manure results in less volatilization of NH_3 than slow drying. (Cameron-East Central)

FARM ANIMAL MANURES: AN OVERVIEW OF THEIR ROLE IN THE AGRICULTURAL ENVIRONMENT,

Department of Soils and Plant Nutrition, California University, Davis
J. Azevedo and P. R. Stout
California Agricultural Experiment Station Extension Service Manual 44, University of California, Berkeley, August, 1974, 109 p. 27 fig, 29 tab, 401 ref.

Descriptors: Farm wastes, Agriculture, California, Chemical properties, Physical properties, Decomposition, Environmental effects, Fertilizers, Fuels, Waste disposal.

This publication presents an overview of the status of livestock manures, their interrelationship with society as well as agriculturists, the problems they create, and the possibilities they offer as sources of energy and of soil enrichment. Specific topics discussed are: (1) animal manures in California, (2) quantity of manure produced by domestic animals, (3) chemical and physical characteristics of manures, (4) decomposition of manures, (5) nuisance factors of manures, (6) effects of manure on water quality and water-body ecology, (7) animal manures as factors in disease transmission, (8) prejudices regarding use of animal manures, (9) fertilization with manures, (10) manure as a soil amendment, and (11) alternative uses of manures. DAIRY CATTLE MANURE–ITS EFFECT ON YIELD AND QUALITY OF COASTAL BERMUDAGRASS,

Soil Scientist, U. S. Department of Agriculture, Auburn, Alabama
Z. F. Lund, B. D. Doss, and F. E. Lowry
Journal of Environmental Quality, Vol. 4, No. 3, p. 358-362, July-September, 1975. 7 fig. 3 tab, 11 ref.

Descriptors: Dairy industry, Crop response, Coastal bermudagrass, Nitrogen, Solid wastes, Liquid wastes.
Identifiers: Land application, Yield.

Three years of experimental tests were designed to define the quantities of solid or liquid manure that may be applied to a sod without impairing yield or quality of forage produced. Coastal bermudagrass was used as a test crop because it utilizes large quantities of nitrogen, thus minimizing the possibility of groundwater contamination. The average N, P, and K content of the manure, based on 20 samples per year, was slightly under 2 percent N, ½ to 2/3 percent P, and slightly over 1 percent K on an oven-dry (65°C) basis. Liquid manure was more effective than solid manure at an equivalent rate for forage production the first year. Accumulations from continuing applications at the 45 metric tons ha^{-1} $year^{-1}$ rate produced excellent yields of high quality forage the second year on the loamy sand and the third year on the sandy loam. Rates of 45 metric tons ha^{-1} $year^{-1}$ can be used for 3 years without impairing forage quality. Three years' application of manure at rates of 90 and 135 metric tons ha^{-1} $year^{-1}$ was detrimental to the forage. It was felt that application of 135 metric tons ha^{-1} $year^{-1}$ over a period of years could produce Coastal bermudagrass forage with levels of nitrate exceeding tolerance levels for ruminant animals. HYDRAULIC CLEANING OF A NEW BEEF-FLOORING SYSTEM,

Agricultural Experiment Station, Iowa State University, Ames
G. B. Parker, R. J. Smith, and H. L. Self
Presented at the 1975 Winter Meeting, American Soc-

iety of Agricultural Engineers, Chicago, Illinois, December 15-18, 1975, Paper No. 75-4555, 13 p. 7 fig, 1 tab, 5 ref.

Descriptors: Confinement pens, Design, Costs, Performance, Iowa
Identifiers: Hydraulic cleaning

An innovative approach to hydraulically handling confinement beef-cattle wastes was developed at Iowa State University Allee Experimental Farm, Newell, Iowa. A system was constructed of precast, hollow-core flat slabs with slots in the top sides of the cores to allow flushing. The flush water passes through the flumes into a collection channel which empties into an anaerobic lagoon. Lagoon liquor flows through a plastic pipe into a wet well. Pumps in a nearby dry well pull from the wet well to recycle water back to the building. The cost of the flooring system, including transportation and foundation preparation, was less than $2.50 per square foot. The recycle system and flushing devices added another $2500. Winter operation of the system proved to be problem-free. At present, no definite conclusions can be drawn concerning differences in cattle performance among different flooring systems. Performance on all floors appears to be equal. (Merryman-East Central)

RECYCLED MANURE – PRACTICAL SILAGE,

Beef, Vol. 12, No. 1, p. 12-13, September, 1975. 2 fig, 1 tab.

Descriptors: Recycling, Feedlots, Cattle, Silage, Economics, Nutrients, Energy, Fertilizers, Iowa.
Identifiers: Refeeding.

At a recent cattle feeder meeting, nutritionist Wise Burroughs described the Iowa State Method for turning manure into silage. Cattle are kept on solid concrete floors where manure and urine collect. Twice a week the material is removed. To aid in picking up moisture, ground corn cobs or chopped stover is spread on the floor a few hours before removal by the tractor-mounted loader that scrapes up the material. The material is then combined with whole plant corn silage, cane molasses and ground corn and is mixed in a well scrubbed flail type manure spreader for unloading in a bunker silo. In the Iowa State experiment, the material was left in the silo 4 months and then used in feeding trials. Burroughs said that the excreta silage was "indistinguishable from whole corn silage, except that it had no whole grain in it." It had no offensive odor and the cattle ate it readily. The experiments were only at the 98-day point at the time of Burroughs' report. Key conclusions were: (1) Ensiled excreta has nutritional value and can supply the protein and minerals needed by cattle when used in corn-silage type ration, (2) At present prices, excreta silage gives no economic advantage. (3) The material is better than necessary for brood cows and appears to be safe at recycling rates of 50 percent or more, and (4) Chemically, it's about like medium quality hay. Bart Cardon, at another recent cattle feeder meeting, gave less enthusiastic endorsement of refeeding manure. Cardon felt that solids in feedlot waste were less valuable than barley straw. He felt that the liquid part of the wastes was more valuable but that separating the nutrients from the wastes was uneconomical and that disposing of the solids was still a pollution problem. Cardon also criticized recycling of wastes as fertilizers, oil, gas, or electricity for economic reasons. (Merryman-East Central)

ELUTRIATION OF MANURE AND ASH IN A FLUIDIZED BED,

Department of Chemical Engineering, Kansas State University, Manhattan
C. R. Engler, W. P. Walawender, and L. T. Fan
Report No. 62, Institute for Systems Design and Optimization, Kansas State University, Manhattan, Kansas, December, 1974, 54 p. 14 fig. 10 tab. 9 ref.

Descriptors: Elutriation, Manure, Ash, Fluidized bed.
Experiments were made with a fluidized bed simulation unit to observe bed behavior under operating conditions approximating those estimated for the manure pyrolysis process. Under selected conditions, the bed operated as a slugging bed; however, addition of Koch static mixers to the bed broke up the gas slug and reduced bed fluctuations. Elutriation rate data were obtained for sand, manure, and ash and were compared to existing elutriation correlations. Although agreement between the experimental values, and the correlations were poor, the correlations were found to be in error for the smaller particle sizes. An extrapolation procedure was developed which gave improved agreement for smaller particle sizes. (Cannon-East Central)

WETZEL V. A. DUDA AND SONS (ACTION BY RIPARIAN PROPERTY OWNERS TO ENJOIN WATER POLLUTION TO LAKE FROM FARMING OPERATIONS),

306 So. 2d 533-534 (4th D.C.A. Fla. 1975)

Descriptors: Trespass, Judicial decisions, Water pollution, Lakes, Farm wastes, Common law, Legal aspects, Riparian rights, Equity, Land tenure, Water law, Water pollution sources, Florida, Riparian land, Wastes, Farms, Chemical wastes, Agricultural chemicals, Chemicals
Identifiers: Injunctive relief, Intentional torts, Nuisance (Legal aspects), Hazardous substances (Pollution), Non-point sources (Pollution)

Plaintiffs, riparian property owners on a lake, brought an action against a nearby farming operation for an injunction to abate water pollution and for damages. Defendants were polluting the lake by discharging noxious chemical and other substances from a nearby farming operation. Plaintiffs alleged that their riparian rights were injured by the defendant's creation of a nuisance, that defendants breached their duty to conduct their farming operation in such a manner as not to injure plaintiffs, that the defendants were engaging in a continuing trespass, and that the actions of the defendants were willful and malicious. The trial court dismissed the action for failure to exhaust their administrative remedies under the Environmental Protection Act. The Fourth District Court of Appeal of Florida reversed and remanded holding that the action was predicated on the right to abate nuisance, continuing trespass, and continuing breach of duty; therefore, the property owners were not required to exhaust administrative remedies before seeking injunctive relief. NUTRIENT LOSSES IN SURFACE RUNOFF FROM WINTER SPREAD MANURE,

Department of Agricultural Engineering, Wisconsin University, Madison
J. C. Converse, G. D. Bubenzer, and W. H. Paulson
Presented at the 1975 Annual Meeting, American Society of Agricultural Engineers, University of California, Davis, 1975, Paper No. 75-2035, 11 p. 1 fig, 6 tab, 10 ref.

Descriptors: Agricultural runoff, Nutrients, Precipitation.
Identifiers: Nutrient losses, Land spreading.

Nutrient losses from 10 alfalfa fields were monitored for 3 years. These fields were 3.0 m by 13.2 m and had slopes ranging from 10 to 12 percent. Dairy cattle manure was applied to 2 of the fields in the fall, winter, and spring of each year. The remaining 4 fields had no nutrients added. Runoff was collected from the fields at the end of each runoff event and daily during snow melting periods. The average amount of rainfall for the three years was 105.4 cm, 107.8 cm, and 108.8 cm respectively. About 12 percent of this was snow. The average runoff was 13.6 cm in the control field, 7.3 cm in the fall field, 10.4 cm in the winter field, and 10.6 cm in the spring field. The reason for the greater runoff in the control field was that it had less ground cover and fewer earthworms than did the manured plots. There were no significant differences in nutrient losses in the test fields and in the control fields, although yearly variations were exhibited. (Cannon-East Central)

MANURE CAN COMPETE WITH COMMERCIAL FERTILIZER,

J. F. Blair
Feedlot Management, Vol. 17, No. 7, p. 20, July, 1975.

Descriptors: Fertilizers, Feedlots, Texas, Rates of application, Nitrogen, Salts.
Identifiers: Land application.

Texas High Plains feedlots are now selling their manure for use as fertilizer. Dr. B. A. Stewart examines the pros and cons of using such wastes on croplands. Factors to be considered before buying feedlot waste are: (1) price comparison between manure and fertilizer, (2) soil type, (3) kinds of crops, and (4) amount of irrigation water. Six tons of dry feedlot waste will make available about 120 pounds of nitrogen the first year, and this is about the amount needed on irrigated crops. The second year the available nitrogen drops to 45 percent, 8 percent, and 4 percent the following years. Because there is no economical way to apply manure to get the exact amount of nitrogen needed, Stewart recommends that farmers apply 10 tons every third year where available and supplement this with commercial fertilizer the following 2 years. This would prevent the dangers associated with applying too much manure—nitrate build-up, salt build-up, and stunting of crops. While heavier soils effectively utilize the nitrogen in manure, more porous soils utilize phosphorus as well. Stewart estimates that 5 steers will produce enough manure to cover an acre at the rate of 10 tons. (Cannon-East Central)

DETACHMENT OF SOIL AGGREGATES BY SIMULATED RAINFALL FROM HEAVILY MANURED SOILS IN EASTERN NEBRASKA,

Professor of Agronomy, Nebraska Agricultural Experiment Station, Lincoln
A. P. Mazurak, L. Chesnin, and A. E. Tiarks
Soil Science Society of America Proceedings, Vol. 39, No. 4, p. 732-736, July-August, 1975. 3 fig, 3 tab, 13 ref.

Descriptors: Soil aggregates, Rainfall, Environmental effects, Soils, Nebraska.
Identifiers: Land application.

A field experiment was established to measure (1) the detachment of soil particles and aggregates by simulated rainfall as affected by various amounts of manure applied annually, (2) the size distribution of aggregates and particles in the splash, and (3) penetrometer resistance of crust formed on the surface by the impact of waterdrops. Effects of incorporating manure into the soil by disk plowing to depths of 10, 20, and 30 cm on stability of soil mass was measured under simulated rainfall conditions. It was found that: (1) Aggregates from manured plots were separated more easily by the impact of simulated raindrops because of reduced cohesion in these aggregates as compared to those from nonmanured plots. (2) The aggregates from manured soils were less dense than those from nonmanured soils because of the low density of the manure. Therefore, less energy was required for detachment of the aggregates with manure from the soil surface as compared to aggregates without manure. (3) Soil crust strength was reduced by the additions of manure. The protective seal on the surface did not form readily and the amount of soil detachment by simulated raindrops remained large. DPW STILL HAS TO BE SOLD,
R. C. Hartman
Poultry Digest, Vol. 34, No. 401, p. 276, July, 1975.

Descriptors: Feeds, California
Identifiers: Dehydrated Poultry Waste, Marketing, Public reaction

Despite the fact that dehydrated poultry waste (DPW) is a low cost method of putting extra pounds on cattle, poultry men have found very little market for their product. California approved the use of DPW in cattle feeds in July, 1974, and since then four firms have been licensed to produce it. Two of the four firms have found a market for DPW, but livestock feeders are in no hurry to buy it. They are afraid of the public reaction to the waste. The feedlots that do use DPW feed only a 5 percent ratio, far less than hoped for. The big problems with DPW at present are high bacterial levels, high concentrations of lead, copper, selenium, and ash and low protein value. The manure must be dried within 24 hours after being produced to keep down bacteria. Spores that are resistant to drying temperatures carry over to the finished product. Even though DPW is a valuable ruminant feed, it will be difficult to overcome public reaction. (Cannon-East Central)

CHICKEN MANURE: WORTH ITS WEIGHT IN CORN,
V. Ehmke
Progressive Farmer, Vol. 90, No. 6, p. 19, June, 1975. 1 fig.

Descriptors: Feeds, Poultry, Economics.
Identifiers: Poultry litter, Silage.

Some cattlemen in North Georgia have found that finishing cattle on poultry litter silage (PLS) is the cheapest way to get their animals to market. Daniel Whitlock and his brother-in-law Dennis Nichols of Toccoa, Georgia, have found that they can cut their feeding costs to about 16 cents per pound of gain by feeding PLS with corn silage. When their cattle reach about 800 pounds, they gradually add hammered corn until the ration is 60 percent corn. At this ratio, the average cost of gain is about 33 cents per pound. Roy Holtzclaw, of Cumming, Georgia, finishes his cattle on corn silage and high-moisture corn but feeds dry poultry litter and PLS for low cost gains before the cattle go into the lot. During the last year, Holtzclaw has been ensiling the litter in a trench silo. Instead of mixing the litter and corn in one silo, he keeps one silo for litter only. Holtzclaw is convinced this is the best way to feed the litter and to make low cost gains on his cattle. (Cannon-East Central)

DAIRY MANURE DEGRADATION UNDER MESOPHILIC AND THERMOPHILIC TEMPERATURES,
Agricultural Engineering Department, College of Agricultural and Life Sciences, Wisconsin University, Madison
J. C. Converse, J. G. Zeikus, R. E. Graves, and G. W. Evans
Presented at the 1975 Winter Meeting, American Society of Agricultural Engineers, Chicago, Illinois, December 15-18, 1975, Paper No. 75-4540, 16 p. 1 fig, 7 tab, 15 ref.

Descriptors: Dairy industry, Waste treatment, Temperature, Degradation (decomposition), Chemical properties, Anaerobic digestion.
Identifiers: Loading rates, Detention times.

Anaerobic degradation studies for maximum methane production were conducted at 35 degrees C and 60 degrees C on 3 types of dairy cattle manure at different detention times. The 3 types of dairy manure and detention times were: feces - 15 days at 35 degrees and 60 degrees C; feces-urine-straw - 15 days at 35 degrees and 60 degrees C; and feces-urine mixture - 10.4 days at 35 degrees C and 6.2 days at 60 degrees C. The manure was diluted with equal parts water giving a volatile solids concentration of about 6.5 percent. Loading rates ranged from 4.18 to 10.28 kg VS/m³ of digester volume. Gas yield ranged from 1.53 to 1.68 m³ gas/m³ reactor volume for the mesophilic and from 1.04 to 2.34 m³ gas/m³ reactor volume for the thermophilic digester. Average percent CH_4 ranged from 53.1 to 57.2 percent for the mesophilic digester and from 49.2 to 54.1 percent for the thermophilic digester. Gas yield ranged from .801 to .924 m³/kg VS destroyed for the mesophilic digester and from .657 to .792 m³/kg VS destroyed for the thermophilic digester. The percent volatile solids reduction dropped from 41.8 percent at 15 day detention time for feces-urine-straw mixture to 29 percent at the 10.4 day detention time for feces-urine mixture for the mesophilic digester. For the thermophilic digester, percent VS reduction dropped from 40.8 percent at 15 day detention time for the feces to 28.9 percent for 6.2 day detention time for the feces-urine mixture. Over 95 percent of the total nitrogen was accounted for in the effluent. Average NH_3/TN ratio of manure was .30. Average NH_3/TN ratio of effluent was .42. Over 91 percent of the total phosphorus and potassium were recovered in the effluent. NH_3 in the off gas ranged from an average of .0075 to .014 m/l of gas. H_2S in the off gas ranged from an average of .79 to 2.55 mg/l of gas. Methogenic bacteria numbers averaged 10^8 and 10^{10} in the mesophilic and thermophilic digesters, respectively, during the evaluation of the feces-urine mixture. Net energy, based on percent of gross energy, ranged from 67 to 74 percent for the mesophilic digester and from a minus to 44 percent for the thermophilic digester. AN ECONOMIC APPRAISAL OF ALTERNATIVE DAIRY WASTE MANAGEMENT SYSTEMS DESIGNED FOR POLLUTION CONTROL,
Agricultural Economist, Farm Production Economics Division, Economic Research Service, U.S. Department of Agriculture, Michigan State University
J. B. Johnson, C. R. Hoglund, and B. Buxton
Journal of Dairy Science, Vol. 56, p. 1354-1366, October, 1973. 8 tab, 27 ref.

Descriptors: Dairy industry, Economics, Agricultural runoff, Feedlots, Confinement pens, Liquid wastes.
Identifiers: Waste management, Land spreading.

Enforcement of existing and proposed legal environmental controls will necessitate adjustments in manure handling practices on many dairy farms in the United States. The cost of these adjustments will depend on dairy herd size and type of production system currently in use. Stanchion or stanchion-switch systems generally would have an excercise lot and/or a feeding lot exposed to precipitation. Runoff can be controlled by diverting around lots uncontaminated waters from areas above the lots and directing lot runoff into a detention facility. Similar control facilities could be used for open-lot housing systems. Runoff from manure spreading operations can be reduced by applying manure to soils only twice a year. Each measure mentioned requires the addition of a storage facility. Open-lot systems which use a tractor scraper-loader-spreader system for daily manure spreading can add a storage facility or can convert to a tractor scraper-lagoon-aerator-irrigation system. Covered housing systems which currently use solid manure handling systems can usually add storage facilities to eliminate daily field spreading. Covered housing using liquid manure handling systems can add a mechanical scraper to the conventional tractor scraper-storage-loader-liquid-spreader. To eliminate field odor problems in liquid manure spreading, soil injector units can be added to liquid spreaders. Some of these adjustments will reduce costs, but most will increase costs and reduce net dairy income. (Cannon-East Central)

HYDRAULIC MANURE REMOVAL FROM DAIRY FACILITIES,
Extension Agricultural Engineer, Cooperative Extension Service, Washington State University, Pullman
R. E. Hermanson and M. H. Ehlers
Presented at the 1975 Winter Meeting, American Society of Agricultural Engineers, Chicago, Illinois, December 15-18, 1975, Paper No. 75-4554, 9 p. 1 tab, 6 ref.

Descriptors: Design, Dairy industry, Hydraulic systems, Economics, Performance.
Identifiers: Manure removal.

Design details of flushing systems for four dairies in Washington are described. Information gathered was quantity of water used, head of water in flush tanks, gate size, alley slope, alley width, alley length, curb height, volume of manure-water storage tank or lagoon, and frequency of flushing. The 3 dairies using flush tanks had an average flushing water use of 317 liters per cow per day. The performance was not any better for the high flush tanks than for the low flush tanks which doubled as a source of drinking water. Of the limited sizes studied, flushing gate size was unimportant to the performance of the flushing system. The 3 percent alley slope of the 3 systems using flushing tanks was steep enough to provide velocity to clean the alleys. The 1 percent alley slope of the pumped-flushing system with recirculation required more flushing water. The system used 3,028 liters per cow per day with 4 daily flushings. The recirculated, settled manure water was satisfactory as flushing water and had only a slight odor. The dairy waste fiber removed from the settling tank served as an acceptable source of free-stall bedding. Concrete storage tanks are more expensive than lagoons because of the large volume of liquid manure generated by a flush system. The great water requirement for flushing and the large storage requirement make the recirculation of flushing water an attractive alternative. (Cameron-East Central)

EFFECT OF SOIL-INCORPORATED DAIRY CATTLE MANURE ON RUNOFF WATER QUALITY AND SOIL PROPERTIES,
Soil Scientist, U.S. Department of Agriculture, Auburn, Alabama 36830
F. L. Long, Z. F. Lund, and R. E. Hermanson
Journal of Environmental Quality, Vol. 4, No. 2, p. 163-166, 1975. 3 fig. 6 tab, 14 ref.

Descriptors: Agricultural runoff, Nitrates, Biochemical oxygen demand.
Identifiers: Land application, Soil properties, Rye, Millet.

A study was made on .04 ha plots of Norfolk sandy loam to determine the effects of cattle manure application on the quality of runoff water and soil properties. Gahi-1 pearl millet and Abruzzi rye were grown separately on 2 plots each. Manure was applied to 2 plots at rates of 45 metric tons per ha on a dry rate basis for 3 years. The 2 check plots received 450 kg N, 160 kg P, and 180 kg K ha⁻¹ year⁻¹. The BOD of the runoff water from manured plots did not exceed that of the control plots. The nitrate levels of runoff water from manured plots were affected very little by either application and all values were less than 5 mg per liter. Nitrates increased slightly in the top 90 cm of the manured plots; organic nitrogen increased only to a depth of 15 cm. Nitrate accumulated in millet forage above the safe level for feeding cattle, but not in the rye forage. Soil pH was increased to a range of 5.7 to 6.6 to a depth of 60 cm by manure application. Organic matter decomposed fairly rapidly and at the end of 3 years only 38 percent of the applied carbon remained. These results indicate that at least 45 metric tons per ha of dairy cattle manure can be disposed of on a Norfolk sandy loam by incorporation into the surface 15 cm of soil for a period of at least 3 years without any appreciable effect on the quality of runoff water or soil. LIVESTOCK WASTE LAGOONS,

Agricultural Engineering Department, Purdue University, Ithaca, New York
D. D. Jones and A. L. Sutton
Department of Agricultural Engineering Mimeo, Purdue University, West Lafayette, Indiana, 1974, 12 p. 6 fig., 2 tab.

Descriptors: Design, Lagoons, Livestock, Costs.

This paper establishes guidelines for the proper design and management of livestock waste lagoons. A lagoon must be large enough to provide sufficient dilution water and detention time so that the bacteria can decompose the manure. Wastes from different species of livestock require different quantities of water. Lagoon depth is dependent upon the type of equipment available for excavation. Anaerobic and mechanically aerated lagoons should be as deep as possible while a second stage lagoon should be no deeper than 6-8 feet. Lagoons should be located adjacent to or near the source of wastes and as far away from the farm home as practical and where prevailing breezes carry odors away from the house. A diversion terrace should be uphill from the lagoon to prevent excess surface runoff from filling the lagoon. Six to eight-inch sewer pipe with driven masonary joints works well for lagoon inlets and outlets. Construction costs can be minimized by using a cut-and-fill technique and building a large portion of the lagoon above ground. Settling basins on the basis of 1 cubic foot of settling basin volume for each 12 square feet of lot area. The Soil Conservation Service and extension personnel can provide more specific information. Fourteen lagoon management guidelines are listed in this paper and also addresses where publications can be obtained concerning lagoon design and operation. (Cameron-East Central)

DRYING OF DUNG-WATER BY BIOGEN RELEASED HEAT. CONTRIBUTION TO THE NONPOLLUTING DISPOSAL OF WASTE FROM ANIMAL MASS BREEDING STATIONS,

A. V. Hirschheydt.
Wasser und Boden, Vol. 26, No. 8, p. 227-229, 1974, 2 fig., 5 tab, 2 ref.

Descriptors: Drying, Germany, Waste treatment, Waste disposal evaporation, Fertilizers.
Identifiers: Composting.

Manure from livestock raising establishments was digested together with sifting remains from trash compost after intense mixing. In the experiments, 70 to 85 percent of the original water contents was evaporated. The further composting not only made the liquid dung spreadable, but led to an extensive decomposition of useful materials latent in the trash compost. From extremely aqueous manure, a larger amount and good quality of dry fertilizer resulted. (Text in German) (Solid Waste Retrieval System)

EFFECT OF CATTLE FEEDYARD RUNOFF ON SOIL INFILTRATION RATES,

U. S. Department of Agriculture Water Quality Management Laboratory, Durant, Oklahoma
O. R. Lehman and R. N. Clark
Journal of Environmental Quality, Vol. 4, No. 4, p. 437-439, October-December, 1975. 5 fig., 6 ref.

Descriptors: Cattle, Feedlots, Agricultural runoff, Infiltration rates, Soils, Groundwater pollution.

A compact clay soil from a playa lake and a relatively porous blocky, buried soil, both representative of feedyard runoff holding basins in the Texas High Plains, were treated with clear water and synthesized feedyard runoff to test the effects of runoff on soil permeability. It was found that infiltration rates changed most notably with the buried soil, where the rate decreases from 5 cm hour for clear water, to less than 0.006 cm hour for the synthesized runoff. The addition of the synthesized feedyard runoff quickly reduced infiltration rates in both the laboratory cores and field basins. Rates were reduced to less than 0.006 cm hour in 14 to 20 days in all cores and basins receiving the runoff. Sealing was attributed to clogging at or near the surface because the initial infiltration rate was restored when the top 2 cm of soil was removed. For basins constructed in porous soil material, clay liners decreased the time required for sealing, but did not necessarily change the degree of sealing. One main benefit of a clay liner would be to decrease the total volume of water infiltrated. (Cameron-East Central)

EXPERIENCES WITH WATER RELEASE DEVICES FOR FLUSHING GUTTERS,

Extension Agricultural Engineer, Kansas State University, Manhattan
J. P. Murphy, M. D. Schrock, and J. K. Koelliker
Presented at the 1975 Winter Meeting, American Society of Agricultural Engineers, Chicago, Illinois, December 15-18, 1975, Paper No. 75-4553, 13 p., 10 fig., 5 ref.

Descriptors: Equipment, Liquid wastes, Waste storage, Siphons, Costs.
Identifiers: Flushing, Dump tanks, Water release, Swine.

The concept of flushing animal waste from confinement buildings is rapidly gaining acceptance, particularly in the swine industry. Two different water release devices were investigated for flushing gutter applications—an automatic tipping and righting dump tank and a self-priming 15 inch diameter siphon. Field testing of the siphons revealed five phases of operation during the discharge of the storage volume 475 gallons-Phase 1-Purging of air from under the bonnet which takes two seconds; Phase 2—establishment of full flow, which requires about eight seconds; Phase 3—maximum flow, which is sustained for about 8 seconds until the air-bleed hole is exposed; Phase 4—then begins and continues until air is sucked in under the bonnet and the siphoning action is broken—about 12 seconds, and Phase 5—requires about two minutes to bleed air into the bonnet to equalize the air pressure and water level inside and outside the bonnet. The total costs for materials for each siphon was about $80. Dump tanks have been used for years to release water to flushing gutters. There are three points on the tank that are of great importance in understanding how the tank dumps—the center of gravity of the empty tanks, the pivot point and the center of gravity of the water itself. Figures show the installation and operation of the two water releasing devices. (Cameron-East Central)

ENGINEERING AND ECONOMIC ASPECTS OF FARM DIGESTERS,

Department of Agricultural Engineering, Missouri-Columbia University, Columbia
D. M. Sievers, J. R. Fischer, N. F. Meador, C. D. Fulhage and M. D. Shanklin
Presented at the 1975 Winter Meeting, American Society of Agricultural Engineers, Chicago, Illinois, December 15-18, 1975, Paper No. 75-4541, 11 p., 4 fig., 3 tab, 5 ref.

Descriptors: Aerobic digestion, Anaerobic digestion, Economics, Design, Waste treatment, Anaerobic lagoon, Minnesota.
Identifiers: Swine, Oxidation ditch, Confinement buildings.

The University of Missouri-Columbia in the early spring of 1975 began construction of a new swine confinement research complex consisting of five buildings—laboratory, gestation, farrowing, nursery, and finishing buildings. Management structures that were installed included pits, gutter flushing, oxidation ditches, and anaerobic lagoons. Study objectives were (1) to build a farm-size anaerobic digester using construction techniques and materials available to practicing farmers, and (2) to gain some practical knowledge of the management problems of such a unit. The finishing building housed 320 hogs over a slotted floor. Manure was flushed beneath the slotted floor. The pump used to pump the settled solids to the digester was a German-Rupp Model 12 B2-B self-priming, trash handling centrifugal. A fixed digester volume of approximately 140 cu. m. (37,000 gal.) was chosen which provided variations in loading rates, some gas storage, and potential volume for treating manure from the other buildings on the swine farm. Potential digesters considered were (1) glass lined silo, (2) fiber glass tank, (3) poured concrete tank, and (4) concrete stave silo. The digester chosen for the UMC Swine Complex was a 6 m (19 feet 9 inches) diameter concrete stave silo with a hoppered concrete base and solid concrete roof. Construction and material costs to the present date are given for the UMC Digester. (Cameron-East Central)

PERFORMANCE OF BEEF CATTLE ON SLATED FLOORS,

Animal Science Department, Tennessee Agricultural Experiment Station, Tennessee University, Knoxville
J. B. McLaren and J. I. Sewell
Tennessee Farm and Home Science Progress Report No. 88, p. 2-4, October-December, 1973, 2 tab, 3 ref.

Descriptors: Performance, Cattle, Design.
Identifiers: Floors, Waste management.

Performance of beef cattle on three types of floors was compared in preliminary feeding trials. Floors compared were: solid-concrete slabs, concrete slats, and aluminum slats. Feed consumption, rateof gain and amount of feed required per 100 pounds of gain were similar for bulls fed on concrete slab and those fed on slatted floors, but feed efficiency was slightly lower for bulls fed on slatted floors. Bulls fed on slatted floors exhibited discomfort during mid-summer. This discomfort resulted in a tendency for bulls to lie down and get up more frequently than normal. Some swelling of the front knees was observed. These preliminary results indicate that cattle can be satisfactorily and efficiently finished for slaughter on slatted floors constructed with either aluminum or concrete slats. WATERWAY CLEANS FEEDLOT RUNOFF,

Beef, Vol. 11, No. 11, p.2, July, 1975. 1 fig.

Descriptors: Agricultural runoff, Feedlots, Nebraska
Identifiers: Runoff control, Field sink, Serpentine waterway

Holding ponds are not entirely satisfactory for handling feedlot runoff. Odor, weed growth, and threat to safety are problems that often accompany their use. Some states do not consider feedlot runoff a water pollution hazard if the runoff flows a relatively long distance overland before reaching a stream. Consequently, USDA's Agricultural Research Service is evaluating two direct disposal systems on farms in Nebraska — "field sink" and a serpentine waterway. The 160 x 325-foot field sink with a 0.1 percent slope was installed between a feedlot and a creek. A one-foot dike was built around it. Feedlot runoff collects in a broad-basin terrace and discharges to the field sink via a riser intake and underground pipe. The system functioned well with above normal precipitation in fall, 1973-June, 1974. Under conditions of severe drought, the sink produced 60 bushels of corn per acre, when much of the nearby crop was a failure. The serpentine or switchback waterway was established below a 3-acre feedlot near Gretna, Nebraska. The waterway zigzags with 8 sharp turns. In effect, the 2,600-foot waterway moves the feedlot back 2,200 feet from a stream that is about 400 feet from the edge of the feedlot. The waterway channel slopes to prevent ponding and is seeded in brome and alfalfa to retard flow. Runoff passes through debris basins before entering the channel. Only a major storm will cause an appreciable amount of effluent to enter the stream. (Merryman-East Central)

MANURE MANAGEMENT ENERGY CONSUMPTION IN SWINE CONFINEMENT SYSTEMS,

Extension Agricultural Engineer, Agricultural Engineering Department, Maryland University, College Park
H. L. Brodie
Energy, Agriculture and Waste Management, Proceedings of the 1975 Cornell Agricultural Waste Management Conference, Ann Arbor, Michigan, Ann Arbor Science Publishers, Inc., 1975, p. 237-243. 3 tab.

Descriptors: Energy, Confinement pens, Costs, Labor, Economics.
Identifiers: Swine, Oxidation ditch, Open gutter flush system, Land disposal.

A survey was conducted on 2 operating swine confinement systems (an oxidation ditch under a slotted floor and an open gutter flush with water recirculation through a lagoon) to determine the energy utilized for the movement of manure from the feeding floor to land disposal. It was found that when compared to an oxidation system, the flush system provided a considerable reduction in energy, dollars, and labor while effectively performing the primary function of manure removal and disposal. Both systems performed this function within existing environmental constraints equally well. (Cannon-East Central)

FROM BIODUNG TO BIOGAS--HISTORICAL REVIEW OF EUROPEAN EXPERIENCE,

Institut fur Pflanzenbau and Saatfutforschung, Forschungsanstalt fur Landwirtschaft, Braunschweig-Voelkenrode, West Germany
C. Tietjen
Energy, Agriculture and Waste Management, Proceedings of the 1975 Cornell Agricultural Waste Management Conference, Ann Arbor, Michigan, Ann Arbor Science Publishers, Inc., 1975, p. 247-259. 5 fig, 1 tab, 51 ref.

Descriptors: Recycling, Fertilizers, Gases, Methane, Fermentation, Anaerobic conditions, Economics.
Identifiers: Germany, Biogas plants.

Conversion of manure to gas is reviewed historically, with emphasis on German experimentation. After World War II, Germany had fertilizer and energy shortages. Experimenters were concerned that manure should serve both needs. The question arose as to how anaerobic treatment of manure affected its quality and quantity. A team consisting of 3 groups, constructed 3 different biogas plants. Plant 1, built according to Ducellier and Isman, had 3 cylindrical containers with a capacity of 7.5 m^3. Two were covered with a sheet iron lid after loading and the third was completed by a gas holder. Glass wool insulation and a water circulation heating system were installed. Plant 2, built according to Reinhold, had a fermentation chamber of 17 m^3. Heating was by steam injection and was found unsatisfactory due to water infiltration into the slag insulation. Plant 3, constructed according to Schmidt and Eggersgluss, but on a smaller scale, consisted of a mixing chamber of 4 m^3, a fermentation chamber of 14 m^3, a manure storage silo divided into 2 compartments of 8 m^3, and a gas container of about 12 m^3. Heating was done by steam injection. Later a fourth plant was built, according to Poetsch, by the Technical University of Hanover as a prototype. In field and pot experiments with different crops, fermentation residues and conventionally rotted stable manure were compared on a balance base in order to evaluate the treatment methods. Products of liquid manure practices gave higher yield, contained more plant-available nitrogen, and required lower labor costs than products of solid manure practice. Gas amounts from a cattle manure substrate with great amounts of straw were nearly twice the amounts of similar substrates with less straw. Fermentation at 55 degrees C yielded much gas with a high methane portion in the first period, contrary to fermentations at lower temperatures. While use of animal wastes upon cropland is Germany's optimum goal, methane from manure may become a valuable by-product due to the energy crisis. (Cannon-East Central)

ENERGY RECOVERY AND FEED PRODUCTION FROM POULTRY WASTES,

Assistant Professor, Agricultural Engineering Department, Maine University, Orono
A. E. Hassan, H. Moustafa Hassan, N. Smith
Energy, Agriculture and Waste Management, Proceedings of the 1975 Cornell Agricultural Waste Management Conference, Ann Arbor, Michigan, Ann Arbor Science Publishers, Inc., 1975, p. 289-305. 10 fig, 1 tab, 21 ref.

Descriptors: Costs, Energy, Methane, Poultry, Algae, Design, Nitrogen, Proteins, Effluent.
Identifiers: Feeds.

A study was conducted to determine optimum conditions for methane production at temperatures of 25.5± 3 degrees C to study effects of depth, aeration, and effluent concentrations on algal yield and to provide preliminary design for a full-scale poultry digestion unit. Fresh caged layer manure was mixed with sawdust at different rates and incubated in 16 one-liter boiling flash laboratory digesters. Water was also added. Inoculum from previously digested effluent was added to all digesters at a rate of 50 percent by volume. Quality and quantity of gases produced were recorded on a routine basis during the process. Green algae, Scenedesmus, were grown in the effluent. The effluent was clarified to allow maximum light penetration. Data showed best results when solid content was 4-7 percent. Above or below that range, methane production declined sharply. The presence or absence of sawdust had little or no effect on methane production. Optimum solids content for a minimum recharging interval is 7 percent. Practically all of the nitrogen from the manure remained in the effluent. The 1 percent treatment provided highest yields and the aerated treatments gave better results than the unaerated. A pond depth of 20 cm provided highest algal yield. Protein content of dried algae flakes varied from 42 to 45 percent. Ten kg of dry waste yielded one kg of algal protein. The 500,000 tons of poultry waste produced in Maine yearly could produce algae protein equivalent to 150,000 tons of soybeans. When algae was fed in barley rations as a replacement for meat and bone meal additives, swine grew and fattened normally. Design criteria for a digester unit are given in detail, along with approximate costs. (Cannon-East Central)

ANAEROBIC DIGESTION IN SWINE WASTES,

Agricultural Engineer, U. S. Department of Agriculture, Agricultural Research Service, North Central Region, Missouri University, Columbia
J. R. Fischer, D. M. Sievers, and C. D. Fulhage
Energy, Agriculture and Waste Management, Proceedings of the 1975 Cornell Agricultural Waste Management Conference, Ann Arbor, Michigan, Ann Arbor Science Publishers, Inc., 1975, p. 307-316. 7 fig, 2 tab, 6 ref.

Descriptors: Anaerobic digestion, Gases, Design, Antibiotics, Alkalinity.
Identifiers: Swine, Volatile solids, pH.

On January 10, 1974, a pilot plant digester utilizing swine waste as a feed source began operation and was monitored to : (1) evaluate the effect of loading rates on gas production, (2) determine the most stable chemical environment for gas production, and (3) determine the most easily managed, best suited system for measuring digester stability. The digester was a long, cylindrical container supported in a horizontal position. It was first loaded with 16 gallons of digester sewage sludge and 29 gallons of tap water. Influent was gradually increased until a loading rate of 0.04 lb VS/ft^3 (0.64 kg/m^3) was reached. Digester temperature was maintained at 95 degrees F. On February 22, gas production declined 50 percent and on March 1, ceased, due to the injection of 1 pig with tylosin and lyncomycin. These antibiotics destroyed digester bacteria. Conclusions that were derived from the study were: (1) Gas production rate is the best indicator of digester activity. (2) Stable digestion of swine waste can be obtained at loading rates ranging from 0.15 to 0.18 lb. VS/ft^3 (2.33 to 2.86 kg VS/m^3). (3) At the loading rate stated above, approximately 16 ft^3 (0.45m^3) of gas per lb VS destroyed is produced, the pH is 7.3, the ammonia is 1000 ppm (1000 mg/l) and the alkalinity is approximately 6000 ppm (6000 mg/l). (4) The manure of hogs given injections with antibiotics can disrupt digester performance. (Cannon-East Central)

ALTERNATIVE ANIMAL WASTE ANAEROBIC FERMENTATION DESIGNS AND THEIR COSTS,

Research Specialist and Associate Professor, Department of Agricultural Engineering, Cornell University, Ithaca, New York
G. R. Morris, W. J. Jewell, and G. L. Casler
Energy, Agriculture and Waste Management, Proceedings of the 1975 Cornell Agricultural Waste Management Conference, Ann Arbor, Michigan, Ann Arbor Science Publishers, Inc., 1975, p. 317-335. 6 fig, 5 tab, 22 ref.

Descriptors: Design, Costs, Economics, Fermentation, Anaerobic conditions, Methane, Recycling, Energy, Nitrogen, Phosphorus, Temperature.
Identifiers: Digesters, pH.

Studies were made with the following objectives: to review the status of anaerobic fermentation technology and its application to animal wastes, to apply this technology to develop system alternatives which are compatible with current farm management practices, and to assess the economic feasibility of incorporating the anaerobic fermentation systems into the farm both as an alternative energy source and a waste management practice. Five systems were identified as technically feasible alternatives for stabilization of animal wastes. They were: (1) completely mixed digester operated in the mesophilic range; (2) completely mixed digester operated in the thermophilic range; (3) batch load digesters; (4) partially mixed digester operated in the mesophilic range; and (5) plug flow digester. Design and costs are discussed. Study results showed that more data is needed to provide engineers with information necessary to design workable alternative systems. Efforts to modify municipal sewage treatment plants are necessary in order to provide economically feasible systems for animal production systems. Under present marked conditions, methane production as an alternative energy source for average sized dairies is not economically competitive with other fuels, but might be feasible with larger operations. As a pollution control device, anaerobic fermentation processes may be economically competitive with liquid manure handling and storage systems. (Cannon-East Central)

COLD WEATHER ENERGY RECOVERY FROM ANAEROBIC DIGESTION OF SWINE MANURE,

Research Engineer, Department of Agricultural Engineering, Manitoba University, Winnipeg, Manitoba, Canada
E. J. Kroeker, H. M. Lapp, D. D. Schulte, and A. B. Sparling
Energy, Agriculture and Waste Management, Proceedings of the 1975 Cornell Agricultural Waste Management Conference, Ann Arbor, Michigan, Ann Arbor Science Publishers, Inc., 1975, p. 337-352. 7 fig, 6 tab, 10 ref.

Descriptors: Anaerobic digestion, Energy, Gases, Ammonia.
Identifiers: Swine, Volatile solids, pH.

Pilot plant anaerobic digestion of swine manure was begun at the University of Manitoba in the late fall of 1974 to assess technical and economical feasibility of energy recovery from livestock manure. The plant consisted of four single-cell digesters which were serviced by a raw manure holding tank equipped with mixing and transfer pumps to facilitate delivery of raw manure at a relatively uniform consistency into the digesters. The digesters were initially seeded with anaerobic digester mixed liquor from a sewage treatment plant. Operations volume of each digester was 2300 liters. Mixed-liquor temperatures for the 4 digesters were maintained at about 35 degrees C. Raw manure influent temperature was 0 degrees C. Digesters A and B were operated at a 15-day solids retention time (SRT) and digesters C and D were operated at a 30-day SRT. Total gas production was higher for digesters A and B than for digesters C and D, but the fraction of volatile solids destroyed was higher for the lower loading rates and higher SRT. Preliminary results from the pilot-plant study indicated that net energy recovery did not occur; however, there were indications that the upper limit of biogas production was not reached. The following conclusions were drawn from the experiment: (1) Process stability was achieved despite adverse environmental conditions within the digesters including high pH (8.0) and high ammonia concentrations (3390-3450 mg/1); (2) Despite relatively high rates of methane gas production, only 50 percent of the energy expended was recovered through gas production at the loading rates used in these initial experiments; and (3) Rational conductive heat-transfer theory accurately predicted energy requirements for digester heating. ENERGY AND ECONOMIC ANALYSIS OF ANAEROBIC DIGESTERS,

College of Environmental Sciences, Wisconsin University, Green Bay
T. P. Abeles
Energy, Agriculture and Waste Management, Proceedings of the 1975 Cornell Agricultural Waste Management Conference, Ann Arbor, Michigan, Ann Arbor Science Publishers, Inc., 1975, p. 353-360. 12 ref.

Descriptors: Energy, Anaerobic digestion, Economics, Algae, Fish, Hydroponics, Hydrogen
Identifiers: Solar Energy, Biogas

In the summer of 1974, Wisconsin University built a small field model (3-4 cows) anaerobic digestion system to serve as a prototype for a large-scale system. Coincidental with Wisconsin University's construction, a local stable built a full scale system which would handle the output of approximately 100 thoroughbred horses. The close proximity of the 2 systems permitted Wisconsin University to develop a research program to determine: the optimum operating system for use on Midwest dairy farms, the social acceptability of anaerobic digesters as a farm management technique, the feasibility of the establishment of new types of agribusiness, and the impact of anaerobic digesters on utility companies. The 100-horse digester cost about $40,000. Because of several base costs, costs for larger capacity systems would only increase modestly until more digesters are added. By the end of the summer, the small digester was to be equipped with solar panels to test the feasibility of reducing the amount of biogas needed to maintain the digester. An idea was developed for using digester effluent for growing algae or fish. Wisconsin University is exploring the possibility of a leasing operation where the fish farmer would manage several aquaculture ponds utilizing digester effluent as a nutrient base. Farmers interviewed in Brown County, Wisconsin, seemed interested in anaerobic digestion and did not seem to mind the $40,000 price. The major concern of utility companies utilizing biogas or solar plants is that of load leveling of power. If a biogas or solar plant failed, the company must supply the energy from another source. Several routes for combatting this problem are being explored. There appears to be little doubt that biogas plants are economically and operationally feasible. But work still needs to be conducted on standardization of system design and components and on development of a viable service industry. (Cannon-East Central)

DRY ANAEROBIC DIGESTION,

Assistant Professor Agricultural Engineering, University of Hawaii, Honolulu
G. M. Wong-Chong
Energy, Agriculture and Waste Management, Proceedings of the 1975 Cornell Agricultural Waste Management Conference, Ann Arbor, Michigan, Ann Arbor Science Publishers, Inc., 1975, p. 361-371. 6 fig, 21 ref.

Descriptors: Anaerobic digestion, Poultry, Dairy industry, Sludge, Gases, Methane.

This investigation examined the anaerobic digestion of animal wastes (dairy and poultry) at relatively high solids concentrations (more than 20 percent) in both batch and batch fed reactors at ambient temperatures (70-85 degrees F). This was done in an attempt to circumvent such problems as postdigestion sludge dewatering and treatment of digester supernatant, thus enhancing the economics of the overall process. The following conclusions were made from the information gathered: (a) From fresh dairy manure 11.3 to 13.0 ft^3 of digester gas was generated per pound of volatile solids destroyed. Methane composition of the gas was 60-65 percent. (b) There is a limit to the amount of volatile solids in a waste which is convertible to gas. (c) Fresh manure has the greater gas potential than aged manure. (d) Ammonia inhibition to methanogenesis would be significant with highly nitrogenous wastes such as poultry manure. (e) Anaerobic digestion of wastes with high solids concentrations is feasible and offers economies in reduced reactor volume, digester sludge handling, and avoids treatment of digester supernatant. TECHNOLOGIES SUITABLE FOR RECOVERY OF ENERGY FROM LIVESTOCK MANURE,

Research Scientist, Waste Control and Process Technology Section, Batelle's Columbus Laboratories, Columbus, Ohio
C. N. Ifeadi, and J. B. Brown, Jr.
Energy, Agriculture, and Waste Management, Proceedings of the 1975 Cornell Agricultural Waste Management Conference, Ann Arbor, Michigan, Ann Arbor Science Publishers, Inc., 1975, p. 373-396. 9 fig. 6 tab, 24 ref.

Descriptors: Energy, Cattle, Technology, Fuels, Waste treatment, Anaerobic digestion, Hydrogenation, Methane.
Identifiers: Swine, Hydrogasification, Pyrolysis.

The quantity of manure produced from average U.S. dairy, beef, and hog production facilities is too small for an economic recovery of synthetic fuel from the manures. Therefore, efforts to recover fuel economically from animal wastes are being directed to large animal facilities. Fuel may be recovered from animal manure by either biological or thermochemical processes. Biological processes include methane production and biochemical processes for protein and alcohol production. Thermochemical processes include pyrolysis, hydrogenation, and hydrogasification. High moisture content in livestock manure is a prime disadvantage in the application of thermochemical processes. For fuel synthesis, only methane production and pyrolysis hold promise at above 10 tons per day plant capacity. Capital-intensive items in the biological system are the anaerobic digester and the storage tank; the operating cost-intensive items are labor and maintenance. Consequently, process-cost-reduction must focus on these items. Fuel selling prices and the quantity of manure to be processed are important factors in the economic feasibility of the process. Refinement in the engineering-cost analysis made for methane production is recommended. A thorough cost inventory for a pilot anaerobic digestion plant should be made. Although an energy conversion system may be too complex and time consuming for the average farmer, a package plant system for fuel recovery by a private investor may be economically built adjacent to large livestock-production facilities. METHANE-CARBON DIOXIDE MIXTURES IN AN INTERNAL COMBUSTION ENGINE,

Department of Agricultural Engineering, College of Agriculture and Life Sciences, Cornell University, Ithaca
S. Neyeloff, and W. W. Gunkel
Energy, Agriculture and Waste Management, Proceedings of the 1975 Cornell Agricultural Waste Management Conference, Ann Arbor, Michigan, Ann Arbor Science Publishers, Inc., 1975, p. 397-408. 6 fig, 13 ref.

Descriptors: Methane, Carbon dioxide, Anaerobic digestion
Indentifiers: Internal combustion engines, Specific power output

A project was conducted to study the characteristics of gas generated from anaerobic digestion as a fuel for internal combustion engines. A high speed CFR engine was used. Valve timing was set at about 900 rpm. Engine timing was about 30 degrees before top dead center and operating coolant temperature was about 195 degrees F for all tests. Data showed that the best results in terms of specific power output (SPO) were obtained at a compression ratio (CR) of 15:1, although at 15:1 and higher, audible knocking occurred. Below a CR of 10:1, SPO dropped rapidly. Methane ignites at fuel to air ratios ranging from 0.065 to 0.185 by volume. The highest SPO was obtained at a fuel to air ratio of 0.10. Output from engines per unit of methane greatly depends on the engine design and the degree of CO_2 dilution in the engine. The mixture will not combust if the amount of carbon dioxide is greater than three times the amount of methane. In a typical spark ignited engine, of the heating value of the fuel, only about 20 percent results in mechanical output. (Cannon-East Central)

LIMITATIONS OF ANIMAL WASTE REPLACEMENT FOR INORGANIC FERTILIZERS,

Department of Agronomy, Georgia University
D. A. Lauer

Energy, Agriculture and Waste Management, Proceedings of the 1975 Cornell Agricultural Waste Management Conference, Ann Arbor, Michigan, Ann Arbor Science Publishers, Inc., 1975, p. 409-432. 13 tab, 14 ref.

Descriptors: Fertilizers, Livestock, Nutrients, Grains, Nitrogen, Potassium, Phosphorus, Ammonia.
Identifiers: Manure, Land application.

Problems of large quantities of accumulated manure and increasing costs of manufacturing fertilizer have renewed interest in using manure as a fertilizer. In the United States, cattle produce 82 percent of the total manure produced. Two-thirds of the land surface in the United States is used for growing crops and grazing animals. Food and feed grains occupy over 50 percent of the cropland and receive over 50 percent of the United States' fertilizer. Closer integration of cattle production and production of these crops would increase probability of replacing fertilizer with manure. However, use of manure as fertilizer is not without problems. Fertilizer can be formulated to specific nutrients; whereas, manure nutrients must be used together (as they come). This could cause imbalances in nutrients not deficient. Nutrient contents of manure are extremely variable. Water and organic matter, the main components of manure that are nonnutritive, decrease nutrient concentrations and make manure handling characteristics less desirable. Manure produced in confinement could potentially replace about 42 percent of the nitrogen, 29 percent of the phosphorus, and 57 percent of the potassium consumed as fertilizer. Experiments show that, under favorable conditions, 70-100 percent of ammoniacal nitrogen in dairy manure spread volatilizes. Relative to human nutrition, ammonia volatilization from confinement manure amounts to 7.6 kg N/ person/year, which exceeds dietary protein consumption for both plants and animals combined. This nitrogen leakage from the nitrogen cycle may be the final determinant of substitutability of manure for fertilizer. (Cannon-East Central)

WASTE MANAGEMENT SYSTEMS IN RELATION TO LAND DISPOSAL/ UTILIZATION,

BacteriologyDivision, School of Agriculture, Aberdeen, Scotland
K. Robinson
Energy, Agriculture and Waste Management, Proceedings of the 1975 Cornell Agricultural Waste Management Conference, Ann Arbor, Michigan, Ann Arbor Science Publishers, Inc., 1975. p. 443-452. 1 fig, 5 tab, 8 ref.

Descriptors: Waste treatment, Lagoons, Anaerobic digestion, Effluent, Nitrogen, Phosphorus.
Identifiers: Land disposal, Swine, Scotland, Raw wastes, Oxidation ditch.

Studies were made at Aberdeen to compare different waste management-stabilization systems with a system of no stabilization process. Types of waste used were: (1) Swine waste collected and stored in slurry channels. (2) Anaerobic lagoon supernatant. (3) Mixed liquor produced by anaerobic stabilization of lagoon supernatant. (4) Mixed liquor produced by anaerobic stabilization of slurry (17 days). (5) Mixed liquor produced by anaerobic stabilization of slurry (68.5 days). (6) Mixed liquor produced by second-stage denitrification of mixed liquor from (4). (7) Anaerobic digester effluent. It was found that anaerobic stabilization reduced ammonia-nitrogen and increased oxidized nitrogen. Total nitrogen losses occurred in all processes except anaerobic digestion and were greater in second-stage denitrification. Potassium was unaffected by stabilization. Phosphorus was present mainly in suspended solids, which settle out in a lagoon causing a reduction in phosphorus. For the purposes of this study, it was assumed that all wastes were produced by stabilization systems associated with a 1000-head swine fattening unit, that 6000, 3000, and 3000 units of N, P_2O_5, and K_2O, respectively, were required for crops, and that waste could not be applied during a 6 month winter period. Except for raw waste and digester effluent, wastes were unable to supply crop requirements for nitrogen. Phosphate exceeded crop requirements except in the case of lagoon and lagoon oxidation ditches. Potash was also in excess, assuming that application rates were based on supplying sufficient nitrogen. Based on costs prevalent for Northeast Scotland, costs represented losses of from 2-5 pounds per pig place. Only raw waste recycling showed a profit. (Cannon-East Central)

PROTEIN AND ENERGY CONSERVATION OF POULTRY AND FRACTIONATED ANIMAL WASTE,

Department of Animal Sciences, Colorado State University, Fort Collins
G. M. Ward and D. Seckler
Energy, Agriculture and Waste Management, Proceedings of the 1975 Cornell Agricultural Waste Management Conference, Ann Arbor, Michigan, Ann Arbor Science Publishers, Inc., 1975, p. 467-474. 2 fig, 2 tab, 13 ref.

Descriptors: Feeds, Proteins, Energy, Poultry, Cattle, Sheep, Trout, Nitrogen.
Identifiers: Refeeding, Soil amendment, Cereco process, Ash.

Ruminant waste contains about 5 g of nitrogen or 30 g of endogenous protein for each kg of feed dry matter consumed. About 50 percent of this protein is microbial protein and 25 percent is tissue cells from the digestive tract. Although of high quality, this protein is mixed with ash and fiber, which are largely indigestible by nonruminants. The waste must be fractionated to increase protein concentrations. The Cereco process, developed by Ceres Ecology Co., separates manure into three fractions: one high in fiber for feeding to ruminant animals, a second high in protein (20-30 percent) for feeding to either ruminants or nonruminants and a third high in ash intended as a soil amendment. Fraction 1 has been evaluated as a feed for cattle and sheep. Fraction 2 has been evaluated as a protein supplement for cattle, sheep, broilers, layers and rainbow trout. Fraction 1 is equal in feed value to average corn silage; fraction 2 approaches the protein value of equivalent amounts of soybean meal. The ability to fractionate a high protein fraction makes possible a fully integrated cycle in which crude protein of poultry manure provides supplemental protein for cattle and the high quality microbial protein of cattle manure supports poultry. The replacement value of corn by fraction 1 and soybean by fraction 2, if all the waste from feedlot and dairy cattle in the United States were processed, is estimated to equal 14 million acres of cropland. (Cannon-East Central)

PROTEIN PRODUCTION RATES BY ALGAE USING SWINE MANURE AS A SUBSTRATE,

Oregon State University, Corvallis
L. Boersma, E. W. R. Barlow, J. R. Miner, H. K. Phinney, and J. E. Oldfield
Energy, Agricultural and Waste Management, Proceedings of the 1975 Cornell Agricultural Waste Management Conference, Ann Arbor, Michigan, Ann Arbor Science Publishers, Inc., 1975, p. 475-493. 2 fig, 15 tab, 27 ref.

Descriptors: Proteins, Algae, Feeds, Recycling, Phosphate, Nitrogen, Carbon dioxide.
Identifiers: Swine waste, Substrate, Clarification.

A waste management system is described in which manure is transported hydraulically from a livestock confinement building to a nutrient recovery unit maintained at elevated temperatures by means of cooling water from a power plant condenser. A solid-liquid separator forces the solid fraction into an anaerobic digester, while the liquid flows into basins for the culture of algae. The most encouraging aspect of the studies has been the stability of Chlorella vulgaris 211/8K cultures growing in fresh swine manure diluted to an ammonium nitrogen content of 250 mg/liter. When manure was clarified by filtration through activated carbon and by ferric chloride flocculation in hopes of improving algal growth, the opposite proved true. Light transmission improved, but algal growth slowed down. The superiority of the untreated swine manure was attributed to the higher organic matter content which provided carbon dioxide for algal potosynthesis. The average algal growth rate for a 12-hour photoperiod at 37 degrees C and a retention time of 3.3 days was about 22 $g/m^2/day$. Development of optimum management techniques requires additional experimentation to establish interactions between temperature, light intensity, retention time, and culture depth. Yields of 25 to 30 $g/m^2/day$ for a 12-hour photoperiod appear easily attainable. Neither nitrogen nor phosphorus content of wastes appeared to limit algal growth. Nitrate did not accumulate in the ponds due to volatilization and nitrogen recovery by the algae (20-30 percent recovery). Short term feeding trials with rats indicated that the algal material harvested by centrifugation was an excellent protein source. (Cannon-East Central)

THERMAL AND PHYSICAL PROPERTIES OF COMPOST,

D. R. Mears, M. E. Singley, G. Ali, and F. Rupp III
Energy, Agriculture and Waste Management, Proceedings of the 1975 Cornell Agricultural Waste Management Conference, Ann Arbor, Michigan, Ann Arbor Science Publishers, Inc., 1975, p. 515-527. 5 fig, 3 tab, 20 ref.

Descriptors: Thermal properties, Physical properties, Density, Compressibility, Pathogenic bacteria.
Identifiers: Composting, Swine wastes, Windrows.

In 1969, large-scale composting of organic waste was researched at Rutgers University. Swine wastes were deposited in windrows up to 2 m high and 3 m wide. The windrows were turned with varying frequencies by means of a commercial composting machine. Other materials were added to the windrows to determine which combinations would compost most rapidly. Addition of 70 percent straw or 25 percent municipal refuse by volume to swine waste was found to add sufficient carbon and bulking properties to reduce composting time to about 4 weeks. Several studies were conducted on specific aspects of the composting process, including: determination of thermal properties of composting materials and changes in these properties during composting, determination of particle size distribution of composting materials and changes that occurred during composting, determination of the compressibility of composted material, and determination of total volume reduction and changes in bulk density of composting materials. Composting material can be regarded as having low thermal conductivity and specific heat. To prevent thermal inhibition of the biological processes, it is necessary to aerate and/or frequently turn the pile. Although particle size is continuously reduced with decomposition, more work is needed to establish a reliable relationship between particle size and stage of decomposition. Compressibility of all samples of completed compost from windrows of swine waste and some additive were not significantly different from each other. However, the finished compost of windrow 8, which was swine waste with no additive, was significantly less compressible. Also, windrow 12, which was composed of swine waste and straw, but was still composting, was significantly more compressible than the others. Figures in the report illustrate volume reduction and changes in bulk density that occurred in the windrows studies. (Cannon-East Central)

BUILD-UP OF MINERAL CONTENT IN LAKE DARDANELLE AND THE EFFECT ON ZOOPLANKTON,

Department of Biological Science, Arkansas Polytechnic University, Russellville
T. N. Palko
Arkansas Water Resources Research Center, Fayet-

teville. Publication No. 24, 1974, 186 p. 57 fig, 48 tab, 38 ref.

Descriptors: Arkansas, Zooplankton, Eutrophication, Nutrients, Water pollution effect, Poultry, Effluents, Rotifers, Nitrates, Phosphates, Chlorides, Oxygen, Temperature, Carbon dioxide, Productivity, Streams, Hydrogen Ion Concentration, Water chemistry, Reservoirs, Waste disposal, Water spreading, Mineralogy.
Identifiers: Poultry effluents, Lake Dardanelle (Arkansas), Uric acid, Land spreading.

The effects of poultry effluents on water quality of Lake Dardanelle and its feeder streams in West Central Arkansas were studied during three sampling periods in 1970, 1971, and 1972. To determine these effects, the following factors were investigated: (1) Physico-chemical analysis; (2) Zooplankton community identification; (3) Limited phytoplankton studies by the qualitative-quantitative assessment of chlorophylls. Feeder streams of the Lake Dardanelle Reservoir are major contributors of soluble nutrients which are available to primary producers. Their heavy load of poultry effluents is the result of large poultry operations consisting of both chicken houses and turkey ranges which are located in the watershed of these streams. The addition and the retention of these nutrients in the lake are greatly affected by the magnitude of the flow of feeder streams into the lake. The most influential stream is the Illinois Bayou, owing to its size and consistency of flow. Land spreading is the method of disposal of litter from poultry houses. The magnitude of these soluble nutrients in the streams is dependent on several factors. These include (1) soil conditions at the time of the spreading of litter; (2) the period of time for integration into the soil after spreading before the occurrence of the next rainfall in the area which has the capacity of carrying or leaching this material into the stream bed. LIVESTOCK MANURE DISPOSAL VIA HYDROGASIFICATION,

Kansas University, Water Resources Research Institute, Lawrence
H. F. Rosson
Kansas Water Resources Research Institute Contribution No. 155, December, 1974, 126 p. 24 fig, 36 tab, 33 ref.

Descriptors: Feedlots, Farm wastes, Waste disposal, Water pollution, Gases, Livestock, Waste water treatment, Energy, Organic compounds.
Identifiers: Hydrogasification, Hydrogasification yield, Optimum water content, Molten salt, Manure disposal, Supplemental energy, Low sulfur gases, Hydrocarbon gases, Batch reactions.

Manure could be an important source of carbonaceous material and its hydrogasification could help solve the water pollution potential of feedlots as well as provide a supplemental energy resource. Manure can be hydrogasified to produce a mixture of low sulfur gases containing principally water, hydrogen, methane, ethane, and carbon dioxide. The yield of hydrocarbon gases in batch reactors is dependent on the reaction temperature and the hydrogen feed to carbon ratio with higher values producing higher yields. The presence of water is beneficial to yield with an optimum initial water content in the manure of about 50 percent. When using a molten carbonate salt reaction medium, the optimum initial water content may be slightly smaller. The hydrogasification thermic yield is defined to be the heating value of the dry product gases minus the heating value of the hydrogen feed per unit mass of manure. At a reaction temperature of 1050 degrees F., a maximum thermic yield of 3700 BTU/lb dry manure occurs at a hydrogen feed to carbon ratio of about 0.25 moles/mole. Use of a salt medium increases hydrocarbon yield slightly and increases thermic yield to a maximum of about 5500 BTU/lb dry manure at a hydrogen feed to carbon ratio of .93 moles/mole. BIFIDOBACTERIA FROM THE FAECES OF PIGLETS,

Istituto di Microbiologia Agraria, Universita di Bologna, Bologna, Italy
G. Zani, B. Biavati, F. Crociani and D. Matteuzzi
Journal of Applied Bacteriology, Vol. 37, No. 4, p. 537-547, 1974.

Descriptors: Bacteria.
Identifiers: Swine, Bifidobacteria, Identification, Taxonomy.

This investigation concerned a taxonomic study of the bifidobacteria isolated from the faeces of piglets, based both on phenotypic characters and on their genetic relatedness, measured with a DNA-DNA hybridization technique. A total of 52 piglets 2-6 weeks old, from 19 different farms, was studied. Ninety-five strains of bifidobacteria were isolated. The majority of the strains were identified as Bifidobacterium suis Matteuzzi et. al. Strains that could not be assigned to any known species of the genus were allotted provisionally to 2 unassigned bacterial groups. (Merryman-East Central)

AUTOMATED SYSTEM DISPOSES OF HOG WASTES,

Progressive Farmer, Vol. 91, No. 2, p. S22, February, 1976.

Descriptors: Aerobic treatment.
Identifiers: Swine, Flushing, Wastewater recycling, Land spreading.

Ohio researchers have built a new 500-pig nursery-to-finishing unit which combines automated flushing, treatment, and recycling to dispose of animal wastes. Hogs inside the building are trained to defecate in open gutters, which are flushed hourly. A sloping screen removes solids for aerobic digestion and deodorization. The digested solids then flow to a tank for later removal by a vacuum tank wagon. Liquids separated at the screen flow into an oxidation ditch for aerobic treatment. The ditch effluent is clarified in a settling tank and then is recycled through the gutters as flushing water. This system controls odors and minimizes the amount of liquid spread on cropland. CHARACTERIZATION OF THE DOMINANT AEROBIC MICROORGANISM IN CATTLE FEEDLOT WASTE,

Northern Regional Research Laboratory, Agricultural Research Service, U. S. Department of Agriculture, Peoria, Illinois
G. R. Hrubant
Applied Microbiology, Vol. 26, No. 4, p. 512-516, October, 1973. 1 fig, 1 tab, 17 ref.

Descriptors: Cattle, Biological properties, Microorganisms, Antibiotics.
Identifiers: Feedlot waste, Corynbacterium.

Feedlots and related sites were tested for the presence of microflora as a basis for potential solutions for waste utilization and pollution control. Corynbacterium was found to be the dominant aerobic microorganism in cattle feedlot waste (FLW), representing 2-70 percent of the total viable aerobic population. Corynbacterium was widespread in FLW except on sites where antibiotics were a regular part of the animals' diet. The organism decreased both in numbers and in percentage of the total population as FLW was diluted in runoff to a field ditch and after application of FLW to cropland or during "composting." Corynbacterium required DL-aspartic acid as its nitrogen source for growth, and individual strains also required or were stimulated by L-tyrosine; acetate served as the carbon source. Amylolytic activity was weak; protease, lipase, and cellulase activities were nil. Despite the abundance of the microorganism, it was felt that the microorganism probably did not decompose the waste appreciably. (Merryman-East Central)

DISPOSAL OF BEEF-FEEDLOT MANURE: EFFECTS OF RESIDUAL AND YEARLY APPLICATIONS ON CORN AND SOIL CHEMICAL PROPERTIES,

Assistant Professor of Soil Science, Minnesota University, Northwest Experiment Station, Crookston, Minnesota
G. W. Wallingford, L. S. Murphy, W. L. Powers, and H. L. Manges
Journal of Environmental Quality, Vol. 4, No. 4, p. 526-531, October-December, 1975. 8 fig, 3 tab, 9 ref.

Descriptors: Crop response, Feedlots, Waste disposal, Chemical properties, Nitrates, Salinity.
Identifiers: Land disposal, Nutrient uptake, Corn.

A project was established in the fall of 1969 to study the effects of a wide range of yearly and residual treatments of solid, beef-feedlot manure on the growth of furrow-irrigated corn forage composition and nutrient uptake, and on the chemical properties of a Kansas soil. Feedlot waste was applied annually to a silty clay loam soil at rates that after 4 years ranged from 114 to 2,750 metric tons/ha. For 3 years, in the spring and fall, surface soil samples and soil cores were taken. It was found that chemical composition of manure from a single feedlot varied greatly. Average composition (dry weight basis) of the samples collected was 20.5 percent H_2O; 0.92 percent N; 0.52 percent P, 1.14 percent K, 0.92 percent Ca, 0.41 percent Mg, and 0.26 percent Na. Electrical conductivities of extracts from saturated pastes of the surface soil samples from plots receiving yearly manure treatments were linearly related to cumulative tons of applied manure. Electrical conductivity values of more than 10 mmho/cm were recorded for the spring samplings. Both yearly and residual manure treatments caused Na and NO_3-N to move downward, accumulating to depths of at least 1 m after 3 years. Movement of K and P was restricted to 50 and 30 cm, respectively. Corn-forage yields increased at low and intermediate rates of manure application, but high rates depressed corn yield. Uptake of N and P was depressed by high yearly rates. Yearly rates of 29-68 dry metric tons ha^{-1} $year^{-1}$ produced near maximum forage yields without causing excessive salt accumulation in the soil. (Merryman-East Central)

DISPOSAL LAGOON,

Soil Conservation Service, Hawaii
Miscellaneous Publication, Cooperative Extension Service, University of Hawaii, Volume 113, p. 7-11, January, 1974.

Descriptors: Design criteria, Lagoons, Waste disposal, Hawaii, Aerobic conditions, Anaerobic conditions, Operation and maintenance.
Identifiers: Effluent disposal.

A disposal lagoon is defined as an impoundment made by constructing an excavated pit, dam, embankment, dike, levee or combination of these for biological treatment of animal waste. This publication establishes, as an engineering standard for Hawaii, the minimum acceptable quality for design, construction, and maintenance of disposal lagoons located to serve predominantly rural or agricultural areas. DESIGN STUDY TO REFEEDING BEEF CATTLE WASTES,

Department of Agricultural Engineering, Colorado State University, Fort Collins
M. L. Stone, R. W. Hansen, and A. L. Frey
Presented at the 1973 Winter Meeting, American Society of Agricultural Engineers, Chicago, Illinois, December 11-14, 1973, Paper No. 73-4504, 13 p. 1 fig, 6 tab, 9 ref.

Descriptors: Costs, Cattle, Feedlots.
Identifiers: Refeeding.

The costs of a standard feeding system are compared to the costs of a refeeding system. Thousand head finishing lots with minimum facilities are compared. Because the refeeding system required concrete surfacing of the pens for easy collection of wastes, the refeeding system required a higher initial investment than the standard feeding system. However, the refeeding system was $9,000 per year cheaper to operate based on 1,000 head. The refeeding system was found to be economically feasible. Two factors not considered in this analysis were consumer acceptance and odor reduction. (Merryman-East Central)

CLEANING THE ANIMAL FARM ENVIRONMENT,

School of Agricultural and Life Sciences, North Carolina State University, Raleigh
F. J. Humenik, M. R. Overcash, L. B. Driggers, and G. J. Kriz
Environmental Science and Technology, Vol. 5, No. 3, p. 984-989, November, 1974.

Descriptors: Water pollution, Legislation, Waste treatment, Waste disposal, Economics
Identifiers: Land disposal

As a result of Federal Water Pollution Control Act amendments of 1972, the EPA has published 2 sets of regulations affecting the animal production industry which establish a permit program and compliance criteria. The National Pollution Discharge Elimination System (NPDES) guidelines and permit form were published in the July 5, 1973, Federal Register, and the effluent limitation guidelines were published in the February 14, 1974, Federal Register. Because food production has increased and fertilizer prices have gone up, land application of feedlot wastes is very desirable. The problem is that feedlots are not always distributed closely enough to cropland to make land disposal economically feasible. Wastes may be handled as solids or liquids. They may be used either in their raw state or they may be pretreated. Among the pretreatment systems discussed are lagoons, barriered landscape water renovation system, solar still-type reactors, ensiling of wastes into wastelage, and production of algae or single-cell protein. All pretreatment alternatives have residues that must be terminally disposed. Ultimate land application of both solids and liquid is most practical for animal producers. Methods for disposing of wastes on land are discussed. Meeting government regulations concerning waste disposal will have economic ramifications. The Economic Analysis of Proposed Effluent Guidelines for the Feedlot Industry concludes that the effects of these criteria upon product price increases or employment would be quite small, while overall production is likely to increase. However, the cost-benefit aspects of any treatment system designed to produce a dischargeable effluent for animal waste, as is commonly done in conventional waste treatment systems, appear most unfavorable at present. (Merryman-East Central)

COLD CONFINEMENT MOST PROFITABLE IN MINNESOTA TEST,

Beef, Vol. 12, No. 6, p. 81, February, 1976. 1 fig, 2 tab.

Descriptors: Confinement pens, Minnesota, Performance, Economics.
Identifiers: Housing.

Five types of housing were compared at the University of Minnesota Experiment Station. They were: (1) Open lot, allowing 250 square feet per animal, (2) "Conventional", using an outside, concrete lot, plus a shed shelter, (3) A manure scrape building, which allows a manure pack to build. The building includes a scrape alley for cleaning, (4) A cold confinement building with slatted floors, and (5) A warm confinement building with controlled environment and ventilating system. Performance data for the 5 systems, revealed that there were not any huge differences in either gains or feed efficiency. However, according to Minnesota economists, assuming that a feeder kept his lot full year-around, he would get the best return to labor and management from the cold confinement barn with slatted floors. (Merryman-East Central)

CHEMICAL AND BIOSTIMULATORY PROPERTIES OF CATTLE FEEDLOT RUNOFF,

Division of Environmental Engineering, Utah State University, Logan
D. S. Filip, E. J. Middlebrooks, and D. B. Porcella
Water Research, Vol. 9, No. 5-6, p. 573-579, 1975. 8 fig, 3 tab, 20 ref.

Descriptors: Feedlots, Agricultural runoff, Chemical properties, Algae, Nitrogen, Phosphorus.
Identifiers: Biostimulatory properties, Growth.

Chemical and biostimulatory characteristics of snowmelt runoff from 2 small cattle feedlots were assessed. Nutrient supplements were used to determine the levels at which nitrogen and phosphorus became limiting to algal growth. The study resulted in the following conclusions: (1) Although available nitrogen and phosphorus concentrations may be adequate to support algal growth, the nitrogen: phosphorus ratio in runoff water is the critical factor for determining which element will first become limiting to algal growth. (2) Levels of inorganic nitrogen and phosphorus were sufficient to support excessive algal growth and indicate the serious eutrophication potential of feedlot runoff. (3) Evidence of toxicity to algal growth was found in feedlot runoff, but the effect was removed by dilution. Toxicity would not likely be evident in a receiving stream because of the dilution by the receiving stream. (4) Characteristics of feedlot runoff are highly variable because of temperature, intensity of runoff, topography, and feedlot conditions. (Merryman-East Central)

CELLULASE PRODUCTION BY TRICHODERMA VIRIDE ON FEEDLOT WASTE,

Northern Regional Research Laboratory, Agricultural Research Service, U. S. Department of Agriculture, Peoria, Illinois
H. L. Griffin, J. H. Sloneker, and G. E. Inglett
Applied Microbiology, Vol. 27, No. 6, p. 1061-1066, June, 1974. 3 fig, 4 tab, 12 ref.

Descriptors: Waste treatment, Fermentation, Fungi, Chemical properties, Odor, Protein, Nitrogen.
Identifiers: Cellulase, Trichoderma Viride, Refeeding.

Feedlot waste was fermented with the fungus Trichoderma viride with consequent reduction of BOD, COD, odor, and organic matter. Trichoderma viride utilized two-thirds of the carbohydrate in feedlot waste while elaborating cellulase in quantities comparable to commercial preparations. The fermented waste retained all of the original nitrogen but had 24 percent less organic matter. Because crude protein content of the residue was increased, it was felt that refeeding of this fermented waste as a protein supplement might be feasible. (Merryman-East Central)

CADMIUM TOXICITY AND METABOLISM IN ANIMALS,

Georgia University, Athens
M. W. Neathery and W. J. Miller
Feedstuffs, Vol. 48, No. 3, p. 30-32, January 19, 1976. 3 tab, 36 ref.

Descriptors: Cadmium, Toxicity, Metabolism, Public Health.
Identifiers: Animal health, Refeeding.

Experimentally-induced cadmium toxicity in cattle and other animals may result in anemia, retarded testicular development or necrosis, enlarged joints, scaly skin, liver and kidney damage, reduced growth, lower milk production and increased mortality. However, cadmium toxicity is seldom a problem in modern livestock production. Although a significant proportion of inhaled cadmium is absorbed, farm animals usually obtain very little from dust or fumes. Generally, feeds contain very little cadmium and only a small portion of that is absorbed. However, borderline toxicity could arise in animals fed recycled waste materials, such as sewage sludge. Although little cadmium is absorbed from the gut, that which is absorbed remains in the body for a long time, primarily in the liver and the kidney. Very little is deposited in muscles or secreted into milk; hence, these are safe for human consumption. (Merryman-East Central)

BROILER LITTER AS A WINTERING FEED FOR BEEF COWS AND HEIFERS,

K. E. Webb, Jr., J. P. Fontenot and W. H. McClure
1973-1974 Livestock Research Report, Research Division Report 158, Virginia Polytechnic Institute and State University, Blacksburg, July, 1974, p. 125-128. 6 tab.

Descriptors: Litter, Cattle, Sheep, Toxicity, Copper, Performance
Identifiers: Refeeding, Animal health

Two experiments were conducted with ewes to determine the effect of feeding broiler litter on performance. In both experiments, there were no differences in performance of ewes fed 0, 25, or 50 percent broiler litter, but copper toxicity was encountered in the litter-fed animals. The high copper content of the litter was a result of having fed copper sulfate to the chicks utilizing the litter. One experiment was completed and another started at the Shanandoah Valley Research Station to study the long term effect of feeding high levels of litter containing high levels of copper to cows and heifers during the winter. High copper rations did not affect cattle performance. Liver copper levels were elevated by the feeding of such rations, but copper toxicity did not result. Heifers fed litter rations tended to gain more than those fed control rations. (Merryman-East Central)

RECYCLED MANURE: A MONEYSAVER AND ANSWER TO A PROBLEM,

W. Thompson
Progressive Farmer, Vol. 90, No. 12, p. 20-21, December, 1975. 3 fig.

Descriptors: Recycling, Cattle, Economics, Feeds, Feedlots.
Identifiers: Refeeding, Manure.

Sam B. Hay, Jr., of Covington, Georgia, has turned the cattle manure problem into a profitable venture by refeeding the manure from his concrete beef feedlot. Based on 1975 prices, the manure is worth $62 a ton when used for feed as compared to $5-$7 a ton when used as a fertilizer. Mr. Hay found that beef cattle gained as fast on feed made from recycled manure as they did on conventional hot rations, as long as manure did not exceed 40 percent of the ration. The manure was scraped from the concrete lot and augered into a chain conveyor that dropped it into an Oswalt mixer truck. Silage, haylage or hay, and rolled grain were then added. When thoroughly mixed, a blower took the feed into an oxygen-controlled, top-loading, bottom-loading, poured concrete silo. The mixture had to be stored a minimum of 10 days before using it as feed. Feeding the mixture to two different groups of steers, the average daily gain was 2.82 pounds. The net return for the steers amounted to $160 to $170 per head. Panel taste-and-tenderness tests showed no difference in the meat from these steers. (Cannon-East Central)

ECONOMIC IMPACTS OF SELECTED WATER POLLUTION CONTROL RULES ON MICHIGAN BEEF FEEDLOTS OF LESS THAN 1,000-HEAD CAPACITY,

Department of Agricultural Economics, Ohio State University
D. L. Forster, L. J. Connor, and J. B. Johnson
Michigan State University Agricultural Experiment Station Research Report 270, April, 1975, 16 p. 2 fig, 15 tab, 10 ref.

Descriptors: Economics, Michigan, Feedlots, Water pollution control, Legislation, Cattle, Agricultural runoff.

The objective of this study was to analyze the economic impacts of fed-beef producers and consumers of alternative water pollution control rules on beef feedlots of less than 1,000-head capacity. Four alternative water pollution rules with the potential for application to Michigan beef feedlots of less than 1,000-head capacity were investigated. The rules were: (1) Require beef feedlots of less than 1,000-head capacity to control runoff from a 10-year, 24-hour storm by 1977 and a 25-year, 24-hour storm by 1983. (2) Require that beef feedlots of less than 1,000-head capacity have facilities to control runoff from a 25-year 24-hour storm by 1977. (3) Require that firms of less than 1,000-head capacity have the facilities to control runoff for rainfall over a 6-month period by 1977. (4) Require that firms of less than 1,000-head capacity be prohibited from spreading solid wastes in the winter, plus have retention facilities to control runoff for rainfall over a 6-month period. Static and multiperiod models were utilized in this study. In the static analysis, additional capital requirements and changes in annual production costs attributable to compliance with alternative water pollution control rules were determined for particular capacity-type housing technology combinations. In the multiperiod analysis, a sample of Michigan feedlots with identifiable physical and financial characteristics was simulated over the 1974-1985 period to reflect the performance of Michigan feedlots through time under each of the pollution control rules. Aggregate performance in the absence of water pollution rules. Investigating the effects of the rules on the equity positions allowed an approximation of the losses that feedlot operators would suffer upon complying with these rules. (Cameron-East Central)

CHICKEN MANURE—WORTH MORE THAN EGGS?,

Progressive Farmer, Vol. 91, No. 3, p. 112, March, 1976. 1 fig.

Descriptors: Poultry, Fertilizers, Coastal bermudagrass, Crop response, Costs, Florida, Sprinkler irrigation
Identifiers: Land disposal, Chicken manure

Roger Williams, Gainesville, Florida, uses the manure from his 80,000 layers and pullets as a fertilizer. He grows Coastal bermudagrass on land that is considered to be completely unproductive. Williams has found that by putting out the chicken manure at least every 10 days, he gets a high degree of efficiency in relation to what he puts out and what he recovers in the Coastal bermudagrass. This year he plans to grow 6 tons an acre—a ton from each of 5 or 6 cuttings made 18 to 21 days apart. Williams has found that spreading liquid manure in front of a circular irrigation system is a way to prevent odor in manure spreading. He flushes the chickenhouses clean once a day and stores the liquid in a 150,000-gallon holding pit. Each week, he pumps the manure into a 5,000-gallon-capacity truck. He then spreads the manure, actually spraying out the solution up to 40 feet away just ahead of the moving sprinkler. He then reverses the sprinkler to ensure that all the manure will be washed into the soil, thus minimizing odor, flies, and loss of nitrogen. Each load takes him less than an hour. Williams says that if the price of fertilizer goes up much further, he may expand his poultry operation in order to offset the higher fertilizer prices. (Cameron-East Central)

FARMING BIG ON A SMALL ACREAGE,

J. Bramblett
Progressive Farmer, Vol. 91, No. 3, p. 92, March, 1976. 1 fig.

Descriptors: Fertilizers, Cattle, Poultry, Litters, Performance.
Identifiers: Land disposal.

Bob Mills of Springdale, Arkansas, has on his 100-acre farm two broilerhouses with a combined capacity of 33,000 birds. Each is emptied about 5½ times a year. He has 15 acres of grapes and 80 acres are in pasture where he runs 60 cows and heifers and cuts as much as 6,700 bales of hay per year. Chicken litter, as well as good management, has built the once poor Ozark farm into a lush, productive homestead. Mills raises chickens on contract and in a year's time will produce around 176,000 broilers. Litter is spread over pastures where it transforms thin normally unproductive soil into topnotch grassland. Fescue and orchardgrass pasture plus a small acreage of bermudagrass carry a cow and a calf per acre all year. Mills' usual application is 2 tons of litter per acre each year, plus lime as needed. A ton of litter has about 56 pounds of nitrogen, 48 pounds of phosphate, and 36 pounds of potash, plus other trace elements. Mills' best bull, so far, averaged gaining 2.88 pounds per day with a feed conversion ratio of 1 pound of gain for each 4.28 pounds of feed. Supervised by the Arkansas Cooperative Extension Service, a test indicated cost per pound of gain during the 140-day period was 27 cents. (Cameron-East Central)

THEY FINISH CATTLE ON 80 PERCENT PLS AND 20 PERCENT CORN,

W. Upchurch
Progressive Farmer, Vol. 91, No. 3, p. 67, 70, March 1976. 2 fig.

Descriptors: Cattle, Feeds, Performance, Economics.
Identifiers: Refeeding, Finishing rations, Poultry litter, Corn.

The Acme Poultry Farms are successfully finishing beef cattle on a ration of one-third high-moisture corn and two-thirds ensiled broilerhouse litter. Eric Clark, Acme owner, figures the poultry litter, based on total digestible nutrients (TDN) and protein content, as a feed ingredient is worth about $50 to $100 a ton (about three times what it is worth as a fertilizer). Acme has three airtight Harvestore silos and two concrete feedlots. A 20- x 35-foot silo contains high-moisture corn, a 20- x 70-foot Harvestore contains haylage, and a 20- x 80-foot silo contains the chicken litter. The chicken litter is blown into the top of the largest silo and brought up to about 35 percent moisture. Although the litter is safe to use within 7 days after it goes into storage, Clark advises 30 days to make sure the feed is sweet enough for the cattle. Tests run at North Carolina State University show that the litter has about 20 percent crude protein and a TDN content of 65 percent. That is within 20 percent of the feed value of high-moisture corn. Vitamin A and Aureomycin crumbles are the only other feed ingredients the Clarks use. They use haylage as needed in the feedlots and for the gestating cows. The litter-corn ration has resulted in gains of a fraction over 2 pounds a day for steers and about 1½ pounds of heifers fed in confinement. The Clarks haven't found anything negative about this litter-feeding program except the initial investment. When looked at as a long-term investment, the concern diminishes. (Cameron-East Central)

HYDROGEN SULFIDE EVOLUTION FROM ANAEROBIC SWINE MANURE,

Agricultural Engineering Branch, British Columbia Department of Agriculture, Abbotsford, British Columbia, V2S 1X4, Canada
E. M. Barber and J. B. McQuitty
Hydrogen Sulfide Evolution from Anaerobic Swine Manure. Department of Agricultural Engineering, University of Alberta, October 1974. 69 p. 6 fig, 6 tab, 122 ref.

Descriptors: Hydrogen sulfide, Animal wastes, Gases
Identifiers: Anaerobic wastes, Swine, Desorption, Literature review

Hydrogen sulfide has been implicated as a principal offender in several human and animal casualties involving manure gases, and has been known to cause structural damage to metal and concrete components of livestock facilities. The major objectives of this study were (a) by means of an extensive literature review, to investigate factors affecting the production of sulfides in, and the desorption of hydrogen sulfide from anaerobically fermenting manure; and (b) on the basis of the findings, to assess potential alternate means of controlling the evolution of sulfide-containing gases from anaerobic manure. These observations and conclusions were drawn on the basis of the literature review: (1) hydrogen sulfide produced during the anaerobic fermentation of livestock manure is a major constituent of the characteristic manure odor and is known to adversely affect the health of livestock and farm operators; (2) sulfur-containing gases are produced by biological and bio-chemical transformations from sulfur compounds in manure; (3) chemical control of hydrogen sulfide seems to offer several advantages, including lower capital costs and convenient adaptability to existing waste management facilities; (4) from the standpoint of acquisition and safety in handling, iron appears to be the most suitable metal for precipitating sulfides from manure; (5) lime may exert an effect on odor released from anaerobic manure by retarding bacterial action or by minimizing the volatilization of soluble odorous constituents; (6) chemical oxidizing agents may offer an alternative to aeration as a means of controlling the oxidation-reduction potential of stored animal manure. (Cameron-East Central)

FLUSH-FLUME MANURE SYSTEM WORKING WELL,

Wallaces Farmer, Vol. 101, No. 2, p. 98-99, January 24, 1976. 3 fig.

Descriptors: Cattle, Waste disposal, Iowa, Confinement pens, Feedlots, Design, Performance, Moisture content.
Identifiers: Flush-flume manure system, Land spreading, Waste water reuse, Feed additives.

The Co-op confinement feedlot near Sioux Center, Iowa, operating over 2 years, is successfully using the flush-flume waste disposal system for heifers fed in confinement. The operators have found they get optimum results by keeping water flowing through the flumes continuously, rather than trying to flush out accumulated manure at intervals. The co-op installed a manure reclaiming unit to remove solids from the flushed water. The waste water goes through a vibrating screen to separate solids from water. Collected solids are then passed through a press to remove additional moisture. The final product is a 70 percent moisture material, something like corn silage. The collected manure is spread on cropland to reclaim its fertilizing value. Evan Vermeer, nutritionist of the feedlot's mill, reports that heifers have performed more consistently in the buildings than steers. To prevent injury problems with confined heifers, the feed additive MGA is used as a growth promotant which suppresses heat. The material's growth promoting effects probably increase gains by 10 percent—or a savings of $15 or $20 per heifer. Typical rate of gain for feedlot heifers has been about 2 to 2½ lb. per day. Steers have been going 2¼ to 3 lb. per day. The co-op soon plans to erect a fourth building of equal size, widening the gap under the eaves to provide slightly more ventilation. (Cameron-East Central)

EARTH MANURE PIT EASES SPREADING PRESSURE ON CONFINEMENT OPERATION,

Beef, Vol. 12, No. 5, p. 6-7, 10, January, 1976. 3 fig.

Descriptors: Cattle, Waste storage, Confinement pens.
Identifiers: Slatted floors, Manure pits, Outdoor earthen manure pits, Land spreading.

Gene Haen solves the problem of a full manure pit under a slatted floor by "backstopping" his regular under-the-floor storage with two huge outdoor earthen manure pits. When an inside pit gets full, he agitates the pit and pumps the manure into one of the outside structures, where it is held until it's convenient to spread it on cropland. Haen's outdoor pits measure 110 feet by 120 feet for each pit. The units are 12 feet deep, with a one-foot slope across the bottom. The pits have concrete floors, but earth sidewalls (the heavy soil in the area guarantees no real leakage from those pits). Haen uses a lot of the manure on hayland. He feels one key to getting full value out of the manure is a continuing, complete soil analysis program. Haen reports that the big earthen pits have not created any odor problems around his operation. The Wisconsin cattleman also reports very little maintenance is necessary. For Gene Haen, outdoor manure pits have offered an ideal, economical way to expand the capacity of those under-the-floor pits. (Cameron-East Central)

HEALTH ASPECTS OF RECYCLING ANIMAL WASTES BY FEEDING,

Department of Animal Science, Virginia Polytechnic Institute and State University, Blacksburg
J. P. Fontenot and K. E. Webb, Jr.
Journal of Animal Science, Vol. 40, No. 6, p. 1267-1277, June, 1975. 7 tab, 89 ref.

Descriptors: Public Health, Feeds, Animal wastes, Nutrients, Pathogenic bacteria, Molds, Pesticides, Heavy metals, Recycling
Identifiers: Refeeding, Animal health, Drugs

The United States produces about 1.6 billion tons of animal wastes annually. These wastes must be handled with the least risk to human and animal health. These wastes contain nutrients and can be fed to farm animals without affecting meat, milk, or eggs. F.D.A. does not sanction waste recycling because of potential dangers from pathogenic bacteria, molds, and residues of pesticides, drugs, and heavy metals. Pathogens are destroyed by heat and chemical treatment of the waste. Proper storage and handling of wastes eliminate waste molds, and pesticide residues have not been reported. Extensive research is needed concerning the effect of drugs and heavy metals on animals and withdrawal times for animals fed high levels of these should be set. No indication of harmful effects from these on humans have been reported. The only effect on animals was copper toxicity in sheep fed poultry manure containing high levels of copper. Apparently animal wastes may be safely recycled by refeeding. This would increase the food supply and decrease environmental pollution. (Cannon-East Central)

AN HONOR FOR SUPER SLURPER,

Agricultural Research, p. 12-13, January, 1976. 3 fig.

Descriptors: Absorbtion, Gels.
Identifiers: Super slurper, Grafting.

Industrial Research magazine recently congratulated Northern Regional Research Center chemists M. Weaver, George Fanta, William Doane, and Edward Bagley for their work on super slurper. This product can absorb 1400 times its weight in distilled water, half in 30 seconds and most of it in 10 minutes. It can absorb 50 to 100 times its weight in mineral solutions such as hard water and has 20 times the urine-holding capacity of cellulose against a force 45 times gravity. It congeals water to a gel that is like soft, rubbery ice, but not cold, which can be handled more easily than a liquid. Super slurper is made by grafting. Starch from corn or other farm crops is combined with acrylonitril. This is treated with lye to produce a hydrolyzed starchpolyacrylonitrile graft copolymer. It is made in the form of flakes, film, powders, or mat. These forms swell to duplications of their own shapes but do not dissolve. In studies made by Iowa State University, oats planted in a slurper-sand mixture lived 11 days longer than oats in sand alone and had 10 times as much top growth. Super Slurper can be used in animal bedding, kitty litter, diapers, bandages, surgical pads, and dental absorbents. Samples are available at Northern Regional Research Center, Peoria, Illinois. THE ECONOMIC VALUE OF ORGANIC MATTER IN CROP PRODUCTION,

J. Cox
Compost Science, Vol. 16, No. 5, p. 24, Autumn, 1975.

Descriptors: Economics, Energy, Fertilizers, Pesticides, Organic wastes, Costs, Crop response.
Identifiers: Land application.

A study conducted at St. Louis's Washington University by Dr. Barry Commoner and 6 others, concludes that farmers who have built up soil humus, fertilized with green and animal manures, and practiced crop rotations achieved a net profit about equal to conventional farmers, and comparable yields, but used one-third less energy in the production. The researchers examined 16 organic farms in Iowa, Missouri, Illinois, Minnesota and Nebraska, matching each to a farm of similar size operated with conventional crop-production practices. The farms ranged in size from 175-785 acres and were selected over a wide area to include as many types of soil and terrain as possible. Principle crops produced were corn, soybeans, wheat, oats, and hay. All farms also raised hogs or cattle or had dairy herds. On the conventional farms, expenditures for fertilizers, other soil amendments and pesticides constituted about one-half of variable operating costs, amounting to an average of $23 per acre of cropland. This compares to an average of $7 per acre on the organic farms. This additional investment in increasingly-expensive production inputs generated only $14 per acre more gross income than the average for the organic farms. Organic farms are much less vulnerable to disruptive effects of growing energy shortages and price increases and profitability of organic farms is less vulnerable to the impact of declining crop prices. Additional research shows that a humusy soil protects crops from a host of soil-borne diseases. Thus the economics involved in using organic wastes on land are becoming obvious to more and more farmers. (Merryman-East Central)

HYDRAULIC MANURE REMOVAL FROM LIVESTOCK AND POULTRY FACILITIES,

Extension Agricultural Engineer, Washington State University, Pullman
R. E. Hermanson
Publication No. EM3797, Cooperative Extension Service, College of Agriculture, Washington State University, Pullman, September, 1973, 8 p. 4 fig.

Descriptors: Confinement pens, Livestock, Poultry, Liquid Wastes, Hydraulic systems, Lagoons, Irrigation, Waste storage.
Identifiers: High Pressure cleaning, Flush system, Oxidation ditch.

The manure handling system is often the controlling factor in successful, large, confinement livestock and poultry facilities. The system must be economically and technologically feasible without polluting the land, air, or water. In hydraulic systems, large amounts of water transport the manure. This high-volume, liquid manure is carried to a storage tank, lagoon, outside oxidation ditch, or irrigation system. Gravity-flow gutters should slope at least 2 feet per 100 feet and pipe should be at least 8 inches in diameter. The 2 basic hydraulic manure removal methods are high-pressure cleaning and the flush system. High-pressure cleaning saves time. Solid manure is softened, scrubbed and transported to a disposal system. The necessary equipment includes a high-pressure water source, hose, and nozzle. In hog and poultry facilities, cleaning is most effective when using 8-10 gallons per minute at 70-80 pounds per square inch through a 3/16 inch nozzle. A 1/4 inch nozzle with a flow of about 15 gallons per minute at a pressure of 80-100 pounds is recommended for cattle manure. In flush systems, manure is moved by a fast-moving wall of water provided by a quick-opening gate in a storage tank, a dipping flush tank, or a pipe and valve system. Gutter or alley slope should be 1 foot per 100 feet. Flush tank depth is important and varies from 2.5 to 10 feet. Tipping flush tanks are usually triangular or trapezoidal cross sections with an off-center pivot point on each end of the tank. Cattle manure flushing requires about 10 gallons per foot of alley. The maximum alley length is about 200 feet. Lagoon intakes and outlets should be located 4-6 feet below the surface. Hog manure can be flushed 150 feet. Apparently, 15 gallons of water per hog per day are required. Poultry systems may also use flush systems. (Cannon-East Central)

ENSILED USE OF CAGE WASTE, CHOPPED ROUGHAGE DETAILED,

Feedstuffs, Vol. 47, No. 53, p. 15, December 29, 1975

Descriptors: Poultry, Fermentation, Silage, Nitrogen, Economics
Identifiers: Ensiled cage waste, Refeeding, Roughage, Crude protein

J. W. Claybaugh of DeKalb AgResearch, Inc.'s poultry division, says that ensiled cage waste with the proper proportion of chopped roughage is a good way to utilize these two wastes. Converting cage wastes into silage eliminates the need for a manure drier and fuel to operate it. Fresh manure, which has undergone bacterial decomposition, does not smell. After ensiling, the manure contains maximum amounts of nitrogen and crude protein and it is palatable. The manure is then added to chopped roughage, which may consist of corn field residue, straw, hay, or pasture clippings. The silage thus derived is about equal to alfalfa hay and can provide a maintenance ration for pregnant dry cows, stockers, and developing heifers with only vitamins A, D, and E needed to be added. Good silage depends on proper fermentation. This depends on correct moisture, proper nutrients, and adequate packing in an oxygen-free environment. The ensiling process changes the value of cage waste from that of fertilizer at about 30-40 cents per year per bird, to 80 cents, based on crude protein value compared with $100 per ton soybean meal. (Cannon-East Central)

SHOULD DPW BE USED IN POULTRY RATIONS?,

Poultry Digest, Vol. 34, No. 405, p. 438, November, 1975.

Descriptors: Feeds, Nutrients, Costs, Toxins.
Identifiers: Dried poultry wastes, Refeeding.

Points to consider before deciding to refeed dried poultry waste are: (1) Samples of DPW brought together from different sources may vary widely in composition and nutrient value. (2) Despite variability of DPW from different sources, it should be possible for an individual producer of DPW to put out a uniform product of known nutrient value if the raw material is being produced by birds under his management and the drying process is carefully controlled. (3) Crude protein values of DPW are fairly high, but much of the nitrogen is nonprotein and of limited use to nonruminant animals. (4) Because true protein values (10-11 percent) are in the same general range as the common cereal grains, DPW cannot be considered a protein supplement for poultry rations. (5) Because DPW has a low energy value, it has a distinct diluting effect on the final energy level of a ration. (6) DPW is a good source of phosphorus. (7) Most nutritionists would not recommend DPW for rations formulated to produce rapid growth (broilers, turkeys). Uric acid may be toxic to chicks and poults. (8) Experimental results suggest DPW can be used in layer rations at levels up to 10-12 percent without significant effect on production, feed efficiency or egg size. (9) Whenever DPW is used in a ration, it should not be merely as a substitute for another ingredient on a pound-for-pound basis. Actual nutrient analysis and cost should be considered in the ration formulation so that DPW competes with alternative feed ingredients. (10) Research on the use of DPW in poultry rations is still scanty. There is need for exploring the potential for including DPW in rations for replacement pullets, molting layers, and broiler breeders. (Cocon-East Central)

ODOR CONTROL FOR CONFINED BEEF CATTLE FEEDLOTS,

Agricultural Engineering Department, Texas Tech University, Lubbock
J. P. Ford and W. L. Ulich
Presented at the 1st Annual Symposium on Air Pollution Control in the Southwest, Texas A&M University, College Station, November 5-7, 1973, p. 189-204. 1 fig, 3 tab, 19 ref.

Descriptors: Cattle, Feedlots, Liquid wastes, Solid wastes
Identifiers: Odor control, Masking agents, Counteraction

The importance of the cattle industry to agriculture and an introduction to odor problems from confined animal feeding operations are discussed. Odor control methods considered feasible for beef cattle feeding in conventional lots are reviewed. Seven materials which were felt to have a capability of controlling or modifying the production of malodors were tested. Sulfurous compounds, amines, and possibly ammonia were shown to be important components of cattle feedlot odors. Both liquid and solid manures were found to produce the same classes of odorous gases under anaerobic conditions. Housekeeping, combined with the application of of odor control material when necessary, was judged to be capable of economical cattle feedlot odor control. Potassium permanganate and Ozeno were found to be the most economical odor control materials considered in the tests. (Ford and Ulich-Texas Tech)

THE CHEMICAL CONVERSION OF BOVINE WASTES,

Department of Chemical Engineering, Texas Tech University, Lubbock
H. D. Young, J. E. Halligan, and H. W. Parker
Presented at the 1st Annual Air Pollution Control Symposium in the Southwest, Texas A&M University, College Station, Texas, November 5-7, 1973, p. 233-256. 6 fig, 3 tab, 11 ref.

Descriptors: Gases, Design, Physical properties, Chemical properties, Energy, Char.
Identifiers: Chemical conversion, Fluidized bed reactor, Anhydrous ammonia.

A small scale fluidized bed reactor was operated at elevated temperatures with manure, air, and steam as the principal feed streams. The product gases contained considerable amounts of valuable constituents such as CO, CH_4, H_2, $C_2D_2H_4$. Calculations are presented which suggest that, using conventional technology, the product gases could be shifted and purified to ultimately lead to a gas which could be converted to anhydrous ammonia. Material and energy balances around the reactor are presented to permit projections concerning the feasibility of the overall process. (Young-Texas Tech)

DISPOSAL OF CATTLE FEEDLOT RUNOFF ON AGRICULTURAL LAND,

Department of Agricultural Engineering, Nebraska University, Lincoln
H. D. Wittmuss
Completion Report, Water Resources Research Institute, University of Nebraska, June, 1975, 50 p. 11 fig, 26 tab.

Descriptors: Feedlots, Agricultural runoff, Waste disposal, Crop production, Pollution effluents, Sprinkler irrigation, Nutrients, Deep percolation, Absorption, Corn (field), Chemical analysis, Waste treatment.
Identifiers: Effluent irrigation.

Cattle feedlot runoff was applied to sod planted corn for three years at rates up to 30 inches per year without pollution of soil, crop, surface water or groundwater. Data were collected on many areas of crop production to check the effect of effluent irrigation compared to water irrigation on sod planted corn. All tests to date show no discernible difference in forage or grain nutrient content. The grain yield was suppressed 20 percent or more by the sprinkler application of effluent every two weeks, compared to water irrigated plots, during the growing season. Water and effluent were applied to sod planted corn in ten applications with maximum applications of 30 inches a year for three years. The application was measured and analyzed chemically for nutrients. Forage and grain yields were determined and each was analyzed chemically for nutrient composition: The percentage of crop uptake of applied nutrients was determined and ranged from 1 to over 100 percent and could be related to crop response in many cases. Percolate samples were collected from the 7-foot depth and analyzed chemically showing a slight increase in the nitrogen content below the effluent plots. The chemical composition of the soil was determined before, during and after the study. (Wittmuss-Nebraska University)

ANIMAL WASTE UTILIZATION FOR POLLUTION ABATEMENT TECHNOLOGY AND ECONOMICS. PHASE 2,

Department of Agricultural Engineering, Nebraska University, Lincoln
O. E. Cross
Nebraska University Water Resources Research, Lincoln, Institute Project Completion Report, February, 1974, 25 p. 15 fig, 2 tab, 6 ref.

Descriptors: Water pollution sources, Groundwater pollution, Agricultural runoff, Waste disposal, Fertilizers, Irrigation practices, Return flow, Nitrates, Sodium, Potassium
Identifiers: Land disposal

The pollution potential of the runoff from manured soil involves nitrate, sodium, and potassium. High manure applications to cultivated soils will cause limited pollution of surface runoff water and only during the first fifteen minutes of the first runoff event. The concentration of pollutants in this runoff water is below the limits set for irrigation water. Hence, all runoff should be recycled for irrigation uses. After four years of testing heavy manure application groundwater retained potable quality. Repeated annual application of heavy rates of manure on land may lead to deterioration of the physical properties of soil, owing to the large amounts of sodium and potassium in manure. In 1972 and 1973, these two elements did not continue to increase in concentration. Also, feeding excess quantities of sodium and potassium beyond the minimum requirement for the animals is being avoided. The initial intake of water into the soil increases as high manure loadings are applied. The basic intake rate is higher on areas plowed 8 inches deep. The basic intake rate on any specific manure loaded area increases with time elapsed from date of manure application. (Knapp-USGS)

LABORATORY SIMULATION OF SWINE MANURE LAGOONS,

Department of Agricultural Engineering, Clemson University, Clemson, South Carolina
C. L. Barth
Presented at Seventieth Annual Meeting of the Association for Southern Agricultural Workers, Incorporated, Atlanta, Georgia, February, 1973, 9 p. 6 fig, 5 tab, 11 ref.

Descriptors: Anaerobic lagoons, Design criteria, Chemical properties, Physical properties, Waste treatment, Biodegradation, Temperature, Load distribution, Southeast U.S.
Identifiers: Swine, Laboratory simulation, Detention time, Loading rates, Volatile-solids-reduction.

Anaerobic lagooning of swine manure waste is widely used and is considered successful in the southern region of the United States. Evaluation of the variations in design standards employed by individual states in the region indicates that much uncertainty exists in the application of present knowledge and design values. A progress report is presented on a study of anaerobic lagooning properties of swine waste. Findings indicate the effect of loading rate and temperature on lagoon operations. This research provides basic knowledge on lagoon operation under conditions prevalent in the southern region and contributes to more uniformly applied design criteria. (Barth-Clemson University)

BIOLOGICAL CONVERSION OF ANIMAL WASTES TO NUTRIENTS,

Department of Avian Sciences, Colorado State University, Fort Collins
B. F. Miller
Environmental Protection Agency Report No. EPA 670/2-73-09 June, 1973, 68 p. 9 fig, 30 tab 36 ref.

Descriptors: Recycling, Feeds, Proteins, Poultry, Larvae.
Identifiers: Catabolism, Feeding trials, Feed conversion, Fly egg hatchability, Musca Domestica.

As part of studies to determine how living organisms may be used to catabolize poultry manure, larvae of house flies (Musca Domestica) were used to process poultry manure, with the pupae being used as a feed supplement. Temperature and relative humidity conditions were determined to produce an optimum yield of dry pupae. Three feeding trials were conducted to evaluate fly pupae and catabolize poultry manure residue as protein sources for growing chickens. White Leghorn chicks, White Plymouth Rock chicks, and New Hampshire and Indiana River broiler chicks were fed the various diets and differences in body weight and feed conversion were reported. The results indicated that fly pupae have potential as a protein supplement in chick starter and broiler diets; the protein quality was found to be similar to that of meat and bone meal or fish meal, and superior to soybean oil meal. DAIRY MANURE MANAGEMENT METHODS,

Washington State University, Pullman
D. E. Proctor
Environmental Protection Agency Report No. EPA SW 530 67D, 1974, 130 p. 34 fig, 9 tab, 5 ref.

Descriptors: Dairy industry, Anaerobic lagoons, Confinement pens, Sprinkler irrigation, Agricultural runoff, Crop response
Identifiers: Waste management, Hydraulic flushing, Seasonal storage, Land application.

New pens for the confinement and feeding of dairy cattle were constructed under a continuous roof area to prevent the addition of precipitation to the cattle excrement. The manure was collected in underground sumps, pumped to large anaerobic lagoons, for wet season storage, and subsequently applied to cropland during the comparatively dryer summer months. Observations were made to evaluate, at least partially, the effect of the roofed environment upon the cattle. Some unsuccessful attempts were made to collect the excrement by hydraulic flushing techniques alone. The pump and pipeline transport of manure slurries either to storage or to large bore field irrigation nozzles was quite successful. Observations of surface pondings and runoff, soil penetration, and crop response indicated that the concept of seasonal storage and seasonally scheduled cropland disposal of dairy manure slurries can be an environmentally acceptable and agriculturally compatible method of dairy manure management. Attempts to aerobically treat manure slurry supernatant liquor were technically successful but still impractical. (Proctor-Washington State University)

METHANE GENERATION,

Department of Agricultural Engineering, Michigan State University
J. B. Gerrish and Fred Hall
Agricultural Engineering Facts Sheet No. 25, File No. 18.1, Michigan State University, July, 1974, 2 p. 1 tab.

Descriptors: Methane, Energy, Animal wastes, Anaerobic digestion.

While methane generation from anaerobic digestion of animal wastes sounds inviting, there are many problems yet to be solved, including: (1) Methane bacteria require warm (95 degrees F) temperatures. Lowering the thermostat to 68 degrees F reduces methane production by more than half. In January, a good portion of the gas produced in Michigan would have to be sacrificed just to keep the digester warm. (2) Methane bacteria cannot tolerate a sudden slug of manure. The digester must be fed a small amount of manure daily which has been diluted 2 parts water to 1 part manure. This increases the amount of waste and aggravates the waste disposal problem. (3) Methane gas contains hydrogen sulfide which burns to sulfur dioxide, a well-known air pollutant which reacts with water to form sulfurous acid. Sulfurous acid reacts with oxygen to form sulfuric acid which can eat the insides out of engines, furnaces, and lungs. (4) Because methane gas contains a lot of carbon dioxide, there is waste space in any storage tank. To get a cruising range of 40 miles in a small methane-driven car, the tank must hold 36 cubic feet at 150 lb. pressure. Thus the tank would be as large as the car! Obtaining higher pressures would involve expensive multi-stage water-cooled explosion-proof compressors. (5) Energy storage may be an unforeseen expense. Large pressure tanks are expensive. Gas production is best in the summer when the need for heating fuels is not very great. However, the methane might be used to dry some crops. (6) Capturing methane from animal manures probably does not fit in very well with current American farming practices. Until energy shortages approach the severity of post-war Europe, methane production probably will not catch on. (Merryman-East Central)

EFFECT OF DAIRY CATTLE MANURE ON MILLET AND RYE FORAGE AND SOIL PROPERTIES,

Department of Natural Resource and Environmental Studies, Alabama A&M University, Normal
L. M. Mugiwra
Journal of Environmental Quality, Vol. 5, No. 1, p. 60-65, January-March, 1976. 6 fig, 4 tab, 15 ref.

Descriptors: Dairy industry, Crop response, Forages, Soil properties, Nutrients, Nitrates, Alabama, Rates of application.
Identifiers: Land application, Millet, Rye, Soil depth intervals.

A study was conducted to determine maximum loading rates of dairy cattle manure as measured by forage yields, nitrate levels in plants and soils, and recovery of plant nutrients on Decatur silty clay loam under northern Alabama conditions. Dairy cattle manure was incorporated into Decatur silty clay loam plots at rates of 0, 22, 44, 89, 178, and 267 metric (dry weight) for 3 successive years. Pearl millet was grown in summer and was clipped twice and "Wrens Abruzzi" rye was grown as a winter cover crop. Manure application increased growth of and nitrate-N content in millet grown in summer, but generally no increases in forage yields were obtained with annual applications of manure higher than 44 metric tons per half acre. Although dry matter and nitrate-N content in the winter crop were not affected by manure applied in the first 2 years, rye yields accounted for 44.4, 39.8, and 44.6 percent of the total dry matter produced each season. Rye forage removed only 8 percent in each of the first 2 seasons and 12 percent in the third year of the total nitrate-N removed by both crops. The uptake of P, Ca, and Mg by plants was less affected by high manure rates than N, K, and Na uptake. Nitrate-N measured each season in the 0-90 cm depth of manured plots indicated that 58, 47, and 55 percent of the total nitrate remained within the surface 30 cm. However, annual applications of manure at 89, 178, and 267 metric tons per half acre resulted in the greatest downward movement of nitrates. Data did not indicate accumulation of nitrate-N in plants and soil with consecutive manure applications. Manure effects on the soil parameters measured were largely restricted to the top 30 cm of soil, except for exchangeable K and Na which accumulated deeper in the profile at 178 and 267 metric tons per half acre. (Merryman-East Central)

EFFECT OF BEEF-FEEDLOT-LAGOON WATER ON SOIL CHEMICAL PROPERTIES AND GROWTH AND COMPOSITION OF CORN FORAGE,

Kansas State University, Manhattan
G. W. Wallingford, L. S. Murphy, W. L. Powers, and H. L. Manges
Journal of Environmental Quality, Vol. 3, No. 1, p. 74-78, 1974. 6 fig, 3 tab, 6 ref.

Descriptors: Feedlots, Lagoons, Soil properties, Crop response, Irrigation, Salinity, Cattle, Nutrients, Rates of application.
Identifiers: Land application.

A study was conducted to determine growth and composition of corn (Zea mays L) forage and chemical properties of a Kansas soil as affected by furrow irrigation with beef-feedlot lagoon water. The study site was located 9.6 km north of Pratt, Kansas, on a silty clay loam soil with a cation exchange capacity of 19 meg/100g and a pH of 7.0 Rates of 0, 8, 15, 26, and 46 cm per year of lagoon water from a nearby feedlot were applied during the summers of 1970 and 1971 by furrow irrigation. Corn forage yields were recorded and plant content of N, P, K, Ca, Mg, and Na were measured. Surface soil samples and soil cores were taken from the plots after harvest each year. It was found that continued applications of feedlot-lagoon water significantly increased salt content of soil. Increases in electrical conductivity of the soil were linearly related to the amount of lagoon water applied. The heaviest lagoon-water treatments contributed more salts than could be utilized by corn plants or leached into the lower portions of the soil profile. The resultant accumulations could have produced higher osmotic pressures in the soil solution. Nitrate-N accumulated in the soil from the 26 and 46 cm/year lagoon water application reflecting the relatively high N content of lagoon water. Phosphorus also accumulated with lagoon water applications but accumulations were restricted to the surface 20 cm, reflecting lack of movement of P in the soil. Yields of corn forage were maximized at accumulative application rates of about 25 cm of lagoon water over 2 years. At higher rates, yields declined. Maximum removal rates of applied nutrients, an important consideration in maintaining viability of soil, were achieved at the same application rates that produced maximum yields. OUR LAND AND WATER RESOURCES: CURRENT AND PROSPECTIVE SUPPLIES AND USES,

U. S. Department of Agriculture. Economic Research Service.
Miscellaneous Publication No. 1290, U. S. Department of Agriculture, Economic Research Service, May, 1974, 54 p. 18 fig, 34 tab, 26 ref.

Descriptors: Land, Water, Land use, Natural resources, Conservation, Legal aspects, Economics.
Identifiers: Cropland, Land ownership, Government programs, Projections, Energy supplies, Forest land, Timber.

U.S. land and water resources are analyzed as a basis for projecting national agricultural cropland and other land needs to the year 2000. Impact of changes in technology and resource development as well as environmental and institutional factors affecting the availability of these natural resources are discussed. Emphasis is placed on the continuing responsibility of Federal, State, and local governments to assess the adequacy of our natural resources to meet future needs and to improve the quality of the environment. (U.S.D.A.)

PERMIT AND POINT SOURCE PONDERABLES,

Calf News, Vol. 13, No. 10, p. 38, 50, October, 1975

Descriptors: Permits, Feedlots, Legal aspects, Water pollution
Identifiers: Point sources, Environmental Protection Agency, ANCA, Hearings

On September 11, 1975, a hearing was held following the issuance of a Federal Court order requiring EPA to move quickly into an expansion of its discharge permit program for feedlot point sources. ANCA, present at that hearing, recommended that the following additions be made to the current Federal Register definitions of a feedlot. A. Open Lots—(1) The space allotted per animal is equal to or less than four square feet per pound of finished live weight, (2) The period of animal occupancy is 45 days or more per year, and (3) The distance to a receiving stream is less than two feet per 100 pounds of finished live animal weight. B. Housed Lots—(1) Period of animal occupancy is 45 days or more per year, (2) The processed generated waste water exceeds 20 cubic feet per day. Dr. Bart Condon, President of ANCA, stated at the hearing that direct disposal of runoff by switchback waterways and terrace systems provides lower costs as well as best possible technology. He strongly recommended the land application of manure, listing the advantages of this system and suggesting that plant-soil life (serving as a terminal receiver for manure) be classified as a non-point pollution source. It was concluded that the state-operated permit issuing system was the optimum approach. (Cannon-East Central)

VALUE OF POULTRY MANURE IS INCREASING,

Anonymous
Feedstuffs, Vol. 47, No. 33, p. 6, 50, August 18, 1975.

Descriptors: Poultry, Recycling, Economics, Chemical Properties, Fertilizers, Litters.
Identifiers: Refeeding.

Three speakers at a turkey management seminar reported on research concerning reuse of poultry wastes. Dr. Hileman of the University of Arkansas stated that there has been little research dealing specifically with chemical analysis and soil application of turkey wastes. He stated that University of Georgia research showed turkeys to produce 2 pounds of manure for each pound of feed consumed consisting of 70-80 percent moisture and 20-30 percent solids. Average composition of the wet manure was 75 percent moisture, 1.4 percent nitrogen, 0.85 percent phosphorus and 0.7 percent potassium, wet basis. North Carolina research showed average composition of turkey manure with litter to be 74 percent moisture, 1.30 percent N, 0.70 percent P, and 0.50 percent K, or 1.61 percent P_2O_5 and 0.60 percent K_2O. Hileman reported, based on current fertilizer prices, that average value of a ton of turkey litter is $38.96 and average value of a ton of liquid manure is $9.49. Hileman described alternative methods for using turkey manure as fertilizer or soil amendment. Dr. T. Lionel Barton pointed out in his speech that slightly more than 50 percent of the N content of poultry waste is non-protein nitrogen and that its greatest recycling potential is in refeeding to beef cattle. Its chief limitation as a feed is its low energy content. Barton stated that ensiling appears to be the best approach to recycling poultry litter as feed. Dr. M. L. Ray described work in Arkansas in which broiler litter was fed to weaned steers and fattening steers during the winter and in which the litter was used as a supplement in wintering beef cows and calves. He felt that this was the most promising use of poultry litter. (Merryman-East Central)

ACCUMULATIVE EFFECTS OF MANURE AND N ON CONTINUOUS CORN AND CLAY SOIL. II. CHEMICAL CHANGES IN SOIL,

Department of Plant and Soil Science, Vermont University, Burlington
J. L. McIntosh and K. E. Varney
Agronomy Journal, Vol. 65, No. 4, p. 629-632, July-August, 1973. 6 fig, 2 tab, 13 ref.

Descriptors: Soils, Chemical properties, Organic matter, Fertilizers, Nitrogen, Crop response.
Identifiers: Land application, Soil amendments, Manure.

Plots were established in West Addison, Vermont, in 1965 to evaluate the effects of treatments of manure and nitrogen on a Panton clay soil and on corn yield and nutrient uptake. Changes in chemical content of the soil as a result of the treatments are presented. Results concerning corn yield and nutrient uptake were presented in a previous paper. Four rates of manure (0, 22, 44, and 66 tons per ha) and five rates of N (0, 56, 112, 168, and 224 kg per ha) were combined in a factorial arrangement and applied each year to the same plots. Also 120 kg per ha of P and 90 kg per ha of K were applied for 4 years to all plots. Maintenance of structure and fertility had been difficult in this soil. It had not been intensively cultivated even though it lay in large, level fields. Annual applications of about 44 tons per ha of fresh manure were needed to maintain soil organic matter. Percentage of application did not significantly increase rate of breakdown of soil organic matter nor decrease pH. A higher proportion of P originating from manure than from inorganic fertilizer was extracted by soil test for available P (pH 4.8 NH_4OAc. Availability and fixation of K were not affected by source of K nor presence of manure. Moderate applications of manure (up to 44 tons per ha) did not maintain initial levels of soil Ca and Mg. At least 10 times more Ca was lost by leaching than by plant uptake. Similar calculations show 3 times more Mg was lost by plant uptake than by leaching. Test data show the value of fresh manure as a soil amendment in addition to its nutrient content. (Merryman-East Central)

DPW CUTS RUMINANT FEED AND VET COSTS IN DENMARK,

Poultry Digest, Vol. 35, No. 408, p. 74, February, 1976.

Descriptors: Feeds, Performance, Cattle, Costs, Legal aspects.
Identifiers: Refeeding, Denmark.

Denmark has recently allowed marketing of dried poultry waste (DPW) for a period of two years. A successful concentrate mixture contains 40 percent poultry waste which provides 66 percent of the protein intake. Young stock have also been fed successfully on a concentrate containing 50 percent DPW and steers have been fed on a fattening mixture containing 40 percent DPW. Commonly, the waste is mixed with molasses and fat and then pelleted, which gives it a pleasant appearance and texture and a pleasant odor. One interesting claim after 3 years' use of the DPW concentrate mixture was that veterinary bills were reduced 50 percent. Savings in feed costs were estimated at $119 per cow per year. (Merryman-East Central)

CHEAPER WAY TO BUILD MANURE PITS,

Wallaces Farmer, Vol. 101, No. 3, p. 83, February 14, 1976.

Descriptors: Waste storage, Economics, Construction costs.
Identifiers: Manure pits.

The "trench and fill" method for constructing concrete liquid manure pits has been found to cut building costs and get the job done easier and faster. The method works like this. Narrow trenches are dug where the walls will be. The trenches are then filled with concrete, with soil acting as forms for the walls. After the concrete has cured, soil inside the walls is dug out with a backhoe. Then a concrete floor is poured to complete the pit. Agricultural engineers headed by E. C. Miller conducted a study concerning the costs, strength, and practicability for building liquid manure tanks with the trench and fill system. Principles of construction and cautions to be observed are outlined. Soil should be tested to learn more about possible ground water and bearing quality of the soils. The site must be leveled in order to operate effectively with a trencher. The building must be carefully measured and laid out. Pit walls must be reinforced. Six inches of gravel should be tamped into the bottom of the trench in order to reduce time needed to clean up dirt and clay. The operation should be organized so that the trench can be filled in a minimum of time (to guard against the soil collapsing). The trench walls should be lined with polyethylene sheets, which keeps the gravel and dirt out of concrete as it is poured. Final cost of the entire pit project conducted under Miller was $7016. This represented a cost of 5.5 cents per gallon of storage the pit provided. (Merryman-East Central)

WATER POLLUTION FROM AGRICULTURE,

Kungliga Lantbrukshogskolan, Uppsala, Sweden.
N. Brink
Journal Water Pollution Control Federation, Vol. 47, No. 4, p. 789-795, April, 1975. 3 fig, 9 tab, 1 ref.

Descriptors: Agricultural runoff, Water pollution, Fertilizers, Farm wastes, Groundwater, Urine, Livestock, Nitrogen, Phosphorus, Nitrates, Nutrients, Water pollution sources, Europe, Feeds, Feedlots, Sludge, Silage.
Identifiers: Sweden.

Risks of surface and groundwater pollution in Sweden are increasing due to increased livestock production and use of commercial fertilizers in agriculture. Urine and silage juice are especially rich in organic contaminants. Wastewater from dwellings is usually treated in septic tanks before release into open water or infiltration into the ground. To prevent water pollution, manure and silage juice should be spread on arable land. The application of sewage sludge as a fertilizer should not exceed 150 tons per half acre in wet form and be spread at widely spaced intervals. Urine, dungyard water, liquid manure, and silage juice may leak into surface and groundwater from animal stables. Commercial fertilizer use has increased, thus climatic and soil factors are crop growth limiting. Nitrogen is mostly in the form of nitrates, with very small amounts of ammonia. Phosphorus is sometimes very high in groundwater. Chemical reduction probably plays a role in deeper layers, especially in clay soils. The nitrogen budget for a field at Nasbygard, Sweden is given; most of the input went to grain, some to air and water. Neither burning of straw nor excessive fertilizer is acceptable husbandry. EQUIPMENT FOR INCORPORATING SEWAGE SLUDGE AND ANIMAL MANURES INTO THE SOIL,

Department of Biological and Agricultural Engineering, Rutgers — The State University, New Brunswick, New Jersey
H. Reed
Presented at Proceedings of Conference on Land Disposal of Municipal Effluents and Sludges, Rutgers University, New Brunswick, New Jersey, March 12-13, 1973, p. 91-100a.

Descriptors: Equipment, Sewage sludge, Sludge disposal, Farm wastes, Soil disposal fields, Application equipment
Identifiers: Land application

The incorporation of wastes directly into the soil is superior to surface spreading because there is no odor, no opportunity for flies or other pests to feed or breed, and no runoff or surface erosion of wastes. Also, the wastes are placed in the best possible media for immediate degradation to plant nutrients and utilization by plants. The design of an effective land treatment system and the selection of appropriate equipment necessitates the consideration of many factors, some of which are outlined. Presented are equipment and devices used for such application techniques as the ridge-and-furrow method, sub-sod-injection, and plow-furrow-cover. (Sandoski-FIRL)

LITTER AS A FEED FOR BEEF ANIMALS,

Texas A&M University, College Station
C. R. Creger
Poultry Digest, Vol. 35, No. 409, p. 116-117, March, 1976. 6 tab.

Descriptors: Litters, Feeds, Performance, Cattle, Fermentation, Silage, Moisture content.
Identifiers: Refeeding, Ensiling, Poultry litter.

At a Texas A&M University laboratory, poultry manure was fed to beef cattle. The broiler litter was fermented in an upright silo at a moisture content of 35 to 40 percent for a 6 to 8 week period. The protein content varied not only with the number of groups of birds reared on the litter, but also with the type of feed management that takes place in the house. Broiler litter silage was fed ad libitum to 15 heifer calves weighing an average of 477 pounds each. Eight pounds per head of a 12 percent protein mixture, consisting of ground milo, dehydrated alfalfa meal, soybean meal, molasses and vitamin A and D, was poured over the silage daily. An average of 12 pounds of silage per head, per day was consumed. After 120 days of feeding, the calves gained 2.54 pounds per head, per day when fed the broiler litter silage ad libitum along with 12 percent protein mix. Feed was also formulated from chicken and turkey droppings without going through the fermentation process. This increased the chance of salmonella contamination of the feed. The dried poultry waste was found to be an acceptable ration when mixed with one half corn or sorghum grain and 200 pounds of molasses per ton. In a field study, 350 head of feeder calves gained 2.63 pounds per head, per day and consumed an average of 10.8 pounds of a 60:40 mix of litter: milo ration over a 120-day period. SWINE WASTE CHARACTERIZATION AND EVALUATION OF ANIMAL WASTE TREATMENT ALTERNATIVES,

Department of Biological and Agricultural Engineering, North Carolina State University, Raleigh
F. J. Humenik
Report No. 61, Water Resources Research Institute, North Carolina State University, Raleigh, June, 1972, 152 p. 19 fig, 41 tab, 48 ref.

Descriptors: Swine, Land disposal, Lysimeter studies, Chlorotetracycline

A study was made to evaluate analytical techniques for the characterization of swine wastes and to study methods for the treatment and disposal of animal wastes. Laboratory work provided for the analytical evaluation of the following swine waste treatment alternatives: a single unaerated lagoon, two unaerated lagoons in series, and packed soil lysimeters for land application of lagoon effluent. Work was also initiated on the application of liquid dairy manure to lysimeters. The concentrations of feed additive chlorotetracycline, copper, and zinc in swine feces, lagoon influent, lagoon effluent and BOD bioassay solutions were determined. Analyses of the experimental data for the BOD bioassay showed that results depend upon sample history, type and amount of seed organisms, incubation conditions and sample size. It was found that the unaerated series lagoon system for swine waste provides greater reduction in pollutional potential than just the original single unaerated lagoon. Data correlations and characterization values for the Precision Scientific instrumental chemical oxygen demand analyzer and Beckman organic carbon analyzer were developed for animal waste. Recommendations were presented for obtaining accurate and consistent characterization data for animal waste and suggestions were made for obtaining the most reliable BOD5 results, particularly for swine waste. AGRICULTURE'S PLACE IN THE ENVIRONMENT: CONSIDERATIONS FOR DECISION MAKING,

Senior Specialist, Agricultural Chemicals, Office of Agriculture, Technical Assistance Bureau, Agency for International Development, Washington, D. C.
W. H. Garman
Journal of Environmental Quality, Vol. 2, No. 3, p. 327-333, 1973. 22 ref.

Descriptors: Rainfall, Runoff, Nitrogen, Eutrophication, Water quality, Nutrients, Phosphorus, Carbon.
Identifiers: Livestock wastes, Nutrient cycling.

In terms of land area and value of natural resources, agriculture and forestry constitute the largest environmental complex on earth. The major problems are sediment and dust and organic wastes from livestock and the food and forestry processing industries. Near livestock feedlots, cities, and certain types of industrial plants, large amounts of N in such forms as nitrogen oxides and ammonia occur in the rain. Many people believe that the only solution to the 2 billion metric tons of livestock manure is to spread more and more of it on rural lands. This will cause a shift from huge feeding operations to smaller ones with lower-density stocking. This shift will facilitate control of waste runoff as well as getting manure spread on the surrounding land. The cost will be high because the value of the nutrients will not pay for the equipment and labor required. Hopefully, new on-farm technology will provide means of handling livestock wastes to protect both streams and underground waters. Small amounts of nutrients are lost to surface or underground water when farmland is maintained in a high state of fertility. Many towns, cities, and factories have added waste treatment before dumping effluents into streams. This has greatly reduced the biological oxygen demand (BOD) on the stream. (Cameron-East Central)

TWO-PHASE ANAEROBIC DIGESTION OF POULTRY WASTE,

Agricultural Engineering Department, University of Georgia, Athens
R. E. Smith, M. J. Reed and J. T. Kiker
Presented at the 1975 Winter Meeting, American Society of Agricultural Engineers, Chicago, Illinois, December 15-18, 1975, Paper No. 75-4544, 23 p. 4 fig, 3 tab, 17 ref.

Descriptors: Design, Animal wastes, Anaerobic digestion, Poultry, Methane, Recycling.
Identifiers: Volatile acid, Digesters, Kinetic reaction.

Research was carried out at the University of Georgia to design and construct an anaerobic filter to demonstrate and obtain operating experience in the production of methane gas from animal waste. Tests were conducted with practical arrangements to produce a volatile acids substrate from poultry waste for use with the anaerobic filter. The objective was to produce a substrate relatively free of suspended solids and with a high concentration of volatile acids. It was noted during the preliminary operation of the methane digester that during a period of steady-state there was an apparent mass balance between the total gas production and the mass decrease in volatile acids from the influent and effluent concentrations and the mass flow rate of wastewater. Steady-state operation was effectively obtained after 2-3 days of operation under a set of conditions. The greatest time lag for a parameter to reach a steady value was in the effluent concentration. Research results appear to support the statement that the specific growth rate, O_c^{-1}, is related only to the hydraulic control of the reactor. It was observed that in the volatile acids digesters the concentration build-up of ammonia usually was about numerically equal to the volatile acids concentration. Values of pH for the effluent of the digester during the period was most often in the range of 6.5 to 7.5 (Cameron-East Central)

DISPOSAL OF CATTLE FEEDLOT WASTE IN AN ANAEROBIC LAGOON ON THE ORGANIC SOILS OF SOUTH FLORIDA--PRELIMINARY RESULTS,

Assistant Animal Nutritionist Agricultural Research and Education Center Belle Glade, Florida
F.M. Pate, B. G. Volk, T. W. Casselman, and J. R. Crockett
Proceedings, Soil and Crop Science Society of Florida, Vol. 33, p. 224-227, 1974. 4 fig, 2 tab, 15 ref.

Descriptors: Groundwater pollution, Feedlots, Florida, Lagoons, Waste disposal, Chemical properties

A study was conducted to determine the effectiveness of an anaerobic lagoon for holding beef feedlot wastes on the organic soils of south Florida. A series of tests wells were drilled 7.6, 30.5, and 61.0 m from the lagoon to monitor changes in groundwater quality. NH_3-N, NO_3-N, dissolved PO_4-P, chemical oxygen demand, and K were 2.0, 0.02, 0.04, 225, and 15 mg/liter, respectively. The highest levels of NH_3-N, NO_3-N, dissolved PO_4-P, chemical oxygen demand and K observed in lagon water were 125, 0.7, 36, 4000, and 280 mg/liter, respectively. These levels occured when manure disposal was stopped, 5 months after disposal began. The chemicals monitored rapidly diminished after manure disposal into the lagoon stopped. The only observed increase in groundwater of these chemicals was in one of 6 wells 7.6 from the lagoon. From these results, it was deducted that a moderate sized waste disposal lagoon on the organic soil region of south Florida will not immediately contaminate the surrounding groundwater, even though there was active water movement to and from the lagoon. AN EXPERIMENTAL STUDY ON THE PRODUCTION OF SUBSTITUTE NATURAL GAS BY HYDROGASIFICATION OF LIVESTOCK MANURE,

J. Martinez and A. Carlos
PhD Dissertation, Department of Chemical and Petroleum Engineering, University of Kansas, 1973, 113 p. 18 fig, 27 tab, 29 ref.

Descriptors: Recycling, Gases, Moisture contents, Temperature, Cattle.
Identifiers: Hydrogasification, Livestock wastes.

An experimental program was conducted in a batch reactor to determine the effects of process parameters on the yield of products when cow manure is hydrogasified. The assumption was made that the most valuable product would be the mixture of combustible gases resulting from hydrogasification of the carbon in the manure. Experiments were conducted for various (1) moisture contents, (2) initial amounts of hydrogen charged to the reactor, and (3) final maximum reactor temperatures. The general performance of the hydrogasification unit was highly satisfactory during the development of the experimental procedure. The best run yielded a product gas with a calculated heating value of 3722 net Btu/lb dry manure. This experiment was conducted with a 50 percent manure moisture content and 50 psig of hydrogen charged per 25 g. of dry manure. The analysis (on dry basis) of a gas sample taken two hours after reaching 1050 degrees F was: 14.6 percent CH_4, 11.5 percent C_2H_6, and 34.5 percent CO_2. For this run, 51 percent of the carbon in the manure was gasified to hydrocarbons and carbon dioxide, or 32 percent gasified to hydrocarbons. The heating unit was designed for a maximum temperature of 1350 degrees F but only temperatures of about 1280 degrees F were obtained. The maximum temperature reached in the reactor under these circumstances was between 1050 and 1080 degrees F. Further research is needed to determine fully the economic feasibility of the process when applied to this feedstock. (Cameron-East Central)

CHEMICAL AND MICROBIOLOGICAL CHANGE IN POULTRY LITTER APPLIED TO SOIL AS INFLUENCED BY THE TIME AND METHOD OF APPLICATION,

A. M. Rao
PhD Dissertation, University of Georgia, 1973, 90 p. 22 fig. 12 tab, 75 ref.

Descriptors: Poultry, Litter, Chemical properties, Microorganisms, Waste disposal, Application rates, Soils, Ammonia, Coliforms.
Identifiers: Land application, Application method, Decomposition.

An investigation was conducted to determine the number and types of microorganisms during decomposition of poultry litter in soil and the effect of interval and method of poultry litter application on some soil properties with particular emphasis on possible contribution to surface and underground water pollution. The persistence and effect of ammonia concentration on coliform bacteria were also studied. These experiments were conducted both in the laboratory and in the field over a two-year-period. Laboratory studies were conducted mainly to obtain initial information for the field experiment. Separate experiments were conducted to determine (a) the effect of drying on N loss in fresh droppings, (b) the effect of rate, method and time of application of litter on nitrification, and (c) the changes in the microbial ecology of decomposing poultry droppings and litter upon incubation with and without soil. The field experiment was initiated to determine the effect of method and time of application of poultry manure on (a) soil NO_3-N and other nutrients' vertical distribution in the soil profile, and (b) the number and relative abundance of major groups of soil microflora including coliform bacteria. Specific results obtained in these experiments are given for both the laboratory and field studies. It was felt that the combination of an N responding crop with litter application might provide a safer and more efficient disposal method than trying to reduce nitrates by frequent applications. The abundance and movement of soil microflora was increased by litter application, but coliforms were not greatly increased. Pollution of streams by pathogens from poultry manure would more likely occur from surface runoff than from groundwater. (Cameron-East Central)

REFEEDING ANIMAL WASTE,

Beef editor
B. Eftink
Successful Farming, Vol. 74, No. 5, p. 26-27, March 1976. 5 fig.

Descriptors: Dairy industry, Feeds, Silage, Legal aspects, Economics

Identifiers: Refeeding, Ensiling, Grazon process

Although other segments of the animal industry are experimenting with refeeding waste, the beef feeding industry has confirmed that cattle actually do better on rations containing manure. Cattle have three advantages over other animals. They can use all three forms of nitrogen, they can extract energy from fibrous materials and their system acts as a filter for undesirable contaminants. W. B. Anthony of Auburn University says there are two approaches to refeeding—separate the waste into its liquid and dry component parts or handle it as it is. He feels that for small operators, using fresh manure as part of a silage mix is the most practical. Sam Hay, of Covington, Georgia mixes 40 lbs. of manure with 45 lbs. of cracked shelled corn and 15 lbs. of silage to form a 12 percent protein ration. Gains are better than on standard feed, and this way manure is worth $62 a ton when corn is selling for $3.50 a bushel. At Illinois, researchers have skipped the ensiling process by spraying a chemical on the raw manure to deodorize and kill pathogens, then mixing 50 percent manure, 25 percent corn, and 25 percent cottonseed hull. Although the FDA remains mute, Dave Seckler states that manure is valuable as fertilizer but more valuable as feed and fuel. (Cameron-East Central)

AMMONIA ELIMINATED WHILE DROPPINGS ARE DRIER,

Poultry Digest, Vol. 35, No. 408, p. 66, February, 1976.

Descriptors: Waste treatment, Ammonia, Poultry.
Identifiers: Animal health, Superphosphate, Drying effect.

Hy Cross Chick Company applied superphosphate to the droppings in the earth bottom pits of brooder grow cages and in cage laying houses in order to prevent possible eye burn in the chicks. When superphosphate became unavailable and too expensive, a new odor control product, consisting of a soluble extract of seaweed dissolved in natural steroid saponins, was used in the place of the superphosphate. This new product was applied in liquid form every three days. Ammonia was completely eliminated in less than 12 hours, and a terrific drying effect on the manure was noticed in the same length of time. (Cameron-East Central)

GAS TOXICOSIS: SUDDEN DEATH IN CONFINEMENT,

Successful Farming, Vol. 74, No. 5, p. H33, March, 1976.

Descriptors: Confinement pens, Air pollution, Carbon dioxide, Ammonia, Hydrogen sulfide, Methane, Toxicity.
Identifiers: Swine, Gas toxicosis.

Gas toxicosis may be a cause for sudden death of hogs in confinement. Signs of gas toxicosis are muscular spasms, breathing difficulty, and then unconsciousness. Ventilation should be increased immediately upon first notice of these signs. There are four major gases released from anaerobic swine manure pits, all of which can kill—carbon dioxide, ammonia, hydrogen sulfide and methane. Carbon dioxide must be present in extremely high atmospheric levels before adversely affecting the swine. According to Iowa State University Extension veterinarian Jim McKean, ammonia levels in confinement are often the cause of gas toxicosis. Ammonia irritates the mucous membranes of the pig, and prolonged exposure may irritate the respiratory passages, leading to tracheitis or bronchopneumonia. Hydrogen sulfide is the most harmful toxic gas released from anaerobic pits. This gas is most prominent when the pits are emptied or contents are agitated. Methane is explosive in high concentration and affects swine by reducing the available oxygen in the building. To prevent gas toxicosis, confinement buildings need a minimum ventilation rate of 20 cu. ft. of fresh air per minute per sow and litter. During winter months, miminum ventilation rates are 15, 25, and 36 cu. ft. of air per minute for hogs weighing 50, 125 and 200 lbs. respectively. (Cameron-East Central)

MANURE AND THE NITRATE PROBLEM,

Delaware University, Newark 19711
W. C. Liebhardt
Lime and Fertilizer Conference, Delaware-Maryland Plant Food Association Proceedings, 1972, 2 p. 2 tab.

Descriptors: Recycling, Crop response, Poultry, Nitrates, Groundwater pollution.
Identifiers: Land disposal, Application rates.

In Delaware there are approximately 140 million chickens grown each year. The amount of waste these chickens produce is greater than the amount of solid waste produced by New York City. The waste is being recycled back to the soil at so great a rate that it is reducing the crop yield. Another problem is that with the sandy soil and high water table, nitrates may leach into the ground water supply. Public health standards set the limit for NO_3-N at 10 ppm. In soil samples taken at a depth of 4 ft, the level found in the ground water usually exceeded this amount. Poultry manure is being added to the soil at rates of 10 to 100 tons per acre. Ten tons of manure contains approximately 254 pounds of N, 108 pounds of P_2O_5 and 185 pounds of K_2O plus secondary and micronutrients. The corn yield at this rate is about 55.6 bushels per acre. At 100 tons of manure per acre, the yield was about 14 bushels per acre, a substantial reduction. (Cannon-East Central)

AN EVALUATION OF A RECYCLING WASTE TREATMENT SYSTEM FOR DAIRY CATTLE MANURE,

J. C. Nye
PhD Dissertation, Purdue University, 1971, 120 p. 9 fig, 38 tab, 68 ref.

Descriptors: Recycling, Proteins, Microorganisms, Feeds, Proteins, Physical properties, Separation techniques.
Identifiers: Substrate, Dairy manure.

This study evaluated the feasibility of growing micro-organisms on manure as a source of protein for animal feed. The study was conducted as a four phase investigation including: (1) evaluation of a particle size separation of dairy cattle manure (the objective was to determine the optimum particle size limit and dilution level for separation of usable feed and feed residue from the dairy cattle manure), (2) batch culture of micro-organisms (the objective was to determine the time of maximum microbial population for a mixed culture of micro-organisms), (3) continuous cultures of micro-organisms (the objective was to investigate the conditions associated with the highest quality microbial protein supplement), and (4) evaluation of the centrifugally harvested micro-organisms as a high protein feed supplement (the objective was to determine the chemical and biological value of the microbial product as a protein supplement). Conclusions of the study were: (1) Separation of dairy cattle feces through a 595 micron opening removes a low quality roughage material from the remaining liquid waste, (2) The liquid waste removed by such a separation is a suitable substrate for the growth of bacteria, (3) The bacteria grown are a satisfactory protein supplement containing 30 percent crude protein, (4) The microbial protein product is an adequate feed supplement as 20 percent of the ration, and (5) The waste treatment-food synthesis system proposed is an economically feasible alternative for livestock operations. (Cameron-East Central)

HOW TO SAVE SWINE WASTE VALUE,

Successful Farming, Vol. 74, No. 5, p. 46, March, 1976.

Descriptors: Farm wastes, Fertilizers, Nitrogen, Phosphorus, Potassium, Economics
Identifiers: Swine, Land disposal

Nearly 70 percent of the nitrogen and phosphorus and almost 90 percent of the potassium in swine rations are excreted in waste and urine and can be recycled again for fertilizer. How these waste resources are handled makes a big difference in their value. Seventy percent of nitrogen, phosphate, and potash are excreted in the form of solid wastes. Urine contains the other 30 percent of the nitrogen, 20 percent of the phosphorus and 55 percent of the potassium. Bedded systems and deep anaerobic pit systems best conserve nitrogen. Much nitrogen may be lost from manure if it is subjected to warm, dry conditions before being disked or plowed under. Nitrogen losses may also result if runoff or snow melt occurs prior to incorporating the manure into the soil. Most systems conserve phosphorus and potassium quite well with two exceptions: (1) where runoff from outside lots is significant; (2) where prolonged use of lagoon allows a sludge buildup in the bottom of the lagoon. Unless this sludge can be reconstituted, the elements will be lost. (Cameron-East Central)

AGRICULTURE AND CLEAN WATER—PROCEEDINGS OF A CONFERENCE TO EXPLORE CONTROL STRATEGY FOR AGRICULTURAL NONPOINT SOURCE WATER POLLUTION,

Midwest Research Institute, Kansas City, Missouri
C. C. Chappelow
Agriculture and Clean Water—Proceedings of a Conference to Explore Control Strategy for Agricultural Nonpoint Source Water Pollution, Kansas City, Missouri, April 3, 1975, 153 p.

Descriptors: Water pollution control, Water quality, Legal aspects, Farm wastes, Sediment control, Soil conservation.
Identifiers: Nonpoint source pollution, Plant nutrients, Control planning.

A 1-day conference was held to promote a constructive dialogue on the development of plans for the control of agriculture related nonpoint source pollution arising from sediment erosion, fertilizer runoff, livestock wastes and pesticide residues. The morning session was devoted to an analysis of the state of the art on nonpoint source pollution related to agriculture with presentations on: (1) regional aspects and viewpoints; (2) agricultural pollution control; (3) technical basis of control; (4) conservation districts; (5) soil conservation; and (6) plant nutrients. The luncheon session was concerned with an economic overview, consisting of an address on economic problems and opportunities of pollution control. The afternoon session was designed to explore elements of control strategy planning for nonpoint pollution from agricultural sources with papers on: (1) the state's role; (2) one state's approach; and (3) the role of the farmer and agribusiness. The afternoon session was concluded with a panel discussion on the development of a practicable agricultural pollution control plan. Over 175 individuals from 20 different states representing local, state, regional, and federal agricultural and environmental agencies attended the conference. Also, included in the 75 different organizations represented at the conference were attendees from farmer associations, educational institutions, and agribusiness.

AGRICULTURAL SEDIMENT CONTROL FOR WATER QUALITY PROTECTION,

Chief, Special Sources Control Branch. Office of Air and Water Programs, Environmental Protection Agency
W. C. Shilling
Agriculture and Clean Water—Proceedings of a Conference to Explore Control Strategy for Agricultural Nonpoint Source Water Pollution, Kansas City, Missouri, April 3, 1975, p. 19-26.

Descriptors: Sediments, Agriculture, Water quality, Soil conservation, Animal wastes, Control
Identifiers: Public Law 92-500

William C. Shilling briefly discussed three major areas of agricultural sediment control. They are the (1) impact of agricultural sediments on water quality and the control of these sediments, (2) nonpoint control features of Public Law 92-500, and (3) state and local control programs. The impact of agricultural sediments on water quality generally falls into three categories. First, there are the direct effects of the sediments. These sediments settle to the bottom of some body of water and smother some of the bottom organisms. They reduce penetration of light, thus affecting the photosynthesis processes. They also have an aesthetic effect. Second, the sediments act as carriers of potentially pollutional materials. Third, they place varying oxygen demands on the water body. Animal waste and crop residue that forms a part of the sediments in a total sense are organic materials and will utilize oxygen in their decomposition. Different sections of Public Law 92-500 are given in relation to the control of nonpoint sources or agricultural sediments. Mr. Shilling believes that local expertise must be involved from the beginning in the planning, development, and inplementation of the management programs. Four items which he deems important are: (1) if a control program for agricultural sediments is to be effective, it must be tailored to local conditions, (2) we must determine our priorities and develop and implement an effective control program, (3) a distinction must be made between soil conservation and water quality protection, and (4) 208 planning and 305 (b) state reports preparation are either on-going or being initiated, and those with specific knowledge in the control of agricultural sediments should make their expertise available for these efforts. (Cameron-East Central)

STATES ROLE IN FORMULATING CONTROL STRATEGY,

Secretary of Health and Environment, Kansas State Department of Health and Environment
D. F. Metzler
Agriculture and Clean Water—Proceedings of a Conference to Explore Control Strategy for Agricultural Nonpoint Source Water Pollution, Kansas City, Missouri, April 3, 1975, p. 83-92.

Descriptors: Sediments, Water pollution control, Agriculture, Nitrogen, Kansas.
Identifiers: Fecal coliforms.

Mr. D. F. Metzler states that in the Kansas area, the problem of controlling agricultural pollution is caused by too much sediment and too much nitrogen. He feels in order to develop a strategy which is rational in controlling the pollution, one should ask—does it affect human health, is it needed because it affects human health, is it needed because it improves the quality of fish or wildlife, or is it needed in order to control algal growth or the growths of weeds. Every river basin is different and different control strategies are required. Most of the time, all the major streams within Kansas are in compliance with the standards which Kansas has adopted and which are a part of the standards filed with EPA. The total dissolved solids concentration and the fecal coliform content represent the areas of most frequent violation. Fecal coliform violations occur usually as a result of rainfall and excessive runoff or snowmelt and the accompanying runoff. The fecal coliform standard was violated approximately 25 percent of the time directly as a result of nonpoint source runoff. The fecal coliform effluent limitation for treated domestic wastewater discharges are 200 fecal coliforms per 100 ml, and this is an extremely stringent limit; few wastewater discharges in Kansas now meet it. However, at low stream flow, the fecal coliform standards of 400/100 ml in Class A waters and 2,000/100 ml in Class B waters are rarely violated. In summary, the solution to the control problem requires careful planning and a rational approach. It requires major financial commitment on the part of the agricultural industry, and government. PROPERTIES RELATED TO UTILIZATION,

Department of Agricultural Engineering, University of Illinois at Urbana-Champaign
D. L. Day and B. G. Harmon
Presented at the Animal Waste Conference, ASAE Committee SE-412, Chicago, Illinois, December 11-12, 1972, 11 p. 7 tab, 21 ref.

Descriptors: Animal wastes, Physical properties, Chemical properties, Biological properties, Livestock, Recycling, Fuels, Pyrolysis, Hydrogenation, Nutrients.
Identifiers: Refeeding, Land disposal, Soil builders.

Throughout the ages, the major methods of livestock manure utilization have been (a) spreading on cropland for crop production and to build the soil, (b) consumption of manure by animals (coprophagy), and (c) heating (manure pack and burning dried dung). This paper reviews properties of livestock manures that are of interest for utilizing the manure as crop nutrients, soil builders, animal nutrients, and fuels. Physical, chemical, biological, and thermal properties are discussed as related to some current utilization methods. At least sixteen elements are considered necessary for the growth of green plants. These are: carbon, hydrogen, oxygen, nitrogen, phosphorus, sulfur, potassium, calcium, magnesium, iron, manganese, zinc, copper, molybdenun, boron, and chlorine. Practically all of these plant nutrients can be found in manure. Animal waste, as excreted, consists of undigested and unabsorbed feed ingredients, catabolic products of metabolism, expended secretions, and tissue and microbial cells. Because these contain both organic and inorganic dietary essentials for animals, refeeding of these wastes has been found feasible. Production of gas and oil from manure has been developed by two processes. One is a pyrolysis method in which the manure is heated for about six hours at about 900 degrees C in a closed system at atmospheric pressure without the addition of air or other gas. The manure is converted to gas, oil, and solids, all of which can be used as fuels. The second method, hydrogenation, consists of heating the manure for twenty minutes at 380 degrees C under pressures of 2,000 to 6,000 p.s.i. in the presence of carbon monoxide and steam. Because of the calcium, sodium, and potassium content of the manure, the addition of catalysts is not necessary. The resulting product is a heavy, largely parafinic oil with a heating value of 14,000 to 16,000 Btu per pound. (Cameron-East Central)

THE POTENTIAL OF MANURE PYROLYSIS FOR AMMONIA PRODUCTION AND ELECTRIC POWER GENERATION IN KANSAS,

Department of Chemical Engineering, Kansas Agricultural Experiment Station, Manhattan
C. R. Engler, W. P. Walawender, and L. T. Fan
Contribution No. 39, Department of Chemical Engineering, Kansas Agricultural Experiment Station (Project Ch.E. 0880-Feedlot Waste Conversion), Manhattan, Kansas, 16 p. 3 fig, 4 tab, 5 ref.

Descriptors: Recycling, Ammonia, Electric power, Kansas, Costs.
Identifiers: Feedlot wastes, Pyrolysis, Synthesis gas.

To determine the potential for large capacity pyrolysis plants in Kansas, feedlot manure generation and possible synthesis gas usage in the southwest quarter of the state were studied. Feedlot capacity data were collected and organized into regions that could support moderate-to large-scale pyrolysis plants. The process consisted of a feed preparation section where incoming manure was dried and ground, a pyrolysis section where the manure was gasified at 1500 degrees F in a fluidized bed reactor, and a gas clean-up section where CO_2 and other undesirable gaseous by-products were removed. Heat requirements for the pyrolysis reactor and manure drying were supplied by burning char in a fluidized bed combustion reactor. Annual operating costs for a moderately large plant processing 2500 T/D would be approximately $10 million. Assuming the manure would be available within an average hauling distance of 25 miles, the cost basis for transportation would be $0.06/T/mile. The annual usage of nitrogen from commercial fertilizers was estimated for the southwest quarter of Kansas in order to determine the potential contribution of manure synthesis gas. Based on sales reported for that area, approximately 175,000 T of nitrogen were used annually, which is equivalent to 212,000 T of ammonia. Feedlot manure could be used as fuel for the small generating plants in western Kansas. However, it would not be economical to gasify the manure since low-capacity pyrolysis plants are quite expensive. An alternate route would be direct combustion of the manure to fire steam boilers. Results show that the potential for utilization of synthesis gas from moderate-to large-scale manure pyrolysis plants appears to be good for southwestern Kansas. In particular, either producing ammonia or generating electricity could directly benefit feedlot operators and other residents of the area. (Cameron-East Central)

ANIMAL SCIENTIST WARNS RESTRICTIONS COMING ON RECYCLING, ANTIBIOTIC USES,

Beef, Vol. 12, No. 7, p. 17, March, 1976

Descriptors: Feed additives, Legal aspects, Antibiotics, Cattle, Nitrates, Nitrites.
Identifiers: Refeeding, Restrictions, Food and Drug Administration, Drug residues, Chemical residues.

Bill Hale, University of Arizona animal scientist, reported on the drug and chemical residue problems in cattle at a meeting of the ANCA environmental sciences committee at Phoenix. Hale warned: (1) The latest FDA efforts seem to be that new rules would eliminate both DES and other growth promotants, such as Ralgro and Synovex-with far reaching consequences to the cattle industry. (2) Restrictions on low-level antibiotic feeding are possible in the near future. The rules probably will prevent using any antibiotic for low level feeding that is also used in human medicine. Also it is likely that any new antibiotic will be quickly moved from livestock to human use, and taken out of the livestock medicine chest. (3) With six states already having rules about refeeding livestock wastes, the FDA probably will stay out of the refeeding problem. (4) The increase in the number of pesticide and herbicide residues in beef cattle carcasses is liable to continue. Cattlemen who feed byproducts need ways to check for chemicals on the byproducts. (5) There is a nitrate and nitrite question in cured meats. Hale warned the ANCA session that a lot of beef goes into sausage, which might be hit hard if the feed preservatives were outlawed. He also noted that the current publicity is unfair—since only 20 per cent of the nitrates and nitrites in a human diet come from cured meat. The other 80 per cent comes from natural levels in vegetables. (Cameron-East Central)

RECYCLING ANIMAL WASTE AS A FEEDSTUFF: A REVIEW,

Consultant, World Bank Project, Adakale Sokāk No. 51, Yenisehir, Ankara, Turkey
A. N. Bhattacharya and J. C. Taylor
Journal of Animal Science, Vol. 41, No. 5, p. 1438-1457, November, 1975. 5 tab, 25 ref.

Descriptors: Recycling, Literature review, Poultry, Cattle, Sheep, Feed additives, Performance, Chemical properties, Biological properties, Nutrients, Diseases, Public health, Arsenic, Antibiotics, Hormones, Pesticides, Waste storage, Microorganisms, Waste treatment, Physical treatment, Chemical treatment.
Identifiers: Refeeding, Swine, Broiler litter, Animal health.

The solid waste from farm animals in the United States is estimated at two billion tons annually. It is also estimated that 50 percent of these wastes are produced by intensive animal production systems. Studies have been conducted and others are planned which have been designed to establish the safety of processed animal wastes to animal and man. This paper summarizes the available information on: (1) the nutritional value of different kinds of animal wastes as feed for livestock and poultry; (2) the identity of possible agents which may cause human and animal health hazards; and (3) the effect of processing methods on the safety of such animal waste feed. LAGOON LINER STOPS SEEPAGE,

Successful Farming, Vol. 74, No. 5, p. H24, March, 1976. 1 fig.

Descriptors: Lagoons, Seepage, Waste storage, Costs.
Identifiers: Swine, Liners, Manure, Chlorinated polyethylene, Land disposal.

Because light, sandy and very permeable soil posed a problem for a lagoon system, Boar Power (a breeding stock firm) selected a reinforced chlorinated polyethylene liner for the lagoon. This type of material is used for similar purposes at chemical manufacturing plants. The liner is 30 mils thick and costs approximately $10,000, including installation. Minimum expected life for the liner is 20 years. Jim Church, supervisor of the project says the plan is to pump out of the lagoon, losing nothing through seepage. Stewart Melvin, Iowa State agricultural engineer, says it would be difficult to justify that kind of expense for a commercial operation, but says lagoons of this type plus a low-cost irrigation system "could be the most practical" hog waste disposal system. (Cameron-East Central)

DETERMINATION OF AMMONIUM NITROGEN IN ANIMAL SLURRIES BY AN AMMONIA ELECTRODE,

The Agricultural Institute, Johnstown Castle, Wexford, Ireland
E. Byrne and T. Power
Communications in Soil Science and Plant Analysis, Vol. 5, No. 1, p. 51-65, 1974. 4 tab, 6 ref.

Descriptors: Nitrogen, Slurries, Cattle, Poultry, Measurement.
Identifiers: Ammonia electrode, Ammonium, Extractants, Swine.

The use of the Orion ammonia electrode technique to measure ammonium nitrogen in animal slurries is described. The twenty-two animal slurries used were selected from various sources and include a range of cattle, pig and poultry samples. Four different extraction times were tried for both 0.1N HCl and H_2O, "Quick" (10 secs.), 10 minutes, 1 hour and 16 hours. Analysis of the "HCl" data showed no difference between times of extraction. In the "H_2O" series the overnight result was significantly lower (P less than .001) than the other times between which there was no difference. Extraction with 0.1N HCl gave a result intermediate between the 0.1N HCl and H_2O. For all samples the 0.1N HCl result was higher than the H20 result. Results indicated that several extractions are necessary to remove all the water soluble ammonium. One extraction with 0.1N HCl will remove the same amount. Conclusions showed that the ammonia electrode is rapid and sufficiently accurate for the determination of ammonium in animal slurries. No interference effects were detected and it compares satisfactorily with the distillation procedure. Ammonium nitrogen, closely related to soluble nitrogen in animal slurries, may be used to give an estimate of the total nitrogen content, or could be used to indicate the efficiency of the slurry relative to fertiliser nitrogen. STATE OF THE ART OF THE PREPARATION TECHNIQUE OF LIQUID MANURE,

A. G. Forster
Landtechnik, No. 22, p. 584-586, November, 1971. 4 fig.

Descriptors: Liquid wastes, Waste treatment, Physical treatment, Biological treatment, Solid wastes, Lagoons, Drying.
Identifiers: State of the art.

Several methods of preparing liquid manure are known. Mechanical treatment is performed by centrifuge, decanter, screening machine, or mangle. It serves the purpose of separating liquid from solid substances, in order to economize the storage of the manure or to treat the liquid biologically as in Italy, England, or the United States. The thermal treatment, drying the dung, deodorizes, sterilizes, and reduces volume but it does not solve the emission problem. In the biological method, microorganisms decompose the organic substance in the dung. In the anaerobic process, microorganisms take the necessary oxygen from oxygen compounds like nitrates; however, this process does not furnish many final products, but a lot of intermediate products which can still be oxidized. For highly concentrated liquids, like manure, this process is not adapted. In the aerobic process, organic compounds oxidize into carbon dioxide and water; the developing energy is used for further cell construction. The aerobic process can be conducted in cold, warm and hot treatment systems. Cold treatment systems can be placed outside, like oxidation ditches. Outside systems are storage bins, oxidation towers, and aerobic lagoons. Both systems handle only easily decomposable substances but not the total organic substance. (Solid Waste Information Retrieval System)

HOW ONE TRIES IN THE USA TO SOLVE ANIMAL WASTE PROBLEMS?,

G. Blanken
Landtechnik, Vol. 23, No. 24, p. 609-612, December, 1971. 7 fig.

Descriptors: Lagoons, Liquid wastes, Drying, Recycling, Humus.
Identifiers: Oxidation ditch, Composting, Soil amendments.

The most economic method of disposing of animal waste is the lagoon, into which the animal waste is led. Another method is removal by oxidation ditches, which are situated directly under the stable floor, provided with gaps. The ditches are connected with each other, so that liquid manure can circulate; this is effected by a rotor provided with brushes. The rotor also continuously adds oxygen to the manure, to promote decomposition. Tests have been done to transform manure into dry feces or humus, by continuous air ventilation in the stable, and by using a revolving device, in the ditches, which dries the manure down to 30 percent water. A special kind of compost is prepared by adding bark flour to the manure. This mixture is kept in clamps and then processed into flower soil. (Solid Waste Information Retrieval System)

MOLE MOUNDS—A NEW SYSTEM OF MANURE REMOVAL,

Landtechnik, Vol. 26, No. 10, p. 263, May, 1971.

Descriptors: Waste storage, Solid wastes.
Identifiers: Mounding, Mole mounds, Sweden.

A new method of cleaning cattle barns has been developed in Sweden. A hydraulically driven piston presses the dung from the stable into the dung stock through a subterranean tube system, 180 mm in diameter. The tube system is protected against freezing by the soil; the opening of the tube is protected by the dung itself. The new dung settles in the middle of the mound which avoids bad odor formation. The tube system is independent of the quality and quantity of dung. (Solid Waste Information Retrieval System)

ENGINEERING CHALLENGES OF ANIMAL PRODUCTION ODOR CONTROL,

Department of Agricultural Engineering, Oregon State University, Corvallis
J. R. Miner
Presented at the Second National Conference on Complete Water Reuse: Water's Interface with Energy, Air and Solids, Chicago, Illinois, May 4-8, 1975, 16 p. 1 fig, 3 tab, 20 ref.

Descriptors: Feedlots, Management, Biological treatment, Physical control.
Identifiers: Odor identification, Odor measurement, Odor control, Olfaction, Chemical treatment.

This paper examines the nature of livestock odors, their identification, measurement and control, and design and management techniques that facilitate their control. Odor contributors are fresh manure, livestock feeds, and odors from the animals themselves. Among the theories of olfaction, the stereochemical theory of Amoore is one of the most popular. According to this theory, there are different kinds of receptor sites. By determining the silhouettes of various molecular models of compounds known to have similar odors, these sites may be described. By combination of more than one primary odor being received simultaneously it is possible to fabricate a large number of different combinations based upon relative concentrations. The most accepted method for evaluating odor concentrations has been the measurement of odor intensity based upon the number of dilutions required to reduce the concentration to a barely detectable level. This measurement may be accomplished by use of a Scentometer. Among chemicals used to control odor are: potassium permanganate, potassium nitrate, paraformaldehyde, hydrogen peroxide, and Ozene. Enzymes and other digestive aids have also been proposed for the control of livestock production odors. Feed additives for this purpose are also being researched. Because current levels of understanding of odor control by chemicals, feed additives, or odor-masking techniques are not sufficient to offer solutions to livestock producer problems, site selection, facility design, and careful management assume great importance in the prevention of odor and the prevention of odor complaints by neighbors. Further research is needed to evolve odor control systems which are compatible with intensive livestock production and which are economically compatible with the problem. (Penrod-East Central)

WATER QUALITY IMPLICATIONS OF LIVESTOCK PRODUCTION,

Department of Agricultural Engineering, Iowa State University, Ames
T. E. Hazen, D. H. Vanderholm, and J. R. Miner
Ames Reservoir Environmental Study. Appendix 4. Physical Relationship With the Agricultural Sector, Iowa State University Report ISWRII-60-A4, 1973, p. 4-4-i—4-4-32. 13 tab, 13 ref.

Descriptors: Waste disposal, Water quality, Farm wastes, Water pollution control, Waste treatment, Economics, Farm management, Cost analysis, Capital costs, Operating costs, Iowa, Feedlots, Runoff, Reservoirs, Physical properties, Chemical properties, Biological properties, Watersheds.
Identifiers: Ames Reservoir (IA), Skunk River Basin (IA), Land application.

Animal wastes are major water pollution sources; however, the impact of such wastes can be controlled through alternative management techniques. A survey of the literature indicates that the application of wastes by spreaders, manure tank wagons, and irrigation can reduce to less than 1 percent the portion of excreted pollutants escaping into the environment. Treatment methods, including oxidation ditches, anaerobic and aerated lagoons, are also considered although none yield acceptable effluent for surface water courses. The impacts of animal waste and potential management policies on the water quality of Iowa's Ames Reservoir basin is evaluated. Though livestock production in the region is not intensive—no cattle or swine operations exceed 1000 head—it is still of major importance. Over 2 million pounds of manure are produced daily most of which is applied to cropland. Management practices including prevention of direct waste discharges, locating feed lot boundaries away from streams, and fencing animals where they might disturb banks are recommended. Runoff control costs vary from $1.00 to $10.00 per head according to feed lot size. Manure management, loss of grazing areas adjacent to water, and aesthetic conservation are also costs to be evaluated. (Schroeder-Wisconsin)

DENITRIFICATION IN SOIL TREATED WITH BEEF-FEEDLOT MANURE,

Minnesota University, Northwest Experiment Station, Crookston
G. W. Wallingford, L. S. Murphy, W. L. Powers, and H. L. Manges.
Communications in Soil Science and Plant Analysis, Vol. 6, No. 2, p. 147-161, 1975. 6 fig, 1 tab, 8 ref.

Descriptors: Denitrification, Soils, Cattle, Feedlots
Identifiers: Land disposal, Nitrogen loss.

Yearly fall applications of beef feedlot manure were begun in 1969. Four plots were selected for detailed study in the summers of 1972 and 1973 to determine if denitrification significantly affected the N balance of an irrigated silty clay loam soil. The four plots received 0, 58, 306, and 68 t/ha/yr of dry manure by the summer of 1973. Nitrogen balance calculations showed that large amounts of N were not accounted for by soil and manure analyses. Of the plots receiving manure, the plots receiving the heaviest manure treatments had the least amount of unaccountable N loss. Atmospheric and other soil analyses suggested that N loss could have occurred from denitrification reactions. Organic carbon increased relative to the control at the 10-cm depth in all three manured plots in 1972 and movement of C to the 50-cm depth was evident in the plot that had received 687 t/ha/yr. Some of the increased C would be available for oxidation in denitrification reactions. The 1973 data showed lower percentages of N_2 at all depths beneath the plot that received 687 t/ha/yr of manure. In 1972 lower percentages of O_2 were found at several depths beneath the plots receiving 687 t/ha/yr of manure; in 1973 they were lower beneath plots receiving 306 and 687 t/ha/yr. The 1972 samplings revealed higher CO_2 percentages in the surface 40 cm under plots receiving 687 t/ha/yr than under the control plots; 1973 samplings revealed higher CO_2 percentages at all sampling depths beneath plots receiving 306 and 687 t/ha/yr. No CH_4 or N_2O was found in the 1972 gas samples. Because N_2O is an end product of denitrification its presence indicates that denitrification did occur. It was shown that in land disposal of manure, the potential for NO_3-N contamination of groundwater can be lowered by denitrification. (Cameron-East Central)

ATMOSPHERIC AMMONIA AND RELATED NITROGEN GASES EMANATING FROM DAIRY WASTE,

USDA, ARS, California University, Riverside
R. E. Luebs
Summaries of papers, Statewide Conference on Fertilization and Waste Management in Relation to Crop Production and Environmental Problems, University of California, Riverside, December 18-19, 1972. p. 22-23.

Descriptors: Dairy industry, Air pollution, Ammonia, Nitrogen, Gases.
Identifiers: Volatilization.

Distillable nitrogen was measured as an air pollutant in 2 different dairy areas in southern California. Data were obtained (1) in and around an area of 150,000 dairy animals in 60 square miles and (2) around a 600-cow dairy isolated from other major ammonia sources. Absorption by acid surface traps for a 39 week period indicated that distillable nitrogen concentration in the atmosphere averaged 28 times that in an urban area. The following conclusions were drawn from data related to Area I (150,000 cows): (1) Volatilization increased atmospheric concentrations of distillable nitrogen over an area of 210 square miles. (2) Three-fourths of this area was downwind. (3) Concentrations in the dairy area away from the cows were inversely correlated with average weekly wind speed. (4) Nitrogen content of rainfall in the large dairy area was 200 percent greater than at an urban sampling site. (5) Approximately 20 percent of the nitrogen absorbed by the acid-surface traps was not ammonia nitrogen. Area II (600-cows) yielded these conclusions: (1) Maximum concentration of distillable nitrogen along the fence was 1081 ug per cubic meter of air, as compared with 15 ug at a distance of .6 mile during the same period. (2) Highest concentrations of distillable nitrogen were always much higher along the downwind fence. (3) During a period of high volatilization and continuous wind averaging 5 miles per hour, the maximum distance from the dairy that increased distillable nitrogen concentrations could be detected was about 1600 feet. Data showed great diurnal variation in atmospheric concentrations of distillable nitrogen and in the patterns of this variation, depending on factors affecting volatilization, temperature inversions in the atmosphere, and proximity to the source. LAND DISPOSAL OF MANURE,

Agriculturist, California University Agricultural Extension, Modesto
J. L. Meyer
Summaries of papers, Statewide Conference on Fertilization and Waste Management in Relation to Crop Production and Environmental Problems, University of California, Riverside, December 18-19, 1972. p. 23-25. 3 fig.

Descriptors: Fertilizers.
Identifiers: Land disposal, Nitrates, Salts, Leaching, Soil profiles.

Large amounts of fertilizer applied to the soil can produce excessive amounts of nitrate-nitrogen and salts which become available for leaching into ground waters. The presence or absence of restrictive soil layers and their effect upon leaching will affect manure rate usage. In Central San Joaquin Valley, under restricted soil (hardpan), nitrogen movement seems to be a lesser problem than under open soils. For 12 consecutive years, 12 yards of dairy manure plus 150 pounds of commercial nitrogen were applied per acre to an area where restrictive soil was present at 18 feet. When cropped to silage corn and winter oats, no excess movement or accumulation of nitrogen occurred. A slight increase in nitrates and salinity was observed just below the root zone of growing crops. During the 12-year study, 40 yards of manure and 150 pounds of commercial nitrogen were also applied to separate plots of soil under the same conditions. Silage corn and winter oats were also grown on these plots. This results in both salt and nitrogen accumulations at the soil surface, under the root system, and lower in the profile. Accumulations lower in the profile were probably caused by successive irrigations. Manure amounts greater than crop requirements, perhaps 12 to 20 yards per acre, may cause nitrogen and salt leaching below crop root systems in open soils and slight salt accumulations in restricted soils. NITRATE CONTENT OF BARLEY AND SUDANGRASS IN RELATION TO RATES OF BOVINE WASTES AND WATER,

Professor, Soil Science and Agricultural Engineering, California University, Riverside
P. F. Pratt, R. G. Sharpless, and K. M. Holtzclaw
Summaries of papers, Statewide Conference on Fertilization and Waste Management in Relation to Crop Production and Environmental Problems, University of California, Riverside, December 18-19, 1972. p. 25-26.

Descriptors: Nitrates, Crop response, Barley, Sudangrass, Evapotranspiration.
Identifiers: Land application, Hanford sandy loam, San Emigdio clay, Arlington sandy loam.

In the fall of 1970, dry dairy manure at rates of 0, 20, 40, and 80 tons per acre per year, and a liquid manure from a feedyard at rates of approximately 13 to 26 tons of air dry material per acre per year, were added to plots of Hanford sandy loam. Forty tons per acre per year of dry dairy manure was applied to plots of Arlington sandy loam and San Emigdio clay soils as well. Water at rates equal to evapotranspiration (ET) and at ET + 33 percent were imposed on all manure rates. Barley was grown in winter and sudangrass was grown in the summer. In most cases, the higher water rates reduced the NO_3^- content of the forage, sometimes by 80 percent or more. During the first year results showed sudangrass to have unsafe levels of NO_3^- in each of its 3 cuttings from plots receiving liquid feedyard manures. Unsafe NO_3^- levels were shown in forage from the Hanford soil receiving rates of forty and eighty tons of dry manure. At the twenty ton rate, the forage had unsafe levels at the low water rate and safe levels at the high water rate. In most cases, the barley showed safe NO_3^- levels. In the second year, the twenty ton rate of dry manure showed safe levels in all cases. At forty and eighty ton rates of dry manure and at both liquid manure rates, unsafe NO_3^- levels were found. Also, sudangrass had higher NO_3^- contents in the low as compared to the high water rates and higher NO_3^- contents in the Hanford as compared to the Arlington and San Emigdio soils. (Cannon-East Central)

EFFECT OF VARIOUS APPLICATION RATES OF DAIRY WASTE EFFLUENT ON PRODUCTION OF CORN SILAGE IN A PERCHED WATER-TABLE AREA,

Agriculturist, California University Agricultural Extension, Hanford
S. W. Kite, R. S. Rauschkolb, and R. S. Ayers
Summaries of papers, Statewide Conference on Fertilization and Waste Management in Relation to Crop Production and Environmental Problems, University of California, Riverside, December 18-19, 1972. p. 26-27.

Descriptors: Rates of application, Effluents, Crop response.
Identifiers: Dairy wastes.

In October, 1970, the effects of various rates of dairy waste effluent on soil productivity were studied. The soil was a Tulare fine sandy loam with the water table at approximately forty inches. The effluent was a liquid mixture of dairy manure and wash water. During first year, plots were treated with high, intermediate, and low volumes of the effluent and a control. The following year, the intermediate volume was replaced by intermittent flooding. Ceramic cups were installed at various depths in the soil under the continuously flooded plots to monitor changes in the soil solution. Corn silage was produced each year after the flooding to determine any effect of effluent loading on yields. Nitrogen treatments were superimposed on the plots during the second year to evaluate nitrogen response under different loading rates. There were no differences in the yields of either year. Soil and soil solution analyses suggested that phosphorus and nitrogen move downward through the soil as water-soluble organic compounds. Nitrate-nitrogen levels decreased to less than 1 ppm in the soil solution because of denitrification caused by the flooding application of the effluent. (Cannon-East Central)

DAIRY MANURE RATES RELATED TO GREEN CHOP PRODUCTION,

U. S. Department of Agriculture, Agricultural Research Service, Western Region, Riverside, California

S. Davis
Summaries of papers, Statewide Conference on Fertilization and Waste Management in Relation to Crop Production and Environmental Problems, University of California, Riverside, December 18-19, 1972, p. 27-29. 1 fig. 1 tab.

Descriptors: Crop response, Nitrogen, Salts, Barley, Sudangrass, Soils.
Identifiers: Land disposal, Application rates.

In a field manure trial, three soil types in three locations were studied to determine the amounts of manure that can be applied to soil without reducing production. Nitrogen and salt movements resulting from these applications were also studied. Barley was grown in the winter and sudangrass in the summer for green chop feed. Dry manure was applied at the three locations at rates of 0, 20, 40, and 80 tons per acre per year, and 38 and 76 liquid tons per acre per year. At the Hanford site, the results showed a considerable decrease in barley and sudangrass production for the 80 ton per acre rate of dry manure and a fairly high decrease for the 76 ton per acre wet-manure rate. At 40 tons of dry manure per acre, Hanford soils produced an average of 3687.66 pounds per acre, Ramona soils an average of 4200.33 pounds per acre, and Moreno soils an average of 3545.33 pounds per acre of barley. Hanford soils produced an average of 4151.66 pounds per acre, Ramona soils an average of 3518.5 pounds per acre, and Moreno soils an average of 3398.33 pounds per acre of sudangrass. EVALUATION OF DEHYDRATED POULTRY WASTE FROM CAGE REARED BROILERS AS A FEED INGREDIENT FOR BROILERS,

Research Department, Crawfords Foods Limited, Wynyard, Saskatchewan SOA 4TO and Department of Poultry Science, University of Saskatchewan, Saskatoon, Saskatchewan S7N OWO
K. K. Bhargava and J. B. O'Neil
Poultry Science, Vol. 54, No. 5, p. 1506-1511, September, 1975. 8 tab, 15 ref.

Descriptors: Feeds, Poultry, Growth rates, Performance.
Identifiers: Dehydrated poultry wastes, Feed efficiency.

A study was performed to observe the growth performance of broiler chicks fed dried poultry waste from cage reared broilers. Straight-run day-old Peel broiler chicks were used in all experiments. In experiment 1, chicks 4 weeks of age were tested for the effects of DPM on their growth response. In experiment 2, chicks were fed a commercial broiler starter for 4 weeks and then randomly assigned to experimental rations of either 5 or 10 percent DPW. Experiment 3 diets were computed to be isocaloric and isonitrogenous. To test the availability of methionine and lysine in experiment 3 diets, experiment 4 was designed to ascertain the response of chicks to diets containing the same levels of DPW as in test 3, but with additional amounts of the 2 amino acids or a combination of both. Data from experiment 1 showed that there was a significant depression in growth when chicks were fed 10 percent DPW, but levels of either 15 or 20 percent DPW did not result in a further depression. The 10 percent diet significantly decreased feed efficiency. A further depression of feed efficiency was observed with the 14-20 percent feedings. Performance index was significantly lower with the addition of any level of DPW. Experiment 2 results showed that the inclusion of 10 percent DPW into the ration resulted in a significant decrease in body weight at about 8 weeks. No significant differences were observed in feed efficiency or performance index. The results of experiment 3 showed that levels up to 20 percent DPW had no adverse effects on growth characteristics and carcass quality. Data from experiment 4 indicated that availability of both lysine and methionine was similar irrespective of the percentage of DPW included in the diets. (Penrod-East Central)

ELIMINATION OF SULFAMETHAZINE FROM EDIBLE TISSUES, BLOOD, URINE, AND FECES OF TURKEY POULTS,

Division of Veterinary Medical Research, Food and Drug Administration, Beltsville, Maryland
G. E. Heath, D. A. Kline, C. J. Barnes, and D. H. Showalter
American Journal of Veterinary Research, Vol. 36, No. 7, p. 913-917, July, 1975. 6 fig, 3 tab, 11 ref.

Descriptors: Public health.
Identifiers: Drugs, Sulfamethazine, Animal diseases, Turkey poults, Metabolites, Blood samples, Tussie samples, Residue depletion, Elimination, Urine, Feces, Drug withdrawal.

The objective of this study was to determine the rates of depletion of free (unaltered) sulfamethazine from blood and several edible tissues of turkey poults given usual therapeutic doses. Tissue samples were analyzed for free sulfamethazine using Tishler's method; sensitivity of the method was found to be 0.1 ppm. Blood samples were analyzed by Annino's method; sensitivity was found to be 1 ppm. Data generated from the study supported the view that sulfamethazine undergoes elimination at an exponential rate from the various tissues and blood of turkey poults. However, this generalization did not hold true at small concentrations in kidney, liver, and skin; these organs seemed to retain the parent compound at concentrations ranging from 0.1 to 0.4 ppm. The authors concluded that since only 8.6 percent of the oral dose and 16.5 to 17 percent of the intravenously administered dose was recovered in urine-feces as the parent sulfamethazine, it was indicated that the drug might be extensively metabolized. (Penrod-East Central)

POTASSIUM IS RESPONSIBLE FOR SALINITY IN SOILS AMENDED WITH POULTRY MANURE,

Department of Plant Science, Delaware University, Newark
W. C. Liebhardt and J. G. Shortall
Communications in Soil Science and Plant Analysis, Vol. 5, No. 4, p. 385-398, 1974. 5 fig, 3 tab, 17 ref.

Descriptors: Soils, Salinity, Potassium.
Identifiers: Land disposal, Poultry manure, Application rates.

Research was done to determine which ion(s) are responsible for the high salinity associated with poultry manure applications on coastal plain soils. Applications of poultry manure were made each March in 1971, 1972, and 1973 and plowed into an Elkton sandy loam at rates of 0, 22, 56, 90, 165 and 224 Mt/ha. In addition, there was a fertilizer treatment of 224-5-186 kg/ha (N-P-K) and a treatment consisting of 22 Mt/ha of poultry manure plus the previous fertilizer treatment. As rates of poultry manure application increased, electrical conductivity and concentrations of double acid extractable and H_2O extractable cations increased. Potassium in the soil was also elevated by increasing rates of poultry manure. Double acid and water extractable K increased six and ten fold, respectively, over the range of applications made in this study. Water extractable K, however, was much higher than either Ca or Mg, making K the prime suspect for the increasing salinity associated with poultry manure. The high coefficient of determination ($r^2 = .95$ and $r^2 = .97$) further indicated a highly linear relation between K and salinity. Sodium and ammonium were also contributors to the salinity problem, however, they were considerably less important than K. Data also substantiated the relative unimportance of Ca and Mg, as concentrations were generally less than 100 PPM. In conclusion, it would appear that K was primarily responsible for the salinity associated with heavy applications of poultry manure on sandy coastal plain soils. (Cameron-East Central)

EVALUATION OF AMMONIA AND INFECTIOUS BRONCHITIS VACCINATION STRESS ON BROILER PERFORMANCE AND CARCASS QUALITY,

Department of Animal Science, Colorado State University, Fort Collins
C. L. Quarles, and H. F. Kling.
Poultry Science, Vol. 53, P. 1592-1596, 1974. 1 fig. 4 tab, 11 ref.

Descriptors: Ammonia, Poultry, Performance, Air pollution.
Identifiers: Infectious bronchitis vaccination, Broiler chicks, Animal health.

The response of broilers to infectious bronchitis vaccine and atmospheric ammonia was studied. Eighty Indian River Cross male broiler chicks were randomly assigned to each of 12 chambers in a controlled environment building. Anhydrous ammonia gas was injected into the test chambers at rates of 0, 25, and 50 ppm of NH_3 during the time period when the chicks were 4-6 weeks of age. The chicks were vaccinated at 5 weeks of age, with a commercial strain of infectious bronchitis dust vaccine. At 8 weeks of age, body weights and feed efficiencies of broilers exposed to ammonia were significantly reduced. At 6 and 8 weeks of age, some severe cases of airsacculitis existed in chicks in the 25 and 50 ppm NH_3 chambers. During the eight week period, airborne bacteria were significantly greater in the 25 and 50 ppm NH_3 chambers. Results on carcass quality showed that low levels of ammonia and infectious bronchitis stresses may not affect carcass tenderness, flavor, or juiciness. However, such stresses can have an economically detrimental effect by increasing incidence of breast blisters and condemnation and by decreasing growth performance and grade. (Penrod-East Central)

DRIED POULTRY MANURE REVEGETATES SPOIL BANKS,

E. L. Bergman and G. W. McKee
Science in Agriculture, Vol. 23, No. 2, p. 8-9, Winter, 1976. 1 tab

Descriptors: Reclamation, Revegetation, Mulching, Nutrients, Potash, Lime, Phosphate.
Identifiers: Dried poultry manure.

Revegetation experiments using dried poultry manure were conducted at nine locations in Lackawanna, Luzerne, and Schuylkill counties of Pennsylvania. It was soon found that the ground must be prepared before the sites could be seeded successfully. It was also found that a heavy application of dried poultry manure, over 1300 lbs. per acre with hydroseeding, prevented germination due to a high chemical salt content. Winter loss of new seedlings was observed when urea was applied too heavily and too early in the fall. Mulching was found to be vital to production of a good stand of grass. The following planting tips resulted from these experiments. (1) The seedbed should be graded to contours to prevent washing out. (2) 800 lbs. per acre of dried poultry manure can be used successfully in establishing a ground cover. (3) Dried poultry manure can be mixed with a 10-20-20- or 0-20-20- fertilizer if higher levels of phosphate and potash are needed. Lime should not be mixed with manure unless an anti-foamant is available. (4) Under the conditions of the experiment, the following gave the best cover: Kentucky 31 tall fescue, 30 lbs. per acre, and Empire birdsfoot trefoil, 20 lbs. per acre, on flat ground — or Penngift crownvetch, 20 lbs. per acre, on slopes. (5) Seeding should be completed by June 15 and can be started as early as possible in spring. If a fall maintenance application is made, it should be applied when vegetation is dormant. (6) Anthracite spoil and refuse banks can be revegetated by use of dried poultry manure since the pH is not very acid. Banks with incinerated materials showed best results. (Penrod-East Central)

FETILIZATION WITH POULTRY LITTER,

S. R. Wilkinson and J. A. Stuedemann
McGraw-Hill Yearbook of Science and Technology reprint, McGraw-Hill Book Company, Inc., 1974. 2 fig. 9 ref.

Descriptors: Fertilizers, Potassium, Magnesium.
Identifiers: Poultry litter, Land disposal, Animal health, Grass tetany, Fat necrosis, Nitrate toxicity.

The problems of fat necrosis, grass tetany, and nitrate toxicity in cattle grazing fescue pastures heavily fertilized with poultry litter are studied. Fat necrosis, the presence of masses of hard fat primarily in the fatty tissues of the abdominal cavity, was investigated in Kentucky-31 tall fescue pastures fertilized with different amounts of nitrogen. Test results indicated that the incidence of fat necrosis in cows was related to high nitrogen fertilization of fescue pastures rather than to any residual feed additive in the litter or any other factor of the litter except its plant nutrient content. Grass tetany, a complex nutritional disease of ruminants, is associated with low levels of blood magnesium. Recent research has determined that heavy poultry litter fertilization (which adds nitrogen and potassium) is related to an increased incidence of grass tetany in cattle. S. R. Wilkinson, J. A. Stuedemann and associates have developed the promising technique of foliar application of magnesium oxide in sodium bentonite water slurries to prevent hypomagnesemia and grass tetany in cattle grazing where poultry litter was used as a fertilizer. Increased incidence of nitrate toxicity is attributed to such things as: excessive nitrogen fertilization, drought, cloudy weather, herbicides, imbalance of soil nutrients, kind of plant, age of plant, and plant part. Nitrate toxicity is also related to the animal, its health, susceptibility to nitrates, and amount consumed. Health problems encountered in cattle grazing heavily littered pastures are essentially those associated with highly fertilized, intensively grazed, and managed pastures. Control of these problems requires judicious use of poultry litter or fertilizer, good pasture management, and special techniques to supply needed nutrients. (Penrod-East Central)

CHINA RECYCLES HER WASTES BY USING THEM ON THE LAND,

R. Blobaum
Compost Science, Vol. 16, No. 5, p. 16-17, Autumn, 1975. 3 fig.

Descriptors: Recycling, Animal wastes.
Identifiers: China, Land disposal, Waste management, Night soil.

China recycles a tremendous amount of human, animal, and plant waste. In the winter, an important job is scraping silt and other material from the bottoms of fish ponds, canals, and rivers and applying it to crop lands. Other important sources of fertilizer are night soil (human wastes); garbage; and animal wastes, particularly hog wastes. In fact, pig production is being increased because pigs make such good garbage disposals and because their manure is so valuable. Chinese scientists also espouse high sanitation standards, use of herbal insecticides, crop rotation for weed control, composting of agricultural wastes, green manure crops to increase fertility, propagation of beneficial insects, use of biological controls, and elimination of as many chemicals in the food chain as possible. FEEDING DRIED POULTRY WASTE FOR INTENSIVE BEEF PRODUCTION,

Ministry of Agriculture, Fisheries and Food, Boxworth Experimental Husbandry Farm, Cambridge CB3 8NN
J. M. Oliphant
Animal Production, Vol. 18, No. 2, p. 211-217, 1974.

Descriptors: Feeds, Performance, Cattle, Copper, Diets.
Identifiers: Dried poultry manure, Refeeding, Deep litter poultry manure, Battery poultry manure, Pathogens, Carcass grading.

Dried poultry manure was substituted for soya and fish meals in an intensive beef ration to determine if it was a satisfactory alternative source of nitrogen and in an attempt to reduce feed costs. During the 3 years of experimentation, Autumn-born British Friesian male castrates were taken from 150 kg live weight to slaughter at 400 kg on various rations. The treatment rations were made isonitrogenous with the control (14.5 percent crude protein). Mean values for animal performance and feed intake were calculated. The reduced live-weight gain in animals receiving the deep litter poultry manure diet was significant in 1969 and 1971, and was associated with reduced daily intakes of dry matter and poorer conversion ratios. Values for the 'mixture' diet were usually intermediate between those for the control and the deep litter poultry manure diets and none of the differences were significant. Performance on the battery poultry manure diet was similar to that on the control diet, except for a poorer feed conversion which was significant in the 1971 trial. Because of the differences in live-weight gain, there were differences in the time taken to reach slaughter weight but, after allowing for differences in the average slaughter weights, the effect was significant only for the deep litter poultry group in 1969. Copper toxicity was not found to be a problem. Examination of the cold carcasses 24 hr after slaughter showed no significant differences, but there was a tendency for diets containing poultry manure to be associated with a lower carcass grading, a lower killing-out percentage and lower scores for round and rump; there was, however, less fat overall and a larger eye muscle and the percentage of hindquarters to whole carcass was higher. It was concluded that dried poultry manure can increase profitability of intensively produced beef. (Penrod-East Central)

FEEDING BROILER LITTER DIRECT TO RUMINANTS,

Department of Animal Science, Arkansas University, Fayetteville
M. L. Ray
Poultry Digest, Vol. 35, No. 408, p. 73-74, February, 1976. 1 fig, 1 tab.

Descriptors: Feeds, Litters, Cattle, Performance, Additives, Nitrogen, Public health.
Identifiers: Refeeding, Animal health, Digestibility, Arsenic, Zoalene, Amprol, Bloat.

At the Arkansas Agricultural Experiment Station, Fall, 1953, an experiment was started to determine if gestating-lactating ewes would eat chicken litter in adequate amounts to furnish their requirements for supplementary nitrogen without harm to the ewes or their lambs. A second test, using broiler litter as a nitrogen source for fattening steers, was conducted in spring, 1954. There were no excessive feed refusals or digestive disturbances noted in either of the two feeding trials. Two trials were conducted to determine the digestibility of 12 different base materials for broiler litter when fed to steers. Five out of the 12 chicken litters fed were found to be higher in digestible dry matter, digestible energy, and digestible crude protein—oat straw litter, sage grass litter, wheat bran litter, cotton boll hull litter and layer house wood shavings litter. All litters had acceptable digestion coefficients. The most promising use for broiler litter appears to be as a supplement to wintering beef cows and their calfs. No significant difference was noted in arsenic content of liver muscle and fat tissue of steers fed litter rations as compared to those fed the control ration. The fate of Zoalene or its primary metabolite ANOT when used in litter did not accumulate in the steers. Steers consuming Amprol had no Amprol residues in their liver tissues. The most common problem associated with feeding broiler litter is its dusty nature. Ways to minimize this problem are given. No digestive disturbances of consequence occurred and bloat was a minor problem. Studies of carcasses indicated that chicken litter ration had no different effects on ruminant carcasses than any other rations of similar chemical composition. (Penrod-East Central)

FACTORS AFFECTING DEGRADATION OF POULTRY MANURE BY FLIES,

The Connecticut Agricultural Experiment Station, New Haven
R. L. Beard and D. C. Sands
Environmental Entomology, Vol. 2, No. 5, 1973, p. 801-806.

Descriptors: Degradation, Aerobic conditions, Anaerobic conditions, Microorganisms, Bacteria, Fungi, Yeasts.
Identifiers: Poultry manure, Flies, Waste management, Egg maturation, Larval development.

Studies were conducted to determine interrelating and interacting factors of manure as a culture medium for flies, as well as fly characteristics that favor development in and degradation of manure. In studying the adaptability of flies to poultry manure, it was determined that flies could not be used to biodegrade the already stored bulk of manure in commercial plants without aerating or modifying the manure. The only fly that consistently showed the kind of adaptability to poultry manure that was required for managed degradation was the housefly (Musca domestica L.) The study of poultry manure revealed that flies discriminate against manure only if a more attractive oviposition medium is available. Fresh manure constitutes the best manure medium. As manure was biodegraded, metabolic activity of contained organisms increased to a plateau, ammonia was produced, nitrogen was lost, and pH increased. Bacteria, rather than fungi and yeasts, were primarily responsible for these changes, but metabolism of bacteria and developing maggots interacted. Some bacteria, such as Mima polymorpha, retarded fly development. The conditions necessary for the degradation of manure by flies were found to be aeration (augmented by ventilation), desired moisture gradient in the medium, and favorable temperatures for flies and bacteria. BIOENGINEERING ASPECTS OF ANAEROBIC DIGESTION OF PIGGERY WASTES,

The Scottish Farm Buildings Investigation Unit, Craibstone, Bucksburn, Aberdeen, Scotland
A. M. Robertson, G. A. Burnett, P. N. Hobson, S. Bousfield, and R. Summers
Unpublished paper, 16 p. 3 fig, 4 tab, 4 ref.

Descriptors: Anaerobic digestion, Byproducts, Methane, Fertilizers, Economics.
Identifiers: Swine, Detention time.

A large problem in the animal productions system over the last decade has been the disposal of animal waste. Many studies have been centered around aerobic methods of disposal, but these will not handle pig wastes. Anaerobic digesters have been found to reduce pig solid particulates while retaining essential nutrients of pig waste. Digesters can give optimum reductions of: 40 percent total solids, 90 percent volatile fatty acids, 90 percent BOD_5 and 40 percent COD. At digester detention times of 30, 20, and 15 days and at solid input rates of 5 percent, the quality of the gas was found insufficient to maintain the required temperature for the digester in North-east Scotland (where this study was made). However, increasing input solid levels and reducing retention times increases gas production. Also, less gas is required in a warmer climate. The cost of installing a digester of 45 m^3 capacity, together with ancillary equipment would be approximately 10,000 pounds. Writing off the equipment over ten years and charging interest on half the capital would give an annual cost of 1 pound, 90 pence per pig: At a ten day retention time, running costs would amount to 1 pound, 35 pence per pig place per year, based on the running cost of the existing digester, giving a total annual cost of 3 pounds and 25 pence per pig. The value of the surplus gas is estimated at 1 pound, 97 pence per pig and fertilizer recovered from the effluent would have a value of 1 pound 31 pence per pig. This would bring the value of the digester output to 3 pounds, 28 pence per pig, making anaerobic digestion feasible on a large scale basis. (Cannon-East Central)

INITIAL RATION SEEN AFFECTING CATTLE WASTE REFEED VALUE,

Feedstuffs, Vol. 48, No. 18, p. 4, May 3, 1976.

Descriptors: Diets, Performance, Nitrogen, Potassium, Phosphorus, Manganese, Nutrients.
Identifiers: Refeeding, Crude fiber, Crude protein.

Scientists from the U. S. Department of Agriculture's Agricultural Research Service and from the University of Nebraska conducted a study to determine if the initial ration affects the cattle waste refeed value. Although supplemental manganese may be needed, feces and manure from housed cattle on a low-roughage ration generally meet requirements for refeeding as a high-roughage ration. Dr. James R. Ellis, ARS microbiologist stated that the practical limitation on refeeding cattle wastes is the large quantity of digestable dry matter and the high handling costs. The research group found that wastes from outdoor feedlots contain 45-95 percent soil and are not suitable for refeeding because of low feed value. Study results showed that the suitability of excreted materials for refeeding declines as the amount of roughage in the original ration increases. The researchers concluded that the roughage level in the ration influences gross energy, crude fiber, crude protein, nitrogen in all forms, potassium, phosphorus, manganese and other mineral elements in the wastes. INFLUENCE OF DRY MATTER AND NITROGEN INTAKES ON FECAL NITROGEN LOSSES IN CATTLE

Department of Animal Science, Arkansas University, Fayetteville
O. T. Stallcup, G. V. David, and L. Shields
Journal of Dairy Science, Vol. 58, No. 9, p. 1301-1307. 1 fig, 3 tab, 22 ref.

Descriptors: Nitrogen, Diets, Effects, Forages.
Identifiers: Dry matter.

A study was conducted at the University of Arkansas to (1) examine influence of intakes of dry matter and nitrogen of steers fed forage diets on output of fecal nitrogen, (2) estimate excretion of metabolic fecal nitrogen from indirect methods based on extrapolation to zero of fecal nitrogen losses from varying intakes of nitrogen, and (3) measure the relationship of fecal nitrogen to excretion of fecal dry matter. Growing Holstein steers were confined in metabolism stalls in a room at 20 degrees C and 50 percent relative humidity. Thirty-two sorghum silages, 13 corn silages, 9 hays, 8 cereal silages, and 6 lots of sudan and sorghum-sudan hybrid forage were fed to the steers. Each forage was fed to 3 steers for a 14-day preliminary and a 7-day collection period. In a preliminary analysis, correlations were .93 between total fecal nitrogen and dry matter intake, .90 between total fecal nitrogen and total nitrogen intake, and .95 between total fecal nitrogen and total fecal dry matter. However, at high and low nitrogen intake there was evidence of departure from a linear relationship. The authors discuss the relative usefulness of 3 regression analyses to estimate metabolic fecal nitrogen. (Penrod-East Central)

LIVESTOCK AND POULTRY WASTE DISPOSAL CONTROL,

North Carolina State University Agricultural Extension Service, Raleigh
G. Kriz
Circular 556, North Carolina State University Agricultural Extension Service, February, 1973, 8 p.

Descriptors: Air pollution, Water pollution, North Carolina, Regulation.
Identifiers: Waste management, Land disposal.

Questions on air and water pollution control for livestock and poultry waste are answered in this publication by the North Carolina Agricultural Extension Service. Areas of pollution control covered, include (1) Definitions of pollution and nuisance according to North Carolina Law, (2) Factors which determine how animal wastes become a nuisance or cause pollution, (3) Responsibilities of various state agencies, (4) Regulations—local, state or federal—that apply to animal waste disposal, (5) Services provided by the Board of Water and Air Resources, and (6) Assistance that is provided to animal producers by agencies, conservation services and agricultural departments in pollution control and prevention. Conditions affecting pollution potential of animal wastes, methods of animal waste management and land application rates are discussed. Final questions are answered that examine (1) where responsibility lies in insuring that pollution does not result from an animal operation, (2) methods for avoiding pollution when a production unit continues at the same level and (3) methods for avoiding pollution when a production unit either expands or builds a new facility. INTERACTIONS OF BEEF CATTLE WASTES WITH SOIL,

Soil Scientists, USDA, P.O. Box E, Fort Collins, Colorado
F. A. Norstadt and L. K. Porter
Environmental Biogeochemistry, Vol. 2, Chapter 47, Ann Arbor Science, Ann Arbor, Michigan, p. 763-775, 1976. 4 fig, 7 tab, 8 ref.

Descriptors: Soil profile, Cattle, Feedlots, Sampling, Groundwater.
Identifiers: Manure pack, Soil water tensions, Soil temperature, Soil gases.

A soil core study was conducted at a commercial feedlot in Fort Collins, Colorado in 1972. The soil was a silty-clay loam with a water table varying between 240 and 360 cm, according to season and irrigation scheduling of adjacent cropland. Two metal cylinders or caissons were installed to a depth of 450 cm in a nearly square pen. One was located two meters from the feedbunk concrete apron (area receiving the most animal traffic, urine and feces) and the other in the center, about 30 m away from the bunk caisson (area of less traffic and excretion.) A third caisson was located in a nearby alfalfa field for comparison. The lot was usually stocked at 30 m^2 per animal. The caissons monitored five depths (15, 60, 90, 180, and 270 cm) for soil water tensions and soil temperatures and permitted sampling of soil gases and soil solutions. Study results indicated that differences in animal traffic and excretion distribution in the feedlot caused 2 distinct soil regions to develop — one aerobic, and one anaerobic. The former was near the center of the lot, and the latter was along the concrete apron in front of the feedbunk. Essentially the feedlot surface was sealed and little if any water infiltrated and percolated. Soil water tensions were stable during the year in the upper feedlot soil profile as compared to alfalfa field. The composition of soil gases differed markedly among the 3 caisson sites. It was found that the soil and micro-organisms responded with interesting reactions not easily observed in cultivated soils. The authors concluded that a northeastern Colorado feedlot, stocked and managed as reported in the study, does not appear to be a hazard to soil and groundwater. (Penrod-East Central)

CONTROLLING FEEDLOT SURFACE ODOR EMISSION RATES BY APPLICATION OF COMMERCIAL PRODUCTS,

Agricultural Engineering Department, Oregon State University, Corvallis
J. R. Miner and R. C. Stroh
Presented at the 1975 Winter Meeting, American Society of Agricultural Engineers, Chicago, Illinois, December 15-18, 1975, Paper No. 75-4566, 16 p. 19 tab, 4 ref.

Descriptors: Odor, Ammonia, Zeolites.
Identifiers: Odor control, Odor intensity, Ammonia absorption rate, Ammonia evolution rate, Potassium permanganate, Sodium bentonite, "Odor Control Plus", "The Nose Knows", LSS10, Sanzyme.

An attempt was made to identify those measurements which would be useful in evaluating the odor problem and in measuring the effectiveness of abatement techniques. The measurements selected for evaluating surface additives were odor intensity, ammonia absorption rate, and ammonia evolution rate. Nine commercially available products for feedlot odor control were applied to one or more pens, each to determine their effectiveness. These included: potassium permanganate, sodium bentonite, "THE NOSE KNOWS", Agco, "ODOR CONTROL PLUS", zeolites, LSS10, and Sanzyme. The four products that were found to effectively control ammonia release were sodium bentonite, ODOR CONTROL PLUS, and the two zeolites. The cost of the effective materials ranged from $300 to $600 per acre for treatment during the odor production season. (Penrod-East Central)

DESIGN AND OPERATION OF A DEMONSTRATION UNIT FOR METHANE GENERATION,

Agricultural Engineering Department, Maine University, Orono
A. El-Domiaty Hassan, G. S. Putnam, and N. Smith
Presented at the 1975 Winter Meeting, American Society of Agricultural Engineers, Chicago, Illinois, December 15-18, 1975, Paper No. 75-4539, 20 p. 6 fig, 5 tab, 8 ref.

Descriptors: Design, Methane, Anaerobic digestion, Costs.
Identifiers: Research and development.

An investigation of the design and development of a full scale pilot plant for methane generation was conducted at the University of Maine poultry facilities. This study was conducted as part of a larger project conducted by the University of Maine Agricultural Engineering Department. The digester used for the laboratory scale studies consisted of 1-liter flasks and 8-liter bottles. The digester used in the early field studies was an insulated 700 gallon cylindrical steel tank. Results from the laboratory kinetic studies showed that the maximum yield of methane was a result of initial solids concentration in the range of 4.6 to 7.6 percent. The most economical operation was found at the higher end of the range (7.0 to 7.5 percent). Methane production in the digester was stimulated by an added carbon source provided that the source was easily degradable and that the concentration was not too high. Time lag in starting the digester was greatly reduced by using inoculum or seed culture. The authors suggested using a continuously fed system or a batch system where 50 percent or less of the digester volume is emptied at one time. Under the conditions of the laboratory study, the optimum temperature for methane production was 35 $\pm$ 2 degrees C (93 $\pm$ 3 degrees F). The field studies showed that a methane recovery of 130 to 160 l/kg (2.0 to 2.5 ft^3/lb.) dry manure with an average methane content of approximately 56 percent. Hydrogen sulfide and water vapor were present in the gas in amounts sufficient to be very corrosive and might need to be removed for several applications. Unless ground up before entering the digester, feathers were found to present a pump clogging problem. (Penrod-East Central)

CRYSTALLINE PHOSPHATE PRECIPITATION FROM ANAEROBIC ANIMAL WASTE TREATMENT LAGOON LIQUORS,

Agriculture and Home Economics Experiment Station, Iowa State University, Ames
C. V. Booram, R. J. Smith, and T. E. Hazen
Transactions of the ASAE, Vol. 18, No. 2, p. 340-343, May-June, 1975.

Descriptors: Waste treatment, Lagoons, Anaerobic conditions, Chemical properties, Equipment.
Identifiers: Crystalline phosphate precipitation, Encrustation, Phosphate deposition.

A study of the flushing system at Iowa State University was conducted to determine ways to cope with the problem of crystal deposition and pipe blockages. Considerations were given to: (1) anaerobic lagoon conditions that can cause precipitation, (2) the interaction of chemical components in a simplified waste management system, (3) changes in concentration of the component ions Mg^{++}, $NH_4{}_+$, and P in the lagoon, and (4) practical solutions that will allow anaerobic liquid to be pumped with a minimum of difficulty. Equipment utilization and maintenance are also described. Study conclusions included the following: (1) The liquor from certain anaerobic waste treatment lagoons may be expected to cause $MgNH_4PO_4$ deposition in metal pumps and plumbing fittings, (2) Solubility calculations for $MgNH_4PO_4$ indicate that only marginal precipitation should be expected because the solution is only mildly supersaturated, (3) Phosphate concentrations in the bottom sludge of an anaerobic lagoon are much higher than those in the liquor, but the concentration in the liquor does not change much from year to year, (4) All plumbing and pumps to be used for flushing with anaerobic lagoon liquor should be constructed of plastics or of synthetic rubber, (5) Some residual $MgNH_4PO_4$ deposition will take place, even in plastic and this should be controlled by using 1:50 (volume basis) acetic acid solution as a periodic cleaning agent. (6) Relatively speaking, irrigation equipment used to apply anaerobic lagoon effluent to land will pass far less liquid each year than the recycle equipment; hence, encrustation is less of a problem. (Penrod-East Central)

3018 - B2
DESIGNING AN OPEN CHANNEL FOR TRANSPORT OF WASTE,

Agricultural Engineering Department, Purdue University, West Lafayette, Indiana
J. C. Nye and D. D. Jones
Presented at the 1975 Winter Meeting, American Society of Agricultural Engineers, Chicago, Illinois, December 15-18, 1975. 1 fig, 7 tab, 7 ref.

Descriptors: Design, Mathematical models, Slope, Modification, Velocity.
Identifiers: Waste transport, Flushing, Discharge, Volume.

Design principles for transporting waste through an open channel are presented. Study objectives were: (1) to develop a mathematical model that would predict the ability of flush water to transport manure as it flows down an open channel, (2) to determine from this model the length of gutter that could be flushed with a given volume of discharge, duration of discharge, initial velocity and gutter slope. In order to accomplish these objectives, a computer program was developed. Input variables for the program were (1) volume of discharge: 100 to 500 gallons (.38 to 1.9 m^3), (2) duration of discharge; 10 to 30 seconds, (3) slope of channel; .005 to .02 ft/ft or m/m and (4) initial velocity of water in channel; 2 to 3 fps (36.5 to 54.8 m/min.). The Manning "n" roughness coefficient was 0.02. Although verification of the model has not been completed, the following conclusions can be made: (1) For channels longer than 100 ft, a higher velocity and longer duration of flush should be used. (2) Flushing gutter systems can be designed for older buildings using a .005 ft/ft slope if the depth of flow is between 3 and 4 inches and the length of gutter is less than 80 ft. (3) For extremely long gutters over 200 feet, variable slopes or tapered gutters should be used. Further comparisons with existing gutter flushing facilities should produce a computer program that can design more efficient flushing gutter systems. (Penrod-East Central)

CHEAP EFFECTIVE CURE FOR A SMELLY LAGOON,

Missouri University
B. George
Beef, Vol. 12, No. 8, p. 28-29, April, 1976. 1 fig.

Descriptors: Lagoons, Design, Aeration, Odor, Costs.

To cure a smelly lagoon, Bob George, University of Missouri agricultural engineer, reported on a last resort aeration system that is cheap to build and inexpensive to operate. Mr. George built a giant cross over the lagoon using two-inch pipe. For a lagoon diameter of 100 feet, he used about a 60-foot length of pipe in each direction. A four-way connector at the center hooked the pipes together. Caps sealed off three of the pipes and the remaining end was hooked to a one-half horse power pump which delivered up to 30 psi of pressure. Quarter inch holes were spaced along the length of each pipe, reducing the pressure to 14 psi. The pump mixed lagoon water with oxygen and forced the water and oxygen mixture through the pipes and to the lagoon surface. The aerobic layer that this produced at the top of the lagoon sealed off odors. The cost of construction for a 300 head-hog lagoon was approximately \$250.00-\$300.00 and operated for \$7.00-\$8.00 per month. Bob George stated that it took just 5 days to eliminate odor from the lagoon. Mr. George suggested that his apparatus be used for other types of feetlot lagoons as well. (Penrod-East Central)

AGRICULTURAL WASTE MANAGEMENT FIELD MANUAL,

U. S. Soil Conservation Service
Agricultural Waste Management Field Manual, U. S. Department of Agriculture, Soil Conservation Service, August, 1975, 345 p. 63 fig, 55 tab.

Descriptors: Agriculture, Legal aspects, Regulation, Water pollution, Air pollution, Water quality, Waste water treatment, Solid wastes, Agricultural runoff, Chemical properties, Livestock, Poultry, Crop response, Geology, Fish, Liquid wastes, Solid wastes, Lagoons, Waste treatment, Waste storage, Waste disposal, Food processing wastes, Pesticides, Equipment, Monitoring, Sampling.
Identifiers: Waste management, Land disposal.

This manual presents information, data, and guidelines for planning, designing, and operating agricultural waste management systems. It is intended for use by field offices of the U. S. Soil Conservation Service (SCS). It supplements but does not supersede national or state standards, specifications, or requirements of SCS as they pertain to various conservation practices. Topics considered are: (1) Laws, rules, and regulations, (2) Water quality, (3) Municipal waste water treatment, (4) Waste characteristics, (5) The role of soils in waste management, (6) The role of plants in waste management, (7) Geologic considerations in waste management, (8) Fish and wildlife aspects of waste management, (9) Livestock and poultry waste management systems, (10) Food processing waste management systems, (11) Land application of wastes, (12) Waste management system components, (14) Pesticides and other chemicals, (15) Waste management equipment, (16) Monitoring and Sampling. Conversion factors and tables are also supplied along with a glossary of terms. (Merryman-East Central)

MANURE MANAGEMENT IN A 700-HEAD SWINE FINISHING UNIT IN THE AMERICAN MIDWEST: AN INTEGRATED SYSTEM INCORPORATING HYDRAULIC MANURE TRANSPORT WITH RECYCLED ANAEROBIC LAGOON LIQUOR AND FINAL EFFLUENT USE BY CORN (ZEA MAYS),

Department of Agricultural Engineering, Iowa State University, Ames
C. V. Booram and R. J. Smith
Water Research, Vol. 8, No. 12, p. 1089-1097, 1974.

Descriptors: Lagoons, Anaerobic conditions, Irrigation, Nitrates, Groundwater pollution, Hydraulic systems.
Identifiers: Land disposal, Crop response.

In recent years livestock production has shifted from pasturing to intensive confinement, resulting in manure management problems. In the midwestern states, anaerobic lagooning has been tested as a management method, with use of renovated waste water for hydraulic transport. Such lagoons convert mixtures of mucal, granular and fibrous solids in manure into a liquid suspension capable of being pumped, with simple, low capacity equipment. However, lagoon liquor has proven to be far too potent to discharge into a watercourse. One solution has been to employ standard irrigation equipment to discharge excess lagoon liquor to croplands. When anaerobic lagooning was first introduced, it was thought that periodic sludge removal would be necessary. However, three sludge removal surveys in a 10 year period have failed to produce evidence that such sludge accumulation occurs. Problems associated with land application of lagoon liquor have been largely due to nitrates. It has been found that annual applications of less than 280 kg N ha^{-1} can be made on corn with little danger of groundwater pollution and minimal effects on plant tissue. Because anaerobic lagoons are sources of odor, they should be located at least 1 km from residences. Because these lagoons are temperature dependent, they are not recommended for cold climates. Anaerobic lagoons should be as deep as local conditions allow, usually 3-9 m. A loading rate of about 0.08 kg VS m^{-3} day^{-1} is recommended. Purple sulphur-fixing bacteria control H_2S odors and should be encouraged by seeding from other active lagoons. (Penrod-East Central)

BENEFICIAL USE OF WASTE HEAT FOR AGRICULTURAL APPLICATIONS.

Department of Soil Science Oregon State University Corvallis
L. Boersma
Presented at the 1975 Winter Meeting, American Society of Agricultural Engineers, Chicago, Illinois, December 15-18, 1975, Paper No. 75-3540, 29 p. 4 fig, 9 tab, 36 ref.

Descriptors: Energy, Agriculture, Recycling, Electricity, Irrigation.
Identifiers: Waste heat, Land availability, Waste management, Warm water use, Single cell protein, Protein extraction, Food processing, Aquaculture, Greenhouses, Open field soil warming.

The development of beneficial uses for power plant waste heat is a hard task that needs to be approached with adequate justification. On this basis, the author discusses the justifications for agricultural applications of waste heat and the concepts of proposed applications. The growth of the gross national product during this century has roughly been paralleled by the growth in total energy consumption. An increase in population and the resulting affluence has stimulated the need for increased agricultural production. Increased food production requires large energy inputs. A recent Farm Electrification Council publication estimates that food related activities consume a little over 11 percent of the total energy consumption. The author states that the potential problems of energy shortage, lack of arable land, and water shortage can in part be solved through the development of an integrated production system where resources are recycled. Waste products must become raw materials. Potential contributions to the integrated system of food and fiber production can be evaluated from the standpoint of food production problems, the efficient use of energy and the problems of waste management. Specific applications that are described include single cell protein production, protein extraction, food processing, aquaculture, greenhouses and open field soil warming. (Penrod-East Central)

EXPERTS VIEW USE OF POULTRY WASTES IN ANIMAL FEEDING, SAVINGS, LEGAL ASPECTS,

Feedstuffs, Vol. 48, No. 13, March 29, 1976, p. 25-27.

Descriptors: Costs, Economics, Performance, Nutrients, Legal aspects, Proteins, Nitrogen, Calcium, Phosphorus.
Identifiers: Refeeding, Dried poultry wastes.

To update feed companies on animal waste refeeding issues, the Agricultural Waste Processors Association recently invited some experts in the field of waste recycling to define the usefulness of poultry waste and to address the problem of emotional opposition to feeding animal wastes. Among those presenting data were John Bergdoll, general manager, Bunnett-Smallwood and Company, Indianapolis, Indiana; Dr. W. Bolton, head of the nutrition section, Agricultural Research Council's Poultry Research Center, Edinburgh, Scotland, and Dr. Robert Blair, formerly of the Poultry Research Center, and now with Swift Canadian Company, Ltd. Topics considered by these men included: the newer applications of poultry wastes in animal feeding, experiences with feeding levels of the waste material, and legal considerations. DPW was found to be a source of protein, calcium, phosphorus, trace minerals, and nitrogen. While DPW was found to be a variable product, some factors causing this variability are controllable. Bolton found that properly sterilized DPW did not present a disease hazard, but he urged that DPW should come only from birds not fed diets containing drugs or growth stimulants. DPW was effectively fed as a feed supplement for broilers, rearers, layers, and pullets. DPW was found to be an even more effective food supplement for ruminants because ruminants can utilize the non-protein nitrogen. In the poultry industry, Blair took the low figure of \$2/ton as the potential savings and projected a total savings throughout the industry as being about \$5.8 million annually. Taking as the low figure throughout the ruminant industry, \$4/ton as the potential savings, he projected an annual savings of about \$12 million. Alan Ashby, general secretary of Agricultural Waste Processors Association, London, asserted that laws may be needed to enforce the use of wastes in feeds to overcome the emotional ignorance toward such feed stuff and thereby release grains for human consumption. DAIRY MANURE UTILIZATION AND FIELD APPLICATION RATES,

Area Soil and Water Specialist, Parlier, California
J. L. Meyer, R. S. Rauschkolb and E. Olson
Unpublished paper, 14 p. 3 fig, 3 tab, 9 ref.

Descriptors: Salts, Nitrogen, Crop response, Nutrients, Liquid wastes, Solid wastes, Soil profile, Leaching, Denitrification.
Identifiers: Dairy manure, Volatilization.

Alarm concerning nutrient and other salt movement in soils and their possible entry into water supplies has caused researchers to examine dairy manure management practices. It has been found that in storing solid wastes, deep percolation losses of nutrients and salts can be prevented by not disturbing the bottom of the pack. Also, liquid waste storage ponds have been found to be self-sealing. Both liquid and solid dairy wastes have been found to be beneficial when applied to crops. The key to conserving nitrogen applied to the croplands is to incorporate it into the soil as soon as possible in order to prevent denitrification or leaching. Factors affecting nitrogen availability and conservation include: amount of nitrogen released for plant use, method of application, handling, storage between collection and use and rate of application. Excessive nitrogen from organic or inorganic sources may be leached to the water table. Improved manure management with less nitrogen loss will mean fewer total salts added to the soil, since less manure will be needed to meet the nitrogen requirements of crops. (Penrod-East Central)

FERMENTATION OF FEEDLOT WASTE FILTRATE BY FUNGI AND STREPTOMYCETES,

Northern Regional Research Laboratory, Agricultural Research Service, U.S. Department of Agriculture, Peoria, Illinois
B. A. Weiner and R. A. Rhodes
Applied Microbiology, Vol. 28, No. 5, p. 845-850, 1974 6 tab, 15 ref.

Descriptors: Fermentation, Waste treatment, Byproducts, Feeds, Fungi, Nitrogen, Glucose, Carbohydrates, Liquid wastes.
Identifiers: Streptomycetes, Filtrates, Dairy Whey.

The soluble and dispersed carbon and nitrogen components in cattle feedlot waste filtrates provide a nutrient source from which single-cell protein could be produced for animal feeds. A study was conducted to find filamentous organisms that could reduce pollutants and filter easily for cell recovery. More than 200 fungi and streptomycetes were studied for their ability to use nitrogen and organic material in the waste, the latter being measured by chemical oxygen demand. The production of cell mass and the effect of adding glucose and dairy whey to waste filtrates also were investigated. Only 20 percent of the organisms were able to grow appreciably in the filtrate. Of these, it was found that dry-weight yields varied from 0.6 to 2.7 grams of mycelium per liter. From 21 to 50 percent of the nitrogen in the filtrates was used during growth. Chemical oxygen demand levels diminished from 4 to 60 percent. Streptomycetes isolated from the feedlot used filtrate nutrients better than fungi did. Addition of glucose or whey increased cell yields of selected organisms by as many as six times; nitrogen was better utilized; and chemical oxygen demand varied from 0 to 33 percent in increase. FEEDING VALUE OF ANIMAL WASTE NUTRIENTS FROM A CATTLE CONFINEMENT OXIDATION DITCH SYSTEM,

Department of Animal Science, Iowa State University, Ames
R. L. Vetter, R. D. Christensen, G. Frankl, and W. R. March
A. S. Leaflet R170, Iowa State University Cooperative Extension Service, Ames, July, 1972, 7 p. 5 tab.

Descriptors: Nutrients, Feeds, Liquid wastes.
Identifiers: Refeeding, Oxidation ditch, Animal health, Meat quality.

Effluent from an oxidation ditch system was studied to determine the nutritional value of the waste nutrients and to evaluate any effects of refeeding on animal health and meat quality. The same control ration was fed in all three tests with adjustments made in the dry supplement in tests 2 and 3 for protein, calcium and phosphorus contained in the animal waste nutrient feed. The experimental ration was made by directly pumping liquid animal waste material from the oxidation ditch into a mixing wagon which contained the adjusted control ration, thoroughly mixing it, and then augering it into the feed bunk. This feed mixture was prepared and fed on a twice daily basis. Results indicated that animal waste biologically processed through the oxidation ditch system has an acceptable nutritional value and can be used effectively as a partial protein and mineral supplement. No animal health or meat quality problems occurred. Extensive research data are still needed to adequately evaluate the system as an approved feeding concept. Other feeding outlets or methods of concentrating the effluent material are needed if feeding is the desired procedure for utilizing all the animal waste production. (Penrod-East Central)

GENERATING METHANE GAS FROM MANURE,

Department of Agricultural Engineering, College of Agriculture, Missouri University, Columbia
C. Fulhage, D. Sievers, and J. R. Fischer
Science and Technology Guide, Columbia Extension Division, University of Missouri, 1975, 4 p. 2 fig, 3 tab.

Descriptors: Methane, Recycling, Anaerobic digestion, Design, Equipment, Energy, Management, Costs.

This paper provides quantitative information for evaluating the feasibility of methane generation in specific situations. There are many factors that determine how much methane may be obtained. These include: (1) gas yield, cu. ft. per lb. volatile solids destroyed, (2) volatile solids voided, (3) percent reduction of volatile solids, (4) potential gas production per animal, (5) energy production rate, and (6) available energy BTU/hr after heating digester. An anaerobic digester's design volume is based on the amount of volatile solids that must be treated daily and detention time. The equipment necessary to generate usable quantities of methane from an anaerobic digester is complex and requires a substantial investment. The main structure is a digestion tank, usually cylindrical in shape to promote better mixing. Digester loading must be regular to insure a continuous supply of food for the anaerobic bacteria. Maintenance of correct loading rates and detention times and the facilitation of mixing and pumping require a manure slurry of the proper solids content. System imbalance may be caused by (a) loading rate, (b) temperature, and (c) nature of the waste. The addition of toxic materials such as antibiotics can also cause imbalance. Once an imbalance is discovered, pH control should be maintained until the cause of the upset is discovered. The gas produced can either be burned for energy right away or it can be stored. The advantages and disadvantages of each are discussed. High investments in money and management along with difficulties in efficiently using methane make anaerobic digestion a questionable venture for most farmers. Research is needed to reduce capital costs of methane generation systems and provide techniques for proper management of such systems. (Penrod-East Central)

EVALUATION OF ALTERNATIVE APPROACHES TO CONTROL OF ODORS FROM ANIMAL FEEDLOTS,

3131 N. W. Norwood Place, Corvallis, Oregon
J. R. Miner
Project Report, National Science Foundation Program of Research Applied to National Needs, Grant Number ESR74-23211, December, 1975, 83 p. 5 fig, 53 tab, 8 ref.

Descriptors: Odor, Feedlots, Cattle, Agricultural runoff, Waste storage, Chemical treatment, Economics, Idaho.
Identifiers: Odor control, Green belt barrier, Sodium bentonite, ODOR CONTROL PLUS, Zeolites, Potassium permanganate.

Alternate techniques for control of odors from a cattle feedlot were evaluated at a southeastern Idaho site. The odor sources studied were the feedlot surface and the runoff collection and storage ponds. Nine products were applied to the various feedlot pen surfaces at rates and frequencies suggested by the manufacturers. Ammonia release rates and odor intensities of the feedlot litter were measured. Sodium bentonite, ODOR CONTROL PLUS, and two neutral zeolites were found to consistently reduce the rate of ammonia release from the treated area. The cost of the effective materials ranged from \$300 to \$600 per acre for treatment during the odor production season. Two materials were added to the feed ration as potential odor control techniques. Neither material proved effective based upon the ammonia release rate or the odor intensity measurements made. A green belt odor barrier was established along the two sides of the feedlot where odor control is essential. Three species of trees and shrubs were planted. The success of this procedure cannot be measured until the plantings mature. A spray system was installed in the same area as the plantings to create a mist extending 20 ft into the air along these borders. This system is effective only under low wind velocities which is also the time of greatest odor transport. The spray system was also used to spray a dilute potassium permanganate solution. When applied at concentrations below 74 mg/l, no plant effects were noted. When added to the spray at 10 mg/l, potassium permanganate seemed to further speed the odor intensity reduction with distance. Two chemicals were sprayed on the runoff retention ponds as on odor control effort, but certain factors made evaluation difficult. Further experimentation is necessary. Examination of the climatic data indicate that for the Blackfoot, Idaho area, climatic conditions would transport odor from the Harding Feedlot toward the Moreland community approximately three percent of the time. INVESTIGATION OF REMOTE SENSING TECHNIQUES FOR AGRICULTURAL FEEDLOT POLLUTION DETECTION,

Remote Sensing Institute, South Dakota State University, Brookings
F. A. Schmer, D. W. Ryland and F. A. Waltz
Project Completion Report SDSU-RSI-72-14, Remote Sensing Institute, South Dakota State University, April, 1973, 166 p. 37 fig, 9 tab, 14 ref.

Descriptors: Research and development.
Identifiers: Remote sensing techniques, Feedlot pollution, Water quality analysis, Thermal imagery analysis, Visual analysis.

This research effort was directed toward the application of remote sensing techniques to the detection and monitoring of pollution from cattle feeding operations. Five livestock feeding operations were selected for the study along the James River from Huron to Redfield, South Dakota. Thirteen aerial missions were flown from January 1, 1971 through June 30, 1972, providing aerial photography and thermal infrared data under various weather conditions. Water samples were collected during nine of the aerial flights at fourteen river locations. Water samples were collected a minimum of every three weeks on a regular schedule to allow independent analysis of the water quality data. Data analysis consisted of visual interpretation of aerial photography and statistical analysis of film densities and water quality parameters. Analysis of variance and linear regression techniques were also utilized. In addition, an attempt was made to adjust the film densities for variations in incoming radiation. Results indicated that remote sensing techniques utilizing low and high altitude aircraft photography can be used to locate potential feedlot pollution sources. The statistical analysis showed good results for specific aerial missions but considerable variability was noted between aerial flights indicating that additional study is warranted. THE USE OF AEROBIC PROCESSES FOR THE STABILIZATION OF ANIMAL WASTES,

School of Agriculture, The North of Scotland College of Agriculture
K. Robinson
CRC Critical Reviews in Environmental Control, Vol. 4, No. 2, p. 193-220, July, 1974. 4 fig, 130 ref.

Descriptors: Aerobic treatment, Nitrogen, Economics.
Identifiers: Oxidation ditch, Waste stabilization.

Aerobic treatment is presented as any process which attempts to improve oxygen supply to aerobic microorganisms responsible for converting waste into a relatively biologically stable product. The concentrated effort which has gone into the study of animal wastes and oxidation ditches is recognized. A major problem of oxidation ditch systems has been an inability to relate the waste's oxygen demand to the system's oxygen supply and to the activity of the microorganisms. An understanding of the relationship of degradation rate to rate of microbial activity should eliminate the problems of foaming and oxygen depletion. Nitrogen transformation is emerging as a very important fundamental aspect of aerobic treatment. Much more needs to be done on the factors influencing the growth and activity of the microorganisms involved in the transformation processes so that operation parameters can be established which will specify modes of operation for maximum nitrogen retention, as ammonia, nitrite, or nitrate, or maximum nitrogen removal. The only true costing of treatment is one obtained under commercial conditions. Demand for composting processes for solid wastes has been limited; therefore, research effort has also been limited. The following are recommended for future investigation: (1) development of alternative methods for measuring oxygen demand of agricultural wastes, (2) a detailed assessment of the treatability of wastes, (3) development and use of alternative aeration devices, (4) in-depth study of treatment under limited oxygen conditions, (5) determination of fundamental factors controlling nitrification-denitrification processes, (6) feasibility study of methods which will relate loading to microbial activity, (7) study of solids separation, (8) attention to the design and operation of simple aerobic treatment systems, (9) detailed study of aerobic composting processes, (10) consideration of modification of aerobic waste treatment processes to maximize final utilization of waste on land or as feedstuff. SLURRY IS VALUABLE,

Agricultural and Food Chemistry Research Division
S. N. Adams
Agriculture in Northern Ireland, Vol. 48, No. 11, p. 387, 1973.

Descriptors: Slurries, Economics, Nitrogen, Phosphate, Potash.
Identifiers: Land application.

Farmers should regard slurry not as a "problem", but as a valuable source of expensive fertiliser nutrients. Slurry is a valuable organic manure which provides nitrogen, phosphate and potash for grass and crops. The following fertiliser nutrients are produced each year in excreta of housed livestock: (a) One dairy cow (housed 6 months) produces 90 lbs of nitrogen, 35 lbs of phosphate, and 90 lbs of potash. (b) One pig produces 25 lbs of nitrogen, 20 lbs phosphate, and 20 lbs of potash. (c) One hundred broilers produce 55 lbs of nitrogen, 55 lbs of phosphate, and 30 lbs of potash. (d) One hundred laying hens produce 120 lbs of nitrogen, 120 lbs of phosphate, and 50 lbs of potash. Phosphate and potash in slurry are less quick acting than in fertiliser, but this does not matter for grassland. Monetary value of the nutrients available from the above-mentioned livestock slurries is given in terms of pounds. (Merryman-East Central)

THE DECOMPOSITION OF CATTLE DUNG AND ITS EFFECT ON PASTURE,

The Hannah Research Institute, Ayr
M. E. Castle and E. MacDaid
Journal of the British Grassland Society, Vol. 27, p. 133-137, 1972. 9 ref.

Descriptors: Cattle, Pastures, Dairy industry, Crop response.
Identifiers: Decomposition, Dung, Herbage, Swards.

To investigate the effect of the intensity of grass-land management on the rate of decomposition of dung, and on the area of herbage rejected, a study was made in which swards received either a high or a low rate of fertilizer N and were then grazed by dairy cows. In early spring, 1967, four plots with swards of a similar botanical composition were fenced and fertilizer treatments were imposed throughout 1967 and 1968. N was applied as nitro-chalk (21 percent N) at approximately monthly intervals, beginning in April, 1967 and May, 1968. A total of 228 separate dung pats voided by lactating dairy cows between May and October on a ryegrass /clover swards were studied for 2 years. The pats were on grazed swards receiving, on average, either 440 or 110 lb N /ac (492 or 123 kg /ha) per year. The mean output of the plots was 520, 440, 280 and 310 cow grazing-days /ac per year, respectively. The plots receiving the highest weight of fertilizer N clearly gave the highest number of grazing-days /ac, exerted on that treatment. The mean area of the dung pats was 0 • 62 + 0 • 18 ft². On average, the pats on the high- and low-N treatments crumbled in 63 and 55 days, respectively, and disappeared in 115 and 113 days, respectively. The average area of rejected herbage around the pats was 2.63 and 0 • 84 ft² respectively, 1-2 months, and 1 year after they were voided. In conclusion, it was found that the level of fertilizer N applied to the grazing sward had no direct effect on the rate of breakdown of the dung. (Cameron-East Central)

EFFECTS OF COW SLURRY ON HERBAGE PRODUCTION, INTAKE BY CATTLE AND GRAZING BEHAVIOR,

National Institute for Research in Dairying, Shunfield, Reading, Berkshire
B. F. Pain and J. D. Leaver
Journal of the British Grassland Society, Vol. 29, p. 85-91, 1974. 1 fig, 5 tab, 9 ref.

Descriptors: Slurries, Cattle, Animal behavior, Crop response, Grazing, Nutrients.
Identifiers: Land disposal, Herbage production.

Experiments were done to compare the effect of different levels of slurry application on herbage production and on intake by grazing heifers. Grassland plots received different amounts of cow slurry in January or March and were grazed by dairy heifers at intervals from late April to August. In the first experiment (which had slurry level applications up to 56 tons /ha) there was a clear response of herbage DM production to the amount of slurry applied. Even though the plots received the same amounts of inorganic N, the total herbage DM produced on the 36.8 and 56.6 t /ha slurry treatments was 60-70 percent greater than the control. In the second experiment, although slurry levels as high as 100 tons /ha were used, the herbage DM production was very similar on slurry treatments and on controls to the results in the first experiment. No significant differences were found in herbage production on the plots spread with slurry in January or in March. The percentage of nutrients in the slurries used in the two years was very similar, except for K levels, which were higher in 1971. The levels of N, P and K in herbage for both experiments were only slightly increased after slurry treatment. There was evidence from behaviour observations that the animals were better able to detect the slurry, or its effects, in the plots dressed at 75 or 100 t /ha in March. During periods of observation, the heifers were less likely to lie and to ruminate in plots treated with these amounts. It is likely that the effects of slurry application on herbage production, animal intake and grazing behaviour recorded in these experiments would be modified by different soil and climatic conditions. (Cameron-East Central)

THE EFFECT OF HEAVY DRESSINGS OF SLURRY ON FORAGE MAIZE PRODUCTION,

National Institute for Research in Dairying, Shinfield, Reading, Berks
B. F. Pain and R. H. Phipps
Journal of the British Grassland Society, Vol. 29, p. 263-267, 1974. 8 tab, 11 ref.

Descriptors: Slurries, Crop response, Potassium, Nitrates, Magnesium.
Identifiers; Land disposal, Application rates.

A study was conducted to investigate the effects on the quality and quantity of forage maize produced when heavy dressings of cow slurry were incorporated into the soil shortly before drilling the seed.

Sandy loam soil overlying valley gravel formed the experimental site. Slurry of 15 percent dairy manure was dressed on the soil in amounts of 0, 125, 250 or 500 tons per half acre and then ploughed to a depth of 15 cm. The slurry plots were in randomized blocks, replicated 3 times. The control plots, which received only inorganic fertilizer, were offset to avoid contamination. All plots were sown with maize. Quantity and quality determinations were made 73, 93, 115, and 137 days after plant emergence. It was found that the slurry dressings delayed the emergence of maize plants. While the 250 tons per half acre treatment gave significant increase in yield at final harvest, 500 tons per half acre depressed yields of the whole crop and of the ear. Slurry applications increased the level of K and nitrate-N in the plants, but depressed Mg. Crude protein and invitro digestibility were not affected. In view of the high levels of nitrate-N encountered and evidence of K/Mg imbalance, further work would be required to assess the status of maize grown under these conditions as a livestock feed. (Penrod-East Central)

COMPARISONS OF HORN FLY DEVELOPMENT IN MANURE OF FIVE ANIMAL SPECIES,

Department of Entomology and Nematology, Florida University, Gainesville
N. I. Greer and J. F. Butler
Florida Entomologist, Vol. 56, No. 3, p. 197-199. 1973. 1 tab, 3 ref.

Descriptors: Farm wastes, Livestock, Cattle, Larvae.
Identifiers: Fly breeding, Horn flies, Feces, Horses, Sheep, Bison, Swine, Pupae.

Laboratory and field studies were conducted to determine if horse, bison, sheep, and swine manure could serve as a medium for rearing horn fly larval stages to viable adults. The standard larval medium, a modification of the Kerrville rearing medium, consisted of a dry mix (246 g sugar cane pulp, 48 g wheat flour, 36 g fish meal, 6 g sodium bicarbonate, 29 g alfalfa meal), cattle manure, and distilled water mixed in a ratio of 2:3:5 by weight. Larvae were maintained at 25 degrees C and 60-70 percent RH. Adults were maintained at 32 degrees C and 70-80 percent RH. Field observations of female horn flies ovipositing on fresh horse and cattle manure were made. The horn fly populations on cattle and horses were counted. Analysis of variance was used to determine significant differences in development on the larval media. Results showed that pupal survival in cattle manure was 31 percent. Horn flies developed to the pupal stage in feces of bison, sheep, horse, and the standard laboratory medium. Significantly more adults were reared from feces of sheep, bison, horse, cattle, and laboratory media than from swine feces. No larvae developed to pupae in swine manure. Data on the percent eclosion showed that bison, sheep, and horse manure were excellent media for development. The adults reared from the laboratory medium, and cattle, sheep, horse, and bison feces produced viable eggs. No significant differences in fly larval development among manure of cattle, sheep, bison, and horse, and laboratory medium was demonstrated. Data indicated that horn flies in the laboratory can complete their larval life in the manure of bison, sheep or horse in addition to cattle manure. In field observations, adult horn flies were found in low numbers on sheep, horse, and bison. (Cameron-East Central)

CATTLE MARKET WASTES,

J. M. Sidwick, F. D. Watson, and D. M. Watson
Water and Pollution Control, Vol. 71, No. 4, p. 533-539, 1972.

Descriptors: Waste treatment, Waste water treatment, Sampling.
Identifiers: Cattle market wastes.

The author comments that the extremely varied and seasonal nature of cattle market wastes, combined with the fact that the markets are usually located in small towns with limited ability to handle large amounts of troublesome wastes, make this form of agricultural waste particularly problematic. He suggests that high-power hoses be used to minimize the amount of water needed to wash out pens and stalls, and that clean water from the market, such as rainwater from roofs, be kept separate from the polluted wash water. All drains should be provided with screens so that straw and other large objects cannot pass into the sewer along with the water. As much of the waste as possible should be cleaned out of the pens in its solid state before any water is added to it. Except for screening, any pretreatment of the waste water prior to its entry into the sewer is not feasible. Once the water reaches the sewage treatment plant, it may create problems, since it is not so biodegradable as municipal sewage, does not produce as much gas, and is highly colored. Suggestions are offered regarding sampling and prediction of quantity and composition of market wastes. An extensive bibliography on management and health aspects of market wastes is included. At the end of the paper there is a short discussion by those present at the reading of the article. (Solid Waste Information Retrieval System)

FDA GUTS DPW USE,

Anonymous
Egg Industry, Vol. 9, No. 4, p. 28, April, 1976.

Descriptors: Regulations, Legal aspects.
Identifiers: Food and Drug Administration, Dried poultry wastes, Refeeding.

This aspersive attack on the Food and Drug Administration's attitude toward refeeding dried poultry wastes (DPW) charges that within a few months, the Food and Drug Administration will publish its long-awaited waste recycling proposals and that they will be so restrictive that the only animals allowed to be fed DPW will be animals that nobody feeds a supplement to anyway, such as overwintered beef stock or dry cows. The article charges that the reason for this bureaucratic tokenism is that the Bureau of Veterinary Medicine and the Bureau of Foods within FDA cannot agree on the safety of the practice. It is suggested that the poultry associations may have to take the lead in demonstrating to FDA that the practice is safe and that perhaps a suitable monitoring system could be established that could be translated into a national program. Another alternative might be to test FDA's decision in court. (Merryman-East Central)

MANURE DISPOSAL, POLLUTION CONTROL, AND THE NEW YORK DAIRY FARMER,

Agricultural Waste and Watershed Researcher, Engineering Research Service, Department of Agriculture, Ottawa, Canada
D. R. Coote and P. J. Zwerman
New York's Food and Life Sciences Bulletin, No. 51, Physical Sciences: Agronomy, No. 3, April, 1975, 19 p. 3 tab, 100 ref.

Descriptors: Dairy industry, Waste disposal, New York, Economics, Regulation.
Identifiers: Land disposal, Pollution control.

Fifty New York dairy farms were visited in 1971 to investigate dairy waste management problems and farmer attitudes toward economic and environmental effects of alternative waste management methods. Two distinct types of dairy farms were noted (1) those with conventional barns (cattle stayed mostly in pasture) and (2) those with freestall barns (cattle permanently confined in barn and exercise yard or pasture). In the pasture system, cattle spread their own manure; in the freestall barn, farmers disposed of the manure. Most farmers felt that all their manure could beneficially be used in field spreading. However, some freestall farmers favored "dumping" of manure on fields, regardless of environmental effects. Existing regulations that limit pollution by dairies are discussed. Other possible legal approaches are: (1) Restrict the manure amounts to be spread on an area in one year, (2) Restrict manure spreading to soils that are not excessively permeable or excessively impermeable, (3) Restrict manure spreading to flat or only gently-sloping fields, (4) Restrict manure spreading to areas greater than some acceptable distance from surface water capable of leaving the operator's property, (5) Restrict the housing of animals and the spreading of manure to areas greater than some acceptable distance from dwellings and public areas, (6) Restrict manure spreading to certain times of the year, (7) Require that a certain minimum land area be zoned and controlled by the farm operator according to the quantity and type of animals kept, (8) Require that any form of manure disposal, other than land application, meet the same controls and standards as those required for industrial or municipal effluent disposal, (9) Require that manure managing be such that no disease, odor, insect, or rodent nuisance is caused. (Penrod-East Central)

IMPLICATIONS OF EPA PROPOSED REGULATIONS OF NOVEMBER 20, 1975 FOR THE ANIMAL FEEDING INDUSTRIES,

U. S. Department of Agriculture, Animal Waste Subcommittee
Implications of EPA Proposed Regulations of November 20, 1975 for the Animal Feeding Industries, U. S. Department of Agriculture, January 30, 1976, 39 p. 21 tab.

Descriptors: Regulations, Economics, Water pollution, Point sources, Feedlots, Livestock.
Identifiers: National Pollutant Discharge Elimination System, Waste management.

The Environmental Protection Agency's National Pollutant Discharge Elimination System (NPDES) proposed regulations of November 20, 1975, for livestock operations could require an estimated 94,500 operators to apply for permits. The information contained in this report is based on expert opinion (not surveys) of USDA and State research and extension personnel located in major livestock producing States and was not available when EPA proposed the regulations. Of the estimated 94,500 operations affected by NPDES regulations—manmade waste conveyance, navigable water traversing the operation, and large operations—there are 14,000 beef, 32,000 dairy and 48,500 swine operations. In addition, as estimated 250 turkey range operations would be affected. Estimates indicate that less than 4 percent of the operations that would be affected have capacities of more than 300 animal unit equivalents (300 beef animals, 750 swine and 210 dairy cows). Over 70 percent of the operations judged to be affected had capacities of less than 100 beef animals, 250 swine and 70 dairy cows. In order to comply with the proposed regulations, it is likely that affected operations would have to install systems to control discharges. Additional investments to install these systems would amount to about $205 million. For an additional 10 percent of the operations, the least-cost method of meeting proposed regulations would be to relocate the operation. The estimated 94,500 operations affected account for 20 percent of total fed beef marketings, 19 percent of milk sales, and 11 percent of hogs and pigs marketed. The proposed regulations contain a further provision for identifying a "concentrated animal feeding". This provision allows for "case-by-case" designation of additional operations, regardless of size, that must apply for an NPDES permit, but the factors determining the outcome of these determinations are not listed in the proposed regulations. THE INFLUENCE OF LAND USE ON STREAM NUTRIENT LEVELS,

Eutrophication Survey Branch, Corvallis Environmental Research Laboratory, Crovallis, Oregon
J. M. Omernik
Environmental Protection Agency Report Number EPA-600/3-76-014, January, 1976, 106 p. 29 fig, 8 tab, 31 ref.

Descriptors: Land use, Water quality, Nutrients, Watersheds, Agricultural runoff, Drainage patterns (geologic), Phosphorus, Nitrogen, Concentrations, Eutrophication, Stream flow, Animal unit density, Soils, Eastern U. S.
Identifiers: Non-point source.

National Eutrophication Survey (NES) data for 473 non-point type drainage areas in the eastern United States were studied for relationships between drainage area characteristics (particularly land use) and nutrient levels in streams. Both the total and inorganic forms of phosphorus and nitrogen concentrations and loads in streams were considered. The objectives were to (1) investigate these relationships as they were evidenced by the NES data and (2) develop a means for estimating stream nutrient levels from knowledge of "macro" drainage area characteristics. Mean nutrient levels were considerably higher in streams draining agricultural watersheds than in streams draining forested watersheds. The levels were generally proportional to percentages of land in agriculture, or the combined percentages of agricultural and urban land use. Variations in nutrient loads (exports) in streams, associated with differences in land use categories, were not as pronounced as the variations in nutrient concentrations. This was apparently due, in large part, to differences in areal stream flow from different land use types. Regression and analysis of the combined percentages of agricultural and urban land uses against both the total and inorganic forms of phosphorus were performed. Equations for these analyses, together with maps illustrating the equations residuals offer a limited predictive capability and some accountability for regional characteristics. (Mernik-EPA)

CATTLE MANURE KEY TO METHANE GAS SUPPLIES,

Western Livestock Journal, Vol. 54, No. 30, p. 5, April 19, 1976.

Descriptors: Recycling, Methane, Fertilizers, Economics.
Identifiers: Cattle manure, Ethane, Ethylene, India.

Cattle manure was viewed by scientists at the American Chemical Society meeting in New York City as a large potential source of methane gas, nitrogen and other fertilizers, and chemical feedstocks. Experiments performed at Texas Tech University, Lubbock, demonstrated that significant yields of ethane and methane, anhydrous ammonia synthesis gas and ethylene could be obtained by processing cattle waste in a partial oxidation (thermal) reactor. It was pointed out that if only one eighth of India's supply of cattle dung were treated in this way, it could result in a seven fold increase in India's critically low fertilizer rate, bridging the gap between projected demand and supply, not only in fertilizer but also in food. (Merryman-East Central)

LOADING FUNCTIONS FOR ASSESSMENT OF WATER POLLUTION FROM NONPOINT SOURCES,

Midwest Research Institute, 425 Volker Boulevard, Kansas City, Missouri
A. D. McElroy, S. Y. Chiu, J. W. Nebgen, A. Aleti, and F. W. Bennett
Environmental Protection Agency Report No. EPA 600/2-76-151, May, 1976, 444 p. 50 fig, 75 tab.

Descriptors: Water pollution, Non-point sources, Water pollution, Nutrients, Pesticides, Salinity, Irrigation return flow, Heavy metals, Radiation, Livestock, Pollutants, Sediments, Phosphorus, Agricultural runoff, Mining, Soil erosion, Groundwater pollution, Coliforms.
Identifiers: Land disposal, Urban runoff.

Methods for evaluating the quantity of water pollutants generated from nonpoint sources including agriculture, silviculture, construction, mining, runoff from urban areas and rural roads, and terrestrial disposal are developed and compiled for use in water quality planning. The loading functions, plus in some instances emission values, permit calculation of nonpoint source pollutants from available data and information. Natural background was considered to be a source and loading functions were presented to estimate natural or background loads of pollutants. Loading functions/values are presented for average conditions, i.e., annual average loads expressed as metric tons/hectare/year (tons/acre/year). Procedures for estimating seasonal or 30-day maximum and minimum loads are also presented. In addition, a wide variety of required data inputs to loading functions, and delineation of sources of additional information are included in the report. The report also presents an evaluation of limitations and constraints of various methodologies which will enable the user to employ the functions realistically (McElroy-Midwest Research Institute)

MANURE POWER,

Calf News, Vol. 14, No. 6, p. 14, 46, June, 1976.

Descriptors: Energy, Recycling, Feeds, Methane, Economics.
Identifiers: Cattle manure, Land spreading.

Developing new energy sources is a top priority for most of the world, and a number of scientists are eyeing feedlot manure as one potential. However, Dr. Judson M. Harper, head of the Agricultural Engineering Department at Colorado State University, Fort Collins, reported to CALF that producing methane gas from manure is not economically feasible. Methane fermentation is time consuming, requires large quantities of water, and solids remaining after fermentation still have to be disposed of. He suggested a better approach to be drying it to some extent and then burning it as a fuel in a trash-type broiler. The heating value of dry manure is essentially the same as the heating value of low-grade coal. By using the recycling system developed by Ceres Ecology, Inc., of Sterling, Colorado, a plant would obtain from feedlot manure a 45 percent non-protein-nitrogen product equal in value to soybeans and a fuel to operate the feed mill and other such community plants. The cost of a complete recycling unit including all the environmental protection requirements capable of handling the manure from 100,000 cattle would fall between one and two million dollars, according to Dr. Harper; whereas, a methane plant to handle 100,000 head, at one time considered for Monfort of Colorado, was pegged at ten million dollars. THE FATE OF FERTILIZER NUTRIENTS AS RELATED TO WATER QUALITY IN THE NORTH CAROLINA COASTAL PLAIN,

Department of Soil Science, North Carolina State University, Raleigh
R. P. Gambrell, J. W. Gilliam, and S. B. Weed
North Carolina Water Resources Research Institute Report No. 93, August, 1974, 151 p. 24 fig, 5 tab, 79 ref.

Descriptors: Fertilizers, Nutrients, Water quality, North Carolina, Nitrogen, Nitrates, Phosphorus, Agricultural runoff.

Quantities of nitrogen and phosphorus moving into surface and subsurface waters from cultivated soils of the North Carolina Coastal Plain, as affected by internal drainage, were determined. In a moderately well-drained soil, little denitrification was found; in a poorly drained soil with a high water table, much of the unutilized fertilizer nitrogen was lost from the field through denitrification. Little phosphorus was lost from either location studied except by surface movement with eroded sediments. Application of fertilizer nitrogen (224 kg/ha) resulted in an increase in loss of total nitrogen by surface runoff from both soils. Values were 29 percent for the moderately well-drained soil and 10 percent for the poorly drained soil. Nitrogen lost in surface runoff was almost exclusively organically bound, indicating that fertilizer applications serve to maintain the level of soil organic nitrogen. A 2-year nitrogen budget indicated that about 46 kg of residual nitrate-nitrogen/ha moved annually from moderately well-drained soil by subsurface drainage into nearby surface waters. Tile drainage accounted for about half of this nitrogen movement. Denitrification did not remove significant amounts of residual nitrate from the moderately well-drained soil. About 15 kg of nitrate-nitrogen /ha annually moved from poorly drained soil by subsurface drainage during the two winters. The smaller loss from poorly drained soil resulted from denitrification of residual nitrate in the shallow groundwater. Water management may increase the denitrification of unused soil nitrate and thus reduce the pollution potential. (Gambrell-North Carolina State Univ.)

THE DIETARY-FECAL RELATIONSHIP OF CALCIUM AND PHOSPHORUS LEVELS IN WHITE LEGHORN HENS,

Department of Poultry Science, Florida Agricultural Experiment Station, Gainesville
B. L. Damron, A. R. Eldred, D. A. Roland, Sr., D. B. Underhill and R. H. Harms
Poultry Science, Vol. 54, No. 5, p. 1716-1718, 1975. 2 tab, 2 ref.

Descriptors: Diets, Calcium, Phosphorus, Poultry. Identifiers: Physiological requirements.

Chemical determinations indicate that hen feces contain appreciable quantities of several nutrients such as protein, calcium and phosphorus. This indicates the possible use of hen feces as an ingredient In poultry feeds. The authors collected manure from caged White Leghorn hens in an attempt to study the dietary and fecal interrelationships of calcium and phosphorus. When fecal calcium was increased by increasing dietary calcium, phosphorus levels in the feces decreased in an inverse relationship to calcium levels. When calcium levels were held constant, fecal calcium levels remained fairly constant as the phosphorus level increased. Each increment of supplemental phosphorus resulted in a concomitant increase of fecal phosphorus. The ratio of dietary to fecal phosphorus tended to stabilize at dietary levels above 0.43 percent, possibly indicating a "pass-through" situation after physiological requirements were met. DISPOSAL OF BEEF FEEDLOT MANURE,

Texas Agricultural Experiment Station, El Paso
D. L. Reddell and P. Lyerly
Progress Report PR-3279C, Texas Agricultural Experiment Station, Texas A & M University, September, 1975. 5 fig, 19 tab, 21 ref.

Descriptors: Waste disposal, Crop response, Water pollution, Groundwater pollution, Agricultural runoff, Nutrients, Soil profile, Odor, Nitrates. Identifiers: Land disposal, Plowing.

Research was conducted at the Texas Agricultural Experiment Station in El Paso to study the following: (a) the ability of various tillage equipment to plow under up to 900 tons per acre of manure and cover with sufficient soil to eliminate odors, (b) deep plowing disposal techniques for possible pollution of surface water and (c) crop quality and yields from deep plowed field plots receiving large manure application rates. In May, 1970, beef manure was deep plowed into Vinton fine sandy loam at rates of 0, 300, and 900 tons per acre wet basis. Pollution level of irrigation runoff increased with manure application rate immediately following application, but rapidly decreased to background levels within a couple of months. Soil solution extracts taken from the unsaturated manure disposal plots indicated an increase in ammonium, organic-nitrogen, COD, sodium and chloride with manure application rate. These chemical constituents peaked and in most cases were decreasing by August, 1972. Ground water samples revealed an increase in chemical constituents with manure application rate. Concentrations peaked during 1971 and reduced to background levels by August, 1972. Although significant levels of nitrate accumulate in the soils receiving large manure applications, no detrimental nitrate level occurred in groundwater samples. Denitrification must have prevented this. Yields of corn silage and forage sorghum that were grown on plots receiving up to 900 tons per acre of manure were diminished the first year. However, yields increased during the second and third years. Nitrate levels in these crops were below the nitrate toxicity levels for feeding livestock. Nitrate levels of forage grown on the 300-ton per acre plots and the 900-ton per acre plots were comparable. (Penrod-East Central)

POULTRY MANURE DEHYDRATION BY AIR-DRYING AND MACHINE IN A CAGED LAYER-HOUSE HANDLING SYSTEM,

Agricultural Engineering Department, Michigan State University, East Lansing
M. L. Esmay, C. J. Flegal, C. C. Sheppard, J. B. Gerrish, J. E. Dixon, et. al.
Research Report 269, "Poultry Pollution: Research Results", Agricultural Experiment Station, Michigan State University, February, 1975, p. 2-13. 6 fig, 3 tab, 5 ref.

Descriptors: Dehydration, Energy, Costs. Identifiers: Poultry manure, Air drying, Mechanical drying, Refeeding.

A demonstration project was conducted to design, construct and test a poultry laying house that would incorporate a complete system for waste removal and dehydration of the excreta for refeeding to poultry or other livestock. Excreta from caged poultry was allowed to accumulate on dropping boards in a poultry house throughout a 24 hour period. The droppings were hand scraped daily from the dropping boards into manure pits. They were scraped from the pits daily by a cable-blade scraper into a cross-conveyer and immediately onto a drying belt where they stayed for another 24 hours. On the second day, the excreta on the belt was conveyed into the dryer. A drying period of 2 or 3 hours of machine time was required during which waste heat from the dryer and afterburner was directed through the dryer and out of the house. Thus it is seen that water was removed from the poultry excreta in four stages: (1) on the dropping boards by ventilation air, (2) on the belt by ventilation air, (3) on the belt by waste heat from the dryer, and (4) as it was being run through the dryer. The dry matter output and moisture removal capability of the machine dryer appeared to decrease when lower moisture excreta was fed into it (as in June, July, and August) during which the excreta going into the dryer varied from 48-59 percent as compared to the colder months when it varied at a higher level from 58-68 percent. Fuel cost for the heated air machine drying was about one cent for each pound of water removed with an assumed fuel cost of 34 cents a gallon. This research was still in process at the time this paper was written. (Merryman-East Central)

CORN GRAIN YIELDS AND CHANGES IN SOIL FERTILITY LEVELS AS AFFECTED BY FIVE RATES OF POULTRY MANURE,

Department of Crops and Soil Sciences, Michigan State University, East Lansing
L. S. Robertson and J. H. Wolford
Research Report 269, "Poultry Pollution: Research Results", Agricultural Experiment Station, Michigan State University, February, 1975, p. 14-20. 1 fig, 4 tab, 3 ref.

Descriptors: Soil profile, Crop response, Nutrients, Water pollution. Identifiers: Corn, Disposal rates, Poultry manure, Soil pollution.

Field experimental plots were established in Huron County, Michigan, in 1967 to determine how much manure could be used before problems would be caused in relation to the corn production or to the soil. Five treatments were originally made with a sixth added after the first year. The soil treated was of the Sims and Breckenridge series, and for years had annually received varying rates of poultry manure. Thus, it was a fairly fertile soil even before these experiments began. The treatments, which were replicated four times, included: (a) no manure and no fertilizer (check), (b) commercial fertilizer only, 150 + 150 + 150 (N + P_2O_5 + K_2O), (c) 5.8 tons/acre/year (moist weight) of chicken manure, (d) 11.6 tons/acre/year of chicken manure, (e) 23.2 tons/acre/year of chicken manure, (f) 46.4 tons/acre/year of chicken manure. Both the fertilizer and the manure were broadcast and plowed under in the fall. After 5 years, composite soil samples of the surface soil were collected from each plot and analyzed. Corn grain yields were determined each year. The average corn grain yields were exceptionally high, ranging between 139 and 151 bushels per acre for the 5-year period. The manure increased the carbon, nitrate nitrogen, phosphorus, potassium, calcium, magnesium, zinc, and sodium levels in the soil in varying degrees. With rates of chicken manure in excess of 20 tons/acre, the possibility of soil and water pollution increased rapidly. (Merryman-East Central)

NUTRIENT DISTRIBUTION IN PROFILE OF SOIL TREATED WITH A HIGH RATE OF CHICKEN MANURE,

Department of Crops and Soil Sciences, Michigan State University, East Lansing
L. S. Robertson, J. H. Wolford, and P. Godz
Research Report 269, "Poultry Pollution: Research Results", Agricultural Experiment Station, Michigan State University, February, 1975, p. 21-28. 5 tab.

Descriptors: Nutrients, Soil profile, Poultry, Crop response, Fertilizers. Identifiers: Corn.

Research was done to evaluate the accumulation of plant nutrients from chicken manure in surface soil and to determine the extent of nutrient movement into subsurface zones when chicken manure was used at high rates in a corn monoculture system. Check plots ("no manure" and "no fertilizer") and manure treated plots were established on a Sims-Breckenridge soil in Huron County, Michigan. Only the plots receiving 46.4 tons /acre /year were compared in this report to the check plots. Statistically, the manure did not increase the corn yield to a higher level than was produced on the check plots. Two factors may account for this. High rates of manure had been used in the plot area for some time before the experiment was initiated. Also, the Breckenridge soil is a two-storied soil, where there are opportunities for lateral movement of certain nutrients, especially nitrate nitrogen, from the treated plots into the check plot areas. However, poultry manure was found to be a good source of plant nutrients for corn. It was estimated from the average composition of chicken manure that 20 tons per acre used on an annual basis would more than satisfy the nutrient requirements for a 150-bushel corn crop. It was found that poultry man-

ure used at the rate of 46.4 tons /acre decreased the pH of the soil and increased the levels of available phosphorus within the soil profile to a depth of 42 inches by 140 percent; potassium, 172 percent; nitrate-nitrogen, 954 percent; ammonium-nitrogen, 126 percent; and total nitrogen, 53 percent. Sodium levels were increased slightly. Zinc collected in the surface soil, as did copper. The manure did not greatly change the levels of available calcium, magnesium, iron, manganese, or chloride. The nitrogen in the manure was retained within the soil profile. (Merryman-East Central)

FERTILITY AND HATCHABILITY IN SINGLE COMB WHITE LEGHORNS FED VARYING LEVELS OF POULTRY ANAPHAGE,

Poultry Science Department, Michigan State University, East Lansing
C. J. Flegal, D. Dorn, M. X. Gomez and H. C. Zindel
Research Report 269, "Poultry Pollution: Research Results", Agricultural Experiment Station, Michigan State University, February, 1975, p. 29-38. 6 tab. 1 ref.

Descriptors: Poultry, Performance, Diets.
Identifiers: Fertility, Hatchability, Refeeding, Poultry anaphage.

Twenty-four troups of 5 ready-to-lay S.C.W.L. females plus one S.C.W.L. male were randomly assigned 4 experimental diets, with 6 replicate groups being fed each diet. Diet 1, a basal diet, was a typical corn /soya layer ration. The other 3 diets contained 3 levels of poultry anaphage (6.25, 12.5, and 25 percent) which replaced an equivalent percentage of corn in the basal diet. In the first 3 weeks of the experiment, only egg production data were recorded. During Phase I (week 4 to week 11) of the experiment, all females were inseminated once each week. During Phase II (week 12 to week 15), the inseminations were increased to twice per week. There was statistically no significant difference in the percent egg production from the birds fed any of the poultry anaphage supplemented diets and the egg production of the birds fed the control diets. Percent fertility of eggs produced during Phase I by the birds fed the poultry anaphage diets showed no statistical difference from those fed the corn /soya diet. The poultry anaphage diets had no significant effect on the percent hatchability of fertile eggs produced during Phase I. With continued feeding of the diets that contained poultry anaphage during Phase II, the mean percent fertility declined 1.7 percent, when compared to the fertility data from the corresponding earlier period. The poultry anaphage diets continued to show no effect on percent hatchability of fertile eggs when the diets were fed for the continued period of week 11 to week 15. The inconsistent trends in fertility among the birds fed increasing levels of supplemental poultry anaphage need to be further investigated. More valid data on fertility could be obtained during a combined system of natural mating and artificial insemination. (Merryman-East Central)

BIOLOGICAL AVAILABILITY OF PROTEIN FROM POULTRY ANAPHAGE,

Poultry Science Department, Michigan State University, East Lansing
D. Polin and K. M. Chee
Research Report 269, "Poultry Pollution: Research Results", Agricultural Experiment Station, Michigan State University, February, 1975, p. 39-51. 2 fig. 7 tab. 9 ref.

Descriptors: Poultry, Diets, Proteins, Performance.
Identifiers: Refeeding, Poultry anaphage, Quail.

Day-old Japanese quail were reared in a battery-brooder for 7 days and fed a diet that contained 15 percent protein, with the idea that protein from growth would be marginal. On day 7, the quail were weighed, then sorted by weight and transferred as groups of 15 of nearly equal body weight to a battery-brooder with 24 pens. Twelve dietary treatments, with 2 replications per treatment, were assigned at random. The test diets and a practical diet were then fed for 7 days. One set of diets was formulated to provide protein only from isolated soy protein (I.S.P.), supplemented with methionine. The other set of diets contained the same gradient amounts of isolated soy protein, plus poultry anaphage as the other source of protein. All diets were isocaloric. Quail receiving anaphage ate consistently more feed than the check group. However, when the total feed consumed was corrected for the anaphage as 30 percent of the dietary weight, the actual amounts of the basal mix and thus I.S.P. consumed by the quail receiving anaphage were less than those fed the diets without anaphage. Despite this, the final body weights and body weight gains were consistently greater than their counterparts receiving the comparable feed level of I.S.P. Nitrogen intake per bird was much higher in quail fed anaphage. Carcass N was generally higher for this group. It was determined that between 12.3 to 13.7 percent of crude protein was available from anaphage. Based on the "true protein" value determined by precipitation with trichloroacetic acid or amino acid analysis, essentially all of this protein would appear to be available to the bird. The "true protein" value obtained by chemical methods would appear to be a good assessment of the true protein in anaphage. ((Merryman-East Central)

EFFECT OF DEHYDRATED POULTRY ANAPHAGE ON TURKEY BREEDER HEN EGG PRODUCTION,

Poultry Science Department, Michigan State University, East Lansing
J. H. Wolford, G. O. Fadika, J. R. Beck, and C. J. Flegal
Research Report 269, "Poultry Pollution: Research Results", Agricultural Experiment Station, Michigan State University, February, 1975, p. 52-57. 2 fig. 2 tab. 9 ref.

Descriptors: Poultry, Feeds, Performance, Design, Mortality.
Identifiers: Dehydrated poultry anaphage, Refeeding, Cracked eggs.

A project was designed to evaluate the performance of caged turkey breeder hens fed dehydrated poultry anaphage. In addition, different types of cage floor bottoms were evaluated. Large white turkey hens were housed two per cage in a light-controlled building. The cages were 18 inches deep by 28 inches wide, with a 2-inch back-to-front slope. The dehydrated poultry anaphage was obtained by collecting the feces of these caged turkeys from 20 to 24 weeks of age and dehydrating them in a machanical heat dehydrator. The anaphage was fed from 31 weeks of age to the end of the experimental period at the dietary rate of 12.5 percent. Mortality was not appreciably influenced by feeding dehydrated poultry anaphage nor by the type of cage in which the birds were housed. The number of eggs produced was not significantly influenced by cage design; however, egg production was significantly improved by feeding a diet containing 12.5 percent dehydrated poultry anaphage. The number of cracked and broken eggs was significantly decreased in the cages having rubber-coated wire floors. The welded wire floor resulted in a 15.8 percent incidence of cracked and loss eggs, whereas the incidence was 8.3 and 4.9 percent for the floors having a thin or thick rubber coat, respectively. Neither feeding dehydrated poultry anaphage nor cage height had a significant influence on cracked and loss egg incidence. (Ott-East Central)

EGG PRODUCTION AND FERTILITY OF CAGED TURKEY BREEDER HENS FED DEHYDRATED POULTRY ANAPHAGE,

Poultry Science Department, Michigan State University, East Lansing
J. H. Wolford
Research Report 269, "Poultry Pollution: Research Results", Agricultural Experiment Station, Michigan State University, February, 1975, p. 58-62. 2 tab, 2 ref.

Descriptors: Poultry, Feeds, Performance.
Identifiers: Dehydrated poultry anaphage, Refeeding, Egg production, Fertility, Hatchability.

In a preliminary experiment, Wolford showed that dehydrated poultry anaphage could be fed to caged turkey breeder hens without any detrimental effect on egg production. This experiment was conducted to further evaluate dehydrated poultry anaphage as a feed ingredient for caged turkey breeder hens. In addition to egg production data, fertility and hatchability records were kept. Forty-eight Nicholas large white turkey hens were obtained from a commerical grower when the birds were 30 weeks of age. The birds were placed in cages (2 birds per cage) and provided a 14 hour artificial light day. The experiment was conducted for 84 days. Dehydrated poultry anaphage was incorporated into the diet at the 10 percent level and fed to the hens throughout their entire reproductive period. During the last 23 days of the experiment, fertility and hatchability data were collected. Each hen was imseminated weekly with 0.05 ml of pooled semen collected from males that received the control diet. The egg production was not significantly altered by feeding a diet containing 10 percent dehydrated poultry anaphage; however, there was a four egg per bird advantage for the birds fed dehydrated poultry anaphage. The percentage of shell-less, cracked, and broken eggs was not appreciably affected by the dietary alteration. Fertility and hatchability were not detrimentally influenced by feeding dehydrated poultry anaphage to turkey breeder hens during the reproductive period. Livability, ending body weight, and foot swelling score were not affected by feeding dehydrated poultry anaphage. (Ott-East Central)

CAGE FLOOR TYPE AND DEHYDRATED POULTRY ANAPHAGE: EFFECT ON REPRODUCTIVE PERFORMANCE OF TURKEY BREEDER HENS AND THEIR PROGENY,

Department of Animal and Veterinary Sciences, University of Maine, Orono
J. H. Wolford, G. O. Fadika, S. Iturri, and R. K. Ringer
Research Report 269, "Poultry Pollution: Research Results", Agricultural Experiment Station, Michigan State University, February, 1975, p. 63-73. 5 tab. 5 ref.

Descriptors: Poultry, Performance, Reproduction, Fertility, Hatchability.
Identifiers: Anaphage, Refeeding, Floors, Cracked eggs.

Four experiments, 2 with adult and 2 with poults (both sexes), were performed. In experiment 1, fifty-six 28-week old Nicholas large white hens (female-line) were placed in cages. Cage floors were 2" x 4" welded wire covered by either a soft plastic insert mat, hard plastic, or Bressler plastic. A 10 percent dehydrated poultry anaphage diet was fed to the appropriate birds. From December 10, 1973-February 11, 1974, each hen was inseminated weekly with pooled semen collected from males not fed anaphage. Fertility and hatchability data were collected. Experiment 2 was like experiment 1 except: (1) 88 day-old Nicholas large white turkey poults were grown to 17 weeks of age on litter or in cages, then transferred to cages like those in experiment 1 or placed in a litter floor pen at 8.25 sq. ft /bird density and fed a standard growing ration until 28 weeks old. (2) Then, all birds received a breeder "control" diet. (3) The cage floors were covered with either a soft plastic mat or hard plastic slats. The litter floor was covered with wood shavings. In experiment 3, 60 poults were randomly selected from a scheduled hatch of eggs produced by experiment 1 birds—30 from eggs produced by hens on the anaphage diet; 30 from eggs produced by hens not fed anaphage. The poults were grown to 4 weeks of age in wire floor batteries and received a starter diet. They were then weighed and serum samples were collected at the time of sacrifice from the first 10 males and 10 females handled. Samples were analyzed for creatinine, calcium, phosphorus, alkaline phosphatase, glutamic pyruvic transaminase, cholesterol, total phosphokinase, phosphokinase enzyme, glucose, and total protein. Experiment 4 was like experiment 3, except that it was conducted 16 days later with poults hatched on January 31, 1974. Floor type significantly influenced the number of intact eggs produced. In experiment 1, birds housed on soft plastic insert mats averaged 8 percent cracked eggs whereas, birds housed on hard plastic slats and Bresler plastic averaged 26.8 and 10.4 percent cracked eggs, respectively. Feeding dehydrated anaphage to caged turkey breeder hens did not significantly alter egg production, fertility, or hatchability of fertile eggs. The percentage of cracked eggs in experiment 2 was greater in the floor-housed turkey breeder hens than in the breeder hens housed in cages with soft plastic insert mats. Fertility and hatchability were lower for floor-housed birds. (Merryman-East Central)

PERFORMANCE AND BLOOD ANALYSES OF GROWING TURKEYS FED DEHYDRATED POULTRY ANAPHAGE,

Poultry Science Department, Michigan State University, East Lansing
G. O. Fadika, J. H. Wolford, and C. J. Flegal
Research Report 269, "Poultry Pollution: Research Results", Agricultural Experiment Station, Michigan State University, February, 1975, p. 74-87. 1 fig, 8 tab. 26 ref.

Descriptors: Performance, Poultry, Phosphorus.
Identifiers: Turkeys, Blood analysis, Dehydrated poultry anaphage, Refeeding, Uric acid.

An experiment was conducted to study the effect of feeding dehydrated poultry anaphage on the performance and blood constituents of growing turkeys from 9-17 weeks of age. Commercial 9-week-old straight run Broad Breasted White turkeys were weighed and randomly assigned to 4 diets which contained 0, 5, 10 and 30 percent dehydrated poultry anaphage. Mortality was not affected by feeding poultry anaphage. The overall body weight gain during the study was not significantly altered by the poultry anaphage. However, a numerical decrease of 0.33 kg per bird, in comparison to the control group, was observed in the birds that received 30 percent dehydrated poultry anaphage in their diet. Feed efficiency was inversely related to the level of anaphage in the diet, with conversion figures being 3.35, 3.40, 3.48, and 3.63 kg feed per kg body weight gain for the 0, 5, 10, and 30 percent anaphage diets, respectively. Feeding of poultry anaphage appeared to have no significant effect on plasma uric acid levels. Plasma phosphorus level was significantly increased by feeding 30 percent poultry anaphage. THE EFFECT OF DEHYDRATORS ON THE NUTRIENTS OF POULTRY ANAPHAGE,

Department of Poultry Science, Michigan State University, East Lansing
T. S. Chang, D. Dorn, and E. Linden
Research Report 269, "Poultry Pollution: Research Results", Agricultural Experiment Station, Michigan State University, February, 1975, p. 88-92. 3 tab, 8 ref.

Descriptors: Dehydration, Equipment, Chemical properties, Physical properties, Nutrients.
Identifiers: Anaphage, Poultry excreta.

Five experiments were conducted to compare the nutrient value of anaphage dried in 2 different dehydrators. The anaphage was analyzed for calcium, phosphorus, ash, crude fiber, moisture, crude protein and protein nitrogen. Dryers were operated according to the manufacturers' instructions. Two thousand pounds of fresh poultry excreta were collected and divided into 2 portions, each of which was immediately dried by a designated dehydrator (Dryer I or II). The results showed that the calcium, ash and protein values of the anaphage from Dryer I were consistently higher than those of the anaphage from Dryer II. The pattern of certain nutrient ingredients changed when values were converted to dried weight basis. However, the overall comparison of nutrient values between the 2 dryers remained the same. Average nutrient values for the 5 experiments were calculated. According to Lohrding's test of 2 means, the results showed that the values of calcium, ash, moisture, crude protein, and corrected protein were significantly different. (Ott-East Central)

PRELIMINARY REPORT ON THE MICROBIOLOGICAL AND CHEMICAL ANALYSES OF ANAPHAGE FROM A COMPLETE IN-HOUSE DRYING SYSTEM,

Department of Poultry Science, Michigan State University, East Lansing
T. S. Chang, D. J. Currigan, J. E. Dixon, M. L. Esmay, C. J. Flegal, et. al.
Research Report 269, "Poultry Pollution: Research Results", Agricultural Experiment Station, Michigan State University, February, 1975, p. 93-97. 1 fig, 1 tab, 8 ref.

Descriptors: Microorganisms, Chemical properties, Bacteria, Physical properties, Moisture content, Nutrients, Costs.
Identifiers: Anaphage, Dehydration.

Microbiological and chemical analyses were performed on anaphage produced by drying fresh excreta in an in-house drying system at Michigan State University. The purpose of the microbiological analyses was to comply with FDA recommendations to safeguard animal health. Anaphage samples were collected directly from the dehydrator to lessen the possibility of contamination. Moisture content was immediately determined and microbiological analyses were performed. Average aerobic microbial count was 1,407 bacteria per gram of anaphage. Anaerobic count was 1,102 bacteria per gram of anaphage. Most of the organisms were Bacillus sp. and Streptococcus sp. No Salmonella sp. or mold was isolated. It was evident that moisture content of the sample affected the microbial count. Low moisture content seemed to coincide with the low aerobic bacterial count. Average crude protein and corrected protein were found to be 39.37 percent and 18.65 percent, respectively. Calcium and phosphorus values were 9.11 percent and 1.74 percent, respectively. Moisture content of the anaphage was extremely low. The cost of dehydration would be lower if the moisture content was increased to about 10 percent, since most feed ingredients have approximately 10-15 percent moisture content. (Merryman-East Central)

AMMONIA CONTENT OF CAGED LAYER EXCRETA,

Department of Poultry Science, Michigan State University, East Lansing
T. S. Chang, D. J. Currigan, and E. Linden
Research Report 269, "Poultry Pollution: Research Results", Agricultural Experiment Station, Michigan State University, February, 1975, p. 98-107. 3 fig, 5 tab, 12 ref.

Descriptors: Ammonia, Waste storage, Temperature, Humidity.
Identifiers: Excreta, Magnesium oxide.

Results are reported for 8 experiments which determined the ammonia content of cage layer excreta at various storage periods after excretion. Experiments were set up as follows: Trial one — Excreta samples were collected from 3 hens. Samples were placed on non-absorbent paper and left on a laboratory bench. Ammonia content was determined at 10-, 20-, 30-, and 120-minute intervals; Trial Two — A composite excreta sample from 4 hens was collected and placed on a laboratory bench. Ammonia content was determined each half hour from 1½ to 5 hours at 24 degrees C with a relative humidity of 25 percent; Trial Three — A composite excreta sample from 5 hens was collected at half-hour intervals. Samples were kept at 34 degrees C and a relative humidity of 30 percent with a fan running continuously; Trials Four through Seven — A composite excreta sample of 8 hens was collected at half-hour intervals. Samples were stored immediately in an oven at 34 degrees C with a relative humidity of 60 percent. A total of 4 samples was collected. Three replicates of each sample were tested for ammonia content. Gas chromatographic and organoleptic techniques were used by other investigators to determine the odor-producing materials. The magnesium oxide method for ammoniacal nitrogen can be adopted for determining the ammonia content of the excreta after conversion from the ammoniacal nitrogen value. The moisture content in the oven can offset the rate of ammoniacal release from excreta. The amount of ammonia content in the excreta increases with length of storage time. (Merryman-East Central)

DAIRY COWS GO IN CIRCLES,

T. Curl
Progressive Farmer, Vol. 91, No. 5, p. 30, May, 1976. 1 fig.

Descriptors: Dairy industry, Design.
Identifiers: Waste management, Waste disposal.

Mud problems and increasing automation costs have prompted the Millers to adopt a new milking system — a double rotary parlor arrangement. The milking time has been cut from 18 hours per day to 8 hours and several people who were previously tied up with milking have been moved to the farming operation that grows forage for the cows. In the new system, the milking crew consists of one milker in each rotary parlor and one man who brings cows to the concrete crowding pen, washes them, and inspects them for sickness and heat periods. Each unit handles 8 cows at a time as they travel a circle before leaving the parlor. A free-stall loafing area, a minimountain that is 12 feet high on top and slopes at a 3 percent grade to 12 inches above grade at the lower end, has been provided for the cattle. Alleys are concrete and the stalls are dirt. Animal waste in the loafing area is moved by use of 3,000 gallons of water impounded in holding tanks at the top of the slope at each alley or pen. This cleaning takes place twice daily. The waste and water are gathered at the bottom of the slope where a separator takes out most of the solids. The liquid portion is returned to the holding tanks at the top of the slope for reuse. The solids are used as farm fertilizer. While the radical shift in housing and milking facilities hasn't had any dramatic effect on milk production yet, the Millers now feel that they have the equipment and potential to expand the herd while keeping a tight rein on labor expenses. (Merryman-East Central)

AEROBIC DIGESTED MUNICIPAL GARBAGE AS A FEEDSTUFF FOR CATTLE,

Georgia Coastal Plain Experiment Station, Tifton 31794
J. C. Johnson, Jr., P. R. Utley, R. L. Jones, and W. C. McCormick
Journal of Animal Science, Vol. 41, No. 5, p. 1487-1495, November, 1975. 2 fig, 6 tab, 16 ref.

Descriptors: Feeds, Cattle, Performance, Polychlorinated biphenyls, Heavy metals.
Identifiers: Garbage, Intake.

The potential of Fairfield process garbage as a feedstuff in cattle diets for support of lactation and growth was assessed at the Georgia Coastal Plain Experiment Station. Diets of similar composition formulated with 17.5 percent digested garbage product (garbage diet) or 17.5 percent cottonseed hulls (control diet) were fed to lactating Jersey cows, growing Jersey bull calves, and Charolais cross bred and Hereford steers. Measurements were taken of voluntary intake, digestibility, animal performance, and heavy metal, pesticide and polychlorinated biphenyls (PCB's) content of dietary materials and animal tissues. The study data showed dry matter, crude fiber and nitrogen-free extract in the garbage diet to average 12, 29, and 16.8 kg of daily intake and milk produc-

tion per cow for the control diet. Intake and weight gains by calves during 91 days of comparison averaged 34 and 61 percent higher for the control diet and 6.12 or 6.86 kg of control or garbage diet was required per kg of gain. Beef steer intake of the control diet in a two-period, 14 days per period, reversal experiment exceeded that of the garbage diet by 29 percent. While the study showed that Fairfield process garbage has nutritional value as a feedstuff, depressed intake and relatively high levels of lead and PCB's were identified as potential dangers associated with utilizing digested garbage in high fiber diets for cattle. GUIDELINES FOR ODOR CONTROL.

Anonymous
Wallaces Farmer, Vol. 101, No. 6, p. 55, March 27, 1976.

Descriptors: Legal aspects, Iowa, Regulation.
Identifiers: Odor control, Guidelines, Permits.

By law, the Department of Environmental Quality (DEQ) has the authority to control odors, but it can't take any action until it has departmental rules. An odor advisory control panel is trying to set up recommendations. Three basic assumptions made in setting the regulations are: (1) An Iowa law can't be passed which violates federal law; (2) It is assumed that nonhog raisers don't like the smell of hogs, and (3) It must be noted that if someone detects a hog smell, it doesn't necessarily mean that he is badly offended. Presently, file 367, which has passed the senate and is in the house, would allow a 10-year exemption from future regulations for facilities issued a permit under the Iowa code. It also says that a facility owner is no longer liable for a nuisance suit if he has a permit. The former rule could be negated if the Iowa code did not meet new federal regulations. The second rule has been ruled by the attorney general to be unconstitutional. Another bill currently in committee deals with construction compliance permits. According to this bill, if a facility is built to DEQ standards and is issued a construction compliance permit, it is exempt from further odor regulations for 10 years. A big problem is measuring odors. Methods tried include the threshold approach and odor panels. The advisory committee for Iowa's Department of Environmental Quality is considering the use of a butyl alcohol for measuring odor intensity. The advisory committee also plans to suggest that odor complaints first be filed with the county board of health. If the person making the complaint isn't satisfied, he can then appeal to the Air Quality Commission of the Department of Environmental Quality. Odor intensity and frequency would then be measured. There could then be a formal request for compliance if odor was found to be a problem. Court action would be a final step if the problem isn't resolved. (Merryman-East Central)

CHICKENS PROVIDE NEW PROTEIN FEED,

Anonymous
Calf News, Vol. 14, No. 6, p. 29, June, 1976.

Descriptors: Feeds, Cattle
Identifiers: Refeeding, Poultry manure, Ceres Ecology, Inc., Non-protein-nitrogen, Drying.

Ceres Ecology, Inc. of Sterling, Colorado, which has finished its laboratory and pilot plant work on converting poultry manure into 40-45 percent non-protein-nitrogen feed value at $70 per ton, is constructing a demonstration poultry manure processing plant at their feedlot location in Sterling. Three ingredients similar to their cattle manure processing products will be produced: (1) C-1 silage, (2) C-2 protein, and (3) C-3 residue material. C-2 is the best form of non-protein-nitrogen. It has been tested by the USDA and was found to be a much better form of non-protein-nitrogen than urea or biuret. It is slow releasing. David Seckler, head of Ceres Ecology, feels that the system may offer a good supply of non-protein-nitrogen for the cattle feeding industry. (Merryman-East Central)

THE EFFECTS ON EGG PRODUCTION AND EGG COMPOSITION OF ADDING SUPPLEMENTS OF AMINO ACIDS AND /OR UREA OR DRIED AUTOCLAVED POULTRY MANURE TO A LOW-PROTEIN LAYER DIET,

Agricultural Research Council's Poultry Research Center, King's Buildings, West Mains Road, Edinburgh, Scotland
R. Blair and D. J. W. Lee
British Poultry Science, Vol. 14, No. 1, p. 9-16, 1973. 4 tab, 21 ref.

Descriptors: Poultry, Diets, Performance, Amino acids, Urea, Nitrogen, Proteins.
Identifiers: Egg production, Egg composition, Dried autoclaved poultry manure.

Thirty-five medium weight hens, aged 10 months, were used in an eight week experiment. They were fed a basal diet containing 11.5 percent protein or the same diet supplemented with 1.54 percent essential amino acids and /or with 2 sources of nitrogen for the synthesis of non-essential amino acids (1.15 percent urea or 9.7 percent dried autoclaved poultry manure.) Supplementation with essential amino acids resulted in improved egg production, food intake, food conversion efficiency, gross efficiency of nitrogen conversion, and the ability of hens to maintain body weight. Supplementation with dried autoclaved poultry manure improved food intake, total egg mass, and mean egg weight. Supplementation with urea alone did not significantly increase food intake or improve egg production. It was also found that supplementation with essential amino acids and urea to give the equivalent of 16 percent protein did not result in significantly higher egg production than that obtained with urea alone. While gross composition of eggs was not influenced significantly by dietary treatment, albumen quality was found to be significantly lower on the basal diet and significantly higher on the supplemented diets. (Penrod-East Central)

CONSIDER PREVAILING WINDS IN FEEDLOT SITE SELECTION,

Texas Agricultural Extension Service, Texas A&M University, College Station
J. M. Sweeten
Publication G 73-53, University of Nebraska, Cooperative Extension Service, November, 1973, 4 p. 3 fig, 7 ref.

Descriptors: Odor, Feedlots, Winds, Temperature, Rainfall, Climates.
Identifiers: Site selection.

The most important element of a feedlot odor abatement program consists of judicious site selection. This involves a study of local climatic factors to minimize the probability of odor drift into nearby population centers. Feedlots should be located as far as possible away from population centers or closest neighbors in the direction of least probability of wind occurrence. The optimum direction can be determined from published wind rose diagrams or from tabular wind direction data. Of particular importance is wind data from summer months when peak temperature and rainfall (and hence odors) occur. An ideal criterion for feedlot site selection would be to select a location that has the least chance of an adverse wind direction occurring in conjunction with or soon after a rainfall event. If feedlot odors are minimized during the most critical periods of adverse moisture and temperature, the wind speed factor is probably less important than wind direction consideration. (Merryman-East Central)

FORMULAS FOR APPLYING ORGANIC WASTES TO LAND,

Kansas State University, Manhattan
W. L. Powers, G. W. Wallingford, and L. S. Murphy
Journal of Soil and Water Conservation, Vol. 30, No. 6, p. 286-289, November-December, 1975. 3 fig, 1 tab, 15 ref.

Descriptors: Organic wastes, Nutrients, Nitrogen, Salts, Toxicity.
Identifiers: Land application, Formulas, Soil-plant system, Application rates.

Organic wastes can supply needed plant nutrients. However, to insure the continued functioning of the soil-plant system, application rates should be determined. The ability of the soil-plant system to recycle nitrogen could be the best criteria for determining application rates, since nitrogen may limit plant growth and threaten groundwater quality. Some consideration should be given to other toxic substances that may build up in the soil-plant system. The authors have developed two formulas for application rates based upon the criteria mentioned above and other parameters. A sample demonstration of the formulas shows the potential salt build-up in the soil from inorganic salts in beef feedlot manure. Field data proves the validity of the calculations. The authors suggest that the formula can be used to plan research into values of unknown parameters. (Penrod-East Central)

ADDITIVE CUTS CATTLE FEED NEEDS 10 PERCENT,

Anonymous
Chemical and Engineering News, Vol. 54, No. 1, January 5, 1976.

Descriptors: Additives, Performance, Digestion, Methane, Carbon dioxide.
Identifiers: Feed additives, Rumensin, Food and Drug Administration, Rumen.

To improve weight gain per pound of feed consumed in beef cattle, Eli Lilly Co. has introduced a chemical called Rumensin (monensin sodium). The use of Rumensin has been approved by FDA for use in feedlot cattle. Rumensin alters the digestive process in the beef animal's rumen where cellulose and starch are converted to sugars. Anaerobic bacteria convert the sugars to pyruvic acid and then to volatile fatty acids. These fatty acids are the rumen animal's source of energy. The Rumensin reduces the waste of energy by allowing less carbon dioxide and methane to be formed. In tests, cattle were fed Rumensin at a rate of 30 grams per ton of total ration. On the average, when Rumensin was added, 8.46 lbs of feed was required per pound of weight gain as compared to 9.46 lbs of feed per pound of weight gain without the additive. Thus, a 10 percent increase in efficiency was achieved. Rumensin left no detectable residue and had no effect on quality of meat composition. (Penrod-East Central)

NEAT LOT STOPS ODOR COMPLAINTS, EXPERT ADVISES,

Anonymous
Beef, Vol. 12, No. 7, p. 25, March, 1976.

Descriptors: Odor, Legal aspects, Management, Agricultural runoff, Water pollution.

Ron Miner, agricultural engineer at Oregon State, emphasized that "feedlot odors have never hurt anybody—and never made anybody sick!" But he went on to outline some steps feedlot operators could take to prevent being caught in an odor lawsuit. Miner noted that the feeder who insists on building upwind from a residential area is simply asking for trouble. He emphasized the importance of keeping feedlot waste as dry as possible. If an operation looks dirty—people will detect odors much faster than around a neat, clean operation. Feedlot waste in the river is sure to bring complaints about odors. Miner noted there are chemicals that offer some promise in controlling odors—but there still aren't any magic ingredients that will eliminate the problem. Finally, if a lawsuit comes, don't take it lying down. He advises calling in expert help—to get an accurate measure of intensity and duration of odor problems. Usually measurements will show it isn't as bad as the outsiders claim. (Ott-East Central)

THE EFFECTS OF SLURRY ON THE ACCEPTABILITY OF SWARDS TO GRAZING CATTLE,

Department of Zoology, University of Reading
D. M. Broom, B. F. Pain, and J. D. Leaver
Journal of Agricultural Science, Vol. 85, Part 2, p. 331-336, October, 1975. 7 fig, 3 tab, 4 ref.

Descriptors: Slurries, Cattle, Crop response.
Identifiers: Swards, Grazing, Land disposal.

An experiment was designed to determine whether or not cattle would distinguish between, or prefer swards dressed with slurry at different rates and, if so, for how long. In this experiment 8 plots, each measuring 16m x 16m with 5-m-wide pathways, were set out on a meadow fescue, timothy, perennial ryegrass, white clover ley on a sandy soil. In each plot, 4 rates of application of cow slurry were allocated at random to four sub-lots. The slurry was applied at 0, 25, 40, and 100 t/ha to half of the plots on March 15, 1973, and to the rest of the plots on March 23, 1973. All plots received 100 kg /ha N as 'Nitro-Chalk' in early spring and again after they were grazed in May. Twelve Friesian heifers were used in the experiment. Their live weight at the beginning of the experiment averaged 303 kg and their age 13 months. The heifers were divided into three groups according to their live weight. The heifers were put into the plots 7 and 13 weeks after slurry application and were able to choose in which of the sub-plots they spent their time and grazed. The main effect of slurry on the pasture at 7 weeks was to increase the height of sward but to decrease herbage dry-matter production. Herbage dry-matter utilization over the 4 days ranged from 94 percent on the no-slurry sub-plot to only 41 percent when slurry had been applied at 100 t/ha. The heifers spent the most time in and grazed more often in sub-plots with little or no slurry for the first 2 days, but as the grass was eaten down the frequency of grazing on areas with more slurry increased. This was reflected in the amount of grass removed by the heifers from each treatment on each day. At the beginning of the second grazing, grass height and herbage dry-matter production were both directly related to level of slurry application. The heifers did not distinguish between treatments up to 50 t/ha, but herbage utilization on the 100 t/ha sub-plot was reduced. (Ott-East Central)

NBC REQUESTS EXEMPTION FROM RUNOFF RULES,

Anonymous
Feedstuffs, Vol. 48, No. 6, p. 22, February 9, 1976.

Descriptors: Poultry, Regulation, Water pollution.
Identifiers: Broilers, National Pollutant Discharge Elimination System.

The National Broiler Council (NBC) has filed a request with the Environmental Protection Agency asking an industry exemption from proposed regulations that would require National Pollutant Discharge Elimination System (NPDES) permits for large broiler operations. Broiler growout operations with more than 290,000 birds for a cumulative total of 45 days in any 12-month period would be considered a "concentrated animal feeding operation point source" in the eyes of the regulation. In the event EPA cannot grant an industry exemption, NBC said the criteria for determining whether a broiler operation has a measurable discharge of pollutants into navigable waters should be clarified. (Ott-East Central)

ECONOMIC ANALYSIS OF DAIRY-MANURE BIO-GAS SYSTEMS,

Vermont University, Burlington
J. C. Oppenlander, E. A. Cassell, and R. N. Downer
Presented at the 1975 Winter Meeting, American Society of Agricultural Engineers, Chicago, Illinois, December 15-18, 1975, Paper No. 75-4545, 32 p. 1 fig, 15 tab, 4 ref.

Descriptors: Recycling, Economics, Dairy industry, Vermont, Gases, Fuels, Anaerobic digestion.
Identifiers: Bio-gas systems.

With the rapid upward trend in fertilizer and farm energy costs, considerable interest has been shown in the development of systems which can efficiently utilize the fertilizer and the energy potential of cow manure. Therefore, a research project was conducted at the University of Vermont to determine a technically feasible anaerobic digestion system which is compatible with dairy farm management practices in Vermont. This report summarizes the assessment of the economic feasibility of these anaerobic digestion systems as an energy source for tie-stall operations on Vermont dairy farms. Various design, energy, and economic recommendations were developed in this study. Minimum annual costs ranged from $8600 for 20 cows to $24,000 for 200 cows in the tie-stall operation. At the present time, the generation of bio-gas from the anaerobic digestion of dairy farm manures does not provide an alternate source of energy that is economically feasible in Vermont environment. Minimum unit costs for net available bio-gas ranged from $0.171 to $0.046 per kwh, respectively, for the 20 cow and the 200-cow dairy operations. (Ott-East Central)

BACTERIOLOGICAL WATER QUALITY METHODS FOR DETERMINING RUMINANT FECAL POLLUTION,

Department of Microbiology, South Dakota State University, Brookings
P. R. Middaugh
Completion Report, South Dakota Water Resources Institute, Brookings, June, 1975, 56 p. 4 fig, 7 tab, 45 ref.

Descriptors: Water pollution sources, Farm wastes, Pathogenic bacteria, Enteric bacteria, Livestock wastes, Microbiology, Bioassay, Indicators, Bacteria, Bioindicator, Water quality, Human diseases.
Identifiers: Ruminant fecal pollution.

Studies have been completed on development of microbiological methods for detection of farm animal waste pollution of lake and river water. To differentiate ruminant fecal pollution from domestic sources, the fecal streptococcus, Streptococcus bovis, which is reported to be unique in ruminants, was detected by specific selective methods and media. S. bovis cells are differentiated by their starch hydrolyzing ability. The method as developed utilizes a membrane filter, 0.45 micron porosity, to concentrate the S. bovis cells. In one method the membrane is placed on modified Kenner-Fecal Streptococcus agar in a 60 mm petri dish. An overlayer of 3 ml of 1 percent agar which contains 0.2 percent starch-dye complex, Remazol Brilliant Blue-R dye coupled to amylose starch, is placed on the membrane. The cells are incubated at 37°C in a moist chamber with an atmosphere of 75 percent N_2 and 25 percent CO_2 gas for 24 to 48 hours. Visible clear zones develop around cells containing amylose or starch hydrolyzing ability. A further development uses commercial Pfizer Selective Enterococcus agar medium (modified to exclude esculin and with added 2, 3, 5 triphenyltetrazolium chloride to pigment the colonies red). In this method the membrane filter carrying the S. bovis cells is overlaid with 3 ml of the modified PSE agar to which was added 0.2 percent amylose-azure dye to indicate starch hydrolysis after anaerobic incubation. The method has been evaluated by tests on lakes and rivers. A small number of related streptococci also hydrolyze starch. These are typical S. faecalis cells which are biochemically differentiated, if necessary. (Wiersma-South Dakota State University)

PROCEEDINGS OF CONFERENCE ON FARM ANIMAL WASTES: "FARMER EXPERIENCES, CODES, GUIDELINES, RESEARCH PROGRESS, EQUIPMENT",

R. E. Graves, ed.
Proceedings of Farm Animal Waste Conference "Farmer Experiences Codes, Guidelines, Research Progress, Equipment", Stevens Point, Wisconsin, February 9-10, 1972. 63 p.

Descriptors: Regulation, Legal aspects, Farm wastes, Equipment, Water pollution, Air pollution, Public health, Agricultural runoff, Confinement pens, Liquid wastes, Dairy industry, Waste storage, Drying, Irrigation, Lagoons, Wisconsin.
Identifiers: Waste management, Cost sharing, Land disposal, Ducks.

This conference focused on the proposed Wisconsin code on animal wastes, existing and proposed manure handling guidelines, farmer experience with various manure handling methods, and systems and equipment that industry has availed today. Conference objectives were: (1) To give farmers, industry, and public agencies who have pioneered new waste handling systems a chance to tell their story, (2) To review the contents of animal waste regulations proposed for Wisconsin and their implications, (3) To develop discussion of present and future guidelines for handling animal wastes, (4) To consider the adequacy of research, handling systems and equipment, and current programs for animal waste management, and (5) To further discussion and communication among individuals, groups and agencies who have an interest and concern in this area. (Merryman-East Central)

A REVIEW OF THE POLLUTION ABATEMENT SITUATION IN INDUSTRY, MUNICIPALITIES AND GOVERNMENT,

Acting Chief, Technical Services Office, Processing and Disposal Division, Office of Solid Waste Management Programs, U. S. Environmental Protection Agency
T. W. Bendixen
Proceedings of Farm Animal Waste Conference "Farmer Experiences, Codes, Guidelines, Research Progress, Equipment", Stevens Point, Wisconsin, February 9-10, 1972, p. 5-9.

Descriptors: Water pollution, Air pollution, Regulation, Liquid wastes, Solid wastes.

Mr. Bendixen reviews activities and programs of the Federal government related to pollution abatement. Among regulations reviewed are: (1) the Clean Air Amendment of 1970, (2) the Refuse Act of 1899, and (3) the Federal Water Pollution Control Act. Geographical coverage, variation in local conditions, varying assimilative capacities of water bodies and nature and interaction of pollutants complicate any attempt to accurately rank sources as to severity or to show trends of water pollution. However, using biochemical oxygen demand as the criterion, many people feel that industrial wastes are the largest source of organic water pollutants nationwide; then municipal wastes; then agricultural wastes. Environmental improvement is a task of all the people, and every segment of society, whether it be cities, towns, industry, agriculture, business or governmental activities. (Merryman-East Central)

A REVIEW OF ANIMAL WASTE REGULATIONS AROUND THE NATION,

Dane County Environmental Quality Agent, Madison, Wisconsin
D. G. Last
Proceedings of Farm Animal Waste Conference "Farmer Experiences, Codes, Guidelines, Research Progress, Equipment", Stevens Point, Wisconsin, February-9-10, 1972, p. 10-15.

Descriptors: Water pollution, Regulation, Design.
Identifiers: Animal wastes.

Modern agriculture contributes a variety of quality degrading substances to our waterways. In particular livestock operations have been singled out as being a threat to water quality. It may be noted that regardless of whether a state has a specific law governing animal waste storage, transport, or disposal, all states, since the passage of the Water Quality Act in 1965, are required by federal law to have approved water quality standards. Such standards list minimum acceptable BOD levels, bacteria counts, etc. for each water body. These standards can be used to bring about a cease and desist order against a livestock owner or operator. A number of states have gone one step further and enacted animal waste pollution legislation. Approximately 14 states have present or proposed laws dealing with feedlot construction and/or operation. Eighteen states and several provinces of Canada have or are proposing specific animal waste regulations. An inventory of the states having specific animal waste control regulations reveals a great deal of difference in the content of the regulations. Many of the animal waste codes contain in or outside the body of rules, some statement of purpose, intent, or objective. Nearly every code has a definitions section. Most of the rules contain information on water pollution abatement facilities. They establish a procedure for determining the need for such facilities, their design requirements, operation and upkeep. Another common feature of animal waste regulation is some form of permit system. The enforcement of the regulations may be handled either through a state natural resources commission or a state health agency. (Merryman-East Central)

POLLUTION ABATEMENT IN WISCONSIN, HISTORICAL DEVELOPMENT AND PRESENT STATUS,

Assistant Administrator, Division of Environmental Protection, Stevens Point, Wisconsin
O. D. Williams
Proceedings of Farm Animal Waste Conference "Farmer Experiences, Codes, Guidelines, Research Progress, Equipment", Stevens Point, Wisconsin, February 9-10, 1972, p. 16-20.

Descriptors: Regulation, Air pollution, Water pollution, Wisconsin.
Identifiers: Pollution abatement.

Mr. Williams traces pollution problems and attempts at pollution abatement from colonial days to the present, citing specific pollution problems and regulations. This is all done as background for speeches to come later which deal with the proposed Animal Waste Rules. (Merryman-East Central)

ANIMAL WASTE PROBLEMS NOW FACING THE DEPARTMENT OF NATURAL RESOURCES,

Chief of Industrial Waste Water Section, Department of Natural Resources, Wisconsin
P. P. Didier
Proceedings of Farm Animal Waste Conference "Farmer Experiences, Codes, Guidelines, Research Progress, Equipment", Stevens Point, Wisconsin, February 9-10, 1972, p. 21-28. 3 fig.

Descriptors: Regulation, Water pollution, Animal wastes, Wisconsin, Water storage, Waste disposal, Agricultural runoff.

The Wisconsin Department of Natural Resources' statutory authority and responsibilities in relation to water pollution and more specifically as related to animal wastes are reviewed. Various types of agricultural pollution are pinpointed. Manure management problems include: manure storage and disposal, the need for manure management alternatives, feedlot runoff, and livestock destroying banks of unfenced streams. Regulatory, advisory and cost sharing agencies must be coordinated to solve these problems. Any solution to the animal waste management problem will involve a mix of programs, combining regulation, research, education, financial assistance, voluntary actions by the farmer himself and even tolerance on the part of the non-farming population. (Merryman-East Central)

LEGAL BASIS FOR ANIMAL WASTE REGULATION IN WISCONSIN'S WATER, AIR AND PUBLIC HEALTH,

Bureau of Legal Services, Department of Natural Resources, Wisconsin
J. Kurtz
Proceedings of Farm Animal Waste Conference "Farmer Experiences, Codes, Guidelines, Research Progress, Equipment", Stevens Point, Wisconsin, February 9-10, 1972, p. 29-31.

Descriptors: Regulation, Water pollution, Air pollution, Public health, Animal wastes, Wisconsin.

The proposed animal waste regulations of Wisconsin are the result of an ad hoc committee appointed by the Department of Natural Resources. The rules represent almost a year of work, representing an interdisciplinary approach. Before a hearing is held concerning them, the rules will be made available on a statewide basis to people that might be interested in them for review and comment. The rules will not be final and official until such time as the National Resources Board votes by a majority vote that the rules are to be published in the Administrative Code, and then they will be effective upon publication. The code is looked upon as a state of the art for handling agricultural wastes and applying them to the land at various times of the year; as the states advance, the requirements will advance. These requirements will not be imposed unilaterally; these requirements will be imposed by the hearing process. (Merryman-East Central)

PROPOSED ANIMAL WASTE REGULATIONS FOR WISCONSIN,

Professor of Soil Science, Wisconsin University, Madison
M. Beatty
Proceedings of Farm Animal Waste Conference "Farmer Experiences, Codes, Guidelines, Research Progress, Equipment", Stevens Point, Wisconsin, February 9-10, 1972, p. 32-36.

Descriptors: Regulation, Animal Wastes, Point sources, Agricultural runoff, Waste storage, Wisconsin.
Identifiers: Waste management, Water pollution control, Land spreading.

Background is given on how the ad hoc committee on agricultural waste pollution operated and how the animal waste rules were developed. Some of the major provisions of the rules are discussed. The rules begin with definitions of terms. The rules focus on water pollution. They give standards for systems of manure storage and handling. Plans for storage ponds and retention ponds must be reviewed by the Department of Natural Resources. The rules require plans for large operations, those that are greater than 800 animal units, to be submitted to the Department of Natural Resources for review. If manure is spread in the winter and no erosion control program is used, the spreading must be back a minimum of 200 feet from streams, lakes, ditches and ponds. The rules concentrate on point sources. Streams, lakes and ponds must be fenced out of the barnyards by 1975; and the runoff from animal lots and enclosures must be controlled so that the manure won't simply go under the fence and into a stream. A feedlot operator must have a minimum land area under his control for spreading of manure. One-third of an acre per animal unit for dairy, beef, swine, and sheep, and half an acre per animal unit for birds are the minimum areas suggested. The problem of odors is not dealt with due to their subjective nature. (Merryman-East Central)

COMMENTS BY MEMBERS OF THE DNR ADVISORY COMMITTEE ON AGRICULTURAL WASTE POLLUTION,

G. Blaska, K. Kreul, M. Stellrecht, and R. Venable.
Proceedings of Farm Animal Waste Conference "Farmer Experiences, Codes, Guidelines, Research Progress, Equipment", Stevens Point, Wisconsin, February 9-10, 1972, p. 37-39.

Descriptors: Regulation, Animal wastes, Wisconsin.

Four members of the Advisory Committee, all of whom are Wisconsin farmers, served as a panel during a discussion of the "Proposed Rules". Prior to the discussion each man made a statement concerning the rules and his thoughts about them. Initial apprehension was expressed, but put at rest. There seemed to be a general consensus that the rules were at least a step in the right direction. (Merryman-East Central)

DEPARTMENT OF NATURAL RESOURCES PROPOSED ANIMAL WASTE MANAGEMENT RULES,

Wisconsin. Department of Natural Resources. Ad Hoc Committee.
Proceedings of Farm Animal Waste Conference "Farmer Experiences, Codes, Guidelines, Research Progress, Equipment", Stevens Point, Wisconsin, February 9-10, 1972, p. 40-44.

Descriptors: Regulation, Waste storage, Waste disposal, Animal wastes, Waste treatment, Agricultural runoff, Wisconsin, Water pollution.
Identifiers: Inspection.

The Proposed Animal Waste Management Rules are given. The preamble states that when wastes from agricultural activities impair water quality, systematic prevention or remedial action is required. The proposed rules establish standards and define procedures whereby the state can protect the public interest in maintaining the quality of water in Wisconsin. The recycling of animal wastes to the land and the continued development of new and innovative systems are encouraged. Coordination of the efforts of regulatory, educational, technical, and financial assistance programs of other governmental agencies is also encouraged. Further technical development is necessary before rules controlling odors can be formulated. The Department of Natural Resources will continue to handle odor complaints individually and will promote further study of the problem. The rules will be periodically reviewed and, when necessary, revised to reflect the advancing technologies of agricultural production and environmental protection. Outlined in the proposed rules are: (1) Definitions, (2) Collection, storage and disposal of animal wastes, (3) Treatment of animal wastes, (4) Runoff control (animal shelters, enclosures and lots), (5) Filing of reports, plans and specifications, (6) Violations and enforcement, (7) Hearings, orders and appeals, (8) Inspection, (9) Limitations, (10) Severability, and (11) Applicability and effective date. (Merryman-East Central)

SUMMARY OF TECHNICAL ASSISTANCE AND COST-SHARING PROJECTS IN WISCONSIN,

I. Bolstad, J. Densmore, and M. Knabach
Proceedings of Farm Animal Waste Conference "Farmer Experiences, Codes, Guidelines, Research Progress, Equipment", Stevens Point, Wisconsin, February 9-10, 1972, p. 45.

Descriptors: Cost sharing, Wisconsin, Waste storage.
Identifiers: Pollution control, Rural Environmental Assistance Program, Lake Mendota Watershed, Soil Conservation Service.

The 1970 National Rural Environmental Assistance Program made provision to cost-share on pollution abatement measures. Diversions above and/or below the barnyard were the initial practices installed on approximately 100 Wisconsin farms. The special manure storage project in the Lake Mendota Watershed was offered statewide in 1971, resulting in cost-sharing on 109 facilities. Soil Conservation Service approval was required for all cost-shared projects as being in compliance with their standards. Accomplishments as of February, 1972, were the grading of 110 acres of barnyard and the construction of 26 miles of diversions, 3 settling basins, 3 detention ponds, 56 stacking facilities, 3 manure storage ponds, and 33 liquid manure tanks. THE REVIEW OF RESEARCH PROGRESS IN MANURE MANAGEMENT,

Branch Chief, Livestock Engineering and Farm Structures Research Branch, Agricultural Engineering Research Division, Agricultural Research Service, United States Department of Agriculture, Beltsville, Maryland
R. G. Yeck
Proceedings of Farm Animal Waste Conference "Farmer Experiences, Codes, Guidelines, Research Progress, Equipment", Stevens Point, Wisconsin, February 9-10, 1972, p. 46-52.

Descriptors: Livestock, Poultry, Hydraulic transportation, Waste storage, Aerobic treatment, Drying, Separation techniques, Costs, Fertilizers.
Identifiers: Waste management, Land disposal, Composting, Odor control, Refeeding.

Research concerning components of animal waste systems are summarized and discussed. Because animal manures are biologically active materials, they undergo continual changes. The role of the engineer and designer of livestock waste treatment facilities is one of controlling these changes. Hydraulic transport, land disposal, waste storage, composting, aerobic treatment, odor control, refeeding, drying, and solid-liquid separation are discussed. The beef slatted floor and pits systems appear to be adaptable anaerobic pits. The bulk of broilers are raised on deep litter. Storage is built into the systems, but odor, feather and dust nuisance problems as well as [illegible]ernitrification of land, are possible if good judgment is not shown in managing the wastes. There are many alternative courses of action for managing animal wastes. All will require additional costs in production. Some cost offsetting returns may be realized through utilizing the wastes. Utilization as cropland fertilizer remains the most practical for the majority of livestock producers. (Merryman-East Central)

REPORT ON FARMERS EXPERIENCES WITH MANURE HANDLING FACILITIES,

Assistant Professor and Extension Agricultural Engineer, Wisconsin University—Extension
R. E. Graves
Proceedings of Farm Animal Waste Conference "Farmer Experiences, Codes, Guidelines, Research Progress, Equipment", Stevens Point, Wisconsin, February 9-10, 1972, p. 53-57.

Descriptors: Waste storage, Liquid wastes, Odor, Ventilation, Separation techniques.
Identifiers: Waste management, Land spreading, Ducks, Swine, Flies, Oxidation ditch.

Descriptions are given of waste management methods tried by farmers at 8 different farms. The Allen Johnson Farm employed a storage facility for manure from 65 milk cows and runoff from a 75' x 105' paved barnyard. Storage area was sufficient for 6 months. A tractor-mounted loader removed the manure to a spreader for field spreading. The Fair Peak Dairy Farm utilized a solid manure stacking system with a commercially available swinging elevator. The major problem with this system was clean out of storage. Dilution by additional water yielded a material too thin to scoop and too thick to pump. The Kenver Farms used a conventional liquid manure handling system. The manure storage tank that was built was not adequate. Odor, flies, and the time required to scrape the barns were also problems. The Klug Farm employed an inexpensive solid manure storage structure with 6 months storage. The storage area was formed with earth walls. Crushed rock limestone 8-10 inches thick was used to line the entire structure. A perforated pipe inlet located in the low corner directed liquids that leached from the manure to a plastic lined retention pond. The Blue Mound Farm utilized a manure drying facility to obtain dried pulverized manure which was either bagged for sale or handled in bulk. The Hawkins Farm employed a confinement feeding operation with cold slatted floor barns. Manure storage was provided by six 30' x 30' x 8' tanks below the slats. Pits were emptied by a high pressure chopper type pump through an irrigation system. Irrigating required little labor or investment, but problems occurred with flies, odors and pit ventilation. The Pride Seed Co. Research Farm utilized an oxidation ditch beneath a slatted floor building to handle manure from a 24 sow and nursery unit. Overflow went to a holding basin. Material was removed from the ditch or holding basin by a vacuum liquid manure tank. Major problems were odor and foaming. The C and D Duck Farm directed its efforts to handling and eventually disposing of its concentrations of manure and water. A liquid handling system utilizing mechanical screening and settling to remove solids followed by aeration and chlorination of the water was considered. (Merryman-East Central)

MANURE SYSTEM:FIVE YEARS OLD...GOOD AS NEW,

Successful Farming, Vol. 74, No. 6, p. D2, April, 1976.

Descriptors: Waste storage, Dairy industry.
Identifiers: Waste management, Land spreading.

In 1971, Gerald Robinson, Morrow County, Ohio dairyman, decreased waste handling labor demands by installing a pump system. When utilizing this system, manure is scraped into an opening at the lowest part of the concrete lot, which slopes from feeder and free stalls down to near the milking parlor. A utility sized tractor is used to blade manure across an opening where it drops into a pipe just ahead of the pump. Powered by a 7½-hp electric motor, the piston type pump quietly pushes the liquid manure through a 9-in. diameter vinyl pipe 250 ft. uphill underground to a large capacity 380,000 gallon dirt-sided lagoon. The pipe through which the manure is pumped goes into the bottom of the giant holding lagoon. Thus, the thick crust that forms atop the pit is left unbroken and seals off fresh manure odors as effectively as a tight fitting concrete slab. Since the pit holds 6 months storage, the manure is hauled and spread only when it's convenient. Spreading is done when there is no chance of runoff. Health inspectors have approved the system. (Ott-East Central)

IDENTIFICATION OF SULFUR GASES EVOLVED FROM ANIMAL MANURES,

Department of Agronomy, Iowa State University, Ames
W. L. Banwart and J. M. Bremner
Journal of Environmental Quality, Vol. 4, No. 3, p. 363-366, July-September, 1975. 6 tab, 17 ref.

Descriptors: Odor, Gases, Sulfur, Gas chromatography, Feedlots, Livestock, Aerobic conditions, Anaerobic conditions.
Identifiers: Identification techniques.

One major problem from the increased use of feedlots is the release of gases due to manure decomposition Research on these gases has led to the development of gas chromatographic techniques. These techniques are used for direct identification of the gases. Manure from beef cattle, dairy cattle, swine, and sheep was studied. When incubated under anaerobic conditions, all manures studied released dimethyl sulfide, hydrogen sulfide, and methyl mercaptan and some released carbonyl sulfide and or carbon disulfide Only trace amounts of one sulfur gas (dimethyl sulfide) was detected in the gaseous products of decomposition of manures under aerobic conditions, and no evidence could be obtained that sulfur gases contribute to the odors of dried manure. Most of the sulfur volatilized when manures were incubated under anaerobic conditions was in the form of hydrogen sulfide and methyl-mercaptan. The amount of sulfur volatilized in one month at 23 degrees C represented less than 1 percent of the total sulfur in the manures studied. (Talley-East Central)

ALFALFA SAFEGUARDS GROUNDWATER,

Anonymous
Wallaces Farmer, Vol. 101, No. 5, p. 117, March 13, 1976.

Descriptors: Groundwater pollution, Nitrates, Crop production, Alfalfa.
Identifiers: Abandoned feedlots, Corn, Pollution control.

G. Schuman and L. Elliott found out that planting alfalfa in unused feedlots will prevent nitrate pollution of ground water. Nitrogen builds up in the top 5 to 6 feet of soil when feedlots are in use, but it is in a form that will not pollute ground water. But when feedlots are abandoned, this organic nitrate can be converted to a form that moves down through the soil with water. In a feedlot where 13.5 tons of total nitrogen per acre was found, corn took up 152, 265, and 81 lb. of nitrogen per acre. Corn was found less efficient than alfalfa in removing nitrogen from the soil. (Edwards-East Central)

PILOT-PLANT HIGH-RATE DIGESTION OF PIGGERY AND SILAGE WASTES,

Rowett Research Institute, Bucksburn, Aberdeen
S. Bousfield, P. N. Hobson, and R. Summers
Journal of Applied Bacteriology, Vol. 37, p. 1-2, 1974.

Descriptors: Anaerobic digestion, Waste treatment, Chemical properties.
Identifiers: Swine, Silage waste.

Anaerobic digestion of waste from pig fattening houses was shown to be possible using 15-liter heated (35 degrees C) stirred digesters loaded once daily, but a 100-liter digester mechanically loaded every five minutes proved more efficient. Pump capacity limited total solids (TS) input to around 4-5 percent with no sign of digester failure and maximum solids input should be considerably higher. Less than 2 percent solids caused washout. Percentage diminutions in waste properties were similar at all loading rates and some average results were (percent reduction): BOD 80, COD 57, TS 43, VFA 79. Ammonia was unchanged or slightly reduced. Settling the output for 14-15 days gave a liquid with only 4 percent of original BOD, 9 percent of COD and 22 percent of TS. Digestion was stable and activity was restored after stoppages with or without heating of 6 weeks or more, or aeration of digester contents due to system leaks or maintenance. Gas production (65-70 percent CH_4, remainder CO_2) at 35 degrees C averaged 6.4 cu. ft/lb VS loaded; abrupt changes to 38 degrees C or 40 degrees C did not appreciably alter gas production: change to 30 degrees C lowered production, but over 8 days it returned to normal. Silage effluent was treated in a stable digestion with piggery waste. With about 10 percent (v/v) silage effluent added to piggery waste, the BOD input was up to 45,000 ppm compared with an average 10,000 ppm before, and COD was about 200,000 ppm compared with 50,000. The purification obtained (whole digester output) average (percent reduction): BOD 87, COD 61, TS 36, VFA 78. Gas output (69 percent CH_4, 30 percent C was increased by about 22 percent and shock loading of 30 percent silage did not upset digestion. (Abstract only; Abstract edited by Ott-East Central)

STUDIES ON FARM LIVESTOCK WASTES,

Agricultural Research Council
Studies on Farm Livestock Wastes. London, Agricultural Research Council, 1976, 156 p.

Descriptors: Research and development, Slurries, Physical properties, Chemical properties, Biological properties, Biological treatment, Aerobic treatment, Odor, Separation techniques, Sludge, Crop response, Soil profile, Equipment, Waste storage, Pathogenic bacteria.
Identifiers: England, Land disposal, Anaerobic treatment, Dewatering.

This bulletin reviews findings from the 3-year research and development programs undertaken jointly by the Agricultural Research Council and the Ministry of Agriculture, Fisheries and Food. The bulletin was compiled by specialists who took part in these programs and it includes much unpublished work. It was compiled primarily for those engaged in research, development, and advice and gives substantiated scientific and technical information on the biological processes involved and their engineering implications. The emphasis is on treatment and use, with the conclusion that, whenever possible, all such wastes should be returned to the land. The bulletin concludes with reports of seven separate farm trials utilizing experimental treatment plants. Recommendations for future study are given. (Merryman-East Central)

UTILIZATION OF PAUNCH-BLOODMEAL BY FEEDLOT CATTLE,

K. C. Byington
MS Thesis, Colorado State University, August, 1975, 46 p. 12 tab, 32 ref.

Descriptors: Feeds, Performance, Cattle, Nitrogen, Feedlots.
Identifiers: Refeeding, Blood and paunch meal, Cottonseed meal.

A project was undertaken to investigate the possibilities of using two by-products of the packing industry, dried rumen contents and blood meal (blood and paunch meal), as a substitute for vegetable protein in beef cattle rations. Blood and paunch meal was found to be highly insoluble and of superior amino acid make-up compared to cottonseed meal. A nylon bag trial indicated that approximately 60 percent of the nitrogen in cottonseed meal was liberated in the rumen compared to 35 percent for blood and paunch meal. Apparent nitrogen digestibility of blood and paunch meal was calculated to be 74.9 percent. A digestion trial was run using six Hereford steers to compare the ability of blood and paunch meal and cottonseed meal to support animal gains when used as the sole source of supplemental nitrogen. Cottonseed meal proved to be somewhat superior in promoting nitrogen retention. The differences were not, however, statistically significant (P less than .05). The results of the feeding trial indicate that substituting blood and paunch meal for cottonseed meal in the finishing ration increases gain and improves feed efficiency. Viewed from an overall standpoint, blood and paunch meal would appear to be most valuable in situations where essential amino acid availability is the factor limiting production. In addition to the fattening phase of beef production, the potential of blood and paunch meal seems to merit research into its applicability to other classes of livestock. (Cameron-East Central)

HOW NOW BROWN COW: REGULATION OF FEEDLOT POLLUTION IN WISCONSIN,

C. E. Blackwell, III
Environmental Affairs, Vol. 3, No. 4, p. 769-789, 1974.

Descriptors: Feedlots, Pollution control, Wisconsin, Legal aspects, Water pollution, Point sources.
Identifiers: 1972 Federal Water Pollution Control Amendments, National Pollutant Discharge Elimination System.

Water pollution due to feedlot runoff has become a serious problem. Several legal steps are reviewed in this article which are (or have been) directed toward pollution abatement. Of major importance among such legal steps is the 1972 Federal Water Pollution Control Amendments. Section 402 of the 1972 Act establishes the National Pollutant Discharge Elimination System which has been utilized to reduce point source water pollution by feedlots. The Environmental Protection Agency (EPA), which was granted authority to administer the permit program established by this Act, has attempted to abrogate the effectiveness of the Act. This may be due to any or all of the following: (a) To include greater numbers of small feedlots would place an unacceptable economic and manpower burden on the EPA, (b) EPA pollution control efforts have been focused on urban sources of water pollution, and (c) The EPA is sensitive to criticisms from Agribusiness. While the major concern has been that strict pollution controls would cause economic dislocation, some sources such as David Blitzer (National Resources Defense Council), maintain that such controls would foster reorganization of the industry into larger and more efficient production units. The threat to water quality by agricultural runoff pollution cannot be dealt with in the manner employed to date. The problem can only be solved through the cooperation of federal, state, and local governments which, unfettered by self-interested pressure groups or concerns over administrative burdens, have the resolve and energy to obtain a high standard of water quality. (Merryman-East Central)

STREAM QUALITY MEASUREMENTS ALONG A LIVESTOCK WINTERING OPERATION,

G. Hagfeldt
MS Thesis, Department of Agricultural Engineering, Montana State University, December, 1971, 61 p.

Descriptors: Water pollution, Livestock, Sampling, Measurement, Nitrates, Chlorides.
Identifiers: Wintering operations.

A project was conducted to develop instrumentation and techniques necessary for determining if animal wintering operations located along streams are polluters. The location of the test site was the Holmstrom Ranch located northwest of White Sulphur Springs, Montana. Through the winter of 1970-71, there were 1100 sheep, 243 calves, 85 hogs, and 185 cows wintered along the creek. Four water sampling stations were set up along the creek, 3 in the wintering area and a fourth approximately 4 miles upstream. Samples were taken periodically and the nitrate and chloride ion concentrations were recorded using a specific ion meter. Conductivity, sample temperature, stream flow, and weather conditions were also recorded. Nitrate and chloride concentrations were very small—much less than the upper limits allowed by the U.S. Public Health Service. Because the levels were so low, the actual concentrations could not be determined using the equipment and techniques available. Averaging all the readings taken over the project period did indicate that both nitrate and chloride ions decreased slightly along the wintering area. It was felt that more testing was needed to ascertain if these parameters did actually decrease, or if this was a result of the testing methods. (Ott-East Central)

MANURE MANAGEMENT RELATED TO SOIL, WATER & AIR—THE CHALLENGE TO AGRICULTURAL SCIENTISTS,

New Brunswick Department of Agriculture and Rural Development, Fredericton, New Brunswick
J. A. Roberts
Presented at Canadian Society of Agricultural Engineers Annual Meeting, Charlottetown, P.E.I., June 26, 1972, Paper No. 72-220, 6 p.

Descriptors: Waste management.
Identifiers: Manure, Canada, Land disposal, Refeeding.

A general discussion was given of the farm animal waste problem. The author presented and elaborated on three major challenges facing agricultural scientists: (1) to become involved in land use, economic, and systems planning; (2) to solve the problems of recycling livestock wastes; and (3) to make livestock production systems compatible with high density human populations. (McQuitty, Barber-University of Alberta)

LIVESTOCK WASTES AS A SUBSTITUTE FOR COMMERCIAL NITROGEN FERTILIZER,

T. Stucker and S. Erickson
Illinois Research, Vol. 17, No. 3, p. 10, 11, Summer, 1975. 5 tab.

Descriptors: Farm wastes, Nitrogen, Fertilizers, Costs, Livestock, Feedlots.

Because of the rise in commercial fertilizer prices, many farmers are either having to reduce fertilizer inputs or substitute relatively less expensive material, such as livestock manure, for the commerical fertilizers now on the market. Farmers may now find it profitable to consider livestock wastes as a substitute source of nitrogen rather than a supplement to commercial fertilizer. The nitrogen content of manure will vary according to animal sources, waste-handling system, and other factors. The total value to Illinois farmers of mechanically collected and distributed (nonpasture) swine manure handled by liquid and bedded solid systems is more than \$4 million. Another consideration for livestock producers in times of soaring commercial fertilizer prices is the distances they can afford to haul livestock wastes. (Cameron-East Central)

PHYSICAL AND THERMOCHEMICAL PROPERTIES OF PIG MANURE,

Department of Chemical Engineering, University of Newcastle Upon Tyne, NE1 7RU, ENGLAND
Fuel, Vol. 52, No. 10, p. 302-303, October, 1973. 1 fig, 2 ref.

Descriptors: Incineration, Waste disposal, Waste treatment, Physical properties.
Identifiers: Swine, Thermochemical properties.

Pig manure presents severe disposal problems, and in the long term it is likely that incineration may prove the only acceptable solution. A series of tests was carried out in conjunction with a pig-feeding trial reported recently, in which densities, viscosities and calorific values of pig feces were measured with the development of a pilot-scale incineration in mind. The results showed relatively high caloric values which would contribute significantly towards reduced fuel costs in any combined drying incineration disposal operation. It will be seen that the high values obtained for caloric value go a long way toward promoting incineration as a viable commercial proposition, regardless of its probable ultimate necessity. BASICS OF POLLUTION CONTROL,

Gurnham and Associates, Inc.
Basics of Pollution Control. Chicago, Gurnham and Associates, Inc., 1973, 44 p.

Descriptors: Dairy industry, Water pollution sources, Pollutant identification, Water pollution, Wastes, Industrial wastes, Wisconsin, Pollutants, Farm wastes, Waste water (pollution), Surveys, Flow measurement, Analytical techniques, Equipment, Sampling, Water analysis.
Identifiers: Seminars.

This text outlines the technical measurements used by pollution control technologists, as they apply to the dairy industry, and defines the technical terms used in federal, state, and local laws controlling waste water discharges from dairies. Sources of water borne wastes from dairies are listed, and the significance, loadings, and limitations for each and methods of analysis are described. A program for conducting a plant waste water survey, for the purpose of determining specific sources of pollution and measuring the quantities of each, is outlined. The appendix is a paper (by C. F. Gurnham and M. I. Beach) that explains the devices and techniques used for measuring flows and for sampling waste water streams. (Witt-IPC)

FLUSHING AWAY MANURE UNDER METAL SLATS,

R. Mercer
Good Farming, Western Edition, p. 12-14, March, 1974. 4 fig, 1 tab.

Descriptors: Confinement pens, Liquid wastes, Design criteria.
Identifiers: Swine, Flushing.

A flush system for manure disposal in confinement barns where total slats are installed has several advantages. The author discusses a system in an Ontario new weaner barn that takes pigs at the 15-20 pound range to the saleable weight of 45 pounds. The use of total slats has resulted in clean, dry hogs. The barn is almost odor free because the flush system is coupled with cross ventilation. Swine feet and leg problems are minimal. Feed loss is kept at a minimum with special feeders. The flush disposal system consists of 3 large tanks that are designed to dump their total volume of water when a specific level has been reached. The water used to fill the tanks is recycled. Two of the most important factors in a flushing system is water volume required and the slope of the gutter floor. A paper by Professor Hazen of Iowa is cited. Hazen summarizes the hydraulic flushing system in terms of the size of the area to be flushed, water velocity, flushing frequency, and the depth of the flushing stream. Professor Hazen then discusses the advantages and disadvantages of the hydraulic system. Design considerations for construction specifications, the positioning of the tank and the liquid requirements of a flushing system are given. Two areas of concern that still require research are disease transmission and control from anaerobic lagoons. (Penrod-East Central)

THE RESIDUAL EFFECT OF HEAVY APPLICATIONS OF ANIMAL MANURES ON CORN GROWTH AND YIELD AND ON SOIL PROPERTIES,

West Central Experiment Station, University of Minnesota, Morris
S. D. Evans, J. M. MacGregor, R. C. Munter, and P. R. Goodrich
A Report on Field Research in Soils, Soil Series 91, Department of Soil Science, University of Minnesota, March, 1974, p. 98-110. 11 tab.

Descriptors: Crop response, Soil profile, Chemical properties, Insecticides.
Identifiers: Land disposal, Application rates.

Experimental treatments were arranged in 3 replications of a complete randomized block. Each plot was split into 2 parts of sub-plot treatments. Treatments of the main plots were : (1) No fertilizer or manure. (2) Recommended amounts of inorganic fertilizer each year (120 N + 40 P_2O_5 + 40 K_2O). (3) Solid manure from a conventional beef feeding facility (manure + straw) at 100 tons/acre (wet weight) in the fall of 1970 and of 1971. (4) Liquid beef manure from a slatted floor beef feeding barn at 284 tons/acre (wet weight) in the fall of 1970 and of 1971. Half of the sub-plots were treated at planting with insecticide for rootworm control. The plots were planted. Furadan at 10 lbs./acre was applied to the east 14 rows of each plot and the west 6 rows were left untreated. Starter fertilizer was used only on the fertilized treatment. Lasso was broadcast at 2¼ lb/acre; 2, 4-D amine at ½ lb/acre was applied as a postemergence spray on June 5. The soils in each plot were sampled to a depth of 10 ft in the fall of 1970, to a depth of 4 ft in the fall of 1971, and to a depth of 10 ft in 1972. These samplings were done prior to manure application. Sampling results indicated that NH_4-N levels were all quite low and the levels in soils treated with manure were no higher than check or fertilized soils. NO_2-N levels were also very low and there were no increases due to manure applications. The NO_3-N in the top foot of the liquid beef manure plots was 20 times higher than on the fertilized plot. Levels on solid beef and liquid hog manure were also very high. With all manures, there was some movement of NO_3-N into the 9-10 ft. zone. Conductivity of a soil: water mixture was increased by all manure applications. Bulk density was significantly reduced by solid and liquid beef manure in the 6-12 inch layer. Though higher electrical conductivity was found in manure plots, plant growth was not affected. Chemical analyses of the 1972 fodder, grain, and root samples were made for N, P, K, Ca, Mg, Fe, Cu, zinc, manganese and boron. The levels of P, K, and Mg were significantly lower where insecticide was used. Plant yields and measurements were also determined for the various treatments. (Ott-East Central)

THE RESIDUAL EFFECT OF RATES OF SOLID BEEF MANURE ON CORN GROWTH AND YIELD,

West Central Experiment Station, University of Minnesota, Morris
S. D. Evans
A Report on Field Research in Soils, Soil Series 91, Department of Soil Science, University of Minnesota, March, 1974, p. 111-117. 5 tab.

Descriptors: Crop response, Chemical properties, Insecticides.
Identifiers: Land disposal, Application rates.

The main experimental treatments were arranged in 3 replications of a complete randomized block design. Each plot was split into 2 parts for sub-plot treatments. Main plot treatments were: (1) Recommended amounts of inorganic fertilizer each year (120 N + 40 P205 + 40 K20), (2) Solid beef manure at 33⅓ tons/acre (wet weight) in the fall of 1971, (3) Solid beef manure at 66⅔ tons/acre (wet weight) in the fall of 1971, (4) Solid beef manure at 100 tons/acre (wet weight); 33⅓ tons applied in the fall of 1971 and 66⅔ tons in the spring of 1972. Half the sub-plots received Furadan insecticide treatment for rootworm control. The plots were planted to Pioneer 3956A (corn) on May 10, 1973. Starter fertilizer was used only on the fertilized treatment. Lasso was broadcast at 2¼ lbs/acre on May 13; 2, 4-D amine at ¼lb/acre was applied as a postemergence spray on June 5; 2, 4-D ester at ⅓ lb/acre was applied on June 22. Corn leaves were collected from the insecticide treated portion of each plot in 1973 and analyzed. It was found that the 2 higher manure rates increased the leaf nitrogen levels. All manure rates increased leaf phosphorus and potassium levels. All manure rates decreased leaf magnesium and zinc levels. The lowest rate of beef manure was highest in leaf copper level. The other 2 rates were not significantly different from the fertilized treatment. At final harvest each year, grain samples were saved from all plots and analyzed. 1972 results revealed that all manure rates increased phosphorus, potassium, and magnesium levels in grain. It was also found that the use of insecticide brought about a slightly higher ear moisture content and higher yield. (Ott-East Central)

MANURE RATE STUDY,

S. D. Evans, R. C. Munter, and P. R. Goodrich
A Report on Field Research in Soils, Soil Series 91, Department of Soil Science, University of Minnesota, March, 1974, p. 118-126. 7 tab.

Descriptors: Crop response, Chemical properties, Insecticides.
Identifiers: Land disposal, Application rates.

The main environmental treatments were arranged in 3 replications of a complete randomized block design. Each plot was split into 2 sub-plots—half of which received insecticide (furadan) treatment for corn rootworm control. The main experimental treatments were : (1) No manure or fertilizer, (2) Recommended amounts of inorganic fertilizer each year, (3) Solid beef manure at 10 tons/acre (dry basis) each fall, (4) Solid beef manure at 20 tons/acre (dry basis) each fall, (5) Solid beef manure at 30 tons/acre (dry basis) each fall, (6) Liquid beef manure at 19 tons/acre (wet basis) each fall, (8) Liquid beef manure at 57 tons/acre (wet basis) each fall. The plots were planted to Pioneer 3956A corn on May 10, 1973. Furadan was applied at 10 lbs/acre to half the subplots at planting. Starter fertilizer was used only on the fertilized treatment. Lasso was broadcast at 2¼ lbs/acre on May 13; 2, 3-D amine at ½ lb/acre was applied as a postemergence spray on June 5; 2, 4-D ester at ⅓lb/acre was applied on June 22. Manure was applied for the first time in the fall of 1972 for the 1973 crop. The soils in each plot were sampled to a depth of 10 feet in the fall of 1972 prior to manure application. In the fall of 1973 the soils were sampled to a depth of 8 feet. (Results are not yet available.) Leaf samples were taken at silking and fodder, grain, and root samples were taken at the silage stage. Samples were dried and analyzed. Manure increased the leaf content of nitrogen, phosphorus, and potassium and decreased magnesium and zinc levels. Manganese and boron levels were variable. Yield and plant measurements made in 1973 prior to harvest gave the following results. (1) Manure treated plants were tallest. (2) Root damage was reduced where insecticide was used. (3) In early September many plants died prematurely, apparently from stalk rot. Increasing amounts of manure resulted in more dead plants. There were also more dead plants in the artificially fertilized and the check plots. Insecticide reduced the percentage of dead plants. (4) Stalks broken above the ear were reduced by the insecticide. (5) Stalks broken below the ear in general increased where manure was used. (6) Ear moisture at harvest was quite variable. (7) The check or "no fertilizer" plot had the least grain yield. (Ott-East Central)

NEW EPA PROPOSALS FOR FEEDLOT RUNOFF TAKE REASONABLE APPROACH,

R. D. Wennblom
Farm Journal Vol. 100, No. 1, p. G3, January, 1976.

Descriptors: Water pollution, Feedlots, Agricultural runoff, Regulation, Permits.
Identifiers: Point sources, Environmental Protection Agency, National Resources of Defense, Inc., Exemption.

The Environmental Protection Agency (EPA) is now taking a more reasonable approach to the possible pollution of streams by farm and feedlot runoff. Latest indication of this change in attitude came during a discussion of which size animal feedlots will require a wastewater permit. EPA Deputy Administrator John R. Quarles Jr. said that "EPA doesn't want to have to go out and regulate every feedlot. EPA has already prepared an exemption amendment and sent it to the White House for clearance before it goes to the Congress. Last March, in a suit brought by National Resources of Defense, Inc., (NRDC), the court ruled that the Corps of Engineers is responsible for all "the waters of the U.S.," not just the navigable waters. This decision gives the Corps authority over practically every natural and artificial body of water in the country, including farm ponds and streams where normal flow is 5 or more cubic feet/second. Next, NRDC challenged EPA's ruling that only the largest agricultural operations require a permit for the discharge of their wastewater into navigable streams. On June 10, 1975, the court ruled that EPA cannot exempt an animal feedlot or another agricultural operation simply because it's small. Forced to comply with this court order, EPA has now proposed new regulations to spell out the conditions under which concentrated animal feeding operations would be required to get a wastewater permit. Under EPA's latest proposals a permit would not be needed unless more than 1,000 slaughter and feeder cattle, 700 mature dairy cows, 4,500 slaughter hogs, 12,000 sheep or lambs, 55,000 turkeys, 180,000 laying hens, or 290,000 broilers are confined for 45 days or more during a 12-month period. Otherwise, a permit would not be needed unless "measurable wastes" are discharged directly into: (1) navigable waters that run through the feedlot; or (2) navigable waters by means of man-made pipe, ditch or flushing. A feeding facility, no matter what size, will require a permit if EPA and state authorities decide that it's a significant source of pollution. (Ott-East Central)

THE ECONOMICS OF POULTRY WASTE FEEDING,

G. C. Masters
Egg Industry, Vol. 9, No. 6, p. 20, June, 1976. 1 tab.

Descriptors: Feeds, Performance, Economics, Cattle, Nitrogen.
Identifiers: Refeeding, Poultry wastes, Contaminants.

Three ways of processing poultry wastes to be used as cattle feed are dehydration, ensiling and chemical treatment. While dehydration is the most expensive on a per ton basis, the dehydrated form has been found to be easily transported and can be used in commercial feed meals. In contrast, ensiling requires less facility and operating costs, but the product is not as easily handled due to its moist form. A new chemical process called "Grazon" is now being used to treat animal wastes. The product is used on cattle waste, broiler waste and cage layer waste. The treated wastes are fed primarily to beef cattle. While all 3 methods destroy pathogenic organisms and improve palatability, there are dangers in feeding wastes. Any feed material, including animal waste, may be contaminated with hard metals and numerous other substances. Feeders must know their waste and run analyses to confirm levels of contaminants. Withdrawal periods can be used to reduce residue levels of some contaminants. Waste feeding, nevertheless, offers a fantastic financial opportunity for the poultry industry. (Merryman-East Central)

EPA SETS FINAL RULES ON FEEDLOT PERMITS.

Wallaces Farmer, Vol 101, No. 8, p. 42, April 24, 1976.

Descriptors: Regulation, Permits, Water pollution.
Identifiers: Environmental Protection Agency, Point sources, Animal units.

Final regulations that establish the conditions under which feedlots will need waste water discharge permits have been issued by the Environmental Protection Agency. It is estimated that about 3,240 livestock operations nationwide will need a permit under these regulations. In the final regulations, operations that do not discharge pollutants into navigable waters will not need a permit. But feeding operations will need a permit if there is a discharge of pollutants and their operations have more than 1000 slaughter and feeder cattle, 700 mature dairy cattle, 2,500 swine weighing over 55 lb., 500 horses, 10,000 sheep and lambs, 55,000 turkeys, 100,000 laying hens or broilers (continuous overflow watering), 30,000 laying hens or broilers (liquid manure handling), 5,000 ducks, or 1,000 animal units. An animal unit is a way to measure an operation that involves several types of livestock. A feedlot with 301-999 animal units will also need a permit if the facility discharges pollutants by means of a man-made conveyance or discharges into waters that pass through or have contact with animals. This includes operations larger than: 300 slaughter or feeder cattle, 200 mature dairy cattle, 750 swine over 55 lb., 150 horses, 3,000 sheep, 16,500 turkeys, 30,000 laying hens or broilers (continuous overflow watering), 9,000 hens or broilers (liquid manure handling), 1,500 ducks, or 300 animal units. This size feedlot may also need a permit if designated by the EPA or Department of Environmental Quality as requiring one. Livestock producers who will need a permit should file a short form B by September 1, 1976. (Ott-East Central)

ADVISED AGAINST LIQUID POULTRY MANURE SYSTEM,

Anonymous
Poultry Digest, Vol. 35, No. 412, p. 234, June, 1976.

Descriptors: Liquid wastes, Poultry, Economics, Waste disposal.
Identifiers: Waste management, Land spreading.

Herb Jordan, Pennsylvania State University extension poultry specialist, advises the poultry producer to avoid installation of a liquid system for handling poultry manure for the following reasons: (1) To get a tank full of dry manure taken out onto the field, you must haul 19 loads of useless water, because liquid manure is 19 parts water to one part dry manure. This causes a loss of $6,000 per year for the operation of a family-sized poultry farm. (2) Liquid manure can be toxic to crops if applied too heavily. (3) The majority of poultry farmers who get cited, called into hearings and fined for pollution are those with liquid manure systems. (4) Nearly all poultrymen who initiate liquid manure systems find that within 6 years they change from this system, or they go out of business, or they go bankrupt. (5) A liquid manure system always costs the poultryman many times more dollars than it brings into the farm family. (Merryman-East Central)

AMMONIA VOLATILIZATION FROM DAIRY MANURE SPREAD ON THE SOIL SURFACE,

Coastal Plain Experiment Station, Georgia University, Tifton
D. A. Lauer, D. R. Bouldin, and S. D. Klausner
Journal of Environmental Quality, Vol. 5, No. 2, p. 134-141, April-June, 1976. 6 fig.

Descriptors: Ammonia, Volatility, Dairy industry, Chemical properties, Fertilizers.
Identifiers: Land spreading, Surface spreading, Waste management.

An investigation was conducted to measure ammonia volatilization from dairy manure spread and left on the soil surface under natural field conditions. The ammonia volatilization was measured in 5 experiments carried out over a period of 2 years in spring, summer, and winter. Manure application rates were 34 and 200 metric tons/ha. Ammonia volatilization was determined after spreading by periodically measuring the total ammoniacal nitrogen (TAN) content of manure samples collected from the soil surface. Corrections were made for increase in ammoniacal N in the soil. Quantities of ammonia volatilized were large from dairy manure spread in the field. The mean loss of ammonia, excluding the January, 1974 experiment, was 85 percent on the total ammoniacal nitrogen spreading. Results indicated high probabilities of large quantities of ammonia volatilization from manure across a wide range of weather conditions. In general, 3 stages of ammonia volatilization from bovine manure can be hypothesized. The first stage is a very rapid initial loss of ammonia driven by very high P_{NH_3} values resulting from urea hydrolysis in the manure. Half-lives of less than 1 day characterize first-stage losses. Second-stage ammonia volatilization losses, characterized by half-lives of 2-4 days, begin as manure is subjected to drying either in the facility or after spreading. The third-stage ammonia volatilization loss is characterized by a drop in P_{NH_3} and rates exhibiting half-lives over 4 days. In order to insure maximum utilization of nitrogen in manure applied to cropland, management techniques have to be developed to minimize ammonia volatilization in the field and in the animal facility. (Ott-East Central)

BILL PROTECTS FARMS FROM NUISANCE SUITS.

J. Carlson
Wallaces Farmer, Vol. 101, No. 8, p. 41, April 24, 1976.

Descriptors: Regulation, Legal aspects, Iowa, Air pollution, Water pollution, Management, Odor, Feedlots.
Identifiers: Nuisance suits.

A bill (Senate file 367), currently in the Iowa legislature could help protect livestock producers from nuisance suits. One section of the bill says, basically, that whoever is there first is right. However, if the cattle feeder expands his operation and is then sued, he loses his protection and could be liable to the degree of his expansion. The producer's protection is good as long as he meets environmental regulations. The bill also tries to protect livestock producers from regulation changes. If a producer has to make a management change (one that costs less than 2 per cent of the cost of establishing the facility), to control an odor problem on a facility that's less than 10 years old, he has 2 years of exemption. If the facility is older than 10 years, he has a one-year exemption. If a producer is faced with a design change (one that costs more than 2 per cent of the cost of building the facility) for air quality on a facility less than 10 years old, he has a 10-year exemption from the change. If the facility is older than 10 years, he has a 10-year exemption from the change. If the facility is older than 10 years and he doesn't have a feedlot permit, the operator gets a 5-year exemption. If he has a feedlot permit, the length of his exemption from the change is the same as the time remaining on his feedlot permit. Exemptions from changes in water quality regulations are also included. A nonpermit holder would get an exemption of either 5 years from the change, or 10 years from when the facility was established, whichever is greater. A producer with a feedlot permit gets either 10 years from when the facility was built or the time remaining on his permit, whichever is greater. Senate file 367 says a feedlot should be exempt from both city and county zoning changes for 10 years from date of change. However, this doesn't apply to livestock operations currently within the city limits. This bill is currently under debate in the House of Representatives. (Merryman-East Central)

MANURE HANDLING SYSTEMS,

Poultry Science Department, The Pennsylvania State University, University Park
G. O. Bressler
Summary of talk delivered at London Poultry Industry Conference, London, Ontario, Canada, June 15, 1972, 6 p. 2 tab.

Descriptors: Drying, Economics, Costs, Moisture content, Physical properties, Recycling.
Identifiers: Dried poultry waste, Odor control.

A two-stage drying system was developed at Penn State which offers several advantages. It improves the physical characteristics of the manure and makes handling easier; it eliminates offensive odors; and the final product is felt to have more sales appeal. The two stages of the system are: (1) blowing air at high velocity over the manure, and (2) stirring the manure automatically 4-10 times daily. This system has been found to remove about 80 per cent of the water from the manure and to reduce the weight of the manure to be handled to about 1/3 the original weight before the manure is removed from the house prior to mechanical drying. The drying system has been found to be economically sound, with total costs for drying estimated at about $15/ton. Poultrymen who have adopted this system are finding ways to sell the product at a profit. New uses will be found for the product in the future. (Penrod-East Central)

BACTERIOLOGICAL QUALITY OF SURFACE RUNOFF FROM AGRICULTURAL LAND. PART II.

Department of Civil Engineering, South Dakota State University, Brookings
L. L. Harms, P. Middaugh, J. N. Dornbush, and J. R. Anderson
Water and Sewage Works, Vol. 122, No. 11, p. 71-73, November, 1975. 4 fig, 2 tab, 22 ref.

Descriptors: Agricultural runoff, Bacteria, Coliforms, Snowmelt, Water pollution.
Identifiers: Identification techniques, Fecal coliforms, Fecal streptococcus.

Density determinations of total coliform, fecal coliform, and fecal streptococcus in surface runoff from agricultural lands were found using the multiple-tube fermentation technique. The methods utilized for confirmation were brilliant green lactose bile broth for total coliforms, ethyl violet azide broth for fecal streptococci and EC medium at 45° C for fecal coliforms. Primary factors influencing the organism levels were: (a) source of runoff (snowmelt or rainfall runoff), and (b) ground cover conditions (ie, corn stubble, fall plowed, pasture, Brome or alfalfa, and oats stubble). Graphs and tables are given that correlate the finding to cognizable units. Rainfall runoff was found contaminated to pollution levels suggesting that runoff from agricultural lands may be a source of pollution for surface waters. The actual health hazard has not been determined. (Penrod-East Central)

THE KINETICS OF MICROBIAL NITRIFICATION AS APPLIED TO THE TREATMENT OF ANIMAL WASTE,

G. M. Wong-Chong
PhD Dissertation, Cornell University, June, 1974, 244 p. 49 fig, 26 tab, 134 ref.

Descriptors: Animal wastes, Waste treatment, Nitrification, Kinetics, Ammonification, Nitrogen, Nitrates, Bacteria, Temperature.
Identifiers: Reaction rates, Ammonium-nitrogen oxidation, Nitrite-nitrogen.

Two phases of experimentation were conducted. Phase 1 concerned ammonification, ammonium-nitrogen oxidation, and nitrite-nitrogen oxidation—the 3 steps for converting nitrogen to nitrate. Batch experiments were conducted using acclimated enriched cultures. Specifically sought were: (a) the nature of the reaction in each step and (b) the effects of environmental factors on reaction rates. Observations of ammonification by mixed cultures demonstrated the ability of the organisms to adjust to changes in substrate either by enzyme induction or by population change. Observations of the nitrifying organisms indicated that bacterial populations may also conform to population control mechanisms. Free nitrous acid inhibition of nitrification was observed. Phase 2 experimentation observed the reaction steps in sequence: firstly, ammonium oxidation to nitrate and secondly, conversion of organic nitrogen to nitrate. Experimental conditions were 20 degrees C with controlled pH levels and with ammonium sulfate as the ammonium-nitrogen substrate and a urea + casean mixture as a source of organic nitrogen. Cultures used were enriched, acclimated organisms grown in the laboratory and a ODML culture. It was found that reaction characteristics could be predicted by a system of simultaneous equations describing ammonification as a first order reaction and both nitrification reactions as zero order reactions. Lag periods were noted prior to the onset of nitrification. ODML culture experiments showed that the organisms made no distinction between urea and uric acid as organic nitrogen source. Ammonification rates were about 0.115 hr^{-1}. The ammonium oxidation step was the rate limiting stage in the reaction sequence if the nitrite accumulation was disregarded, because k_2 after ammonium depletion was always greater than k_1. The author concluded that in treating poultry waste, about 75 percent of the total organic nitrogen in the fresh waste was convertible to the inorganic form. Nitrogen loss occurred in reaction systems in which there was appreciable dissolved oxygen (0.5-1.0 mg 1.) (Penrod-East Central)

UTILIZATION OF LIVESTOCK WASTES AS FEED AND OTHER DIETARY PRODUCTS,

Department of Agricultural Engineering, Illinois University at Urbana-Champaign
D. L. Day
Presented at the International Seminar on Animal Wastes, Bratislava, Czechoslovakia, September 28-October 5, 1975, 27 p. 10 fig, 12 tab, 22 ref.

Descriptors: Feeds, Drying, Nitrogen.
Identifiers: Refeeding, Livestock wastes, Dietary products, Wastelage, Oxidation ditch mixed liquor, Cereco, Corral, Grazon.

Livestock manure has historically been utilized for plant nutrients, soil builders, animal nutrients, and fuels. This paper discusses utilizing livestock wastes as nutrients in animal diets, commonly referred to as "refeeding." Properties of manure are influenced by such factors as ration fed, species of livestock and methods of manure handling, storage, and treatment. The amount of nitrogen in manure is of particular interest for refeeding because it is a major component of protein. Various methods of processing wastes for refeeding are reviewed as well as properties of the wastes that are of interest for refeeding. Probably the oldest method of processing wastes is the drying of poultry manure, with heated or natural air, and incorporating it into feed for cattle. Production of wastelage by collecting fresh manure from cattle feedlots, mixing it with hay, and ensiling the mixture is another method. Oxidation ditch mixed liquor (ODML) is a method of refeeding aerobically treated liquid wastes as a nutrient-rich drinking water. There are three major commercial methods of processing cattle wastes for refeeding in the U.S.A. They are the Cereco, Corral, and Grazon systems. The Cereco and Corral systems involve complex expensive equipment that limits their use to large feeding operations. Grazon can be used for small operations as well as for large ones. All the refeeding methods discussed include a process for controlling disease and odors and the methods range from simply mixing dried manure with new feed to complex waste processing schemes that yield several usable products including protein, vitamins, minerals, and water. The processed wastes are fed to the same and to different species of livestock. In all of the processing methods discussed except ODML, only about 40 percent of the wastes produced from confinement livestock can be refed to the same animals. The surplus must be utilized elsewhere. (Cameron-East Central)

ELIMINATION OF WATER POLLUTION BY PACKINGHOUSE ANIMAL PAUNCH AND BLOOD,

Beefland International Inc.
Water Pollution Control Research Series, Environmental Protection Agency, November, 1971, 41 p. 15 fig, 10 tab, 6 ref.

Descriptors: Water pollution, Dehydration, Drying, Costs, Recycling, Cattle, Chemical oxygen demand, Biochemical oxygen demand, By-products, Chemical properties, Waste water treatment.
Identifiers: Packinghouse wastes, Blood, Rumen, Paunch manure, Feed additives.

The operation of two dehydrating machines, for the drying of cattle whole blood as well as paunch contents (rumen), at the Beefland International, Inc., slaughtering plant at Council Bluffs, Iowa, was studied. The BOD5 and COD of the blood and rumen were established. The mean BOD5 of the whole blood and rumen was determined as 156,500 ppm and 50,200 ppm, respectively. The mean COD of the blood and rumen was established as 218,300 ppm and 177,300 ppm, respectively. The economics of the drying process in costs per ton of dried product, per 1000 lbs live kill weight (LWK), and per animal were determined. The dehydrating costs per ton of dehydrated product were found to be $43.75/ton for blood and $38.46/ton for rumen. The average cost (blood and rumen) was $40.93/ton. Laboratory studies were carried out on the dried whole blood and rumen with a view toward their actual and potential use as legally accepted feeds or feed additives. Percent moisture, protein, fat, carbohydrate, and other analyses of the dried products are reported. (Lowry-Texas)

Identifiers: Permuted indexing.

This bibliography contains 158 abstracts with full bibliographic details for selected reports, journal articles, and various documents published mostly since 1967. Produced from a computerized information base containing 25,675 abstracts at the time of search, the bibliography is representative of the information on agricultural runoff contained in the journal "Selected Water Resources Abstracts" through December 15, 1971 (Volume 4, Number 24). A significant descriptor index is given of representative weighted terms that best describe the information content of the abstracted items. A comprehensive index is also given that represents all descriptors and identifiers used to index the various papers and documents represented by the abstracts in the bibliography. Abstract items are arranged in ascending WRSIC Accession Number sequence. (Lang-USGS)

PHYSIOLOGY AND NATURAL DISTRIBUTION OF THE BACTERIUM CARYOPHANON LATUM IN THE FRESH WATERS OF MISSOURI,

Department of Life Sciences, Missouri University, Rolla.
J. B. Hufham, R. Carroll, and J. Hill
Completion Report, Missouri Water Resources Research Center, November 8, 1972, 20 p. 4 tab.

Descriptors: Missouri, Water pollution, Pollutant identification, Ruminants, Ecology, Physiology, Water analysis, Microbiology.
Identifiers: Pollutants, Caryophanon latum, Fecal pollution.

An experimental selective medium was developed for use in quantitatively analyzing stream waters for the presence of the genus Caryophanon. The medium was based on yeast extract-peptone agar and incorporated high concentrations of streptomycin to inhibit growth of other microorganisms. Physiological studies with the organism, C. latum, showed a requirement which was met by using crude agar or an,

extract of crude agar. Resistance to sulfa drugs was also noted. The need to identify the nutrient or cofactor supplied by crude agar prohibits the final development and field trials of the medium. (Hufham-University of Missouri)

WATER QUALITY HYDROLOGY OF LANDS RECEIVING FARM ANIMAL WASTES,

Texas Water Resources Institute, Texas A&M University, College Station
D. L. Reddell, G. G. Wise, R. E. Peters, and P. J. Lyerly
Technical Report No. 50, Texas Water Resources Institute, June, 1973, 110 p. 23 fig, 26 tab, 61 ref.

Descriptors: Feedlots, Water pollution, Groundwater pollution, Agricultural runoff, Cattle, Chemical properties, Salts, Ammonia, Nitrogen, Nitrates, Texas.
Identifiers: Land disposal, Disposal rates.

A significant pollution potential from cattle manure has developed as a result of the cattle feeding industry progressing to large, high density feeding operations. The objectives of this study were to determine the characteristics of storm runoff from a beef feedlot and to evaluate the disposal of large amounts of manure on land. Feedlot runoff was found to carry large amounts of chemical elements. The concentrations of chemical elements did not vary with size and intensity of rainstorm as much as by topographic differences of the watersheds. More ammonia was volatilized from high pH soil columns than neutral pH soil columns. A total nitrogen loss of 10 to 20 percent occurred in the soil columns. Up to 900 tons / acre of manure can be safely plowed under 30 to 35 inches deep without creating a surface water pollution problem. An increase of salts in the groundwater occurred during the first year and then salts were reduced to initial values the second year. No nitrate pollution of groundwater occurred. Crops can be effectively grown on land receiving up to 900 tons / acre of manure. Peak yields occur the second and third year after plowing under. (Runkles-Texas A&M)

AN INVESTIGATION OF THE NITRATE PROBLEM IN RUNNELS COUNTY, TEXAS,

Texas Water Development Board, Austin
D. C. Jones
Environmental Protection Agency Technology Series Report No. EPA-R2-73-267, June, 1973, 214 p. 22 fig, 10 tab, 43 ref.

Descriptors: Nitrates, Texas, Water pollution sources, Groundwater pollution, Soil contamination, Chemical properties, Leaching, Remote sensing, Aerial photography.
Identifiers: Runnels County, Texas, Nitrogen isotope ratio, Infrared photography.

This report describes the investigation of nitrate contamination in Runnels County, Texas. It was found that most water well contamination is due to naturally occurring nitrate. However, all the very high nitrate contamination problems (more than 1000 ppm) are principally due to nitrate from barnyards. The nitrate sources were confirmed by utilizing the nitrogen isotope ratio technique. The nitrate contamination was caused by a rising water table which intersected and dissolved nitrate deposits from the soil. The rising water table was caused by a combination of low porosity aquifers, increased infiltration (decreased surface runoff) due to terracing, and several consecutive years of above normal rainfall. There appears to be no economical way to remove the nitrate from either the water or the soil. Recommendations for ways for the area residents to obtain potable water and for a continued monitoring program are included. (Environmental Protection Agency)

AGRICULTURAL POLLUTION CONTROL AND ENFORCEMENT IN NEW YORK STATE,

Cornell University, Ithaca, New York
T. Flaim
Paper Prepared for the New York Assembly Scientific Staff-Study Performed in Cooperation with Department of Agricultural Economics, Cornell University, November, 1973, 27 p.

Descriptors: Farm wastes, Legislation, New York, Pollution control, Animal wastes, Sedimentation, Nutrients, Pesticide, Air pollution, Effluents.
Identifiers: Food processing wastes, Water quality standards.

The objective of this paper was to summarize briefly the research that has been done to date on the extent, magnitude, control and enforcement of agricultural pollution which would be of interest to New York legislators. Section II of the paper deals with the extent, location and types of agricultural pollution existing in the state. Section III deals with the various available means of abating pollution as well as new methods that might be developed through additional research efforts. Section IV examines the advantages and limitations of the commonly suggested methods of enforcement of agricultural pollution control. Section V analyzes the possible cost impacts of agricultural pollution control legislation. The findings of the study are summarized in Section VI, with conclusions drawn regarding further research needs and implications for policy-makers. (Flaim-Cornell University)

DEMONSTRATION OF THREE RECIRCULATING SWINE WASTE MANAGEMENT SYSTEMS,

Agricultural Engineering Department, Iowa State University, Ames
J. R. Miner, T. E. Hazen, R. J. Smith, and G. B. Parker
Environmental Protection Agency Report No. EPA-660 /2-74-009, December, 1973, 147 p. 48 fig, 26 tab, 29 ref.

Descriptors: Waste treatment, Liquid wastes, Waste disposal, Hydraulic transportation, Lagoons, Irrigation, Odor, Chemical properties.
Identifiers: Swine, Waste water reuse, Land disposal, Aeration basin, Vibrionic dysentery, Flushing.

Three waste treatment systems were used to process liquid swine manure so the effluent could be reused as flush-water. Hydraulic transport was effective in removing manure from all eight buildings. Excess liquid from all three systems was applied to adjacent cropland to achieve nutrient utilization as the final disposal step. Reductions in building odors, manure handling labor, and land requirements for final effluent disposal were major goals of the demonstration. An aeration basin received the manure from two farrowing buildings with a capacity for 14 sows each. As anticipated, solids accumulated in the aeration basin. When the solids content exceeded 4,500 mg / l, plugging problems became frequent in the pump and piping system. A lagoon-aeration basin system served two farrowing buildings with a capacity for 28 sows each. The system performed adequately with only minor mechanical difficulties. A lagoon-RBC system served four finishing buildings with a total capacity of 700 hogs. Frequent mechanical and biological failure resulted in removal of the RBC from use. Lagoon effluent is being used to flush these buildings with success. Repeated outbreaks of vibrionic dysentery has prompted remodelling two of the buildings and flushing in a gutter covered with slats. (Environmental Protection Agency)

EFFECT OF VENTILATION RATE OF BEEF CATTLE PERFORMANCE,

Professor, Agricultural Engineering Department, University of California, Davis
S. R. Morrison, G. P. Lofgreen, and R. L. Givens
Transactions of the ASAE, Vol. 19, No. 3, p. 530-532, May-June, 1976. 5 tab, 5 ref.

Descriptors: Ventilation, Cattle, Performance, Ammonia, Temperature, Gases.

A refrigerated air-conditioned barn at the Imperial Valley Field Station of the University of California was used for testing the effect of ventilation rate on beef cattle performance. Beef cattle in rooms with slotted floors over anaerobic manure pits were subjected to 3 ventilation rates: 8.8, 3.2, and 0.3m^3 / min per head. Feed intake and rate of gain were significantly higher at the highest ventilation rate for only the first 28 days. Manure gases were suspected to account for the differences. Ammonia concentrations were lower than those commonly thought to adversely affect cattle performance. (Rowe-East Central)

METHANE GENERATION FROM LIVESTOCK WASTES,

J. C. Lorimor and S. W. Melvin
Iowa State University Cooperative Extension Service Publication Pm-593, July, 1974, 4 p. 1 fig, 2 tab.

Descriptors: Methane, Anaerobic digestion, Livestock, Waste treatment, Gases, Odor, Nutrients, Design.

Advantages of methane generation in the treatment of animal wastes are: (1) Energy is harvested from waste which would otherwise be lost. (2) Odors which would otherwise escape and cause problems are contained in digestors. (3) Valuable nutrients are retained. Disadvantages are: (1) Digestors are expensive. (2) Anaerobic digestion is complex and sensitive to environmental conditions. (3) Digestion is not a disposal system. Anaerobic digestion is a two-part process, and each part is performed by a specific group of organisms. The first part is the breakdown of complex organic matter (manure) into simple organic compounds by acid-forming bacteria. These bacteria break down complex organics and produce primarily acetic acid and propionic acid, along with some ammonia, and carbon dioxide. The second group of microorganisms, the methane-formers, breakdown the acids into methane and carbon dioxide. In a properly functioning digestor, the 2 groups of bacteria must be balanced so that the methane-formers just use the acids produced by the acid-formers. If the acid-formers get ahead of the methane-formers, acids begin to accumulate, the pH drops, the methane-formers are inhibited, and ultimately digestion ceases. The balance of the 2 groups of bacteria is affected by several factors including loading quantity, quality, and frequency, as well as temperature, toxic elements, and pH. The gas produced is generally in the range of 60 percent methane and 40 percent carbon dioxide. An average of 10 cubic feet of gas may be produced per pound of COD or 12 cubic feet of gas may be produced per pound of volatile solids digested. When using the anaerobic digestor described, submerger inflow and outflow lines are needed to prevent gas from escaping. Either a mechanical mixer can be used or the liquid or gas can be recirculated for mixing. Flushing or scraping systems are well adapted because they can provide frequent waste removal and feeding. Disposal of the waste can be by hauling, dumping into lagoons, or pumping. Sludge must be periodically removed. For gas utilization, compressor and storage tanks are used, along with the associated plumbing which would include flame traps, pressure gages, regulator hydrogen sulfide scrubber, and pressure relief valves. (Ott-East Central)

NO ODOR, NO WASTE: 'SUPER STRAINER' TAKES HOG MANURE WITH EASE,

Anonymous
Successful Farming, Vol. 73, No. 10, p. H1, September, 1975. 1 fig.

Descriptors: Waste treatment, Waste disposal, recycling, Separation techniques, Fertilizers, Solid wastes, Liquid wastes, Lagoons, Odor.
Identifiers: Swine, confinement pens.

A particular problem of the new giant sow complexes has been what to do with the manure. One such sow unit, North Central Pork Producers, Inc. of Clear Lake, Iowa, thinks it may have a solution to the problem. The corporation owners installed a manure treatment unit which acts like a giant, mechanical squeegee. All waste from the 6,000-head capacity flushes through 10- and 12-in. sewer lines to a 16-cu.-ft. concrete holding pit. A pump takes waste from the pit to a microstrainer. Brushes pass lightly across the screen on a revolving drum forcing the liquid through the screen. The strained solids brush to a horizontal auger which carries them to a vertical auger. The vertical auger has a squeezing action to remove as much additional water as possible. The solid then augers into a manure spreader. The strained liquid is pumped to a lagoon with overflow going to a second. The recycled water becomes the flushing agent in the facility. The unit removes approximately 90 cu. ft. of the solids per day and can process 75,000 gallons of manure. The cost of the unit is nearly $27,000 but the fertilizer value of the solid waste is expected to cover the operating cost of the unit. In this unit, by removing the large, solid particles before it goes into the lagoon, odor problems have been virtually eliminated. The solid waste will either be used as a crop fertilizer or bagged and sold commercially in garden shops. (Ott-East Central)

THE FEASIBILITY OF USING WASTE MATERIALS AS SUPPLEMENTAL FISH FEED,

Department of Fisheries and Wildlife, Michigan State University, East Lansing
J. D. Lu and N. R. Kevern
Progressive Fish-Culturist, Vol. 37, No. 4, p. 241-244, October, 1975. 5 tab, 10 ref.

Descriptors: Feeds, Performance, Nutrients, Fish.
Identifiers: Dried poultry waste, Sewage sludge, Refeeding, Catfish, Goldfish.

Since sewage sludge and dried poultry waste are high in protein, crude fat and carbohydrate content, a study was carried out to investigate the feasibility of using such waste materials as supplemental fish feed. The nutrient value of sewage sludge and dried poultry waste was tested on the growth rates of goldfish fingerlings and channel catfish fingerlings. A 30 percent sewage sludge diet was prepared by combining 3 parts sludge and 7 parts ground salmon feed. Three varying mixes for the DPW diets (30, 70, and 100 percent DPW) were prepared in much the same manner. In the goldfish experiment, 20 fish were placed in each of 3 tanks and were fed equal amounts equal to 3 percent of their body weight daily. One tank received salmon feed; one tank received the 30 percent sewage sludge diet; the other tank received the 30 percent DPW diet. In the catfish study, 18 fish were placed in each of 12 tanks. The tanks were separated into 3 groups of 4 tanks each. The first, second, and third groups of fish were fed 2 percent, 3 percent, and 4 percent of their body weight, respectively. Within each group of 4 tanks, fish were fed different types of diets: fish in the first, second, third, and fourth tanks were fed 0 percent (control), 30 percent, 70 percent, and 100 percent DPW diets respectively. Because of unequal initial weights, comparison of growth among different groups was based on the average monthly percentage weight gains for fish from each tank. Goldfish fed 30 percent DPW or 30 percent sewage sludge grew as well or better than controls. The average weight gain of control catfish in all 3 groups was greater than those in the experimental groups. Catfish fed on 100 percent DPW diets in all 3 groups showed little or no growth, and thus, were not included in the report. Growth results of control catfish in all 3 groups were significantly higher than those fed 30 percent or 70 percent DPW diets. Thus, the results from the experiment using goldfish appeared encouraging and results from the catfish experiment slightly less promising. Nevertheless, the concept of converting waste substances into usable materials is highly desirable. (Ott-East Central)

NO-WASTE FEEDING SYSTEM,

Anonymous
Progressive Farmer, Vol. 91, No. 7, p. 18-20, July, 1976.

Descriptors: Feedlots, Separation techniques, Design, Recycling, Lagoons, Methane, Carbon dioxide, Odor, Flies.
Identifiers: Waste management, Refeeding.

Don Kaplan of Bartow, Florida, has developed an innovative and efficient feedlot which has offset the factors which work against efficient feeding and finishing. Among these factors are: (1) Heat—Kaplan's feedlots use slotted roofs which create air drafts that keep the air moving and "cut the edge off" the sun. (2) High rainfall—The high open roofs protect the cattle. Slatted floors prevent belly-deep mud and allow collection and use of waste. (3) Flies and odor—Waste is removed every 2 hours, which greatly cuts down fly breeding and odor problems. Alleys are swept daily. (4) Lack of grain—Grain is received in bulk by train and truck. (5) Manure—Manure has been turned into a feed source. The animal wastes are handled in this manner. The wastes fall through concrete slatted floors to a concrete floor and are collected by an automatic scraper every 2 hours and pumped to an open holding tank. The contents of the holding tank are pumped to vibrating screens that separate undigested ground hay and other coarse solids. Water is added to wash the finer materials through the screens. The moist undigested feed is dumped onto a paved area beneath the separating screens. It is loaded into trucks, spraying with formalin, and stockpiled elsewhere on the paved area. It is later taken in trucks to the feed supply center where it becomes a feed additive. The liquid wastes that pass through the separating screens are pumped to a holding pond, the first in a series of 6 deep ponds and 3 shallow ponds. The first pond is anaerobic. The waste is further digested as it overflows into adjacent lagoons. The tenth pond is electrically aerated, and it and the final 2 settling ponds are used for raising tilapias which are harvested and sold. Water from the last pond is treated and returned to the feedlot for drinking water. A full-sized methane digester is under construction which will provide methane to the packinghouse and feedyard operation. Bartow is considering recovering carbon dioxide and converting it to dry ice. (Ott-East Central)

RAPID METHOD FOR DETECTION AND ENUMERATION OF FECAL COLIFORMS IN FRESH CHICKEN,

U. S. Department of Health, Education, and Welfare, Public Health Service, Food and Drug Administration, Division of Microbiology, Cincinnati, Ohio
D. W. Francis, J. T. Peeler, and R. M. Twedt
Applied Microbiology, Vol. 27, No. 6, p. 1127-1130, June, 1974. 1 fig, 3 tab.

Descriptors: Poultry.
Identifiers: Fecal coliforms, Sanitary quality, Identification techniques.

A study was conducted to modify the rapid water fecal coliform procedure for use with foods and to evaluate it by comparing it with the Association of Official Analytical Chemists standard method for Escherichia coli. An agar pour-plate medium was formulated after intensive preliminary studies. This medium allowed the growth of fecal coliforms only, after 7 hours of incubation at 4.15 ± 0.05 C. Twenty-one samples of fresh, cut-up chicken were enumerated for fecal coliforms utilizing these 2 procedures. Verification of picked colonies was carried out in EC broth using parallel incubation temperatures of 45.5 and 44.5 ± 0.05 C. Verifications for these temperatures averaged 79 and 98 percent, respectively. All positively verified isolates were Escherichia coli types I and II, as were the negatives. Since the geometric means of the 2 methods were no more than 12 percent apart, it was felt that the method tested performed very well in comparison with the standard procedure. The rapid method showed value as a rapid screening procedure for the detection and enumeration of organisms indicative of fecal contamination of fresh chicken, and it appears to have potential application to other foods. Continuing studies are being directed toward evaluating the wider applicability of the rapid method for enumeration of total, as well as fecal, coliforms. (Ott-East Central)

FEEDERS WARNED STATE, LOCAL RULES ON POLLUTION ARE COMING THREAT,

Anonymous
Beef, Vol. 12, No. 7, p. 11, March, 1976.

Descriptors: Regulation, Feedlots, Legal aspects, Permits, Agricultural runoff, Cattle, Costs.
Identifiers: Impact statements.

A recent report submitted by John Sweeten, Texas A&M agricultural engineer, to the American National Cattlemen's Association asserted that cattlemen must meet 2 criteria to head off environmentalists' pursuit of beef feedlot waste restrictions. Cattlemen must do a good job of preventing pollution from their operations and they must become politically involved. Sweeten told the ANCA that recently proposed rules concerning discharge permits were substantially influenced by the input of cattlemen. One area with which feedlot owners should become concerned is the construction of new beef feedlots. An EPA requirement that new feedlots file an economic impact statement could delay construction as much as 3 years. "Front end" costs such as hiring outside consultants for such construction are difficult to finance. There are 3 alternatives to filing an economic impact statement: (1) Congressional action to eliminate the requirement for an environmental impact statement, (2) Get states certified to issue permits, so the impact statements would not be required, and (3) Avoid being classified as a "new" source of pollution by staying under 1,000 head, buying an existing lot, or building plenty of runoff storage capacity. Sweeten also warned that cow-calf men are about to get their first exposure to EPA rules, as the federal government starts working on "non-point source pollution" which will eventually involve every non-feedlot cattle operation in the country. (Penrod-East Central)

LAND APPLICATION OF WASTE MATERIALS,

Anonymous
Calf News, Vol. 14, No. 6, p. 28, June, 1976. 3 fig.

Descriptors: Organic wastes, Animal wastes, Nitrogen, Salts, Soils, Economics, Water pollution, Groundwater pollution.
Identifiers: Land disposal, Plant residues, Forest residues, Food processing wastes.

The Soil Conservation Society of America sponsored a national conference in Des Moines dealing with the application of plant and forest residues and animal and food processing wastes to the land. In one paper presented by Dr. B. A. Stewart of Bushland, Texas, Agricultural Research Station, the following points were made concerning the ability of the soil to accept manure: (1) Applications of manure and other wastes should be made in dry seasons to minimize water pollution and denitrification losses. (2) Salt is the limiting factor in areas with less than one inch percolation per year such as West Texas. (3) Nitrogen is the limiting factor in high percolation areas east of the Mississippi River. (4) Sandy soils with low-cation exchange capacity can receive less waste than soils high in clay or organic matter which have a high-cation exchange capacity. Though a number of papers were presented, Dr. John Sweeten of Texas A&M found the following common threads in all of the presentations: (1) A farmer or rancher is generally safe in applying organic wastes at rates that balance available nitrogen in the waste material with plant nitrogen requirements. (2) Most of our so-called waste materials provide economic benefits if used wisely for agronomic purposes. (3) There is a tremendous amount of technical information available on land disposal of organic wastes. (4) Practicing good soil conservation will automatically keep nearly all the organic matter, nutrients and pesticides out of streams and groundwater. (Ott-East Central)

ENERGY FROM AGRICULTURAL WASTE—METHANE GENERATION,

Department of Agricultural Engineering, New York State College of Agriculture and Life Sciences, Cornell University, Ithaca, New York
W. J. Jewell

New York Agricultural Experiment Station, Cornell University, Agricultural Engineering Extension Bulletin 397, January, 1974, 13 p. 2 fig, 14 ref.

Descriptors: Energy, Methane, Anaerobic digestion, Recycling, Farm wastes, Design.

Of the several types of energy capturing processes available for converting animal wastes to fuel, anaerobic digestion seems most feasible for the majority of agricultural operations. Sufficient data have been developed to demonstrate that anaerobic digestion is capable of stabilizing most agricultural wastes while producing large quantities of methane. This concept has been widely applied in Europe during energy shortages and is presently used in India. However, large scale anaerobic digesters have not been used in American agriculture. The problems which would be created by installing and using such systems are not yet well understood. Research teams at Cornell and other institutions are attempting to determine the place of agricultural waste processing for energy conservation as well as pollution control. The feasibility of this approach should be clearly delineated within 2 years. Advantages and disadvantages of the anaerobic digestion process are outlined; operational limitations of anaerobic digester conversion of animal wastes to methane gas are stated; and energy equivalent of some common fuels in comparison to anaerobic digester gas are given. (Ott-East Central)

CONVERT HATCHERY WASTES INTO FEEDSTUFFS,

Department of Poultry Husbandry, University of Missouri, Columbia 65201
J. M. Vandepopuliere

Poultry Digest, Vol. 35, No. 412, p.247-248, June, 1976. 2 tab, 4 ref.

Descriptors: Poultry, Feeds, Dehydrating, Costs, Performance.
Identifiers: Hatchery wastes, Refeeding, Processing, Cooking.

Estimated hatchery wastes currently being produced in the United States are: broiler, 56,000 tons; egg-type chick, 20,000 tons; and turkey, 8,200 tons. Disposal of the wet mass from the poultry industry is expensive. Factors such as larger hatcheries, high disposal cost, increased feed prices and greater pressure on pollution make the possibility of processing poultry wastes a possible alternative. While processing equipment has not been designed specifically to handle poultry waste, in a few operations cookers that are normally used to process poultry by-product meal have been used to cook hatchery wastes. Experimental work has been conducted at the University of Missouri using a triple pass rotary dehydrator to process both types of hatchery waste. Processing costs would include such variables as quantity of waste, size of equipment, utilities, and labor. Each operation would need to conduct an economic analysis of processing poultry waste into a feedstuff. Hatcheries with a capacity of 150,000 eggs, operating 5 days per week, could expect to spend at least $40 to $50 per ton of hatchery by-product meal. To produce a high quality hatchery by-product meal, it is essential that the raw product be managed to prevent decomposition. The most desirable procedure would be to process the wastes on stream as the chicks are pulled. Collecting and storing the wastes for a limited period of time is discouraged. The basic research completed verifies that hatchery by-product meal can be utilized efficiently as a feedstuff by poultry. (Ott-East Central)

FEEDING SALT TO BEEF CATTLE,

California State Polytechnic University, Pomona
T. J. Cunha

Feedstuffs, Vol. 48, No. 20, p. 18, 20, May 17, 1976. 1 fig, 1 tab, 13 ref.

Descriptors: Cattle, Performance, Crop response.
Identifiers: Salt, Intake rates, Urinary calculi, Land disposal.

Salt needs for cattle are not always the same. Factors influencing salt needs are: (1) Kind of concentrates, pasture, hay or silage being fed. (2) The level of salt or other minerals in the water or in the ration being used. (3) The animal's life cycle stages. (4) Genetic differences in animals. (5) Growth rate, level of production, reproduction rate and level of milk production. (6) Temperature and/or humidity in the area. (7) The level of potassium in the ration. Salt deficiencies may be noted by changes in appetite, appearance and milk yield. Experiments have shown that cattle fed salt perform better and require less feed than those fed no salt. Research studies have shown that salt needs of beef cattle may vary from 0.9 to 0.5 percent in the ration. To be on the safe side, levels of 0.25 to 0.5 percent salt should be fed in the total ration dry matter. Also, cattle should be fed salt free-choice so they can eat more if the level in the ration is not adequate. It has been found that grazing cattle consume at least twice as much salt as those on dry feeds. Many large feedlots add 0.5 to 1.0 percent salt to feedlot rations because they feel the extra water consumption and increased urination caused by the higher salt levels help prevent urinary calculi. Research studies have not revealed harmful effects from the salt in the manure on soil or crops as long as the manure is applied at proper levels to the soil. (Ott-East Central)

GOOD SANITATION STOPS STABLE FLY BUILDUP,

Anonymous

Wallaces Farmer, Vol. 101, No. 12, p. 23, June 26, 1976.

Descriptors: Feedlots, Insecticides.
Identifiers: Fly control, Sanitation.

Stable flies need to be controlled if cattle are to gain efficiently. Stable flies breed on manure and spilled hay and feed. Good sanitation is a must in controlling them. Sanitation tips are: (1) Scrape your feedlot if possible. (2) Pick up spilled feed outside the feedlot. (3) If possible, spread manure or move it where it can be tramped down. (4) Cover manure with tarps, and (5) Stack manure as far from cattle as possible. In addition to sanitation, insecticides can help control flies. Mist applications can be applied to the livestock. Residual insecticide sprays, which give longer fly control, may be applied to buildings, fences, walls, and posts or areas where flies rest. They should never, of course, be applied on cattle, feed bunks, or waterers. As most residual sprays last 10-21 days, they should be applied every 10-15 days during the summer and immediately after rainfall. Feed additives containing the fly control Rabon can be fed to cattle daily as a new method of fly control. Baits add another weapon to the fly control arsenal. Comparing methods, the mist blower is probably most expensive. A mist blower may cost $200 although treatments may be rather inexpensive. Other methods cost as little as 1¢ to 2¢ per head daily. (Ott-East Central)

LIQUID HAUL VS. LAGOON-IRRIGATION: THE BEST WAY TO HANDLE SWINE WASTES,

Swine editor, Successful Farming
R. J. Fee

Successful Farming, Vol. 73, Nov. 12, p. H2-H3, November-December, 1973. 6 tab.

Descriptors: Liquid wastes, Waste disposal, Costs, Irrigation.
Identifiers: Liquid-haul system, Lagoon-irrigation system, Land spreading, Swine.

Purdue University researchers in charge of the Baker Research Farm just completed a study of that 2,500 swine per year operation. They compared lagoon-irrigation systems vs. liquid-haul systems. Components of the lagoon-irrigation system were a liquid pit inside the building and a tile line which drained to an earthen lagoon. A sprinkler irrigation system pumped the waste from the lagoon onto the fields. Liquid-haul system components were a storage pit beneath the building and a 1,500 gal. vacuum tanker wagon. It was found that investment costs, annual operational costs, and labor requirements were lower for the lagoon-irrigation system than for the liquid-haul system. The researchers determined that the liquid-haul system appeared to be best for operations 2,500 head per year and less. The larger the operation, the more the balance would swing in favor of the lagoon-irrigation system. (Ott-East Central)

ANIMAL WASTES FOR FEED,

Feedlot Management, Vol. 18, No. 4, p. 36-37. April, 1976.

Descriptors: Feeds, Legal aspects, Toxicity.
Identifiers: Refeeding, Food and Drug Administration, Drugs, Pathogens, Heavy Metals.

A year ago, it seemed that the FDA was going to make a formal proposal advocating the use of at least some waste as a feed ingredient. But 2 FDA branches, the Bureau of Veterinary Medicine and the Bureau of Foods, argued over the details, and the questions raised were of sufficient concern to sidetrack the issue. Recently, BVM and Food committees have been trying to iron out the differences, dealing primarily with keeping out various toxic substances, drugs, pathogens, heavy metals, and other undesirable components. They have worked out a plan that would allow feeding waste to cattle not being finished for slaughter. All cattle fed waste would have to be taken off that feedstuff at least 60 days prior to slaughter, if they are intended for human consumption. Feeding waste to laying hens, breeder poultry, milk producing dairy cattle, and all poultry intended for human consumption would be prohibited. The agency estimates that 20 million tons of dry waste a year could be used in feed under the plan, compared with estimated U.S. production at about 1.7 billion tons. (Ott-East Central)

MANURE APPLICATION MERIT ANALYSIS AND CALIBRATION, TOO,

Agronomist, Nebraska University
L. Chesnin

Nebraska Farmer, Vol. 118, No. 4, p. 66, 68, 73, February 21, 1976.

Descriptors: Fertilizers, Economics, Cattle, Nebraska, Waste disposal, Legal aspects, Toxicity, Nitrogen, Salts, Copper, Arsenic.
Identifiers: Land application, Paunch manure, Nutrient analysis.

When commercial fertilizers became cheap sources of needed plant nutrients, interest in proper storage, handling, and application of animal wastes declined. Water pollution increased and was ignored until controls were required by federal and state agencies. Recent shortages of commercial fertilizers, along with the tremendous increase in their cost, has resulted in a new interest in proper storage, handling and application of animal wastes. Environmental controls have increased interest in proper disposal measures. The amounts of animal manures and paunch manure to be disposed of in Nebraska have led Nebraskans to take particular interest in the economics and environmental factors related to waste control. The value of application of manure to land as a fertilizer source has been recognized, but it has also been noted that the nutrient composition of the manures should be individually calibrated so that the land will suffer no detrimental effects from nitrogen, salt, or mineral buildups. Animal wastes vary greatly in composition with kind, age and health of the animal as well as the composition of the ration and, method of handling the waste. Manures should be handled and stored to conserve nutrients for application to and immediate incorporation into the soil. (Ott-East Central)

RAISED BUILDING COMBINES SLATS WITH SOLID WASTE HANDLING,

Managing Editor, Feedlot Management
G. Ashfield
Feedlot Management, Vol. 18, No. 5, p. 607, May, 1976. 4 fig.

Descriptors: Solid wastes, Cattle, Economics, Performance.
Identifiers: Waste management, Slatted floors, Land spreading, Flies, Costs.

Two years ago, brothers James and Roger Holt of Delavan, Wisconsin, decided to do something about muddy pens, less than optimal gains and high labor demand. They decided to reduce labor and to get the animals out of the mud with a non-liquid manure system. They built a slatted floor facility with 200 head capacity which would utilize the solid waste handling machinery already on hand. The building represents a perfect combination of slatted floor feeding and solid waste handling. The cattle produce 350 bushels of manure daily, which is enough to fill their spreader. During the summer months the ground level waste collection floor is scraped clean daily to minimize flies and the manure is hauled to nearby fields. During the winter, the collection floor is only cleaned about 3 times a week. It takes approximately ½ hour to clean the building. An additional 15 minutes is required for each round trip to the field with a load of manure. Labor requirements are further reduced with an automated feeding system. A feed bunk and waterers are located along a center section running the full length of the building. Construction costs on the building were $30,000, but that was 2 years ago. Today, the Holts estimate that the same building would cost 25 percent more, due to increased labor and construction costs. The 40 ft. x 80 ft. building was built to withstand a great deal more than normal stress. Walls are 10 in. thick with metal rods throughout for added support. The upper half of the building is of ribbed metal construction with eight sliding windows opening to give full ventilation during hot summer months. With prevailing winds from the north, the south side of the building is open and the roof on that side extends well beyond the building's edge. The roof has 1½ in. of styrofoam insulation. The new building seems to have no problems. (Ott-East Central)

ODORS: THE NEXT BIG POLLUTION BATTLE,

B. George, C. Fulhage, and S. Matthews
Beef, Vol. 12, No. 8, p. 26-28, April, 1976.

Descriptors: Odor, Cattle, Legal aspects, Lagoons, Management, Feedlots.

Odor control is becoming very important to livestock owners because livestock operations are larger and more concentrated and because more non-rural people are moving into rural areas. State-imposed fines and civil suits may be avoided by: (1) Using proper management, (2) Responding promptly to a neighbor's complaints (3) Using common sense when picking a location, and (4) Utilizing good housekeeping techniques. Chemical treatments should not be totally relied upon. Treatments are usually needed at least once a week and after every rain. Lagoons, which have become popular around cattle operations, may create odor problems if not properly managed. A lagoon should be started by pumping it half-full of water before adding any manure to it. A new lagoon should be started in mid-summer. A lagoon should be diluted annually. About ¼ of the total volume should be pumped out and replaced with fresh water. A lagoon should be fed daily and should never receive a sudden, huge overload. Odors can be controlled; but, like all other parts of an operation, it takes management attention. (Ott-East Central)

SLUDGE, MANURE, AND GLASS WASTES ARE MADE INTO BRICKS: THREE TROUBLESOME WASTES BECOME A RAW MATERIAL SOURCE,

J. Rudestedt
Kemist Tidskrift, Vol. 84, No. 5, p. 36-37, May, 1972. 2 fig.

Descriptors: Recycling, California.
Identifiers: Bricks, Manure, Glass.

Processes have been developed in California for the economical conversion of dried manure, sewage sludge, and glass wastes into bricks. Glass-manure bricks are obtained from pulverized dried manure which has been treated to obtain a black powder similar to carbon black, and then mixed with pulverized glass (5 to 10 percent of treated manure to 90 to 95 percent of glass powder). The molded bricks are treated at low temperatures. The bricks thus obtained have densities ranging from 100 to 2,000 kg per cu m, are both gastight and flameproof, can be bored, sawed, glued and painted. They can be used for roofing, walls, waterproofing, or for water tanks. Odorless and flameproof bricks are obtained in another similar process from 50 percent dried and specially treated sewage sludge and 50 percent pulverized glass waste by applying heat and pressure treatment after molding. The density of such bricks is about 50 percent of that of customary bricks. The bricks to which pigments or metal chips can be added for decorative purposes before molding, can be used for wall and floor covering, and for bathrooms. THE FATE OF RECYCLED URATE IN HENS FED ON A DIET CONTAINING DRIED POULTRY MANURE,

Agricultural Research Council's Poultry Research Centre, King's Buildings, West Mains Road, Edinburgh, Scotland
L. Martindale
British Poultry Science, Vol. 16, No. 4, p. 389-393, July, 1975. 3 tab, 8 ref.

Descriptors: Poultry, Feeds, Performance.
Identifiers: Refeeding, Dried poultry manure, Urate, Non-urate nitrogen, Non-protein nitrogen.

A quantitative examination was made of the fate of urate ingested in a diet containing 20 percent dried poultry manure (DPM). Seven colostomised hens were fed on a diet free of DPM and a diet including 20 percent DPM. The control diet (no DPM) was fed to all birds for 14 days followed by the DPM diet for another 14 days. Faeces and urine were collected only on the final 4 days of each treatment to allow the birds to equilibrate to the diets. DPM feeding was continued for a further 6 days for 2 hens which were given C-urate. Study results supported the view that urate is not available as a source of non-protein nitrogen for the chick and that the improvement of growth was due to the metabolisable energy content of DPM and to its non-urate nitrogen. The total daily urinary excretion of urate from the DPM diet ranged from 2.24 grams to 7.25 grams. Even the highest rate was probably less than the mean tubular secretory capacity (T_m urate) of the kidneys. However, this parameter varies widely among birds and in some cases significant increases in plasma urate concentration may result from high intakes of DPM when excretion rates approach the T_m urate. The specific activity of urate (μCi/g urate) in the final solution did not differ significantly from that found initially. Thus, results revealed that none of the urate present in DPM was utilized by the laying hen. (Penrod-East Central)

UTILIZATION OF ALGAL ASSAYS TO ASSESS THE EFFECTS OF MUNICIPAL, INDUSTRIAL AND AGRICULTURAL WASTEWATER EFFLUENTS UPON PHYTOPLANKTON PRODUCTION IN THE SNAKE RIVER SYSTEM,

U.S. Environmental Protection Agency, Pacific Northwest Environmental Research Laboratory, Corvallis, Oregon.
J. C. Greene, W. E. Miller, T. Shiroyama, and T. E. Maloney.
Water, Air and Soil Pollution, Vol. 4, No. 3-4, p. 415-434, July-August, 1975. 11 fig, 3 tab, 9 ref.

Descriptors: Water pollution, Algae, Nutrients, Sampling, Growth rates, Laboratory tests, Effluents, Waste water (pollution), Nitrogen, Phosphorus, Bioassays, Water pollution effects.
Identifiers: Snake River, Selenastrum capricornutum.

Industrial wastes, natural phosphate levels, irrigation return flows, municipal wastes, and the decay of aquatic biota contribute to high concentrations of nitrogen and phosphorus which stimulate aquatic growth and thick algal blooms in the Snake River system. Algal assays (Selenastrum capricornutum) were conducted on waters of 18 Snake River and tributary sites to (1) determine if algal growth was consistent with results predicted from review of chemical analysis for orthophosphorus and total soluble inorganic nitrogen; (2) determine if algal yields were eliminated by P, N, or some other nutrient essential to algal growth; and (3) predict the effect of N or P additions on algal productivity. (Klein)

AGRICULTURE'S CONTRIBUTION TO THE SOLID WASTE PROBLEM,

720 Anderson Road, Davis, California
S. A. Hart
Water, Air, and Soil Pollution, Vol. 4, No. 2, p. 189-190, May, 1975.

Descriptors: Agriculture, Solid wastes, Water pollution, Economics.
Identifiers: Waste management, Pollution control.

Waste is a by-product of productivity. For every pound of beef produced, 25 lbs of manure is produced. Poultry is lower at only 8 lb/lb meat and fruit is even less at from 1 to 5 lbs of crop residue wastes left in the field for every pound of plant material for consumption. The same five steps are used in the management of agricultural wastes as those used in the management of any other waste commodity. The waste must be properly stored, collected, transported, processed, and discharged without degradation of the environment. Since the farmer doesn't willingly want to spend the money necessary for proper management, agricultural waste management is not always successfully completed. The most widespread, hazardous waste material, pesticides, is associated with agriculture. Although the crops are harvested and consumed, pesticide residues linger. Steps have been taken to alleviate the problem. This shows that as in other agricultural wastes, the technology exists to properly dispose of the waste. The reason the farmer doesn't utilize such technology is the economic expenditures associated with such technology. Only when the consumers demand a specific level of pollution control applied equally to all farmers will agriculture as a whole more properly manage its wastes. (Merryman-East Central)

THE EFFECT OF SLURRY ON WATER PERCOLATION RATES IN SOIL,

Agricultural and Food Chemistry Research Division Ministry of Agriculture for Northern Ireland.
I. S. Cornforth
Record of Agricultural Research, Vol. 21, p. 23-30, 1973. 4 fig, 3 tab, 14 ref.

Descriptors: Slurries, Percolation, Soil management, Soil microbiology.
Identifiers: Land application, Polysaccharides.

Laboratory experiments were performed to investigate the effects of cow and pig slurry on water percolation rates in columns of soil aggregates. It was found that slurry can decrease water percolation rates. So long as soils remained aerobic, microorganisms were able to remove organic matter restricting soil pores. Even if light applications of slurry were repeated frequently, there was evidence that after an initial lag period, organisms could prevent soil pores from becoming completely blocked. In sterile or anaerobic conditions, the effects of slurry were more marked. Organic matter accumulated near the soil surface, where pore blockage and water flow impediment most probably take place. Polysaccharides applied in the slurry were responsible for much but not all of the blockage of soil pores. It is reasonable to assume that heavy dressings of slurry applied to poorly drained soils or in very wet conditions may have a marked, and possibly persistent effect on soil physical conditions. If soil and climatic conditions allow the soil surface to dry periodically, the effects of slurry are not likely to persist, but if the soil surface remains permanently damp, slurry will probably intensify the already poor physical conditions in the soil. This effect may be decreased if the solids content of slurry is reduced by aerobic treatment. (Merryman-East Central)

ENHANCED TREATMENT OF LIVESTOCK WASTEWATER II. ENHANCEMENT OF TREATMENT BY SOLIDS REMOVAL,

Research Assistant, Agricultural Pollution Control Laboratory, Department of Agricultural Engineering, Michigan State University, East Lansing
J. P. Harper, P. O. Ngoddy, and J. B. Gerrish
Journal of Agricultural Engineering Research, Vol. 19, p. 353-363, 1974. 5 fig, 7 tab, 9 ref.

Descriptors: Waste water treatment, Slurries, Cattle, Separation techniques, Aerobic conditions, Anaerobic conditions, Particle size, Liquid wastes, Solid wastes, Chemical oxygen demand, Nutrients.
Identifiers: Swine, Biological degration, Composting, Sand filtration.

An investigation was made of the theory that removal of suspended solids should improve the efficiency of aerobic or anaerobic treatment of the residual liquid fraction. Waste samples from cattle and swine were utilized. In each experiment, a composite sample was prepared and allowed to stand at room temperature for 24 hours. The composite material was then passed sequentially through U.S. Standard Tyler Screens to obtain the desired particulate size in the liquid fraction. The screen cake made up the solids fraction. Pollutional characteristics of the composite, component liquid and solid fractions were determined. A sand filter was constructed and used to filter screened waste to further reduce the particle size and suspended solids content. Degradation studies were performed by composting solid fractions and by aerobically and anaerobically digesting the liquid fractions. Conclusions drawn from the study were: (1) The solid fraction of screened waste is apparently stable in storage for extended periods of time. (2) Salt buildup in a water re-use system can be retarded by prior solids separation. (3) An enhanced rate of anaerobic removal of COD is observed for screened swine waste. (4) Screened swine waste water has a greater COD removal rate than that of cattle. (5) The aerobic removal rate of COD is superior in screened samples to rates reported for unscreened material. (6) Anaerobic pretreatment appears to cause a substantial improvement in the rate of subsequent aerobic digestion. (7) Particle size is the governing factor in the enhancement of treatment from screening. (8) The enhancement of treatment due to separation has a lower limit in particle size, i.e., there is an optimum particle size for treatment. This size is found in the no. 60 to no. 100 mesh region. BOVINE VIRUS DIARRHEA,

Animal Disease Research and Diagnostic Laboratory, South Dakota State University, Brookings
M. W. Vorhies

NebGuide G75-243, Cooperative Extension Service, Institute of Agriculture and Natural Resources, University of Nebraska, Lincoln, July, 1975, p. A-8.

Descriptors: Diseases, Cattle, Infection, Viruses.
Identifiers: Feces.

Bovine Virus Diarrhea is a viral disease of the mucosal epithelial cells of the digestive and respiratory systems and associated regional lymphoid tissues of cattle. This virus is transmitted when it is excreted in the feces and discharges from the nasal, or oral mucosa of a susceptible animal and reproduces itself. After 1 to 3 weeks of incubation of the virus, an infected animal will usually have signs of illness. The virus can infect a fetus and its effect on the fetus will vary with the stage of gestation at the time of infection. This disease affects cattle of all ages, but younger calves are most susceptible. Clinical signs of illness are (1) fever, (2) depression, (3) anorexia, (4) diarrhea, (5) excessive salivation, and (6) lacrimation. The disease may progress rapidly with these symptoms: (1) dehydration, (2) cessation of rumenation, (3) severe conjunctivitis, (4) congestion and ulceration of the mucous membranes of the oral cavity. (Lameness may also occur in smaller animals.) From 1 percent to 10 percent of infected animals may fail to recover and may develop a form of the disease described as the mucosal disease syndrome. Symptoms are (1) severe dehydration, (2) failure to eat, (3) chronic diarrhea, and (4) progressively lose condition until death occurs. No treatment is effective against mucosal disease. (Edwards-East Central)

FLIES SLOW GAINS: SPRAYING PAYS BIG RETURN, SAYS KANSAS LOT MANAGER,

Anonymous
Beef, Vol. 12, No. 10, p. 20-21, June, 1976. 2 fig.

Descriptors: Feedlots, Performance, Cattle, Economics, Spraying, Kansas, Management.
Identifiers: Flies.

The common housefly costs U.S. cattlemen millions of dollars each year. Although this scavenger doesn't feed on animals like blood-sucking varieties, it causes acute irritation and nervousness, keeping cattle restless during warm weather. This results in nervousness and weight loss. With a life cycle of 10 days or less, common houseflies multiply at breakneck speed. An average feedlot, maintaining minimum sanitary procedures, faces infestation levels of at least 5-6 flies per square foot through late spring, summer and early fall. The flies then reproduce into literally millions per acre. Migrating flies may also contribute to infestation levels. Fly control depends on 3 factors: good lot management, proper chemicals and drainage. To prevent fly caused energy conversion losses among his cattle, Les Keller bought an FMC 1229 air sprayer last year to help control his burgeoning fly population. His aim was to use a machine with enough reach to cover his pens with a fine mist, and yet have the power to penetrate manure piles, killing larvae. By wiping out early season flies, Keller was able to cut down his warm weather population levels dramatically. Texas Extension entomologist Bill Clymer gives the following recommendations for fly control. Feedlots should be designed to facilitate cleaning and prevent areas of continual waste accumulation. Removal of manure from under fence lines and spilled feed from bunk areas will eliminate important fly breeding sites. By stocking pens at heavy rates, maximum tramping will prevent fly larval development. Pens should be scraped clean shortly after removal of cattle as larval development may occur in 5 days. Observing these and other control hints along with a strong spraying program is paying dividends for many Western feedlots. (Ott-East Central)

FINAL POLLUTION RULES RELEASED,

Feedstuffs Washington Correspondent
F. Girres
Feedstuffs, Vol. 48, No. 11, p. 5, March 15, 1976

Descriptors: Water pollution, Feedlots, Regulation, Point sources

The Environmental Protection Agency has released its final regulation defining the conditions under which animal feeding operations are considered point sources of pollution and must obtain a wastewater discharge permit. Essentially the final regulation is a three-tiered definition that designates animal feeding operations as point sources of pollution according to size. Criteria for permit requirements are divided into 3 categories: for operations with 1,000 or more animal units; for operations with more than 300 but less than 1,000 animal units; and for operations with less than 300 animal units. The basic provisions of the regulation are: (1) Feeding operations with 1,000 or more animal units must obtain a permit if there is a discharge of pollutants into navigable water. (2) Feeding operations of 300-1,000 animal units are required to obtain a permit if the facility discharges pollutants through a man-made conveyance constructed for that purpose, or there is discharge into waters that pass through or comes into direct contact with animals in the confined area. (3) Feeding operations of less than 300 animal units do not require individual discharge permits. Feeding operations that fall into either of the latter 2 categories that do not meet the criteria for discharge permits may still be disignated point sources of pollution and require a permit if EPA determines that they are significant polluters. FLUSHING GUTTERS FOR HOG BUILDINGS,

Agricultural Engineering Department, Cooperative Extension Service, Purdue University, Lafayette, Indiana
D. D. Jones, B. Horsfield, J. C. Nye, and R. George
Purdue Cooperative Extension Publication AE87, 1975, 30 p. 15 fig, 6 tab.

Descriptors: Design, Indiana, Guidelines.
Identifiers: Swine, Flushing, Gutters.

This publication is a design and operating manual for gutter flushing systems in hog buildings. The manual includes: (1) explanations of the system and how it works, (2) a basis for evaluating its potential for individual swine operations, and (3) guidelines to help develop a tailored system for individual swine producers. Worksheets, drawings, design tables and sources of additional information are included to aid in determining particular flushing system requirements. (Penrod-East Central)

PREDICTING THE PERFORMANCE OF FEEDLOT CONTROL FACILITIES AT SPECIFIC OREGON LOCATIONS,

Water Resources Research Institute, Oregon State University, Corvallis
R. B. Wensink and J. R. Miner
WRRI Project Completion Report No. 34, Water Resources Research Institute, Oregon State University, Corvallis, August, 1975, 56 p. 3 fig, 10 tab.

Descriptors: Feedlots, Agricultural runoff, Legal aspects, Oregon, Computer models, Waste storage, Design, Economics, Climatology, Irrigation, Equipment.
Identifiers: Land disposal.

A mathematical simulation model was developed to size feedlot runoff retention reservoirs based upon previous climatological records. Two versions of the model were programmed. The first, called the return period design technique, investigated the results of employing EPA's performance standards as design criteria. The second model, entitled the sufficient design method, determined the minimum reservoir storage volume required to prevent illegal discharge as defined by the EPA Effluent Guidelines. The two techniques demonstrated that to use design procedures based upon a factor times the 10 year-24 hour or the 25 year-24 hour storm led to designs that were either unreasonably expensive or which led to illegal discharges for which the livestock producer was subject to monetary penalties. The sufficient design technique was also used to determine pollution control performance with various combinations of pumping rates and storage facility volumes. In some Oregon locations, the use of high capacity irrigation equipment allowed reduction of storage volume by over 45 percent; in other Oregon locations, due to precipitation patterns, no benefit was obtained from high capacity pumping equipment. (Wensink-Oregon State University; Merryman-Abstract editor)

GROWTH OF INDIGENOUS ORGANISMS IN AERATED FILTRATE OF FEEDLOT WASTE,

Northern Regional Research Laboratory, Agricultural Research Service, U.S. Department of Agriculture, Peoria, Illinois
B. A. Weiner and R. A. Rhodes
Applied Microbiology, Vol. 28, No. 3, p. 448-451, September, 1974. 2 fig, 1 tab, 12 ref.

Descriptors: Recycling, Microorganisms, Substrate, Liquid wastes, Fermentation, Aeration, Fungi, Yeasts.
Identifiers: Feedlot wastes, Flora, Nutrients, pH.

The liquid fraction of cattle wastes contains soluble and finely divided material potentially usable to microorganisms. A study was conducted to evaluate the ability of indigenous flora to grow under aerobic conditions in such liquid and to utilize the nutrients present. Filtrates from feedlot wastes were incubated in 9-liter aerated jar fermentors. One-third of the nitrogen and three-fourths of the organic material were taken up in 4 days. Acid was produced initially, but the aerated liquid rapidly became alkaline. With pH controlled at 7.0, a comparable pattern of carbon utilization occurred, but nitrogen was incompletely used. Maximal growth of organisms occurred at 48 hours, with gram-negative organisms representing ⅓ the total count of $3.5x10^{9}$/ ml. At 96 hours both total and gram-negative counts decreased sharply (82 percent) and then steadily diminished until numbers were nearly constant at about 20 days. Fungi and yeasts increased more slowly, and then they too decreased. (Penrod-East Central)

HANDLING DAIRY WASTES,

J. M. Rakes and O. T. Stallcup
Arkansas Farm Research, Vol. 23, No. 1, p. 14, 1974. 1 fig, 1 tab.

Descriptors: Dairy industry, Arkansas, Water pollution, Groundwater pollution, Costs, Nutrients, Salts.
Identifiers: Land disposal, Application rates, Fly control.

Most of the dairy manure produced in Arkansas is applied to the soil. This may result in nitrogen accumulation in surface or ground waters. The key to solving this problem is to incorporate the manure into the soil at such a rate that the proper amount of nitrogen is made available for plant utilization for forage and grain production. Two methods of manure handling are compared—scraping the manure into a pile and loading it with a front-mounted tractor loader and scraping it and then loading from a concrete ramp. Loading time was reduced 75 percent when the concrete ramp was used. It is estimated that the reduction in time and labor costs on a 35-cow herd would pay for ramp construction in 450 days, not including greater convenience, better manure utilization, fly control, and difference in machinery investment. In a study on incorporation of dairy lot manure into soil, manure was applied during October to a field of Boone orchardgrass and Victoria alfalfa. The field contained 3 types of soil. Rates of application were 100 tons and 10 tons per acre. Soil organic matter, potassium, sodium, and magnesium were found to be higher following application at the 100 ton per acre level, while calcium content was higher in the plots receiving 10 tons per acre. Nutrient levels on the 100-tons treatment area were not detrimental to plant growth. Neither was salt accumulation. It is believed that most dairy farms in Arkansas have enough land available to permit manure application or incorporation at a rate that would allow utilization of nitrogen without deleterious accumulation. (Penrod-East Central)

HARNESSING 'COW POWER',

Lebanon County Field Agent, Pennsylvania Extension Service
D. A. Harter and D. L. Nelson
Extension Service Review, U. S. Department of Agriculture, Vol. 44, No. 11/12, p. 8-9 November/ December 1973, 1 fig.

Descriptors: Recycling, Fuels, Methane, Anaerobic digestion, Energy, Organic wastes, Pennsylvania, Economics.

An untapped source of methane gas energy exists on farms almost everywhere in the United States. Methane gas has ⅔ the calorific value of natural gas and burns almost pollution free. Organic wastes from 100,000 cattle can service the needs of 30,000 people and with the energy crisis as it is, the low economy factor of methane gas production is quickly losing its importance. Cattle manure anaerobic digestors are commonly used in India as a power source. The idea to build and demonstrate a manure machine was developed by Don Harter, Area Resource Development Agent and chairman of the Environmental Committee for the 1973 Ag Progress Days. Don Harter obtained research data through a literature search of United States research on methane production and from the Gobar Gas Research Station in Ajitmal (U.P.) India. Using this data, Lebanon County Agent Glenn Miller and Assistant County Agent Newton Bair built a 30-gallon capacity digestor which uses a mixture of cow manure and water heated to 90 degrees. The builders exhibited the device to farmers at the 1973 Ag Progress Days sponsored in Lebanon County by Pennsylvania's Cooperative Extension Service. Ninety-eight percent of the farmers who filled out comment cards at the exhibit thought that further research was needed in the production of methane gas by anaerobic digestors. REFEEDING WASTES TO BEEF CATTLE

W. W. Martin
Agricultural Research, Vol. 25, No. 2, p. 5, August, 1976.

Descriptors: Nutrients, Physical properties, Costs.
Identifiers: Refeeding, Cattle wastes.

High costs of feed and the desire to make use of wastes has led many people to consider refeeding wastes. The type of feed initially fed determines the value of wastes for refeeding. Wastes from cattle fed a low roughage ration usually meet the requirements for refeeding as a high-energy ration. When the amount of roughage in the original ration increases, the suitability of the manure for refeeding decreases. Dr. James Ellis of the University of Nebraska analyzed the manure composition of cattle fed low, medium, and high roughage rations. He found that the gross energy, crude fiber, protein, nitrogen, potassium, and other mineral elements were influenced by the roughage level. (Edwards-East Central)

ANAEROBIC TREATMENT OF ANIMAL WASTES: A SURVEY,

Department of Animal and Range Sciences, Montana State University, Bozeman
J. C. Boyd
Research Report 65, Montana Agricultural Experiment Station, Montana State University, December, 1974, 13 p. 56 ref.

Descriptors: Waste treatment, Anaerobic digestion, Research and development, Design, Feedlots, Methane, Energy, Recycling, Separation techniques, Economics, Livestock, Poultry.
Identifiers: Refeeding.

In connection with a research project entitled "Animal Waste Stabilization", a survey was conducted to determine the present status of both the commercial application and the research effort on anaerobic treatment of animal wastes. Fifty state agricultural experiment stations were contacted. Forty-five replies, including those from two USDA Regional Laboratories and two commercial concerns, were received and are summarized. This survey showed only one commercial animal production unit to be using an anaerobic digester in a waste management program. Another unit is reported to be under construction in Canton, Georgia. A trench type anaerobic digester was found to be in the planning stages for use for a 100,000 head feedlot. This is an arrangement between Monfort of Colorado, Feedlot Division and Skelley B. Don and Associates of Denver in which Monfort Feedlots agree to supply the waste and to take back the digested sludge at a 50 percent moisture content. Four references to small family type digesters of 50 to 100 gallons capacity were mentioned in the responses to the survey. At least two concerns are offering services aimed at design and construction of such units. They are Les Auerback, 242 Copse Road, Madison, Connecticut and Biofuels Company, P.O. Box 609, Noxom, Montana. Twenty states have or are planning anaerobic treatment research. Research and development projects of various universities include: studying anaerobic digestion of some organic acids that are intermediates to the overall process, recovery of methane from anaerobic lagoons, anaerobic degradation of swine manure mixed with municipal digestion sludge, testing a fiber membrane which follows liquid-solids separation, kinetics and economic factors involved in the anaerobic digestion of livestock waste, and methane gas production problems in methane generation from chicken waste. NEBRASKA STUDIES METHODS TO USE WASTES IN FARMING,

Center for Rural Affairs, Walthill, Nebraska
D. Demmel
Compost Science, Vol. 17, No. 1, p. 31-32, January-February, 1976.

Descriptors: Fertilizers, Organic wastes, Nitrogen, Nutrients, Crop response, Insecticides, Salts, Costs.
Identifiers: Land disposal, Refeeding.

The December 10th Workshop, "Organic Residues and By-Products in Crop and Animal Production," was designed for both farmers and University and Extension Service staff members. The event was prompted by the rising interest shown for the return to crop rotations and greater use of organic farming methods. Dr. T. M. McCalla stated at the meeting that he prefers to call crop and animal residues "resources rather than wastes" because addition of organic matter makes the soil easier to till and gives it better water-holding capacity. Dr. McCalla also stressed that more research needs to be done concerning the symbiotic relationship of bacteria as a possibility for nitrogen production by corn or grasses. Dr. Howard Wittmus emphasized at the meeting that "crop residues are more important in erosion control than any other factor, including land terracing." Dr. Warren Sahs discussed research being initiated at the Mead Station to compare the use of legumes, rotations and manure with a conventional program of continuous corn using chemical fertilizers and insecticides. Dr. Terry Klopfenstein discussed the use and value of crop residue for cattle feed. In regard to animal manure as feed, he explained, "Refeeding manure to cattle is a possibility, but whether it is economical compared to its use as a fertilizer is yet to be seen." Dr. Conrad Gilbertson reported that swine manure has the best N value, about 7.5 percent, compared to dairy or beef and also is the driest and therefore requires less transport of moisture. Dr. Edwin Penas stated that studies in Scottsbluff, Nebraska, dating back to 1910, have shown the value of manures in returning nutrient depleted soils to original native N values. Dr. Leon Chesnin, soil chemist discussed manure loading on soils, saying one should "spread on as many acres as possible". He also emphasized that composition of animal waste can be controlled by what is fed. For instance, high salt rations will result in an alkaline soil over the long term. Dr. Glenn Helmers indicated that residue handling costs are rising and that one must look at the value of wastes and for the most efficient application methods. (Ott-East Central)

NO ADVERSE EFFECTS FOUND IN DPW FEEDING TESTS,

S. Gross
Feedstuffs, Vol. 48, No. 26, p. 14, June 28, 1976.

Descriptors: Performance, Proteins, Nutrients, Diets.
Identifiers: Dried poultry wastes, Refeeding, Broilers, Pullets, Laying hens.

United Kingdom scientists have found no adverse effects in the refeeding of dried poultry waste (DPW) to poultry. Researchers at the Poultry Research Center, Edinburgh, Scotland, said that their studies utilizing DPW from caged layer hens revealed the DPW to contain about 30 percent crude protein, of which 1/3 was true protein and the rest was mainly uric acid. The true protein and amino acid content approximated that of barley and was fairly digestible. The DPW contained low levels of available carbohydrates, was a good source of calcium and phosphorus, and contained many trace elements at non-toxic levels. Bacterial content of DPW samples was low. Once the nutritive value of DPW was established, diets containing DPW, formulated on a least-cost basis, were fed to broiler chickens, replacement pullets and layers under commercial conditions. Broilers were fed starter diets containing 0 and 50 g DPW/kg and finisher diets containing 0, 50b, and 100 g DPW/kg, the true protein, amino acid, calcium and phosphorus content of the DPW being used in the diet formulation. The DPW had no adverse effects on growth, and efficiency of feed conversion was increased. A more severe test of DPW was carried out when light hybrid replacement pullets between 6 and 18 weeks old were given diets containing 160 g or 140 g crude protein/kg with or without 50 g DPW/kg. In this experiment, the ME, calcium, and phosphorus content of DPW was used in the diet formulation, together with the crude protein and not just the true protein content. The DPW again had little or no adverse effect on growth of the chickens. Diets containing 0, 100, and 200 g DPW/kg also were fed to laying hens of 2 strains and of ages between 18 and 70 weeks. In this experiment, the energy, calcium, phosphorus and true protein contents were used in the diet formulation. The over-all laying performance of the flock was poor, but hens given diets containing DPW performed significantly better than those fed diets without DPW. Mortality was reduced among hens fed the DPW-containing diets. DPW had no adverse effects on albumen quality, but shell thickness was reduced. (Ott-East Central)

AMMONIA SYNTHESIS GAS GENERATIONS FROM CATTLE FEEDLOT MANURE,

Department of Chemical Engineering, Texas Tech University, Lubbock
W. J. Huffman, R. L. Peterson, and J. E. Halligan
Presented at Centennial ACS Meeting, Division of Fertilizer and Soil Chemistry, New York, New York, April 6-7, 1976, 27 p. 2 fig, 1 tab.

Descriptors: Gases, Fuels, Ammonia, Feedlots, Research and development.
Identifiers: Hydrocarbons, Ethylene.

Preliminary operational performance of a scaled-up version of a partial oxidation reactor for the production of ammonia synthesis gas (as well as hydrocarbons) from cattle feedlot wastes is presented. Current pilot scale data was found to confirm that an ammonia synthesis gas can be produced. Ethylene and other C_2 hydrocarbons potentially can be produced in the range of 50-180 lb per ton manure, depending upon operating conditions. The partial oxidation reaction of manure was studied at an atmospheric pressure over an approximate average reactor temperature range of 600 degrees to 800 degrees C. The cattle feedlot manure and air were the reactants in the partial oxidation, and steam was employed as a fluidizing medium. It was demonstrated that partial oxidation technology developed from a small scale reactor can be applied to a larger scale unit to produce an ammonia synthesis gas. The potential ammonia production is greater than 0.5 ton NH_3 per ton daf manure. It was also demonstrated that significant ethylene production can be achieved concurrently with ammonia synthesis gas production. Data also suggest that the upper limit on ultimate hydrogen production, total gas yield, or ethylene production per unit of dry ash-free manure feed has not been reached. (Merryman-East Central)

DRIED POULTRY MANURE REVEGTATES SPOIL BANKS,

Anonymous
Poultry Digest, Vol. 35, No. 413, p. 278, July, 1976.

Descriptors: Reclamation, Revegetation, Germination, Mulching.
Identifiers: Land disposal, Dried poultry manure, Application rates.

Application of 800 pounds of dried poultry manure per acre was used successfully in establishing ground covers on spoil and refuse banks located in the anthracite coal regions of Pennsylvania. Refuse banks were sprayed with a mixture of water, dried poultry manure, and seed, and then they were mulched. Fescue and birdsfoot trefoil were found to give the best results on flat ground, while vetch gave a better cover on slopes. It has been reported that up to 1,300 pounds of 5-2-2 dried poultry manure in 1,000 gallons of water can be applied per acre without salt content causing germination problems. (Rowe-East Central)

ECONOMICS AND TECHNOLOGY FOR CONTROLLING DAIRY FEEDLOT RUNOFF

Sanitary Engineer, U.S. Soil Conservation Service, Hyattsville, Maryland
R. L. Phillips and M. R. Overcash
Presented at the 1976 Annual Meeting, American Society of Agricultural Engineers, University of Nebraska, June 27-30, 1976, Paper No. 76-4032, 26 p. 2 fig, 8 tab, 10 ref.

Descriptors: Agricultural runoff, Feedlots, Dairy industry, Economics, Technology, Costs, Soil types, Climate, Topography, Nitrogen, Irrigation, Waste storage.
Identifiers: Herd size.

Research objectives were: (1) Determine various design elements that should be considered in specifying a rainfall runoff pond for a dairy, (2) Prepare a field design, economic analysis, and operational recommendation for several dairy units representing 3 subregions in the Southeast, and (3) Assess the relative economic impact of compliance on a dairy and the impact of altering existing facilities or of building a completely new system. Factors affecting the cost of no discharge systems are: soils to be irrigated, climate, topography, building location and construction, herd size, crops irrigated, and method of harvest. Typical farms were studied on each of the following: (1) Mountain subregion — moderately shallow soils of ridges; (2) Mountain subregion — moderately deep and deep soils of broad valleys and basin; (3) Piedmont — firm clayey solid on felsic rocks; (4) Coastal Plains — loamy and clayey soil of smooth uplands, and (5) Coastal Plains — loamy and clayey soils of wet lowlands. These case studies revealed that the economic impact on the dairy farmer varies mainly with herd size and with yearly milk production. The cost of feedlot runoff control varies from 10 cents per hundred weight for large herds to 27 cents for small herds. Initial investment of controlling feedlot runoff ranges from \$55-\$154 per cow. Annual cost ranges from \$12-\$30 per cow, depending on herd size. Costs are highest for small farms. Building location and feedlot layout are the most important factors affecting cost. Nitrogen was found to govern the size of the irrigation disposal on all 5 study farms. Fixed area for disposal is the most economical. Climate has little affect on costs. Tripling storage capacity from 1 month's capacity to 3 month's capacity increases annual costs by one percent, but increased flexibility of management makes the increase worthwhile. (Rowe-East Central)

OVERLAND FLOW TREATMENT OF SWINE MANURE LAGOON EFFLUENT,

Department of Agricultural Engineering, Oregon State University, Corvallis
J. O. Boda and T. L. Willrich
Completion Report WRRI-40, Water Resources Research Institute, Oregon State University, February, 1976, 149 p. 17 fig, 45 tab, 36 ref.

Descriptors: Overland flow, Waste water treatment, Pollution abatement, Lagoons, Anaerobic conditions, Waste treatment, Water quality control.
Identifiers: Swine, Anaerobic lagoons.

Effluent from an anaerobic swine manure lagoon was applied at the upper end of six, 100 feet long by 3 feet wide, grass covered plots which sloped about 3 percent. Objectives of this study were to measure concentration attenuation and mass reduction of potential pollutants in the wastewater as the result of overland flow, and to examine the influences of experimental variables on the effectiveness of the overland flow wastewater treatment process. Controlled variables included application rate and grass species. Seasonal differences in temperature, precipitation, and related physical, chemical and biological conditions were uncontrolled variables. Wastewater and soil horizons were sampled and analyzed at selected plot intervals, and plot runoff volume, air temperature, precipitation, and water table data were recorded. Amounts of wastewater applied to the experimental plots ranged from 2.0 to 10.8 inches per week. Grass cover on three plots was Alta fescue. The other three plots were seeded with redtop. ODORLESS BEDDING FROM MANURE WITH NEW SURGE TRU,

Anonymous
Successful Farming, Vol. 74, No. 9, p. 12, August, 1976. 1 fig.

Descriptors: Feedlots, Cattle, Recycling, Fertilizers, Liquid wastes, Solid wastes, Separation techniques, Costs, Odor, Design.
Identifiers: Bedding, TRU.

The new machine TRU (Total Recycling Unit), developed by Babson Brothers Co., processes regular free stall barn cow manure which arrives via valley scrapers and a storage pit, and leaves it clean and odorless. Material is pumped into the TRU, which turns it into 2 products: (1) an odorless solid material for bedding and (2) an easy-to-pump liquid fertilizer which retains nearly all of its nutrients. After the separating process, the remaining dry matter is down to 60 percent range in moisture and has no odor. The liquids can be used to fertilize fields by irrigation. Further testing is being done on the TRU. (Rowe-East Central)

METHANE GENERATION ON A FARM,

R. Wolf
Compost Science, Vol. 16, No. 5, p. 28-29, Autumn, 1975. 2 fig.

Descriptors: Methane, Recycling, Costs, Design, Biological treatment, Fertilizers.
Identifiers: Ecotope.

Ken Smith and Evan Brown of Ecotope, in response to the enquiries of the farm manager of Washington's State Reformatory Honor Farm, visited the farm and began the work on the idea of a large scale methane digester. After much study, a digester design was selected. Financed by a Washington State Department of Ecology grant, the digester is now under construction. The 2 main components of the system are two 50,000 gallon manure storing tanks from A. O. Smith-Harvestore. Because the high-rate digester system chosen requires constant mixing, a gas recirculation system has been chosen to facilitate the mixing. The drawback to such a system is that it requires energy to run the pumps to recirculate the gas. In operating the methane digester, manure will be gradually added and removed daily. With an average retention time of 17 days, maximum gas production will be achieved and the system will use all manure produced within a few days of production. The resulting digested slurry will have a higher available nitrogen content than the raw manure. The nitrogen will be in a form more usable by plants and without the pollution potential of raw manure. With increased nitrogen value, the farmer will not need to apply as much of the slurry to the fields to gain the same results as raw manure. Ecotope estimates the digester will transform about 8 tons of nitrogen a year or $6,344 worth of fertilizer. In addition, the conservative estimated gas production of 12,000 cu. ft. per day will be used to heat the creamery boiler at the farm. The value of the gas will be about $4,488. The system will cost slightly more than $100,000. (Rowe-East Central)

WEATHER, RULES SEEN MAKING WASTE HANDLING IMPORTANT,

Feedstuffs editor.
J. D. Kendall
Feedstuffs, Vol. 48, No. 1, p. 16-17, January 5, 1976.

Descriptors: Liquid wastes, Waste storage, Irrigation, Weather, Lagoons.
Identifiers: Waste management, Tank wagon, Tanks, Storage pits, Land disposal, Knifing.

Geography and regulations are two factors that make waste handling important to dairy producers. Climate, particularly winter weather, is important when designing waste management and storage systems. Dairymen must be conscious of sanitary waste handling measures. Too large a container for wastes, whether tank, lagoon, or storage pit, can create problems. Solids may settle to such an extent that agitating won't get the job done. Also, too small a pump for a large basin may consume too much energy and labor before it will break up the crust. Two main problems occur when liquid waste disposal by means of irrigation is used: (1) having to move the irrigation pipes too often, and (2) putting too much of the liquid manure on the field. As an efficient means of disposal of liquid wastes, a tank wagon can put the wastes on any field on the farm. The same pump that agitates the lagoon or holding tank can also be used to pump the waste into the tank wagon. Knifing the liquid waste into the soil instead of broadcasting is more efficient in terms of corn fields because the knifing may be done after the corn is in — not when planting dictates. The tank wagon does have drawbacks. The 3,000 gal. tank and the tractor large enough to haul 3,000 gal. of liquid can easily make a wet field into a mass of ruts and ditches. The tank wagon is also hard to maneuver in close places. Until these problems are worked out, soil injection of cultivated crops will be stymied. (Rowe-East Central)

THE CLOSE-LOOP FOOD PRODUCTION SYSTEM: A NEW CONCEPT,

Associate Member ASAE
A. O. Leedahl
Agricultural Engineering, Vol. 57, No. 7, p. 33-35, July, 1976. 2 fig.

Descriptors: Recycling, Nutrients, Feeds, Fertilizers, Irrigation, Weather.
Identifiers: Closed-loop food production system.

An experimental closed-loop food production system has been developed in which plants and livestock are grown together in an environmentally controlled confinement housing system. Livestock are fed plant material unsuitable for human consumption plus processed livestock wastes. The growing plants utilize nutrients from livestock wastes—plus heat, moisture, and carbon dioxide given off by the livestock. Human food is provided by the fruits, vegetables, meat and dairy products and possibly from nuts, cereal grains, poultry and eggs produced. In this system, plants are grown in terraced beds on hillsides that face south. Coarse gravel or small rocks form the "soil" in which plants are grown. Nutrients are pumped periodically through the "soil" in the top bed. The solution flows by gravity to the rest of the beds and returns to a storage tank at the bottom of the hill. The solution provides all water and nutrients for the plants. Livestock feed is dispensed in bunk feeders. Livestock feed includes unedible portions of human foods, livestock wastes after supplementary treatment, and possibly forages. Advantages of the anticipated system are: (1) a relatively stable food and feed supply, (2) little, if any, pollution, (3) little, if any, outside irrigation water, (4) little, if any, added fertilizer, (5) utilization of most waste materials, (6) dramatic increase in yields per acre, (7) winter operation highly feasible, with little auxiliary heat even in the snowbelt, (8) operation much less dependent on the weather throughout the year. (Rowe-East Central)

VALUE OF DRIED POULTRY MANURE AND UREA AS PROTEIN SUPPLEMENTS FOR SHEEP CONSUMING LOW QUALITY TROPICAL HAY,

University of Zambia, Lusaka, Zambia
E. A. Gihad
Journal of Animal Science, Vol. 42, No. 3, p. 706-709, March, 1976. 3 tab, 17 ref.
Descriptors: Proteins, Feeds, Sheep, Hay, Performance.
Identifiers: Dried poultry manure, Urea, Refeeding, Digestibility.

A study of adding protein supplements to hay made from natural grass growing in Zambia, which is dominated by Hyparrhenia spp., was conducted with sheep. The protein supplements were soybean concentrate meal, poultry manure and a mixture or urea and molasses. The poultry manure used was dehydrated droppings obtained from caged hens. The soybean concentrate meal (SBM) and dehydrated poultry manure (DPM) were fed at the rate of 300 g /day and urea-molasses mixture (UM) at the rate of 350 g /day. Also, each animal received 600 g /day of hay. Hay alone was fed ad libitum as a fourth treatment for comparison. Each ration was fed to 8 sheep in a completely randomized design. The sheep were confined separately in metabolism crates, fed twice daily, and allowed free access to water. Fecal samples were taken and dried in a forced air drying oven for approximately 24 hours at 65 degrees C. The samples were composited and allowed to equilibrate with atmospheric conditions for at least 7 days, weighed, and ground. A representative sample of feeds was taken and ground for later analysis. Gross energy values to feeds and feces were determined by an adiabatic oxygen bomb calorimeter. Urine samples were also tested for nitrogen. It was found that protein supplementation increased dry matter intake. Acceptability to sheep of hay supplemented with DPM or UM was excellent. Rations containing 33.3 percent of DPM or UM were fully as good as soybean meal-containing rations. Balance and utilization values of nitrogen from DPM and UM rations were higher than those of SBM ration. Consequently, it was found that DPM and UM do have value as protein supplements for the high roughage tropical feeds. (Rowe-East Central)

EFFECTS OF BEDDING ON MANURE DURING STORAGE,

Department of Agricultural Engineering, Cornell University, Ithaca, New York
J. Petersen, D. Ludington and R. Cummings
Presented at the 1975 Winter Meeting, American Society of Agricultural Engineers, Chicago, Illinois, December 15-18, 1975, Paper No. 75-4567, 15 p. 4 fig, 2 tab, 12 ref.

Descriptors: Waste storage, Physical properties, Chemical properties.
Identifiers: Bedding, Deep pit system, Biological activity.

This study was conducted to determine the effect of bedding material on manure during storage in the deep pit system. This was accomplished by determining the mechanisms operating in the deep pit, and comparing pit operation at 4 different bedding application rates. The bedding application rate was described by the ratio of bedding applied kg. to the manure production of a standard size animal (450 kg) per day (units= kg/kg. c.d.) This system involved long term collection and storage and covered about 6 months. Animals used were bred dry cows and bred heifers. The study took place in a free stall dairy barn divided into 2 parts. Each half had a slotted floor, loafing area and feeding area. Each area was over a pit about 2 meters deep and 2 meters wide. There were 4 pits. Four different "applied bedding rates" (0, 0.68, 0.90 and 1.59 kg per cow per day) were selected. The bedding material, consisting of kiln-dried hardwood chips and shavings, was applied tri-weekly to the stalls along each side of the loafing alley and to the slats of the feed alley. Conclusions drawn from the study were: (1) Biological activity, moisture migration, and surface-air interaction operate in this system. (2) The use of bedding in the deep pit produces a response similar to that of composting. (3) Bedding acts as an aeration device in a deep pit system. (4) Four zones of bedding application exist. Loss is limited in the zones by oxygen availability, temperature, surface addition of material, and rapid moisture movement. (5) Results of the study apply to warm weather conditions and should not be applied to cold, weather operation. (Rowe-East Central)

THE OXIDATION DITCH - PROBLEMS DUE TO SEDIMENTATION AND THEIR CONTROL,

Department of Agricultural Engineering, College of Agriculture and Life Sciences, Cornell University, Ithaca, New York
J. Martin, Jr. and R. Loehr
Presented at the 1976 Annual Meeting, American Society of Agricultural Engineers, Cornell University, June 27-30, 1976, Paper No. 76-4030, 15 p. 5 fig, 2 tab, 17 ref.

Descriptors: Poultry, Hydraulic design, Sedimentation.
Identifiers: Oxidation ditch.

Aerobic biological stabilization of poultry and other animal manures has been shown to be an excellent method of odor control, waste stabilization, and nitrogen removal. The purpose of this study was to: (1) briefly outline the current hydraulic design approach for oxidation ditches, (2) describe the nature and effects of the sediment accumulations encountered, (3) analyze the deficiencies in the original design approach, and (4) propose changes to improve future oxidation ditch designs. The 2 oxidation ditches involved were located at Manocrest Farms, Camillus, New York. Each ditch received wastes from approximately 4,000 white leghorn laying hens. The birds were located directly above each ditch in two rows of stair-step cages. Both ditches were designed and operated at constant mixed liquor total solids (MLTS) concentrations. Following the completion of construction and equipment installation, oxygen transfer studies were conducted with tap water prior to commencement of operation under process conditions. The results of the study demonstrated that sediment accumulation in oxidation ditches can adversely affect process performance. These accumulations can cause the decrease of mixed liquor velocity to the point of cessation of flow. To prevent sedimentation, the design velocity for oxidation ditches should equal or exceed the scour velocity for the heaviest manure particles. Determination of equipment requirements to provide adequate mixed liquor velocity should be based on friction losses in the ditch channel. This approach should provide a more rational basis for oxidation ditch designs which will prevent sediment accumulations and related problems. (Rowe-East Central)

A ONE-BID BUYER!,

Beef editor.
P. D. Andre
Beef, Vol. 12, No. 11, p. 5, July, 1976.

Descriptors: Cattle, Performance, Feeds, Economics, Costs.
Identifiers: Refeeding.

Mississippian Ed McCaughn turns sorry auction market cast-offs into high demand baby beef. He buys a calf no matter if he has only 1 eye, is odd colored, walks a little funny, or has a hump or sway back. When they arrive on the farm, they are wormed and given an antibiotic shot for a total cost of about $2 per head and then turned out in pens with open sheds. They have to be given some shelter, but can never be over-crowded. The calves are given shots of vitamin A, D and E during the winter when it is cloudy. They eat a mixture of 12 to 15 percent corn, 60 percent broiler litter and 25 to 35 percent soybean stalks. Calves purchased in 1975 averaged about 200 pounds and cost less than $28 each. McCaughn kept them on feed for 165 days and they gained 2.25 pounds a day and were sold weighing 575 pounds for an average of 27 cents a pound. Each had received about $15 worth of corn. This means that a calf that costs $28 was fed for $15 worth of corn and sold for $155. (Rowe-East Central)

BEEF FEEDLOT DESIGN AND MANAGEMENT IN MICHIGAN,

Michigan State University. Agricultural Experiment Station and Economic Research Service. U.S. Department of Agriculture.
Research Report No. 292, Michigan State University, Agricultural Experiment Station and Economic Research Service, U. S. Department of Agriculture, February, 1976. 31 fig, 22 tab, 29 ref.

Descriptors: Feedlots, Design, Management, Cattle, Economics, Costs, Michigan, Chemical properties, Legal aspects.
Identifiers: Housing systems, Pollution control.

Specific objectives of this study were: (1) evaluate the chemical composition of cattle manure as affected by housing system, and the nitrate and salt status of cropland to which manure is applied, (2) estimate the capital outlays, annual costs and energy usage associated with alternative technology-output levels for fed beef, and (3) appraise the economic impacts resulting from the possible imposition of selected pollution control measures. Fresh fecal samples and soil samples were taken from 6 Michigan feedlots utilizing different housing systems. Results indicated that the organic content of manure was highest for open lots, followed by drylots and total confinement systems. Nitrogen content was generally lower. Technological components considered were alternative housing, feed storage, ration and waste handling systems, along with alternative sex and animal types. Fuel consumption increased with the capacity of the feedlot for all technology combinations studied. Land requirements per cwt of beef produced were relatively constant for all technologies studied. Most economies of size that were found for labor, electricity, capital and annual production costs were realized at low capacity levels (250-300 head). Average costs were generally the highest, in terms of economic and energy items, with the open lot and lowest for the confined housing system. The average initial capital investment was also lower with confined housing because of higher feeding efficiencies and turnover rates. Capital economies of size can be attributed in large part to the unavailability of system components small enough to be fully utilized on the smallest lots. Labor economies of size can be attributed to: (1) larger equipment and (2) spreading management time over larger volumes. In considering the economic impacts resulting from stated pollution control measures that may occur in the future, it was found that the open lot feedlot was generally affected most and the confined housing feedlot least. PIT SCRAPERS EASE MANURE HANDLING,

J. Carlson
Wallaces Farmer, Vol. 101, No. 3, p. 49, February 14, 1976.

Descriptors: Odor.
Identifiers: Waste handling, Scrapers, Swine, Field spreading.

Pit scrapers are one means utilized by hogmen to alleviate the waste control problem. This method employs a scraper blade which is pulled inside a shallow pit under a slotted floor. The blade scrapes wastes to one end of the building. Winfred McCreedy, Washington County, Iowa, has utilized the pit scraper in his growing and finishing building for swine since January. The scraped wastes are dumped into a gutter and then flow into a lagoon. Odors are kept to a minimum. Ted Allen, Shelby County, Iowa, put a pit scraper in his growing and finishing building for swine in early June. In his system, the scraped wastes are dumped into a retaining pit and then pumped into a storage tank. This system cuts down on odor and allows Mr. Allen to hold the wastes before field spreading them. Both Mr. McCreedy and Mr. Allen agreed that, should the cable pulling scraper ever break, the slats above the shallow pit would have to be taken out to get to the problem. (Edwards-East Central)

ANIMAL WASTE MANAGEMENT FACILITIES AND SYSTEMS,

University of Tennessee, Knoxville
J. I. Sewell
Animal Waste Management Facilities and Systems, Bulletin 548, University of Tennessee, Agricultural Experiment Station, July, 1975, 47 p. 15 fig, 14 tab, 19 ref.

Descriptors: Research & development, Tennessee, Liquid wastes, Irrigation, Design, Water quality.
Identifiers: Waste management, Land disposal.

Tendencies toward larger animal production units, greater animal concentrations, needs to reduce labor requirements, and concern for environmental quality have led to much interest in the development of animal waste management systems. Since 1967, animal waste management research related to water quality liquid dairy manure systems, dairy manure slurry irrigation, slatted floor swine systems, slatted floor beef finishing systems, liquid poultry manure management systems, and waste applications on crop land has been conducted. This is exemplified by the work summarized in this publication. (Rowe-East Central)

WASTE MANAGEMENT FOR SLATTED FLOOR BEEF FINISHING SYSTEMS,

Professor and Associate Head, Department of Agricultural Engineering, University of Tennessee, Knoxville
J. I. Sewell, J. B. McLaren, G. D. Miller, J. E. Martin, and J. N. Odom
Animal Waste Management Facilities and Systems, Bulletin 548, University of Tennessee, Agricultural Experiment Station, July, 1975, p. 6-10, 1 fig, 3 tab.

Descriptors: Cattle, Performance, Liquid wastes, Costs, Agricultural runoff, Odor, Solid wastes.
Identifiers: Slatted floors, Storage pits, Field spreading.

An existing barn at the University of Tennessee Aluminum Company of America (ALCOA) Farm was remodeled to include aluminum slat and reinforced-concrete slat floors installed over manure collection pits in 14 pens. The already existing concrete slab floor was left intact in 6 pens. Study objectives were to develop waste management criteria, characterize the liquid waste produced, and monitor cattle performance. Liquid manure was removed from the pits by vacuum tank-spreaders and applied to crop or pasture land. Labor requirements for manure management from slatted floor and concrete slab floor systems were compared. Data were also collected on manure accumulation rates, manure agitation, and manure removal procedures. During the 3 years of operation, it was noted that: (1) Cattle on both types of slats were cleaner than those on slabs; however, no bedding was used on the slab. (2) Some slipping and falling occurred on all slats and slabs. (3) Slab pens were scraped and the manure was stockpiled until field disposal was feasible. Careful management was required to prevent water runoff and seepage from the stack. (4) Objectionable odors occurred when the pits were agitated and emptied, (5) Experimental aluminum slats incurred only minor mechanical damage during the first 3 years, but seemed to increase during the fourth year. (6) Slatted floors over collecting pits minimized manure drainage problems in the vicinity of the barn. Slatted floor systems were found to provide additional flexibility in scheduling waste removal. Problems associated with slatted floor systems were high facility investment, odors after spreading waste, and providing satisfactory environmental conditions for cattle during summer. LIQUID MANURE SYSTEMS FOR DAIRIES,

Professor and Associate Head, Department of Agricultural Engineering, University of Tennessee, Knoxville.
J. I. Sewell, J. R. Owen, and J. W. High
Animal Waste Management Facilities and Systems, Bulletin 548, University of Tennessee, Agricultural Experiment Station, July, 1975, p. 11-15, 2 fig.

Descriptors: Liquid wastes, Dairy industry, Waste storage, costs, odor, Vectors.
Identifiers: Liquid manure pits, Land spreading.

In 1967, liquid manure holding pits were constructed at the Dairy Experiment Station at Lewisburg, Tennessee, and the Middle Tennessee Experiment Station at Spring Hill. Field studies were conducted at these sites to evaluate these liquid systems. It was found that liquid manure pits for dairy herds offered advantages in that manure storage was available during periods when field areas were not accessible, labor requirements were often decreased, and the scheduling of manure removal to better coincide with labor availability and field conditions was facilitated. With proper management, few agitation problems were encountered. Primary disadvantages of the systems were: land had to be available on which to spread the waste before the pit became full; odor and fly problems often developed immediately after waste was spread; and facility and equipment investments were high. (Rowe-East Central)

Chemical Oxygen demand.
Identifiers: Swine, Liquid manure pit, Land disposal, Orthophosphate, Settled solids.

A swine testing barn with 24 pens, each 6' X 16', was put into operation at the West Tennessee Experiment Station in October, 1970. The barn had slatted floors and a liquid manure pit. The liquid manure from the collection pit was removed by a vacuum spreader tank equipped with 2 plows for placing the waste beneath the surface of crop land. The pit varied from 3.5 feet deep in the center to 4.0 feet deep at each end, giving a total storage capacity of 4,500 cubic feet. Pit walls were constructed of 8-inch concrete blocks with concrete-filled cores. The concrete floor of the pit sloped 1-inch in 10 ft. toward each end where 6-feet deep sumps were located. The concrete slats were 8 feet long and 5 inches wide, and spaced 1 inch apart. Samples from the bottom of the pit contained much more nitrate nitrogen and orthophosphate than samples from the top of the pit. Bottom samples had a chemical oxygen demand of 80,000 parts per million or 8 percent. During periods when swine-cooling sprinklers were not in use, the waste collected at 0.27 cubic feet per pig per day. During 3 years' operations, the settled solids tended to accumulate from 4 to 8 inches depth in winter and then decline to about 2 inches depth in summer. (Rowe-East Central).

LIQUID POULTRY WASTE,

Professor and Associate Head, Department of Agricultural Engineering, University of Tennessee, Knoxville.
J. I. Sewell
Animal Waste Management Facilities and Systems, Bulletin 548, University of Tennessee, Agricultural Experiment Station, July, 1975, p. 20-21. 1 fig.

Descriptors: Liquid wastes, Poultry, Slurries, Physical properties, Pumping, Viscosity.
Identifiers: Land disposal.

The dry-matter and viscosity characteristics of poultry manure, which are closely related to slurry pumping characteristics, were evaluated at the University of Tennessee Poultry Farm. The 3 caged layer houses studied were equipped with shallow pits under cages and a dragboard system for conveying the liquid manure from beneath the cages to liquid manure pits outside the houses. Following agitation, waste samples were collected from pits next to the houses. The sample viscosity increased markedly with dry-matter concentrations exceeding 10 percent. At dry-matter levels above 10 percent, difficulties in vacuum loading a slurry tank and in pumping with a centrifugal sewer pump were experienced. Accumulations of feathers and other extraneous material compounded the problem. The wide range in dry-matter contents found in the slurry resulted from varying dilutions by wash water, spillage, leaking waterers, rainfall, and relative humidity. While adequately diluting the slurry greatly facilitated pumping, the dilution water had to be hauled and spread on land and total hauling costs were correspondingly increased. (Rowe-East Central)

SPRINKLER IRRIGATION OF DAIRY MANURE SLURRY,

Professor and Associate Head, Department of Agricultural Engineering, University of Tennessee, Knoxville
J. I. Sewell, J. C. Barker, C. R. Holmes and J. N. Odom
Animal Waste Management Facilities and Systems, Bulletin 548, University of Tennessee, Agricultural Experiment Station, July, 1975, p. 22-32. 6 fig, 2 tab.

Descriptors: Sprinkler irrigation, Slurries, Dairy industry, Liquid wastes, Agricultural runoff, Rainfall, Chemical properties, Physical properties, Biological properties, Groundwater pollution, Phosphorus, Potassium, Bacteria, Coliform, Nutrients.

Identifiers: Land disposal.

An experimental manure slurry irrigation system was established at the University of Tennessee Main Station Dairy Farm milking 125 cows to study the collection of lot runoff and its disposal on land. The runoff from approximately 1 acre of lot and roof area was collected into drains and flowed by gravity into the slurry storage tank. A chute was used to direct the manure from the cow and storage barn into the slurry tank. An irrigation pump at the end of the tank carried through portable irrigation pipe and applied it to land through a large sprinkler. Study results indicated that: (1) the dry matter in the slurry form presented no problems of solids accumulation on the ground surface, (2) contamination of shallow groundwater was suspected, (3) rainfall runoff from the surface of the area receiving slurry irrigations exhibited high bacterial and chloride concentrations, (4) waste application by slurry irrigation should not exceed crop fertilization rates, (5) soil phosphorus increased markedly during 4 years of manure slurry applications, and soil potassium increased to a lesser extent, and (6) manure slurry had little effect on soil acidity. (Rowe-East Central)

FURROW IRRIGATION OF CORN SILAGE WITH DAIRY MANURE SLURRY,

Former Graduate Assistant, Department of Agricultural Engineering, University of Tennessee, Knoxville
R. S. Pile, J. B. Wills, and J. I. Sewell
Animal Waste Management Facilities and Systems, Bulletin 548, University of Tennessee, Agricultural Experiment Station, July, 1975, p. 33-36. 1 fig, 3 tab.

Descriptors: Irrigation, Slurries, Crop response, Furrow irrigation, Rainfall.
Identifiers: Dairy manure, Corn silage.

This study was conducted during the 1971 through 1974 growing seasons at the Cherokee Dairy Farm in Knoxville to determine the effects of furrow irrigation with dairy manure slurry on the corn silage yield of an East Tennessee stream terrace. Irrigation needs were determined by observing the crop, apparent soil moisture conditions, and precipitation data. Corn silage yields were determined by hand-harvesting and weighing green corn from two 50-foot, two-row subplots in the irrigated plot and two similar subplots from a nearby non-irrigated area. It was found that dairy manure slurry irrigation of corn increased corn silage yields during all of the four growing seasons considered. This increase was attributed to the combined effect of plant nutrients and water. Growing-season rainfall was above normal during all seasons considered. Cultivator furrows carried the irrigation water and manure slurry satisfactorily. It was felt that the layer of fibrous material and manure solids which formed at the soil-slurry interface may have restricted slurry intake. (Rowe-East Central)

LIQUID SWINE WASTE ON SOILS AND CROP YIELDS,

J. R. Overton, J. I. Sewell, and G. M. Lessman
Animal Waste Management Facilities and Systems, Bulletin 548, University of Tennessee, Agricultural Experiment Station, July, 1975, p. 37-43. 4 tab.

Descriptors: Liquid wastes, Crop response, Soils, Slurries, Soybeans, Potassium, Nitrogen, Phosphorus.

Identifiers: Swine, Land disposal, Corn, Nodulation.

Liquid swine waste was applied on the surface of and injected into a Collins fine sandy loam and a Dexter loam soil on the West Tennessee Experiment Station. The Collins is a moderately well-drained, permeable, friable soil from young alluvium. The Dexter is a well-drained terrace soil with a friable silt loam or loam topsoil and a firm silty clay loam subsoil. A similar experiment was conducted on Hatchie and Almo soils employing different rates of waste than used on Collins or Dexter. Hatchie and Almo soils are more poorly drained and less permeable than the Dexter soils. Test plots were planted to corn and soybeans. Yield and soil-test data were obtained. Results were: (1) Some grain yield depression occurred in 1971 under poor growing conditions, (2) Yields remained low in 1972 because of late planting dates, (3) Effects of waste applications were not marked on soybeans except for nodulation effects observed in 1973. (4) Soil test results indicated some increases in P and K after repeated applications and some penetration of K on Collins and Dexter to 12-18 inches, and to 18-24 inches, on the Almo soil. (5) The manure applied varied in nitrogen content and possibly in distribution and incorporation. The manure treatments raised soil test values for potassium. (Rowe-East Central)

EFFECTS OF AGRICULTURAL LAND USES ON RUNOFF QUALITY,

Professor and Associate Head, Department of Agricultural Engineering, University of Tennessee, Knoxville
J. I. Sewell and J. M. Alphin
Animal Waste Management Facilities and Systems, Bulletin 548, University of Tennessee, Agricultural Experiment Station, July, 1975, p. 44-46. 1 tab, 19 ref.

Descriptors: Agricultural runoff, Land use, Water pollution, Tennessee, Bacteria, Biochemical oxygen demand, Dissolved oxygen, Nitrates, Agriculture.
Identifiers: Orthophosphates, Fecal coliforms.

Twenty-four test sites from 5 locations and representing much of Tennessee's agriculture were selected for study. The purpose was to evaluate the effect of several agricultural land uses on surface runoff quality near the areas of study. Grab samples were collected 4 to 10 times from each site. Bacterial cultures were made for both total and fecal coliform counts. Biochemical oxygen demand and dissolved oxygen tests were conducted. Also nitrate-nitrogen and orthophosphate sample concentrations were determined. It was found that concentrations of livestock increased the biochemical oxygen demand, orthophosphates, and bacterial counts of samples collected from nearby streams. Of 13 sites examined on flowing streams, none had dissolved oxygen or nitrate-nitrogen levels which failed to meet EPA standards; and only one failed to meet the bacterial count criteria. METHODS AND TRENDS IN LIVESTOCK WASTE MANAGEMENT IN JAPAN,

Department of Animal Husbandry, Faculty of Agriculture, Niigata University, 2-Igarashi, Niigata, Japan
M. Yamaguchi
Managing Livestock Wastes, Proceedings 3rd International Symposium on Livestock Wastes-1975, University of Illinois, Urbana-Champaign, April 21-24, 1975, p. 622.

Descriptors: Livestock, Legislation, Pollution abatement, Economics.
Identifiers: Japan, Waste management.

High density livestock production, started and encouraged by the Japanese government after World War II, has become a big source of pollution. Consequently, environmental pollution laws have been passed to combat this situation. Among these are the water pollution control law, the law of prevention of odors, and the law of treatment and purification of substances discharged from economic production units. In response to these laws, the Japanese are trying to develop better management techniques. Methods that are currently considered applicable under Japanese conditions are the following: (a) land disposal, (b) hydraulic collection and transport, (c) dehydration and incineration, (d) refeeding. Subsidies and agricultural cooperatives have been established to assist the farmers in constructing facilities and purchasing equipment for waste disposal. Subsidies and cooperatives have also encouraged development of animal production units away from urban areas, even to the point of defraying costs of moving existing facilities away from the cities. Educational and research programs have also been implemented. In the meantime, agricultural pollution and perennial feed shortages have tended to depress growth of the livestock industry in Japan. Practical management methods suited to the small-size production units of Japan must be found. (Cocon-East Central)

ANIMAL WASTE MANAGEMENT IN FINLAND,

Retired Director, Work Efficiency Association, Vantaa, Finland
M. Sipila
Managing Livestock Wastes, Proceedings 3rd International Symposium on Livestock Wastes-1975, University of Illinois, Urbana-Champaign, April 21-24, 1975, p. 623.

Descriptors: Liquid wastes, Equipment, Design, Economics, Solid wastes.
Identifiers: Finland, Waste management, Field disposal.

In Finland, studies on manure have been aimed at: (1) examining methods that reduce and facilitate labor, (2) developing cheap construction, and (3) investigating the economic benefit that manure gives by means of crop farming. Labor requirements have been examined at different sized cow farms and piggeries with different manure systems. Experiments have shown that in a stall cow barn with liquid manure, the cleaning, disposal, and littering take only about half the time per cow as compared to the same job where solid manure is disposed by manual methods. Liquid manure can be loaded, transported, spread, and plowed in less than half the time needed for the same job using the solid manure method. Most liquid manure systems in Finland use the damming up method in which manure is gathered in a channel covered with a steel grille and then the channel is emptied by opening a drain into a concrete collecting pit outside the building. Runoff is usually collected and handled with the manure. The collecting pit is usually emptied in the spring and autumn by means of slurry tankers which surface spread the wastes on fields. In stall cow barns, another method may be utilized in which liquid manure continually floats along a flat-bottomed channel into a collecting pit. This is the "floating manure method". Experiments have been made with placement slurry tankers. In comparison with tankers that spread on the surface, considerable yield increases, odorless spreading, prevention of flowing on the surface, and improved hygienic qualities of grassfeed are obvious advantages. The expense of such machines, however, make them more suitable for group ownership. (Edwards-East Central)

STUDIES ON THE COLLECTION AND DISPOSAL OF SLURRY IN NORTHERN IRELAND,

Reader in Agricultural and Food Chemistry Department, Queen's University, Belfast, and Principal Scientific Officer, Department of Agriculture, Northern Ireland
J. S. V. McAllister
Managing Livestock Wastes, Proceedings 3rd International Symposium on Livestock Wastes-1975, University of Illinois, Urbana-Champaign, April 21-24, 1975, p. 624.

Descriptors: Slurries, Poultry, Cattle, Climates, Physical treatment, Chemical treatment, Water pollution, Air pollution, Soil contamination.
Identifiers: Northern Ireland, Land Spreading, Swine, Toxic gases, Refeeding, Recycling.

Soil type, cropping system, and climate are the three factors which decide the amount of slurry that can be safely spread on land. A relatively dry climate with a considerable amount of arable cropping is the most satisfactory condition. Conditions deteriorate in a humid climate with heavy rainfall, lower evaporation, and much of the land under grass, as in Northern Ireland. Due to this fact, much investigation is being undertaken concerning problems with the collection and disposal of slurry. When slurry is stored, toxic gases are produced, the most dangerous being hydrogen sulfide. Slurry which is being carelessly spread or handled can cause pollution of water, of the atmosphere, and of the land. Poultry slurry can be dried for use as a ruminant food, and cattle slurry is produced under conditions where there is adequate land for disposal, but pig slurry presents a major problem. Removal of solids by centrifugation and incineration gives an ash high in calcium and magnesium phosphates. Study is being conducted concerning the use of effluents as a substrate for producing single cell protein. (Edwards-East Central)

STUDIES ON THE USE OF SOLID SUBSTANCES OF PIT WASTE (SLURRY) IN THE FEEDING OF FATTENING CATTLE,

Animal Feeding Department, Animal Production and Veterinary Medicine Section, Karl-Marx University of Leipzig, Jena, German Democratic Republic
G. Flachowsky, H. J. Lohnert, and A. Henning
Managing Livestock Wastes, Proceedings 3rd International Symposium on Livestock Wastes-1975, University of Illinois, Urbana-Champaign, April 21-24, 1975, p. 625.

Descriptors: Slurries, Cattle, Performance, Physical properties, Chemical properties, Sheep.
Identifiers: Refeeding, Swine wastes.

The solid substances of liquid manure from pigs were fed in tests to sheep and cattle. The solid substances of pigs being fattened contained, after the elimination of the liquid matter, 16 percent crude protein, 66 percent cell wall parts, 2 percent ether extracts and 16 percent ash. The digestibility of the organic substances gained in this way varied between 45 and 55 percent. It was found that one kg dry matter equaled 90 g digestible protein and about 400 energetic feeding units for cattle. The solid substances of pig liquid manure were fed to 520 head of cattle. When 30 percent of the solid substance was worked up into ready-made pellets, a weight growth of up to 1000 to 1200 g occurred over a long period of time. A combination of the pellets plus straw, grain and sugar beet proved to be most efficient. At the end of the fattening period, the bulls were slaughtered and various organs and body parts were biochemically, bacteriologically and gustatorially tested. The quality of the meat of those animals had not been affected. (Edwards-East Central)

AGRICULTURAL CONDITIONS AND LIVESTOCK WASTES IN NORWAY,

Professor, Agricultural Structures Department, Agricultural University of Norway, N-1432 Aas-N.L.H.
O. Hjulstad
Managing Livestock Wastes, Proceedings 3rd International Symposium on Livestock Wastes-1975, University of Illinois, Urbana-Champaign, April 21-24, 1975, p. 626.

Descriptors: Waste storage, Liquid wastes, Solid wastes, Gases, Odor, Pathogenic bacteria, Separation techniques, Parasites.
Identifiers: Norway, Bedding, Waste management.

Although the total land area of Norway is 324,000 sq. km., only 2.8 percent of this total land area is agricultural land. Rocks, mountains, and lakes make Norway short of arable land. Potatoes and some vegetables can be raised any place where people are settled and good grass crops grow in all parts of the country. The country is self-supplied with livestock products, but it must import concentrates and small grains and fruits. Most of the income for farmers, however, is from the high standard of livestock production. Most manure is stored in cellars beneath animal pens, but in some sections of the country the liquid part of the manure is separated from the solid part and stored in separate tanks. The shortage of bedding in many parts of the country causes anaerobic fermentation and gas and odor problems, as well as risk of the development of pathogenic bacteria. Experiments with liquid composting manure are presently being conducted to: (1) reduce poisonous gas and odor problems, (2) reduce development of pathogenic agents and parasites, and (3) bring the manure to a consistency which can be easily handled as a liquid. (Edwards-East Central)

THE SWEDISH EXPERIENCE IN CONNECTION WITH ENVIRONMENT PROTECTION AT ANIMAL PRODUCTION SITES,

Head of Section, National Swedish Protection Board, Fack, 171 20 SOLNA, Sweden
S. Berglund
Managing Livestock Wastes, Proceedings 3rd International Symposium on Livestock Wastes-1975, University of Illinois, Urbana-Champaign, April 21-24, 1975, p. 627.

Descriptors: Regulation, Legal aspects, Water pollution, Odor.
Identifiers: Sweden, Environmental protection.

The Swedish Environment Protection Act of 1969 specifically prohibited some forms of pollution, such as the discharge of animal urine and silage effluent into streams and lakes. In 1973, the 1969 Guidelines for Environment Protection at Animal Production Sites were revised in terms of location of new animal units, requirements of cultivated land area to number of animals, and manure storage and handling requirements. These new requirements are supervised and enforced by provincial administrators. Investigations on different methods of reducing odors from spreading manure, along with emissions from animal stables and water pollution problems are being carried out. Cooperation among authorities, local agricultural advisors, and farmers' unions have been successful. (Edwards-East Central)

A FARM-SCALE COMPOSTING METHOD IN OREGON,

Delphian Foundation, Sheridan, Oregon
J. W. Nunley
Compost Science, Vol. 17, No. 2, p. 20-22, March-April, 1976. 3 fig, 3 ref.

Descriptors: Oregon, Nitrogen, Anaerobic conditions, Aerobic conditions.
Identifiers: Composting, Land spreading.

Due to prior leasing arrangements, the Delphian Foundation, located near Sheridan, Oregon, was unable to occupy most of their agricultural land until early fall. This left very little time to incorporate compost into more than 200 acres of heavy clay soil. Two methods of applying compost were studied: (1) Sheet composting—organic matter is spread on the land and the land is allowed to lie fallow for a couple of seasons while the organic matter breaks down. Disadvantages of this method are that the land is taken out of production, and nearly half of the nitrogen content of the matter is lost to the air while it is being converted to compost. (2) Anaerobic method — mixtures of organic matter are formed into windrows through use of dump trucks and manure spreaders. The organic matter remains in piles without being turned. Advantages are a tremendous saving of time and labor, and 100 percent of the nitrogen can be retained. The Delphian Foundation utilized the anaerobic method. After the windrows were made, they were wetted down to near field capacity and then covered with black polyethylene plastic. The plastic was held in place by old tires. Using this method, they were able to produce more than 2100 tons of compost during a two and one-half month period in the fall of 1974. Other methods that will be tested for compost production include the application of municipal sewage sludges and biodynamic and mechanical methods. (Edwards-East Central)

HORMONE INDUCED LACTATION IN THE BOVINE. III. DYNAMICS OF INJECTED AND ENDOGENOUS HORMONES,

Department of Dairy Science, Ohio Agricultural Research and Development Center, Wooster
L. B. Willet, K. L. Smith and F. L. Schanbacher
Journal of Dairy Science, Vol. 59, No. 3, p. 504-514, March, 1975. 7 fig, 4 tab, 47 ref.

Descriptors: Urine.
Identifiers: Hormones, Lactation, Dairy cattle, Estrogen, Progesterone, Feces, Excretion.

A study was conducted to determine rate and route of excretion of radiolabeled E_2 and P mixture used for inducing lactation. Also, immunoreactive total estrogen, progesterone (P), and prolactin of plasma, and urinary total estrogen were measured in samples collected at close intervals during and following hormone injections. Feces accounted for about 90 percent of the P and 60 percent of the E_2 excreted. Approximately 1/3 of the estrogen excreted was via the urine. Milk was found to be a minor pathway for excretion of metabolites of female sex steroids. (Rowe-East Central)

YIELD AND GROWTH OF CORN AS AFFECTED BY POULTRY MANURE,

Assistant, Department of Plant Science, College of Agricultural Science, University of Delaware
J. G. Shortall and W. C. Liebhardt
Journal of Environmental Quality, Vol. 4, No. 2, p. 186-194, March-April, 1975. 6 tab, 10 ref.

Descriptors: Crop response, Salinity, Corn.
Identifiers: Poultry manure, Land disposal.

At the rates of 0, 22, 56, 90, 168, and 224 metric tons/ha, poultry manure was surface applied and plowed under on an Elkton loamy sand. A treatment of 22 metric tons/ha of manure plus the 224-5-186 kg/ha plus a fertilizer treatment 224-5-186 kg/ha (N-P-K) was also conducted. Each of these treatments was replicated four times in a randomized block design. Excessive salt in soil was found to be the most important cause of yield reduction after high rates of poultry manure had been applied. Reduction in germination of corn was caused by high rates of poultry manure. (Edwards-East Central)

PHOTOSYNTHETIC PURIFICATION OF THE LIQUID PHASE OF ANIMAL SLURRY,

Department of Agricultural and Food Chemistry, The Queen's University of Belfast, Newforge Lane, Belfast, Northern Ireland and Agricultural and Food Chemistry Research Division, Department of Agriculture, Northern Ireland
M. K. Garrett and M. D. B. Allen
Environmental Pollution, Vol. 10, No. 2, p. 127-139, February, 1976. 6 fig, 2 tab, 15 ref.

Descriptors: Slurries, Algae, Nitrogen removal, Recycling, Effluents, Water pollution.
Identifiers: Phosphorus removal.

A strain of Chlorella vulgaris was selected from 18 species of freshwater algae which were screened for their ability to grow in and remove phosphorus from slurry supernatants. In a laboratory batch culture system, phosphorus was found first to be solubilised by the developing endogenous bacterial community, then accumulated by the algal cells. Phosphorus removal from the slurry was most rapid on a per cell basis during the early stages of algal growth; however, significant removal occurred even after the maximum algal cell concentration was achieved. The kinetics for nitrogen removal differed from those for phosphorus. The major loss of nitrogen seemed to be due to volatility and the algal contribution was seen only in the later stages of growth. Cells harvested at the end of the logarithmic phase contained 42 percent true protein. Thus, the product might be useful in a cereal-based diet. The study data provide preliminary evidence that algal culture is a biologically feasible method of treatment for the liquid phase of slurry, potentially capable of producing an effluent approaching Royal Commission Standards. (Rowe-East Central)

THE OXYGEN-ETHYLENE CYCLE AND THE VALUE OF COMPOST,

Plant Pathologist, Washington State University, Pullman.
R. J. Cook
Compost Science, Vol. 17, No. 2, p. 23-25, March-April, 1976.

Descriptors: Organic wastes, Oxygen, Cycle, Soils, Crop response.
Identifiers: Ethylene, Plant diseases.

Today it is widely recognized that most soilborne diseases of crops and ornamental plants can be controlled to one degree or another with the incorporation into the soil of a decomposable organic amendment. Dr. Alan Smith and R. James Cook, working at the Chemical and Biological Research Institute of the New South Wales Department of Agriculture in Sidney, have discovered a basic soil microbiological process which is believed to have far reaching implications for soil and plant health. The process involves the production of a biologically very active gas, ethylene, which seems to serve as a basic regulator in soil biology. Evidence indicates that ethylene is produced in virtually all soils of the temperate and tropical regions, and that it may be inhibitory to some organisms and stimulatory to others. Of all soil treatments tested to date, organic amendments are the best promoters of ethylene production. Organic amendments stimulate greatly accelerated aerobic activity and hence increased volume of ethylene-producing anaerobic microsites, and the organic substrates provide the energy-rich food necessary for ethylene production. The discovery of ethylene production by anaerobes has opened many new and exciting doors for future research on the soil-micro-organism-plant ecosystem, both for the naturalist interested in biology of wild habitats and for the agriculturalist interested in farm and garden. BOVINE LEPTOSPIROSIS,

National Animal Disease Center, North Central Region, Agricultural Research Service. U. S. Department of Agriculture, Ames, Iowa.
O. H. V. Stalheim
NebGuide G75-270, Cooperative Extension Service, Institute of Agriculture and Natural Resources, University of Nebraska, December, 1975, p. A-11.

Descriptors: Cattle, Diseases, Urine.
Identifiers: Leptospirosis.

A leptospire is a slender, spiral bacteria with a characteristic hook in one or both ends. The leptospire causes an infectious disease in man and animals called leptospirosis. Leptospirosis can be transmitted directly by droplets of infected urine, by breeding and artificial insemination, or indirectly by contaminated water. Bloody urine, jaundice, and "storms" of abortions are symptoms of this disease in beef cattle. Of the 125 types of leptospires, only 3 are known to cause disease in cattle — Leptospirapomona, hardjo, and grippotyphosa. In calves and young fattening cattle, the disease causes fever, prostration, jaundice, bloody urine, anemia, and finally death. In older cattle, the symptoms are varied. In milking cows, the milk turns thick, yellow and blood tinged. Anemia and icterus (jaundice) are symptoms in the acute form of the disease. The most significant lesions are found in the kidneys in the form of a reddish-brown mottling of the cortex. The urine is a clear-red or port-wine color. Hemorrhages in the heart and lymph nodes are also seen in severe cases. Mortality for cattle infected with the diseases ranges from 5 to 15 percent. No form of treatment will have an effect once destruction of the red blood cells has developed. (Edwards-East Central)

EFFICACY OF CERTAIN CHEMICAL AND BIOLOGICAL COMPOUNDS FOR CONTROL OF ODOR FROM ANAEROBIC LIQUID SWINE MANURE,

Pennsylvania State University, University Park 16802.
C. A. Cole, H. D. Bartlett, D. H. Buckney, and D. E. Younkin.
Journal of Animal Science, Vol. 42, No. 1, p. 1-7, January, 1976. 5 fig, 4 tab.

Descriptors: Liquid wastes, Biological treatment, Chemical treatment, Anaerobic conditions, Denitrification, Sulfides.
Identifiers: Odor control, Swine, Manure pits.

The use of biological and chemical treatments to control malodors in swine pits was investigated. Some treatments were studied as batch odors, while others were applied over a period of months. The discovery of effective and economical application rates was the primary goal of this investigation. It was found that: (1) The reduction of sulfide concentrations and associated odor could be obtained by treating the contents of swine pits with H_2O_2, $KMnO_4$, NaOCL, or ClO_2. (2) While $NaNO_3$ changed the odor in simulated swine manure pits when active denitrification was occurring, total odor strength was not reduced. (3) Disinfecting and emulsifying compounds containing orthodichlorobenzene, dried bacterial preparations, and dried enzymes were all ineffective in improving sulfide or ammonia levels. (Edwards-East Central)

HUMAN BEHAVIORAL FACTORS IN WASTE MANAGEMENT,

Soil Scientist, Agricultural Research Service, U.S. Department of Agriculture, Fort Collins, Colorado 80521
F. A. Norstadt
Proceedings of the 30th Annual Meeting of the Soil Conservation Society of America, San Antonio, Texas, August 10-13, 1975, p. 153-157. 1 tab, 17 ref.

Descriptors: Recycling.
Identifiers: Waste management, Attitudes, Economics.

Solutions to waste management problems inherently lie in the realm of the psychology of the common man. He is the polluter and he is the one to make the decisions and takes the actions to solve our waste management problems. Part of the problem with wastes can be ascribed to people's attitudes and motives toward the wastes and waste management. The solution to waste problems requires new technological methods and changes in the innate or natural behavior of man. The ultimate responsibility for improved maintenance and control of the environment rests with the individual citizen. The object of total waste management should be to manage each area of economic activity to provide the greatest yield consonant with improving the quality of life for mankind. In addition, we must modify waste generation and management, providing incentives to eliminate, reduce, recycle, and reuse waste products. We cannot expect to effectively change people's attitudes and behavior by telling them something or by coercion. They must become involved by interests and concerns. The overwhelming motivation for recycling is the cash incentive. (Rowe-East Central)

METHANE GAS FROM MANURE NOT READY YET,

Anonymous
Nebraska Farmer, Vol. 118, No. 16, p. 52-53, August 21,

1976.

Descriptors: Fuels, Methane, Organic wastes.
Identifiers: Recycling.

Methane gas is being studied as a fuel for home use. This gas is produced when bacteria called acid formers break down the organic material into a series of fatty acids. Then bacteria called methane formers reduce the organic acids to methane gas and carbon dioxide. Richard White, Extension agricultural engineer at Ohio State University, said this methane gas would make a cleaner environment and fuel for home use, but large-scale production isn't practical because of the costly equipment necessary to generate usable quantities of methane. The greatest benefit would be the energy value of the gas. A well insulated home could be heated every day by 535 hogs, or ninety-nine 1,200 pound dairy cows. Since the gas is highly explosive, storage and transportation are two major problems. Heating demands are seasonable and storage would be required for long periods of time and this presents another problem. White feels more study is needed before methane gas can be marketed for commercial use. (Edwards-East Central)

HOUSE FLY CONTROL GUIDE,

Extension and Research Entomologist, University of Nebraska, Lincoln.
J. B. Campbell
Nebguide G75-212, Cooperative Extension Service, Institute of Agriculture and Natural Resources, University of Nebraska, March, 1975, D-5, 3 tab.

Descriptors: Insecticides, Diseases, Management.
Identifiers: Fly control.

The house fly can breed in a variety of areas, such as manures, garbage, sewage, food wastes, lawn clippings, septic tanks and silage. Since the house fly can carry more than 20 human and animal diseases, such as mastitus, pinkeye, typhoid fever, chloria, and tuberculosis, it is a pest to both man and animal. Finding and eliminating breeding places if the first step in fly control. Screening windows and doors, along with placing sticky traps at entrance points, will reduce the number of flies getting into buildings. Residual sprays can be sprayed on surfaces where flies rest. Flies resting on the sprayed surface will pick up enough insecticide to kill them. Care should be taken so that residual sprays do not contaminate feed or water. Space sprays are sprays that must hit the fly to kill it. These sprays are used with mist blowers, hydraulic sprayers, foggers, or aircraft around livestock rearing facilities. Insecticide baits should be used around window sills or other areas where flies rest, but out of reach of children or pets. (Edwards-East Central)

WORKERS STUDY DPW USE IN LACTATING COWS' RATIONS,

Feedstuffs Southeastern Correspondent.
R. H. Brown
Feedstuffs, Vol. 48, No. 21, p. 130, May 24, 1976.

Descriptors: Performance.
Identifiers: Dairy cattle, Refeeding, Dried poultry wastes.

At the Latin American Conference on Livestock and Poultry, Dr. H. H. Van Horn and L. A. Silva said that dried poultry waste in levels up to 10 percent can be fed to lactating cows with little or no reduction in feed intake or milk production and can serve as a source of calcium and phosphorus. The nutritional value of dried poultry waste (DPW) depends on (1) source of waste, (2) type of litter used, (3) initial feed, (4) amount wasted in manure, (5) ventilation, and (6) temperature. DPW obtained from a layer operation of about 50,000 hens was used to test for effects of different levels of dried waste in complete rations, milk production, and composition and digestibility. With different formulations utilizing 0, 10, 20, and 30 percent DPW substituted for citrus pulp, it was found that the 24 lactating cows tested disliked the 30 percent DPW, ate the 20 percent more readily, but ate the 10 percent DPW ration as well as the control ration. It was also found that the milk yield on 10 percent DPW was equal to that of the control diet. Higher levels of DPW depressed feed intake, milk yield, milk protein percent, and total yields of milk nutrients as well as body weight. The loss of citrus pulp in the ration resulted in a decrease of the fat percentage in the milk. (Edwards-East Central)

HOW SLATTED FLOORS AND ALLEY SCRAPERS COMPARE,

Anonymous
Hoard's Dairyman, Vol. 12, No. 5, p. 302, 312-313, March 10, 1976. 3 fig. 2 tab.

Descriptors: Costs, Wisconsin, Aluminum oxide, waste storage.
Identifiers: Waste handling, Free stall barns, Slatted floors, Solid floors, Slipping, Scraping, Land disposal.

Wisconsin research was conducted in order to examine 3 types of free stall barns on a side-by-side basis and compare the investments, operating costs, strong points and weaknesses of each system. Wisconsin's experimental unit was divided into three 42' X 50' "barns" which each housed 20 cows. One section of the barn had slatted floors with a liquid manure tank underneath (Barn A). The second section (Barn B) was also a warm barn but had solid floors which were cleaned with a mechanical scraper operated by a time clock. The scraper also cleaned the alleys in the third barn which was a cold unit (Barn C) with no insulation or mechanical ventilation. Slippery floors were prevented in Barns B and C by applying aluminum oxide to the concrete floors just before troweling. The cost of the recommended rate (25 lb 100 sq. ft.) was 17 ½ cents per square foot. The disadvantage of aluminum oxide application was that it wore out the manure scraper more readily. There was little difference in the annual cost per cow between Barns B and C. The heating of the floor in Barn C (for eliminating buildup of frozen manure) was expensive and offset the cost of insulation and mechanical ventilation of Barn B. If an alternative method, such as tractor scraping, had been used in Barn C, a yearly savings of more than $30 per cow would have been realized. Barn A had a $15 per cow higher annual cost than Barn B and a $7 higher cost than Barn C due to the expense of the concrete liquid manure tank. However, an advantage of the slatted floor system was that there was no mechanical scraping equipment to cause the inconvenience of breakdowns. (Penrod-East Central)

CONFINED ANIMALS AND PUBLIC ENVIRONMENT,

Region Extension Specialist, Oklahoma State University, Stillwater 74074
M. D. Paine
Publication GPE-7000, University of Nebraska, Cooperative Extension Service, 1972, 4 p. 5 fig.

Descriptors: Confinement pens, Agricultural runoff, Water pollution, Ground-water pollution, Great Plains, Cattle, Costs, Nutrients, Nitrates, Biochemical oxygen demand.
Identifiers: Land disposal, Total solids.

The major indicators for the magnitude of pollution in water are: total solids, biochemical oxygen demand, nitrates, and nutrients. Under normal circumstances, manure from cattle falls on land where the cattle eat. The amount of total solids or biochemical oxygen demand that reaches water depends upon rainfall which causes runoff. Research studies indicate that about 2 percent of the total possible biochemical oxygen demand loading reaches a water stream. Under severe conditions caused by heavy storms or snowmelt, up to 5 percent of the biochemical oxygen demand may reach a stream. In the past, feedlots that developed in the Great Plains caused severe pollution problems because climatic conditions were ignored and feedlots were built in convective thunderstorm areas. However, great headway has been made in those states through the use of runoff control measures. Another problem that must be guarded against is nitrate pollution of groundwaters under feedlots. In cases where the feedlot surface is lightly stocked, is maintained for only a portion of the year, or is abandoned without cleaning, natural processes break up the compacted lower layer and allow nitrates to move downward toward groundwater. There is little evidence of nitrate buildup under active feedlots. It is estimated that 80-100 million tons of manure must be hauled to adjacent cropland every year. However, the cost of processing solid waste from municipalities and industries is at least 40 times greater than hauling animal manure produced in confinement. Estimates of the total solid materials produced by animals must consider factors for confinement, moisture, and the type of ration. (Rowe-East Central)

INFILTRATION ON A CATTLE FEEDLOT,

U. S. Department of Agriculture, Lincoln, Nebraska.
L. N. Mielke and A. P. Mazurak
Presented at the 1975 Annual Meeting, American Society of Agricultural Engineers, University of California, June 22-25, 1975, Paper No. 75-4028, 14 p. 2 fig, 4 tab, 16 ref.

Descriptors: Feedlots, Cattle, Infiltration rates, Nitrates, Soil profiles, Groundwater pollution, Permeability.
Identifiers: Soil interface layer.

The most common single criterion that is used to indicate water pollution is the nitrate-nitrogen NO_3-N content. A common assumption that is made is that since NO_3-N is very soluble and mobile in water, where water goes, NO_3-N goes also. A study was conducted at a Platt River Valley feedlot to determine some of the characteristics of infiltration of water into and water and gas movement through a feedlot profile. Since physical soil characteristics indirectly affect nitrogen conversion, they also directly influence the nitrogen status under the feedlot. Water infiltration in the feedlot was determined by the double-cylinder method. Two methods, the fixed hook and the float-controlled calibrated supply tank, were used. The equipment was protected from cattle destruction by a fence. Using a Giddings hydraulic soil probe, undisturbed feedlot soil cores encased in heat-shrink plastic were taken. The interface layer in the feedlot developed as a result of the hoof action and manure cover, and was the most restrictive layer to water movement. Study data showed that air and water permeabilities were lowest in the interface section and increased in the soil below. The average rate of water entry was 1.7 g/cm² at 18 percent water content. The authors concluded that undisturbed feedlot soil cores and feedlot interface material compacted at water content for maximum density are effective barriers to water movement. STABLE FLY CONTROL GUIDE,

Extension and Research Entomologist, University of Nebraska, Lincoln
J. B. Campbell
NebGuide G75-211, Cooperative Extension Service, Institute of Agriculture and Natural Resources, University of Nebraska, March, 1975, D-4. 3 tab.

Descriptors: Insecticides, Cattle, Performance.
Identifiers: Stable flies, Fly control, Breeding areas.

The life cycle of the stable fly from egg to adult averages about 24 days, with the total life span of the female being about 20-30 days. Each female lays between 200-400 eggs in this short span. The most common breeding sites are in feedlots or dairy lots where the female deposits her eggs in spoiled or fermenting organic matter mixed with animal manure and dirt. Stable flies feed by piercing the skin and sucking blood. The bite of the fly is painful and large numbers of flies can often make cows go off feed. Sanitation is the first step in controlling the fly population. Steps to follow are: (1) Manure should be removed or mounded. (2) Sick pens, feed storage areas, water systems, fences and gates, feed bunks, and feed aprons should be cleaned regularly. (3) Chemical sprays should be used. There are 3 methods of insecticide fly control: (1) Residual spray is used to spray areas where flies rest. When flies rest on the sprayed areas, they pick up enough insecticide to kill them. These sprays are used on fences, feedbunks, and buildings and usually last between 20-21 days. (2) Area sprays are used to spray directly on flies and should be used 2 or 3 times a week. (3) Animal sprays are used directly on the cattle and this method needs to be repeated at 4-7 day intervals. Applying insecticides to breeding areas is not recommended due to the danger of animal or crop contamination. (Edwards-East Central)

THE HORN FLY: METHOPRENE IN DRINKING WATER OF CATTLE FOR CONTROL,

U. S. Livestock Insects Laboratory, Kerrville, Texas 78028
M. L. Beadles, J. A. Miller, W. F. Chamberlain, J. L. Eschle, and R. L. Harris
Journal of Economic Entomology, Vol. 68, No. 6, p. 781-785, December 15, 1975. 2 fig, 1 tab, 5 ref.

Descriptors: Insecticides.
Identifiers: Fly control, Methoprene.

The U. S. Livestock Insects Laboratory at Kerrville, Texas, is involved in a pilot program in Hawaii to determine the feasibility of an integrated approach to eradication of the horn fly, Haematobia irritans (L.). A promising orally-administered material that has been investigated at the Kerrville laboratory is methoprene, an insect growth regulator (IRG.) Data from Kerrville tests has indicated that cattle will readily accept drinking water containing methoprene. A field trial was therefore conducted on the Kalaupapa peninsula to examine a method of administering methoprene in drinking water and to determine the effect of methoprene on the population of adult flies. Devices were constructed to meter 0.34 mg of methoprene / liter of water automatically into the troughs of drinking water and a 350-animal herd of cattle. The effect on the population of Haematobia irritans (L.) was determined by bioassay of fresh manure collected at intervals from the pasture. Complete inhibition of development of adult horn flies was achieved. As a result, the number of horn fly eggs on manure droppings in the pasture declined from an average 75 to 13 eggs / dropping, and the number of flies was reduced from an average 360 to 7 / animal. However, reinfestation occurred due to migration of horn flies into the area. Also, the control herd in the fattening pen provided a source of reinfestation. (Rowe-East Central)

AN ICONIC MODEL OF AN UNDER-SLAT FLUSHING SYSTEM,

Agricultural Engineering Department, Michigan State University, East Lansing, 48824
R. J. Ballard, J. B. Gerrish, and T. L. Loudon
Presented at the 1975 Annual Meeting, American Society of Agricultural Engineers, Chicago, Illinois, December 15-18, Paper No. 75-4556, 15 p. 4 fig, 1 tab, 12 ref.

Descriptors: Model studies, Design, Slope, Volume, Waste storage.
Identifiers: Flushing, Swine manure, Manure transport, Odor control.

An under-slat flushing system for the transport of manure out of a swine confinement building has the following advantages: odor control within the building, reduction of manual labor, and a direct tie-in to an aerobic lagoon. Because there is insufficient knowledge for a good engineering design of such a flushing system, a manure transport system is being studied in the form of an iconic model and its prototype. The system consists of a self-tipping elevated water tank which discharges 3-4 times daily into a sloped flume. Manure which has accumulated in the flume beneath the slatted floor is transported to an anaerobic lagoon. An attempt is being made to develop information that will suggest optimal combinations of tipping tank volume, slope, dumping frequency, and the height of the dump tank above the pit floor. The experimenters also hope to learn how to avoid solids deposits along side walls as sometimes happens in real life. Evaluation of the system is in progress. (Rowe-East Central)

CHICKEN MANURE, AN EXCELLENT FERTILIZER FOR CORN,

Department of Soil Science, University of Florida, Gainesville
D. Graetz
Proceedings of the 34th Annual Florida Poultry Institute, Gainesville, Florida, May 19-21, 1975, p. 42-46. 3 tab, 2 ref.

Descriptors: Fertilizers, Crop response, Nitrogen, Nitrates, Groundwater pollution.
Identifiers: Poultry manure, Land application.

In 1974, a randomized complete-block experiment was conducted to evaluate chicken manure as a fertilizer for corn. Treatments of 0, 2, 4, 8, 16, and 32 tons / acre of chicken manure (cage manure at 35-40 percent moisture) and 1,000 lbs. of 4-8-16 + 80 lbs. side-dressed N/ acre were replicated 5 times. These amounts were applied to 24 x 30 ft. plots on Eustis fine sand. The nitrogen content of this manure was about 2.3 percent. Observations of the treatments early in the growing season indicated that germination was good in all but the 32 ton treatment. From the first data, it appeared that about 8 tons of manure would provide optimum corn yield from the standpoint of both nutrition and prevention of groundwater contamination by nitrates. To meet plant nutrient requirements at application rates less than 6 tons, commercial fertilizer may have to be added. (Rowe-East Central)

FEEDING ENSILED POULTRY WASTES TO RUMINANTS,

D. L. Cross
Proceedings of the 34th Annual Florida Poultry Institute, Gainesville, Florida, May 19-21, 1975, p. 47-55. 5 tab, 42 ref.

Descriptors: Legal aspects, Chemical properties, Physical properties.
Identifiers: Refeeding, Ensiling, Poultry wastes, Dienestrol acetate.

With recent implementation of Environmental Protection Agency regulations, many producers have been keenly aware of the polluting effects of poultry waste and the costs involved in properly dispersing of the wastes. An alternative to land disposal is to recycle poultry wastes into the diets of ruminant animals. Ensiling may prove to be a good means of preparing wastes for this purpose. Broiler litter is an excellent source of nitrogen for protein and minerals and is similar to corn silage in fiber content. Presently, the feeding of animal wastes is not sanctioned by the Food and Drug Administration. F.D.A. officials are concerned about potential problems from disease organisms, mycotoxins, heavy metals, pesticides, parasites, and drug residues. There have been no reports of harmful effects on animal health from refeeding poultry wastes except where broilers were receiving high levels of $CuSO_4$ or dienestrol acetate. Although the refeeding of wastes is not sanctioned by the F.D.A., some states have published guidelines for the refeeding of wastes. Federal agencies are not concerned with the refeeding of wastes unless there is interstate shipment of wastes or of the final meat product. Recommended procedures for ensiling poultry wastes are given. (Rowe-East Central)

HATCHABILITY UNAFFECTED BY FEEDING POULTRY LITTER,

Department of Poultry Science, Clemson University, Clemson, South Carolina 29631
J. B. Cooper and B. L. Hughes
Poultry Science, Vol. 55, No. 3, p. 1138-1140, May, 1976. 2 tab, 8 ref.

Descriptors: Poultry, Litters, Performance.
Identifiers: Refeeding, Hatchability.

An experiment was conducted to determine whether or not feeding litter to hens in wire cages would improve hatchability. Three levels of litter, 0, 2, and 5 percent, were mixed with a chicken breeder diet. Each of the 3 diets was fed to 3 groups of 9 hens each for 20 weeks, making a total of 27 hens on each diet and 81 hens in the experiment. S. C. White Leghorn hens kept in individual wire cages for about 13 months of lay were used. The hens were artificially inseminated each week with 0.05 ml. of pooled semen from a broiler strain of males. The males were fed the basal diet containing no litter. Eggs were marked so that fertility and hatchability could be calculated on a per bird basis. Eggs were set weekly for 20 weeks. All eggs candled as being infertile or early dead were examined macroscopically to determine fertility. A statistical analysis was made using the analysis of variance test. No significant differences were found among treatments for fertility or hatchability. Fertility varied from 89.8 percent for the zero poultry litter diet pens to 88.1 percent for both the 2 and 5 percent litter diet pens. Hatchability of fertile eggs was 80.4, 80.0 and 80.2 percent respectively, for hens fed diets containing 0, 2, and 5 percent litter. (Rowe-East Central)

HYDROGEN SULFIDE PRODUCTION IN SWINE CONFINEMENT UNITS,

Air Pollution Division, Michigan Department of Natural Resources, Lansing.
G. L. Avery, G. E. Merva, and J. G. Gerrish
Transactions of the ASAE, Vol. 18, No. 1, p. 149-151, January-February, 1975. 2 tab, 7 ref.

Descriptors: Confinement pens, Gases, Toxicity, Hydrogen sulfide, Sampling, Temperature, Ventilation.
Identifiers: Odor control, Cadmium hydroxide-methylene blue method.

Three specific problems stemming from confinement-feeding of swine were identified by J. A. Merkel. The first dealt with odor control for the comfort of the producer and his neighbors. The second and third dealt with the possible toxic effects of the individual gases and gas combinations generated in animal wastes and in confinement buildings. A study was conducted to determine the effect of certain parameters on the rate of production of hydrogen sulfide from some typical confinement buildings. Parameters studied included outside temperature, the ratio of the pit area to building volume, the air retention time (ventilation rate) and daily sulfur intake of the animals. Six units, including farrowing and finishing houses, were studied. The units differed in the type of roofing and siding used; use of partial pits or pits under the entire floor; and use of fans. Also, one unit used Wham, a commercial product for odor control. An air sampling machine was built to take 8 air samples in a 24-hour period. Hydrogen sulfide concentrations in the samples was determined by the methylene blue method. The trapping efficiency of hydrogen sulfide was tested by connecting 3 midget impingers in series, so that the air sample was drawn through all 3 impingers. Fan exhaust flow was determined by averaging air velocity over the area of the fan. Study data showed the production of hydrogen sulfide was highly correlated with the following parameters for swine finishing buildings of similar construction: (a) average outside temperature, (b) ratio of pit area to building volume, (c) air retention time for the building and (d) daily sulfur intake. No significant difference of hydrogen sulfide content was noted between samples taken at different times of the day. However,

study data did show a significant difference of the hydrogen sulfide content between samples taken on different days. The authors concluded that the cadmium hydroxide-methylene blue method was a very effective procedure for trapping and testing for hydrogen sulfide in swine confinement units. (Penrod-East Central)

CAN ORGANIC MANURES IMPROVE CROP PRODUCTION IN SOUTHERN INDIA?

Assistant Professor, Department of Agricultural Economics, University of Georgia, Athens.
G. C. W. Ames
Compost Science, Vol. 17, No. 2, p. 7-11, March-April, 1976. 4 fig, 5 tab, 13 ref.

Descriptors: Organic wastes, Crop response, Soils, Fertilizers.
Identifiers: India, Land application.

A study was conducted to measure the effect of organic manures on crop yields under actual farm situations in southern Karnataka State, India. A survey was taken of 136 farms. Paddy and sugar cane received the largest applications of organic manures. There was some evidence that excessively large applications of organic manure reduced paddy yields in a few cases. However, the correlation of organic manures with levels of other inputs, such as fertilizer, pesticides and irrigation, were not known. A more detailed study of farm level yield response to organic manure is required before definite conclusions can be drawn. Such a study should account for such factors as initial soil fertility; rainfall and irrigation; variety and quantity of seed; formulas, quantity, timing and method of fertilizer application; quantity and nutrient content of organic manures; and careful measurement of yields. This data would help Indian farmers allocate scarce resources in a more efficient manner. (Rowe-East Central)

STUDY OF CURRENT AND PROPOSED PRACTICES IN ANIMAL WASTE MANAGEMENT,

Texas Tech University
G. A. Whetstone, H. W. Parker and D. M. Wells
Study of Current and Proposed Practices in Animal Waste Management, Environmental Protection Agency Report No. EPA 430/9-74-003, January, 1974, 400 p. 1 fig, 6 tab.

Descriptors: Farm wastes, Bibliography.
Identifiers: Thermochemical Processing, Coprophagy.

Current and proposed practices in animal waste utilization and/or disposal were reviewed by means of a detailed search of the literature, by correspondence and by visits with active investigators in the field. Abstracts were prepared of 1162 publications dealing with animal waste utilization and/or disposal, or closely related materials having a direct carry-over potential. These latter publications pertained to some other aspect of manure management or to thermochemical processing of some other organic material. In addition, abstracts of 111 pertinent projects sponsored by the USDA were included in a separate appendix. Land spreading, with or without advantage being taken of the fertilizer and soil-conditioning values, is the ultimate destiny of nearly all manure produced at present. Attention was focused in the report, however, on the less-used but potentially more rewarding processes of gas or oil recovery, refeeding to animals after more or less processing, and using as a culture medium for fly larvae, worms, algae, fungi, yeast, etc., with ultimate disposal of the catabolized manure as a soil conditioner, and utilization of the organisms as feedstuffs. This report was submitted in fulfillment of Contract No. 68-01-0785 under the sponsorship of the Office of Air and Water Programs, Environmental Protection Agency. (Whetstone, Parker, and Wells-Texas Tech University)

A DESIGN AND MANAGEMENT MODEL OF THE OXIDATION DITCH FOR LIVESTOCK WASTE TREATMENT,

E. J. Kroeker
MS Thesis, Cornell University, August, 1974, 131 p. 19 fig, 16 tab, 49 ref.

Descriptors: Design, Waste treatment, Model studies, Nitrogen, Aeration, Poultry.
Identifiers: Oxidation ditch, Odor control, Solids removal.

Societal trends have turned attention to agricultural problems associated with the disposal of wastes from animal confinement. This thesis deals primarily with one alternative that may be applied to animal waste treatment. A mathematical model was presented to be used as a tool for the design and management of an in-house continuous flow oxidation ditch. The model may be directly applied to describe the treatment of caged-layer poultry wastes for control of odors, conservation of nitrogen or removal of nitrogen. Collected operational data from two oxidation ditches verified the model. The model made reasonable predictions for three aeration design requirements. However, at high concentrations of total solids (greater than 35,000 mg/1), it appears that additional design criteria should be used. The empirical equation used to describe solid removal in the model, however, did not make reasonable predictions. (Penrod-East Central)

TREATMENT AND DISPOSAL OF CATTLE FEEDLOT RUNOFF USING A SPRAY-RUNOFF SYSTEM,

D. E. Eisenhauer
MS Thesis, Department of Agricultural Engineering, Kansas State University, 1973, 91 p. 7 fig, 66 ref.

Descriptors: Feedlots, Agricultural runoff, Cattle, Irrigation, Waste treatment, Chemical properties, Water pollution.
Identifiers: Spray-runoff, Overland flow.

Land disposal by irrigation has been the most prevalent method for handling feedlot runoff. This thesis evaluates the spray-runoff technique, a special adaptation of the sprinkler irrigation system, as a possible disposal practice. The general principle is to apply wastewater at the top of a uniform grassed slope by sprinkler nozzles at a rate such that a high percent returns as overland flow. Since the biological organisms utilize certain impurities in the water as a food and energy source, the water is treated as it flows over the grass slopes. The treated water is then carried off the field by terrace channels and either released or recycled, depending upon the degree of treatment desired. An experimental spray-runoff system was installed at a 22,000 head feedlot in Kansas. The 10.9 acre treatment field contained 4 sprinkler laterals on which 100 foot spray diameter sprinkler heads were installed. Two parallel terraces, spaced on about 200 foot centers, were constructed to carry the water between laterals off the field. The land slopes varied from 1-3 percent. The loam soil was seeded to a grass mixture of reed canarygrass and tall fescue. Flow measuring and sampling equipment were installed so that both quantity of the applied wastewater and the runoff water could be evaluated. Instantaneous loading rates of 0.04 and 0.08 inches/hour were used. The system was operated during the summer and early fall of 1972. Concentration reductions ranged from 27-60 percent for BOD_5, 29-44 percent for Kjeldahl nitrogen, and 35-49 percent for ammonia nitrogen. During the total season, only 25-27 percent of the applied waste water ran off. Due to the low runoff percentage, mass removal percentages ranged from 77 to 97, 74 to 90 for BOD_5, Kjeldahl nitrogen, and ammonia nitrogen, respectively. The rainfall runoff from the treatment field also contained considerable amounts of pollution causing material and was of questionable quality for release to surface waters. Further study will be required to determine if crop growth can be maintained. (Ott-East Central)

RECYCLING POULTRY NUTRIENTS,

Department of Poultry Science, Michigan State University, East Lansing
H. C. Zindel
Animal Nutrition and Health, Vol. 26, No. 9, p. 6-7, September, 1971. 1 tab.

Descriptors: Dehydration, Odor, Performance, Fertilizers, Recycling, Poultry, Feeds.
Identifiers: Refeeding, Dried Poultry Wastes.

The Poultry Science Department at Michigan State University has concluded that dehydration of raw poultry manure holds the greatest potential for reducing odor and other forms of pollution while rendering a reusable product. In a yet unfinished test begun in late 1970, commercially-grown pullets are fed on mixtures of 12½ percent dried poultry waste (DPW) and 87½ percent corn, 25 percent DPW and 75 percent corn, or 100 percent corn. Up through the twenty-second pass the usable protein was running at a fairly constant 10 percent, the mortality rates were about the same for all three groups, and the production of eggs was slightly, although insignificantly, in favor of the corn birds. The possibility of seasonable influences is being further investigated. The non-odorous DPW also has potential as a fertilizer for lawns, athletic fields, golf courses, greenhouses, and potted house plants. (Solid Waste Information System)

FINAL REPORT - MANURE HANDLING AS RELATED TO FLY (HOUSE AND/OR STABLE) CONTROL PROJECT 1763,

W. L. Gojmerac
Final Report—Project 1763, College of Agricultural and Life Sciences, University of Wisconsin, 1972, 12 p. 3 ref.

Descriptors: Wisconsin, Lime, Automation.
Identifiers: Fly control, Manure, Bedding, Slatted floors.

Recent technology has added a new dimension to fly-control in farm sanitation programs. Summer feeding, automated equipment that is not self-cleaning, slatted floors, etc. can retain manure or feed which breeds flies. In 1971 and 1972 several farms in Wisconsin were inspected and studied to observe causes, major problems and possible solutions to fly infestation of manure. Variables that were investigated that could affect fly-breeding in relation to manure were: (1) bedding, (2) the effectiveness of lime treatment, (3) old manure, (4) allowing chickens to run and work manure stocks, and (5) location of fly maggots in a production unit. Investigation of farms showed that house fly numbers were reduced by not using any bedding. Lime was not found to be a practical method for fly control. Problem areas of fly infestation were found to be: (1) between slats or slatted floor operations, (2) in and around sprockets, gears, chains, and other machinery parts where manure accumulates, (3) in the crust formed on liquid tanks and detention ponds, (4) during the exercise year, anywhere animal traffic tends to be light, and (5) liquid manure pits. The season during which flies were the most prevalent was the summer. Areas needing further investigation are listed. (Penrod-East Central)

FERTILIZER: ANIMAL HEALTH PROBLEMS AND PASTURE FERTILIZATION WITH POULTRY LITTER,

S. R. Wilkinson and J. A. Stuedemann
McGraw-Hill Yearbook of Science and Technology, McGraw-Hill Book Company, Inc., 1974, p. 180-182. 2 fig, 4 ref.

Descriptors: Fertilizers, Litters, Cattle, Toxicity, Nitrogen herbage.
Identifiers: Land disposal, Poultry wastes, Fat necrosis, Grass tetany.

The occurrence of fat necrosis, grass tetany, and nitrate toxicity in cattle grazing fescue pastures heavily fertilized with poultry litter has mobilized researchers to investigate the application and effects of poultry litter on grazing land. Fat necrosis, referred to as lipomatosis, is the presence of hard fat masses in the abdominal cavity. Digestive disturbance, scanty feces, bloating, and difficult birth are some of the symptoms associated with fat necrosis. Fat necrosis has been investigated in Kentucky-31 tall fescue pastures fertilized over a several-year period with different amounts of nitrogen in the poultry litter. Fat necrosis free cattle that were introduced to the pasturage soon suffered rectally palpable lesions that increased with time in size and number. The results indicated that incidence of fat necrosis was related to high nitrogen fertilization of fescue pastures rather than feed additives in the poultry litter. Grass tetany is a complex nutritional disease associated with low blood magnesium levels. Cattle producers in areas of concentrated poultry production have reported an increase in the incidence of grass tetany. Nitrogen and potassium inputs increase herbage nitrogen and potassium. When such herbage is ingested by the tetany susceptible cow, the possibility of grass tetany is increased. It has been found that magnesium oxide in amounts of 1.5 to 2 ounces per cow added to feed will prevent grass tetany. Excessive nitrate concentrations in herbage has also been attributed with causing some cattle losses. Although the problem of nitrate toxicity is complex, some factors that affect the accumulation of nitrate are: (1) excessive nitrogen fertilization, (2) drought, (3) cloudy weather, (4) herbicides, (5) imbalance of soil nutrients, (6) kind of plant, (7) age of plant, and (8) plant part. Control of health problems such as these may depend upon the sensible use of poultry litter and good pasture management. (Penrod-East Central)

METHANE GENERATION FROM LIVESTOCK WASTES IN NORTHERN GEORGIA.

Agricultural Engineering Department, Georgia University, Coastal Plains Experiment Station, Tifton
C. V. Booram, G. L. Newton, and F. Haley
Presented at 1975 Winter Meeting, American Society of Agricultural Engineers, Chicago, Illinois, December 15-18, 1975, Paper No. 4543, 8 p. 3 fig, 2 tab.

Descriptors: Methane, Georgia, Design, Lagoon, Irrigation.
Identifiers: Anaerobic digester, Swine.

This paper describes an on-farm anaerobic digester near Canton, Georgia. At Fred Haley Farms, Inc. wastes are produced by three separate swine units located near the anaerobic digester. The first unit is a boar test facility which contains 230 animals at any one time with each animal in an individual pen. Both sides of the building are open and ventilation depends on natural air movement; the floor is partially slatted. Wood chips are used for bedding. Once a day, manure is hydraulically transported out of the building using dosing siphons as the mechanism for the release of fresh water. Unit 2 is a farrowing unit with a maximum capacity of 48 sows. Wastes are hosed out of the partially slatted building daily. Unit 3 is a 250 head confinement building where wastes are scraped daily into an open channel located at the side of the building. Twice a week, the manure in this channel is flushed into the digester. The digester is 24 feet in diameter with a maximum fluid depth of 19 ft. and has an operating volume of 8600 cu. ft. or 65,000 gallons. The gas produced is piped into the farrowing unit to be used for heating during the winter. A maximum of 665 ft^3 of gas per day or about 14,900 BTU's per hour are produced in the digester. Effluent from the digester is discharged into a lagoon and kept for use in irrigation. (Edwards-East Central)

MINNESOTA LAMB TRIALS SHOW POORER GAINS WITH POULTRY WASTE THAN CORN-SOY,

Anonymous
Feedstuffs, Vol. 48, No. 15, p. 24, 29-31, April 12, 1976. 6 tab.

Descriptors: Feeds, Performance, Nitrogen, Energy, Litters, Sheep.
Identifiers: Poultry wastes, Refeeding.

At the University of Minnesota a study was done to explore the possibilities of using the tremendous amounts of turkey litter as a nitrogen and energy roughage source for lambs. This poultry wastage was pelleted (¼" pellets). The poultry wastage or litter was basically wood shavings with a bit of rice hulls upon which 3 groups of turkeys were fed. The material going to the dehydrator was 25-30 percent moisture. To determine its value as a source of nitrogen and possible energy as well, 6 lots of 12 lambs each were fed the following concentrate mixtures: (1) control-corn 85 percent, soybean meal (SBM) 15 percent, (2) corn 70 percent, poultry wastage 30 percent, (3) corn 60 percent, poultry wastage 40 percent, (4) corn 80 percent, SBM 20 percent, (5) corn 50 percent, poultry wastage 50 percent, and (6) corn 40 percent, poultry wastage 60 percent. Results showed that initially the lambs showed no reluctance to consume the pelleted poultry wastage. Daily protein intake per lamb in lots 1, 2, and 3 was about equal and in all cases exceeded requirements. Higher but equivalent "protein" levels were provided to lambs in lots 4, 5, and 6. It appears that the weight gain data were a direct reflection of energy intake. While the poultry wastage contained 280 ppm copper, the researchers experienced no difficulty with copper toxicity. Also studied were: whether pelleted beet pulp could be used advantageously in finishing rations for lambs, feeding cull navy beans to study their value as a sheep feed, the effect of forage species and grazing management on lamb production and grain feeding lactating ewes. MANURE SYSTEM NEEDS FIRST PRIORITY IN CONFINEMENT PLANNING,

Anonymous
Beef, Vol. 12, No. 5, p. 6, 10-11, January, 1976. 4 fig.

Descriptors: Confinement pens, Design, Waste storage, Equipment, Nutrients, Lagoons.
Identifiers: Waste management.

Planning a complete manure handling system before building a confinement barn can save countless headaches. The most common problems of poor planning are: (1) too small lagoons or storage pits, (2) inadequate agitation equipment, (3) inadequate ventilation, (4) top filling lagoons, (5) lagoons built without any thought of an alternative handling system, (6) odors, and (7) freezeups. The most common problems caused by management errors are: (1) undersized removal equipment, (2) insufficient water in lagoons, (3) improper agitation of manure pits, (4) build-up of solids in the bottom of the pit, (5) bedding in the manure, (6) insufficient animal traffic on the slotted floors. Bob Maddex, Michigan State agricultural engineer says to "plan your system first - then pick a building to match that system." A checklist for evaluating manure systems is given. There are four different areas in planning a manure handling system which one must contemplate very seriously. They are: (1) type of system, (2) method of collection, (3) storage and (4) utilization equipment. Proper handling and storage is also important if the manure is to be used for fertilizer because of the effect that handling and storage has on the value of the manure. Several ways of preventing losses of nutrients from the manure are also mentioned. James Moore, University of Minnesota engineer, said there are 4 rules to be followed by owners of liquid manure lagoons: (1) start the lagoon with ample amounts of water, (2) start the lagoon in warm weather to work the "bugs" out before winter, (3) do not overload the lagoon, and (4) withdraw liquid annually. (Edwards-East Central)

MANURE VALUE NEXT TO EGGS IN EGG PRODUCTION,

Poultry Digest, Vol. 35, No. 408, p. 74, February, 1976.

Descriptors: Nutrients, Fertilizers, Economics, Nitrogen, Phosphorus, Potassium.
Identifiers: Poultry manure.

Edward C. Naber, Ohio State University, says that poultry manure is the second most valuable product produced in an egg operation. Wholesale value of nitrogen is 18¢ a lb.; phosphorus, 38¢ a lb.; and potassium, 8¢ a lb. Each hen has annual output of about 80 pounds of manure having about 40 percent moisture when removed from the house. On the basis of this fact, it is calculated a hen produces between \$1 and \$1.20 worth of fertilizer elements a year. Naber says that poultry men must take advantage of the economic value of poultry manure. (Edwards-East Central)

CORNELL TEAM WORKING ON ANIMAL WASTE DIGESTER,

Feedstuffs, Vol. 48, No. 34, p. 42, August 23, 1976.

Descriptors: Recycling, Methane, Feeds, Fertilizers, Nutrients, Costs.
Identifiers: Refeeding, Digester.

A grant-funded three-year project is underway at Cornell University to develop a waste digester capable of producing methane gas as well as fertilizers and protein-rich feedstuffs from cow manure. The proposed digester will produce methane gas, and at the same time will recover nitrogen in ammonia form, phosphorus and potassium from wastes. Also, bacteria in the waste will be harvested as a basic material for animal feeds. The processed waste, an odorless material, will be suitable for use in home gardens and for improvement of soil properties. Another digester to produce only methane will also be designed. It will be for use on dairy farms with as few as 20 cows. The main objective of Cornell's study is to develop lower cost energy generation systems. (Rowe-East Central)

MANURE EFFECTS ON RATE OF ADVANCE, INTAKE, AND QUALITY OF RUNOFF FROM IRRIGATED PULLMAN CLAY LOAM,

Soil Scientist, USDA Southwestern Great Plains Research Center, Bushland, Texas 79012
A. C. Mathers, B. A. Stewart, and J. D. Thomas
Unpublished paper, Soil, Water, and Air Sciences, Southern Region, Agricultural Research Service, U.S. Department of Agriculture and Texas Agricultural Experiment Station, Texas A&M University, 1975, 18 p. 1 fig, 7 tab, 12 ref.

Descriptors: Agricultural runoff, Irrigation, Crop response, Nitrates, Phosphorus, Chlorides, Sorghum.

At the USDA Southwestern Great Plains Research Center, Bushland, Texas, manure was incorporated into Pullman clay loam. Manure treatments of 0, 22, and 67 metric tons / hectare were applied annually. Additional treatments of 67 / ha were applied the first year only and 22 kgN / ha was applied annually. Grain sorghum was grown and irrigated. It was found that manure applications slowed the advance rate of irrigation water in graded furrows and increased intake rates. Increased grain yields of plots receiving manure over those receiving N was attributed to more available water. Incorporation of manure in soil did not significantly increase NO_3 or Cl in runoff except when rain fell on saturated soil. Phosphorus in runoff was low in all measurements. These data indicate that runoff quality is not markedly reduced when manure is incorporated into soil. (Edwards-East Central)

EFFECT OF WINTER APPLIED MANURE ON RUNOFF, EROSION AND NUTRIENT MOVEMENT,

Agricultural Engineer, U. S. Department of Agriculture, Agricultural Research Service, Morris, Minnesota
R. A. Young
Presented at the 1976 Annual Meeting, American Society of Agricultural Engineers, University of Nebraska, June, 1976, Paper No. 76-2080, 9 p. 1 fig, 9 tab.

Descriptors: Agricultural runoff, Erosion, Oats, Alfalfa, Corn, Sampling.
Identifiers: Land application, Application rates, Frozen ground.

A study was set up to determine the contribution of manure applied on frozen ground to the annual nutrient losses associated with runoff and erosion from plowed corn ground and hayland. Eight experimental plots, 4.1 m wide and 23.4 m long, were set up on a 9 percent slope on Barnes Loam (Udic Haploborall) in west central Minnesota. Four of the plots were planted in corn, 2 in newly seeded alfalfa with an oat cover crop, and the remaining 2 were left in 6-year-old alfalfa. Treatments on the 8 plots consisted of the following: CORN — (1) check, no manure, (2) 44.8 metric tons/ha solid dairy manure, wet basis, applied in fall and plowed under, (3) 44.8 metric tons/ha solid dairy manure, wet basis, applied in fall on frozen ground, (4) 44.8 metric tons/ha solid dairy manure, wet basis, applied in spring on top of snow; NEW ALFALFA—(5) 44.8 metric tons/solid dairy manure, wet basis, applied in fall on frozen ground, (6) 44.8 metric tons/ha solid dairy manure, wet basis, applied in spring on top of snow; OLD ALFALFA — (7) 44.8 metric tons/ha solid dairy manure, wet basis, applied in fall on frozen ground, (8) 44.8 metric tons/ha solid dairy manure, wet basis, applied in spring on top of snow. Each plot was equipped with runoff measuring equipment for measuring all water and soil coming off the plot surface during runoff events. Soil and nutrient loss from manured plots was lower than expected. The effects of winter manuring extended into the growing season, causing decreased soil loss, runoff, and nutrient movement and increased yields. (Rowe-East Central)

INTER-RELATIONSHIPS BETWEEN NITROGEN BALANCE, pH AND DISSOLVED OXYGEN IN AN OXIDATION DITCH TREATING FARM ANIMAL WASTE,

Chemistry and Microbiology Divisions, North of Scotland College of Agriculture, Aberdeen
I. Murray, J. W. Parsons and K. Robinson
Water Research, Vol. 9, No. 1, p. 25-30, January, 1975. 4 fig, 1 tab, 15 ref.

Descriptors: Nitrogen, Hydrogen ion concentration, Dissolved oxygen, Nitrification, Denitrification Ammonia.
Identifiers: Oxidation ditch, Land disposal.

Major pathways of nitrogen in aerobic farm waste treatment systems are outlined, and attempts are made to explain the observed data and fate of nitrogen, in terms of the mode of operation of the field scale system. The changes in DO, oxygen uptake rate, pH and nitrogen balance were monitored under steady and nonsteady state conditions in an oxidation ditch treating undiluted pig waste. Undesirable nitrite accumulations occurred in the presence of high levels of free NH_3 and HNO_2. The influx of raw waste encouraged this self-promoting process. DO and pH were found to be inversely related. High DO was associated with an acid mixed liquor and nitrification. Low DO was associated with high pH and a denitrifying or non-nitrifying mode of operation. Aerobic treatment of concentrated farm waste inevitably results in some degree of nitrification and subsequent nitrogen loss through denitrification when the mixed liquor ceases to be aerobic. This is desirable if the settled liquor is to be discharged to a water course; however, if conservation of nitrogen for land application is required, then the aerobic system is wasteful and the use of nitrification inhibitors would lead to accumulation of NH_3 and high pH. (Penrod-East Central)

EFFECTS OF CATTLE DUNG AND DUNG BETTLE ACTIVITY ON GROWTH OF BEARDLESS WHEATGRASS IN BRITISH COLUMBIA,

Division of Entomology, CSIRO, Private Bag No. 3, Indooroopilly, Queensland 4068, Australia
A. MacQueen and B. Beirne
Canadian Journal of Plant Science, Vol. 55, No. 4, p. 961-967, October, 1975. 3 tab, 23 ref.

Descriptors: Crop response, Productivity, Nutrients, Nitrogen.
Identifiers: Dung beetles, British Columbia, Crude Protein.

This study was conducted to evaluate the effects of adding nitrogen to soil in various ways on the growth of beardless wheatgrass. One of these ways was to use a dung-burying beetle, Onthophagus nuchicornis (L.). The experimental work was done at the Research Station, Agriculture Canada, Kampoops, British Columbia. Beardless wheatgrass was grown in pots containing typical Brown Chernozemic sandy loam soil from severly overgrazed grassland. Six treatments, replicated 10 times were as follows: (1) 200 g of fresh dung hand-mixed with the soil, to stimulate total burial of the dung by beetles, (2) 200 g of fresh dung plus 5 pairs of O. nuchicornis beetles that buried some dung mainly in the form of brood balls to provision their larvae, (3) 200 g unburied fresh dung to stimulate the current rangeland situation where dung normally remains unburied, and (4) a control, where no dung or nitrogen fertilizer was added to the soil. Total incorporation of the fresh dung into the soil increased total crude protein production, potential seed production, and the vigor of the grass over the 2 year period. Burial of an average 37 percent of the available dung by beetles caused a 38 percent increase in crude protein over that of the control. These rangelands have an impoverished native dung beetle fauna in comparison with some other climatically similar areas of the world. Efficient dung beetles should bury cattle dung more effectively during the growing season than do the present species. Establishment of such new species might provide an aid to nutrient recirculation and, through this, to maintenance of rangeland productivity. (Rowe-East Central)

FEEDLOT WASTES TO USEFUL ENERGY — FACT OR FICTION?,

Associate Professor of Civil Engineering, Kansas State University, Manhattan
L. A. Schmid
Journal of the Environmental Engineering Division (Proceedings of ASCE), Vol. 101, No. EE5, p. 787-793, October, 1975. 2 fig, 6 ref.

Descriptors: Energy, Feedlots, Anaerobic digestion, Recycling, Fuels, Fertilizers, Economics.
Identifiers: Case studies.

The present energy shortage makes it necessary for new sources of energy to be sought. One such source is feedlot wastes which can be used to produce gas or other energy. Although the buffalo chips used by early pioneers contained much of their original fuel value, present feedlot conditions make it impossible for wastes to maintain their maximum fuel value and therefore place a restriction on the uses of wastes for fuel. The author's first and last law of energy conservation is: Total energy expended to obtain energy must not exceed return energy. There are several methods of energy conversion, four being (1) conversion to heat by incineration methods; (2) conversion to gas by high temperature pyrolysis; (3) conversion to gas by biological methods; and (4) conversion to other organic forms. Because of the energy lost on present feedlots, all of these methods suffer substantially. Three case studies to examine in detail biological conversion to gas by anaerobic digestion are discussed. The conclusion reached by the author was that net energy production from present feedlots is neither practical or possible, and that the best use of feedlot wastes is as fertilizers. DUNG AS AN ESSENTIAL RESOURCE IN A HIGHLAND PERUVIAN COMMUNITY,

Department of Anthropology, Cornell University, Ithaca, New York
B. Winterhalder, R. Larsen and R. B. Thomas
Human Ecology, Vol. 2, No. 2, p. 89-104, April, 1974. 5 fig, 5 tab, 29 ref.

Descriptors: Recycling, Fuels, Fertilizers, Sheep, Cattle, Energy, Nutrients.
Identifiers: Llamas, Ecology, South America.

In the community studied, dung was used as both fuel and fertilizer. Interestingly enough, native choice among available dungs corresponds to their qualities: sheep dung, richest in nutrients, is applied as fertilizer; llama and cattle dungs, each with a high caloric value, are burned as fuels. The emphasis of the bulk of the paper is on anthropological ecology, using the concepts of energy flow, nutrient cycling and environmental adaptation to demonstrate the importance of efficient use of animal excrement in the adaptation of highland peoples. NUTRIENT CYCLES INVOLVING PHOSPHORUS AND POTASSIUM ON LIVESTOCK FARMS IN NORTHERN IRELAND,

Agricultural and Food Chemistry Department, Queen's University of Belfast, Northern Ireland
S. N. Adams and J. S. V. McAllister
Journal of Agricultural Science, Vol. 85, No. 2, p. 345-349, 1975. 2 fig, 2 tab, 12 ref.

Descriptors: Phosphorus, Potassium, Fertilizer, Economics.
Identifiers: Nutrient balance sheet, Northern Ireland, Land spreading.

The Netherlands Ministry of Agriculture has suggested that the net need of livestock farms for fertilizer P and K can be determined by comparing the P and K produced in the excreta of housed livestock with the needs of the crops grown. This study was done to see if the principle could be used in advising farmers by developing a simple form of nutrient balance sheet to ensure efficient recycling of nutrients, while avoiding deficiencies of excesses. About 100 farms throughout Northern Ireland were selected by the Department of Agriculture's advisory staff to cover the main farming types in the area. The farmers provided records of the stock carried, the area of the crops grown, and the fertilizer used from November 1, 1972 to October 31, 1973. The soils of all fields were sampled for P and K determinations. An arbitrary deduction of 10 percent of the P and K was made to allow for losses from P and K "balances". It was found that the amounts of P and K fertilizers applied on the predominantly grassland farms bore little relation to needs; furthermore, almost all farmers applied more fertilizer than was needed to cover deficits. It was felt that nutrient balances would encourage farmers to regard organic manures as a valuable source of nutrients rather than as a waste product to be disposed of. Furthermore, the nutrient balance sheets are readily understood and could help the farmer make substantial savings in fertilizers. However, the nutrient balance sheet is subject to large errors. NORTH CAROLINA SWINE OPERATION SOLVES ODOR, WASTEWATER PROBLEMS

Feedstuffs, Southeastern Correspondent
R. H. Brown
Feedstuffs, Vol. 47, No. 48, p. 34-36, 38, November 24, 1975. 3 fig.

Descriptors: Management, Design, Odor, Wastewater treatment, Aeration, Lagoons, Anaerobic conditions, Irrigation, Denitrification, Oxygen demand, Water pollution, Feedlots, North Carolina.
Identifiers: Swine, Land disposal.

Lexington Swine Breeders, Inc. developed some disposal and odor problems which were compounded by the building of a large furniture factory and several new homes nearby. The manager of Lexington Swine Breeders, Inc., Dr. George Wetherill, secured the assistance of 4 faculty members of North Carolina State University who helped develop a satisfactory waste management system. The plan called for the emptying of 1 of 4 manure pits (1 pit for each swine house) into a newly built aerobic lagoon. Here the odors were eliminated and the oxygen demand, organic carbon, and solids loading were reduced. The wastes then went into an anaerobic lagoon. This aerated-unaerated treatment sequence provided a suitable condition for biological denitrification or nitrogen removal. Since nitrogen is usually the limiting factor in determining the amounts of wastes or wastewaters to be applied to fields, there was great advantage in this. The wastewater was then sprinkler irrigated out on pasture land about 1 ½ hours a week. A creek, which had run through the feedlot, was diverted around the feedlot into a larger creek in order to prevent it from being polluted any longer. The system seems to be working quite effectively. (Rowe-East Central)

MECHANICAL MANURE HARVESTING FROM FEED-LOTS,

Department of Agricultural Engineering, Colorado State University, Fort Collins 80523
J. D. Kellerby and J. L. Smith
Presented at the 1976 Annual Meeting, American Society of Agricultural Engineers, University of Nebraska, Lincoln, June 27-30, 1976, Paper No. 76-3038, 16 p. 11 fig, 1 tab, 3 ref.

Descriptors: Feedlots, Equipment, Design.
Identifiers: Manure harvestor

Study objectives were: (1) to design and build a prototype manure harvester for use on concrete or hard surfaced beef feedlots, (2) to test the manure harvester using wood shavings, wood paste and beef feedlot manure and make practical recommendations for improvement of the machine, and (3) to determine the power required to operate various components of the manure harvester with respect to efficiency of loading, forward speed, variation in speed and position of various machine components and depth of manure. The harvester was constructed on a small modified manure spreader. All components were hydraulically powered. A loader was bolted to the front of a small manure spreader after removal of the front wall. The rear spreader components were removed. The manure harvester operated in this manner. The tracter moved forward. A crustbreaker pulverized the surface and threw the material back into a beater. A scraper blade under the beater cleaned the material to the desired depth. The beater's helical blades cut any large pieces and threw the material back to the inclined conveyor where it was moved up a platform into the harvester bin which was unloaded when full. Study conclusions were: (1) The manure harvester loaded most efficiently from the standpoints of tractor speed, power required, and pulverization, when the material was approximately 5 cm deep and the surface was reasonably smooth. Approximately 40 m^3/hr could be loaded and about 75 percent of the material encountered was loaded. (2) At the optimum material depth of 5 cm and tractor speeds ranging from 1 to 2 km/hr, less than 10kW was required to operate the loader. (3) A smooth hard surface was the most desirable feedlot condition. It was observed that the hydraulic motor for the crustbreaker needed increased torque and that the conveyor needed to be redesigned to prevent plugging at the entry. (Rowe-East Central)

LOTS GET OK TO PRODUCE GAS TO COOK STEAKS.

G. Richardson
Western Livestock Journal, Vol. 54, p. 1, January 5, 1976.

Descriptors: Methane, Feedlots, Recycling, Oklahoma, Texas, Costs.

Natural Gas Pipeline Company of America has been authorized by Judge Israel Convisser to transport and sell methane gas produced by cattle manure. The pipeline company plans to buy the gas from Calorific Recovery Anaerobic Process, Inc. of Oklahoma City at an approved price of $1.33 per 1000 cubic feet. The gas will by produced from a plant which Calorific has under construction close to several feedlots near Hooker, Oklahoma. Completion is scheduled for mid-1976. Natural has also just entered a second agreement to purchase commercial quantities of methane from a generating plant to be built by Ecological Research Associates, Lubbock, Texas, near a feedlot in Deaf Smith County, Texas. Natural hopes to purchase the gas from Ecological Research Associates at a base price of $1.30 per 1000 cubic feet. While the firm notes that the gas produced from cattle manure is higher than current wellhead prices for natural gas, it is "significantly less expensive than other forms of synthetic gas now being developed and lower than the cost of liquified natural gas being imported by some U.S. utilities." The 2 contracts are believed to be the first commercial-volume purchases by an interstate pipeline company of methane gas generated from manure. (Edwards-East Central)

MANAGE HOG WASTE FOR FERTILIZER VALUE,

Anonymous
Wallaces Farmer, Vol. 101, No. 4, p. 43, February 28, 1976.

Descriptors: Fertilizers, Nutrients, Management, Nitrogen, Phosphorus, Potassium, Economics.
Identifiers: Swine.

Almost 70 percent of the phosphorus and nitrogen and 90 percent of the potassium in swine rations are excreted in wastes. Correct management of these wastes helps conserve these nutrients for fertilizer. Stuart Melvin, Iowa State University extension agricultural engineer, says that in a farrow-to-finish operation, a 220-lb. pig excretes 14-16 lb of elemental nitrogen, 7-8 lb of phosphate, and 3-6 lb of potassium when fed common rations. About 70 percent of these nutrients are excreted when the pig is fed from 40-220 lb. The bedded and deep pit systems are best for conserving nitrogen. Nitrogen losses are highest in aerobic-anaerobic treatment combinations and in anaerobic lagoons. Nitrogen is also lost in the form of ammonia when wastes are field spread. Much phosphorus and potassium are lost in systems having high runoff from outside lots or in sludge buildings in the bottom of lagoons. Fertilizer value per pig marketed varies from $1.50 to $5, depending on the system used. Disposal costs vary from 50c to $2.50 per head marketed. (Edwards-East Central)

NUISANCE LAW OFFERS FEEDERS PROTECTION,

Anonymous
Wallaces Farmer, Vol. 101, No. 8, p. 20, April 24, 1976.

Descriptors: Legal aspects, Iowa, Costs, Livestock.
Identifiers: Nuisance suits.

A bill being considered by the Iowa legislature would give livestock producers some protection against nuisance suits and changing environmental regulations. The proposed law grew from the belief that present nuisance regulations discourage livestock producers from expanding operations because they fear possible court action which might close them down. It scares livestock men to think that they might invest thousands of dollars in a new livestock facility and then have to defend themselves in court against someone who may build a house next door and then claim the facility a nuisance. The bill (SF 367) states that whoever is there first is right. If the livestock operation was built to meet current environmental regulations and zoning, the operator has a 10-year exemption from major design changes. Such a change is defined as one that would cost more than 2 percent of the facility's value. If the producer has to make a less expensive change to conform to rules on a facility that is less than 10 years old, he would have a year to make changes. Today, livestock sales account for slightly more than 50 percent of Iowa's cash farm receipts. Passage of SF 367 should help encourage Iowa farmers to make the investment to continue livestock programs. (Rowe-East Central)

MEDICINAL DRUG RESIDUES IN BROILER LITTER AND TISSUES FROM CATTLE FED LITTER,

Virginia Polytechnic Institute and State University, Blacksburg 24061
K. E. Webb, Jr. and J. P. Fontenot
Journal of Animal Science, Vol. 41, No. 4, p. 1212-1217, October, 1975. 3 tab, 32 ref.

Descriptors: Litters, Virginia, Cattle
Identifiers: Drug residues, Tissue accumulations, Refeeding, Animal health.

An evaluation was made of the degree of broiler litter contamination by drug residues and the effect of feeding broiler litter containing drug residues on tissue accumulation in cattle. Samples of broiler litter were obtained from several houses in the main broiler producing areas of Virginia. The samples were analyzed for oxytetracycline, chlortetracycline, penicillin, neomycin, zinc bacitracin, nicarbazin, amprolium, furazolidone, arsenic and copper. The only drug residues not detected in the litters were neomycin and zinc bacitracin. In the feeding trials, Longissimus muscle, liver and kidney fat samples were tested for drug residues. Chlortetracycline, amprolium, nicarbazin, arsenic and copper assays were conducted on the samples. Low-level chlortetracycline, amprolium, nicarbazin, arsenic and copper assays were conducted on the samples. Low-level chlortetracycline residues were observed in kidney fat from 3 of 20 animals fed litter. Arsenic residues in muscle and liver increased as the amount of litter fed increased. Litter feeding resulted in copper accumulation in the liver. Amprolium or nicarbazin residues were not detected. The study thus indicated that drug residues are commonly found in broiler litter, but that feeding litter to cattle results in little or no drug accumulation in tissues tested after a 5-day withdrawal of litter. (Rowe-East Central)

FAECAL COLIFORMS AND FAECAL STREPTOCOCCI IN STREAMS IN THE NEW GUINEA HIGHLANDS,

Department of Civil Engineering, University of Birmingham, P.O. Box 363, Birmingham B 15 2TT
R. Feachem
Water Research, Vol. 8, No. 2, p. 367-374, June, 1974.

Descriptors: Water pollution, Coliforms, Streptococcus, Public health, Agricultural runoff.
Identifiers: New Guinea, Swine, Domestic water sources, Pollution indicators.

A detailed study was made of fecal coliform and fecal streptococci concentrations in the streams of the Saka Valley in the Highlands of New Guinea. The Saka Valley supports large populations of humans and domestic pigs, whose feces are washed into the streams by surface runoff following rain. Researchers hoped to determine whether the fecal content of the streams, which are used as domestic water sources, would render the waters unsafe. If so, the researchers further wanted to determine what action could be taken to minimize this hazard. Study conclusions were: (1) Natural waters in the New Guinea Highlands are contaminated with fecal material, which may derive largely from herds of domestic pigs. (2) The polluted waters are used for all domestic water needs and are a health hazard. Only the spring water is of reasonable quality and the encouragement of greater use of spring water, and spring protection, are obvious public health improvement measures. (3) Fecal coliforms and fecal streptococci proved to be excellent indicators of fecal pollution in the New Guinea Highlands. The membrane filtration techniques, used to enumerate these bacteria, were highly suited to the remote field conditions and the primitive laboratory. (4) Fecal streptococci concentrations were extremely sensitive to animal pollution and peaked rapidly following stormwater runoff into the streams. (5) Water temperatures ranged from 13 to 26.2 degrees C and there was no evidence of coliform regrowth at these temperatures. This may be due to the absence of major discharges of domestic or industrial wastes into the streams. (Rowe-East Central)

THE $446,700 BIT OF ADVICE: DON'T SWIM IN THE MANURE PIT!

J. Richter
Beef, Vol. 12, No. 12, p. 55, August, 1976.

Descriptors: Feedlots, Safety.
Identifiers: Occupational Safety and Health Administration.

The Occupational Safety and Health Administration (OSHA) of the U. S. Department of Labor published a booklet entitled "Safety with Feed Cattle" which caused a real battle between bureaucrats and beef producers. Beef producers, however, are emerging from the field without a visible scratch to reap a just reward — a measure of relief from the rules and meddlesome ways of OSHA. Congressman Tom Hagedorn of Minnesota, noting that the pamphlet was one in a series of OSHA pamphlets which would cost taxpayers an estimated $466,700, said: "The material in these pamphlets seems to be written for a New Yorker about to visit a farm for the first time... I can't believe these (booklets) are intended for persons who have spent all their lives on farms." The feedback got through to Washington, and the Assistant Secretary of Labor Morton Corn, who runs OSHA, announced that distribution of the booklet was being halted "pending its revision." A compromise between the House and Senate on the number of ranches and farms to be let off the hook seems to be in the making. (Rowe-East Central)

HOW THEY HANDLE FREE STALL MANURE,

Anonymous
Hoard's Dairyman, Vol. 121, No. 1, p. 12-13, 46-47, January 10, 1976. 5 fig.

Descriptors: Waste storage, Design, Costs, Equipment, Dairy management.
Identifiers: Waste management, Free stall manure.

In a round table discussion, Michigan, Vermont, and Wisconsin dairymen told how they handle their free stall manure. The 4 men contributing to the discussion were: E. Budd Gerrits, Wisconsin; Erwin Walker, Wisconsin; Tom Howlett, Vermont; and Jerry Cameron, Michigan. Waste storage was handled on each man's dairy as follows: Gerrits—earthen basin; Walker—silo; Howlett—earthen basin; and Cameron—earthen basin. Equipment, materials, and total costs for each system were as follows: Gerrits—alley scrapers, barn cleaner, transfer pump, dock on pond, excavation and concrete, pump and spreader; Total cost—$21,080; Walker—transfer pump in lot, silo and pump, 3,000 gallon spreader; Total cost—$19,500; Howlett—all weather road, excavation, pump, truck-mounted tank, and trailer-mounted spreader; Total cost—$18,000; Cameron—barn cleaner, garden tractor, excavation and picket dam, side-unloading spreader, box spreader and tractor loader; Total cost $12,147. When asked what changes they would make if they could plan each system over again, their replies were as follows. Gerrits said he would slope the bottom of the earthen basin more and possibly concrete the bottom of it. He would also have his underground pipe from the barn be either level or down hill. Walker didn't have any changes. Howlett recommended making the basin lower than the barn to allow for gravity flow. He also recommended a trailer-mounted pump with a 30-foot high pole which would enable the tractor to stay on the level at the top of the pond. Cameron could think of no changes that should be made. METHANE PRODUCTION FROM MANURE IS TODAY'S REALITY IN FLORIDA,

Calf News, Vol. 14, No. 4, p. 48, April, 1976.

Descriptors: Methane, Recycling.
Identifiers: Anaerobic fermentation, Kaplan Feedyards, Refeeding.

Kaplan Feedyards of Bartow, Florida, may be the first feedyard to commercially produce methane gas according to Don Kaplan. They built a waste conversion system for an 8,000-head feedyard. The anaerobic fermentation process will produce 60 million BTU's per year and 2,900 tons of a 25 percent protein feed product. Kaplan plans to use the methane to power the boilers in his packing plant. (Rowe-East Central)

PIT VENTILATION SYSTEM FOR SWINE BUILDING,

Agricultural Engineering Department, Illinois University at Urbana-Champaign
R. A. Keller and D. L. Day
Presented at 1975 Annual Meeting, American Society of Agricultural Engineers, University of California, June 22-25, 1975, Paper No. 75-4048, 14 p. 9 fig, 7 tab, 9 ref.

Descriptors: Design.
Identifiers: Swine buildings, Slatted floors.

A ventilation system for exhausting air from manure pits was installed in a hog-finishing building with a partially slatted floor at the Illinois Agricultural Experiment Station and its operation was monitored during the winter of 1964-1965. Air was exhausted from the manure pit through a 4-inch diameter PVC sewer pipe. The building was insulated on the ceiling, but the walls were not insulated and the doors along the walls were not closed completely in certain locations; thus temperature differences and drafts were noticable. Although smoke tests revealed a downward air flow at the slat level, the percent of slat area was not large enough to determine all the effects from the pit ventilation system. The design and installation of this system can be adapted to fit any building. (Edwards - East Central)

HATCHERY INSTALLS NEW WASTE MANAGEMENT SYSTEM, WAITS RESULTS,

Feedstuffs Southeastern Correspondent
R. H. Brown
Feedstuffs, Vol. 48, No. 30, p. 52-53, July 26, 1976. 2 fig.

Descriptors: Management, Design, Wastewater treatment, Wastewater disposal, Lagoons, Sprinkler irrigation, Odor, Chemical oxygen demand, Nitrogen.
Identifiers: Hatchery, Land disposal.

A North Carolina hatchery, Chick Sales, Inc., Siler City, has installed a waste management system that is hoped to meet 1985 environmental standards. Scattered over the 23 acres that adjoin the hatchery, the waste management system includes washroom water, egg shells, and no-hatch eggs. The system generates little or no odor. Basically the facility involves a series of treatments in a separator-grinder in the washroom, an aerated lagoon and a second reservoir known as the "polishing" pond. Water goes through these various stages before being put into a sprinkler irrigation system which disperses the waste water and fertilizes fescue during cold weather periods and Bermuda grass during summer growing periods. Cattle graze on the 15 acres of fescue and 8 acres of Bermuda. Maintenance of the system has not been much problem. Most of the time is spent on walking around the lagoons and inspecting the pump and aerators. Hatchery manager, Gail Phillips, also spends part of this time keeping records, primarily for researchers at North Carolina State University who are still studying the system. (Rowe-East Central)

METHODS OF TREATING ODORS,

C. L. Barth and D. T. Hill
Presented at the 1976 Annual Meeting, American Society of Agricultural Engineers, University of Nebraska, June 27-30, 1976, Paper No. 76-4015, 13 p. 7 tab, 7 ref.

Descriptors: Ammonia, Hydrogen sulfide, Ozone.
Identifiers: Odor control, Methylamine, Land spreading.

Two basic approaches for odor control are: (1) Prevent odor production. This requires establishing conditions which are unfavorable for anaerobic bacterial growth. (2) Treat the odor after it is produced. Drying, refrigeration, aeration, oxidation, the use of absorptive and absorptive chemicals, and the use of masking agents, counteracting agents, deodorants, and enzyme and bacterial cultures are all means of controlling odor. A test was made using 3 of the main odorants in manure — ammonia, hydrogen sulfide, and methylamine — in concentrations that might be expected to be found in livestock production units. Tests were made of the strength of these odorants in various combinations and the effect of ozone in reducing their strengths. Most tests showed that ozone (O_3) was effective in reducing the concentration of each odorant with time. However, the reaction time was not as fast as had been previously reported. A surprise reaction was that when O_3 was tested against methylamine, it was found that when the dosage of O_3 increased and as the time increased, the odor strength also increased. Practical planning and operating practices can help control odor. The livestock owner should: (1) select building sites that are one-half mile from neighboring residences or a mile from communities, schools, institutions or places of employment, (2) try to locate production facilities so that prevailing winds blow odors away from the nearest residents, and (3) use sites that have adequate slopes or sites where slopes can be built for good drainage. Land spreading, a source of odor, should be carefully controlled. Odor problems may be minimized by (1) spreading on a cool day, (2) spreading when the wind is in a favorable direction, (3) spreading early in the day, (4) avoiding spreading just before weekends and holidays, (5) avoiding spreading near highways, homes, schools, or places where people work, and (6) incorporating the manure into the soils as quickly as possible. (Edwards-East Central)

THE INFLUENCE OF APPLIED PHOSPHORUS, MANURE, OR LIME ON UPTAKE OF LEAD FROM SOIL,

Department of Botany and Plant Pathology, Colorado State University, Ft. Collins.
R. L. Zimdahl and J. M. Foster
Journal of Environmental Quality, Vol. 5, No. 1, p. 31-34, January-March, 1976. 17 ref.

Descriptors: Lead, Soil contamination, Crop response, Phosphorus, Hydrogen ion concentration.
Identifiers: Land application, Liming.

A study was conducted at Colorado State University, Fort Collins, to determine the effects of phosphorus, organic matter, and pH on uptake of lead by corn (Zea Mays L.). The corn was grown in soil that was contaminated at levels that may be encountered in some agricultural areas. Except for the pH experiment, a sandy clay loam soil of the mallisol order, with 58 percent sand, 17 percent silt, 25 percent clay, and 1.3 percent organic matter, a pH of 7.9 a cation exchange capacity of 13.8 meq/100 g, and a native lead content of 6.4 ug/g was used. All experiments were conducted in 6 replications with 1 corn variety. The experimenters determined that while phosphorus applications decrease lead uptake, translocation is affected and at higher lead levels. Also, addition of phosphorus has not proved to be economically or ecologically feasible. It was found that lead uptake decreases when cow manure is added to attain a total organic content of 6 percent, but there is no effect of additional manure. Liming does not have a consistent effect on uptake, but lead translocation does appear to decrease with liming. (Penrod-East Central)

METHANE GENERATION FROM AGRICULTURAL WASTES: REVIEW OF CONCEPT AND FUTURE APPLICATIONS,

Cornell University, Ithaca, New York.
W. J. Jewell, G. R. Morris, D. R. Price, W. W. Gunkel, D. W. Williams, and R. C. Loehr
Presented at 1974 Northeast Regional Meeting, American Society of Agricultural Engineers, West Virginia University, August 18-21, 1974, Paper No. NA74-107, 30 p. 7 fig, 5 tab, 27 ref.

Descriptors: Methane, Fermentation, Anaerobic digestion, Costs, Dairy industry, Recycling, Fertilizers, Energy.
Identifiers: Poultry.

Study objectives were: (1) to review the status of anaerobic fermentation in converting organics to methane gas, (2) to approximate the size of animal production operations which could utilize this technology on an economical basis and (3) to project possible future applications of this technology. Advantages of anaerobic digestion were found to be: (1) production of more easily dewatered sludge, (2) odor free sludge, (3) sludge with undiminished fertilizer value, (4) particulate matter in sludge suitable for refeeding, (5) reduction of organic content by 50 percent which prepared the sludge for ultimate disposal, (6) production of a large amount of methane gas as a by-product, and (7) possible reduction of pathogenic organisms. Disadvantages were: (1) explosion possibilities, (2) high capital cost, (3) sensitive to operation and difficult to control, (4) developed much more waste volume to be handled, (5) generated potential water pollution problem, and (6) energy required in terms of heat input. The most serious anaerobic digestion limitation appeared to be ammonia toxicity to the biological mass and may be avoided by controlling the digester loading rate. A gross economic analysis indicated that dairy and poultry farms of 155 and 5200 animals, respectively, could obtain total energy and residue fertilizer benefits equal to the cost of the waste handling system. In the future, this system may provide more than 95 percent of the energy requirements in large broiler operations. Anaerobic fermentation offers promise in conversion of animal wastes to usable energy, conserving fertilizer value equal to the energy value of the methane, and may be useful in large scale energy generation schemes. PROGRESS IN ANIMAL HYGIENE,

University of Veterinary Science, Budapest, Hungary
R. Kovacs and P. Rafai, eds.
Progress in Animal Hygiene, F. Kovacs and P. Rafai, (ed). Budapest, Akademiai, Kiado, 1975. 501 p.

Descriptors: Liquid wastes, Cattle, Poultry, Dairy industry, Air pollution, Soil contamination, Water pollution.
Identifiers: Waste management, Hygiene, Animal health, Disinfection, Swine, Bioclimatology, Mastitis, Lambs, Pathogens.

This book consists of papers presented at the First International Congress for Animal Hygiene, Budapest, Hungary, on October 2-5, 1973. A total of 105 papers, chiefly research reports dealing with 9 main topics, were read and discussed. Topics covered were: (1) Disposal, treatment and utilization of liquid manure, (2) Disinfection in large scale management systems, (3) Hygienic problems of large scale cattle husbandry, (4) Hygienic problems of large scale poultry husbandry, (5) Hygiene of feeding, (6) Hygienic problems of large scale swine husbandry, (7) Bioclimatology, (8) Influence of stable hygiene on milk production and incidence of mastitis, and (9) Calf rearing, calf fattening, and lamb fattening. HYGIENIC PROBLEMS OF DISPOSAL, TREATMENT AND UTILIZATION OF LIQUID MANURE,

University of Hohenheim, Stuttgart-Hohenheim, German Federal Republic
D. Strauch
In: Progress in Animal Hygiene, F. Kovacs and P. Rafai, (ed). Budapest, Akademiai Kiado, 1975. p. 33-36.

Descriptors: Liquid wastes, Waste treatment, Waste disposal, Aeration, Water pollution, Groundwater pollution, Crop response, Electrolysis.
Identifiers: Hygiene, Pathogens, Land disposal, Radioactive irradiation.

In modern agriculture, excrements of animals are produced mostly as liquid manure. From the hygienic point of view, the main difference from solid manure is the lack of self-heating so that a very important influence on pathogenic microorganisms is absent. Therefore, the liquid manure must be disinfected in the livestock production unit to prevent pathogens from being carried out of the production site. This is often done by means of chemical disinfectants, but care must be taken in using them. Such chemical disinfectants as caustic soda and chlorinated lime will cause damage to plants and therefore prevent the liquid manure from being used as fertilizer. Also, despite the availability of disinfectants for treatment of slurry, most known disinfectants have the disadvantage that there is none with a universal effect. Other methods of treatment that are being utilized involve electric current (ie. radioactive irradiation and electrolysis) and aeration (ie. surface aeration and the ventilating process). Most of these systems are based on the fundamental principle of separating liquid from solid phase. Such separation is not satisfactory from the hygienic point of view as long as the pathogenic microorganisms are not destroyed. Other problems associated with these waste management systems arise with collecting and spreading slurry. Odor is a particular problem at these times, especially from pigs and poultry. Various methods of deodorization by biological, chemical or technical means are being investigated. Final statements cannot yet be made. The problem of residues of chemical deodorants in the organs of animals requires special attention. Also, the question of soil and plant tolerance for large amounts of slurry is being extensively studied. It is known that fertility of the soil is damaged by large amounts of liquid manure. Large doses of slurry also cause a very heavy leaking of NO_3 into the groundwaters. (Merryman-East Central)

ANALYSIS OF LIQUID MANURE TREATMENT IN HUNGARY, WITH SPECIAL REGARD TO ENVIRONMENTAL PROTECTION,

Research Institute for Management of Water Supplies, Budapest, Hungary
L. Vermes
In: Progress in Animal Hygiene, F. Kovacs and P Rafai, (Ed). Budapest, Akademiai Kiado, 1975. p 37-39. 1 tab.

Descriptors: Liquid wastes, Waste treatment, Waste storage, Waste disposal, Fertilizers, Irrigation.
Identifiers: Hungary, Land disposal, Hygiene, Fish farming.

In Hungary, the general tendency has been the agricultural utilization of as much liquid manure as possible, or at least its disposal into the soil, but attempts have also been made at its purification. Agricultural utilization may be accomplished by fertilization of land or use in farm ponds to grow fish. Promising results of the latter warrant further study. The liquid manure may be utilized either after separation of liquid and solid phase or without separation of the phases. If the liquid manure is separated, the solid and liquid phases are treated distinctly. The solids phase is deposited and later used for dunging; the liquid phase is stored for a given time and then carried to the fields or disposed of in another way. Separation of liquid manure is sometimes omitted in order to preserve the manure's valuable components as much as possible until utilization. In Hungary, purification of liquid manure has been attempted unsuccessfully in 2 units — the Pasveer-type oxidation ditch and a combined mechanical-chemical-biological procedure. Chemical analysis of liquid manure has revealed it to be a dangerous water pollutant. Analysis has also showed that liquid manures contain important plant nutrients and thus are valuable fertilizers. In view of the requirements of water quality and environmental protection, direct disposal of liquid manure into the soil under well controlled conditions would appear to be the most feasible waste management method. Transport to the fields should take place in the shortest possible time, by the shortest route, and under consideration of the capacity of the soil so that its fertility may be maintained as long as possible. The use of homogenated liquid manure for continuous irrigation meets not only the hygienic requirements but it is also profitable from the agricultural point of view. The separated liquid phase can be utilized in the same manner if appropriate facilities can be provided for its all-the-year-round storage with due consideration of the hygienic requirements, also under the conditions of quarantenization. (Merryman-East Central)

SOME BACTERIOLOGICAL CHARACTERISTICS OF SEWAGE AND SLURRY FROM LARGE SCALE SWINE UNITS,

Agricultural College, Institute for Animal Hygiene, Timisoara, Roumania
V. Tomescu, F. Marschang, R. Mora-Minzat, O. Rusu, E. Crainiceanu, and I. Grozav
In: Progress in Animal Hygiene, F. Kovacs and P. Rafai, (ed). Budapest, Akademiai Kiado, 1975. p 40-44. 1 tab, 16 ref.

Descriptors: Bacteria, Slurries, Irrigation, Fertilizers, Sampling, Liquid manure, Pathogenic bacteria.
Identifiers: Swine, Roumania.

Only limited investigations have been carried out in Roumania recently into the bacteriological characteristics of sewage from animal units, especially from large swine farms. Since such sewage is employed for irrigation and the slurry is used as fertilizer, investigations centered on its epidemiological and epizootological role. During 1971, 1972 and 1973, 159 samples of sewage and slurry were taken from 5 large-scale units and 2 swine farms. Bacteriological tests were performed for (a) determination of total germ count per ml of sewage, (b) determination of the E. coli- index, (c) typing of E. coli isolates, (d) detection of salmonellas, and (e) detection of leptospires. Sewage and slurry samples from swine units were found to contain a heavy bacterial load. 142 strains of E. coli, belonging to 23 serogroups, and serogroups pathogenic for humans and animals, were isolated and identified. 106 Salmonella strains, belonging to 12 serotypes were isolated. 32 Leptospira strains were isolated and identified. They were found in 33 percent of the samples collected and in 58 percent of those processed, and belonged to 2 serotypes, 29 to L. pomona and 3 to L tarassovi. The rough and partially purified sewage and the wet settled slurry originating from large pig units and farms have a great potentiality for spreading pathogenic microorganisms, which may have severe epidemiological and epizootological consequences. Purification plants should be properly equipped for the destruction of pathogenic agents in liquid manure and sewage. (Merryman-East Central)

BACTERIOLOGICAL CONTROL OF EFFICIENCY OF LIQUID MANURE HANDLING,

University of Veterinary Science, Budapest, Hungary
G. Tamasi
In: Progress in Animal Hygiene, F. Kovacs and P. Rafai, (ed). Budapest, Akademiai Kiado, 1975. p. 45-51.

Descriptors: Liquid wastes, Bacteria, Waste treatment, Sampling.
Identifiers: Hungary, Waste water reuse.

Examinations were conducted in Hungary to assess the microbiological efficiency of 4 manure handling systems — (1) untreated liquid manure, (2) manure stored in mechanically aerated lagoons, (3) separation of liquid manure into liquid and solid phase by filtration through bundles of straw, and (4) a combined physical-chemical-biological handling system. Total germ count, coliforms, staphylococci, enterococci, and lactobacilli were measured in each of these systems. Treatment in mechanically aerated lagoons was found to be of good microbiological efficiency. In a model experiment, sterile liquid manure was infected with microorganisms isolated from liquid manure, and one sample each was incubated at +4 and +20°C. The counts of aerobic sporeformers and Salmonella rose in the initial period of incubation at + 20°C. In another experiment, filtered and purified liquid manure was infected with Salmonella and thereafter was passed through a settling column and a semi-anaerobic bacteriological bed. Germ count determinations in 3 passages showed that this procedure was not in itself sufficient to ensure a salmonella-free end product, but it should be taken into consideration that only the biological conditions were modeled; physical and chemical treatment were not. The authors seemed to feel that recirculation of part of the liquid manure might be beneficial in washing the drains and probably also the floors of fattening houses. This use would reduce the amount to be disposed of by about 30 percent. However, it was recognized that special treatment might need to be performed on the waste water to prevent dangers to human and animal health. Studies will be concerned with disinfection and the fate of microorganisms after the deposition of liquid manure. (Merryman-East Central)

THE INFLUENCE OF SOME ENVIRONMENTAL FACTORS RELATED TO MANURE HANDLING ON HEALTH OF FATTENING PIGS,

Royal Veterinary College, Skara Division, Skara, Sweden
J. O. Lindqvist
In: Progress in Animal Hygiene, F. Kovacs and P. Rafai, (ed). Budapest, Akademiai Kiado, 1975. p. 52-56. 2 fig, 11 ref.

Descriptors: Liquid wastes, Design.
Identifiers: Animal health, Swine, Sweden, Waste management, Housing.

During the last decade, liquid manure handling has been a new alternative in Sweden, especially in the production of fattening pigs. Liquid manure management involves in environment with little or no use of straw. This has led to different animal health problems among purchased pigs, which is usually most evident during the first weeks after installing in the fattening house. In order to reduce the stress for pigs on arrival at the farm, different methods have been tried. For example, the so-called "welcome-stable" is usually a separate room where the total floor is covered by straw, except for the feeding area, which is on an elevated concrete plate. Studies were conducted in a herd of 5,400 fattening pigs in the south of Sweden. On the farm there are two "finishing houses" with 580 fattening pigs in each and 4 "welcome-stables" with 145 purchased pigs in each. The health of the herd was checked by a veterinary surgeon at least 2 times during each rearing period — 10 days after installing the pigs and then 2 months later. A few cases of respiratory disease were recorded. Visible abscesses, localizing in different parts of the body or the legs, were found in 18 pigs. 5-15 percent of the pigs showed injuries from Aarcoptes scabei at the clinical examination 2 months after installing. It was found at meat inspection that the main reasons for condemnation of carcasses of normally and emergency slaughtered pigs were parasitic injuries of the liver, abscesses and arthritis. In the "welcome-stables" the mortality rate was comparatively low, 38 percent of the total mortality. Most pigs died during the fifth week after being moved to the "finishing stable". This was probably the result of the changed environment. In this light, the extra change of environment involved by use of "welcome-stables" seems to be a negative factor but if the advantages of the entire system are considered, its effects on animal health can be judged as overwhelmingly positive. (Merryman-East Central)

MANURE HANDLING AND THE CONDITIONS OF AMMONIA FORMATION IN SWINE KEEPING WITHOUT LITTER,

University of Veterinary Science, Budapest, Hungary
E. Sallai
In: Progress in Animal Hygiene, F. Kovacs and P. Rafai, (ed). Budapest, Akademiai Kiado, 1975. p. 57-62. 3 fig.

Descriptors: Ammonia, Air pollution, Liquid wastes, Confinement pens.
Identifiers: Swine, Animal health.

Two experiments were performed in climatic chambers. In Experiment 1, fluctuations of ammonia concentration were determined at different temperatures as a function of time. In Experiment 2, the effect of the adjustment of liquid manure to a mildly acid pH on aerial ammonia concentration was examined. Various groups of bacteria present in the liquid manure were also examined for influence on air ammonia level, with special regard to urease-active bacteria. In Experiment I, 3 swine groups, each consisting of 4 animals weighing on average 75 kg, were placed in 3 climatic chambers in which all environmental conditions except temperature were identical. Before the experiment, stable floors were scrubbed. Air was completely exchanged and the inlet of the waste drains was closed. Air samples were taken at 0, 3, 7, 11, 16, 20, 24, 28, and 32 hours. After taking air samplings, samples were secured from the liquid manure for pH-determination and measurements of floor temperature were taken. Experiment 2 was performed on 2 groups of swine in 2 climatic chambers in which all environmental conditions were identical, but the floor of 1 chamber was strewn with 100 grams of superphosphate per square meter floor space. It was found that ammonia content of stable air is directly related to degree of floor contamination by liquid manure, population density, and moisture absorption properties of the flooring; whereas, it is inversely related to cleaning frequency and the degree of ventilation. If the floor is soiled with liquid manure, ammonia concentration will rise above the maximum tolerated level within 12 hours at the higher ambient temperatures. Liquid manure should be removed more than once daily if air exchange is poor. In stables with slatted flooring, continuous exhaustion of air from the dung passage is imperative, and if temperature rises, frequent evacuation of the dung passage is also necessary. If this is not possible, air exchange should be so controlled that it prevents the accumulation of ammonia. (Merryman-East Central)

LARGE-SCALE MANAGEMENT SYSTEMS AND ENVIRONMENTAL PROTECTION,

Agricultural College, Wroclaw, Poland
M. Cena
In: Progress in Animal Hygiene, F. Kovacs and P. Rafai, (ed). Budapest, Akademiai, Kiado, 1975. p. 63-65.

Descriptors: Pollution, Farm wastes, Waste storage.
Identifiers: Waste management, Environmental Protection, Hygiene.

All changes in the composition of soil, water, air and animal feed affect in due course man, who thus has to face not only the favorable but also the unfavorable consequences of his interference with the laws of nature. Thus the responsibility of the animal hygienist for the protection of human environment is multiple and great. His cooperation is wanted in the prevention of soil and water pollution by the wastes of large-scale animal production and he has the major share in establishing appropriate methods for the reduction of the bacterial load in liquid manure by disinfection in order to prevent the mediation of pathogenic agents to man and animals. Apart from the bacteriological, epidemiological and epizootological aspects, the disposal and handling of liquid manure present a score of other problems in respect to storage and utilization. Liquid manure may provide a haven for the eggs of many insects and pests. It also may be the source of obnoxious odors. (Merryman-East Central)

THE EFFECT OF AMMONIA ON THE ORGANISM OF POULTRY UNDER EXPERIMENTAL AND FIELD CONDITIONS,

Veterinary College, Kosice, Czechoslovakia
J. Rosocha, L. Para, O. Garaj, and M. Sitko
In: Progress in Animal Hygiene, F. Kovacs and P. Rafai, (ed). Budapest, Akademiai, Kiado, 1975. p. 66-68

Descriptors: Ammonia, Air pollution, Poultry, Performance.
Identifiers: Animal health, Czechoslavakia, Haematology.

The effect of various concentrations of aerial ammonia on health and production of layers and broilers was examined under Czechoslovakian laboratory and field conditions. Health state, behavior, qualitative and quantitative blood picture, haemoglobin and blood ammonia level were determined throughout the experimental period and examinations were made for gross and microscopic lesions related to excess aerial ammonia. Layers kept at 75-100 ppm ammonia concentrations developed keratoconjunctivitis, which lasted the initial 10-12 weeks and then disappeared. Birds exposed to 200±25 ppm aerial ammonia in boxes became restless and irritable. By day 2-3, the birds were apathetic, refused most of their food, drank much, and had sporadic occurrence of diarrhoea. At the end of the experiment, the birds were recumbent, lost appetite almost completely and showed cojuctivitis accompanied by lacrimation or exudation and a slight keratitis, as well as difficult respiration and exudation of the upper airways. Broilers exposed to excess ammonia consumed less food, showing weight gain decrease. Three-month exposure of layers to 40-60 ppm and 75-100 ppm ammonia resulted in a significant increase of erythrocyte count, and rise of haemoglobin level. Haematological data of the other experimental birds did not, however, differ significantly from control values. Differential blood cell counts showed a distinctive leukocytosis in birds exposed under field conditions and in those exposed in boxes to 200±25 ppm. Blood ammonia levels didn't differ significantly between experimental and control birds. Grossly, the birds exposed to 200±25 ppm showed a greyish-white cataract of the cornea, slight thickening, minor haemorrhages and hyperaemia of the mucosa of the lower lids and the upper airways. Birds exposed to lower concentrations showed similar changes for 3 months, after which degenerative changes of different degrees were found in hepatic and renal parenchyma. Microscopically, lesions of the corneal epithelium, heaemorrhages of the respiratory mucosa, epithelial desquamation, infiltration of the mucosa, submucosa and perivascular, area by lymphocytes and polymorphonuclear cells were found. (Merryman-East Central)

SOME RESULTS REGARDING LIQUID MANURE GAS POISONING,

Royal Veterinary College, Sakra Division, Sweden
O. Hogsved
In: Progress in Animal Hygiene, F. Kovacs and P. Rafai, (ed). Budapest, Akademiai, Kiado, 1975. p. 69-72. 13 ref.

Descriptors: Air pollution, Hydrogen sulphide, Liquid wastes, Waste storage, Ammonia.
Identifiers: Animal health, Sweden, Poisoning.

Many poisonings of cattle and pigs have occurred in Sweden as a result of heavy agitation of long-stored liquid manure. Acute cases have also occurred when agitation has taken place in manure tanks out of doors if there was an open connection between building and tank. Hydrogen sulphide is considered as the main cause of such poisonings. In acute poisoning, there is a general propensity for haemorrhaging and extravasation. Severe lung oedema and extensive haemorrhages in muscles and visceral organs are common. In many cattle houses with liquid manure handling, a special type of chronic disease has been observed (chiefly in dairy cows). Hydrogen sulphide and or other components of liquid manure gases are believed to be responsible for this chronic disease. The symptoms may vary depending on the degree of poisoning, but include tramped teats, hoof disorders, dullness of hair, loss of weight, and propensity to haemorrhage. It is also felt that gases may cause abortions in dairy cows and sows. The main therapeutic measure for combatting chronic poisonings is to improve the climate in the stable. Proper ventilation is of special importance in those animal houses in which agitation and/or recirculation of liquid manure is used. When designing new farm buildings, indoor storage of liquid manure should be avoided. (Merryman-East Central)

CONSIDERATION OF THE PARASITOLOGIC AND HYGIENEIC CONSEQUENCES OF INTENSIFICATION IN ANIMAL HUSBANDRY,

Agricultural Academy, Olsztyn, Poland
St. Tarczynski
In: Progress in Animal Hygiene, F. Kovacs and P. Rafai, (ed). Budapest, Akademiai, Kiado, 1975. p. 73-75

Descriptors: Parasitism, Management, Health.
Identifiers: Parasitology, Animal health, Poland.

The veterinary parasitologist is confronted with a score of new problems, which might be approached along the following lines of research: (1) Fluctuation of whole parasite populations under the conditions of intensive animal keeping, (2) Probable biological, dimensional, and structural alterations of parasite groups at extreme population densities of the host, (3) Impact of large-scale animal management systems on invasiveness of parasites, and its epizootological and hygienic consequences, with special regard to zoonoses, and (4) Development of new natural interrelationships between host and parasite, including the circulation of the latter in nature and in the man-made environment of large-scale farms. A deeper understanding of these problems is indispensable, not only for the prevention and control of parasitoses in intensively managed large groups of animals, but also for the protection of the environment of man from heavy contamination by those infective stages (cysts, eggs, larvae) which may also establish themselves in humans. (Merryman-East Central).

HYGIENIC PROBLEMS OF LIQUID MANURE TREATMENT ON LARGE-SCALE FARMS OF THE COUNTY TOLNA,

County Public Health Station, Szekszard, Hungary
A. Kovacs
In: Progress in Animal Hygiene, F. Kovacs and P. Rafai, (ed). Budapest, Akademiai Kiado, 1975. p. 76-77.

Descriptors: Liquid wastes, Waste treatment, Public health, Irrigation, Water pollution.
Identifiers: Hungary, Animal health, Waste management, Pathogens, Land disposal.

Large-scale management of livestock units has great technical advantages, but present methods of manure-handling permanently and perhaps irreversibly pollute the environment. This can only be prevented by the collaboration of agricultural technical, animal hygienic and public health experts. Liquid manure emanating from livestock units in county Tolna, Hungary, consists of non-composted diluted fresh feces and urine containing many pathogenic microorganisms. Because the liquid manure also contains many valuable ingredients, extensive studies are being conducted on its utilization for irrigation. In one pig unit of the county Tolna, the liquid manure flows through an expensive precipitating apparatus into a storage pond. The original idea was that the irrigation pipe system should be supplied directly from the pond, but this failed because of technical defects. At present, an emergency storage pond is used nearby the unit. In another unit, the liquid manure is collected in cisterns. Originally, a liquid manure tank with filling and emptying pump was planned to transport the manure onto arable land, but it could not manage the large amounts produced. Then, composting of the manure with grass was tried, but it was soon found that this manure doesn't yield to composting. At present, the manure is conducted in open ditches and is allowed to trickle away into the deep ploughed soil. This spoils the arable land which may become unfit for agricultural production within a few years, for agrobiological reasons. In order to resolve the waste management problem so that the requirements of hygiene and agricultural utilization may both be met, county health officials suggested the separation of the liquid and solid phase of the liquid manure in earth-pits. The solid phase could be used for fertilization or composting, whereas the liquid phase could be purified in ponds by using a suitable flora. This waste management is still in the experimental phase, and only the laboratory tests will testify to its efficiency. (Merryman-East Central)

NON-MECHANICAL VENTILATION OF ANIMAL HOUSING FACILITIES,

Extension Agricultural Engineer, The Pennsylvania State University, University Park
G. R. Bodman
Presented at the 1976 Annual Meeting, American Society of Agricultural Engineers, University of Nebraska, Lincoln, June 27-30, 1976, Paper No. 76-4041, 17 p. 9 fig, 1 tab, 8 ref.

Descriptors: Ventilation, Management, Design.
Identifiers: Cold housing, Non-mechanical ventilation.

Maintaining a quality environment for animals provides improved herd health, increased growth efficiency and eased management. Consequently, in planning an animal housing facility, a system must be developed which provides healthful environmental conditions within the animal space. In the case of an animal housing ventilation system, the functions are to remove moisture, excess heat, odors, and dust from the building while providing a continual supply of oxygen-rich fresh air for support of metabolic processes. With the advent of "cold" animal housing, "natural" or non-mechanical ventilation has gained interest. Variables which affect the performance of non-mechanical ventilation systems are: (1) animal heat production, (2) structural orientation, (3) ridge opening, (4) roof slope, (5) eave opening, (6) sidewall openings, (7) sidewall height, (8) insulation, and (9) miscellaneous structural details. Ventilating animal housing facilities without the use of mechanical equipment has been demonstrated to be practical and capable of providing the desired environmental conditions within the animal zone. The importance of certain structural details makes it essential that the ventilation system is considered from the beginning planning stages through to completion of the facility. MODELING THE EFFECTS OF MANAGEMENT ALTERNATIVES ON THE DESIGN OF CATTLE FEEDLOT RUNOFF CONTROL FACILITIES,

Department of Agricultural Engineering, Oregon State University, Corvallis
R. B. Wensink and R. J. Miner
Presented at the 1976 Annual Meeting, American Society of Agricultural Engineers, University of Nebraska, Lincoln, June 27-30, 1976, Paper No. 76-4034, 20 p. 2 fig, 10 tab, 2 ref.

Descriptors: Agricultural runoff, Design, Model studies, Feedlots, Climate, Precipitation, Effluents, Crop response.
Identifiers: Runoff control, Land disposal.

A cattle feedlot runoff control simulation model was developed which would integrate the effects of alternate dewatering policies on minimum facility volumes. The simulation model determined relationships between historical climatological data, dewatering schedules, and minimum feedlot runoff control volumes. The model was used at 7 selected locations in the United States to determine the effects of 5 pumping rates and 7 management dewatering alternatives on the minimum storage volumes required to prevent discharges as defined by EPA Effluent Guidelines. Stations were selected from each major climatic region in the United States and represented a broad spectrum of precipitation patterns. The 7 management policies were partitioned into 2 major classes. The first class permitted pond dewatering throughout the year while the second class allowed only non-winter disposals. The first management class required the minimum pond volume to satisfy the design criteria at all stations. The non-winter dewatering class simulated effluent disposal onto both corn and hay crops with variations of pre-planting and post-harvest disposals. At all stations, the corn scenario without post-harvest disposal, required the largest pond volumes. In addition to the minimum pond volume, the model also listed the average number of yearly pumpings for each simulated management alternative at a selected pumping rate. (Rowe-East Central)

MINNESOTA REGULATIONS FOR ANIMAL WASTE CONTROL,

Extension Agricultural Engineer, University of Minnesota, St. Paul
P. R. Goodrich
Minnesota Regulations for Animal Waste Control, Special Report 41, Agricultural Engineering, Agricultural Extension Service, University of Minnesota, 1973, 12 p. 3 fig.

Descriptors: Minnesota, Regulation, Feedlots, Waste storage, Transportation, Waste disposal, Permits.
Identifiers: Waste control.

This publication presents Minnesota animal waste control regulations, which were enacted in April, 1971, in a form that feedlot operators can easily understand. The regulations govern the storage, transportation, and disposal of animal wastes and the registrations and issuing of permits for the construction and operation of animal waste disposal systems. Control measures, where deemed necessary, are to be individually designed and developed to provide the specific controls needed for the operation in question. (Rowe-East Central)

NEW PRODUCT FOR MANURE ODOR CONTROL,

Wallaces Farmer, Vol. 101, No. 15, p. 80, 1976.

Descriptors: Livestock.
Identifiers: Odor control, NONScents.

A new product, NONScents, is being introduced by Haze Products of Trenton, Missouri to control manure odor. The product can be broadcast or sprinkled directly into areas where manure odor is a problem. NONScents provides a healthier environment for livestock and increases manure value. It can be used wherever animal waste is found. (Rowe-East Central)

NITROGEN IN SOIL CORES AND GROUND WATER UNDER ABANDONED CATTLE FEEDLOTS,

Soil Scientist, United States Department of Agriculture, Lincoln, Nebraska
L. N. Mielke and J. R. Ellis
Journal of Environmental Quality, Vol. 5, No. 1, p. 71-75, January-March, 1976. 5 fig, 2 tab, 17 ref.

Descriptors: Groundwater pollution, Nitrates, Sampling.
Identifiers: Abandoned feedlots, Soil cores.

Soil core samples were taken from 4 abandoned beef cattle feedlots and analyzed to determine their chemical and physical characteristics, The cores were compared with those from active upland, intermittently used feedlots and croplands. By means of continuous-flow automated analysis methods, ammonia-N and NO_3-N were determined on 1 M KCl soil extracts and clarified water samples. Percent soil water was determined on each sample. Soil cores were selected to characterize the percent water distribution at time of sampling and at 1/3 and 15 bars tension. The average of 7,210 kg/ha of NO_3-N in a 9.1 m soil core of the abandoned feedlot was higher than for any other of the comparable feedlot management practices. It was determined that an abandoned feedlot has great potential for nitrogen mineralization. Drying and cracking of the feedlot surface will open the feedlot surface to water and oxygen, and promote mineralization and leaching of NO_3-N into the deep profile and ground water. (Rowe-East Central)

MODEL STUDY OF FIVE TYPES OF MANURE PIT VENTILATION SYSTEMS,

District Agricultural Engineer, Nebraska University, Nebraska Experiment Station, Concord
S. H. Pohl and M. A. Hellickson
Presented at the 1976 Annual Meeting, American Society of Agricultural Engineers, University of Nebraska, Lincoln, June 27-30, 1976, Paper No. 76-4042, 37 p. 19 fig, 3 tab, 28 ref.

Descriptors: Model studies, Ventilation, Confinement pens, Design.
Identifiers: Swine, Air velocities, Air distribution, Manure pits.

A study was conducted to: (1) determine the influence of manure pit ventilation system geometry on air removal from a swine building and (2) evaluate the effects of pit ventilation system geometry on swine building ventilation characteristics. The performance of 5 types of pit ventilation systems were studied in a 1/12 size scale model swine finishing building. The systems were: (1) a slotted pipe underslat ventilator, (2) a centered duct pit ventilator, (3) an outside wall pit ventilator, (4) a hooded manure pit exhaust system, and (5) a pressurized pit ventilator. It was found that pit ventilation system design had a significant effect on average air flow velocities in the pit, but not at the swine level. Also, pit ventilation system location with respect to baffle ceiling inlet arrangement was important in developing proper ventilation design. Satisfactory air velocity distribution was achieved from the front to the back of the model for all pit ventilation systems with the exception of the outside wall pit ventilator. Relatively uniform air velocity flows were found in the model for the pressurized pit ventilator system, the centered duct pit ventilator, and the slotted pipe under-slat ventilator, when used with a center-baffled ceiling inlet. The fastest evacuation times were recorded using the pressurized pit ventilator system and the hooded manure pit exhaust system. The pressurized pit ventilator system had the best overall ventilation performance, with the centered duct pit ventilator also providing adequate ventilation characteristics. Poor ventilation characteristics were noted for the slotted pipe under-slat ventilator. (Rowe-East Central)

NITROGEN AND PHOSPHORUS LOSSES FROM WINTER DISPOSAL OF DAIRY MANURE,

Research Associate, Department of Agronomy, Cornell University, Ithaca
S. D. Klausner, P. J. Zwerman, and D. F. Ellis
Journal of Environmental Quality, Vol. 5, No. 1, p. 47-49, January-March, 1976. 3 tab, 2 fig, 16 ref.

Descriptors: Agricultural runoff, Watersheds, Nitrogen, Phosphorus.
Identifiers: Land disposal, Dairy manure, Nutrient losses.

An evaluation was made of surface runoff losses of inorganic nitrogen and total soluble phosphorus from fields receiving winter applications of dairy manure. Runoff losses, as derived from natural precipitation, were accumulated for the time period January 1 to March 31 for 3 consecutive years, (1972-1974). The manure treatments for a continuous corn cropping system were 35, 100, and 200 wet metric tons/ha. The 100 and 200 metric ton/ha rates were replicated twice, the 35 metric ton/ha was replicated 4 times for a total of 8 experimental plots per year. After each runoff event, a 250-ml subsample of the runoff was utilized for analysis. Runoff samples of 250-ml were centrifuged at 37,000 RCT (relative centrifugal force) for 30 minutes. The supernatant was analyzed for NH_4-N, NO_3-N, inorganic-P, and total soluble P. Adverse weather conditions during and after the winter disposal in 1972 caused increased nutrient discharges in runoff. This was especially evident at the 100 metric tons/ha rate which was applied on top of melting snow. The data clearly indicated that manure disposal during active thaw periods can result in excessive nutrient losses, while nutrient losses were minimized when manure was applied and then covered with snow, melting at a later date. The 35 metric tons/ha application rate, applied on frozen soil and then covered with snow before a thaw period, resulted in the lowest nutrient losses when compared to areas that received no manure at all. MIGRATION OF SALT FROM FEEDLOT WASTE AS AFFECTED BY MOISURE REGIME AND AGGREGATE SIZE,

Graduate Assistant, Department of Soils, Water and Engineering, Arizona University, Tucson
A. Amoozegar-Fard, W. H. Fuller, and A. W. Warrick
Journal of Environmental Quality, Vol. 4, No. 4, p. 468-472, October-December, 1975. 2 fig, 6 tab, 14 ref.

Descriptors: Salts, Nutrients, Saturation.
Identifiers: Land application, Feedlot wastes, Moisture regime, Aggregate size.

Migration of salt from 3 different aggregate sizes of feedlot manure under 3 moisture regimes was studied. The 3 sizes were small (to pass through a 40-mesh sieve), medium (0.9 cm in diameter, 2.25 cm in length), and large (4.8 cm in diameter, 2.6 cm in length). The 3 moisture regimes were: (1) 12 hours saturation, 12 hours drainage by gravity, repeated with 5 saturation cycles, (2) 12 hours saturation, 12 hours drainage by gravity, and 48 hours oven drying at 60 degrees C, also repeated with 5 cycles, and (3) continuous leaching for 60 hours at a constant rate. The experiment was assigned a completely randomized design with factorial combinations and 4 replicates for each treatment. After each 12 hour saturation, the leachates were collected and the electrical conductivity, pH, and concentrations of K, Na, Ca, Ma, NH_4, NO_3, Cl, S, P, and 8 trace elements were determined. The results indicated that the hazardous salts, K and Na, present in the manure were highly soluble and could be leached out readily. However, the divalent cations, Ca and Mg; and the nutrient materials, N and P; and trace elements were less soluble and migrated more slowly. The results also indicated that the larger the aggregate, the less of a chance for fast removal of salts under any water treatment. For best land application results, medium size aggregates of manure are probably best. They will provide a more uniform distribution and also a better salt management program than large-sized aggregates. It was found that intermittent irrigation is preferable to continuous leaching for salt management purposes. The total loss of nutrients under continuous leaching was greater than the total loss under intermittent saturation, although the loss in K, Na, Ca, and Mg was less severe. (Rowe-East Central)

A NOTE ON THE RECOVERY OF POLYETHYLENE PARTICLES FROM FAECES AND RUMEN CONTENTS OF STEERS,

School of Agriculture, 581 King Street, Aberdeen, Scotland
J. Fordyce and M. Kay
Animal Production, Vol. 18, No. 1, p. 101-104, 1974.

Descriptors: Feeds.
Identifiers: Polyethylene particles, Roughage, Retention time.

Two experiments were conducted with 3 types of polyethylene particles to determine their retention time in castrated male cattle offered diets which contained predominantly cereals ad libitum. Three types of polyethylene particles were used: (1) corrugated particles, of length 1.27 cm, breadth 0.95 cm, depth 0.63 cm and specific gravity 0.92 (RT), (2) rods, of length 1.27 cm, diameter 0.32 cm and specific gravity 0.94 (BP), and (3) particles having the same dimensions and specific gravity as RT, but being circular in cross-section, without the corrugated edges of RT (RBP). In all the steers used in the experiments, polyethylene passed through the alimentary tract to be lost in the feces. The loss was most rapid in the heaviest of the steers. The short retention time of the plastic in these steers suggests that it does not remain in the rumen long enough to act as an effective substitute for roughage. Since polyethylene also passed through the alimentary tract of steers weighing 170 and 250 kg live weight at an appreciable rate, it may be necessary to repeat doses of the polyethylene particles at frequent intervals. (Rowe-East Central)

MANAGING FEEDLOTS FOR ODOR CONTROL,

Agricultural Engineer, Texas Agricultural Extension Service, Texas A&M University System, College Station
J. M. Sweeten and D. L. Reddell
Presented at the 1976 Annual Meeting, American Society of Agricultural Engineers, University of Nebraska, June 27-30, 1976, Paper No. 76-4016, 24 p. 4 fig, 2 tab, 30 ref.

Descriptors: Feedlots, Agricultural runoff, Liquid wastes, Solid wastes.
Identifiers: Odor control, Location, Odor measurement, Manure pack, Stockpiling, Land disposal, Chemical control, Settling basins, Retention ponds.

While location is considered the key to feedlot odor abatement, there are specific odor alleviating techniques that may be employed by feedlots that are not well located and that have odor problems. Economically feasible odor control practices include the following: (1) Maintain excellent surface drainage at uniform feedpen slopes of 1 percent (for dry areas) to 4 percent (for moderately humid areas). (2) Collect only loose surface (aerobic manure) at frequent intervals. (3) Use elevating scrapers or road graders for collection. (4) Maintain a compacted (anaerobic manure pack on the feedlot surface at all times. (5) Dispose of dead animals within 48 hours. (6) Dewater feedlot runoff retention ponds as quickly as possible. (7) Separate manure solids from feedlot runoff by maintaining ideal pen slopes and constructing settling basins on channels. Temporary odor control may be achieved by the use of chemicals in the form of masking agents, counteractants, chemical deodorants, or digestive odorants. (Merryman-East Central)

MANAGING DAIRY WASTE HOLDING PONDS IN THE CENTRAL VALLEY,

Farm Advisor, Stanislaus County, California
E. H. Olson, G. A. Hutton, Jr., and J. L. Meyer
Leaflet 2326, Division of Agricultural Sciences, University of California, August, 1975, 5 p. 3 fig, 1 tab.

Descriptors: Waste storage, Irrigation, Nutrients, Odor, Insects, Legal aspects.
Identifiers: Holding ponds, Land disposal, Animal health.

Waste holding ponds are efficient and economical for collecting, temporarily storing, and diluting animal waste for use in basin or flood irrigation systems. However, proper management of waste holding ponds is necessary for conserving nutrients, controlling odors and insect vectors, meeting legal requirements, and improving animal health. Tips for good management are: (1) Empty the entire pond, including all sludge, at every possible irrigation to save nutrients. (2) During hot summer months, empty the pond completely at least once a month. Empty the pond during the last irrigation of the season to ready it for winter storage. (3) Whenever the pond is emptied, add about 1 foot of fresh water to prevent odors. (4) Install liquid-solid separators when floating solids are a problem. Such solids can clog small irrigation valves or siphon tubes, encourage vectors and cause odors. (Merryman-East Central)

METHANE FARMING IN KENYA

Tunnel Estate, Fort Ternan, Kenya
T. H. Hutchinson
Compost Science, Vol. 13, No. 6, p. 30-31, November/December, 1972.

Descriptors: Recycling, Methane, Sludge, Crop response.
Identifiers: Kenya, Land disposal, Coffee, Compost.

The methane plants discussed in this article were designed to operate from (a) grass, straw, coffee pulp and other organic material mixed with manure and (b) manure mixed with water to make it into a liquid sludge. The difference between them is that type (a) consists of a series of compartments which are filled and emptied in rotation, and which produces compost and liquid manure and type (b) is one large compartment that is topped up daily with fresh manure. This displaces an equal quantity of digested sludge, and so the fermentation is continuous. Since 1955, 150 tons of compost and 18,000 gallons of liquid manure have been produced from the type (a) plant, and since 1957, approximately 90,000 gallons of sludge has been produced each year from type (b) plant. The compost and sludge was applied to 3 different blocks during different time periods. Block 1 (12.5 acres) was first planted in 1925. Block 2 (14 acres) was first planted in 1932. Block 3 (24 acres) was first planted in 1937. For 7 years prior to the building of the first methane plant (1948-1954) the average coffee yield for these blocks was 2.56 cwt. clean coffee per acre, and for the 7 years after commencing to use the residue from the plants the average yield rose to 5.93 cwt. It may also be noted that the fertility appears to be rising progressively. The figure for the last 3 seasons (1959-1961) has risen to 6.95 cwt. The gas produced by the plants is used in the house for cooking, water heating through a geyser, and a converted paraffin refrigerator. The gas has also been found to be an excellent fuel for stationary engines and production of electricity. (Rowe-East Central)

INFILTRATION OF WATER ON A CATTLE FEEDLOT,

Soil Scientist, Agricultural Research Service, U.S. Department of Agriculture
L. N. Mielke and A. P. Mazurak
Transactions of the ASAE, Vol. 19, No. 2, p. 341-344, March-April, 1976. 3 fig, 4 tab, 15 ref.

Descriptors: Feedlots, Infiltration rates, Groundwater pollution, Hydraulic conductivity, Porosity, Bulk density.
Identifiers: Manure pack, Air permeability.

Four undisturbed soil cores from an active cattle feedlot, encased in heat-shrink plastic, were used in the laboratory to measure infiltration. Six additional undisturbed feedlot soil cores and 2 cores from adjacent cropland were taken for measurements of air permeability, hydraulic conductivity, porosity, particle-size distribution, bulk density, and organic matter content. Early field observations of outdoor cattle feedlots showed that a dense layer exists near the soil surface that apparently decreases water intake. Research results showed a low NO_3-N content in the groundwater (1-2 m depth) in the immediate vicinity of the feedlot in contrast with much higher NO_3-N content in wells under cropland. Water intake in the feedlot and into undisturbed complete feedlot soil cores was extremely slow (range from 0.38 x 10^{-4} to 2.3 x 10^{-3} cm/day. Air and water permeabilities were lowest in the interface section and increased in the soil below. Water permeability increased 28-fold between the interface layer and the next layer 10 cm deeper. Bulk density was 1.68 g/cm^3 in the mineral soil in the interface layer. Interface soil showed maximum compaction of 1.70 g/cm^3 at 18 percent water content. No water moved through the interface material during 6 days. Undisturbed feedlot soil cores and feedlot interface material compacted at water content for maximum density were found to be effective barriers to water movement, an important fact in understanding feedlot hydrology and protecting groundwater quality. KEARNEY FEEDER'S EARLY EFFORT EARNS ENVIRONMENTAL AWARD,

Anonymous
Nebraska Farmer, Vol. 118, No. 14, p. 18, July 17, 1976. 2 fig.

Descriptors: Management, Feedlots, Design.
Identifiers: Awards, Holding ponds, Land disposal.

Lewis Feedlot, Inc. won the third annual J. L. Higgins Award for outstanding efforts in controlling livestock waste. Between $150,000 and $200,000 was spent on construction of the 4 waste control systems in use on his 160-acre feedlot. The feedlot is located on flat valley land adjacent to the Wood River northeast of Kearney which, Lewis said, complicated the waste disposal problem. It meant that all the rainfall that falls on that lot had to be controlled so it wouldn't flow into the river. The difficulty was overcome by building mounds at the center of each pen in the feedlot and sloping the land away from the feed bunks toward the other side of the lot, where the drainage ditches channel wastes into holding ponds. Several wire-screened debris traps made of hardware cloth were located in the drainage ditches to separate solid from liquid wastes and slow the liquids. From the holding pond, an electrical pump is used to pump the liquid wastes through gated pipeline so it can be distributed down rows on cropland whenever the pond requires emptying. Solid wastes are spread on the cropland as fertilizer. The Lewis farm unit includes about 1,200 acres of irrigated land and 600 acres of dryland. Corn lot silage is the main crop. (Rowe-East Central)

LAND DISPOSAL OF SWINE MANURE,

Texas Agricultural Extension Service, The Texas A&M University System, College Station
J. M. Sweeten and C. D. Welch
Publication MP-1269, Texas Agricultural Extension Service, Texas A&M University, March, 1976, 8 p. 3 fig, 5 tab.

Descriptors: Anaerobic lagoons, Effluents, Nutrients, Fertilizers.
Identifiers: Land disposal, Swine manure, Storage pits.

Information is given concerning the nutrient content, the effects on soils, and the application rates of swine manure and anaerobic lagoon effluent. It was determined that: (1) Liquid swine manure from underfloor storage pits can be safely applied to most Texas soils at the rate of 5000 gal/acre/year. (2) Effluent from anaerobic lagoons serving swine confinement units can be safely applied to most soils in Texas at the rate of 20,000 gal/acre/year without causing nitrogen accumulations in the soil, provided that high nitrogen requiring crops are grown. (3) At these rates, the amount of land recommended for terminal disposal of liquid swine manure without lagoon treatment is 1 acre/sow (farrowing unit capacity) for total confinement farrow-to-finish operations, or 9 acres per 100-market-hor capacity for finishing operations. (4) Lagoon treatment of swine wastes results in an appreciable loss of the fertilizer value of manure, but also reduces the land area requirements for disposal. (Rowe-East Central)

ISOLATION OF INFECTIOUS BOVINE RHINOTRACHEITIS VIRUS FROM FECES OF A FEEDER STEER,

Laboratories of Veterinary Diagnostic Medicine, University of Illinois, Urbana
R. A. Crandell
American Journal of Veterinary Research, Vol. 35, No. 7, p. 951-952, July, 1974. 1 tab, 13 ref.

Descriptors: Viruses, Animal health.
Identifiers: Feces.

A study was conducted to describe the isolation of infectious bovine rhinotracheitis (IBR) virus from a rectal swab. Isolation was made from a feeder steer during a feedlot epizootic of IBR involving 246 non-vaccinated steers. Thirty percent of the steers had mucopurulent ocular discharge; 1 percent had mucopurulent nasal discharge; and many steers were coughing. Viral specimens were grown in cultures containing 2 times normal concentration of antibiotics and stored at -70 degrees C until tested Madin-Darby bovine kidney cells were grown in culture mediums containing 200 units of penicillin, 200 μg of streptomycin, and 2.5 μg of amphotericin B per milliliter. The kidney cell cultures were inoculated with 0.1 and 0.2 ml of the supernatant of each specimen. The cells were incubated at 36 degrees C and observed each day for cytopathic effect. Serum-ne Serum-neutralizationhtests were conducted by mixing 200-800 median tissue culture infective doses of each of the isolates with an equal volume of twofold dilutions of known IBR-immune serum, incubating for 30 minutes at 37 degrees C, and inoculating each of 3 MDBK tubes with 0.2 ml of each serum-virus mixture. The MDBK cell cultures inoculated with the conjunctival and nasal swabs from steer 2 and the conjunctival swabs from steer 4 had cytopathic effect (CPE) characteristics of IBR virus 48-72 hours after inoculation. The CPE in the cultures inoculated with rectal swab from steer 4 was observed 96 hours after inoculation. Results of examinations of all other specimens were negative for virus. Study results indicated that virus was active in the herd several weeks before the clinical illness was recognized and that the infection was limited to the upper respiratory tract. MANAGEMENT OF LAGOONS FOR ODOR CONTROL,

Department of Biological and Agricultural Engineering, North Carolina State University, Raleigh
M. R. Overcash, F. J. Humenik and P. W. Westerman
Presented at the 1976 Annual Meeting, American Society of Agricultural Engineers, University of Nebraska, Lincoln, June 27-30, 1976, Paper No. 76-2017, 18 p. 5 fig, 6 tab, 13 ref.

Descriptors: Lagoons, Management, Aeration, Nitrogen, Dissolved oxygen, Chemical oxygen demand.
Identifiers: Odor control.

The response of unaerated lagoons to different loading intensities and variable aeration was studied. Particular attention was given to constituent removals and odor potential. Liquid samples from field pilot-scale lagoons were taken at mid-depth. Samples were refrigerated at approximately 4 degrees C until analyzed. All tests were run in accordance with procedures outlined in Standard Methods (1971) and demonstrated animal waste adaptations (Overcash, 1975). Based upon periodic field observation and odor panel rankings, it was determined that there was a discernible odor threshold for unaerated swine waste lagoons loaded at approximately 9.2-18.4 m^3/45-kg hog. Individual consensus indicated that the frequency or probability of odor detection, when visiting the unaerated lagoon site, was 80 percent for the unit at 0.6 m^3/45-kg hog; 60 percent for 2.3 m^3 45-kg hog; 20 percent for 4.6 m^3/45-kg hog; and little odor for units with 9.2 m^3/45-kg hog. No dissolved oxygen was found at depths greater than 10 cm. Supernatant organic and nitrogen concentrations for surface aerated units without bulk phase dissolved oxygen was found in aerated units. Reduced odor potential existed for surface aerated units at the same loading intensity in comparison to similar unaerated reactors. Supernatant COD and TOC concentrations increased with increased aeration rates from 37-120 watts and associated greater bottom scour, while TKN concentrations only modestly increased, indicating that the greatest impact of surface aeration was on nitrogen reduction by ammonia volatilization. IRRIGATION WITH FEEDLOT RUNOFF,

Animal Waste Management Research Unit, North Central Region, Agricultural Research Service, U. S. Department of Agriculture
C. L. Linderman and L. N. Mielke
In: Proceedings, Nebraska Irrigation Short Course, Agricultural Engineering, "Irrigation" No. 9, Lincoln, Nebraska, January 20-21, 1975, p. 26-37, 2 fig, 4 tab, 7 ref.

Descriptors: Irrigation, Feedlots, Agricultural runoff, Crop response, Nitrates, Salts, Sampling.

A plan for feedlot runoff disposal should consider: (1) the volume of runoff, (2) the cropland area available for disposal, (3) soil types and problems, (4) crop grown, (5) irrigation method, (6) existing usable irrigation systems or equipment, and (7) the time available for effluent disposal. Feedlot runoff may be either surface or sprinkler irrigated onto cropland. When furrow irrigation is used, the furrow should be left in place after harvest, since it is usually desirable to dispose of runoff in fall and early spring. Sprinkler irrigation has the disadvantage of depositing effluent solids on the crop foliage, a fact of particular importance if the whole plant is to be harvested. Sprinkler irrigation also increases the odor problem. Research in eastern Nebraska has shown the effect of frequent feedlot runoff applications on growth and yield of corn, perennial forages, and forage sorghum. Runoff was collected in a holding pond and applied weekly to small plots during the irrigation season. Application was made by furrows to corn and forage sorghum and by surface flooding on perennial forages. Corn and forage sorghum received the most benefit from feedlot effluent when about 10 to 15 inches were applied per year. Anyone planning a disposal system to apply effluent in amounts greater than about 5 inches per year should consider the solids, nutrients, and salt content of the effluent used. Effluent sampling should be done close to application time because the effluent may change greatly with time in storage. A soil sampling program should also be conducted. Where salt is force-fed in the feedlot, particular attention should be given to the salt content of the effluent and the soil. When large amounts of nitrogen are applied, followed by stress on plants, the nitrate content of the forage should be checked. (Rowe-East Central)

SOME SOIL STRENGTH PROPERTIES INFLUENCED BY LIVESTOCK WASTE,

Agricultural Engineering Department, South Dakota State University, Brookings
C. E. Johnson, R. J. Devine, M. E. Bjerke, and C. A. Onstad
Presented at 1974 Annual Meeting, American Society of Agricultural Engineers, Oklahoma State University, Stillwater, June 23-26, 1974, Paper No. 74-1014, 10 p. 8 fig, 10 ref.

Descriptors: Crop response, Moisture content, Bulk density, Adhesion.
Identifiers: Land disposal, Soil properties, Penetration resistance, Soil-metal friction angle, Apparent cohesion.

Total livestock wastes produced in the United States are almost two billion tons a year. Utilization and disposition of these wastes are a critical concern of the public. Disposal of livestock wastes on cropland for decomposition and mineralization has been concluded to be the most efficient method. Because of this, questions have been raised as to how much livestock wastes can be applied to cropland areas without causing harmful effects to crop production and to the soil. Cattle manure was applied to 12 experimental field plots of Egan-Wentworth silty clay loam soil in the fall of 1971, 1972, and 1973, after the soil was frozen. Application rates of 0, 55.8, 83.7, and 111.7 wet tons per acre were used in the fall of 1971. During the fall of 1972 and 1973, the application rates were almost tripled. All plots were plowed, disked, and planted to corn in the spring following the fall application of cattle manure. Moisture content, bulk density, and soil characteristics were measured during the experimental period. Experimental data revealed that (1) there was no significant difference due to application rate in the forces required to till the soil, (2) moisture content increased when application rates were above 120 wet tons per acre, and (3) soil-metal friction angle decreased. THE EFFECT OF RATION FORMULATION ON THE SUBSEQUENT GENERATION OF VOLATILE GASES AND ODORS FROM BOVINE WASTE,

R. O. Kellems
PhD Thesis, Oregon State University, June, 1976, 59 p. 5 fig, 15 tab, 81 ref.

Descriptors: Odor, Gases, Rations, Waste storage, Hydrogen sulfide, Ammonia, Amines, Moisture content.
Identifiers: Cattle wastes.

This study was conducted to determine the effect that ration formulation has on volatilization of gases and offensiveness of the odor associated with the wastes from Holstein replacement heifers. The relationships between different variables on the release of hydrogen sulfide, ammonia, total nitrogenous gases and amines were studied in 6 separate experiments. Experimental results were: (1) As the cereal grain level of supplementation was increased from 50 to 75 percent of the diet, the rate of hydrogen sulfide evolution also increased. (2) After studying the urine and feces obtained from animals maintained on the various grains and levels of 25, 50, and 75 percent, the pH indicated a difference between grain sources. Milo caused the lowest pH and barley caused the highest. (3) When urine was stored, the rate of volatilization was highest during the first 5 days and then the rate declined. However, when feces only were stored, the rate increased as the storage period increased. This showed that urea is rapidly hydrolyzed to form ammonia under anaerobic storage conditions. (4) About 0.11 percent of the volatile basic nitrogenous gases initially volatilized from the waste was found to be amines. (5) A positive correlation was found to exist between the ammonia release and the amine evolution rate. (6) The moisture content of the waste samples were negatively correlated with the volatilization of the nitrogenous gases. (Edwards—East East Central)

MAKE A PROFIT ON MANURE,

American Farmer, Vol. 47, p. 30, January, 1972.

Descriptors: Fertilizers, Recycling, Feedlots, Dehydration, Odor, Economics.
Identifiers: Cattle manure.

The Thomason Ranch feedlot near Fayetteville, North Carolina, has begun to capitalize on manure. A dehydration operation was started about 8 years ago and the ranch now makes a profit out of manure by dehydrating, bagging, and selling it for the garden trade. Thomason Ranch buys manure for a small fee from a number of dairy farms in Cumberland County and processes it along with what comes from their feedlot. Since manure mixed with dirt wears out grinding equipment, only manure from dairy cows on concrete is used. A payloader tractor scoops up the manure and dumps it into big bins where it is mixed with pine bark to absorb much of the moisture. A big revolving drum drier is used to dehydrate the manure. The manure is then sterilized to kill weed seeds. A hammermill is then used to grind the manure into uniform consistency. It is then bagged in 50 or 100 lb bags for the gardeners. Chicken manure was experimented with, but the feathers mixed in with the manure caught on fire in the drier. The manure mixture, as sold, has been analyzed as 1-1-1. Problems encountered by this ranch have been: (1) a tornado which did widespread damage, (2) continued equipment investment, (3) fire hazard of stored manure, (4) seasonal nature of fertilizer sales requires a high inventory, and (5) complaints from the city of Fayetteville about feedlot odor when the wind is from the east. UTILIZATION OF ANIMAL MANURES AND SEWAGE SLUDGES IN FOOD AND FIBER PRODUCTION

Council for Agricultural Science and Technology
Report No. 41, Council for Agricultural Science and Technology, Iowa State University, February, 1975, 27 p.

Descriptors: Recycling, Animal wastes, Sewage sludge, Feeds, Fertilizers, Soil amendments, Economics, Salts, Heavy metals, Water pollution, Management, Land reclamation, Public heath, Crop response, Odor.
Identifiers: Land disposal.

Proper use of animal manure and sewage sludges as fertilizers, soil additives, and animal feed could improve water and air quality and save fuel and feeds resources. Application to agricultural and forest lands is influenced by physical, chemical, microbiological, sociological, economic, political, and legal factors. Limitations to use as fertilizers are bulk, low quality, variable composition, inefficiency of application and expense of transportation. They may require drying, are difficult to store, and may contain large quantities of soluble salts (especially nitrates), heavy metals, pathogenic microorganisms, odors, etc. Fear of disease has hindered use of animal manure in animal feeds. Decreasing salts, trace metals, and bacteria accompanied by quality control would make these waste products more competitive with chemical fertilizers. Conservation of the ammonia produced and development of storage systems would be beneficial. Guidelines for use which are based on facts and acceptable risks which can be interpreted in terms of local and regional conditions are needed to protect public health and environmental quality. Educational, research, and demonstration projects would improve management of sewage sludges and animal manures and would convince the population that their use can be beneficial. (Buchanan; Davidson-Wisconsin)

MODELING THE ENVIORONMENTAL AND ECONOMIC EFFECTS OF DAIRY WASTE MANAGEMENT

Agricultural Waste and Watershed Research Engineer, Stittsville, Ontario, Canada
D. R. Coote, D. A. Haith, P. J. Zwerman
Transactions of the ASAE, Vol. 19, No. 2, p. 326-331, March-April, 1976. 3 fig, 2 tab, 35 ref.

Descriptors: Model studies, Dairy industry, Economics, Management, Nitrogen, Phosphorus, Regulation.
Identifiers: Farm income, Soil losses.

Study objectives were: (a) to develop a mathematical model of sufficient general applicability to permit its use in analyzing a variety of environmental problems for the New York dairy farm, (b) to utilize the model to provide quantitative estimates of farm income and soil, nitrogen, and phosphorus losses associated with different cropping, manure handling and fertilizer-practices and herd sizes, and (c) to apply the model to selected dairy regions in New York to determine whether nutrient management policies which maximize farm income result in significant losses of soil, nitrogen and phosphorus to the environment. Average dairy farms were modelled in Western Jefferson and southwest Oneida counties. The Jefferson County region has poor soils and flat slopes; whereas, the Oneida location has highly productive soils and relatively steeper slopes. Results showed that, while a dairy farm model provides less than exact estimates of economic and environmental impacts, it can provide useful insights which the agricultural engineer or scientist can use to supplement both his experience and field experiments. The degree of conformity with environmental objectives is likely to be more a function of the farmer's land and soil resources than his management practices. It is felt that attempts to regulate the dairy farm to achieve protection of the environment will be successful only if regulations are sensitive to the natural resources limitations within which each farmer must operate. Waste management and cropping, fertilization and soil conservation decisions are best made on a case by case basis, recognizing the unique land resources of each farm. (Rowe-East Central)

LONG-TERM NITROGEN RATES AND SOURCES INFLUENCE SUGARBEET YIELD AND QUALITY,

Soil Scientist, ARS-USDA
A. D. Halvorson and G. P. Hartman
Agronomy Journal, Vol. 67, No. 3, p. 389-393, May-June, 1975. 3 fig, 3 tab, 22 ref.

Descriptors: Crop response, Organic wastes, Fertilizers, Nitrogen, Sugar beets.
Identifiers: Land applications, Sucrose, Crop rotation.

This study was made to evaluate the longtime residual effects of applying various rates and combinations of organic and inorganic N-fertilizer sources on sugarbeet yields, sucrose content, apparent sucrose purity, and other factors related to maximum production. The experiment was conducted at Disney, Montana, on a nearly level, irrigated Savage silty clay soil having an organic matter content of 2.99 percent. The 11.6 x 24.6 m plots were arranged in a completely randomized design with 3 replications. The experiment consisted of 14 treatments, 8 of which were sugarbeets followed by barley, until 1963; thereafter, barley was replaced by Spring wheat. Highest gross sucrose yield for the inorganic N treatments was obtained with the application of 112 kg N/ha. Application of more than 168 kg/ha of inorganic N resulted in sucrose yields that were not significantly greater than the check. Application of 22.4 metric tons/ha barnyard manure resulted in a significant yield increase when compared with the check (O-N) treatment, and the highest gross sucrose yield for all treatments in this study. Adding 67.2 metric tons/ha of barnyard manure, with or without supplemental inorganic N, reduced gross sucrose yield when compared with the 22.4 metric tons/ha manure treatment. Application of inorganic and organic N resulted in increase production of dry matter in the beet tops and reduced the root/top ratio, with the exception of 22.4 metric tons/ha barnyard manure treatment, which had a dry matter root/top ratio as high as the check. The data indicated that barnyard manure can be utilized to produce quality sugarbeets and at the same time dispose of a waste and potential pollution product. (Rowe-East Central)

SOIL-PLANT RUNOFF CHARACTERISTICS FROM LAGOON EFFLUENT DISPOSAL AREAS,

Department of Agricultural Engineering, Virginia Polytechnic Institute and State University, Blacksburg
E. R. Collins, Jr., E. T. Kornegay, and D. C. Martens
Presented at the 1975 Winter Meeting, American Society of Agricultural Engineers, Chicago, Illinois, December 15-18, 1975, Paper No. 75-2559, 11 p. 7 fig, 3 ref.

Descriptors: Lagoons, Anaerobic conditions, Aerobic conditions, Biological treatment, Virginia, Soil contamination, Agricultural runoff, Nutrients, Chemical properties, Physical properties, Biological properties.
Identifiers: Swine.

Two separate concrete treatment tanks were constructed at the Virginia Polytechnic Institute and State University. They were designed so that they could be operated as a two-stage lagoon system or could be maintained as separate systems. Pits were connected to the separate tanks. One unit is being operated as an anaerobic system based on design volumes required by USDA Soil Conservation Service Virginia Standards. The other unit is equipped with a 3-housepower floating aerator operated on a percentage timer to provide aeration at a rate equivalent to twice its estimated daily BOD_5. Each treatment tank contains a small submersible pump for recycling effluent from the tank to flush its companion waste collection pit. Pits are flushed 5 times daily. A permanent waste irrigation system has been installed to distribute treatment tank effluent on soil-plant disposal plots. Sampling of all stages of each system is being done in order to obtain data to support meaningful conclusions. The experiment is still in progress, but study objectives are: (1) to compare 2 systems of biological treatment for swine wastes in Virginia, (2) to monitor wastes from the 2 confinement swine production facilities and effluent from their companion waste treatment systems to determine the degree of biological treatment afforded and fate of mineral feed constituents, and (3) to measure the effects of application of the lagoon effluent from the 2 systems on runoff water quality and pollutant accumulation in soil-plant disposal areas. METHANE RECOVERY FROM ANAEROBIC LAGOONS,

Associate Professor, University of Florida
R. A. Nordstedt, J. P. Bowden, A. B. Bottcher, and J. Kutt
Presented at the 1976 Annual Meeting, American Society of Agricultural Engineers, University of Nebraska, Lincoln, June 27-30, 1976, Paper No. 76-4029, 19 p. 4 fig, 9 tab, 9 ref.

Descriptors: Methane, Recycling, Anaerobic lagoons, Economics, Corrosion.
Identifiers: Gas collection, Floating covers.

Methane gas, which is a component of biogas produced in the anaerobic decomposition of organic material, is being studied as a substitute for electrical and fossil fuel energy. This study was done with the following objectives in mind: (1) to demonstrate the construction and use of floating covers to collect gas from anaerobic lagoons, (2) to characterize the gas with regard to composition, corrosiveness, and potential for use on the farm, (3) to evaluate materials and equipment used in the system, and (4) to determine the economic feasibility of methane collection from anaerobic lagoons, storage requirements and potential for use in animal production units. Three floating biogas collectors were constructed with different size, type of membrane and method of gas removal. The membrane used in collector A only weighed 0.16 kg per sq m. It was chosen due to its: (1) excellent resistance to outdoor exposure, (2) relatively high tear strength, (3) low cost, and (4) low weight. The membrane used for Collectors B and C was 0.61 kg per sq m polyvinylchloride coated 10 x 10 1,000 denier polyester scrim fabric which was reported by the manufacturer to be resistant to acids, alkalies, salts, fungi and livestock waste and soil microorganisms. Problems did develop during the experiment, ie. Collector A quickly developed leaks due to punctures in the membrane and the polyethylene and polyvinyl chloride pipe membrane supports in collectors A and B softened and collapsed. However, such problems can be recitified. Overall, the experiment was considered successful; however, the system was not in operation long enough to identify any corrosion problems which may arise in the compressor storage tanks or in equipment utilizing the gas. ECONOMIC EFFECTS OF SURFACE WATER RUNOFF CONTROLS ON MICHIGAN BEEF FEEDLOTS,

Agricultural Economist, Economic Research Service, U.S. Department of Agriculture.
J. B. Johnson and G. A. Davis
Michigan Farm Economics, No. 374, Department of Agricultural Economics, Michigan State University, March, 1974, 4 p. 4 tab.

Descriptors: Agricultural runoff, Legal aspects, Feedlots, Michigan, Management, Economics.
Identifiers: Point sources, Housing, Permits.

On or before July 1, 1977, effluent guidelines for all categories of point source dischargers will require the application of the best practicable control technology available. This study assesses the economic effects of implementing these guidelines on the Michigan beef feeding industry. Four primary types of housing are currently used in Michigan feedlots. Most prevalent is the dry-lot unpaved housing system which combines a shelter and an exposed area. Total confinement and open-lot systems are not prevalent in Michigan. The total confinement systems consist of either a cold-covered shelter enclosed on 3 sides with the fourth side fenced, or a warm-enclosed shelter with all sides enclosed. The open-lot systems have no roofed shelter. In Michigan, most open-lot systems consist of a fenced lot with a fenceline bunk and an adjoining surfaced apron. Generally, runoff and process waste water control problems are greatest for those systems with more exposed area per animal if other conditions (location and rainfall) are similar. In Michigan, the open-lot systems provide the largest square footage per animal. Followed closely by dry-lot unpaved housing systems. Capital outlays for diversion terraces and size of settling basin depend on the size of the exposed feedlot area. In Michigan, there are only a few beef feeding operations exceeding 1,000 head capacity which will be subject to announced EPA effluent guidelines and permit program. (Rowe-East Central)

DON'T SLACKEN FEEDLOT FLY CONTROL,

Nebraska Farmer, Vol. 118, No. 13, p. 59, July 3, 1976.

Descriptors: Insecticides, Performance, Feedlots.
Identifiers: Fly control, Sanitation, Feed additives, Rabon, Wasps.

Jerry De Witt, an Iowa State University Extension entomologist, says that a regular sanitation program throughout the summer is the key to effective control of feedlot flies. Houseflies and stable flies prefer to breed in the type of manure and organic matter found in and around feedlots. Houseflies are a nuisance because they spread bacteria and pathogens. Stable flies have been shown to reduce weight gains of beef animals due to the irritation that their bite produces. Both stable and house flies multiply rapidly until their populations peak in August. A sanitation program involving regular removal of potential fly breeding areas should be practiced both in the feedlot and in adjacent areas. Chemical treatments may also be used. Residual sprays can be applied to sunny areas where flies rest. A second chemical treatment is to use a tractor-mounted mistblower to spray a fine mist onto areas where adult flies are resting. This should be done once a week. The use of a feed additive will also assist in fly control. Rabon can be used as a pre-mix for feedlot animals, but each animal must eat the required amount daily for the additive to be effective. Experimentation is in progress in which parasitic wasps are being released in feedlots to control flies. (Rowe-East Central)

BACTERIOLOGICAL IMPACTS OF NONPOINT SOURCES ON RECREATION LAKES,

Sanitary Engineer, Soil Conservation Service, Jackson, Mississippi
J. P. Burt
Presented at the 1976 Annual Meeting, American Society of Agricultural Engineers, University of Nebraska, Lincoln, June 27-30, 1976, Paper No. 76-2082, 21 pg. 5 fig, 7 tab, 4 ref.

Descriptors: Water quality, Lakes, Agricultural runoff, Bacteria, Sampling, Water pollution control.
Identifiers: Non-point sources.

Bacteriological impacts of nonpoint sources on recreation lakes were studied. The planning process requires the evaluation of numerous variables related to recreation, and water quality has proved to be one of the most difficult to evaluate. The water quality evaluation procedure can be separated into 3 components — field reconnaissance, water sampling analysis, and projections of impoundment water quality. Specific parameters for which water samples are analyzed are: dissolved oxygen, pH, temperature, bacteria, specific conductance, dissolved solids, and toxic substances, color, taste and odor producing substances. The projection technique used in these studies for estimating future impoundment bacterial quality is based on the geometric mean of the bacterial concentration of bacteria in the reservoir. Results showed that nonpoint waste sources have a definite impact on the water quality of storm runoff, but the magnitude appears to be influenced by numerous factors that cannot be easily recognized and measured. Sampling a storm event provides a rough indication of the bacterial magnitude from nonpoint sources, but accurate modeling may prove to be difficult until additional research has been completed. Nonpoint source control may be too elusive, and a proposed recreation site may have to be relocated. Controlling inputs from grazing animals and wildlife is not easy. Although some nonpoint sources can be controlled with adequate waste management systems, proper management of the system is essential if it is to be effective. (Rowe-East Central)

HOW THOSE MANURE TRANSFER PUMPS OPERATE.

R. E. Graves
Hoard's Dairyman, Vol. 121, No. 16, p. 933, August 25, 1976. 2 fig.

Descriptors: Waste storage, Pumps, Pistons, Liquid wastes, Solid wastes.
Identifiers: Waste management, Waste transfer, Hollow piston pumps, Solid piston pumps.

About 3 years ago, 2 types of large piston manure transfer pumps were introduced — hollow piston pumps and solid piston pumps. They usually are installed below the barn floor and include a hopper to receive the manure from a tractor scraper or barn cleaner conveyor. The pumps discharge through an 8 to 12-inch plastic pipe buried below the frost line. Allowable pipe lengths to storage vary from 100 to 300 feet. Hollow piston pumps have a flapper-type valve on the lower end of the piston. The piston runs in a loose-fitting square cylinder. There is another flapper-type valve on the end of the cylinder. The pumping mechanism, piston, and cylinder can be removed for exchange or repair. A mechanical pump jack or reversing hydraulic cylinder is used to drive the pump. In operation, the piston is pulled up through the manure in the bottom of the hopper on the return stroke. On the down or pumping stroke, the valve on the piston is forced closed and the manure is pushed through the cylinder. The manure then goes through the cylinder check valve and into the underground pipe. These pumps are most commonly used with more free-flowing manure when liquid storage is planned. Solid piston pumps are installed horizontally at the bottom of a concrete pit with the receiving hopper above it. This pit is about 5 by 12 ft. and 6 to 10 ft. deep. It must be kept dry. In operation, the piston is pulled completely out of the hopper to allow manure to drop down in front of it. On the forward stroke the manure is pushed into the pump cylinder and through a spring-loaded check valve. The cylinder opening contains a relatively close-fitting die. Die and edge of piston serve to shear off any material not completely in front of piston. The fact that the manure does not have to go through a piston or around connecting rods makes this pump well-suited for use where long straw or a low to bedding is used, although this pump is the more expensive of the 2 types. (Rowe-East Central)

A METHOD TO EVALUATE THE COST-EFFECTIVENESS OF OPEN BEEF FEEDLOT RUNOFF CONTROL SYSTEMS,

Agricultural Engineer, U. S. Environmental Protection Agency, Region VII, Kansas City, Missouri.
N. L. Klocke
Presented at the 1976 Mid-Central Meeting, American Society of Agricultural Engineers, St. Joseph, Missouri, March 19-20, 1976, Paper No. MC-75-605, 21 p. 5 fig, 19 ref.

Descriptors: Model studies, Costs, Feedlots.
Identifiers: Runoff control, Cost-effectiveness.

Two computerized models, which simulate the performance and estimate the costs of runoff control systems for open feedlots are reported in the literature. The purpose of this study was to evaluate whether or not these models could be used for a cost-effectiveness analysis of runoff control systems. The performance of 8 assumed configurations of feedlot runoff control systems was simulated by a continuous watershed model, which included the feedlot surface, runoff retention basins, and a disposal system. All of the results from the performance model were in terms of daily depths of runoff overflow, disposal and storage. The test feedlot was assumed to be located at Ames, Iowa. Study conclusions were: (1) When the runoff control system design storm was only one-third the average annual runoff, rigorous disposal management was required. (2) For feedlot sizes between 300 and 2000 head, each added increment of disposal management was less costly than the next increment of design st m. (3) The most effective system was the most costly. The least effective system was the least costly. (4) The most cost-effective system ranked second in both categories of least cost and highest effectiveness. (5) Improving management of runoff control systems resulted in more improvement in cost-effectiveness than increasing the design storm size. (6) For all of the runoff control systems, both unit cost and cost-effectiveness decreased rapidly due to economies of scale between 50 and 1000 head. Little change was found between 1000 and 5000 head. As may be seen by these conclusions, existing computerized cost and performance models can provide a basis for a cost-effectiveness analysis. (Rowe-East Central)

GUIDELINES FOR MANURE APPLICATION IN THE PACIFIC NORTHWEST,

Extension Soil Scientist and Agronomist, Department of Agronomy and Soil, Washington State University.
D. O. Turner
Publication EM 4009, Cooperative Extension Service, Washington State University, February, 1976. 25 p. 10 tab, 6 ref.

Descriptors: Pacific Northwest, Crop production, Soil properties, Agricultural runoff, Nitrogen.
Identifiers: Land application, Loading rates.

Efficient use of animal manure in crop production can result in substantial savings in energy consumption for operations where there is adequate land for manure application within reasonable transport distances. Factors to be considered before field applying manure are: (1) Livestock feed must not be toxic. (2) Feed must be palatable to livestock. (3) Loading must be scheduled to fit the general farming operation. (4) There must be no deleterious effects on soil properties. (5) Runoff must be controlled so that there is no pollution of surface waters. (6) Water percolating through the soil profile must not carry excessive nitrate-nitrogen concentrations into groundwater aquifers. (7) Determination of loading rates and schedules should be made by the operator and related to his specific crops and soils. (8) There must be no adverse effect on crop production. Nitrogen is the major nutrient which more frequently limits crop yields and adversely affects water quality. Equations are given which provide a simple procedure for relating livestock source, handling methods, soils and crops to efficient use of manure as a fertilizer source. (Rowe-East Central)

RECYCLED WASTE FOR FEED IS BECOMING ACCEPTED PRACTICE,

J. F. Blair
Feedlot Management, Vol. 18, No. 8, p. 24, August, 1976.

Descriptors: Recycling, Costs, Performance, Feedlots, Rations.
Identifiers: Refeeding.

Bill Langenegger of Hagerman, New Mexico, began feeding manure to his cattle in the regular rations about 3 years ago. The manure is dry and has no odor. It is prepared by running it through a large tub-like mixer by using a front end loader. The manure is ground and then placed in mixer-delivery trucks along with other ingredients. Protein content is nearly 12 percent. Mr. Langenegger uses 7 percent manure by weight in the starter and growing ration. This is then stepped up to 15 percent in the finish ration. There are also about 13 transition rations where the manure content is increased with each change. Other waste feeds are used too, such as milo stalks, gin trash, small grain straw and corn stover. The materials are analyzed and a nutritionist runs the results through a computer. Since there is so much of this wasted feed in almost every farming area, a feedlot company should make use of it. Daily weight gains are comparable to those of most Southwestern feedlots. Costs for Langenegger's top finishing ration is presently billed to customers at $103.82/ton. (Rowe-East Central)

METHANE GENERATION FROM LIVESTOCK WASTE,

Extension Agricultural Engineer, Colorado State University
R. W. Hansen
Publication G 76-268, Cooperative Extension Service,

University of Nebraska, January, 1976, 4 p. 1 fig, 2 tab.

Descriptors: Recycling, Methane, Anaerobic digestion, Design.
Identifiers: Livestock wastes.

The conversion of organic materials, such as animal wastes, to an easily utilizable form of energy can be accomplished by a number of methods, one of which is anaerobic digestion. The basic elements of an anaerobic digester are described. In the digester system, a heat exchanger and thermostat may be used to maintain the proper temperature. The heat exchanger and thermostat can be either internal or external. Total bio-gas production will vary depending upon the organic material being digested, the digester loading rate, and the environmental conditions in the digester. Under ideal conditions (95 degrees F temperature and proper pH), it is possible to produce about 45 cubic feet of gas at atmospheric pressure from one day's manure from a 1,000 pound cow, or about 60 cubic feet of gas at atmospheric pressure per day from a 1,400 pound cow. Results showed that of the several types of energy capturing processes available, anaerobic digestion appears to be the most feasible for the majority of agricultural operations. Anaerobic digestion is capable of stabilizing most agricultural wastes while producing bio-gas or methane gas. Primarily, disadvantages are the amount of management required due to the sensitivity of the digesters, the high initial investment required for equipment, and the fact that the wastes still must be disposed of after digestion. (Rowe-East Central)

Descriptors: Feedlots, Cattle, Nitrates, Farm wastes, Georgia, Water pollution sources, Soil chemistry, Nutrients, Soil analysis.
Identifiers: Groundwater pollution sources.

Soil samples were taken from 21 beef cattle feedlots in Georgia. Samples to 122 cm. depth were taken upslope, within and approximately a 30 and 90 m downslope from the lots. Soil samples were analyzed for extractable NO_3, NO_2, NH_4, P, K, Ca, Mg, and for electrical conductivity, pH, and organic matter. Soil nitrate was considerably less in the Georgia feedlots than in those in the more arid regions in the West and Midwest. The average topsoil nitrate in feedlots was less than 20 ppm. Nutrients other than potassium did not show appreciable movement into the soil profile. It is concluded that pollution of groundwater from beef cattle feedlots is probably not significant in Georgia. (Giddens-Georgia University)

MICROBIOLOGICAL ANAYLSIS OF POULTRY ANAPHAGE,

Department of Poultry Science, Michigan State University, East Lansing
T. S. Chang, D. J. Currigan, D. W. Murphy and H. C. Zindel
Poultry Science, Vol. 53, p. 1242-1245, 1974. 1 tab, 26 ref.

Descriptors: Sampling, Microorganisms, Bacteria, Dehydration.
Identifiers: Poultry anaphage, Refeeding.

Poultry anaphage samples collected from various locations within the United States and dehydration machines were analyzed microbiologically in this study. Results showed that total bacterial counts of anaphage averaged about 466,900 microorganisms per gram with a range from 5,900 to 3,590,000. In terms of both frequency of isolation and total numbers, the genera Bacillus and Streptococcus predominated. No Salmonella, mold, Penicillium, Proteus, or Neisseria were isolated. It is felt that the poultry anaphage should be acceptable as a feed ingredient as long as no pathogenic organisms are isolated. However, it is preferable that the total bacterial count not be too numerous, so care should be taken not to recontaminate the anaphage after it is processed. (Rowe-East Central)

FLOW PATTERNS AND SEDIMENTATION IN LIVESTOCK OXIDATION DITCHES,

Agricultural Engineering Department, University of Illinois, Urbana
J. K. Mitchell and D. L. Day
Transactions of the ASAE, Vol. 19, No. 1, p. 119-122, January-February, 1976. 3 fig, 4 ref.

Descriptors: Aeration, Sedimentation, Slurries, Design.
Identifiers: Oxidation ditches, Flow patterns.

The main purpose of an aeration device is to provide the greatest possible absorption of oxygen by the slurry. The aeration device in an oxidation ditch for livestock waste treatment propels the liquid at a flow velocity which is supposed to be sufficient for maintaining the solids in a suspended state. When the velocity is insufficient to transport the particles, the particles will settle, and thus create a layer or mound of waste material without a dissolved oxygen supply. Tests were conducted to determine the flow patterns in a simple, oval-shaped recirculation ditch. The ditch was concrete, with a rectangular cross-section flow channel 1.07 m wide and 69 cm depth of flow. In the first test, two different aeration devices were used in an unmodified oval ditch and in the same oval ditch with end-section modifications. Ordinary tap water was used in the test. The first modification used was a guide-vane made of stainless steel, and the second was a teardrop "bulb" added to the end of the wall. Several diagrams are given which demonstrate the similarities and differences between the unmodified and modified ditch conditions. Another test w-s conducted to measure the sedimentation on a complex, U-shaped oxidation ditch which was beneath a large beef confinement unit. It was found that immediately down stream from the rotor aerator, there was little or no sedimentation and the greatest amount of sedimentation was found further down stream within the straight section. It was determined that in a large oxidation ditch, more than one type of aerator should be used. One type could be used for very high oxygenation capacity (rotor) and another type (propeller) for its high ditch bottom velocity capacity. (Edwards-East Central)

CONVERSION OF ORGANIC WASTE TO FUEL GAS,

Research Scientist, Natural Resources Research Institute, Wyoming University, Laramie.
J. L. Cox, W. G. Willson and E. J. Hoff. .an.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol. 100, No. EE3, p. 717-732, June, 1974. 3 fig, 6 tab, 19 ref.

Descriptors: Organic wastes, Recycling, Fuels, Costs, Equipment.

Experimental results of a new and novel concept for the gasification of carbonaceous material to a high beating value fuel gas are presented. The chemistry of the conversion is examined in reference to the feed materials and experimental variables. Experiments have shown that a variety of solid organic waste materials can be converted to gaseous fuel products composed essentially of CH_4, CO_2, and H_2 with a CO_2-free heating value that in many instances exceeds 7.92 kcal / l, a value generally accepted for substitute natural gas. A multiple catalyst, single-stage reactor system was used in the investigation. Temperatures of 600 degrees C-700 degrees C gave satisfactory conversions with all the feed materials, but it is anticipated that somewhat lower temperatures may also show adequate conversions and improved product composition. Although it would be unrealistic to project economics on the basis of these preliminary investigations, it is apparent that the catalyst cost needs the most attention in this respect. Such questions as catalyst alternatives, catalyst life, recoverability, and regeneration deserve particular attention. Some efforts are currently being directed at answering these questions. (Rowe-East Central)

A MATHEMATICAL DRYING MODEL FOR POROUS MATERIALS: PART I - THEORY,

Assistant Professor, Biological and Agricultural Engineering, Department, North Carolina State University, Raleigh
D. H. Willits, I. J. Ross, G. M. White and H. E. Hamilton
Transactions of the ASAE, Vol. 19, No. 3, p. 556-561, May-June, 1976. 5 fig, 24 ref.

Descriptors: Mathematical models, Drying, Equations, Porous media, Fertilizers, Feeds.
Identifiers: Poultry manure, Refeeding.

The basis of the drying model developed in this study to describe the drying of poultry manure is the concept of evaporation from an interface which recedes into the body as drying proceeds. Since poultry manure as excreted possesses no fixed geometry, the model was developed for formed manure. The problem of drying a highly porous body, becomes that of defining the rate at which the interface moves through the body. Two separate versions of the evaporative interface model were developed. They are described in terms of equations. The behavior of the interface temperature for each is also described in terms of equations. (Rowe-East Central)

A MATHEMATICAL DRYING MODEL FOR POROUS MATERIALS: PART II - EXPERIMENTAL RESULTS,

Assistant Professor, Biological and Agricultural Engineering, Department, North Carolina State University, Raleigh.
D. H. Willits, I. J. Ross, G. M. White and H. E. Hamilton
Transactions of the ASAE, Vol. 19, No. 3, p. 562-568, May-June, 1976. 4 fig, 6 tab, 16 ref.

Descriptors: Mathematical models, Drying, Model studies, Temperature.
Identifiers: Poultry manure, Cylinders, Spheres, Evaporative interface.

Two versions of a semi-empirical model based on the concept of a receding evaporative interface were developed to describe the drying of formed poultry manure. The two-parameter version was developed for cylindrical geometries to describe the behavior of the interface temperature. The one-parameter version was developed for both cylindrical and spherical geometries to describe the interface temperature. Data obtained from the drying of poultry manure formed into 2 shapes (cylindrical and spheres) for diameters of 25.4, 19.1, and 12.7 mm for cylinders and 31.8, 25.4, and 19.1 for spheres at air temperatures of 65.6, 93.3, and 121.1 C were used for evaluating both versions of the model. When the one-parameter version was compared to an exponential drying model, the results indicated that both models performed equally well in describing the drying of poultry manure. However, the evaporative interface model had the following advantages over the exponential model: (1) It directly incorporated most of the variables that influence drying into a single expression. (2) It could be more easily extended to situations not covered by available drying data because of the reasonable behavior of the predicted values of h_o and p. (3) It provided a more complete understanding of the mechanisms of drying highly porous materials. (Rowe-East Central)

WILL SOLID WASTES BURY US?,

J. A. MacDonald
Engineering News Record - Probing the Future, Vol. 192, No. 18, p. 251-261, April 30, 1974. 5 fig.

Descriptors: Solid wastes, Recycling, Waste disposal.
Identifiers: Europe, United States, Japan, Waste management.

The U. S. generates 4.4 billion tons of solid waste per year: 1.7 billion tons of animal waste, 1.7 tons mineral waste, 640 million tons agricultural waste, 230 million tons urban waste, 140 million tons industrial waste. It is projected that by the year 2000 the U. S. will have to deal with 12 billion tons of solid waste. The U. S. produces over 1 ton of solid waste annually for every man, woman, and child in the U. S. Figures for other countries are given: Japan, 800 lb; West Germany, 300 to 660 lb; Holland, 660 lb; Belguim, 638 lb; England, 635 lb; Italy, 572 lb; and France, 506 lb per capita per year. These figures are expected to grow by 5 to 8 percent each year. With this as an introduction, the author goes on to say that in order to meet the demands that will be placed upon us in solid waste management a total commitment must be made immediately. He then discussed possible directions that could be taken in the updating of solid waste technology. The author says that total recycling of natural resources from the processing of solid waste and garbage is today a reality in handling municipal and commercial solid wastes. The challenge in the future lies in throwing off prejudices that have fettered wide-scale application of resource recovery concepts, and in making resource recovery a necessary part of materials-use practices. HOUSING OF BEEF CATTLE,

J. J. Troon
Agriculture, Vol. 77, No. 9, p. 416, 418, 421, September, 1970.

Descriptors: Cattle, Liquid wastes, Solid wastes, Waste storage.
Identifiers: Housing, Waste Management, Slatted floors.

Loose housing is being considered for cattle during the second winter or finishing period in buildings where there is no attempt to achieve control over the internal environment. Wastes may be handled as solid, semi-solid, or as a liquid and the decision on which method to use may well be influenced by any existing waste disposal methods on a particular holding. Economy of straw used as litter can be achieved by bedding only part of the yard and making the area adjoining the manger a solid floor. If the waste is to be handled as a liquid, the area adjoining the mangers can be slatted and the effluent stored beneath the slats. Where animals are loose housed on long litter, it is not advisable to have both solid and liquid manure to handle, which would mean extra disposal equipment. The Brambell Committee on Animal Welfare recommends that only half of the area be slatted to produce an inhibiting effect. However, the use of a slatted passage between two rows of cubicles enables the liquid to be stored beneath the slats and maintains a balance between solid and slatted areas. A passage width of 8 ft. combined with usual cubicle dimensions 7 ft. long by 3 ft. wide is effective. Experience has shown that slats 5 in. wide with a 1 ½ in. gap are satisfactory and that concrete slats are less slippery than steel slats. The slats should be designed to carry a load of 500 lb. / square foot. (Solid Waste Information Retrieval System)

FARM WASTE DISPOSAL,

K. B. C. Jones
Agriculture, Vol. 77, No. 4, p. 165-167, April, 1970.

Descriptors: Confinement pens, Cattle, Poultry, Odor, Water pollution, Feedlot runoff, Aesthetics, Economics, Legal aspects, Aeration.
Identifiers: Housing, Great Britain, Land spreading.

Housing of cattle and poultry has created difficulties with manure storage and disposal because of smells, unsightliness, and water pollution by runoff from yard concrete or manure heaps. With profit margins at their present levels nobody can insist on a return to ranching or free range, but high standards of manure management are required to prevent justifiable complaints of nuisance. Regular land spreading of manure will help to keep odors down, and aeration before pumping will ultimately remove much of the smell from liquids. Silage liquor is universally offensive, but cannot be helped. Farmers can cooperate the nonagricultural interests by limiting activities at week-ends and on public holidays when there are more city dwellers in the countryside. The legal position with regard to waste disposal is both complicated and diffuse. There is no tidy consolidating act which defines the whole situation clearly. Legal action for nuisance, e.g., smell or noise, may be brought either at common law, or under section 92 of the Public Health Act, 1936. The principal object of the action is to obtain either an injunction or an abatement order against the offender. The Rivers (Prevention of Pollution) Acts 1951 and 1961 forbid the discharge of farm or trade effluents into a stream or watercourse unless it has been agreed to in writing by the Local River Authority. GROUP OPERATIONS: WASTE DISPOSAL BY TANKER,

W. K. Hall
Agriculture, Vol. 79, No. 10, p. 436-437, October, 1972.

Descriptors: Liquid wastes, Equipment, Economics.
Identifiers: Land spreading.

The article discusses use of liquid manure tankers on the farm. These tankers are seldom operated to capacity on any farm. There may be situations in which it is advantageous to share a tanker and its associated labor in order to reduce the costs invested in machinery. On small farms a group may operate a tanker and improve waste handling. Larger tankers can do more work for a given tractor and labor imput and can handle wastes of varying dry matter, as well. The working rate of any tanker depends on tanker capacity, filling rate, and transport distance. The right kind of tanker for a particular project in hand must be chosen on the basis of such factors as distance and dry matter content of waste. The article outlines a possible scheme arranged among three farms for joint operation of a 700-ton tanker filled by vacuum and emptied under pressure. Accommodation and reason are stressed in this example. (Solid Waste Information Retrieval System)

EFFLUENT DISPOSAL,

Agricultural Engineering Advisory Officer of Palmerston North, Great Britain
F. W. Phillips
Agriculture, Vol. 77, No. 3, p. 23-37, March, 1970. 21 fig, 5 tab.

Descriptors: Water pollution, Dairy industry, Spray irrigation, Effluents, Waste disposal, Confinement pens, Physical properties, Chemical properties.
Identifiers: Land disposal.

This four-part series of articles covers the following: sources of agricultural wastes, stream pollution, dairy wastes, and spray irrigation. The trend toward farming at a greater intensity has meant that the dung and urine which was previously voided in the paddocks will become an increasing problem. In every intensive agricultural system and problem of disposal of unwanted material becomes an important part of the enterprise, and planning for it has to be incorporated from the start. The use of oxygen by organic material in the stream is very important as it effects the whole pattern of life within the stream. As animal wastes discolor the water, contain suspended solids, and have a very high oxygen requirement, their effect on a stream is quite marked and rapid. It is generally cheaper and easier to return all the wastes to the land and so avoid any discharge to streams. Methods of disposal of dairy wastes are discussed: pouring wastes down the drain, a sump to catch suspended solids, ponding, sump and tanker-honey wagon manure spreader trailer, pumping, and spray irrigation. The spray irrigation method of disposal, if properly managed, completely overcomes the problem of direct pollution from cowsheds to streams. All of the shed washings are returned immediately to the pasture, thus gaining maximum benefit from the available manurial value of the wastes. In planning spray irrigation systems, there are a number of points to consider: labor, volume of wastes, soil, soil cover, topography, and management. (Solid Waste Information Retrieval System)

PROTEIN WITHOUT POLLUTION,

Commercial Manager, Process Division, Douglas-Rownson Limited
J. Taylor
Engineering, Vol. 212, No. 11, p. 1081-1083, November, 1972. 1 fig.

Descriptors: Drying, Poultry, Fertilizers, Feeds, Economics, Proteins, Design, Odor.
Identifiers: Dried poultry wastes, Refeeding, Great Britain.

The author describes a method of drying poultry manure developed by Douglas-Rowson, Ltd. The dried manure, which is 27 percent by weight of the wet manure, is 38 percent protein, and can be used both as fertilizer and feed additive. The author claims that a new profit of 8 pounds sterling per ton can be achieved by processing the poultry manure and utilizing it by this method. (Solid Waste Information Retrieval System)

A COMPARATIVE STUDY ON CANALS SPOIL AND FARMYARD MANURE AS CALCAREOUS SOIL CONDITIONERS,

Soil and Water Research Institute, Agricultural Research Center
M. A. Negm, H. K. Bakhati, S. H. Abdel-Malik, E. M. Abdel-Naeim, A. I. Mitkees, and H. M. Hassan
Agricultural Research Review, Vol. 51, No. 2, p. 1-8, March, 1973. 8 tab, 11 ref.

Descriptors: Soil amendment, Crop response, Farm wastes, Chemical properties.
Identifiers: Canals spoil, Land disposal, Loading rates, Residual effect.

An experiment was conducted to show the effect of canals spoil and farmyard manure as a calcareous soil conditioner on maize yield as well as their residual effect on the following crop (wheat). The study took place at Nobaria Experimental Station, near Alexandria. Six treatments were utilized in a complete randomized block design. The treatments were replicated 8 times. Treatments were: (1) Control, (2) 70 ton / feddan of canals spoil, (3) 5 ton / feddan of farmyard manure, (4) 35 ton / feddan of canals spoil, + 2.5 ton / feddan farmyard manure, (5) 70 ton / feddan of canals spoil 5.0 ton/feddan farmyard manure, and (6) 10 ton / feddan of farmyard manure. Results indicated that maize and wheat yields were increased successively by increasing the levels of farmyard manure. Applying canals spoil alone had little effect on yield. Applying farmyard manure plus canals spoil gave better results. Residual effect of these additions on the following crop was clear, but renewing the addition before the next crop had pronounced effects. Canals spoil or any other amendment should not be used without first analyzing it for harmful salts. (Merryman-East Central)

FLOOR TYPES AND VENTILATION ON BEEF ANIMAL PERFORMANCE,

Engineer, Sedimentation Control, North Carolina Department of Natural and Economic Resources, Winston-Salem
G. D. Miller, J. I. Sewell, and J. B. McLaren
Transactions of the ASAE, Vol. 19, No. 2, p. 322-325, March-April, 1976. 2 fig, 5 tab, 12 ref.

Descriptors: Ventilation, Performance, Odor.
Identifiers: Floor types, Knee swelling, Waste management, Slatted floors, Slab floors.

Primary objectives of the study were to determine the effects of floor types and ventilation on animal performance and knee swelling. A secondary objective was to develop waste management criteria for slatted-floor systems. A sheet metal beef finishing barn with 2 rows of 10 pens separated by a feeding alley and having open sides and enclosed ends was completed at The University of Tennessee Aluminum Co. of America (Alcoa) Farm. Bulls and steers weighing from 204 kg to 253 kg each were used in the tests started in 1971 and concluded in 1974. The cattle were fed a finishing ration until they reached slaughter weight (about 430 kg). Few problems were experienced with the cattle on feeding trials except during summers. During a 1-year test when ventilation was not provided, bulls fed on concrete slabs, aluminum slats, and concrete slats were similar with respect to feed efficiency and rate of gain. During summer only, some cattle exhibited swelling of knee joints; and all cattle showed signs of discomfort. Cattle in the ventilated slat pens gained an average of 1.05 and 1.10 kg/animal day more than those in the unventilated slat and unventilated slab pens, respectively. Bulls on ventilated slabs exceeded those on unventilated slats and unventilated slabs in feed conversion. Performance differences were not statistically significant. Problems associated with slatted floor systems were high facility investment, odors after spreading waste, and providing satisfactory environmental conditions during summer. (Rowe-East Central)

RECYCLING AEROBICALLY TREATED WASTE WATER TO LAYING HENS,

University of Illinois at Urbana-Champaign, Urbana, Illinois 61801
H. S. Johnson, D. L. Day, C. S. Byerly, and S. Prawirokusumo
Manuscript submitted to Poultry Science, April, 1976, 9 p. 4 tab, 7 ref.

Descriptors: Wastewater treatment, Aerobic treatment, Recycling, Poultry, Performance, Nitrates, Odor.
Identifiers: Oxygen level.

A study was performed to evaluate the performance of layers that had their waste products aerobically treated and recycled in their drinking water. Aerobic treatment enhanced the wastes by killing pathogens, upgrading the organic matter into single cells with high protein content, and decreasing the wastes' odor. Two groups of White Leghorn pullets were used in this experiment. A mini-oxidation ditch was installed under the experimental cages. The water level in the ditch was maintained at about 30 cm. and the contents were agitated with an aerator. Results showed that the aerator incorporated more oxygen into the oxidation ditch than necessary. As a result, the dissolved oxygen level increased from 4.7 to 6.0 ppm from the fourth to sixth week. Normally, a level of 1 to 2 ppm is desirable. The nitrate levels increased even more sharply during this 2-week period. Egg production dropped sharply during this time. However, the birds were able to recover much of their production loss after being subjected to these levels, or slightly lower ones, for several weeks. (Rowe-East Central)

REFEEDING WASTES,

Feedlot Management, Vol. 18, No. 7, p. 12, July, 1976.

Descriptors: Feeds, Potassium, Sodium, Manganese, Nutrients, Confinement pens, Feedlots.
Identifiers: Refeeding, Minerals, Roughage, Housing.

Scientists of U.S. Department of Agriculture Agricultural Research Service and the University of Nebraska have found that feces and manure from housed cattle on a low roughage ration generally meet the requirements for feeding as a high roughage ration. However, supplemental manganese may be needed. Researchers found that wastes from outdoor feedlots contain 45-95 percent soil and are not suitable for refeeding because of low feed value. The study also showed that the suitability of excreted materials for refeeding declines as the amount of roughage in the original ration increases. Feces from a high roughage ration, for example, could be reused only as the roughage component of a ration. They would be equivalent to those from a low roughage ration if potassium, sodium, and manganese were added. Researchers found that the roughage level in the ration influenced gross energy, crude fiber, crude protein, all forms of nitrogen, potassium, phosphorus, manganese and other mineral elements in the wastes. SEARCH FOR ALTERNATE FUELS LEADS TWO CONGRESSMEN, VOLKSWAGEN, TO METHANOL,

Feedstuffs, Vol. 48, No. 16, p. 8, April 19, 1976.
R. H. Brown

Descriptors: Fuels, Research and development, Costs, Recycling.
Identifiers: Methanol, Volkswagen, Automobiles.

Scientists are doing lab work and some congressmen, in taking a look at substitute fuels, have become interested in methanol, a gas derived from agricultural or minicipal wastes, coal or natural gas. Senator Alan Cranston and six other senators are seeking passage of a bill for road tests on a large scale using methanol as a fuel for the family automobile. Meanwhile, Volkswagen has been doing some research on its own in cooperation with the German government. Preliminary results indicate that methanol produced from coal, natural gas and livestock wastes is a "mid-term" possibility, while over the longer haul hydrogen is a possibility. Volkswagen is using 45 vehicles in the testing program. A gasoline-methanol mixture consisting of 85 percent gasoline and 15 percent methanol is being used in 22 VW Rabbits, 12 VW buses and 11 Audi 100's. The vehicles will be driven almost 20,000 miles a year and so far only minor adjustments have been needed to adapt the engines to methanol gasoline. Hopefully, the studies will show that it will be possible to quickly shift to the methanol-gasoline. (Rowe-East Central)

SCIENTISTS QUESTION USE OF MANURE FOR RECYCLING,

Beef, Vol. 12, No. 8, p. 41, April, 1976.

Descriptors: Recyling, Performance, Nutrients, Calcium, Copper, Magnesium.
Identifiers: Refeeding, Toxicity, Digestibility, Minerals, Ensiling.

Several studies were done to test the value of manure in refeeding. Although chemical analysis of feedlot manure makes the manure look good as a potential feed, there are problems. It is hard to get livestock to eat the manure and about 80 percent of what they do eat becomes manure again because the digestibility is low. Other tests were performed to see if concentrations of certain minerals in the manure that might be harmful increased each time it was recycled. The tests revealed that continued recycling increased calcium, copper and magnesium concentrations in the dried excreta, but that the increases were not sufficient to be harmful. Other research was done utilizing pregnant beef cows. The researchers concluded that manure in combination with barley could be fed as a supplement to pregnant range cows as an alternative to high quality protein supplements such as cottonseed meal. University of California animal scientists W. N. Garrett and J. L. Hull, based on their research as well as the work of others, did not recommend using feedlot manure as a feed. "It's marginal, at best right now," they agreed, adding that research with ensiling the manure and feeding it in other forms may hold some hope for the future. (Rowe-East Central)

RENOVATION OF LIQUID DAIRY AND MILKING PARLOR WASTES,

Assistant Professor, Agricultural Engineering Department, Delaware University, Newark
W. F. Ritter, R. P. Eastburn, and J. R. Harris, Jr.
Presented at the 1976 Annual Meeting, American Society of Agricultural Engineers, University of Nebraska, June 27-30, 1976, Paper No. 76-4031, 25 p. 5 fig, 9 tab, 10 ref.

Descriptors: Liquid wastes, Lysimeters, Chemical properties, Soil profiles, Soil properties, Physical properties, Leachates.
Identifiers: Dairy wastes, Milking parlor waste.

Research on land application of milk-parlor wastes and liquid dairy wastes was conducted at the University of Delaware. Four lysimeters were constructed from plywood and lined with 4 mil polyethylene. Two of the lysimeters contained a loamy sand soil and 2 of the lysimeters contained a silt loam soil. Milking parlor waste (MPW) was applied to one of the silt loam lysimeters and one of the loamy sand lysimeters. Liquid dairy waste (LDW) was applied to the other 2 lysimeters. Influent and leachate samples were collected from each lysimeter and analyzed for COD, nitrate-nitrite nitrogen, ammonia, organic nitrogen, ortho phosphorus, total phosphorus, zinc and copper. Soil samples were taken at the end of the experiments from each lysimeter and analyzed for pH, magnesium, calcium, potassium, phosphorus, Kjeldahl nitrogen, zinc, copper and organic matter. Conclusions that were drawn from the research were: (1) Soil filtration is capable of removing over 90 percent of the COD, over 99 percent of the phosphorus and over 80 percent of the nitrogen from livestock wastes. (2) Temperature did not affect the removal of COD and phosphorus, but had some effect on nitrogen removal. (3) The milking parlor waste was more effectively treated than the liquid dairy waste. (4) Milking parlor wastes and liquid dairy wastes contain low concentrations of zinc and copper. (5) Phosphorus movement will increase in a soil profile with increased phosphorus applications. (6) The pH of the soil profile of acid soils will increase with high applications of livestock wastes. (7) The organic matter content of the upper layers of the soil profile of loamy sand or sandy loam soils will increase with high applications of livestock wastes. (Rowe-East Central)

THEY'RE PACKING UP WASTE PONDS,

Chemical Week, Vol. 116, No. 24, p. 37, June 11, 1975.

Descriptors: Recycling, Anaerobic treatment, Liquid wastes, Chemicals, Fuels.
Identifiers: Packed-bed biological reactor, By-product recovery.

Union Carbide's Nuclear Division, which operates Holifield National Laboratory in Oak Ridge, Tennessee, has developed a technique (Anflow) for packing an anaerobic waste treatment pond into a column. The Anflow unit is an upflow packed-bed biological reactor in which liquid wastes are pumped into the bottom to travel upward through the packing in which anaerobic microorganisms have been implanted. This method of treatment reduces both land requirements and treatment time. Retention times in the equipment are as low as 4 hours. The biggest selling points for Anflow are chemical recovery and fuel generation. Carbide estimates that 13 trillion cu.ft./year of methane could be recovered from all wastes in the U.S. But this would be mainly solid wastes. Anflow could recover methane as an off-gas during treatment of liquid wastes from starch and food processing, and from domestic sewage. More valuable products also can be recovered, including butane-diol from starch waste, sulfur from kraft process black liquor wastes, alcohols from wastes containing sugars. Researchers already have adapted the Anflow process to production of ethanol and report recoveries in excess of 15 percent from pure sugar feeds containing trace elements. (Merryman-East Central)

3307 - A1, A3, A4, A9, A11, A12 RESOURCES UNDER PRESSURE--WATER

Water Pollution Research Laboratory, Department of the Environment, Stevenage, England
M. Owens
Intensive Agriculture and the Environment, North Western European Region Symposium, The University, Newcastle-Upon-Tyne, September 19-21, 1973, p. 33-39. 1 fig, 6 tab, 30 ref.

Descriptors: Water pollution, Agricultural runoff, Pesticides, Herbicides, Fertilizers, Phosphates, Nitrogen, Biochemical oxygen demand, Fishkill.
Identifiers: Agricultural wastes.

In recent years, the agricultural industry has endeavored to increase crop yields and minimize livestock space to such a degree that fertilizers, pesticides, farm wastes and other materials constitute a real threat to the waters which they pollute. Some of these materials have harmful effects indeed. Certain organic wastes have a high BOD and cause the water to lose oxygen necessary for aquatic life. Some of these substances encourage growth of undesirable organisms and slimes in the water. Livestock wastes entering surface waters may introduce bacterial, parasitic, or viral diseases that may infect other animals or man. Feedlot runoff, which has a high concentration of ammonia, can cause fish-kills and can interfere with chlorination at the water works. Pesticides, which often enter surface waters as a result of land runoff, may cause fish-kills; however, short-term exposure of herbicides to aquatic life (in the amounts normally expected to occur) appear not to have toxic effects. Agricultural wastes as pollution sources are hard to treat, mainly due to the difficulties in collecting them at their sources. Seasonal variations of polluting quantities (as in sheep dips, vegetable washings, etc.) also add to the difficulty. (Sanders-East Central)

3308 - A4, A6, A7, A8, A11, A12, B2, C2, D1, D3, E2, E3 RESOURCE MANAGEMENT—FARM EFFLUENTS,

Ministry of Agriculture, Northern Ireland
J. S. V. McAllister
Intensive Agriculture and the Environment, North Western European Region Symposium, The University, Newcastle-Upon-Tyne, September 19-21, 1973, p. 71-79. 8 tab, 24 ref.

Descriptors: Effluents, Slurries, Nutrients, Gases, Waste storage, Odor, Water pollution, Soil contamination, Diseases, Aerobic treatment, Drying, Separation techniques.
Identifiers: Toxicity, Land disposal.

Slurry, silage effluent, and dairy washings are the main liquid or semi-liquid wastes produced in agriculture. Slurry, which is a mixture of feces and urine of farm animals with varying amounts of water, is produced in the greatest quantity and presents the major disposal problem. Slurry should be collected in a way which will minimize the loss of plant nutrients such as phosphorus, potassium, and calcium. It is also important to know that if methane, carbon dioxide, carbon monoxide, ammonia or hydrogen sulphide gases are released in excessive amounts during slurry decomposition, they can be toxic. For this reason, many existing collection and storage systems are hazardous to stock and workers. It is therefore necessary to improve the condition of such storage systems. One form of improvement would be to provide some form of aeration treatment for the slurry in the storage tank and regularly flush the dung channels with effluent from this treatment. Any disposal system must guard against pollution. Therefore, when land disposal is used, it is important that the land area be adequate. Three interdependent factors decide the amount of slurry which can be safely spread on land — soil type, cropping system, and climate. Problems associated with land disposal of slurry are: (1) odor, (2) disease transmission, (3) water pollution which occurs when untreated slurry or manure is allowed to overflow from tanks or storage pits into open ditches or streams, and (4) problems which arise in soil and plants. Other methods of slurry disposal are being studied. These include: (1) aerobic treatment of slurry to reduce biochemical oxygen demand, (2) drying poultry manure for use as a packaged manure or for inclusion in feeds for ruminants, and (3) separation of the solid and liquid fractions of slurry with subsequent disposal of treatment of the fractions separately. (Edwards-East Central)

3309 - A3, A6, B2, B3, B4, C2, D3, E2 RESOURCE MANAGEMENT--THE ANIMAL MANURES PROBLEM,

Agricultural Institute, Dublin
V. A. Dodd
Intensive Agriculture and the Environment, North Western European Region Symposium, The University, Newcastle-Upon-Tyne, September 19-21, 1973, p. 80-87. 2 fig, 4 tab, 8 ref.

Descriptors: Waste treatment, Waste disposal, Waste storage, Anaerobic conditions, Nutrients, Confinement pens, Poultry.
Identifiers: Oxidation ditch, Odor control, Swine.

The problem of manure disposal has arisen for the following reasons: (1) substitution of chemical fertilizers for animal manures in crop production, (2) trend to separate feed production from animal production, resulting in increased costs for manure disposal, (3) current housing techniques together with the growth of intensive animal production units on limited land areas, which are often ill-chosen, (4) properties of animal manures, and (5) expansion of urban centers to rural areas and the public's general concern for the environment. One possible solution to the waste disposal problem is the oxidation ditch which consists of two primary parts — continuous open channel ditch in an oval or race-track like shape which holds the waste, and an aeration rotor motor driven by an electric motor for supplying the necessary oxygen. The waste and water mixture is circulated around the ditch and returned to the rotor at intervals where oxygen is churned into it. Growth of aerobic bacteria, which decomposes the organic matter and produces water, carbon dioxide, and stable solids called activated sludge, is promoted by the mixture of oxygenated water and waste. Land has always been used by man as the ultimate disposal medium for many kinds of wastes, and is possibly still one of the most efficient means of disposal. Several questions are being raised which center around how much and for what periods of the year can manure be applied to land. It is necessary, when land is being used as the disposal medium, to be sure that there is no surface runoff, and that drainage water does not carry with it excessive amounts of nutrients and organic compounds. Another problem associated with manure is odor. Manure stored under anaerobic conditions gives off gases such as ammonia and hydrogen sulphide. The most effective method for odor control is the prevention of the conditions under which odors are generated. Several methods of odor control are given. (Edwards-East Central)

3310 - A2, A8, B2, C2 PROTECT TREES FROM FEEDLOT RUNOFF,

District, Extension Forester, University of Nebraska
N. E. Jennings
Nebraska Farmer, Vol. 118, No. 18, p. 30, September 18, 1976.

Descriptors: Feedlots, Agricultural runoff.
Identifiers: Trees.

Feedlot runoff kills trees. In areas where livestock wastes flow through windbreaks or around trees, the trees soon die. Studies indicate that livestock wastes increase salt and ammonia concentrations in the soil and tie up some of the nutrients. To protect trees, the feedlot surface should be graded away from them. Alternatively, feedlot runoff can be channeled in a narrow ditch through the trees. In planning a new feedlot, ideally it should drain to the east and south. Trees should be planted to the north and west for protection. (Merryman-East Central)

3311 - B2, C1 CHECKING OUT STICKING SLURRY,

M. Looker
Pig Farming, Vol. 21, No. 8, p. 78-79, August, 1973.

Descriptors: Slurries, Design, Flow, Physical properties.
Identifiers: Swine, Housing.

The Agricultural Research Council is investigating the problem of sticking slurry in the handling of animal wastes. The work is to be carried out by the Building Research Station at Garston, near Watford, Herts. The physical characteristics and the flow properties of pig slurry will be investigated in relation to waste handling facility design. An experimental piggery is being erected that will hold 45 fatteners from roughly 100-200 lb liveweight. These will be divided into 3 pens of 15, each with a 4 foot wide dunging passage kitted out with concrete slats. The piggery will be raised 6 feet off the ground to allow easy access to the slurry channel, which is 4 feet wide x 2 feet 3 inches deep and is to be suspended beneath the slats on 2 special heavy-duty weighers. This will enable the exact weight of slurry output to be accurately recorded. It will also be possible to adjust the fall on the channel. In the experimental piggery, trials will not be confined to just gravity-operated systems. Recirculation systems using fluid waste from a nearby lagoon pumped back to the slurry channel with a low horsepower pump will also be studied. Detailed records will be kept of the type of food and how much is fed to the pigs. The water flow to each nipple drinker and washing down hoses will be measured and the electricity supply will be metered. Initial tests will be with floor-feeding but, for comparative purposes, other feeding systems may be tried out at a later stage. At each stage, the flow properties of the slurry and its flow behavior by gravity will be measured. These experiments are not only being designed to give an indication of the best channel shape and slope, but also to give a clue to best type of surface within the channel. The experimental fattening house is due to be completed very shortly and trials will start as soon as it is stocked. (Ott-East Central)

3312 - A7, A11, A12, B2, B4, C2 DANGER-SLURRY,

A. Phelps
Pig Farming, p. 42-45, June, 1970. 6 fig.

Descriptors: Slurries, Air pollution, Gases, Safety, Methane, Carbon dioxide, Hydrogen sulfide, Ammonia.
Identifiers: Swine.

The problems concerning dangerous gases from slurry pits are examined in a question and answer type format. Slurry gases are generated by bacterial activity. Most toxic among these gases are: methane, carbon dioxide, hydrogen sulfide, and ammonia. There are documented cases of swine being killed by such gases, which are usually released as a result of "slurry disturbance" or agitation. If ventilation were adequate, agitation beneath slatted floors would not be such a problem. Management precautions are: (1) Don't let slurries stored in channels and cellars build up to within 12 inches of the slats. (2) When slurry is stored in an underground tank near the piggery, all connections between the pit and drainage channels should be closed to prevent gas blow-back when the effluent is disturbed. If the pit is enclosed, it should also have an outlet pipe to permit the escape of lighter-than-air gases as they are generated. Recommended safety precautions for farmers and their employees are: (1) Always secure manholde covers and suction hoses so they cannot fall into the slurry tank. Covers should be made larger than openings so they cannot fall through, and hoses can be secured to vacuum tankers with safety chains. (2) Never enter a slurry tank without first ventilating it for at least 20 minutes. Either wear a safety harness and have 2 men standing by on the rope in case of emergency or wear a gas mask or breathing apparatus. (3) Never stand over manholes, or sluice gates, or slatted floors when the effluent underneath is being agitated, flushed out, sucked or pumped. Farmers should put up notices warning of the gas hazard at all danger spots in and around their piggeries. Because methane, ammonia and hydrogen sulfide can be explosive, smoking should not be allowed when emptying a slurry pit. Also lighted cigarettes should not be thrown into slatted slurry pits. (Ott-East Central)

IONIC COMPOSITION OF CATTLE FEEDLOT RUNOFF,

A. Liu
MS Thesis, Department of Civil Engineering, Colorado State University, Fort Collins, November, 1975, 79 p. 10 fig, 15 tab, 62 ref.

Descriptors: Feedlots, Agricultural runoff, Cattle, Chemical oxygen demand, Biochemical oxygen demand, aerobic treatment, magnesium, bicarbonates.
Identifiers: Ionic composition.

A study was conducted in 1969-1970 to investigate the ionic composition of cattle feedlot runoff. The runoff was simulated by making 1 percent cattle manure aqueous solutions from a manure suspension consisting of 10 grams of cattle feedlot manure and 990 milliliters of distilled water. The ionic composition of the simulated runoff and the effect of aeration on BOD and COD were studied. The ionic analysis results showed that magnesium and bicarbonate were the major positive and negative ions, respectively. The specific conductance value was 1,400 µmhos/cm at 25° C and $CaCO_3$ was deposited by the solution. It was felt that the manure aqueous solution would be satisfactory for almost all soils as far as the sodium-absorption-ratio was concerned. Aeration treatment data showed that, after 7 days aeration, there was a 74 percent removal of ultimate BOD at 24° C. The study established that the cattle manure mixture did have a high degree of aerobic treatability. (Rowe-East Central)

FIELD TESTS OF LIQUID MANURE SYSTEMS AT TWO DAIRIES,

Associate Professor, Department of Agricultural Engineering, Tennessee University, Knoxville
J. W. High, Jr., J. R. Owen, and J. I. Sewell
Tennessee Farm and Home Science, Progress Report No. 76, October-December, 1970, p. 3-5. 2 fig.

Descriptors: Liquid wastes, Waste storage, Costs, Odor, Safety, Tennessee.
Identifiers: Holding Tanks, Land spreading.

In 1967, 2 concrete liquid manure holding tanks were constructed at the Dairy Experiment Station at Lewisburgh and at the Middle Tennessee Experiment Station at Spring Hill for a cost of $0.85/cu. ft. storage capacity. Construction costs, management data, and operational problems have been recorded since these tanks were put into operation. In these liquid manure systems, manure was stored until weather conditions, cropping systems, and labor schedules allowed the manure to be spread on fields. Each concrete pit was accompanied by concrete slabs for easy loading of the pit, equipment for agitating the manure, and equipment for pumping the liquid wastes for hauling and field spreading. The liquid manure systems made possible more sanitary conditions during the winter months than would have been possible with conventional hauling methods. Objectionable odors were not normally present except during agitation and pit unloading and for a short period after the manure was spread on fields. During summer months, scraping of the lots was done early in the morning before the manure had dried appreciably in order to make agitation easier. It was found that caution should be taken to exclude materials which could damage or clog a pump and safety precautions should be taken for farm workers and animals in relation to the flammable and poisonous gases produced by such liquid manure pits. (Rowe-East Central)

MICRONUTRIENT CONTENT OF FARMYARD MANURE OF THE PUNJAB,

Department of Chemistry and Biochemistry, Punjab Agricultural University, Ludhiana, India
G. S. Mann, S. Mangat and S. M. Sood
Journal of Research, Punjab Agricultural University, Vol. 10, No. 2, p. 203-206, June, 1973. 3 tab, 11 ref.

Descriptors: Sampling, Iron, Manganese, Molybdenum, Copper.
Identifiers: India, Micronutrients, Farmyard manure.

Because very little information is available about the micronutrient content of the farmyard manure being used in India, a study was conducted to evaluate the manure being used in rural areas of the Punjab. The manure was analyzed for iron, manganese, molybdenum, copper, nitrogen, potash, phosphorus, organic matter, and pH. Thirty-nine samples of farmyard manure were collected from different villages of the Faridko, Garhshanker, Banga, Nawan Shahr, Dehlon and Ludhiana N.E.S. blocks of the Punjab State. The samples were oven dried at 60 degrees C for 72 hours. They were then ground and sieved through a 1 mm sieve for analysis. The overall average value for iron was found to be 1.3019 percent. The average manganese value was 40.6 ppm. The average value for copper was 46.3 ppm. The molybdenum value varied from 0.9 to 15.9 ppm. (Rowe-East Central)

THE ANAEROBIC DIGESTION OF CATTLE MANURE,

J. B. Lane
MS Thesis, University of Minnesota, September, 1971, 93 p. 16 fig, 18 tab, 73 ref.

Descriptors: Anaerobic digestion, Methane, Nitrates, Costs, Equipment, Economics.
Identifiers: Soil amendment.

Anaerobic digestion of cattle manure was investigated in terms of gas production and volatile solids reduction. Experiments were performed with the following objectives: (1) comparison of gas production and temperature in adiabatic and isothermal batch digesters, (2) gas production in digester enriched with protein supplement, (3) determine the effect on gas production and volatile solids reduction of aerobic pretreatment of the substrate, and (4) comparison of nitrate production in soil amended with fresh manure. A prototype field digester was then designed and the materials costs estimated. For 10 dairy cows and 10 beef cows, dome digesters of 8.5 ft and 7.0 ft in radius were required. Installed costs were estimated at $2500 for each digester. The return on investment from the methane generated would be 25 percent and 53 percent, respectively. Hence, anaerobic digestion of cattle wastes is not only feasible but economically attractive to the farmer or feedlot operator. However, more technical research, especially at the field pilot plant level, is needed to assure this attractiveness. (Rowe-East Central)

EFFECTS OF DUNG BEETLE ACTIVITY ON THE NUMBER OF NEMATODE PARASITES ACQUIRED BY GRAZING CATTLE,

Animal Parasite Research Laboratory, Agricultural Research Service, U. S. Department of Agriculture, Tifton, Georgia 31794
G. Fincher
Journal of Parasitology, Vol. 61, No. 4, p. 759-762, August, 1975. 1 tab, 10 ref.

Descriptors: Nematodes, Cattle, Grazing, Parasites.
Identifiers: Dung beetles.

A study was conducted to determine the effects of dung beetle activity on the number of nematode parasites acquired by parasite-free calves grazing contaminated pastures under natural conditions. Twelve steers with naturally acquired parasite infections were used to contaminate 3 pastures (4 cows to each pasture) with feces containing parasite eggs. Six parasite-free calves were then allowed to graze the pastures for 43-45 days. Two calves, grazing a pasture with a dung beetle population rendered lower than normal by screening and trapping, acquired 9 times more parasites than 2 calves that grazed a pasture on which captured beetles had been released. Two calves that grazed a pasture with a natural dung beetle population acquired 4 times more worms than the calves on the pasture with the increased beetle population. The 2 major genera of nematodes present (Ostertagia and Cooperia) were found definitely to be significantly reduced in number by dung beetles. (Rowe-East Central)

INCINERATION SYSTEM FOR CONTROLLING NOXIOUS ODORS IN A LAYER HOUSE,

Department of Agricultural Engineering, College of Agriculture, Pahlavi University, Shiraz, Iran
R. P. Kachru
Environmental Research, Vol. 9, No. 3, p. 342-348, 1975. 4 fig, 2 tab, 7 ref.

Descriptors: Incineration, Carbon dioxide, Water, Design, Temperature, Turbulence.
Identifiers: Odor control.

An attempt was made to eliminate obnoxious odors produced by poultry manure by incinerating it. Incineration of gases requires 3 basic conditions: (1) The combustion elements must be raised to their autoignition temperature in the presence of sufficient oxygen to complete the chemical reactions. (2) Gases must be retained at that temperature for a sufficient length of time to permit the oxidation to proceed until only CO_2 and water remain. (It was found that a minimum of 0.5 seconds at about 1400° F is required for the complete combustion of obnoxious gases produced in a layer house). (3) Turbulence: The degree of intimate mixing of the air for oxidation with the waste fuel will affect the incinerator performance significantly. (In general, either mechanical or aerodynamic means are utilized to achieve the intimate scrubbing and mixing of the air and fuel.) Direct flame incineration has proven to be the most positive method of continuous elimination of the obnoxious odorous compounds. Heat recovery, when utilized with this system, can cut down the expenses on fuel consumption by an appreciable amount. This combustion recovery heat can be used either for a heat exchanger placed in the system or for heating the "layer" house in the winter time. Total initial investment should be computed and profitability of the incineration system should be analyzed in relation to the individual poultry production setup in order to determine the system's feasibility in individual cases. (Rowe-East Central)

SETTLING AS A METHOD FOR PRETREATING FEEDLOT RUNOFF,

Extension Agricultural Engineers, Agricultural Engineering Department, Purdue University, West Lafayette, Indiana
J. C. Nye, D. D. Jones, and A. L. Sutton
Department of Agricultural Engineering Mimeo, Purdue University, West Lafayette, Indiana, 1974, 26 p. 9 fig, 7 tab.

Descriptors: Feedlots, Agricultural runoff, Settling basins, Waste storage, Irrigation, Groundwater pollution, Odor, Vectors, Liquid wastes, Solid wastes, Economics.
Identifiers: Pretreatment, Settling channels, Infiltration area, Holding ponds.

Before selecting a particular waste management and runoff control system for a feedlot, the settling system should be considered. The runoff control system is composed of 3 functional elements: a pre-treatment unit, a storage unit and a disposal unit. The pretreatment unit may be a settling basin or a settling channel. When the lot is cleaned only a few times a year and where large amounts of manure are carried off the lot in runoff, a settling basin should be used since it has more room for solids storage and can be more readily cleaned. If the lot is cleaned frequently, the volume of solids will be less and a settling channel may be adequate. The storage element may be either a holding pond or an infiltration area. Holding ponds take less land out of production than infiltration areas, but may not be acceptable in areas where the water tables are very near the soil surface or where the soil is underlain with fractured limestone or sand. If a holding pond is used, some sort of irrigation system will be needed to de-water the holding pond when it becomes full. Advantages of settling systems are: (1) Farm labor can build a settling system with equipment that is usually found on a farm. (2) If an infiltration area is used, the management is very simple. (3) The settling basin will reduce the organic loading on a runoff holding pond or a lagoon, reduce pond odor problems and lengthen pond life. (4) Smaller irrigation equipment can be used when settling system is used to treat runoff before it enters the runoff holding pond. (5) Solid manure handling can be used to handle the settled solids if the settling basin or settling channel is properly designed. Disadvantages are: (1) If settling system is constructed of concrete, it can be expensive. (2) Flies and mosquitoes may breed in the channel if it is not cleaned after runoff events. (3) A settling channel and infiltration area will take land out of crop production. (4) Solids which are removed from the system may have to be stored in a solid manure storage area. (Edwards-East Central)

SURVIVAL OF THE SUGARBEET CYST NEMATODE IN THE ALIMENTARY CANAL OF CATTLE,

Farm Advisor in Imperial County
D. G. Kontaxis, G. P. Lofgreen, and I. J. Thomason
California Agriculture, Vol. 30, No. 3, p. 15, March, 1976. 1 tab.

Descriptors: Sugar beets, Nematodes, Cattle.
Identifiers: Manure.

The cyst nematode can be disseminated from field to field by equipment, cultural implements, irrigation water, manure from grazing cattle, and by any other means which transfers soil from one place to another. In this study, sugarbeet roots remaining in a field with high nematode infestation were collected. Soil samples taken just prior to harvesting had an average of 10,280 viable eggs per 100 grams of dried soil. The roots were sectioned into small pieces and fed along with a conventional milled ration to 6 yearling steers for 10 consecutive days. Feces and a sample of roots were collected from each animal. The study showed that eggs in cysts passing through the digestive systems of cattle remained viable. This was evidenced by the white females (new generation) obtained from the roots of the sugarbeet seedlings. Material eaten by cattle started passing in the manure about 3 days after feeding. Most eaten material was excreted within about 7 days of feeding. (Rowe-East Central)

LEGISLATION PERTAINING TO INTENSIVE AGRICULTURE AND THE ENVIRONMENT,

Ministry of Agriculture and Fisheries, the Netherlands
J. P. Van Zutphen
Intensive Agriculture and the Environment, North Western European Region Symposium, The University, Newcastle-Upon-Tyne, September 19-21, 1973, p. 96-98.

Descriptors: Legislation, Air pollution, Water pollution, Agriculture, Pesticides, Permits.
Identifiers: Netherlands, Manure tanks.

Several laws have been introduced in the Netherlands with the intention of balancing agriculture with a clean environment. Three of these laws are the "Public Nuisance Act," the "Pollution of Surface Waters Act", and the "Air Pollution Act". The Public Nuisance Act prohibits the erection, operation and modification without an official permit of any installation that may constitute an external danger or cause external damage or a nuisance. The Pollution of the Surface Waters Act was instituted to curb the pollution of surface waters such as rivers, streams, and coastal waters. The Air Pollution Act was instituted to reduce to a minimum the discharging of noxious substances (including gaseous substances producing noxious odors) into the atmosphere. Another law, the "Pesticides and Allied Substances Act", prevents a pesticide from being used before its approval. Amendments to this Act plan to provide better ways of assuring that surplus pesticides and empty packages do not contaminate water sources. The government also encourages farmers to burn natural gas to cut down on pollution caused by combustion of heavy fuel oils. Manure removal is controlled by the previously mentioned Pollution of Surface Waters Act which mandates a permit for most waste discharges. "Manure banks" have been established, which provide transportation of manure to areas where it can be put to good use. (Sanders-East Central)

RENEWED EMPHASIS ON BEEF FEEDLOT WASTES AS FERTILIZER: IMPACT ON FARM ECONOMICS AND ENVIRONMENTAL QUALITY,

Professor of Agricultural Economics
A. Jacques, M. Freeman and D. Badger
Oklahoma Current Farm Economics, Vol. 48, No. 2, p. 5-10, June, 1975. 2 tab, 5 ref.

Descriptors: Feedlots, Fertilizers, Soils, Crop response, Cattle, Economics, Nutrients.
Identifiers: Land application.

In the fall of 1974, a survey of 24 beef cattle feedlot operators, 10 farmers, and 3 commercial manure handlers was taken in the Oklahoma and Texas panhandle to determine the supply and demand situation for beef feedlot waste and resulting environmental quality implications. Indications are that recent economic and other events have combined to eliminate much of the livestock waste solids problem in the southwestern beef feeding states, as related to both state and federal environmental quality regulations. Results showed that fertilizer prices have increased 200 to 300 percent in the last 3 years. Consequently, farmers have turned increasingly to beef feedlot wastes as a valuable source of plant nutrients. Beef feedlot operators had a difficult time disposing of these wastes in the late 1960's and early 1970's. Most were losing money hauling the manure. Now farmers in the survey are convinced that the nutrient value of beef feedlot wastes is sufficiently high to pay the current rate of \$2.50 to \$3.50 per ton required for applying beef feedlot waste to their land. Increasing quantities of beef feedlot wastes in drier climate zones such as the Southwest likely will be applied to both irrigated and dryland crops and pastures. (Rowe-East Central)

ODOR CONTROL AND ANAEROBIC DEGRADATION OF SWINE MANURE MIXED WITH DIGESTER SLUDGE,

J. L. Roll
M.S. Thesis, University of Illinois, 1973, 106 p. 32 fig, 30 tab, 28 ref.

Descriptors: Sewage sludge, Degradation, Anaerobic conditions.
Identifiers: Odor control, Swine, Mixing.

The 4 objectives in this study are as follows: (1) Determine potential of adding municipal digester sludge to swine manure as a method of controlling odors of swine manure under anaerobic conditions. (2) Determine the ratio of digester sludge to swine manure which gives the best anaerobic digestion of swine manure. (3) Determine the effects of continuous mixing of the digester contents versus mixing for only 30 minutes a day. (4) Determine whether microbial action due to the digester sludge, buffering capacity of the digester sludge, or dilution by the digester sludge is the cause of any odor control that may be observed during the research. Time degradation, odor panel and off-gas analyses were performed in an attempt to determine what the mechanism of odor control was. Three trials were made and in all three, digesters 1, 2, 3, 4, and 5 contained the following ratios (on a volume basis) of liquid swine manure to municipal digester sludge: 2:1, 1:1, 1:2, 1:6, and 1:10 respectively. It was found that digester sludge is valuable in setting up good anaerobic activity in manure. The better anaerobic activity resulted in odor control and better degradation of the manure. The best degradation was observed in the digester with the most odor, so a trade-off may be required. If good solids reduction is desired, some odor will have to be tolerated. Perhaps a closed digester is the answer. (Edwards-East Central)

POULTRY MANURE PHYTOTOXICITY,

Division of Agricultural Chemistry, 5 Parliament Place, Melbourne 3001, Victoria, Australia
I. R. Minchinton, D. L. Jones, and J. P. L. Sang
Journal of the Science of Food and Agriculture, Vol. 24, No. 11, p. 1437-1448, November, 1973.

Descriptors: Poultry, Phytotoxicity, Crop response, Litters.
Identifiers: Land disposal, Growth deformation.

Reports from field personnel and growers in Western Australia, Victoria, and New South Wales indicated the presence of a plant toxin in deep litter fowl manure. Affected crops have included vegetables, in particular tomatoes, ornamental nursery crops (both field and container grown) and ornamental cut flower species. This investigation was conducted to check the possibility that the toxin was different from 2,4-D (previous reports from Western Australia suggested that the toxin was 2,4-D) and to isolate and identify the toxin. Secondary investigation centered around the examination of poultry feed additives. Extracts were made from toxic Victorian and West Australian samples by shaking 20 g of manure with 50 ml of water and filtering. Bioassays were conducted on the extracts and also on concentrations of 2,4-D ranging from 0.1 to 5 parts / million alone and in combination with a non-toxic manure extract. The results of this and other phases of the experiment show that phytotoxicity associated with the use of poultry deep litter was caused by the impurity 4-amino-3,5-dichloro-2,6-lutidine in clopidol, used in feeds to control coccidiosis. The results of this investigation are in direct contrast to previously published literature which inferred that the damage to plants was due to 2,4-D contamination of wheat seed. The results of the second poultry trial show that phytotoxicity only results when the impurity is ingested by poultry, indicating that an active metabolite is formed in the alimentary system of the bird. The bioassay showed that the metabolite is biologically very active. Bioassay dilution studies on the resulting manure showed that on the basis that the diet contained the major impurity at 0.625 part / million, taking account of the digestibility coefficient of 66 percent and assuming complete conversion of the impurity to the metabolite, 0.16 part /million of 4-amino-3,5-dichloro-2,6-lutidine in the feed would cause phytotoxicity and 0.078 part / million would cause no damage. IMPACT OF FERTILIZERS AND AGRICULTURAL WASTE PRODUCTS ON THE QUALITY OF WATERS,

Organisation for Economic Co-operation and Development

Impact of Fertilizers and Agricultural Waste Products on the Quality of Waters, Organisation for Economic Cooperation and Development, Paris, 1973, 72 p. 4 fig. 9 tab., 47 ref.

Descriptors: Water quality, Water pollution, Groundwater pollution, Nutrients, Fertilizers, Eutrophication, Organic wastes, Economics, Leaching, Nitrogen, Phosphorus, Agricultural runoff, Erosion, Irrigation, Legal aspects, Public Health.
Identifiers: Waste management, Environmental effects, Land application, Educational aspects.

Agricultural waste products (particularly animal wastes) and fertilizers make substantial contributions of nutrients to surface waters, thus contributing to the development of eutrophication. This report, based on an investigation conducted by the Organisation for Economic Co-operation and Development Water Management Sector Group on Eutrophication of Surface Waters and its control, gives an evaluation of nutrient contribution to surface waters and indicates measures and practices that may be employed to reduce such contributions. Sources of nutrient enrichment of surface waters include industrial discharges, urban discharges, agricultural activities, and rainfall. The sources of nutrient loss from soil include those from soil organic matter, soil minerals, fertilizers and all types of organic manures. Mechanisms for nutrient losses which occur from agriculture to the water system are leaching, surface runoff, erosion and direct discharge of animal wastes. These vary considerably, depending on the agricultural system (e.g. crop rotation and fertilizer practice) and the geographical characteristics (e.g. climate, soil type, and slope.) The most serious source of nutrient losses from agriculture to water is from operations with high livestock densities. Since the range of climatic and geographical conditions, and the range of customary agricultural practices vary very greatly from region to region, only a general guide to remedial measures can be given. Factors that must be considered when proposing a change in customary practices include environmental aspects, employment, economic feasibility, need for food production, practical applicability and cost. A change in the education of the farmer is needed, which not only considers the economic factors of fertilizing operations, but also the environmental consequences of nutrient losses. (Penrod-East Central)

METHANE FROM FARM WASTES,

D. M. Paulin

The Soil Association, Vol. 2, No. 4, p. 10, 20, April, 1974, 1 fig.

Descriptors: Methane, Recycling, Fertilizers, Biological treatment, Organic wastes, Design, Anaerobic digestion, Copper, Air pollution, Water pollution, Soil contamination.
Identifiers: Refeeding, Swine, Scotland.

The experiments in progress at the Rowett Research Institute and the Scottish Farm Buildings Investigation Unit, North of Scotland College of Agriculture, were started originally not so much for possible energy production as because of overall public concern about control of land, air, and water pollution. It was realized at once that biological treatment of farm wastes could lead to efficient recycling, but it was also realized that such treatment as is used in domestic sewage systems was not adequate because of the very much higher content of organic material in farm wastes. The team examining the problems, therefore, decided to experiment with anaerobic digestion, using wastes from an intensive pig unit. After experimenting with varying rates and different load mixtures, it was found that a mixture of sow-house and fattening-house waste (3.5 percent solids), with a loading rate of 100 gal /day and at a digester temperature of 35 degrees C, increased gas production to about 500 cu ft /day, comprising 68 percent methane and 32 percent carbon dioxide. However, the actual volume of gas produced depends on the composition of the waste as well as the volume. Three things seem within reach in the foreseeable future: (1) The production of useful fertilizer, complicated in the case of pig slurry by the indestructibility of the copper now apparently included in pig nutrition, (2) The production of feed recycled from the treated wastes, with the same reservations concerning pig wastes, and (3) The production of methane gas with potential for heating and for energy for static farm machinery. The ultimate goal is to produce a design for a cheap, easily run anaerobic plant for the ordinary farm. (Rowe-East Central)

FARM WASTE COMPOSTING PROCESS,

Anonymous

Effluent and Water Treatment Journal, Vol. 15, No. 9, p. 482-488, September, 1975. 1 fig.

Descriptors: Pollution control, Slurries, Solid wastes, Design.
Identifiers: Composting, Land disposal.

Dr. K. R. Gray and Dr. A. J. Biddlestone of the Chemical Engineering Department lead the Compost Studies Group at the University of Birmingham, which for the past 5 years has been studying the application of composting to the treatment of farm manure slurries. The Ministry of Agriculture is encouraging farmers to return to their fields as much animal manure as possible. The new process will enable farmers to do this without the previously attendant risk of pollution of the air, neighboring water courses or the soil. The key to the process is the efficient use of the head from a slurry-straw composting reaction to evaporate the water from the slurry, thereby leaving a solid compost product with no liquid effluent. The equipment consists of 4 specially constructed cubes maintained under forced aeration. In each cube a batch of slurry and straw is composted for about a month; the cubicle is then emptied and refilled. In Week 1, for a particular cubicle, slurry and the straw are carefully blended and the cubicle filled. The straw matrix filters out the suspended solids from the slurry and absorbs much of the liquor. In Week 2, the mass reaches its maximum composting temperature. The drainage liquor from the recycle tank is carefully sprayed over the composting mass and becomes totally evaporated into the stream of air being blown through the matrix. In Weeks 3 and 4, composting continues under forced aeration conditions but without any liquid recycle. The temperature starts to fall back and the cubicle is emptied at the end of week 4. The weight of the mass falls to 1 /3 that of the original charge, owing to the enormous evaporation of water. The technique can handle manure slurries from any source—pigs, cattle, or poultry. The capital installed cost of a manufactured unit is likely to be about 10 pounds per pig place, 100 pounds per cow place. Labor needs for a 1000 pig or 100 cow unit are about ½ hour per day for cubicle filling and 1-2 hours per week for cubicle emptying and stockpiling the compost. (Ott-East Central)

EVALUATION OF B-EXOTOXIN OF <u>BACILLUS THURINGIENSIS</u> BERLINER FOR CONTROL OF FLIES IN CHICKEN MANURE,

3231 E. Lester Street, Tucson, Arizona
R. J. Barker and W. F. Anderson

Journal of Medical Entomology, Vol. 12, No. 1, p. 103-110, 1975. 1 fig, 8 tab, 16 ref.

Descriptors: Insecticides, Feeds, Toxicity, Performance, Poultry.
Identifiers: Fly control, Animal health.

The objectives of this study were to determine the efficacy and safety of B-exotoxin in feed and in water for control of flies in chicken manure, to establish and to describe early symptoms of overdosage to birds to check possible long-range toxic effects, and to obtain a rough indication of the ultimate fate of exotoxin. Because it takes chickens about a week to adapt to new cages or rations, the same birds were used in successive tests. First, they were used to establish what level of toxin should be fed to control flies in feces. Next, soluble and insoluble salts were compared. Finally, dosages were increased until a margin of safety between control of flies and harm to birds could be established. Results were: The B-exotoxin was highly toxic to chickens whether added to feed as a calcium or a sodium salt or to water as the sodium salt. Early poisoning symptoms were loss of vigor, reduced feeding, and undersized eggs. Reduced feeding was not a consequence of palatability. Exotoxin caused severe gizzard erosion, enteritis, and proventriculitis. The exotoxin degraded when manure liquified and lost the ability to kill house fly larvae under such conditions. House flies acquired resistance to B-exotoxin after 6 months continuous selection from larval exposures. The LD_{95} increased 30 times, to the point that larvae grew with 600 ppm of exotoxin in the medium. (Rowe-East Central)

UTILIZATION OF WASTES AND BY-PRODUCTS IN ANIMAL FEEDS,

Agricultural Research Council, Poultry Research Center, King's Buildings, West Mains Road, Edinburgh EH9 3JS, Scotland
R. Blair

Feedstuffs, Vol. 46, No. 39, 1974. 8 tab, 33 ref.

Descriptors: Recycling, Byproducts, Feeds, Energy, Proteins, Minerals, Performance, Legal aspects, Economics.
Identifiers: Plant wastes, Animal wastes, Industrial wastes, Dried poultry waste, Dried poultry litter.

The potential of various wastes and byproducts as animal feedstuffs is surveyed. Included are animal wastes and byproducts, plant wastes and byproducts, and various industry wastes such as bakery wastes, wood wastes, household wastes, vegetable wastes and surplus, and waste potatoes. In the animal waste category, dried poultry waste (DPW) and dried poultry litter (DPL) receive particular attention. Among the points made are: (1) DPW is variable in composition and contains a high content of nitrogen. (2) The main difference in DPW and DPL is the higher content of crude fiber in DPL due to the admixture of droppings with litter. (3) The nutritive value of poultry waste is higher for ruminants than for nonruminants because ruminants can utilize uric acid and some fiber. (4) Studies indicate that DPW can be used as a source of energy, protein and minerals by poultry and, under certain price situations, may be an economic feed ingredient. (5) Studies indicate that both DPW and DPL are suitable protein sources for beef cattle although there may be problems in diet formulation due to the low energy value of the wastes. (6) The main loss of nitrogen from raw poultry waste is due to fermentation and for ruminant feeding, the waste is more valuable if collected and dried soon after being voided. (7) One detrimental feature of DPL is its content of lignin (about 8 percent), which ruminants are unable to degrade and which also reduces the digestibility of the carbohydrate with which it is combined. (8) Recycling animal waste is banned in most EEC countries and in the United States. In the United Kingdom, the use of DPW is not prohibited unless it can be shown that the feed contains deleterious ingredients. (Rowe-East Central)

METHANE DIGESTERS FOR FUEL GAS AND FERTILIZER,

The New Alchemy Institute-East, Box 432, Woods Hole, Massachusetts
R. Merrill and Y. Merrill, ed.

Newsletter No. 3, The New Alchemy Institute, 1973, 46 p. 34 fig, 10 tab, 69 ref.

Descriptors: Anaerobic digestion, Recycling, Methane, Fertilizers, Sludge, Organic wastes, Algae, Fish, Design.

Identifiers: Methane digesters.

This study: (1) presents a general background of the raw materials and processes of digestion, (2) discusses some preliminary ideas for using methane gas and sludge, (3) describes 2 designs for building simple working models of digesters, and (4) develops feedback from readers who are working on digester projects across the country. From a biological point of view, digesters can be considered as a culture of bacteria feeding upon the converting organic wastes. The basic gas producing reaction in the digester is: Carbon plus water = methane plus carbon dioxide. The composition and fuel value of bio-gas from different kinds of organic wastes depends on (1) the temperature at which digestion takes place, and (2) the nature of the raw material. Digesters can be designed for batch feeding (filling all at once, sealing, and emptying when the raw material stops producing gas) or for continuous feeding (feeding a little, regularly, so that gas and fertilizer are produced continuously). The digesters require little daily attention. Anaerobic digestion is about 60-70 percent "efficient" in converting organic waste to methane. Most solids not converted into methane settle out in the digester as a liquid sludge. This sludge may be used as a fertilizer and soil conditioner or as a stimulant in ponds for algae growth, which in turn encourages fish growth. The sludge may also be used in a sludge-algae-methane system in which green algae is grown on diluted sludge, then harvested, dried and digested to produce methane for power and sludge for recycling. Actual digester design information is given on how to build a sump digester and how to build an inner tube digester. (Rowe-East Central)

PERFORMANCE OF SYSTEMS CONTROLLING RUNOFF FROM FEEDLOTS,

Research Assistant, Department of Agricultural Engineering, University of Illinois, Urbana 61801
E. C. Dickey and D. H. Vanderholm
Illinois Research, Vol. 18, No. 1, p. 10-11, Winter, 1976. 1 fig.

Descriptors: Agricultural runoff, Feedlots, Illinois, Regulations, Water pollution, Air pollution, Soil contamination, Design, Costs, Nitrogen, Phosphorus, Potassium, Soil analysis.
Identifiers: Runoff control, Land application.

Although present Environmental Protection Agency (EPA) regulations make runoff control mandatory for large feedlots, EPA and the Illinois Pollution Control Board are now proposing livestock regulations which will apply to all livestock operations regardless of size. These regulations will require modification of many facilities and will present small and medium sized operations with the problem of economically controlling polluted runoff. A runoff control system usually consists of a runoff collection component such as a channel, a settling basin to settle out a portion of the manure solids, and a holding pond to store the liquid after settling. Liquid from the holding pond is usually spread on nearby cropland as a supplemental water supply and a source of nutrients. Because runoff control systems are few in number and fairly new to Illinois, several beef, dairy, and swine operations with runoff control systems in central and northern Illinois have been monitored since the spring of 1974 with the following objectives in mind: (1) to determine whether installations are preventing air, water, and soil pollution, (2) to discover any management problems that could be eliminated by modifying the system, (3) to determine the adequacy of present design criteria, and (4) to study the balance of nutrients, particularly nitrogen, through runoff systems. The runoff control systems under study were found to be helping prevent water and soil pollution. Design capacities for the settling basins and holding ponds were found adequate. None of the systems caused odor complaints. Both liquids and solids were found to be sources for supplying soil nutrients. The quality of the holding pond water was largely determined by the size of the lot, number of animals, and management of the lot and runoff control systems. (Edwards-East Central)

ENERGY AND NUTRIENT CONSERVATION IN SWINE WASTE MANAGEMENT,

Associate Professor, Agricultural Engineering Department, Clemson University, Clemson, South Carolina 29631
C. L. Barth and D. T. Hill
Presented at the 1975 Annual Meeting, American Society of Agricultural Engineers, University of California, Davis, June 22-25, 1975, Paper No. 75-4040, 16 p. 3 fig, 10 tab, 15 ref.

Descriptors: Recycling, Methane, Energy, Fertilizers, Economics, Anaerobic digestion, Design.
Identifiers: Swine.

Even though animal manures have always been highly regarded as a source of nutrients for crop production, recent increases in the cost of inorganic nutrients have made it clear that animal manures can be an economical, as well as a practical, source of nutrients. Animal manures can also serve as an alternate source of energy through methane production. Using animal manures for methane production is attractive because, after the energy is harvested, the nutrients remain for possible recycling on croplands. Farmers can save money by converting their gas fueled equipment to use methane. One major problem related to gas utilization, however, is that because of the expensiveness of storage of methane gas, the gas must be used at a rate approximating its production. Possible uses of methane gas on a livestock farm are: (1) water heating for the farm residence and/or livestock, (2) power for feed grinding, (3) family food preparation, (4) dead animal incineration, and (5) pig and chicken brooding. An anaerobic digester, which is still being used for experimentation with the goal of completing the unit so that it can be a more effective demonstration of the technology and so that it will be useful for further studies on maximizing the conservation of energy and nutrients from swine and other animal wastes. (Edwards-East Central)

THE EFFECT OF AERATION ON THE GASES PRODUCED BY SLURRY DURING STORAGE,

Department of Agriculture, Agricultural and Food Chemistry Research Division, Belfast, Northern Ireland
R. J. Stevens and I. S. Cornforth
Journal of the Science of Food and Agriculture, Vol. 25, p. 1249-1261, 1974. 10 fig, 2 tab, 19 ref.

Descriptors: Aeration, Gases, Slurries, Aerobic treatment, Oxygen, Microorganisms, Waste storage, Hydrogen sulfide, Carbon dioxide.
Identifiers: Anaerobic treatment, Decomposition.

The effect of oxygen supply on the gases produced by decomposing slurry was measured in a series of laboratory experiments. The slurry mixture for the experimental treatment contained 2.9 percent total solids (105 degrees C), 0.7 percent total solids (550 degrees C), 0.26 percent total nitrogen, 0.12 percent ammonia-nitrogen and 1.40 percent total carbon. Aeration treatments were applied in duplicate using identical apparatuses. All experiments were done at laboratory temperature, approximately 18 degrees C. The amount of O_2 consumed and carbon dioxide produced increased with oxygen supply. Decomposition was the greatest when air was passed through slurry, 31 percent of initial total carbon being evolved as carbon dioxide in 14 days. Results showed that readily decomposable substrates, such as volatile fatty acids, were rapidly metabolised under aerobic conditions. Only trace amounts of ethylene were produced in any treatment. CH_4 and H_2S was prevented from forming if the anaerobic treatment was preceded by an aerobic treatment. The evolution of H_2S from settled slurry was prevented by surface aeration. Hydrogen sulfide was released, however, once surface-aerated slurry was agitated. A combination of aerobic followed by anaerobic treatments caused the greatest loss of nitrogen from slurry as NH_3 and N_2O. The use of N_2 to create anaerobic conditions was not ideal since volatile constituents were purged out of solution, resulting in a lowered activity of methane-producing bacteria. (Cameron-East Central)

EFFECTS OF AERIAL AMMONIA, HYDROGEN SULFIDE AND SWINEHOUSE DUST ON RATE OF GAIN AND RESPIRATORY-TRACT STRUCTURE IN SWINE,

University of Illinois, Urbana 61801
S. E. Curtis, C. R. Anderson, J. Simon, A. H. Jensen, D. L. Day, and K. W. Kelley.
Journal of Animal Science, Vol. 41, No. 3, p. 735-739, September, 1975. 1 tab, 23 ref.

Descriptors: Air pollution, Ammonia, Hydrogen sulfide, Dusts, Gases.
Identifiers: Swine, Animal health, Respiratory tract.

This study comprised 7 trials intended to determine the effects of exposure to ammonia (NH_3), hydrogen sulfide (H_2S) and dust at various levels, alone and in various combinations, on the gross and microscopic integrity of the respiratory tract of the pig. Four dynamic-type, air-pollutant exposure chambers manufactured out of stainless steel and glass were used. Each chamber had an exposure zone comprising a cube, 1.22 m. on a side, giving a volume of 1.81 meters. Each chamber could hold 4 pigs to a body weight of 50 kg or 2 pigs to 100 kilograms. Aerial levels of NH_3, H_2S and dust used as treatments in these trials with pigs were as high or higher than those usually encountered in enclosed swine houses. Results showed: with the exception of mild conjunctivities and blepharitis in one of the pigs exposed to NH_3 (50 ppm), there was no evidence of structural alterations in any organ or tissue due to experimental treatment. Turbinates, trachea and lungs of all pigs were classified as "normal" after both gross and microscopic examination. Air factors in swine houses may influence the incidence and severity of chronic pneumonia in swine. However, these results indicate that the rate of gain and respiratory-tract structure of growing pigs, which are free of respiratory disease, are not directly influenced by NH_3, H_2S and dust at levels and in combinations commonly encountered in the air inside enclosed houses at commercial swine production operations. (Rowe-East Central)

OPEN FLUMES SLASH CONFINEMENT COSTS,

B. Fleming
Beef, Vol. 12, No. 12, p. 8-9, August, 1976. 5 fig.

Descriptors: Design, Costs, Confinement pens, Cattle, Performance.
Identifiers: Floors, Open flumes.

A new floor design, the open flume, is being used by Gerald Frankl, a Sioux City Iowa consultant, in recent buildings and waste handling systems that he has designed for cattle feeders in the U.S., Canada, Iran, and South Africa. The design has 2 selling points: (1) It works at least as well as the traditional type of flume floor, and maybe a little better, and (2) The floor costs less than half as much as the enclosed system. Perhaps the first U.S. facility using the new design concept will be Dennis Ducomum farm, northeast of Larrabee, Iowa. A detailed description is given of this facility. Frankl estimates that in most Midwest locations, a feeder can build the floor, plus feedbunks, fences, waterers and plumbing for flushing, for about $25 to $35 per animal space. This figure does not include a lagoon or the building put over the floor. Other design advantages are: (1) There is less chance of cattle hurting themselves, and (2) the narrower building gives better ventilation on hot days and drier floors in damp weather. Frankl also discusses the possibilities of a confinement that will have a floor but no building. (Edwards-East Central)

OHIO LIVESTOCK WASTE MANAGEMENT GUIDE,

Cooperative Extension Service, The Ohio State University, Columbus 43210
R. K. White
Ohio Livestock Waste Management Guide, Bulletin 604, Cooperative Extension Service, The Ohio State University, December, 1975, 32 p. 13 fig, 18 tab.

Descriptors: Farm wastes, Management, Livestock, Liquid wastes, Solid wastes, Design, Feedlots, Confinement pens, Waste storage, Waste treatment, Waste disposal, Poultry, Economics, Agricultural runoff, Safety, Pollution, Chemical properties.
Identifiers: Runoff control, Land application, Odor control.

This guide contains information which will help a livestock owner or operator make decisions in choosing and operating a livestock waste handling system which controls pollution. One important factor in determining the type of system is "how much manure is to be handled and what kind". Many types of systems are discussed, along with the cost and safety features of each. Ways to control rainwater runoff from feedlots are given. Other important factors included in this guide are: (1) land application rates, (2) odor control, (3) treatment units, (4) milking facility waste management, and (5) silage drainage. (Edwards-East Central)

EVALUATIONS OF BEEF FLUSHING GUTTER WASTE SYSTEMS IN MISSOURI, IOWA, AND MINNESOTA,

Agricultural Engineering Department, University of Minnesota, St. Paul 55108
J. A. Moore and R. M. George
Presented at the 1974 Annual Meeting, American Society of Agricultural Engineers, Oklahoma State University, Stillwater, June 23-26, 1974, 10 p. 2 fig, 2 tab, 3 ref.

Descriptors: Missouri, Iowa, Minnesota, Confinement pens, Cattle, Design, Irrigation.
Identifiers: Flushing, Cold confinement facilities, Floors, Land disposal, Floors.

In this study, 3 agricultural engineers observed and evaluated flushing beef systems. The report is based upon site visits and studies of more than 15 such units through the winter and spring of 1973-74. The 4 major components of the system are: (1) A building with sloping gutters or flumes running parallel to the bunk the entire length of the building, (2) the pump and recycle system which introduces the flushing water to the gutter, collects it at the other end and routes it to the storage and treatment facility, (3) A lagoon to store and treat the waste water after it has flushed the manure from the building and before it has again recycled, and (4) An irrigation system for sprinkling this liquid waste on adjacent agricultural land. All of the buildings observed were cold confinement facilities open to south. Construction type consisted of either pole or steel frame. Cattle floor width of 32-36 feet was found satisfactory. A 12-foot eave height seemed adequate. It was observed that the ridge opening should be at least 12 inches wide to avoid frosting shut. Ventilation openings on the back wall should be adjustable. The floor should be at least as rough as a broom finish to provide good footing for the animals. A floor slope of 1-inch per foot was found satisfactory. The number of gutters to be used and the benefits derived needs additional study. The design of the flushing system has to be based on the total manure distribution into the individual gutters. Narrow, shallow gutters need to be flushed more often. At the time of the engineers' visits, lagoons were not very active due to the cold temperature and no substantial evaluation was possible. Land spreading had not yet taken place; hence, it could not be evaluated. (Rowe-East Central)

REMOVE MANURE ODORS,

Anonymous
Hoard's Dairyman, Vol. 121, No. 3, p. 161, February 10, 1976.

Descriptors: Chemicals, Liquid wastes, Costs, Management, Ventilation.
Identifiers: Odor control, Biological compounds, Land disposal, Soil injection.

J. C. Converse, a University of Wisconsin agricultural engineer, says that some of the chemical and biological compounds used for controlling odors in liquid manure tanks are selling for $19 to $21 per pound. These compounds fall into the following categories: (1) Masking agents - those used to cover up offensive odors, (2) Counteractants - those which react with odors to make them inoffensive, and (3) Bacterial or enzyme compounds - those which act on the manure itself to lessen odor production. A study conducted about 5 years ago showed that most of these compounds are not effective and the ones that were effective were extremely expensive. Methods such as (1) soil injection, (2) plow down of manure immediately after spreading, (3) proper ventilation, and (4) proper climatic conditions for spreading should be tried before utilizing chemical and biological compounds. It is recommended that one should try a small amount of odor control chemicals before making a large order. (Edwards-East Central)

COLLECTION AND DISPOSAL OF FARM WASTES,

Ministry of Agriculture, Northern Ireland
J. S. V. McAllister
Water Pollution Control, Vol. 69, No. 4, p. 425-429, 1970. 6 tab, 5 ref.

Descriptors: Farm wastes, Waste storage, Waste disposal, Slurries, Nutrients, Potassium, Odor, Drying, Incineration, Soil contamination.
Identifiers: Ireland, Land application, Odor control, Plant response, Wet combustion.

At present, practically all the slurry collected in the British Isles is disposed of by direct application to the land after a relatively short, 1 to 13 weeks, storage period. Some of the experience acquired in the handling and use of slurry in Northern Ireland is reviewed. Storage tanks in Northern Ireland are generally covered. Spreading is generally done by tanker. Vacuum tankers probably give the most uniform distribution, ensure more thorough agitation of the slurry in the storage tanks, and in wet weather can spread through pipelines. The unpleasant odors which occur during spreading can be minimized by the use of certain organic compounds, but at present these are not extensively used as they are expensive relative to the value of slurry. The manurial value of slurry is variable depending upon factors such as the livestock from which it is obtained, the duration and conditions of collection and storage, and the degree of dilution. Much experimental work is being undertaken to assess the manurial value of the plant nutrients in slurry. No reliable information is available on the long-term effects of regular applications of slurry on soil structure and sward growth under local conditions. A major problem which may arise from the intensive use of slurry as a manure will be a buildup in the concentration of nutrients in the soil and especially of potassium to an excessive level. Alternative methods of disposal as drying of excreta, incineration, and wet combustion are reviewed. (Solid Waste Information Retrieval System)

HANDLE FREE STALL MANURE AS A SOLID WITH PICKET DAM STORAGE,

T. L. Loudon
Hoard's Dairyman, Vol. 121, No. 9, p. 587, 594, May 10, 1976. 3 fig, 1 tab.

Descriptors: Liquid wastes, Solid wastes, Water storage, Separation techniques.
Identifiers: Free stall manure, Picket dam, Land spreading.

There is now an alternative to handling manure as a liquid from free stall barns. Handling free stall manure as a solid with a new innovation — picket dam storage — allows the feedlot owner to be flexible in handling loads, to save time and trips when spreading, to cut hauling fuel costs, and to avoid 2 kinds of manure equipment. In such a system, manure can be moved to storage with a stacker, an underground piston pump which does not require added water during pumping, or a tractor push-off ramp. A picket-type structure with continuous verticle slots about three-fourths of an inch wide between standing planks holds manure solids back and allows liquids to drain from the storage facility. The verticle slats are made of treated 2 x 6's. Drainage should be moved from the manure storage to a holding pond through an open ditch or a pumping system involving a level controlled sewage pump in a sump. (Rowe-East Central)

SOME EFFECTS OF STOCKING FISH IN WASTE TREATMENT PONDS,

Fish and Aquaculture Research Station, Dor, Hof Hacarmel, Israel.
G. L. Schroeder
Water Research, Vol. 9, No. 5-6, p. 591-593, June, 1975. 2 tab, 9 ref.

Descriptors: Fish, Organic wastes, Dissolved oxygen, Chemical oxygen demand, Bacteria.
Identifiers: Waste treatment ponds, pH.

Five, 400 m^2, 1 m deep freshwater, earthen ponds were operated for 4 winter months with or without addition of organic wastes, and with or without fish. Organic waste in the form of liquid cow manure containing urine and feces was added to the ponds once every 2 weeks at rates up to 40 tons ha^{-1}. Observations showed that both DO and pH were significantly and consistently higher in the manured pond stocked with fish as compared with the manured, unstocked pond. Improved disinfection was indicated by the lower bacteria counts in the water of the manured pond with fish as compared to the manured, unstocked pond. Increased pH also improved the effectiveness of the pond as a nutrient trap. As pH increased, nitrogen was more readily lost to the atmosphere as NH_3 and multivalent ions, especially phosphorus, became less soluble and so were precipated more completely. These changes would be improvements to the operation of waste treatment ponds designed to provide an effluent low in BOD, nutrients, and bacteria. Bacteria concentrations were as much as 15 times lower in treatment ponds stocked with fish as compared with unstocked ponds. Lower bacteria concentrations, however, reduced the rate of loss of COD in the solids of the waste. (Rowe-East Central)

POULTRY ENVIRONMENT SYSTEM MODEL FOR DRYING MANURE,

Associate Professor, Agricultural Engineering Department, University of Idaho.
J. E. Dixon, M. L. Esmay, and J. B. Gerrish
Presented at the 1976 Annual Meeting, American Society of Agricultural Engineers, University of Nebraska, Lincoln, June 27-30, 1976, Paper No. 76-4039, 38 p. 4 fig, 2 tab, 24 ref.

Descriptors: Drying, Ventilation, Design, Poultry, Computer models, Moisture content.

The principle thrust of this study is the development of an analytical tool for maximizing pre-mechanical-drying. A computer simulation model for ventilation air pre-drying of poultry manure produced in a cage-type laying house has been developed. A 5000 bird egg production operation was used for validating the model. Experimental measurement of moisture content was made by taking samples of manure from the dropping boards just prior to removal of the manure from the laying house. The moisture content of these samples was determined by finding the difference in the weight of the water in the manure as voided and the weight of water in the manure just prior to removal from the laying house. The range of values for the two categories was 68.87 to 76.25 percent and 70.61 to 76.95 percent, respectively. The correlation coefficient of these data was 0.16. The data means and standard deviations were 73.09; 1.80 and 74.64; 2.07, respectively. The simulation model in its present form does not seem suitable for accurate estimates of in-house poultry manure drying using ventilating air. The basic concepts of the model do seem sound, however. Further work toward development of the simulation model and its verification would seem desirable. (Rowe-East Central)

HOW MANURE APPLICATIONS AFFECT EROSION AND RUNOFF,

R. W. Gunther, W. D. Lembke, and J. K. Mitchell
Illinois Research, Vol. 17, No. 4, p. 11-12, Autumn, 1975, 1 fig, 1 tab.

Descriptors: Erosion, Agricultural runoff, Nitrates, Percolation, Soil investigations.
Identifiers: Land application.

A laboratory study was conducted to determine the effects of manure applications on runoff rates, erosion, and loss of nitrates. Three treatments were compared: 3/8 inch of waste (1.4 tons of solids per acre) applied to the soil surface; 3/4 inch of waste (2.8 tons of solids per acre); no manure, but 3/4 inch of water added to the soil. The water was applied to reduce the effect of the water in the animal waste when runoff comparisons were made. Waste applications decreased runoff by about 50 percent. However, the 3/4 inch application did not reduce runoff any more than the 3/8 inch application. Waste applications reduced the total loss of solids, both because the runoff was smaller, and because it contained a lower concentration of solids. Manure applications increased percolation through the soil. Much of the benefit derived from the liquid manure was due to the stabilization of the soil surface that resulted from the crust formed during drying. (Rowe-East Central)

Standardizing Properties and Analytical Methods Related to Animal Waste Research, American Society of Agricultural Engineers, Winter Meeting, December, 1972, p. 59-62.

Descriptors: Recycling, Fertilizers, Feeds, By-product recovery, Fuels, Economics, Safety.
Identifiers: Manure, Soil conditioners, Refeeding, Construction materials, Waste management, Efficacy.

Most known and suggested uses of animal manure fall into 1 of 4 categories: (1) Soil conditioners and fertilizers, (2) feed and food production, (3) fuel, (4) other uses. After the use is selected, the beneficial and detrimental properties of the manure can be identified and quantified. Most manures have been and probably will continue to be applied to crop lands as fertilizer. Manure is also useful for establishing cover on road banks and other construction sites. Manure may be used as potting soil; however, if the manure is fresh, some processing is necessary. Besides actually refeeding manure to animals, other methods of utilizing manure nutrients include: production of algae and water plants, raising fly larva in poultry manure as a protein supplement, culture of bacteria and fungi, and raising mushrooms on partially composted horse manure. Fuels may be recovered from manure simply in the form of dried manure or in production of gases and oils from manure. Manure may also be considered as a raw material for production of construction materials. Composted manure can be used as an organic carrier for chemical fertilizers. Dried compost can be used for animal bedding. The adoption and success of any of these practices will depend upon their efficacy, safety, and economics in the market place. In determining efficacy, consider: (1) concentration and uniformity of the desired ingredients, (2) availability of those ingredients and the rates at which they can be utilized, (3) public acceptability, (4) stability during storage and handling, (5) special requirements during the process and levels of use for the produce. In determining safety, the presence of extraneous materials, toxic materials, and/or of pathogenic organisms should be considered. Economic factors to consider are: potential for pollution, energy requirements, and possible influence on the animal production system. (Rowe-East Central)

STORED FEEDLOT RUNOFF MAY UNDERGO CHANGES,

Anonymous
Beef, Vol. 12, No. 6, p. 5, February, 1976.

Descriptors: Waste storage, Agricultural runoff, Nutrients, Salinity, Feedlots, Effluent.
Identifiers: Holding ponds.

Holding ponds are not considered as effluent treatment devices, but as storage which should be emptied as soon as possible. The effluent is most valuable when applied to a growing crop in need of moisture and nutrients. Because much of the feedlot runoff in Nebraska comes at a time outside the season for most annual crops or during a time when the soil profile is saturated, scientists studied the changes that can occur in the liquid when it is stored for later use. The effluent was found to be continually changing due to solids settling, microbial activity, evaporation, and dilution by direct rainfall. It was determined that effluent applications to the land should be adjusted according to nutrient accumulation and whether leaching is necessary to control salinity. (Merryman-East Central)

SOLUTION FOR SMALL-FARM RUNOFF,

Anonymous
Farm Journal, Vol. 100, No. 2, p. LK-2, February, 1976.

Descriptors: Agricultural runoff, Design, Settling basins, Nitrogen.
Identifiers: Swine, Infiltration channel, Solids removal.

A simple means of keeping hoglot runoff from streams, exemplified by Purdue University's Lynnwood Farm, is to construct a settling basin and infiltration channel. The cost is about $2 to $3 per hog capacity. This system is best adapted to a 200-700 hog operation. Lynnwood Farm is a 250-head Cargill open-front unit. It has a 16' x 16' x 30" deep settling basin at the low end of the apron across the front of the building. This has been removing 60-76 percent of the solids and 54-75 percent of the total nitrogen from the runoff. Snaking to the rear is a grassed infiltration channel (or ditch or terrace) which ends with a small earthen retention facility. The infiltration channel should cover an area twice the size of the feedlot. At Lynnwood Farm, the total investment for the housing unit, feedlot and runoff control was $52 per head capacity. Exact design specifications for each individual feedlot owner's operation should be based on state regulations and local formulas. (Merryman-East Central)

SLUDGE SAMPLER,

Assistant professor, Agricultural Engineering Department, Institute of Food and Agricultural Sciences, University of Florida, Gainsville 32611.
R. A. Nordstedt and L. B. Baldwin
Agricultural Engineering, Vol. 56, No. 5, p. 47, May, 1975. 1 fig.

Descriptors: Equipment, Sampling, Lagoons, Anaerobic conditions, Design.
Identifiers: Sludge sampler.

A sludge sampler has been developed which collects samples at various depths in anaerobic animal waste lagoons. The procedure for using the sludge sampler is: (1) The sampler is lowered to the desired depth, aided by depth markings on a conduit. (2) The lever arm at the top of the sampler is actuated, removing the rubber stopper from the plastic cylinder and allowing sludge to flow into the sample chamber. (3) The lever arm is released and the spring in the sampling chamber pulls the rubber stopper back into the closed position, preventing mixing of the sample with sludge from other depths. (4) The sampler is removed from the lagoon. The bottom stopper is opened to transfer the sludge from the sampler to a bottle for transport to the laboratory. (Merryman-East Central)

EVERYTHING GOES ROUND AND ROUND AT KAPLAN'S FEEDLOT,

Editor, Beef
P. D. Andre
Beef, Vol. 12, No. 9, p. 4-6, May, 1976. 4 fig.

Descriptors: Recycling, Separation techniques, Confinement pens, Feedlots, Lagoons, Algae, Agricultural runoff, Irrigation.
Identifiers: Refeeding, Nile Perch, Packing plant wastes, Land spreading, Paunch manure.

In 1963, Don Kaplan contracted with Corral Industries, Inc., Phoenix, Arizona, to build 6 quarter-mile long slatted floor barns, along with a manure collection, separation, and recycling system. The confinement barns, alleyways, and drive lanes cover 18 acres. The barns are roofed and all open areas are hard surfaced so that every drop of runoff can be collected. The waste materials which collect under the barns are scraped on a time clock system every 2 hours and then flow by gravity to a nearby collection pit. Materials from the pit are put through a vibration separator and the solids are removed and stockpiled for incorporation back into the ration. The liquid flows to a nearby lagoon system. The lagoons are worked phosphate pits left over from a former phosphate mining operation. Connecting lines allow the water to flow from one lagoon to another. As the material moves through the series of lagoons, the nutrients are utilized by algae. Nile Perch have been placed in the last lagoon to eat the algae. Kaplan has contracted with a commercial fisherman who will seine out the fish, except for some brood stock. This operator will remove the filets and sell them and the unusable portions will be returned to Kaplan for conversion into fish meal to be used in his cattle rations. By using the algae-eating fish, the lagoon water becomes potable after chlorination and is pumped back to be reused in the packing plant and feedyard. Some water is also used for irrigating crops. Other wastes that Kaplan incorporates into his cattle feeding rations are blood from the packing plant and meat and bone meal made from bones and other packing plant residues. Paunch manure is hauled and spread on nearby fields. Among Kaplan's future plans is the construction of a methane production plant for converting wastes to methane. A by-product of this process will be dry Ice. (Rowe-East Central)

THE INFLUENCE OF THE LAGOON STORAGE OF LIQUID MANURE ON ITS VOLUME AND COMPOSITION,

F. Schulz
Wasserwirtschaft-Wassertechnik, Vol. 22, No. 6, p. 190-191, June, 1972. 2 fig, 11 ref.

Descriptors: Lagoons, Waste storage, Physical properties, Chemical properties, Liquid wastes, Biochemical oxygen demand, Nitrogen, Potassium, Phosphorus, Waste treatment.
Identifiers: Land disposal, Purification, Irrigation.

A model experiment on the efficiency of the lagoon storage of liquid manure is described. The rate of volume reduction of cattle manure in unsealed lagoon in pervious soil was 1,055 mm per year or 2.9 mm per day due to the combined effect of leakage and evaporation, while the corresponding value for sealed lagoon was 220 mm per year. Investigations of the liquid component revealed reductions of about 62, 48, and 54 percent in the BOD, the total nitrogen, and the potassium contents, respectively. The reduction of the total organic content in unsealed lagoon was not significant. The results indicate that storing liquid manure in lagoons is incapable of producing satisfactory purification, and that the liquid component must be disposed of on farmland due to its high organic and mineral contents. 3350 - B1, B2, B3, B5, C1, C2, D1, D2, D3, E2, E3, F1, FINISHING CATTLE IN THE SOUTHEAST,

Feedstuffs, Southeastern Correspondent
R. H. Brown
Feedstuffs, Vol. 48, No. 33, p. 20-22, August 16, 1976. 7 fig.

Descriptors: Recycling, Lagoons, Biological treatment, Physical treatment, Chemical treatment, Algae, Chlorination, Fuels, Methane, Carbon dioxide, Byproducts, Separation techniques.
Identifiers: Refeeding, Tilapia, Dry ice.

Kaplan Industries' Florida feedlot is no ordinary cattle operation. Between its integrated feeding-packing business and a sophisticated waste handling system, the company hopes to prove that it is possible to finish cattle in the semi-tropical region of the United States. Kaplan's feedlot has been built on an abandoned strip of land where phosphate was once mined. The yard is designed to benefit from Florida's bountiful rainfall. In addition to the rainfall, 350,000 gallons of water from the packing plant are incorporated daily into the system. The water is handled in an anaerobic-aerobic lagoon system which utilizes algae as part of the biological treatment process. In the final stages, the water goes by gravity from the lagoons to shallow pits where more surface is exposed to oxygen and sunshine and aerobic bacteria do their work. The water is then chlorinated and reused as drinking water for cattle. Any remaining water is sprayed over 100 acres of crop land. In 2 of the lagoons, tilapia are used to harvest the algae. Commercial fishermen then pay 13 cents a pound to harvest the tilapia. The fish are filleted, and the heads and bones are returned to Kaplan's feedlot where they are rendered into fish meal and fed to the cattle. The feces and urine which are generated by the cattle go through a separation process. The recaptured solids are refed to the cattle. The liquids are allowed to ferment, giving off methane and carbon dioxide. The first may be used as fuel to run the meat packing plant, and supply the needs of the city of Bartow. The carbon dioxide may be used to make dry ice. The remaining sludge and dirty water are centrifuged. The solids are refed to the cattle. The dirty water is fed into the lagoon system. 3351 - A11, B3, C1, C2, C3, D3, E3 FERMENTATION, UTILIZATION AND PALATABILITY OF BROILER LITTER ENSILED AT DIFFERENT MOISTURE LEVELS,

L. F. Caswell, J. P. Fontenot, and K. E. Webb, Jr.
Livestock Research Report, Research Division Report 163, Virginia Polytechnic Institute and State University, Blacksburg, Virginia 24061, July, 1975, p. 96-111. 11 tab.

Descriptors: Litters, Fermentation, Feeds, Sheep, Cattle, Moisture content, Performance, Chemical properties, Biological properties.
Identifiers: Refeeding, Ensiling, Palatability.

Experiments were conducted to study the fermentation characteristics of large masses of litter ensiled at 22 and 40 percent moisture and to assess the digestibility, nitrogen utilization and palatability of rations containing these ensiled materials. Wood shaving based broiler litter was obtained from a commercial broiler house, dried for approximately 36 hours, and ground in a hammermill. A 1200 lb. batch, containing 22.3 percent moisture (no water added), was thoroughly mixed and augered into each of 2 silos. Another 1200 lb. batch was mixed with tap water to achieve 40 percent moisture content. This batch was also placed in 2 separate silos. One 22 percent moisture silo and one 40 percent moisture silo were opened after 159 days of ensiling. The litters from these silos were fed concurrently in a metabolism trial with sheep and in the first of 2 palatability trials with cattle. The remaining 2 silos were opened for feeding at the beginning of the second palatability trial, 212 days after ensiling. Each silo was sampled daily at feeding, and the samples periodically were composited according to type of ensiled material and frozen for subsequent chemical analysis. Samples for microbiological determinations were obtained from each silo upon opening and on the last day of feeding from that silo. Study data indicated that active fermentation will occur in litter ensiled at a moisture level of 40 percent. Furthermore, utilization of nitrogen from a ration supplemented with 40 percent moisture litter silage was comparable to that of a conventional ration supplemented with soybean meal when fed to sheep. Although intake by cattle of a ration containing 40 percent moisture litter silage was not satisfactory, this response may have been partially due to the short period of time over which the product was fed. A longer feeding trial is presently being conducted with cattle in an attempt to more accurately evaluate the palatability of litter silage containing 40 percent moisture and to elucidate the cause of depressed intake. (Edwards-East Central)

3352 - A11, B3, C1, C2, D1, D2, E3 DIGESTIBILITY OF UNTREATED AND SODIUM HYDROXIDE TREATED STEER FECAL WASTE,

D. M. Lucas, J. P. Fontenot, and K. E. Webb, Jr.
Livestock Research Report, Research Division Report 163, Virginia Polytechnic Institute and State University, Blacksburg, Virginia 24061, July, 1975, p. 115-122. 5 tab.

Descriptors: Sheep, Feeds, Cattle, Waste treatment, Drying.
Identifiers: Digestibility, Refeeding, Dried fecal wastes, Sodium hydroxide.

A study was conducted to determine chemical composition and digestibility of untreated and chemically treated heat-dried fecal waste from yearling steers fed rations containing either 50 percent roughage ration or 10 percent roughage ration. Each feeding trial consisted of a 10-day preliminary period which was followed by a 14-day waste collection period. On odd days untreated feces were placed in screen wire trays and dried in a forced draft oven at 248 degrees F for 24 hours, while on even days, feces were treated by adding 3 percent sodium hydroxide, by weight, and dried. These processed wastes were later refed in a randomized block design in which 6 lambs received each of the following treatments: (1) basal, (2) 75 percent basal; 25 percent untreated low roughage fecal waste, (3) 75 percent basal; 25 percent sodium hydroxide treated low roughage fecal waste, (4) 75 percent basal; 25 percent untreated high roughage fecal waste, (5) 75 percent basal; 25 percent sodium hydroxide treated high roughage fecal waste. The basal ration contained 30 percent roughage. Crude protein content was 20.69, 17.03, 18.04, and 14.89 percent, dry basis for oven-dried untreated low roughage, treated low roughage, untreated high roughage, and treated high roughage fecal waste, respectively. Treating wet fecal waste with 3 percent sodium hydroxide appeared to cause some nitrogen loss. A similar reduction in crude protein content of sodium hydroxide treated fecal waste occurred for waste from steers fed the high and low roughage rations. Crude fiber content of fecal waste from steers fed a low roughage ration was less than that for fecal waste from steers fed a high roughage ration, and crude fiber content of the fecal waste was reduced by alkali treatment. Apparent dry matter digestibility was decreased by substitution of all types of fecal waste for 25 percent of the basal ration. (Edwards-East Central)

3353 - A11, B1, C2, C3, E4 PROTEIN QUALITY OF RUMEN BACTERIAL PREPARATIONS FROM CATTLE FED RATIONS OF DIFFERENT ROUGHAGE CONTENT,

R. B. Keyser, K. E. Webb, Jr., and J. P. Fontenot.
Livestock Research Report, Research Division Report 163, Virginia Polytechnic Institute and State University, Blacksburg, Virginia 24061, July 1975, p. 123-127, 3 tab.

Descriptors: Proteins, Bacteria, Cattle, Nitrogen, Amino acid, Rations.
Identifiers: Rumen bacteria, Rats, Roughage content.

A study was conducted to determine the protein quality of rumen bacteria from steers fed rations differing in roughage to concentrate ratio. Rumen fluid was collected from 2 steers fed on an 84 percent concentrate ration and from 2 steers fed a 79 percent roughage ration via rumen cannulae. Bacteria were harvested from the supernate by centrifuging at 27,000 x g in a continuous flow system and feed particles and protozoa were removed from the fluid by centrifuging at 1,000 x g. After the bacteria were frozen, lyophilized and ground, they were analyzed for amino acid composition and for total nitrogen content. Bacteria from the roughage fed and concentrate fed steers contained 53.55 percent amino acids on a dry basis. The correlation in amino acid composition between sources for both concentrations and molar ration was .997 ± .020 ($p < .01$). Both total nitrogen and amino nitrogen were very similar between the bacterial sources. Amino nitrogen as a percent of total nitrogen was 76.5 percent for the roughage bacteria and 76.1 percent for the concentrate bacteria. The bacterial proteins were found to contain approximately 13 percent nitrogen for both protein sources. Seventy-five Sprague-Dawley male weanling rats were fed a standard diet for 5 day period. One group was fasted for 24 hours and then sacrificed while the remaining 4 groups were placed in metabolism cages and fed ad libitum purified diets containing one of 4 different protein sources which were: (1) bacteria from roughage fed steers, (2) bacteria from concentrate fed steers, (3) soy protein and (4) zein protein. They were fed and weighed daily for 10 days. At the end of the 10 days, all rats were fasted for 24 hours and sacrificed. The following conclusions were drawn: (1) rats consuming both the soy and concentrate bacteria had the highest nitrogen intakes, (2) rats consuming the zein diet had the lowest nitrogen intake, (3) daily gain was highest for rats consuming the diet with concentrate bacteria and lowest for those fed the diet supplemented with zein, (4) nitrogen retention was greatest for rats fed the diet supplemented with the concentrate bacteria and lowest for those fed the diet supplemented with zein. (Edwards-East Central)

3354 - A11, B3, C2, E3 PERFORMANCE AND LIVER COPPER LEVELS OF BEEF HEIFERS FED BROILER LITTER.

K. E. Webb, Jr., J. P. Fontenot and W. H. McClure
Livestock Research Report, Research Division Report 163, Virginia Polytechnic Institute and State University, Blacksburg, Virginia 24061, July, 1975. p. 128-131.

Descriptors: Performance, Litters, Cattle, Feeds, Copper.
Identifiers: Refeeding, Liver, Toxicity.

Although broiler litter has been shown to have substantial nutritive value, the Food and Drug Administration does not sanction the use of broiler litter or any other animal waste as a feed ingredient. In December, 1972, a study was begun at the Shenandoah Valley Research Station to evaluate the effect of long-term feeding of broiler litter on the performance of cows and upon the accumulation of copper in the liver of cows. This study will continue 5 to 7 years longer. Forty-two weanling heifers were allotted at random by weight and breeding to 3 lots. During the winter of 1972-73, lot 1 animals were fed 8.5 lb of mixed hay, 3 lb of ear corn, and 1 lb of a complex urea supplement per head per day. Animals in lots 2 and 3 were self-fed a mixture of 50 percent broiler litter and 50 percent ear corn. Copper was added in lot 3 to supply an additional 100 ppm copper. During the second and third winters, the heifers were fed the following rations: Lot 1 - Hay; Lot 2 - 75 percent broiler litter, 25 percent ground ear corn; and Lot 3 - 75 percent broiler litter, 25 percent ear corn, and 17 ppm supplemental copper. In order to minimize grazing, the heifers were kept in small lots. Weight and food consumption was recorded at 28-day intervals. Each fall before the cattle were put on the wintering feed and each spring before they were turned out to pasture, liver samples were obtained by biopsy. It was found that (1) ration consumption by heifers was quite good, (2) calving performance for the first calf crop was good, (3) the numbers of calves born showed no detrimental effect of feeding broiler litter or broiler litter plus additional copper. In fact, more calves were born in the groups fed litter. This experiment is still in progress and to date no detrimental effects of feeding broiler litter as a wintering feed have been observed in the animals studied. (Edwards-East Central)

3355 - A11, C1, C2, D3, E3 FERMENTATION, UTILIZATION AND PALATABILITY OF BROILER LITTER ENSILED WITH HIGH MOISTURE CORN GRAIN,

L. F. Caswell, J. P. Fontenot, and K. E. Webb, Jr.
Livestock Research Report, Research Division Report 163, Virginia Polytechnic Institute and State University, Blacksburg, Virginia 24061, July, 1975, p. 132-150. 13 tab.

Descriptors: Fermentation, Litters, Sheep, Cattle, Performance, Corn, Rations, Moisture content.
Identifiers: Refeeding, Ensiling, Palatability.

This study was conducted to study the fermentation characteristics of an ensiled mixture of broiler litter and high moisture corn grain and to assess the digestibility nitrogen, utilization, and palatability of rations containing the ensiled mixture. Corn grain containing 25 percent moisture was harvested and ensiled by weight in a 2 to 1 ration with wood shaving based broiler litter containing 19 percent moisture and 37 percent crude protein. Both were then ground and placed in 6 silos for the corn and 2 for the corn-litter mixture. After 80 days, 3 of the corn and 1 of the corn litter silos were opened and fed in a metabolism trial with sheep and in the first of 2 palatability trials with cattle. The remaining 4 silos were opened for feeding at the beginning of the second palatability trial. Study results indicated that litter fermented with high moisture corn grain appears to be a reasonable approach to utilization of the waste as well as a feasible system of fattening cattle since this material was satisfactorily metabolized when fed to sheep and was readily accepted when offered to beef steers. Additional research is needed to evaluate the utilization and palatability of mixtures containing a greater proportion of litter. This would mean that a greater quantity of the waste would be disposed of, and the cost of feeding the mixture may be lowered. Also, fermented mixtures should be fed experimentally in long term trials in which performance is measured. (Edwards-East Central)

3356 - A11, B1, C1, C2, E3 NUTRITIVE VALUE OF SWINE FECES FOR SWINE,

M. R. Holland, E. T. Kornegay, and J. D. Hedges
Livestock Research Report, Research Division Report 163, Virginia Polytechnic Institute and State University, Blacksburg, Virginia 24061, July, 1975, p. 202-207. 6 tab.

Descriptors: Energy, Rations, Physical properties, Chemical properties, Nutrients.
Identifiers: Refeeding, Swine feces, Digestibility, Minerals, Retention.

The objectives of this study were to characterize wet and dried swine feces as to their proximate energy and mineral composition and to determine digestibilities and retention values for the proximate energy and mineral components. Forty-eight crossbred gilts, averaging 275 lbs each, were fed swine feces collected from finishing hogs. One trial used unprocessed feces with test rations being: (1) basal (15 percent crude protein fortified corn-soybean meal), (2) basal substituted with 22.90 percent swine feces, and (3) basal substituted with 33.83 percent swine feces. In the second trial, dried feces were substituted for the 15 percent basal corn-soybean ration previously used at levels of 20.50 percent and 40.71 percent of the dry matter of the basal rations. Fecal content of crude fiber, ether extract, crude protein, magnesium, copper and zinc were found to increase as the amount of feces substituted for the basal ration was increased. The fecal content of ash, NFE, calcium, phosphorus, and potassium tended to be constant. Urinary phosphorus was the only urinary component that was significantly increased when feces were substituted for the basal ration. The amount of feces excreted increased as the amount of feces substituted for the basal ration was increased, with no difference in urinary output. Swine feces were found to be of less nutritive value than a basal corn-soybean meal ration, but nutrients were available. Digestibilities and retention values were simialr between the wet and dry trials. (Edwards-East Central)

3357 - A5, B2, B4, C2, C3, D3 EFFECT OF ANAEROBIC SWINE LAGOONS ON GROUND WATER QUALITY,

T. G. Ciravolo, D. L. Hallock, H. R. Thomas, E. R. Collins, Jr., D. C. Martens, and E. T. Kornegay
Livestock Research Report, Research Division Report 163, Virginia Polytechnic Institute and State University, Blacksburg, Virginia 24061, July, 1975, p. 208-211. 1 tab.

Descriptors: Lagoons, Anaerobic conditions, Sampling, Virginia, Nutrients.
Identifiers: Groundwater pollution, Swine, Fecal coliforms.

Anaerobic lagoons have become increasingly popular in the Coastal Region of Virginia because of their ease in construction and their inexpensive maintenance. In an effort to study the effects of such lagoons on groundwater quality, tests were conducted at 3 different lagoons. The lagoons were located at (1) Tidewater Research and Continuing Education Center (TRACEC), (2) The Virginia Swine Evaluation Station (VSES), and at a private farm in Suffolk. The lagoons were located on high water table soils ranging in texture from sandy loam to fine sandy loam. Wells to be sampled were located at various depths and distances around the lagoons. Bimonthly groundwater samples were taken from September, 1974, through January, 1975, to determine NO_3-N, NH_4-N, Cl, soluble orthophosphates, Cu, Zn and fecal coliforms. Results of the tests showed that USPHS Standards for drinking water were not exceeded in any well except for one well at the private farm in Suffolk which had over 250 ppm Cl. Future work is being planned which will enable bimonthly sampling of groundwater. Soil samples will also be collected to determine the loading capacity of the soil and the loading effect of seepage from the lagoons on these soils. (Edwards-East Central)

3358 - A8, C2, E2 EFFECT ON SOIL AND PLANT MINERAL LEVELS FOLLOWING THREE ANNUAL APPLICATIONS OF SWINE MANURES OF DIFFERENT COPPER CONTENTS,

Department of Animal Science, Virginia Polytechnic Institute and State University, Blacksburg, Virginia 24061
E. T. Kornegay, J. D. Hedges, D. C. Martens, and C. Y. Kramer
Livestock Research Report, Research Division Report 163, Virginia Polytechnic Institute and State University, Blacksburg, Virginia 24061, July, 1975, p. 212-215. 2 tab.

Descriptors: Plant response, Fertilizers, Nutrients, Copper, Zinc, Magnesium, Phosphorus.
Identifiers: Application rates.

A third year of study was conducted on plots planted to corn in order to evaluate the effect of high copper manures on corn growth and grain composition. The experimental treatments were: (1) no manure, (2) control manure applied and (3) high copper manure applied. There was an accumulation of copper in the surface layer of soil when high copper manure was applied, but the level after 3 annual applications was well within a safe range for good crop production. When both types of manure were applied, there continued to be an increase in zinc, magnesium and phosphorus levels of the soil. However, these increases were not considered harmful. No increase was found in the copper concentration of the grain, and only a small increase was found in the copper content of the corn plant (ear leaf) when high copper manure was applied at a rate of about 26 ton / acre (24 percent dry matter) annually. The phosphorus and zinc content of the ear leaf and the grain were increased slightly when both types of manure were applied. (Merryman-East Central)

3359 - A3, A8, B2, C2, D3, E2 EFFECTS OF SWINE LAGOON EFFLUENT DISPOSAL ON SOIL-PLANT RUNOFF QUALITY,

Department of Agricultural Engineering, Virginia Polytechnic Institute and State University, Blacksburg 24061
E. R. Collins, Jr., D. C. Martens, and E. T. Kornegay
Livestock Research Report, Research Division Report 163, Virginia Polytechnic Institute and State University, Blacksburg, 24061, July, 1975, p. 216-220. 3 tab.

Descriptors: Lagoons, Agricultural runoff, Liquid wastes, Biological treatment, Confinement pens, Chemical properties.
Identifiers: Land disposal, Swine wastes, Plant response.

The most reasonable waste management alternative for swine producers is to design and manage systems so that swine wastes can be collected and applied to land in a controlled manner. To this end, many farmers have begun collecting manure in pits beneath slatted floor housing, and draining or flushing liquid manure into anaerobic lagoons. This study was conducted to (1) compare 2 systems of biological treatment for swine wastes in Virginia, (2) monitor wastes from 2 confinement swine production facilities and effluent from their companion waste treatment systems to determine the degree of biological treatment afforded and the fate of mineral feed constituents, and (3) measure effects of application of lagoon effluent from the above systems on runoff water quality and pollutant accumulation in soil-plant disposal areas. Two enclosed slatted-floor production pens have been in operation since November, 1974. Each pen contains equivalent live weight units of feeder pigs. Pits are flushed into separate sealed concrete treatment tanks. The first tank is operated as an anaerobic lagoon while the other is aerated mechanically at a rate equivalent to twice its estimated daily BOD5. In order to distribute treatment tank effluent on soil-plant disposal plots, a permanent waste irrigation system has been installed. Since November, 1974, samples of waste influent and treatment tank effluent have been taken monthly. NO_3/NO_2-N, NH_4-N, TKN, Cl, total and dissolved volatile solids, and total and dissolved ash determinations have been made but data has not been analyzed. Tests will be continued so that sufficient data can be obtained in order to support meaningful conclusions. (Edwards-East Central)

3360 - A12, B1 EVALUATION OF DIETARY SALT LEVELS FOR SWINE. 1. EFFECT ON GAIN, WATER CONSUMPTION AND EFFICIENCY OF FEED CONVERSION,

King Feed Co., Blandinsville, Illinois 61420
I. Hagsten and T. W. Perry
Journal of Animal Science, Vol. 42, No. 5, p. 1187-1190,

May, 1976. 4 tab, 7 ref.

Descriptors: Performance, Diets, Salts.
Identifiers: Swine, Gain, Water consumption, Feed conversion.

An attempt was made to establish the salt requirement for maximum rate of gain for growing swine. Four experiments utilizing 73 crossbred barrows were designed. Conventional corn-soybean meal diets with varying amounts of supplemental salt and deionized water were offered ad libitum. The salt levels studied ranged from .06 to .48 percent total dietary salt equivalent. Feed conversion and average daily gains were inferior below .20 percent total dietary salt equivalent. The pigs with deficient salt intakes consumed less water. Salt intake had a positive significant correlation with average daily gain and between 15 and 48 percent of the variability in average daily gain was accounted for by the levels of salt added to the diets. Under practical swine feeding situations where the base level of salt content in feed and water is unknown, supplementation with a maximum of .20 percent salt is a safe recommendation. Groundwater, Vol. 11, No. 6, p. 4-13, November-December, 1973. 4 fig, 8 tab, 9 ref.

Descriptors: Groundwater pollution, Nitrates, Water pollution sources, Nebraska, Sampling, Fertilizers, Feedlots.
Identifiers: Hydrogeologic factors, Septic-tank effluents.

Nitrate concentrations in the groundwater of Hall County, Nebraska, were evaluated in relation to soil types, streams, hydrogeologic factors, and cultural practices. These concentrations were correlated with selected physical and chemical parameters of wells, and groundwater, respectively. In the summer of 1971, 161 water samples from wells were collected and analyzed. Nitrate concentrations of less than 10 mg /l were assumed to occur naturally in the groundwater of Hall County. Nitrate enrichment of groundwater was found to be related to conditions existing at or near the wells. High nitrate concentrations were associated with high hydraulic conductivity. Seepage from the Wood River, into which effluents from several sewage-disposal plants are discharged, elevated the nitrate content of groundwater adjacent to the stream. Fertilizers were not found to be contributing to groundwater pollution in Hall County. Seepage from septic-tank effluents and feedlot runoff was found to be a major source of nitrate in groundwater in highly localized rural and urban areas of Hall County. About 54 percent of the irrigation wells containing 10 mg /l and greater nitrate concentrations were associated with domestic wells. Nitrate in groundwater decreased with the increasing well depth and well penetration below the water table. Nitrate in groundwater was stratified where the concentration was high. Highest concentrations were at or near the water table in the immediate area of sampled wells which were close to a potential nitrate source. (Rowe-East Central)

EFFECTS OF AGRICULTURE ON WATER QUALITY,

Chief Agricultural and Marine Pollution Control Branch, Federal Water Pollution Control Administration, Q.S.D.I.
H. Bernard
Relationship of Agriculture to Soil and Water Pollution, Cornell University Conference on Agricultural Waste Management, Rochester, New York, p. 6-10. 1 tab, 3 ref.

Descriptors: Water pollution, Groundwater pollution, Agriculture, Sediment, Pesticides, Animal wastes, Fertilizers, Nutrients, Salts, Eutrophication, Fish kills, Algal blooms, Nitrates.

Pollution problems arising from sediment, pesticides, animal wastes, nutrient runoff from fertilizer use, and inorganic salt pollution from irrigation practices are discussed. About one billion tons of sediment reach the contiguous rivers annually from agricultural sources due to erosion. Sediment deposits in stream channels reduce their capacity to convey water and sometimes seriously impair drainage of adjacent lands. Salts and nutrients adsorbed on sediment particles dissolve in water and contribute to eutrophication of surface waters. Pesticide residues carried by sediment may be released in the stream environment to be taken up and concentrated by various aquatic organisms. The oxidation of organic pollutants is hindered by sediment in streams. Feedlot wastes are also serious pollution contributors. Feedlot runoff has caused serious fish kills. Increases in nitrates in ground waters have been traced to the animal feeding industry. Nitrogen and phosphorous in manures may be present in runoff, and may add to the fertilization of lakes and ponds, increasing the rate of eutrophication. Pathogenic organisms may also be present in such runoff. Another large problem is nutrient runoff associated with fertilizer use. Fish kills algal blooms, and foul odors emanating from surface waters may be associated with such runoff. Groundwater contamination can also be traced to fertilizer use. Salts, which are present in soils and geologic materials of arid regions as a result of mineralogical weathering processes, find their way into water sources through leaching and runoff. To maintain a salt balance in the soil that will support crop growth, the total amount of salt applied in the irrigation water must be leached out in the drainage water. Since the volume of drainage water is much less than the irrigation water applied, the salt content in the drainage is much greater. The distribution and concentration of pesticides through the water cycle and food cycle to the consumer has also become a problem. (Ott-East Central)

AEROSOL DISPERSION OF PATHOGENS FROM A MODEL OXIDATION DITCH,

University of Minnesota
L. A. Will, S. L. Diesch, B. S. Pomeroy, S. L. Spier, P. R. Goodrich
Livestock Environment Affects Production, Reproduction, and Health, Proceedings of the International Livestock Environment Symposium, Nebraska Center for Continuing Education, University of Nebraska, Lincoln, April 17-19, p. 176-181.

Descriptors: Aerosols, Pathogenic bacteria, Salmonella, Model studies, Sampling, Slurries.
Identifiers: Oxidation ditch, Animal health, Leptospira pomona.

With the knowledge that enteric (salmonella) and urinary tract (leptospires) pathogens survive manure treatment in a model oxidation ditch, researchers endeavored to learn whether these microorganisms become aerosolized and transmit disease to laboratory animals housed in confinement pens above the ditch. A 1:10 scale laboratory model of an existing field (Pasveer) oxidation ditch was constructed at Rosemount Experiment Station, University of Minnesota. Virulent Salmonella typhimurium and Leptospira sero-type pomona MLS bacteria were inoculated into the manure slurry of the model system during separate experiments. The slurry and the ambient air of the model system were sampled and the laboratory animals were examined for evidence of infection with either pathogen. L. pomona MLS survived the minimal six-week period; whereas, S. typhimurium was re-inoculated into the slurry to maintain potentially health hazardous microbial conditions in the lab-animal convenient housing unit. Exposed hamsters remained culturally and serologically negative to leptospiral infection. Turkey poults occasionally became infected with S. typhimurium. Leptospiral microbioaerosols were detected only once. S. typhimurium was isolated more commonly. The expressions of leptospiral virulence may have been altered by the slurry environment. Indicator coliform microbioaerosol counts were below those of compared dairy barn tests. (Rowe-East Central)

MICROBIAL AEROSOL MONITORING OF A BEEF HOUSING OXIDATION DITCH,

Assistant Professor, Agricultural Engineering Department, University of Minnesota, St. Paul, 55101
P. R. Goodrich, S. L. Spier, S. L. Diesch, and L. A. Will.
Livestock Environment Affects Production, Reproduction, and Health, Proceedings of the International Livestock Environment Symposium, Nebraska Center for Continuing Education, University of Nebraska, Lincoln, April 17-19, 1974. p. 182-188. 2 fig, 2 tab, 2 ref.

Descriptors: Aerosols, Public health, Sampling, Bacteria, Aeration.
Identifiers: Oxidation ditch, Animal health.

The purpose of this study was to monitor the bioaerosol production from an operational field oxidation ditch (Pasveer), aerated by a rotor, and to assess the public health hazard in relation to bacteria produced by the waste treatment facility. An air sampling program was developed after careful research. The air environment within the housing unit was found to harbor a rich bioaerosol. Counts approximating 100 to 200 total colony forming units per liter of air sampled were observed routinely in the year sampling period. It was evident, however, that these high levels were caused by the animal population and not by the oxidation ditch system. Indicator fecal bacterial aerosols also were higher when the animals were present. Therefore, the oxidation ditch again was not deemed to be the source of the bacterial aerosols. The magnitude of indicator fecal microorganisms was low when compared with the level of total aerosol microorganisms found. It was concluded that the wet floor environment in the buildings suppressed aerosol formation. During cleaning periods when the floor was left dry, usually high potentially hazardous levels of aerosols existed within the barns. During normal operations, however, the oxidation ditch treatment system did not create a health hazard for either man or animals. (Rowe-East Central)

SOME CONSTITUENTS IN THE ATMOSPHERE OF A HOUSED SWINE UNIT,

Microbiologist, U.S. Department of Agriculture.
L. F. Elliott, J. A. DeShazer, E. R. Peo, Jr., T. A. Travis, and T. M. McCalla
Livestock Environment Affects Production, Reproduction, and Health, Proceedings of the International Livestock Environment Symposium, Nebraska Center for Continuing Education, University of Nebraska, Lincoln, April 17-19, 1974, p. 189-194. 1 fig, 5 tab, 13 ref.

Descriptors: Air pollution, Confinement pens, Odor, Waste storage, Anaerobic conditions, Ventilation, Gases.
Identifiers: Swine, Animal health.

A study was conducted in a completely enclosed swine growing-finishing building at the University of Nebraska Field Laboratory, Mead. The portion of the building that was used for the study was equipped with an anaerobic manure-storage pit under a completely slotted floor. The unit was divided into 16 pens, each containing 8 animals. During the study, the building was ventilated naturally because of faulty fans. Aerial CO_2, NH_3-N, non-NH_3-N, and H_2S were measured weekly during the study and intensively during anaerobic pit pumpout. Aerial measurements were taken 1 inch beneath the slotted floor, 1 foot above the floor (swine level) and 4 feet above the floor. No CO_2 levels were found that could be considered deleterious to animal health. CO_2 was higher in the east end than the west end due to air currents.

Significantly higher quantities of non-NH_3 -N were present in the atmosphere. The non-NH_3 -N fraction partially represented amine and /or amine-related compounds which were very odorous. Ambient levels of H_2S in the unit ranged from 0.9 to 0.2 ppm. During pumpout, H_2S varied considerably, with levels ranging from undetectable to 43.4 ppm and averaging 2.7 ppm. (Rowe-East Central)

AIR POLLUTION AND HUMAN WORK CAPACITY,

Director, Max-Planck-Institute, Bad Kreuznach, Germany
G. Preuschen
Livestock Environment Affects Production, Reproduction, and Health, Proceedings of the International Livestock Environment Symposium, Nebraska Center for Continuing Education, University of Nebraska, Lincoln, April 17-19, 1974, p. 195-198. 2 tab, 5 ref.

Descriptors: Air pollution, Confinement pens, Odor, Respiration.
Identifiers: Health.

There are 4 reasons why working capacity in animal production facilities may be reduced: (1) More time must be spent in animal houses due to farm specialization, (2) The same person performs barn work day after day and the change from barn work to open air work is rather seldom. (3) Due to specialization only one kind of stock is kept in large numbers and this leads to an increasing influence of negative environmental factors on barn workers. (4) Modern animal houses differ essentially from traditional houses in 2 ways: (a) No bedding is used, and (b) More animals are confined to a relatively small housing area. Experiments performed on the influence of less annoying air from animal houses on human respiration led to the following conclusions: (1) Bad smell from animal houses is not only unpleasant but health damaging. Irritation of bronchias (coughing) and dizziness are the result. (2) Subjects with a sensible respiratory system tend to shortness of breath and will become easily tired. (3) Existing bronchial allergies may be intensified so that persons smelling emissions from animal houses become unable to work because of asthma. (Rowe-East Central)

EFFECTS OF AERIAL AMMONIA, HYDROGEN SULFIDE, AND SWINE HOUSE DUST, ALONE AND COMBINED, ON SWINE HEALTH AND PERFORMANCE,

Assistant Professor, Animal Science Department, University of Illinois at Urbana-Champaign, Urbana 61801
S. E. Curtis, A. H. Jensen, J. Simon, and D. L. Day
Livestock Environment Affects Production, Reproduction, and Health Proceedings of the International Livestock Environment Symposium, Nebraska Center for Continuing Education, University of Nebraska, Lincoln, April 17-19, 1974, p. 209-210. 1 tab.

Descriptors: Performance, Air pollution, Gases, Dusts, Hydrogen sulfide, Ammonia.
Identifiers: Swine, Animal health.

The effects of ammonia, hydrogen sulfide, and hoghouse dust, alone and in various combinations in the air, on the performance and respiratory-tract health of otherwise healthy growing and finishing pigs were studied in 7 trials. The performance trials were conducted in 4 dynamic-type, air-pollutant exposure chambers. The air temperature was about 18 degrees C at all times in all chambers. The absolute humidity level of the air in all chambers was the same as or lower than that of the outside air. Crossbred pigs were assigned to the 4 chambers from within littermate quartets of the same sex. Pigs were fed a corn-soybean meal diet formulated to contain 22.5 percent crude protein to 18 kg and 16 percent from 18 kg on. The diets contained no antibiotic and were pelleted. Results suggested that the performance of healthy pigs may not be affected by air pollution inside enclosed swine houses. The possibility remains that the incidence and severity to lung disease in pigs may be related to the stress caused by such irritating air pollutants as ammonia. If lung disease were exacerbated by air pollutants, pig performance would be expected to decline in turn as an indirect effect of air pollution. (Rowe-East Central)

CONSTITUENTS OF SWINE HOUSE ODORS,

Professor, Iowa State University, Ames.
E. G. Hammond, P. Kuczala, G. A. Junk, and J. Kozel
Livestock Environment Affects Production, Reproduction, Health, Proceedings of the International Livestock Environment Symposium, Nebraska Center for Continuing Education, University of Nebraska, Lincoln, April 17-19, 1974, p. 364-372. 5 fig, 19 ref.

Descriptors: Odor, Measurement, Confinement pens, Gases, Gas chromatography, Mass Spectrometry.
Identifiers: Swine.

This study reports a number of odorous compounds from the air in a swine confinement building which were identified by gas chromatography, mass spectrometry combined gas chromatography-mass spectrometry and other ancillary techniques. A number of relatively non-odorous compounds tentatively identified solely by combination gas chromatography-mass spectrometry are also reported. Air was sampled in a 700-head swine-finishing building of the Iowa State University Swine Nutrition Research Farm where manure was flushed out hourly with water, and feed was dumped onto the floor of the pens from an overhead conveyor. The odor of the unit was typical of swine but was not an outstandingly intense odor source. Conclusions drawn were: (1) All of the odorous compounds that were found in swine house air were well known flavor constituents in foods. (2) Study results suggested that the number of odorous compounds may be direct products of animal metabolism. (3) Constituents which are below threshold may interact with each other and with constituents above threshold to change the character and strength of the sensation. (4) Possibly some constituents of importance may have escaped the concentration and separation methods. (5) Relatively large amounts of aromatic hydrocarbons were detected in swine house air. (6) It should be possible to develop routine tests for the odorous substances reported, and such analyses should give an objective measurement that will correlate well with the complicated subjective measurements of air quality. (7) One or more of the odorous substances may prove to be a good indicator compound for the intensity and character of the odors from animal facilities. (Rowe-East Central)

MANURE GASES AND THEIR EFFECT ON LIVESTOCK HEALTH,

Royal Agricultural College, Department of Farm Buildings, Lund, Sweden.
K. Sallvik
Livestock Environment Affects Production, Reproduction, Health, Proceedings of the International Livestock Environment Symposium, Nebraska Center for Continuing Education, University of Nebraska, Lincoln, April 12-19, 1974, p. 373-377. 3 fig, 2 tab.

Descriptors: Liquid wastes, Confinement pens, Air pollution, Ventilation, Design, Gases.
Identifiers: Animal health.

The Department of Farm Buildings at the Royal Swedish Agricultural College investigated the effects of different ventilation systems on the gases produced by liquid manure systems. The ventilation systems tested were: (1) High exhausting - fans in ceiling and inlets along side walls. (2) High exhausting - modified with special inlets in center of building, (3) Low exhausting - exhaust ducts parallel with manure channel suck the outgoing air through openings under the slatted floor or manure gutter. Analyses of air movements and H_2S, NH_3, and CH_4 were made in order to obtain a measure of the efficiency of the ventilation systems. The comparisons between different ventilation systems required that the manure be agitated. The tests showed that the location of air inlets is very important. The air inlets should be located over the feeding table and the incoming air directed toward the breathing zone of the animal. Low exhaust and high exhaust have such an inlet design. In piggeries investigations of air movements, gas concentrations and checking of weight gain and health were made. Feed conversion, weight gain, mortality and classification were recorded. It was found that the 2 ventilation systems can be assumed to be equal regarding good environmental conditions in houses with liquid manure handling. (Rowe-East Central)

FERMENTATION OF WHOLE FEEDLOT WASTE AND ISOLATED WASTE FIBER WITH TRICHODERMA VIRIDE IN SUBMERGED CULTURE,

Northern Regional Research Laboratory, Agricultural Research Service, U. S. Department of Agriculture, Peoria, Illinois 61604
H. I. Griffin and J. H. Sloneker
Reprinted from Symposium on Enzymatic Hydrolysis of Cellulose, Aulanko, Finland, March 12-14, 1975, p. 419-431. 2 fig, 4 tab, 14 ref.

Descriptors: Fermentation, Fungi, Chemical treatment, Chemical properties, Physical properties, Recycling, Carbohydrates, Cellulose, Nitrogen, Lignins, Separation techniques.
Identifiers: Trichoderma viride, Refeeding, Hemicellulose.

At the Northern Regional Laboratory, fermentation by the fungus Trichoderma Viride was examined as a possible means of decreasing the bulk of cattle feedlot waste and increasing the quality of its protein so that it could be refed as a feed supplement without interfering with animal feed efficiency. The point of attack by Trichoderma Viride is the structural carbohydrates, cellulose and hemicellulose. When crude feedlot waste fiber is separated from the whole feedlot waste, Trichoderma viride ferments it better, achieving a maximum loss of solids of about 38 percent. Crude protein increases and improves the feed additive potential of the feedlot waste; however, other methods, such as mixed culture and solid-state fermentation, will be necessary to increase solids digestion to a level permitting efficient recycling of animal waste. RECYCLING POULTRY WASTE,

Agricultural Research Council's Poultry Research Centre, King's Building, West Mains Road, Edinburgh EH9, 3JS, Scotland
R. Blair
Canadian Poultry Review, Vol. 97, No. 9, p. 13-14, 16, 18, September, 1973. 1 fig, 5 tab.

Descriptors: Recycling, Economics, Nutrients, Pathogenic bacteria, Chemical properties, Performance, Poultry.
Identifiers: Refeeding, Dried poultry wastes, Scotland.

Recycling dehydrated poultry waste (DPW) through poultry has been advocated for 2 reasons: it is a useful source of nutrients and recycling should help to reduce the pollution problem. Research performed at Edinburgh, Scotland, has revealed that, under certain price situations, dehydrated poultry waste is an economic feed for poultry, mainly as a source of energy, amino acids, calcium, and phosphorus. Recycling would reduce pollution by about one-third and possibly more if a level higher than 20 percent in the ration could be tolerated by hens. Proper processing seems to render poultry wastes innocuous and pathogen free. The risk from residues is potentially greater although the scant evidence available suggests than no serious accumulation may take place even on continual recycling. (Rowe-East Central)

POULTRY EXCRETA CONTAINING POLYCHLORINATED BIPHENYLS AS A PROTEIN SUPPLEMENT FOR LACTATING COWS,

Agricultural Environmental Quality Institute, Agricultural Research Center, U. S. Department of Agriculture, Beltsville, Maryland 20705
L. W. Smith, G. F. Fries, and B. T. Weinland
Journal of Dairy Science, Vol. 59, No. 3, p. 465-474. March, 1976. 1 fig, 8 tab, 16 ref.

Descriptors: Polychlorinated biphenyls, Diets, Dairy industry, Public health.
Identifiers: Refeeding, Dried poultry excreta, Animal health.

A conventional concentrate mixture and a ration containing 32 percent dehydrated poultry excreta were fed to 2 groups of 12 cows each to provide 36 percent of the total dietary nitrogen and 15 percent of the total dry matter intake for 90 days. The objectives were to study: (a) the digestibility, N-metabolism, and milk production of concentrate diets supplemented isonitrogenously with crude protein from conventional sources of or from dehydrated poultry excreta (DPE), and (b) the presence of polychlorinated biphenyls (PCB's) in milk after cattle are fed PCB-contaminated excreta. Manure from caged laying hens fed known concentrations of different PCB's was used. Cattle fed the DPE concentrate consumed less corn silage and concentrates and produced less milk than those fed conventional concentrates. From the feeding of the 2 pelleted concentrates to wethers, it was learned that conventional concentrate ash was 1.5 times more digestible than ash in DPE concentrate. Neither health nor reproductive performance differed in relation to the 2 diets. The conventional concentrate cost \$132/metric ton and the DPE concentrate cost \$77/metric ton as formulated. Pelleting costs were not figured. Residues for chlorinated hydrocarbon pesticides and industrial contaminants were not found to be a problem in utilization of DPE. The residue fed to the chickens from which the excreta was taken was 20 ppm, 100 times as great as the U.S. Food and Drug Administration guideline of .2 ppm for complete animal feeds. The highest residue encountered in milk fat was less than 5 ppm, only twice that listed in the U.S. Food and Drug Administration guideline of 2.5 ppm. Thus, there should be no problem of PCB residues in milk from feeding DPE if the chickens were on diets below 50 times the FDA guideline. (Rowe-East Central)

NITROGEN REMOVAL FROM A CONCENTRATED WASTE BY NITRIFICATION AND DENTRIFICATION,

Senior Research Associate, Department of Agricultural Engineering, Cornell University, Ithaca, New York 14580
T.B.S. Prakasam, Y. D. Joo, E. G. Srinath, and R.C. Loehr,
Engineering Bulletin, Purdue University, 1974, p. 497-509.

Descriptors: Nitrogen, Denitrification, Nitrification, Wastewater treatment, Ammonia, Aerobic conditions, Anaerobic conditons, Poultry.
Identifiers: Oxidation ditch.

Laboratory and pilot plant scale investigations were conducted to study the feasibility of a microbial nitrification-dentrification process for the control of nitrogen in a concentrated wastewater. In continuous flow units high ammonia residuals were noted, while about only 60 percent of the TKN input was nitrified. Investigations on the causes for the occurrence of a high residual ammonia concentration and efforts to minimize it by nitrification led to the development of a repetitive nitrification-dentrification process for the control of nitrogen in highly concentrated wastes. The elimination of NO_2, and NO_3 from a partially nitrified waste in a denitrification stage removed the prevailing inhibitory conditions for the oxidation of the residual mixed liquor NH_4^+ in a subsequent aerobic phase. Studies with the oxidation ditch showed that by manipulating the rotor operation up to 90 percent of the total nitrogen input could be removed without accumulation of significant ammonia residuals in the mixed liquor. The results of this study showed that the nitrogen in concentrated wastes can be controlled in a single treatment unit such as the oxidation ditch by a nitrification-dentrification process without the necessity of an additional dentrification tank or other appurtenances. A NOTE ON DRIED POULTRY MANURE IN THE DIET OF THE GROWING PIG,

School of Agriculture, University of Aberdeen, Scotland
S. Perez-Aleman, D. G. Dempster, P. R. English, and J. H. Topps
Animal Production, Vol. 13, p. 361-364, 1971. 2 tab, 5 ref.

Descriptors: Diets, Performance.
Identifiers: Dried poultry manure, Swine.

Dried poultry manure was evaluated as an addition to a conventional diet at levels of 10, 20, and 30 percent for growing pigs from 23 to 85 kg liveweight. The manure was obtained from a local broiler producer. The manure was pressure-cooked in Douglas offal plant in lots of approximately 500 kg with about 40 liters of water added to each lot to facilitate the raising of pressure. The material was subjected to a pressure of 68·9 kN m^{-2} and a temperature of 115 degrees C for 35 minutes. Then it was dried by injecting hot air into the cooker for 85 minutes. Thirty-two pigs were arranged in 4 pens to give equal numbers of castrate males and females in 2 pens, all castrates in the third pen and all females in the fourth. The pens were equipped with individual feeding stalls so that the pigs lived as a group but were individually fed to appetite. The food was provided twice daily except on Sunday, when a single meal was given. When the pig consumed all his meal, the amount given at the next meal was increased. There was a tendency for the pigs to eat more as the level of manure in the diet increased. However, the actual food consumption of the pigs on the 4 treatments did not differ significantly. The pigs remained healthy and the dried manure had no apparent adverse effect on the carcasses. For every 10 percent addition of manure, growth was reduced by 0·96. The dried manure contained about 30 percent crude protein and was a rich source of minerals. (Rowe-East Central)

OVERLAND FLOW IN NARROW PLOTS TO TREAT FEEDLOT RUNOFF,

Assistant Professor, Agricultural Engineering Department, University of Missouri, Columbia, 65201
D. M. Sievers
Presented at 1974 Mid-Central Meeting, American Society of Agricultural Engineers, St. Joseph, Missouri, April 5-6, 1974, Paper No. Mc-74-302, 14 p. 7 fig, 1 tab, 6 ref.

Descriptors: Feedlots, Agricultural runoff, Overland flow, Wastewater treatment, Biological treatment, Nitrogen, Phosphorus, Chemical oxygen demand, Solids.
Identifiers: Lagoon effluent.

Research was conducted at the J. P. Hampton Feedlot near Brunswick, Missouri, to study the effectiveness of the overland flow method of treating cattle feedlot runoff using gated irrigation pipe. Lagoon effluent from a 2000 head feedlot was applied through the gated pipe to plots 150 feet long and 6 feet wide. The plots sloped 5 percent and were covered with Tall Fescue and Reed's Canary. With an application of 5 gpm, 50 percent of the applied ammonia and 35 percent of the total phosphorus was removed within the 150 foot distance. The removal percentages decreased with time. Little change was observed in chemical oxygen demand or solids. Based on study results the use of the overland flow technique for small feedlots using gated irrigation pipe seems questionable. Small feedlots are not likely to have large enough volumes of wastewater for continuous irrigation of the disposal. Under these circumstances, the microorganism population will not develop to a large extent and the quality of the treated effluent will remain poor. The concentrated flow afforded by gated pipe retards establishment of the trickling filter concept and results in poor treatment. For the small feedlot operator who wishes to utilize feedlot runoff through irrigation, it would probably be better to employ a system in which there is little or no runoff produced. If the overland flow system is to be used, sprinkler application is recommended with some means of collecting and recycling the low quality runoff. (Rowe-East Central)

ODORS FROM EXCRETA OF CATTLE FED SAGEBRUSH AND PEPPERMINT OIL,

Oregon State University, Corvallis
R. O. Kellems, D. C. Church and J. R. Miner
Proceedings, Western Section, American Society of Animal Science, Vol. 27, 1976, 3 p. 1 tab, 6 ref.

Descriptors: Diets, Sagebrush, Sampling, Odor.
Identifiers: Odor control, Peppermint oil, Olfactory panel.

Holstein heifers were fed a basal ration of 25 percent barley and 75 percent alfalfa to which 2 levels (1 percent and 1.5 percent) of ground mountain big sagebrush and one level (0.25 percent) of peppermint oil were added. A control group of 5 replacement heifers was maintained on the basal ration during the experiment period. Fresh urine and fecal samples were collected from the control and the supplemented animals on an individual animal basis. Then composite urine and fecal samples were prepared for each group. Samples containing 50 g feces and 50 g urine were prepared from the composite samples mixed in 300 ml erlenmeyer flasks and incubated at 30 degrees C for 24 hours prior to being evaluated by an olfactory panel. The samples were removed from the water bath, dried, wrapped in paper, and allowed to equilibrate with the ambient temperature for about 30 minutes prior to evaluation. The olfactory evaluations of the groups supplemented with 1 and 1.5 percent sagebrush were not different from the control group. Samples containing both fecal and urine fractions were found to be less offensive than fecal + water samples. A characteristic menthol odor was noted to be present in the urine obtained from the peppermint supplemented animals. It apparently partially masked the normal odor of urine. (Rowe-East Central)

POTENTIAL 800 MILLION TONS OF ANIMAL FEED GOES TO "WASTE" ANNUALLY, SCIENTIST REPORTS,

Anonymous
Beef, Vol. 12, No. 6, p. 70-71, February, 1976.

Descriptors: Feeds, Farm wastes, Recycling, Performance, Poultry, Cattle, Feedlots, Costs, Economics, Pathogenic bacteria, Legal aspects.
Identifiers: Refeeding, Drug residues.

About 800 million tons of animal feed goes to waste every year in the United States. J. P. Fontenot of the Department of Animal Science at Virginia Polytechnic Institute stated at a seminar that animals annually produce about 1.6 billion tons of waste, of which about one-half could be collected and recycled as animal feed. He added that poultry wastes amount to about 50 million tons of the total. Pathogens, which may be present in poultry wastes, can be destroyed by heat or chemical treatment or by ensiling. While broiler litter may contain medicinal drug residues, no harmful levels have been found in the meat or livers of cattle fed the waste followed by a 5-day withdrawal period. Fontenot indicated that pregnant cows would do well on nearly a 100 percent poultry waste ration and for fattening cattle, the level would be in the 10 to 25 percent range. Feeder Sam Hay, Jr., Covington, Georgia, reported that by recycling manure in his 300-head feedlot, he had saved 20 to 25 percent on feed

costs, figuring corn at $3 a bushel. Bobby Joe Lee of Cape Plantation at Tallulah, Louisiana, and George Shepard, manager of the N. B. Hunt Ranch, Dallas, Texas, were both proponents of using corn silage as a basic feed for their cattle. At Lee's feedlot, urea and diacalcium phosphate are added to the silage as it is put into the silo, giving a complete feed to which nothing is added. Brady Anthony of Auburn University reported on a series of feeding trials in which 50 parts of wet manure and 40 parts of ground grass hay were ensiled and then successfully added a basal ration of 82.5 percent ground corn, 12 percent ground Coastal bermudagrass hay, 4 percent of a liquid protein supplement, 1 percent calcium carbonate and 0.5 percent trace mineralized salt. Anthony said, based on the market price of feed ingredients when the feeding trial took place, the manure added at 20, 40, and 60 percent of the ration, reduced feed cost per hundredweight of gain by $4.32, $10.62, and $14.32, respectively. (Rowe-East Central)

POLLUTION REGULATIONS REMAIN ONE OF THE TOP WASHINGTON ISSUES,

Washington Correspondent
J. Richter
Beef, Vol. 12, No. 9, p. 8,9, May, 1976.

Descriptors: Regulations, Water pollution, Point sources.
Identifiers: Beef imports, Checkoff program.

In their present "final" form, regulations say that feedlot operators won't need pollution permits unless there is some discharge into navigable waters. If there is such a discharge: (1) Operators with as many as 1,000 animal units or 700 mature cows will need permits, (2) Those with 300 to 1,000 animal units will need a permit if the feedlot discharges into a waterway directly or through a manmade channel, (3) Operators with fewer than 300 animal units or 200 cows are to be exempt from the control program, unless they have an unusual pollution problem. A proposed checkoff program is being revived. The Beef Development Taskforce has agreed to go along with the Farm Bureau on procedure for conducting a producer referendum on the plan. The Bureau Plan requires: (1) pre-registration of cattlemen 10 days prior to the referendum, (2) at least half of those registered to vote, and (3) two-thirds approval by all those voting for the checkoff plan to take effect. Beef imports are going to be more closely monitored this year, following last year's fiasco when 27.2 million pounds more beef came into the country than the law allowed. Responsibility for monitoring imports will be shifted from the U. S. Census Bureau to the Customs Bureau. (Rowe-East Central)

STANDARDIZING PROPERTIES AND ANALYTICAL METHODS RELATED TO ANIMAL WASTE RESEARCH,

American Society of Agricultural Engineers
Standardizing Properties and Analytical Methods Related to Animal Waste Research, American Society of Agricultural Engineers, December, 1972 and December, 1974, 355 p.

Descriptors: Analysis, Sampling, Chemical properties, Physical properties.
Identifiers: Animal wastes.

To promote an exchange of information which would encourage more uniformity in conducting animal waste research and reporting findings, the ASAE committee SE-412, Agricultural Sanitation and Waste Management, sponsored a conference concerning "Standardizing Properties and Analytical Methods Related to Animal Waste Research" in December, 1972. Approximately 150 engineers and scientists attended. In December, 1974, the ASAE Committee SE-412, Agricultural Sanitation and Waste Management, and T-9, Environmental Quality Coordinating Committee, organized another conference. The purpose of this conference was to summarize and disseminate information concerning changes, refinements, and new developments needed to assess system performance. Papers presented at both of these conferences are included in this publication. (Merryman-East Central)

PROPERTIES RELATED TO MATERIALS HANDLING,

Assistant Professor, Agricultural Engineering Department, Iowa State University.
R. J. Smith
Standardizing Properties and Analytical Methods Related to Animal Waste Research, American Society of Agricultural Engineers, December, 1972 and December, 1974, p. 17-25. 10 ref.

Descriptors: Slurries, Design, Pumping, Solids, Physical properties, Chemical properties, Equations.
Identifiers: Manure, Open channel, Chemical precipitation.

This study is divided into: (1) a general discussion of manure composition and how this should be determined, (2) the parameters necessary to measure manure pumping characteristics, (3) the phenomenon of solids transport in an open channel, and (4) a brief section on mechanical problems arising from chemical precipitation. Manure consists of: (1) a liquid containing dissolved and colloidal solids, (2) a fraction containing very find solids, (3) a fraction containing coarse particulate matter, and (4) hair. Pumping raw manure requires certain considerations. Two areas needing numerical characterization are: (1) how readily the material flows into a pump section and (2) head loss incurred in forcing the material through a closed pipe. It is possible to put a numerical index on the onset of suction starvation by examining a curve of sheer stress vs. strain rate. The head loss in a pipe carrying solids that are in heterogeneous suspension can be expressed by: $(J - J_W) / C_V J_W = K(n_1 C_V)m$. J = head loss for water at velocity V in units of height of slurry column per unit length of pipe. J = head loss for water at velocity V in units of height of water per column per unit length of pipe. K,m = dimensionless constants. A dimensional analysis approach based on Raudkivi (1967) may be helpful in planning the design of open conduits. Precipitation of $Mg(NH_4)PO_4$ and CaCO in manure slurries adversely affects pump performance. Measurement of levels of $Mg^{+2 3}$, NH_4+, and PO_4^{-3} may be a waste of time; it is better to design the pumping system using all-plastic components, where possible. Deposits can be dissolved by using 1:20 dilution of glacial acetic acid flushed through the system for about 3 hours. Centrifugal pumps should employ large clearances between the rotor and the case. PROPERTIES RELATED TO ENVIRONMENTAL POLLUTION,

Associate Professor, Agricultural Engineering Department, Oklahoma State University, Stillwater
A. F. Butchbaker
Standardizing Properties and Analytical Methods Related to Animal Waste Research, American Society of Agricultural Engineers, December, 1972 and December, 1974, p. 26-47. 7 tab, 17 ref.

Descriptors: Pollution, Water pollution, Air pollution, Soil contamination, Recycling, Odor, Dusts, Pathogenic bacteria, Nutrients, Sediments, Radioactivity.
Identifiers: Refeeding.

Determining pollutional parameters of animal wastes is difficult due to the complex nature of the wastes and the variety of management and weather effects. The characteristics of animal wastes vary with ration and animal species. Degradation of the waste causes further changes. In many cases, the impact of the waste on the receptor in the environment is relatively unknown, particularly, for potential long-term effects. To determine the pollutional characteristics of animal waste, the evolvement of water quality standards was reviewed. Four broad categories of media-receiving animal waste may be considered — (1) Water (surface; ground), (2) Soil (crop utilization, disposal), (3) Air (odors, dust), and (4) Utilization or Resource Recovery (Food - Refeeding, Algae production, etc.) Pollutional categories to be considered in water quality include: organic wastes, infectious agents, plant nutrients, synthetic chemicals, inorganic and mineral substances, sediments, radioactivity, and temperature. Some of the pollutional parameters for soil are those that may build up, such as heavy metals, sodium, magnesium, bicarbonates, sulfates, chlorides, potassium and boron. Air pollutants may be categorized as odors and dust. Pollutional parameters to be considered in utilization are dependent upon the actual type of utilization. Besides crop production from irrigation or direct manure application, waste usage may include: food, fuel, and building materials. Food products may also be examined for pathogens, parasites, disease organisms, endocrine secretions, heavy metals, antibiotics and residuals from medicinal compounds. In fuel production, odors and particulate matter are of concern. In creating building materials, if the material is rendered biologically inert by thermal or chemical means or coated with an inert material, few pollutional parameters exist. Guidance in the selection of pollutional parameters may be obtained from the various pollution control and public health agencies. (Rowe-East Central)

SAMPLING OF LIQUID AND SOLID WASTES,

Agricultural Engineer, Agricultural Research Service, U. S. Department of Agriculture, Lincoln, Nebraska
N. P. Swanson, and C. B. Gilbertson
Standardizing Properties and Analytical Methods Related to Animal Waste Research, American Society of Agricultural Engineers, December, 1972, and December, 1974, p. 63-77. 16 ref.

Descriptors: Sampling, Liquid wastes, Solid wastes, Physical properties, Chemical properties, Agricultural runoff, Equipment, Measurement.
Identifiers: Animal wastes.

This paper discussed appropriate sampling techniques and equipment related to sampling animal wastes and identifies some pertinent properties and their proper units of measurement that should be considered in research. Samples should be random and representative. The what, where, and when should be planned for sampling before initiating research and the decisions as to how many samples and how much to sample should be considered. In sampling solids, the stable masses of organic materials and mixtures of soil and organic materials can be sampled with standard soils sampling equipment. Chemical content, organic and physical content, and bulk density may vary with depth; therefore, it is important to obtain samples with uniform cross sections. Meaningful sampling of runoff requires collection of periodic representative samples to accompany measurements of the rate of discharge by units of time or a runoff hydrograph. Factors that affect reliability in sampling runoff are: (1) Frequency of the sample cutting, (2) Technique used in taking the sample, (3) Safeguarding the sample from contamination, and (4) Sample analysis. Equipment should be selected to best meet the practical needs of the research. Conglomerate samples should be avoided if the details afforded by measurements of stratification, changes with time, or changes in connection with other physical, chemical, or biological phenomenon will add materially to the findings. Data should be analyzed promptly to insure that sampling procedures and equipment are adequate. (Rowe-East Central)

SAMPLING OF LIQUID AND SOLID WASTES,

Assistant Professor, Agricultural Engineering Department, University of Wisconsin, Madison.
J. C. Converse
Standardizing Properties and Analytical Methods Related to Animal Waste Research, American Society of Agricultural Engineers, December, 1972 and December, 1974, p. 78-84. 9 ref.

Descriptors: Sampling, Liquid wastes, Solid wastes, Equipment, Preservation, Chemical properties, Physical properties, Analysis.

A discussion is given of the following: (1) the different types of samplers available, (2) sampling statistically, (3) preservation of samples prior to analysis, and (4) preparation of samples for obtaining a representative aliquot from the sample for analysis. The author states that it is better to obtain 2 samples at the same time and make one analysis on each than to take 1 sample and duplicate analyses. This will reduce the likelihood of error. Wood and Stanbridge (1968) determined that it is advisable to incorporate a refrigerator into an automatic sampler to keep samples at 5 degrees C to minimize changes in nitrate and biochemical oxygen demand. In remote locations where refrigeration is not feasible, phenyl mecuric acetate may satisfactorily preserve a runoff sample. Other preservation techniques are also available. No research results have been found concerning the effect of freezing on BOD, COD, total solids, suspended solids, and other characteristics. In evaluating the degree of preparation, the samples can be divided into 4 categories - liquid, semi-solid, solid, and dried samples. Liquid samples need no preparation. Semi-solid samples may contain enough large solids that they have to be broken so a representative aliquot can be taken for analysis. This may be done with a blender. Solid samples can be ground into a uniform mass with a Hobart grinder. Dried samples may also be ground before analysis. It is most unfortunate that more defined procedures are not available on sampling techniques like those for analytical work. Sampling is a very integral part of the research, but it is the impression of the author that more emphasis should be placed on developing reliable sampling techniques. (Rowe-East Central)

SAMPLING OF GASES AND AEROSOLS

Assistant Professor, Agricultural Engineering Department, The Ohio State University, Columbus, 43210
R. K. White and D. P. Stombaugh
Standardizing Properties and Analytical Methods Related to Animal Waste Research, American Society of Agricultural Engineers, December, 1972 and December, 1974, p. 85-109. 3 fig, 1 tab.

Descriptors: Sampling, Gases, Aerosols, Equipment, Dusts, Mist, Bacteria.
Identifiers: Data reporting, Impingement.

The following were discussed: (1) general sampling procedures and equipment, applicable to both gases and aerosols, (2) specific equipment and procedures unique to either aerosol or gas samplings, and (3) the type and form of data reporting. Only aerosols and gases of agricultural origin were considered. Principle aerosols considered were: soil particles from tillage operation, harvesting dust, fertilizer, lime dust, dust from animal and poultry units, mist from pesticide applications, pollen, bacteria, fungi, and smoke. Gases considered were: hydrogen sulfide, ammonia, carbon dioxide, and methane. Specific aerosol sampling procedures that were discussed included: settlement, filtration, and impingement. Specific gas sampling procedures that were discussed included: adsorption and absorption. Check lists were included which can be used for reporting sampling procedures. (Rowe-East Central)

SAMPLING GASES AND AEROSOLS,

Research Associate, Department of Agricultural Engineering, Cornell University, Ithaca, New York.
A. T. Sobel and D. C. Ludington
Standardizing Properties and Analytical Methods Related to Animal Waste Research, American Society of Agricultural Engineers, December 1972 and December, 1974, p. 110-113. 1 tab.

Descriptors: Sampling, Gases, Aerosols, Equipment, Ammonia, Poultry, Ventilation.

Many aspects of sampling gases and aerosols were discussed, including precautions which must be considered. In relation to gas scrubbing equipment, the following comments were made: (1) When using fritted-glass scrubbers, it should be kept in mind that each unit has its own flow characteristics and units should not be interchanged without noting flow changes. (2) Fritted-glass units will change their flow characteristics with time and must be cleaned, usually in acid, periodically. (3) Air flow should be recorded at the beginning and end of sampling when using flow rate meters. (4) For multiple use of gas scrubbers, a constant vacuum source tank is valuable. (5) Indicating flow meters may be used to measure the quality of air that passes through the collector. A specific example is outlined for using gas scrubbing to measure the concentration of ammonia in poultry house ventilation air. The method was absorption of ammonia in dilute acid and measurement of direct nesslerization. (Rowe-East Central)

Standardizing Properties and Analytical Methods Related to Animal Waste Research, American Society of Agricultural Engineers, December, 1972, and December, 1974, p. 167-182. 3 fig, 3 tab, 3 ref.

Descriptors: Liquid wastes, Chemical properties, Physical properties, Sampling, Equipment, Centrifugation, Ammonia, Nitrogen, Nitrates.
Identifiers: Electrode techniques.

The paper, "Evaluation of Methods for the Analysis to Physical, Chemical, and Biochemical Properties of Poultry Wastewater", by T. B. S. Prakasam, E. G. Srinath, P. Y. Yang, and R. C. Loehr has advanced the continuing quest for the most accurate, convenient, and rapid method of analysis, especially when a number of parameters must be tested to properly evaluate complex agricultural wastewaters. The results which they report concerning storage of samples are important and should be included in any critical evaluation of published data. Prakasam, et. al., have shown that the centrifugation method is a reliable estimate of suspended solids and have thus recommended centrifugation with subsequent drying of the sediment for this determination. Results of Prakasam et al for the rapid COD test are very encouraging. The determination of ammonia and organic nitrogen by the standard Kjeldahl method is the most tedious and lengthy analysis that is routinely made in most laboratories. Work is in progress to reduce the time requirements of this method by using the Orion Ammonia electrode. Determination of nitrate in soil-water interflows by means of the Orion specific ion electrode and the ultraviolet spectrophotometric test has had good results. More attention should be given to new and more rapid instrumental and electrode techniques. These techniques will require refinement before confident routine employment can be made for animal wastes, but time and labor benefits will be enormous. (Merryman-East Central)

ANALYZING PHYSICAL AND CHEMICAL PROPERTIES OF SOLID WASTES,

Agricultural and Microbiologist, U. S. Department of Agriculture, Agricultural Research Service, Lincoln, Nebraska
C. B. Gilbertson, T. M. McCalla, and A. T. Sobel
Standardizing Properties and Analytical Methods Related to Animal Waste Research, American Society of Agricultural Engineers, December, 1972, and December, 1974. p. 183-196. 2 tab, 41 ref.

Descriptors: Physical properties, Chemical properties, Solid wastes, Analysis.
Identifiers: Livestock wastes, Poultry wastes.

Physical and chemical analyses required to define the nature of livestock and poultry wastes were outlined. The following procedures may be used in analyzing these physical properties: Total solids (moisture content) — oven dry to constant weight; Fixed solids (Volatile solids) — combustion; Settleable solids — Imhoff cone test; Nonfiltrable solids — vacuum filter; Partical size — wet sieve analysis; Bulk density, specific—gravity—weight/volume measurement phychometer; Flow characteristics — (a) slump test — slump cone; limit; (b) viscosity — stormer viscometer, coaxial cylinder viscometer; Compaction — proctor density test; Liquid and shrinkage limits; Moisture removal — physical and thermal; Equilibrium moisture content — temperature-controlled container; Gross energy — bomb calorimeter; Freezing point — thermocouple; Waste production — laboratory/field collection; Odor — nose; Specific heat — method of mixtures; Thermal conductivity — thermal conductivity probe. Chemical procedures which may be used for analyzing the following properties are: pH—pH meter; EC — conductivity meter; D.O. — dissolved oxygen meter; BOD — 5 day incubation; COD — dischromate reflux method; Odors — gas chromatograph; Total organic carbon — combustion; Total N — micro-Kjeldahl procedure; NO_2-N — steam distillation and colorimetric; NO_3-N — steam distillation and colorimetric; NH_4-N — steam distillation and colorimetric; Total P — ashing, acid extraction, flame photometer; Fe, Cu, Mn, Zn, B, As, Hg — digestion acid extraction, atomic absorption; Cl, I — digestion, acid extraction, colorimetric of gravimetric methods; Digestibility — in vitro digestion with ruminant fluid; Antibiotics — thin-layer chromatography; Pesticides, insecticides — extraction with water and organic solvents; measured in gas chromatograph. The physical properties of animal wastes will be affected by such properties as ration fed, animal environment, climatic conditions, feedlot management, and microbial activity. These variations have made it difficult to develop guidelines for laboratory analyses. By adapting existing techniques and introducing some new ones, information on animal wastes can be documented to assist in basic understanding of the material. (Rowe-East Central)

ANALYZING PHYSICAL AND CHEMICAL PROPERTIES OF SOLID WASTES,

Instructor, Agricultural Engineering Department, University of Minnesota, St. Paul 55108
J. A. Moore
Standardizing Properties and Analytical Methods Related to Animal Waste Research, American Society of Agricultural Engineers, December, 1972 and De-

cember, 1974, p. 197-204. 2 fig.

Descriptors: Solid wastes, Chemical properties, Physical properties, Analysis.

The analysis of solid animal waste is being approached by people in several disciplines by researchers throughout the United States. It is, therefore, very important to develop a uniform technique for the methods not listed in STANDARD METHODS FOR THE EXAMINATION OF WATER AND WASTE WATER. There are no "standard methods" for many of the tests dealing with solid animal wastes. Testing methods, most of which vary from published methods, are discussed. For uniformity in the published literature, the author recommends that 104 degrees C be accepted and used as the standard drying temperature for solid determinations unless a different temperature is stated. Two techniques for filtering suspended solids are: (1) Dilute the semi-solid waste material until the suspension is thin enough so as not to plug up the filter before achieving most of the filtering process. (2) Prefilter the sample. Wet screening has been found to be the most successful method in describing particle size distribution. A crude but useful technique for determining flow characteristics is to measure the angle of internal friction or angle of repose. Equilibrium moisture content may be determined by measuring the humidity or dew point in a closed container or by placing manure samples in a jar, at a constant temperature with a known salt solution in the environment. A bomb calorimeter can be used to measure the decrease over time in total energy of the solids remaining in a continuous aerated treatment system. Determinations of dissolved oxygen may be made through use of dissolved oxygen meters. Nitrate and nitrite measurements may be determined colorimetrically. A chromotropic acid method may also be used for nitrate analysis. (Merryman-East Central)

ANALYTICAL METHODS RELATED TO ANIMAL WASTE RESEARCH: GASES AND AEROSOLS,

Associate Professor, Agricultural Engineering Department, Oregon State University
J. R. Miner
Standardizing Properties and Analytical Methods Related to Animal Waste Research, American Society of Agricultural Engineers, December, 1972 and December, 1974, p. 205-215. 3 tab, 28 ref.

Descriptors: Gases, Aerosols, Analysis, Sampling, Ammonia, Hydrogen sulfide, Odor.
Identifiers: Livestock wastes.

Interest has been generated in the analysis of gases due to possible toxic effect of manure related gases to confined animals, accelerated material degradation, and the potential spread of disease from wind-carried aerosols. Gas analysis techniques basically fit the following classifications: (1) Ammonia, (2) Hydrogen sulfide, (3) Odorant identification, and (4) Aerosol monitoring. At concentrations of approximately 0.3 - 0.5 mg 1, ammonia acts as an irritant to the eye, nose, and throat of humans. At high concentrations, it acts as an asphyxiant. Similar reactions have been noted in the response of domestic animals. The most widely used method of ammonia analysis has been selective ammonia absorption followed by color formation using Nessler's reagent. Ammonia may also be determined by moistening pH test paper with distilled water and exposing it to the air for 15 seconds. Excessive amounts of hydrogen sulfide are also toxic to humans and animals. Methods for measuring hydrogen sulfide include: (1) a titration procedure, (2) a colorimetric procedure, and (3) modification of the method for analyzing hydrogen sulfide concentrations in wastewater as prescribed in STANDARD METHODS FOR THE EXAMINATION OF WATER AND WASTEWATER. Odorant identification techniques are numerous and varied. Included among them are: (1) Paper chromatography, (2) Ammoniamine absorption on silica gel treated with minhydrin, (3) Gas chromatography electron capture detector, and (4) Gas chromatography flame ionization detector. An Anderson sampler which impinges bacterial particles contained in air upon petri dishes located at various stages within the sampler may be used in aerosol monitoring. (Merryman-East Central)

ANALYZING PHYSICAL AND CHEMICAL PROPERTIES OF GASES AND AEROSOLS,

Associate Professor, Agricultural Engineering Department, Clemson University, Clemson, South Carolina 29631
G. L. Barth
Standardizing Properties and Analytical Methods Related to Animal Waste Research, American Society of Agricultural Engineers, December, 1972 and December, 1974, p. 216-224. 4 fig, 16 ref.

Descriptors: Physical properties, Biological properties, Gases, Aerosols, Odor, Air pollution, Legal aspects, Measurement.
Identifiers: Odor intensity.

Animal producers must anticipate that air pollutants originating from their operations are going to be regulated more firmly in the future. Hopefully the technology for odor emission control will keep pace with the technology for odorant concentration determination. The following classification distinguishes between odorous and non-odorous gaseous compounds. (1) Odorants — ammonia, hydrogen sulfide, volatile organic acids, amines, alcohols, carbonyls, mercaptans, and disulfides, and (2) Non-odorants — carbon dioxide and methane. The necessity for objective odor intensity measurement becomes apparent when faced with the fact that some state air pollution control regulations contain limits on odor intensity. At least 8 states and the District of Columbia now include such standards. Methods for measuring odor intensity are outlined. (Merryman-East Central)

ANALYZING BIOLOGICAL PROPERTIES OF WASTES,

Professor, Microbiology Department, South Dakota State University, Brookings 57006
P. R. Middaugh
Standardizing Properties and Analytical Methods Related to Animal Waste Research, American Society of Agricultural Engineers, December, 1972 and December, 1974, p. 238-245. 22 ref.

Descriptors: Biological properties, Odor, Waste treatment, Bacteria, Public health, Clostridium, Bacteroides.
Identifiers: Farm wastes, Land disposal, Pathogens, Animal health.

The need for economic, rapid stabilization of animal wastes with control of odors, ammonia, and other objectionable characteristics will require the application of all available knowledge of the biological characteristics of farm animal wastes. Commercial operators of livestock enterprises and investigators studying waste materials handling and ultimate disposal of livestock wastes on land can appreciate the value of bacteria, both as built-in indicators of environmental pollution and as the means of stabilization of organic wastes. Development of standardized methods for detection of the major pathogenic enteric microorganisms including bacteria, viruses, fungi and protozoa should be a major objective for improved environmental health for both farm animals and man. Methods for determining clostridium and bacteroids are discussed. Microorganisms and their association with odor control are also discussed. (Merryman-East Central)

SAMPLING AND ANALYSES OF GASES/ODORS,

Assistant Professor, Department of Agricultural Engineering, Ohio State University, Columbus 43210
R. K. White, C. L. Barth, D. C. Ludington, and J. R. Miner
Standardizing Properties and Analytical Methods Related to Animal Waste Research, American Society of Agricultural Engineers, December, 1972 and December, 1974, p. 282-296. 7 tab, 29 ref.

Descriptors: Sampling, Analysis, Gases, Odor, Absorption, Adsorption, Condensation, Ammonia, Hydrogen sulfide, Carbon dioxide, Methane, Equipment.
Identifiers: Livestock wastes.

The methodology and equipment suitable for sampling and analyzing gases /odors from livestock wastes are discussed. Gases may be collected by: (1) admitting the gas into an evacuated bulb of known volume (2) utilizing a rigid container filled by gas displacement, or (3) utilizing non-permeable, collapsible bags which can be filled by a blower or a pressurized source of the gas. Gas concentration is usually accomplished by absorption, adsorption, or condensation. There are 4 gases commonly associated with decomposition of animal wastes: ammonia, hydrogen sulfide, carbon dioxide and methane. The first 2 are odorous while the last 2 are non-odorous. Gas chromatography is the principal analytical tool for measuring odorants. Gas chromatograms can be calibrated for quantitative analysis using a measured amount of a known compound. When peak areas on gas chromatograms for an odorant from a waste sample are compared with calibration curves, the concentration of the odorant can be determined. Research has indicated that the only way to evaluate an odor is to sniff the odor with the nose. There are 2 basic ways of measuring the strength of an odor with the nose. One is by sniffing the odor emanating from the source directly and ranking the odor strength based on a predetermined scale. The other is to dilute the odor until the odor is no longer perceptible or the odor threshold is attained. The amount of dilution required to achieve this threshold is used as a measure of the odor strength. Commercial equipment for sampling and measuring gases of importance in livestock waste management is not readily available. The few field devices available have evolved because of the need for more convenient techniques to gather samples in the field, usually by adapting measurement devices built for some other application. However, most measurements are made by using modifications of laboratory procedures, adapted for field use. (Merryman-East Central)

ANIMAL WASTE SAMPLE PREPARATION AND PRESERVATIVE,

Instructor, Agricultural Engineering Department, University of Minnesota, St. Paul
J. A. Moore, M. R. Overcash, and T. B. Prakasam
Standardizing Properties and Analytical Methods Related to Animal Waste Research, American Society of Agricultural Engineers, December, 1972, and December, 1974, p. 297-332. 53 fig.

Descriptors: Sampling, Preservation, Analysis, Chemical properties, Poultry, Cattle.
Identifiers: Swine, Dairy cattle.

Research was done to establish the magnitude and rate of any transformation that occur in animal waste samples as a function of the preparation and/or preservation techniques. In most operations, there is a time lag between sampling and analysis of animal waste. A wide variety of preservation techniques are commonly used. For the purpose of this study, samples were handled in the following ways: stored at room temperature, refrigerated, frozen, and acidified. Comparisons were made of the impact of these techniques on the different parameters considered in the individual studies. Samples were taken from fresh manure (feces + urine), fresh feces, lightly loaded lagoon, heavily loaded lagoon, oxidation ditch mixed liquor, and soil column leachates. They were measured for some, though not necessarily all, of the following parameters: Total Kjeldahl nitrogen, ammonia, nitrates, nitrites, chemical oxygen demand, total organic carbon, conductivity, and pH. The wastes originated from beef cattle, dairy cattle, poultry, and swine. Actual sample preparation techniques, preservation techniques, data analysis, results, and conclusions are outlined for the studies that were conducted. (Merryman-East Central)

SIMULATED BEEF FEEDLOT BEHAVIOR UNDER ALTERNATIVE WATER POLLUTION CONTROL RULES,

Assistant Professor of Agricultural Economics, Ohio State University
D. L. Forster
American Journal of Agricultural Economics, Vol. 57, No. 2, p. 259-268, May, 1975. 1 fig, 5 tab, 17 ref.

Descriptors: Model studies, Feedlots, Water pollution, Management, Costs, Legal aspects, Michigan.

In order to investigate the impact of alternative rules established by federal and state agencies concerning water pollution from feedlots, a simulation model was constructed to represent the behavior of beef feedlots in Michigan and similar states over the 1974-85 period. The model's 4 components were: (1) the farm feedlot component which assumed a whole farm approach to feedlot production by simulating feedlot design and beef production, the production of crops necessary to feed the cattle, the transportation of crop from field to storage facilities, the design of feed storage facilities, and the removal of wastes to the fields, (2) ex ante and ex post price equations which were used to represent the feedlot operator's price expectation and output and input prices which were actually experienced by the operator, (3) a decision-making process which determined the type and level of inputs employed and which was used during each time period by each simulated firm, and (4) an optimization procedure, which was employed to find the values of 4 unknown parameter values. It was concluded that the beef feedlots of less than 1000-head capacity would change their performance only slightly under any of the alternative water pollution control rules tested. Other results from the analysis indicated that costs which the feedlots would bear as a result of the rules investigated vary with feedlot technology. As a means of conducting such investigations, the model was found to have disadvantages in terms of the cost requirements of the analysis, but to have advantages in terms of its flexibility and dynamic attributes. University of Georgia, Athens
J. Giddens
Completion Report, USDI OWRI Project No. A-050-GA, Department of Agronomy, University of Georgia and Environmental Resources Center, Georgia Institute of Technology, December, 1975, 19 p. 4 tab, 20 ref.

Descriptors: Water pollution, Ammonia, Poultry, Cattle, Nitrogen, Sulfur, Georgia, Precipitation (atmospheric).
Identifiers: Air pollutants.

Ammonia traps using .01N H_2SO_4 were placed near poultry and beef cattle operations. Up to 66 kg/ha ammonia was trapped near the animal operations. At distances greater than 500 to 800 meters away, there was no effect from the animals but there was still about 15 kg/ha/yr of ammonium nitrogen trapped. Precipitation was collected at 8 rural locations in Georgia during 1974 and analyzed. The water pH ranged from 4.1 to 5.6. The amounts of fertilizer elements and heavy metals in precipitation, except nitrogen and sulfur, were negligible when considered from the overall content of these elements in soils. The water was low in chemicals when compared to that reported for industrialized and traffic congested areas. (Giddens-University of Georgia)

AUTOMATED PIG WASTEWATER TREATMENT AND EFFLUENT RECYCLE,

Professor of Agricultural Engineering, Agricultural Pollution Control Research Laboratory, Agricultural Engineering Department, Ohio State University, Columbus
E. P. Taiganides, C. R. Mote and R. K. White
Proceedings of the 28th Industrial Waste Conference, Part 2, Purdue University, May 1-3, 1973, p. 778-783. 4 fig, 1 tab, 3 ref.

Descriptors: Waste treatment, Wastewater treatment, Recycling, Liquid wastes, Solid wastes, Performance.
Identifiers: Land disposal, Swine.

A system which appears to have good potential for meeting the waste handling and treatment requirements of the nation's pork producers was built in 1971 on the Research Farm of Botkins Grain and Feed Co. and has been operated as a demonstration project for 2 years. The treatment plant received all the waste produced in a 500 head capacity swine growing and finishing barn. As long as the proper population is maintained, the pigs defecate on the slatted floors and in the gutters and their movement forces the wastes through the slatted floor into a channel below. From here, the water is periodically flushed by siphon flush tanks. The slurry thus formed flows into a sump from which it is pumped to a stationary screen. Solids removed by the screen drop into a solids treatment unit. The effluent goes into an oxidation ditch. Effluent mixed liquor from the ditch flows into the center of a gravity clarifier. Clarified effluent flows into a storage well. Water from the storage well is pumped into the flush tanks for reuse. Settled sludge from the bottom of the clarifier is pumped back into the ditch. Satisfactory operation of the ditch is maintained by regularly wasting some of the sludge from the clarifier to the solids treatment unit. Effluent from the solids treatment unit flows into the solids storage tank. Periodically solids from the storage tank are field spread. Performance of the system may be generalized as follows. The automated flushing has worked extremely well. Odor in the building has been minimal and the pigs have been very clean. Winter freezeup of the treatment plant has been avoided by covering it with plywood and using some type aerator other than a surface aerator. Foaming of the oxidation ditch during cold weather has been satisfactorialy combatted by using a foam suppressing drum or a high velocity spray. General performance of the plant is better in warm weather than in cold. (Rowe-East Central)

INFLUENCE OF PRELIMINARY TREATMENT AND STORAGE ON THE ORGANIC CONTAMINATION OF LIQUID MANURE,

Beitrag aus dem Institut fur Wasserwirtschaft, Berlin
D. Kramer and C. Konrad
Wasserwirtschaft Wassertechnik, Vol. 20, No. 6, p. 189-193, June, 1970. 7 tab, 19 ref.

Descriptors: Liquid wastes, Hydrologic aspects, Cattle, Waste storage, Sampling, Fertilizers, Separation techniques.techniques.
Identifiers: Swine.

A hydrological assessment of liquid manure is presented. Agricultural practices which are unsatisfactory from the standpoint of water resources protection are criticized. Results of investigations of organic contamination by liquid manure of cattle and pigs are discussed in relation to the duration and kind of storage and the influence of phase separation. To avoid undue scatter of measured data due to the use of different sampling procedures, a standard procedure is proposed in which the sample is taken without disturbing the natural stratification 5 cm below the surface, or the floating cover of the liquid. No perceptible decrease of organic contamination was found using the above mentioned parameters when the liquid manure was stored for a maximum of 358 days. Phase separation had a definite influence on the hydrological contamination potential of the liquid manures. However, even though the sediment constituting (in the mean) 30 percent of the raw liquid manure contains 60 percent of the total organic contamination, the centrifuged liquid, constituting the other 70 percent, still is an organically strong contaminated liquid. This contaminated liquid requires a highly effective method of decontamination for use as a fertilizer in agriculture. (Solid Waste Information Retrieval System) (In German)

EFFECTS OF BEEF-FEEDLOT MANURE AND LAGOON WATER ON IRON, ZINC, MANGANESE AND COPPER CONTENT IN CORN AND IN DTPA SOIL EXTRACTS,

Research Assistant, Kansas State University, Manhattan 66505
G. W. Wallingford, L. S. Murphy, W. I. Powers, and H. L. Manges
Soil Science Society of America Proceedings, Vol. 28, No. 3, p. 482-487, 1975. 5 fig, 4 tab, 25 ref.

Descriptors: Feedlots, Cattle, Crop response, Nutrients, Iron, Zinc, Manganese, Copper, Corn, Trace elements.
Identifiers: Land application, Lagoon water, Soil extracts, Soil cores, Micronutrients.

The effects of beef-feedlot manure and lagoon water on DTPA extractable iron (Fe), zinc (Zn), manganese (Mn), and copper (Cu) of a silty clay loam soil, concentrations of these elements in corn forage and leaf tissue, and their uptake by corn forage were studied in the field. Soil cores were taken from the surface 1 m of sets of plots which had received 2 annual applications of manure and 3 annual applications of feedlot lagoon water. DTPA extractions were performed on these cores. It was found that in the 2 years, annual application of beef-feedlot manure did not appreciably change the pH of the neutral-to-alkaline soil studied, though soil availability of Fe, Zn, Mn, and, to a lesser extent, Cu was increased. Three years of field data showed that applications of manure enhanced corn-leaf and forage concentrations of Zn and Mn and corn-forage uptake of Mn. The Mn plant data were consistently highly correlated with the cumulative manure applied, the increased availability of Mn probably resulting from chemical reducing conditions in the soil. Manure applications did not consistently affect corn concentrations of Fe and Cu and uptake of Fe, Zn, and Cu, but were shown to increase the availability of Zn and Mn in the soil studied. Soil cores taken from plots that had received 2 years of beef-feedlot lagoon water contained increased DTPA extractable Fe, Zn, and Mn; Cu was unaffected. Uptake by corn forage of Fe, Mn, and Cu followed yield curves most years. Lagoon water effectively increased the availability of Fe and Mn in the soil studied. Beef-feedlot wastes were shown to be sources of the trace elements Fe, Zn, and Mn. (Rowe-East Central)

METHANE PRODUCTION FROM ANIMAL WASTES II-PROCESS STABILITY,

Department of Civil Engineering, University of Manitoba, Winnepeg, Manitoba, Canada R3T 2N2
E. J. Kroeker, H. M. Lapp, D. D. Schulte, J. D. Haliburton, and A. B. Sparling
Presented at the 1976 Annual Meeting, Canadian Society of Agricultural Engineering, Halifax, Nova Scotia, July 4-8, 1976, Paper No. 76-208, 15 p. 2 tab, 17 ref.

Descriptors: Methane, Pilot plants, Feasibility studies, Anaerobic digestion, Slurries, Ammonia, Economics, Design, Chemical properties.
Identifiers: Animal wastes, Swine.

Pilot-plant experiments to determine the technical and economical feasibility of anaerobic digestion of swine manure have consistently achieved extreme process stability. Despite periodic environmental shocks, including rapid temperature and loading-rate changes, digestion has never been impaired. In addition, ammonia-nitrogen concentrations have consistently been outside the range considered safe for anaerobic digestion. Laboratory experiments were conducted to test an hypothesis which explained the mechanism of process stability and related it to the high concentrations of ammonia in the manure slurry. ANIMAL WASTE MANAGEMENT IN THE NORTHERN GREAT PLAINS,

Water Resources Institute, South Dakota State University, Brookings 57006
M. L. Horton, J. L. Wiersma, and J. L. Halbeisen
Environmental Protection Agency Report No. EPA-600/2-76-188, September, 1976, 83 p. 7 fig, 45 tab, 26 ref.

Descriptors: Salinity, Salts, Rations, Cattle, Feedlots, Crop response, Performance, Nutrients, Cations, Sodium.
Identifiers: Northern Great Plains, Land Application, Application rates.

The effect of salt level of the ration for beef steers upon salinity of the waste and the effects of the applied waste upon the soil and upon crop production was investigated. In addition, the study was conducted in both covered and open feedlot pens to study the effect of shelter in a northern climate upon animal performance and waste characteristics. The field portion of the study included 4 rates of waste up to 179 MT/ha. applied to plots 0.02 ha. in size. Detailed soil analyses were made which included salinity, nutrients, cations, and the dispersion hazard as indicated by the level of exchangeable sodium. The levels of salt used in the ration appeared to have little or no effect on animal performance; however, the salinity and sodium levels of the waste were directly affected. The salinity level of the surface 30 cm of soil where high rates of waste were applied was sufficiently high to affect the growth of corn. The lack of leaching water caused a maximum effect of the applied waste in the surface layer. (Horton, et. al. - South Dakota State University)

PIG SLURRY TREATMENT BY SEPARATION, HIGH RATE FILTRATION AND SLUDGE DEWATERING,

Farm Buildings Department, National Institute of Agricultural Engineering
L. E. Osborne, R. Q. Hepherd, and R. W. Sneath
Water Pollution Control, Vol. 74, Part 5, p. 597-606, 1975. 9 fig, 6 tab, 5 ref.

Descriptors: Slurries, Separation techniques, Filtration, Sludge, Dewatering, Waste treatment, Liquid wastes, Solid wastes, Temperature, Chemical properties, Physical properties, Performance, Flocculation.
Identifiers: Land disposal, Swine, Aluminum chlorohydrate.

A treatment system utilizing separation, high rate filtration and sludge dewatering for treating pig slurry is described. The effects of temperature on the performance of the system is examined. The system reduced the amount of liquid for disposal to about 30 percent of the volume produced by the animal. This liquid was low in suspended solids, allowing it to be as easily pumped and stored as water. The solids resulting from the system were fibers from the separator and dewatered sludge. Both solids and liquids had little odor, were easy to store, and could be applied to land at the optimum time for utilization of plant nutrients. Separation of the raw slurry enhanced pump life and permitted the operation of high rate filters without blocking. After flocculation through use of aluminum chlorohydrate, the sludge was dewatered by gravity in straw bale compounds of hessian-lined pallet boxes. The complete system was automatic. It required less than 1 man hour/day and could be operated by a competent farm worker. As part of the complete system, operation of high rate filters running at mean temperatures of 17·3 degrees C and 5·7 degrees C had similar performances when judged on effluent quality. When considered alone, the heated tower removed about twice as much soluble BOD as the ambient tower. The installation of a high rate filter in a piggery or the heating of the filter by using exhaust ventilation air from the piggery would be worthwhile, if only to avoid freezing. (Rowe-East Central)

A GROWING SUCCESS IN CATTLE FEEDING,

Calf News, Vol. 14, No. 10, p. 20, 22, 42, October, 1976. 8 fig.

Descriptors: Confinement pens, Recycling, Cattle, Economics, Fertilizers.
Identifiers: Farmers' Coop Society, Refeeding, Animal health.

The Farmers' Coop Society of Sioux Center, Iowa, has a service of matching farmers owning extra cattle to feed with farmers owning extra pen space. This led to the construction of 2 large confinement barns, each capable of holding 2500 cattle. Members of the Coop Confinement Feedlot, who must also be members of the Farmers' Coop Society, own the 30 pens in each barn. One person can own up to 6 pens, and can grow or finish his own cattle, or rent his pens to someone else. The operation has been so successful, that 2 more barns have been added. Each barn has 3 gutters 8 inches wide and 10 inches deep in a "u" shape. The slope of the barn floor is half of one percent and the cattle work the manure down to the flume and water flushes it down and out to a recycling shed. A recycling unit separates out the solids which are used for refeeding, and the water is reused to flush down the flumes. Excess water is used as fertilizer. A recent group of 80 cattle weighing 575 pounds was fed the recycled manure at 50 percent of their ration and in 90 days moved out of the growing pen weighing 814 pounds. The final cost of feed was only 35 cents /pound of gain. The Farmers' Coop Society also has an interesting arrangement with their veterinarian. The veterinarian gets half a cent/head/day and in return does the following: (1) vaccinates all cattle, (2) takes an egg count of the manure, (3) worms the cattle, if necessary, (4) if an animal dies, he gives the owner a post mortem report, and (5) the veterinarian walks through each pen once a week. The veterinarian gets 20 percent over his cost for drugs used. One agreement now in force among the members is that the Coop's nutritionist has the discretion over rations. At present, the death loss in this condominium is three-tenths of one percent. (Edwards-East Central)

LAST MINUTE LEGISLATION HELPS SWINE PRODUCERS,

Wallaces Farmer, Vol. 101, No. 12, p. 9, June 26, 1976.

Descriptors: Legal aspects, Iowa, Regulations, Zoning, Feedlots.
Identifiers: Nuisance suits, Swine.

In addition to passing a $100,000 appropriation to study pseudorabies, the Iowa legislature has passed a bill which gives livestock producers some protection against nuisance suits and rapid changes in state environmental and zoning regulations. This bill protects livestock producers against suits by people who move in near facilities which have already been built; however, the bill does not protect livestock producers who are sued by people who were there before the facility was built. The bill protects livestock producers against changes in Iowa Department of Environmental Quality rules for 10 years. Plus, it protects against zoning changes for the same length of time from date of construction of facilities that meet current requirements. Some producers and lenders have been worried that changes in Department of Environmental Quality regulations might make confinement facilities and waste handling systems obsolete. (Edwards-East Central)

PRODUCERS DISCUSS REFEEDING ANIMAL WASTES,

Anonymous
Calf News, Vol. 14, No. 10, p. 57, October, 1976.

Descriptors: Recycling, Fertilizers, Economics, Rations, Litters, Performance.
Identifiers: Refeeding, Animal wastes.

At the annual meeting of the American Society of Animal Science at Texas A&M University, Russell May of Timberville, Virginia, and Sam D. Hay, Jr., of Covington, Georgia, talked about their refeeding operations. May runs an angus herd along with swine, poultry, and sheep. He talked about the use of poultry litter in rations for his herd. Early rations consisted of one pound of corn meal and 3 pounds of litter, supplemented with hay during winter months. Now May mixes corn silage along with the litter and his herd receives a ration of 25 percent litter and 75 percent silage. He piles up the litter for 4 to 6 weeks to allow it to go through a heating period before he uses it. Mr. Hay recycles manure by using a ration consisting of 45 percent corn, 15 percent corn silage, and 40 percent manure for his backgrounding and cattle finishing operation. The silage and corn are mixed with manure and put into a silo for 10 to 14 days before being fed to the cattle. Hay says that with the above ration, an average daily gain of 2.65 per animal has been realized in the finishing operation. Dr. Arnold Peterson from Sear Co., Elburn, Illinois, talked about a $1.5 million plant at Summerfield, Texas, where manure from feedlots is being processed for use in finishing rations, as well as for fertilizer for home gardens. Peterson said that at a feedlot near his home base, a ration containing 30 percent manure and 70 percent corn silage is being utilized. He contended that 30 to 40 percent is the upper limit for feeding manure. He noted that as a feed and as a fertilizer, manure is valued at about $5 million annually in the United States. SYSTEMS AND COSTS OF HANDLING MANURE FROM DAIRY COWS,

Assistant Farm Manager at R. and J. Findlay Ltd. Easter Cadder, Kirkintilloch, Glasgow, Scotland
R. G. Cason and J. T. McAuslan
Farm Management Review, No. 2, June, 1973, 24 p. 2 fig, 8 tab, 8 ref.

Descriptors: Dairy industry, Economics, Design, Waste storage, Costs, Waste disposal, Solid wastes, Liquid wastes, Equipment, Drying.
Identifiers: Waste management, Housing systems, Cowsheds, Cubicle housing, Strawed cattle courts, Bedding, Cleaning, Land spreading.

The economic principles, costs and physical factors relevant to the choice of manure handling systems for cowsheds, cubicle housing and strawed cattle courts are investigated. The various handling systems which can be used with each type of housing are outlined. The systems are compared on a cost per cow basis. Only costs associated with manure handling are included. The following items have been costed: (1) buildings — alterations of additions necessary to accommodate the manure handling system; (2) storage — construction costs, equipment and materials for storing manure; (3) cleaning, removal to storage and disposal — equipment, labor, power and fuel; and (4) bedding — materials and labor. Of the systems analyzed, minimum handling costs are found in cubicle housing systems with herds over 60 cows. (Rowe-East Central)

FUELS AND PETROCHEMICALS FROM AGRICULTURAL WASTES,

Texas Tech University, Lubbock, Texas 79409
H. W. Parker and G. A. Whetstone
Paper 5e, presented at the 76th National American Institute of Chemical Engineers Meeting, Tulsa, Oklahoma, March 10-13, 1974, 24 p. 4 tab, 23 ref.

Descriptors: Energy, Recycling, Fuels, Electricity, Economics, Chemical properties, Organic wastes.
Identifiers: Agricultural wastes, Manure, Pyrolysis, Hydrogasification.

It is both more humanitarian and more profitable to utilize arable lands for the production of food and natural fibers than for the growing of plant materials primarily for fuel or bulk petrochemical feedstocks. For this reason only agricultural wastes, which could yield less than one percent of the nation's energy needs, are available for fuels. These agricultural wastes, both manure and plant materials, could potentially be burned in combination with coal for the generation of electricity. Thermochemical processes such as pyrolysis and hydrogasification are technically feasible for agricultural wastes, but the quantities of wastes available in any one vicinity are too small to supply fuel conversion plants of sufficient size to compete with plants processing coal or oil shale. (Parker and Whetstone-Texas Tech University.)

POLLUTION POTENTIAL OF SNOWMELT RUNOFF FROM AGRICULTURAL FEEDLOTS,

Instructor in Agricultural Engineering, South Dakota State University, Brookings
J. M. Madden and J. N. Dornbush
Presented at the 1970 Annual Meeting, North Central Region, American Society of Agricultural Engineers, North Dakota State University, Fargo, Paper NC70-404, 26 p. 7 fig, 7 tab, 4 ref.

Descriptors: Agricultural runoff, Feedlots, Sampling, South Dakota, Chemical properties, Physical properties.
Identifiers: Snowmelt runoff

A study was initiated in February, 1969, to: (1) determine the quantity and quality of runoff from livestock feeding operations in South Dakota, (2) relate the above information by hydrological and geological considerations in order to appraise the overt influence of this runoff on specific beneficial uses of receiving waters, and (3) determine the influence of spring feedlot runoff as occurs in northern climates. Feedlots were selected for study and were instrumented with a Type H flume and a continuous state recorder to determine the quantity of runoff. Runoff quality was determined from samples taken by an automatic self-starting sampler. After each runoff period the runoff volumes were computed and individual samples were composited according to flow and analyzed. Grab samples representing portions of the runoff hydrograph were also analyzed. Samples were analyzed for biochemical oxygen demand, chemical oxygen demand, dissolved and suspended solids, Kjeldahl nitrogen, and total phosphorus. Conclusions drawn from the investigations were: (1) Spring runoff from livestock feeding operations contains high concentrations of total and suspended solids, plant nutrients, and oxygen demanding material. (2) An empirical relationship considering the animal density, feedlot area, and the depth of runoff can be used to estimate the quantity of pollutional constituents removed during spring runoff. (3) Suspended solids represent a significant portion of the waste concentrations, and detention facilities which provide removal of solids will significantly reduce the pollution potential. (4) Pollution potential is highest from: a series of small runoff events in comparison to one large event, a number of small feedlots as compared to one large feedlot, and a feedlot having a small animal density as compared to one having a high animal density. MACHINERY REPORT. . .CENTER-PIVOT FOR LIVESTOCK WASTE INTRODUCED.

Anonymous
Nebraska Farmer, Vol. 118, No. 20, p. 40, October 16, 1976. 1 fig.

Descriptors: Irrigation, Equipment, Liquid wastes, Waste disposal, Temperature, Costs.
Identifiers: Land spreading.

Valmont's "Valley Water and Waste Irrigation System" was designed for applying liquid livestock wastes directly on the field from pit, holding pond, or lagoon. This stub center-pivot system carries volume guns in place of the sprinkler heads found on the company's conventional center-pivot sprinkler systems. Each volume gun has a 0.6-inch orifice which permits application of liquid wastes with 5 percent solids or slightly higher. Wastes are applied uniformly throughout the area covered by the system. The waste system is electrically driven. It can be operated off either 460-volt or 220-volt electric service. The company offers a portable alternative unit with matched one-cylinder diesel engine to generate electricity to the waste system tower motor. Among benefits Valmont officials list for utilizing wastes through application with this system are the following: (1) Only a limited amount of labor is needed to remove livestock wastes and get them on fields, (2) Spreading can be done whenever temperature is 40 degrees F or higher and the ground isn't frozen, (3) The system provides the dual purpose of irrigation and waste disposal, and (4) Water does the incorporating, making tillage for incorporation of wastes unnecessary. The 10.4-acre Water and Waste Irrigation System will cost somewhere around $9,000 to $10,000, excluding the portable engine-alternator unit. Additional equipment needed includes slurry pump unit and conveyance pipe to the system. (Rowe-East Central)

USE FEED TO FIGURE HOG WASTE VALUE,

Anonymous
Wallaces Farmer, Vol. 101, No. 5, p. 58, March 13, 1976.

Descriptors: Fertilizers, Nitrogen, Liquid wastes, Economics, Sludge.
Identifiers: Swine, Land spreading.

Amount of fertilizer you get from hog waste depends mainly on how much feed the hog eats and how much it absorbs. Feed that isn't absorbed comes out the other end for fertilizer use. Knowing how much waste goes into the pit can tell you how much you have available to spread for fertilizer. You get about 8.2 lb. of N, 7.6 lb. of P_2O_5 and 5.3 lb. of K_2O for every 220-lb hog marketed. Total fertilizer value is computed at $3.01 per 220-lb hog. No P_2O_5 of K_2O should be lost in moving the wastes or in the field if there is no runoff. But the wastes should be stirred before being taken to the field. P_2O_5 is often tied up in the sludge at the bottom of the pit. K_2O is usually in the liquid floating at the top of the pit. Stirring waste before you handle it will give a more uniform fertilizer treatment. (Rowe-East Central)

THE EFFECT OF ANAEROBIC DIGESTION UPON SWINE MANURE ODORS,

Department of Agricultural Engineering, University of Manitoba, Winnipeg, Manitoba, Canada R2T 2N2
F. W. Welsh, D. D. Schulte, E. J. Kroeker, and H. M. Lapp
Presented at the 1976 Annual Meeting, Canadian Society of Agricultural Engineering, Halifax, Nova Scotia, July 4-8, 1976, Paper No. 76-206, 16 p. 3 fig, 4 tab, 15 ref.

Descriptors: Odor, Anaerobic digestion, Sampling, Waste storage, Waste treatment, Temperature.
Identifiers: Odor panels, Swine manure, Retention time, Agitation.

A series of odor panels were established to determine the effect of anaerobic digestion on the odor of swine manure. Samples from digesters operated at various solids retention times, agitation rates, and operating temperatures were tested. Anaerobically digested manure that had been stored for various periods of time and undigested manure samples were also tested. Odor ratings demonstrated that: (1) anaerobic digestion brings about substantial and statistically significant reduction in odors from swine manure; (2) the most effective odor reduction through anaerobic digestion occurs at or beyond a 12 day solids retention time; (3) anaerobic digestion at 35 degrees C is more effective than that at 25 degrees C from an odor-control viewpoint; (4) increased agitation can improve the odor control capability of anaerobic digesters at solids retention times of less than 12 days; (5) odors emanating from anaerobically digested swine manure in storage were reduced from that of undigested manure in storage for storage periods as long as one month and possibly as much as two to three months, and (6) although the odors from anaerobically digested swine manure were considerably reduced in presence and offensiveness, they were still identifiable as manure odors having negative qualities. (Rowe-East Central)

MODELING THE PERFORMANCE OF FEEDLOT-RUNOFF-CONTROL FACILITIES,

Assistant Professor, Agricultural Engineering Department, Kansas State University, Manhattan
J. K. Koelliker, H. L. Manges, and R. I. Lipper
Transactions of ASAE, Vol. 18, No. 6, p. 1118-1121, November-December, 1975. 2 fig, 3 tab, 9 ref.

Descriptors: Agricultural runoff, Feedlots, Watersheds, Model studies, Kansas, Fertilizers, Irrigation.
Identifiers: Runoff control.

A watershed model including a feedlot surface, runoff control structure, and runoff disposal system was developed to help estimate: (a) the percentage of total runoff controlled, (b) conditions under which facilities will overflow, (c) additional requirements to eliminate overflow or limit overflow to prescribed amounts or situations and (d) other sizes of facilities and management alternatives that would allow adequate control with varying intensities of management or that would allow utilization of feedlot runoff for irrigation and fertilizer. The model was used to determine daily runoff evaporation from the structure, precipitation onto the structure, overflow, amount disposed, and volume of runoff in the structure. In Kansas, runoff-control structures sized to contain the volume of a 10-year, or 25-year, 24-hr precipitation event from a feedlot and dispose of 10 percent of the volume per disposal day would control from 91.3 to 99.4 and 93.0 to 100.0 percent, respectively, of all runoff from an unsurfaced feedlot at locations from east to west across the state. About one-third of the average annual precipitation in Kansas is expected to run off an unsurfaced feedlot while about 44 percent is expected to run off a surfaced lot. Based on results from the watershed model presented, evaporation pond sizes in Kansas (to provide control as good or better than land disposal systems) would be 6 ft deep for a surface area 120 percent of the minimum surface area and 4 ft. deep for a surface area 150 percent of the minimum surface area. FIBROUS MATERIAL IN FEEDLOT WASTE FERMENTED BY TRICHODERMA VIRIDE,

Northern Regional Research Laboratory, Agricultural Research Service, Peoria, Illinois 61604
T. Kaneshiro, B. F. Kelson, and J. H. Sloneker
Applied Microbiology, Vol. 30, No. 5, p. 867-878, November, 1975. 2 fig, 1 tab, 5 ref.

Descriptors: Fermentation, Biological treatment, Fungi, Centrifugation, Carbohydrates, Nutrients, Lignins, Cellulose.
Identifiers: Trichoderma viride, Cellulolytic enzymes, Feedlot wastes, Hemicellulose.

A study done by H. L. Griffin, J. H. Sloneker, and G. E. Inglett demonstrated that whole feedlot waste at 2.5 percent concentration is a complete and convenient medium for the production of cellulolytic enzymes by Trichoderma viride. However, higher concentrations were inhibitory to the fungus. This study was performed in an attempt to eliminate this inhibition and improve the overall amount of feedlot waste digestion through fermentation of fibers isolated and compared with whole waste as a fermentation substrate. Isolated fiber different from the whole waste in that no inhibition was detectable at substrate concentrations up to 16.7 percent, but nutrient deficiencies appeared. In all 3 samples, approximately 60 percent of the carbohydrate disappeared and only 68 percent of the solid was recoverable by centrifugation. Lignin content, which is usually 13-20 percent, increased 20-28 percent in the fermentation fibers, and there was a 0.5 and 1.8 percent net increase of insoluble nitrogens. Cellulolytic enzyme production was better with fiber substrates that had been alkali pretreated and had a lower hemicellulose-to-cellulose ratio. (Rowe-East Central)

FARM WASTES PURIFICATION AND SOLIDS DISPOSAL,

Arnhem, The Netherlands
H. M. J. Scheltinga
Berichte der Abwassertechnischen Vereinigung, Vol. 26, p. 125-131, 1973.

Descriptors: Waste storage, Solid wastes, Liquid wastes, Waste disposal, Air pollution, Water pollution, Land contamination, Groundwater pollution, Fertilizers, Composting, Agricultural runoff, Recycling, Legal aspects, Livestock, Poultry, Europe, Canada, United States, Feedlots.
Identifiers: Guidelines

In Holland and Germany, a comparison of the total water pollution produced by inhabitants, industry, and agriculture yielded a ratio of 1 to 1 to 5. Apart from surface water pollution, farm wastes may cause air pollution, soil pollution and either groundwater or surface water pollution as a result of drainage and runoff. Solid farm wastes, with or without bedding material such as straw, can be used as concentrated fertilizer. They can be stored in the open air without causing high costs or nuisance and can also be transported over long distances. The modern trend in farm design and construction involves the production of semi-liquid wastes, with up to 8 percent dry matter. Recycling must be adopted by modern bio-industries. Three key measures are to be provided: enough land area on which to dispose of the waste; sufficient waste storage capacity; and sufficient distance between livestock and poultry buildings and neighboring human dwellings. In order to institute these measures, two approaches are possible: the legal and the guidelines approach. With respect to water pollution, the legal approach is favored in all the European countries. In Canada and the U.S., the trend is toward the guidelines approach. The Ontario Code of Practice is discussed as a good example of the guidelines approach. It is suggested that if the relationship of animals to acreage were left to the free choice of the farmer, he could be forced to deliver the eventual calculated surplus of manure to a so-called manure exchange. SOME EFFECTS OF CATTLE DUNG ON SOIL PROPERTIES, PASTURE PRODUCTION, AND NUTRIENT UPTAKE. I. DUNG AS A SOURCE OF PHOSPHORUS,

Ruakura Soil Research Station, Private Bag, Hamilton, New Zealand
C. During and W. C. Weeda
New Zealand Journal of Agricultural Research, Vol. 16, No. 3, p. 423-430, 1973. 2 fig, 7 tab, 14 ref.

Descriptors: Fertilizers, Phosphorus, Crop response, Nutrients, Soil properties.
Identifiers: Application rates, Pasture production, Superphosphate, Cattle dung.

An experiment was performed to measure the effect of cattle dung and of superphosphate on the yield of pasture, nutrient uptake, and on several soil properties during a 3 year period. The trial consisted of 24 treatments replicated 4 times. Initial basal treatments were: 0 — no basal treatment; SP — phosphorus applied in superphosphate at the same rate as in high-phosphorus dung; LD — low-phosphorus dung, collected from cattle grazing unfertilized pasture; HD — high-phosphorus dung, collected from cattle on good pasture. The basal treatments were put down in all combinations with the following annual treatments: Nil — no annual treatments; PK — superphosphate and potassium chloride at 750 and 250 kg ha/per/annum respectively; and P — superphosphate only at 750 kg/ha/annum. It was found that dung, as a source of phosphate for permanent grass-clover pasture on a soil deficient in phosphorus and with high P sorption characteristics, could be equal or even superior to a quick-acting inorganic fertilizer. Dung was found to increase the level of soil organic matter. Soil acidity was reduced. compared with superphosphate applied at equivalent rates of P, cattle dung decreased phosphate sorption and increased soil pH. Recovery of applied phosphate in herbage was higher from dung than from superphosphate. Yield responses of herbage to dung and superphosphate persisted for 2 years and 1½ years respectively. Yields of P were affected for the duration of the experiment. It was found that the area on which dung influenced P uptake was probably about 5 times the area physically covered by it. Hence, under medium stocking rates (3-4 cattle /hectare), the phosphate uptake of established pasture would likely be influenced by dung spots on over half of the grazing area at any one time. FAT NECROSIS IN BEEF CATTLE GRAZING HEAVILY FERTILIZED FESCUE PASTURES,

Animal Scientist and Supervisory Soil Scientist, U.S. Department of Agriculture, Agricultural Research Service, Watkinsville, Georgia
J. A. Stuedemann, D. J. Williams, and S. R. Wilkinson
Presented at Proceedings of the 1974 Beef Cattle Short Course "Winter Management Problems of the Cow and Calf Producer," Cooperative Extension Service, College of Agriculture, University of Georgia, January, 1974, p. 6-8. 6 ref.

Descriptors: Cattle, Fescues, Fertilization, Bermudagrass.
Identifiers: Fat necrosis, Ammonium nitrate, Grass tetany.

Heavy fertilization of fescue pastures has been accompanied by increased animal health problems such as grass tetany and fat necrosis. Fat necrosis is the occurrence of irregularly shaped, hard fat masses primarily in the fat tissue of a cow's abdominal cavity. Lesions of necrotic fat may be found adjacent or attached to digestive tract organs, around the kidneys or in the pelvic area. Visible symptoms of fat necrosis are loss of weight, coupled with listlessness, poor appetite and a rough hair coat. However, these same symptoms are typical of a severe parasite infestation or other problems resulting from poor management. Fat necrosis has not been reported as a herd problem in cattle grazing predominately bermudagrass pastures. No fat necrosis has been observed in monitored herds grazing Coastal bermudagrass over a several-year period at the Southern Piedmont Conservation Research Center, Watkinsville, Georgia. Until the exact cause of fat necrosis has been defined, there will be some uncertainty as to the exact measures required to prevent it. Research at Watkinsville and observation of many farm herds suggest that little or no fat necrosis will develop when the following measures are taken: (1) Limit broiler or poultry litter fertilization of predominately fescue pastures to 4 tons or less/acre/year (dry matter basis). Nitrogen, as commercial fertilizer, should be limited to 200 lb./acre/year. (2) Have a free-choice, complete mineral mixture available to cattle at all times. (3) Stock heavily enough to utilize the grass grown. (4) Use other grasses, particularly bermudagrass, in the grazing system. (Ott-East Central)

NUTRIENT MANAGEMENT OF CAGED POULTRY WASTE BY THERMOPHILIC AEROBIC DIGESTION,

Department of Agricultural Engineering, South Carolina Agricultural Experiment Station, Clemson University, Clemson, South Carolina
D. T. Hill, and C. L. Barth
Agricultural Engineering Research Series No. 17, Clemson University, September, 1974, 23 pg. 9 fig, 9 ref.

Descriptors: Nutrients, Aerobic treatment, Thermophilic bacteria, Nitrogen, Ammonia.
Identifiers: Refeeding, Land application.

Specific research objectives were: (1) to investigate the feasibility of controlling the form of nitrogen in aerobic biological processes, (2) to establish the degree of nitrogen loss from aerobic biological processes when operated under conditions to promote nitrate formation, and (3) to determine the feasibility of using the waste to sustain the biological growth in the thermophilic temperature range (approximately 40 degrees C). Four plexiglass reactors were utilized in the experiments. It was found that ammonium and nitrate content of the liquid portion after settling can be maintained at either high or low levels depending on the operational mode of the process. The sludge, after settling was approximately .11 percent organic nitrogen at the end of a 9 week study. The organic nitrogen was still increasing rapidly at the end of the test, making the sludge a good crude protein source for refeeding. Nitrogen loss was about 80 percent before nitrification under conditions for promotion of ammonia formation. After establishment of nitrification promoting conditions, nitrogen loss increased to about 95 percent of total loaded. It was not feasible to use poultry waste to sustain biological growth in the thermophilic range (approximately 40 degrees C), using this experimental set-up, since no self-sustained temperature rise could be established. Use of the thermophilic process to manage nutrients must be considered impossible, at least when nitrification is desired. It is impossible to conserve the heat liberated and maintain a residual DO at elevated temperatures simultaneously. (Rowe-East Central)

RESEARCHERS PROVE CATTLE MANURE PRODUCES ETHYLENE,

Anonymous
Eco Systems, Vol. 6, No. 4, p. 5, January, 1976.

Descriptors: Recycling, Feedlots, Byproducts, Ammonia, Ethane, Methane, Waste treatment.
Identifiers: Ethylene, Cattle manure.

Beef cattle manure, long a major pollution problem for the animal feedlot industry, has been found to yield significant amounts of ethylene, an important product derived from petroleum and natural gas. The discovery was made at Texas Tech University. Assuming a realistic value of ten cents per pound for ethylene, a conservative estimate of the value of the ethylene production from manure produced from a 100,000 head feedlot in the Texas high plains alone would be around $1.8 million per year. The objective of continuing research is to optimize the process to increase the yield of ethylene. Evidence to date indicates that the process appears to be economically feasible for large concentrations of feedlots. Engineers suggest that the ethylene production plants be placed at the feedlot because it is easier to ship the gas by pipeline than to transport the manure. (Rowe-East Central)

BIOLOGICAL TREATMENT OF FEEDLOT RUNOFF,

T. J. McGhee, D. S. Backer and M. V. O'Neal
Journal Water Pollution Control Federation, Vol. 48, No. 1, p. 153-162, January, 1976. 7 fig, 3 tab, 12 ref.

Descriptors: Feedlots, Agricultural runoff, Biological treatment, Water pollution, Aerobic treatment, Liquid wastes, Sedimentation, Costs, Chemical oxygen demand, Biochemical oxygen demand.
Identifiers: Fish kills.

The pollutional strength of feedlot runoff is sufficiently great to require prohibiting its discharge into surface waters. It was felt that aerobic biological treatment of the runoff might be a good means of reducing its pollution characteristics. Extensive laboratory studies of the treatability of settled feedlot runoff were carried out. Then a field installation was constructed at the University of Nebraska Field Laboratory near Mead. The waste originated on beef cattle feedlots 1.33 acres in area, passed through a shallow grit basin, and was retained in an anaerobic holding pond. Settled feedlot runoff was pumped from the holding pond by a variable capacity pump into an effluent weir. After a retention time of 3.4 hours the effluent then went into the sedimentation basin. Here the effluent was retained another 3.4 hours and then it went into the aeration basin, which operated at 1 day retention time. It was found that the system (based on 210 days operation/yr and a 2-day retention time) would treat 38,200 gal/yr. When evaporation from and rainfall on the pond surface at Mead were taken into account, this was equivalent to the average annual runoff from 0.97 acres of feedlot. With an animal density of 200 head/acre and an average residence time of 180 days, this gave a cost of $0.58/animal. Study conclusions were: (1) An aerobic biological treatment system can stabilize the readily degradable organic material in settled feedlot runoff. An effluent BOD5 of less than 30 mg/l may be attained at a 2-day liquid retention. (2) Design criteria for such a system are similar to those of high-rate activated sludge if the COD of the settled waste is considered to be equivalent to the BOD. (3) The mixed liquor suspended solids concentration in this system may be estimated with sufficient accuracy from the settled sludge volume. (Rowe-East Central)

RECYCLED DRIED POULTRY MANURE IN CHICK STARTER DIETS,

Department of Poultry Science, University of British Columbia, Vancouver, British Columbia, V6T 1W5, Canada V61
J. Biely and P. Stapleton
British Poultry Science, Vol. 17, No. 1, p. 5-12, January, 1976. 7 tab, 13 ref.

Descriptors: Recycling, Poultry, Diets, Performance, Mortality, Chemical properties.
Identifiers: Refeeding.

This research was concerned with the evaluation of dried poultry manure (DPM) as a substitute for wheat or as a feed ingredient, when incorporated in the diets of chicks up to 3 or 4 weeks of age. In order to obtain a uniform source of DPM, 300 1 day-old chicks were fed on the basal diet for 3 weeks. The chicks were reared in Jamesway electrically heated, raised wire floor, battery brooders in an air-conditioned room. The droppings were combined, dried at a temperature of 45 degrees C for several days and then ground to a fine powder which contained less than 10 percent moisture. The dried manure was incorporated at a level of 0, 5, 10, 15 and 20 percent in a chick starter diet and recycled 4 times. Results showed: (1) There was a linear decrease in body weight and efficiency of food utilization with each percentage increase in DPM. (2) The amount of dried droppings recovered as a percentage of food consumed was proportional to the amount of DPM included in the diet and remained fairly constant during the recycling. (3) Body weights and efficiency of food utilization were substantially the same during the first 3 recycling periods but declined significantly during the fourth period. (4) Mortality was negligible and all chicks appeared healthy and vigorous. (5) Chicks fed on 10 percent DPM in an isocaloric and isonitrogenous diet grew and utilized food as well as those fed on the basal diet; chicks fed on 20 percent DPM did not consume enough to meet their requirements. HOW TO AVOID COMPLAINTS FROM APPLYING MANURE,

Anonymous
Poultry Digest, Vol. 35, No. 416, p. 422, October, 1976.

Descriptors: Nitrogen.
Identifiers: Odor control, Land application.

John M. Sweeten, Animal Waste Management Specialist for Texas A&M University, stated that proper application of liquid and solid poultry manure in such a way as to minimize odors can help avoid pollution complaints. Poultry manure should be applied at such a rate that the available nitrogen (approximately 70 to 90 percent of the total nitrogen) matches the annual soil/plant nitrogen requirement. Disposal sites should be flat to gently sloping and well vegetated. Applications should be made from mid-morning to mid-afternoon. Fields for disposal should always be downwind, rather than upwind, from neighbors. Subsoil injection of liquid manure, using chisel attachments on tank wagons, gives excellent odor control. Sweeten recommended these additional practices to avoid pollution complaints: (1) maintain good general appearances and public relations, (2) good management of waste drinking water, (3) proper disposal of dead fowl, (4) properly locating the facility, and (5) obtain all pollution control permits. PRINCIPLES OF FEEDLOT RUNOFF CONTROL,

Associate Professor, Department of Agricultural Engineering, University of Nebraska, Lincoln
A. F. Butchbaker, and M. C. Paine
NebGuide G 75-214, Cooperative Extension Service, University of Nebraska, 1975, 1976, 4 p. 6 fig.

Descriptors: Feedlots, Management, Design, Agricultural runoff, Diversion, Drainage, Waste disposal.
Identifiers: Runoff control, Debris basin, Detention pond.

Good management of an open feedlot includes control of runoff. The runoff from an open feedlot carries a large amount of organic matter. This organic matter has an oxygen demand that may deplete the oxygen in public streams. Oxygen depletion may cause fish kills. The five principle factors to consider in feedlot runoff control are diversion, drainage, debris basin, detention ponds, and disposal. Diversions should be installed to prevent unpolluted water from running onto the feedlot surface. Drainage of the pens can be accomplished by maintaining the original surface shaping of the pens. A debris basin will reduce the solids reaching a holding pond. The detention pond should temporarily hold the runoff. Final disposal of the runoff can be achieved by returning it to the land or by evaporation. (Rowe-East Central)

PROCESSED POULTRY WASTE COMPARED WITH URIC ACID, SODIUM URATE, UREA AND BIURET AS NITROGEN SUPPLEMENTS FOR BEEF CATTLE FED FORAGE DIETS,

Ruminant Nutrition Laboratory, Nutrition Institute, Beltsville, Maryland 20705
R. R. Oltjen, and D. A. Dinius
Journal of Animal Science, Vol. 43, No. 1, p. 201-208, July, 1976. 3 fig, 5 tab, 19 ref.

Descriptors: Ureas, Biuret, Cattle, Feeds, Performance, Diets.
Identifiers: Poultry wastes, Uric acid, Sodium urate, Refeeding.

Poultry waste products processed to recover compounds for industrial and medicinal uses were compared with uric acid, sodium urate, urea and biuret as non-protein nitrogen sources for cattle fed forage diets. In a metabolism trial, steers fed 50 percent of their dietary nitrogen from uric acid, sodium urate or a processed poultry waste product (containing 28 percent uric acid) were found to digest dry matter, fiber, and nitrogen equally well. Steers fed poultry waste had greater urinary nitrogen losses and retained less nitrogen than those fed the sodium urate diet. Ruminal fluid pH was not different among treatments. Ruminal fluid ammonia concentration was consistently higher for steers fed poultry waste than for steers fed uric acid or sodium urate. During a 90-day growth trial, steers receiving 40 percent of their dietary nitrogen from 2 processed poultry waste products gained weight faster and more efficiently than steers fed similar dietary percentages of nitrogen from either biuret or urea. Neither the concentration of ruminal fluid volatile fatty acids nor the concentration of plasma free amino acids differed among treatments. Adaptation study results indicated that ruminal microbes could not readily degrade biuret after 14 days of diet adaptation, but after 28 days, ruminal ammonia concentrations averaged 30 percent higher with steers fed biuret than with those fed urea. Study results indicated that the processed poultry wastes tested were similar to uric acid and sodium urate but superior to urea and biuret when used as nitrogen supplements for beef cattle fed forage diets. PROPORTIONS OF AMMONIA, UREA, URATE AND TOTAL NITROGEN IN AVIAN URINE AND QUANTITATIVE METHODS FOR THEIR ANALYSIS ON A SINGLE URINE SAMPLE,

Biology Department, Virginia Polytechnic Institute and State University, Blacksburg, 24061
F. M. McNabb and R. A. McNabb
Poultry Science, Vol. 54, No. 5, p. 1498-1505, September, 1975. 30 ref.

Descriptors: Analysis, Ammonia, Ureas, Urine.
Identifiers: Samples, Urate, Total nitrogen.

The purposes of this study were: (1) to develop a dilution method that would evenly distribute all nitrogen compounds in a solvent and (2) to modify existing analytical methods for ammonia (NH_3), urea, urate (UA) and total nitrogen to permit determination of all these nitrogen compounds on aliquots of the same diluted urine sample. After this system was developed, stored samples of rooster urine collected during a study by Ward et. al. (1975) were analyzed to extend information on the proportions of nitrogeneous distribution of all nitrogen compounds (including those in the original precipitate) and performing this step in an ice bath prevented NH_3 loss from the alkaline mixture. This permitted determination of total nitrogen on an aliquot of diluted urine identical to those used for other analyses, thereby permitting determination of an unknown-N fraction not included in UA, NH_3, or urea. Accuracy and precision of these methods were very good. The proportions of urinary nitrogen found were: uric acid — 55-72 percent; ammonia — 11-21 percent; and urea — 2-11 percent. This ranking of proportions was consistent for 4 different dietary protein-water availability regimes. No significant differences in the proportions of these nitrogenous compounds due to either dietary protein intake or changes in water availability were found. (Rowe-East Central)

RESEARCH ON POULTRY WASTE IN THE UNITED STATES,

Cooperative State Research Service, U.S. Department of Agriculture, Washington, D.C. 20250
W. E. Shaklee
World's Poultry Science Journal, Vol. 20, No. 4, p. 323-344, 1973. 104 ref.

Descriptors: Research and development, Recycling, Waste treatment, Waste disposal, Odor, Dusts, Aesthetics.
Identifiers: Poultry wastes, Flies.

The effects of poultry waste on the environment have received much attention in recent years in the United States. With the development of relatively inexpensive commercial fertilizers, poultry waste is no longer needed for soil enrichment. Greater concentration of poultry and egg producing units has resulted in large amounts of waste products near large population centers with limited areas of open land available for disposal. More and more neighbors are complaining about odors, flies, dust, and unsightly manure accumulations associated with poultry producing units. As a result of such animal waste disposal problems, regional research, funded by appropriations under the Hatch Act, has been conducted in an effort to better understand and manage animal wastes. Research projects that are being conducted in the United States on the handling of poultry waste are outlined for 45 different institutions. The research has pointed to several solutions for poultry waste problems. Incorporation into the soil is still one of the most satisfactory methods of handling waste if enough land is available. Much of the research is geared toward reducing disagreeable aspects of poultry waste by minimizing odors, flies, dust and other debris. Other research is designed for processing the waste into useful products. (Rowe-East Central)

FROM RAW MANURE TO FERTILIZER IN 50 DAYS,

Associate Editor, Nebraska Farmer
N. Effertz
Nebraska Farmer, Vol. 118, No. 20, p. 9, 10, and 14, October 16, 1976. 4 fig.

Descriptors: Fertilizers, Feedlots, Costs.
Identifiers: Composting.

The Schliz-McGinley feedlot at Brule cleans its lots and hauls its manure to a composting site at one edge of the feedlot where a Sterling, Colorado company composts the manure for the feedlot. The company charges $12.50 per ton for composting the wastes, but the feedlot has found this charge worthwhile. The composting cuts the manure volume in half. The compost has a nitrogen fertilizer value 15-20 times that of raw manure on an available nitrogen basis. Application rates are much less and the concentrated form of the compost lets them cut their spreading time by about 75 percent. The compost can be stockpiled for more than a year, so there is no waiting until fields dry out for spreading before they can clean the pens. The composting technique employed by the composting company involves these steps: (1) Manure is placed in 5-foot high by 10-foot wide windrows. (2) A special bacterial culture is added to the windrows as a machine custom-designed for the compost corporation passes over the windrows, grinding and aerating the manure. (3) Bacteria multiply and the windrow material heats to about 140 degrees F., killing all disease organisms and weed seeds. (4) The bacteria continue to break down the organic matter which is machine-aerated every 3-6 days. In 6-8 weeks, the fermentation process is complete and what remains is a 25 percent-moisture, odorless, stable humus resembling coarse-ground potting soil. Whatever of the compost that the feedlot owner doesn't choose to use on his own land may be marketed. (Rowe-East Central)

METHANE PRODUCTION FROM ANIMAL WASTES. I. FUNDAMENTAL CONSIDERATIONS,

Agricultural Engineering Department, University of Manitoba, Winnipeg, Manitoba, Canada.
H. M. Lapp, A. B. Sparling, D. D. Schulte, and L. C. Buchanan
Canadian Agricultural Engineering, Vol. 17, No. 2, p. 97-102, December, 1975. 6 tab, 19 ref.

Descriptors: Methane, Biological treatment, Recycling, Anaerobic digestors, Chemical properties, Waste storage, Safety.

Anaerobic digestion, a complex biological process, is dependent upon nutrient balance in the feed material, loading rate, retention times, temperature, alkalinity and pH, volatile acid concentration, total solids, concentration, and degree of mixing for successful operation. These factors and their influences are being monitored in a pilot plant at the University of Manitoba where 4 digestors are being fed hog wastes. Digester gas contains 60-70 percent methane, 30-40 percent carbon dioxide, small amounts of hydrogen sulfide, and traces of additional gases such as ammonia, hydrogen, and oxides of nitrogen. Methane is known as a "permanent gas" because it cannot be liquified by pressure at ordinary temperatures. This property presents a unique storage problem, particularly for use in mobile power units. Procedures for handling, purification and placing the methane into storage must be established for successful production and utilization of this gas on farms. Safety precautions must be observed during the production and utilization of the gas, since methane is explosive when combined with air in ratios ranging from 5 to 15 percent. (Rowe-East Central)

VALUE OF RECYCLED MANURE QUESTIONED,

Anonymous
Western Livestock Journal, Vol. 54, No. 29, p. 11, April 12, 1976.

Descriptors: Recycling, Nutrients, Cattle, Performance, Minerals, Toxicity.
Identifiers: Refeeding, Digestibility.

Two University of California scientists have been studying recycling manure as a cattle feed. Most feedlot manure contains 12-18 percent crude protein. It is also relatively high in carbohydrates which the rumen can digest and has important minerals such as calcium and phosphorus. While the chemical analysis doesn't look too bad, the manure has been found to be essentially a poor quality roughage with high nitrogen content. Digestibility is low. It is hard to get livestock to eat the manure and about 80 percent of what they do eat becomes manure again. University of California scientist W. M. Garrett and former graduate student C. L. Ferrell conducted a study to see if concentrations of certain minerals in manure that might be harmful increased each time the manure was recycled. They concluded that continued recycling increased the calcium, copper and magnesium concentrations in the dried excreta, but that the increases were not sufficient to be harmful. In another study, University of California scientist J. L. Hull and some fellow researchers supplemented 2 groups of pregnant beef cows on dry native range with either pelleted cottonseed meal or a pelleted mixture of 75 percent feedlot manure and 25 percent barley for 84 days. A third group received no supplementation. The study revealed that manure in combination with barley may be fed as a supplement to pregnant cows as an alternative to high quality protein supplements such as cottonseed meal. Based on research as a whole, however, the scientists found the use of manure as a feed to be marginal at best. (Rowe-East Central)

MODELING SHORT-TERM MINIMUM AEROBIC PROCESSING OF SWINE MANURE,

Engineering Research Service, Research Branch, Agriculture Canada, Ottawa, Ontario, Canada.
P. A. Phillips and J. R. Ogilvie
Canadian Agricultural Engineering, Vol. 16, No. 2, p. 86-90, December, 1974. 3 fig, 2 tab, 13 ref.

Descriptors: Model studies, Waste treatment, Aeration, Chemical oxygen demand, Liquid wastes.
Identifiers: Swine manure, Dilution rates, Flow rates.

A short-term minimum aeration cintinuous culture treatment for swine manure—was designed on a laboratory scale. The model was tested at 3 levels of dilution rate and 3 levels of flow rate to determine the effects of these paratmeters on soluble chemical oxygen demand. It was found that measuring change in mixed liquor chemical oxygen demand during batch culture aeration offered a rapid measurement from which necessary oxygen requirements of swine manure could be derived. Using a fixed aeration device, no significant effect of flow rate or detention time on reduction in soluble chemical oxygen demand was observed while varying the oxygen demand of the manure on the short-term minimum aeration processing system. The calculated oxygen demands ranged from about one-half to twice the oxygenation capacity of the aerator (as determined in clean water). Detention time had an effect ($P = 0.9$) on reduction of total chemical oxygen demand. Flow rate had no effect on total chemical oxygen demand reduction. Analysis of covariance indicated that variation of influent-soluble chemical oxygen demand from about 10,000 to 18,000 mg/liter had no effect on effluent-soluble chemical oxygen demand concentration from the short-term minimum aeration processing system. Variation in influent-soluble chemical oxygen demand significantly affected reduction in total mixed liquor chemical oxygen demand. The size of the model tested may be increased 100 percent or more, but it should be emphasized that the model results may be subject to unknown effects of scale. (Rowe-East Central)

REFEEDING SEMINAR BRINGS HOPE FOR LOW-COST FEEDING,

Anonymous
Calf News, Vol. 14, No. 9, p. 46-47, September, 1976. 4 fig.

Descriptors: Litters, Performance, Physical properties, Chemical properties, Biological properties, Costs.
Identifiers: Refeeding, Poultry wastes, Ensiling, Manure.

A Waste Management and Recycling Seminar was held in July by Texas Grazon of Amarillo, Texas, to give feeders a chance to hear from experienced men on the subject of refeeding manure and poultry litter. Dr. W. B. Anthony of Auburn University said that his research has convinced him that blending animal waste with other ingredients and ensiling the combination is the best use of the product. Anthony stated that manure should be left in the silo for at least 10 days with at least 35 percent moisture. Everett Hatfield of the University of Illinois showed data which demonstrated that when waste was used as 10 percent of the ration, conversion was improved and gain was no different. No significant difference in the rate of gain or efficiency was found when Hatfield substituted poultry litter for all the minerals, all the nonprotein nitrogen and part of the roughage. Dr. Gene Masters, president of Master's Agri-Consultants, Athena, Georgia, has been successfully feeding 3,000 cattle a ration with 10 percent grain, 20 percent candy wastes, and 70 percent broiler litter. Another feeder, Sam Hay, Jr., from Covington, Georgia uses 45 percent cracked corn, 15 percent silage and 40 percent manure. This ration is put in an upright silo for 10 days. Walter Paetzold, owner-manager of Western Feedlot of Herford, Texas, uses poultry and cage droppings instead of cattle manure. Manure collecting was a problem because his lot is located on caliche hills. Paetzold purchases poultry and cage droppings for nine dollars a ton at 40-50 percent moisture. (Edwards-East Central)

THEIR LOW COST MANURE SYSTEMS ARE DOING THE JOB,

R. E. Marcoot and W. R. Bock
Hoard's Dairyman, Vol. 121, No. 18, p. 1056, September 25, 1976. 2 fig.

Descriptors: Dairy industry, Feedlots, Lagoons, Costs, Irrigation, Anaerobic conditions.

Since much of the soil in southwest Missouri is not suited to cash crops, the area is largely dairy oriented. For dairymen whose herds do not exceed 30-40 cows, handling manure has not been a problem; however, dairymen with larger herds have turned to semidrylot systems in which runoff is channeled into lagoons. To determine the volume of an anaerobic lagoon, one must figure the amount of manure and lot runoff. Amount of manure is determined by: (1) number of cows, (2) time they are in the lots, and (3) percent of manure from lots that is placed in the lagoon. Amount of lot runoff is determined by: (1) lot size, and (2) annual rainfall. In a lagoon, bacterial action breaks down the solids into small particles which can remain in suspension. This effluent can be distributed onto the land during dry periods through an irrigation system. A small irrigation system will deliver an acre inch of effluent in a little over an hour. Anaerobic lagoons with a 2 percent slope have been most economical for construction costs. The push off ramp on a lagoon is another cost item. Designed so that wastes can be deposited in at least 4 feet of water, these reinforced concrete ramps vary in costs from $400 to $1,000. Lagoons in southwest Missouri have been built with the following objectives in mind: (1) keep cows clean, (2) cut labor needs, (3) control flies, (4) save plant nutrients, and (5) control pollution for the least investment. Cows are kept cleaner because the manure can be pushed into the lagoon when field conditions are unfavorable for hauling. Labor requirements are reduced because it is faster and easier to use an irrigation system for hauling manure. Breeding areas for flies are eliminated when the manure is stored in a lagoon. (Edwards-East Central)

RIVER POLLUTION BY FEEDLOT RUNOFF,

Kansas State Teachers College, Emporia
C. W. Prophet
Conservation Proceedings of the Oklahoma Academy of Science for 1967, Vol. 48, p. 207-209. 1 ref.

Descriptors: Water pollution, Agricultural runoff, Feedlots, Kansas, Ammonia, Coliforms, Dissolved oxygen.
Identifers: Cottonwood River, Fish kills.

The purpose of this study was to draw attention to the problem of feedlot runoff and to report on a preliminary study concerning its effect on the Cottonwood River in the vicinity of Emporia, Kansas. If relatively large numbers of cattle are concentrated into a river or stream, large quantities of organics may be introduced. The amount of contamination will vary depending upon the number of cattle present, the amount of accumulated wastes, and the precipitation. To date, the most evident result of the introduction of feedlot runoff into the Cottonwood River has been fish kills. Adverse river conditions created by the feedlot runoff include decreased dissolved oxygen, increased ammonia, and increased fecal coliform bacteria. During the absence of runoff, dissolved oxygen at all points in the study tended to exceed 4 ppm, ammonia was generally less than one ppm, and fecal coliform bacteria rarely exceeded 1000 cells per 100 ml. Following runoff, ammonia was frequently greater than 10 ppm and dissolved oxygen was decreased. The fecal coliform counts rose whenever there was runoff. (Rowe-East Central)

STORAGE A PROBLEM FOR "BIO-GAS" USE,

Anonymous
Nebraska Farmer, Vol. 118, No. 10, p. 23, May 15, 1976.

Descriptors: Recycling, Methane, Fuels, Waste storage, Economics.
Identifiers: Anaerobic digester.

Methane or "bio gas" may be produced in an anaerobic digester when manure in the digester is broken down by bacteria. Ralph W. Hansen, Colorado State University Extension Agricultural Engineer, says that manure from 50 cows would produce enough methane gas each day to heat a well-insulated three bedroom home during the winter. Since this gas cannot be liquified under normal temperatures, it is best suited for stationary uses such as cooking and heating. Because of the high compression needed to get enough bio gas on a tractor to run it, a serious safety hazard would be created if it were used in this manner. Bio gas has a heat value of 500-600 Btus per cubic foot as compared with natural gas, which has a heat value of 1,000 Btus per cubic foot, and gasoline, which has a heat value of 124,000 Btus per gallon. Hanson said that out of the several types of energy capturing processes available, the production of bio gas appears to be the most feasible for most agricultural operations. He lists the main disadvantages as: (1) amount of management required due to the sensitivity of the digesters, (2) high initial investment for equipment, and (3) wastes still must be disposed of after digestion. Attempts are being made to find new strains of bacteria and culturing techniques for producing this gas, and also to find designs which will reduce the costs and make it more practical. (Edwards-East Central)

STILL TIME TO BUILD FEEDLOT MOUNDS,

Anonymous
Wallaces Farmer, Vol. 101, No. 20, p. 4, October 25, 1976.

Descriptors: Feedlots, Cattle, Design, Management.
Identifiers: Mounds.

Tips are given for planning and constructing a feedlot mound that will keep cattle out of mud during the winter. The tips are: (1) Locate mound close to feedbunk slab so cattle can get from mound to the bunk without crossing a mudhole. (2) Build mound parallel with general lot drainage. (3) Mounds should be 5-8 feet high. (4) Slope the mound as steeply as possible while still allowing cattle to rest comfortably. (5) Crown the mound for good drainage. If the top is left flat, pockets develop where water will stand. Keeping the top fairly narrow helps too. (6) To stabilize the mound, use good firm soil, preferably clay. (7) Covering the mound with bedding helps protect the mound surface and insulates the animal's body from the frozen ground. (Merryman-East Central)

HEAVY MANURING HURTS YIELDS ON DRY SOIL,

Anonymous
Wallaces Farmer, Vol. 101, No. 20, p. 4, October 25, 1976.

Descriptors: Salts, Rainfall, South Dakota, Crop response, Soil sealants, Infiltration.
Identifiers: Land application, Feedlot wastes, Application rates.

Caution should be used in applying excessive animal wastes to soils when there is a lack of sufficient rainfall. South Dakota research found that application of beef feedlot wastes in excess of 20 tons of dry matter/acre in each of 2 consecutive years resulted in large increases of salts within the soil profile. Less than normal rainfall resulted in little or no leaching water, thus increasing salts in the soil and decreasing crop yields. Following those 2 consecutive years, soils receiving greater than 40 tons of waste/acre/year showed a substantial reduction in the ability to infiltrate water. Elimination of the waste treatment for 1 season resulted in increased water infiltration and reduced salinity due to rainfall and weather conditions. Sealing of soil resulting in reduced water infiltration appears to be temporary and can be expected to improve with decay of the applied wastes. (Merryman-East Central)

LEACHED MANURE - A PROMISING SOIL ANTI-CRUSTANT,

Farm Advisor, Monterey County, California.
D. Ririe
California Agriculture, Vol. 30, No. 9, p. 16-17, September, 1976. 4 tab.

Descriptors: Soil amendments, Crop response, Cattle, Leaching, Irrigation, Waste treatment.
Identifiers: Anti-crustant, Land application, Steer manure.

The problem of soil crusting in California has been dealt with by using the following materials: (a) petroleum mulch, (b) stabilized vermiculite, and (c) phosphoric acid; but due to cost, application difficulties, and other reasons, these materials are not always acceptable. Steer manure is being tested as a soil anti-crustant, and when it is leached, it has been found to enhance lettuce seedling emergence under soil crusting conditions. Tests in 1962, where 3- and 10-ton-per-acre applications of chicken manure was tested as a soil anti-crustant, showed no evidence that chicken manure prevented crust formation. In 1964, a test was made in which steer manure was mixed with soil and used to cover lettuce seeds, but no benefit was derived from this method. In 1973, steer manure was leached with water, pulverized, and used to cover lettuce seeds. In this test, it was found that covering the seeds with leached manure greatly improved lettuce emergence. However, this material was still slightly inferior to stabilized vermiculite in all of the evaluation factors except seedling weight. The tests also showed that steer manure used as a seed covering gives results which vary, depending on the amount and frequence of irrigation. Further experiments which appear to be justified include: (1) field-test leached manure, (2) ascertain the amount of leaching necessary, (3) define the irrigation regime necessary for best results, and (4) find a satisfactory mechanical means of applying the material. TEXAS TECH SCIENTIST CITES RATIONS' EFFECT ON WASTE ACCUMULATION,

Anonymous
Feedstuffs, Vol. 43, p. 4, September 25, 1971.

Descriptors: Rations, Cattle, Feedlots, Management, Performance.
Identifiers: Waste accumulation, Roughage.

At the annual meeting of the ASAE in Davis, California, Dr. Robert C. Albin, animal science professor at Texas Tech University in Lubbock, Texas, stated that different rations of feeder steers can affect waste accumulation, without greatly affecting animal performance. Cattle that were fed a zero-percent roughage ration had a waste accumulation of only 2.2 lb daily as compared to cattle fed a 10 percent and 12 percent roughage whose daily wastes ammounted to 4.5 lb. and 5 lb., respectively. Albin said that it isn't practical to feed a zero percent roughage ration for the sole purpose of getting a large waste reduction, but that it is important to realize the practicality of lowering the amount of roughage a small degree to achieve a lower amount of waste accumulation. Rations used in the trials consisted primarily of dry rolled grain sorghum formulated into all concentrate (or no roughage) and the 10 percent and 12 percent roughage finishing rations. Circumstances where no significant differences were found included: (1) different slopes, 7½ percent and 15 percent, which were both concrete surfaces, and (2) shaded and unshaded pens. Differences did occur where there was a variance in animal density. When the amount of sq. ft. per head was changed from 120 sq. ft. to 30 sq. ft., the following reactions developed: (1) lower daily gains, (2) less feed consumption, and (3) reduced efficiency of food utilization. (Edwards-East Central)

WASTE TREATMENT RULES WON'T PUT "IMPOSSIBLE" BURDENS ON PRODUCERS,

Feedstuffs, Washington editor
J. McClung
Feedstuffs, Vol. 48, No. 31, p. 2, August 2, 1976.

Descriptors: Waste treatment, Feedlots, Agricultural runoff, Legal aspects.
Identifiers: 1972 Federal Water Pollution Control Act, Point sources, Nonpoint sources.

Section 208 of the 1972 Federal Water Pollution Control Act requires beef and other livestock producers to use the best possible management procedures but, according to a panel of EPA and USDA specialists, it will not put an impossible burden on these producers. Section 208 is a program which will attempt to get cooperation among local governments in a particular area to find ways where common water problems, too severe or complex for technology solving alone, can be solved. Pollution factors in a given point may include (1) point and nonpoint sources, (2) industrial-municipal pollutants, and (3) agricultural runoff. In addition to agricultural runoff, this plan will speak to forestry, mining, and construction activities and the intrusion of salt water into groundwater supplies do to the reductions in the flow of fresh water from any cause. The 1972 act works in the following way. Governors of states decide which areas in their state need 208 planning. Then designated areas have an agency created with members which include elected officials from the local governments concerned. These men then plan for waste water treatment. Their goal is to have all the treatment works necessary to maintain acceptable water quality over a 20-year period. Once approved by the EPA, federal funds are available to the planners. To minimize water pollution problems with as little federal involvement as possible is the intent of the 208 program. Because of the few options available to ranchers on waste control, cow-calf operations should not be affected. (Edwards-East Central)

USE OF SOIL SYSTEM FOR RENOVATION OF EFFLUENT FROM MINIMAL TREATMENT OF SWINE MANURE,

Department of Agricultural Engineering, Macdonald Campus of McGill University, Ste. Anne de Bellevue, Quebec, Canada
A. M. Shady, and J. R. Oglivie
Canadian Agricultural Engineering, Vol. 18, No. 1, p. 10-13, June, 1976. 6 fig, 4 tab, 10 ref.

Descriptors: Effluents, Nitrogen, Aeration, Leaching, Denitrification.
Identifiers: Land application, Swine manure, Odor removal, Soil systems.

Evaluation of the efficiency of the soil systems on nitrogen and odor removal from effluents and minimally treated swine manure were investigated. Soil columns of 60-cm length and 15-cm diameter were used under controlled temperature and humidity. A total of 2.5 cm of liquid effluent containing an equivalent of 610 kg/ha of nitrogen was added in one, two and four applications. A wet schedule was followed during the experiment. Results showed that the application of 600 kg/ha of total nitrogen resulted in nitrate levels of less than 2 mg/liter from soil columns. While the liquid from the minimum-aeration process contained a high level of ammonia, the general offensiveness as rated by an odor panel was low. Although free drainage was provided from the soil columns, a moist layer was formed, and both the dissolved oxygen and redox potential were low at a depth of 50 cm. The yield of nitrate-nitrogen from the columns was very low. Evidently, denitrification was active. Spreading the manure in multiple applications, rather than a single application, further reduced the possibility of nitrate leaching. Odor offensiveness was found to be related to the volume of application. (Rowe-East Central)

WASHINGTON COUNTY STUDY... HOW HOG WASTES VARY IN THEIR FERTILIZER VALUE,

J. Carlson
Wallaces Farmer, Vol. 101, No. 6, p. 49, March 27, 1976. 1 fig.

Descriptors: Fertilizers, Nutrients, Economics, Waste storage.
Identifiers: Swine wastes, Land application.

Jim Frier, Washington county extension director, discusses the fertilizer value of hog wastes. Fertilizer value of hog manure can be influenced by these factors: type of housing facility, dilution of manure from waterers or rainfall, ration fed, amount of feed wasted, depth of manure pit, and length of manure storage. Separate test samples were taken from 18 manure pits from vacuum tank wagons immediately after loading. The pits had been agitated by recirculating a load back into them before samples were drawn. Hoses were placed on the bottom of the pits. The types of facilities represented were farrowing, nursery, finishing (pits over half full), and finishing (pits less than half full). Average nitrogen, P_2O_5, and K_2O for each of the types of facilities in their respective order were: nitrogen — 28.8, 34.5, 56.4, 61.8; P_2O_5 — 9.4, 10.4, 20.3, 30.5; K_2O — 11.6, 11.0, 23.7, 29.0. Value of wastes from the farrowing pits was $7.08 100 gal. Nursery pit wastes worth $7.95/gal. Finishing pits over half full had a waste value per 100 gal of $13.60. Wastes from a finishing pit less than half full were worth $16.50 per 100 gal. Much of the fertilizer nutrients in wastes are available to plants the first year. Organic nitrogen, however, yields only 50 percent as available the first year. The rest carries over. Frier cautions that every manure pit is different and sampling is the only way to know what and how much nutrients are available. (Rowe-East Central)

MODELING THE OPTIMAL LOCATION OF THE CATTLE FEEDING INDUSTRY,

West Virginia College of Graduate Studies
D. L. Byrkett, R. A. Miller and E. P. Taiganides
American Journal of Agricultural Economics, p. 236-244, May, 1976, 192 fig, 5 tab, 13 ref.

Descriptors: Model studies, Feedlots, Cattle, Locating, Linear programming.

A variety of interregional linear programming models have been used to study the optimal location of the cattle feeding industry. An analysis was performed to determine which factors are most influential in determining feedlot location and thus need to be included in these models. In addition to traditional factors, consideration was given to the effects of region definition and regional land use patterns. A new cost minimization linear programming model was developed on this basis. The following results were obtained: (1) Feeder availability and grain availability is not a primary concern in the location of cattle feeding. (2) Roughage availability is not a primary concern in the location of cattle feedlots. (3) Slaughter capacity will influence the location of cattle feeding in the short run, but in the long run slaughter facilities will move to the feedlots. (4) In modeling the location of cattle feeding, it is important to use a greater number of resource regions than cattle feeding regions, (5) Land use patterns that reflect both the competition for land resources and the conflict resulting from efforts to eliminate problems associated with odors, solid waste disposal, and water pollution in areas of high population density is an important factor influencing the location of cattle feeding. MODELING FEEDLOT RUNOFF POLLUTION. II. QUASILINEARIZATION,

Graduate research assistant, Chemical Engineering Department, Kansas State University, Manhattan
S. F. Kang, L. T. Fan, E. W. Lee, and L. E. Erickson
Transactions of the ASAE, Vol. 13, No. 6, p. 864-869, November-December, 1970. 2 fig, 2 tab, 18 ref.

Descriptors: Equations, Model studies, Feedlots, Agricultural runoff.
Identifiers: Quasilinearization.

Estimation of the parameters of a nonlinear model for the feedlot runoff system may be done by the quasilinearization technique. In this work, the parameter estimation problem is treated as a multipoint boundary-value problem in which the resulting set of differential equations of the boundary-value is solved by the quasilinearization technique. The advantages of the quasilinearization technique is that, if the process converges, it converges quadratically. This technique has been proven useful not only in parameter estimation, but also in solving nonlinear boundary value problems in partial and ordinary differential equations. However, the quasilinearization technique also had disadvantages. Two of the most important ones are the ill conditioned problem and convergence problem. (Merryman-East Central)

RHEOLOGICAL PROPERTIES OF AERATED POULTRY WASTE SLURRIES,

Agricultural Engineer, Agricultural Engineering Department, Cornell University, Ithaca, New York
Y. R. Chen and A. G. Hashimoto
Transactions of the ASAE, Vol. 19, No. 1, p. 128-133, January-February, 1976. 6 fig, 2 tab, 15 ref.

Descriptors: Slurries, Aeration, Rheology, Equations, Temperature.
Identifiers: Pipeline transport, Shear rate, Shear stress, Volume fraction index.

This study was undertaken to find a master equation for describing the rheological properties of aerated poultry waste slurries under laboratory and field scale treatments. The study revealed aerated poultry waste slurries to be pseudoplastic and a master equation involving shear stress, shear rate, and volume fraction index was developed. For the temperature ans and shear rate range studied, the effect of temperature on the apparent viscosity of aerated poultry waste slurries was negligible. Thus, for the temperature range experienced in the field (10-25 degrees C), temperature effects may be disregarded when estimating apparent viscosities for design purposes. Because data from rotational and capillary tube viscometers were comparable, the results obtained from rotational viscometer studies can be used for designing pipeline transport systems. Further research is needed to correlate the Fanning friction coefficient with the generalized Reynolds number for pipeline transport of livestock slurries under field conditions. SMELL LIKE MONEY...OR PIG MANURE,

Successful Farming, Vol. 74, No. 12, p. 50, November, 1976.

Descriptors: Odor, Management, Waste treatment, Biological treatment, Chemical treatment.
Identifiers: Swine, Odor control.

Probably the most important step in keeping odors within tolerable limits is to select a site for livestock facilities where odors will be less of a problem. Prevailing wind patterns should be checked. Management practices which may be utilized to combat odor problems include: dilution, ventilation, aeration, covering, burning, absorption, adsorption, masking, and filtration. Chemical treatment of wastes can also reduce odors. Hydrated lime reduces production of hydrogen sulfide and carbon dioxide, but increases ammonia liberation and therefore decreases fertilizer value. Chlorine stops bacterial action, reducing odors, but it also stops breakdown of wastes. Both treatments require relatively large amounts of chemicals. (Merryman-East Central)

TURKEY LITTER SILAGE IN RATIONS FOR DAIRY HEIFERS,

Department of Poultry Science, Clemson University, Clemson, South Carolina
D. L. Cross and B. F. Jenny
Journal of Dairy Science, Vol. 59, No. 5, p. 919-923, May, 1976. 1 fig, 3 tab, 20 ref.

Descriptors: Litters, Feeds, Performance, Rations.
Identifiers: Dairy heifers, Turkey litter silage.

Turkey litter silage was evaluated as a replacement for corn silage in diets for replacement heifers. Twenty-four Holstein heifers from 8 to 12 months of age and averaging 215 kg were assigned randomly by weight to one of 4 groups. All rations contained (dry matter basis) 10 percent of a concentrate supplement plus (1) 90 percent corn silage, (2) 15 percent turkey litter silage and 75 percent corn silage, (3) 30 percent turkey litter silage and 60 percent corn silage, or (4) 45 percent turkey litter silage and 45 percent corn silage, and were formulated to be isonitrogenous. Average daily gains for heifers on 15 percent turkey litter silage were higher than for controls. Urea nitrogen of plasma was higher for animals on 30 percent than 45 percent turkey litter silage. Ruminal ammonia was higher for heifers receiving 30 percent turkey litter silage than for those receiving 15 percent or 45 percent turkey litter silage. Calcium of plasma was highest for the control ration, while plasma phosphorus was highest for the 30 percent and 45 percent turkey litter silage. Ruminal propionate was lower and butyrate higher for the control ration. Turkey litter was found to have potential as a feed ingredient in rations for young dairy animals. However, further research in this area should evaluate the true potential of this feed source to the dairy industry. (Rowe-East Central)

SLUDGE ACCUMULATION AND STRATIFICATION IN ANAEROBIC DAIRY WASTE LAGOONS,

Assistant Professor, Agricultural Engineering Department, Institute of Food and Agricultural Sciences, University of Florida, Gainesville
R. A. Nordstedt and L. B. Baldwin
Transactions of the ASAE, Vol. 18, No. 2, p. 312-315, March-April, 1975. 2 fig, 6 tab, 7 ref.

Descriptors: Sludge, Dairy industry, Lagoons, Anaerobic conditions.

A lagoon system on a commercial dairy near Bradenton, Florida, was studied in order to: (1) determine the rate of sludge accumulation, and (2) determine the physical characteristics and stratification of the sludge as they related to sludge removal from the lagoon. The anaerobic lagoon received waste from the holding, cow washing, and milking parlor areas. Sludge accumulated in the lagoon at a rate of 14.9 and 16.9 percent of lagoon volume per year. Three zones of biological activity developed. In the first zone, extending from the point of inflow a distance of about 70 meters, the sludge resembled raw manure in appearance. Sludge depth was less than in the other 2 zones, and gas evolution was extensive. The second zone, extending about 70-130 meters from the inlet, contained stratified sludge with lifting occurring from the dense bottom layer. The third zone contained sludge which was darker in color and had a smaller particle size. There was slightly less gas evolution. Vertically, the top layer was supernatant through which masses of sludge were lifted by evolved gas. As the masses of sludge dissipated and settled out of the supernatant, a light sludge layer formed beneath the supernatant. The lower layer was dense, viscous, dark in color, and contained very small particles. The light sludge layer probably contained the most active digestion, and its volume seemed to depend upon the organic loading rate. As this layer was pushed nearer the water surface due to dense sludge accumulation on the bottom, the supernatant volume was reduced and the detention time decreased. When the light sludge level reached the outflow structure, sludge was discharged in the effluent and sludge removal became necessary. (Rowe-East Central)

SETTLING CHARACTERISTICS OF SWINE MANURE,

Sanitary Engineer, Natural Resources and Environmental Protection Department, Division of Water, State of Kentucky, Frankfort
S. C. Jett, H. E. Hamilton, and I. J. Ross
Transactions of the ASAE, Vol. 18, No. 6, p. 1128-1129, 1135, November-December, 1975. 3 fig, 2 ref.

Descriptors: Settling basins, Design, Physical properties, Separation techniques, Liquid wastes, Sludge.
Identifiers: Swine manure, Solids.

The development of data for the design of settling basins for fresh swine feces and urine was studied. A settling column was used to obtain data for the development of settling curves. Sedimentation characteristics were determined for swine waste with solids concentrations of 0.5, 1, 2 and 3 percent. The data for solids removal as a function of time indicated that a solids concentration of 1 percent would give the highest solids removal efficiencies in a settling basin with no sludge removal. As solids built up in the 2 percent and 3 percent solids concentration studies, they hindered the settling of the particles remaining in suspension. This was caused by the displacement of the water by the settling particles which decreased the removal efficiency of solids at the 4.5 ft. level and below. The 0.5 percent solids concentration study indicated removal efficiencies lower than those achieved in the 1 percent and 2 percent studies after 14 minutes. Overflow rates of 2,000 to 15,000 gal/day-sq. ft. gave estimates of solids removals of about 70 to 45 percent respectively depending on solids concentration in a 6-ft deep settling basin. A mechanical removal device would improve the efficiency of a settling basin and reduce the depth required for storage of solids. The sludge removed should be in the order of 70 to 75 percent of the total solids. (Rowe-East Central)

EFFECTS OF SHORT-CHAIN FATTY ACIDS EXTRACTED FROM BEEF CATTLE MANURE ON GERMINATION AND SEEDLING DEVELOPMENT,

Agricultural Research Service, High Plains Grasslands Research Station, Cheyenne, Wyoming 82001
G. E. Schuman and T. M. McCalla
Applied and Environmental Microbiology, Vol. 31, No. 5, p. 655-660, May, 1976. 4 fig, 6 tab, 11 ref.

Descriptors: Crop response, Bioassay, Sorghum, Germination.
Identifiers: Short-chain fatty acids, Composted manure, Fresh manure, Corn, Seedling development.

Germination and seedling development of sorghum and wheat were examined in relation to the short-chain fatty acids extracted from beef manure. Composted and fresh beef manure samples were extracted with distilled water, methanol, acetone, 2 N sodium hydroxide, 2 N hydrochloric acid, and ether. The extracts were bioassayed with wheat and sorghum seeds. Bioassays of the composted manure extracts generally showed limited phytotoxic effects on germination and seedling development. All the extracts of fresh manure, except distilled water, retarded germination. While acetic, butyric, propionic, valeric and isovaleric acids were found in ether extracts of fresh manure at average concentrations of 348, 876, 578, 34, and 19 $\mu g/g$, respectively, on a dry-basis, only trace amounts of these acids were found in composted manure. Presence of these acids in manure could reduce seed germination and seedling growth if high levels of fresh manure were applied to the soil. Composting the manure on the feedlot would reduce the fatty acids to insignificant levels, making the manure more beneficial to crops. (Rowe-East Central)

POLLUTED GROUNDWATER: A REVIEW OF THE SIGNIFICANT LITERATURE,

Department of Civil Engineering, University of California, Berkely
D. K. Todd and D. E. O. McNulty
Polluted Groundwater: A Review of the Significant Literature, Water Information Center, Inc., Huntington, New York, 1975, 179 p.

Descriptors: Bibliographies, Farm wastes, Animal wastes, Pesticides, Herbicides, Pollutants, Health, Monitoring.
Identifiers: Groundwater pollution, Literature review, Urban pollution, Industrial pollution, Agricultural pollution, Irrigation return flows, Disposal wells, Injection wells, Recharge wells.

This literature review is concerned with groundwater pollution resulting from man's activities. Literature included was selected on the basis of its significance and relevance from a variety of bibliographies, general references, and abstracts. Excluded from consideration were all unpublished materials, administrative regulations at all government levels, and legal reports. The study was limited to literature of the United States, with the exception of a few Canadian reports and a recent book on the European groundwater pollution situation. Items of historical interest were excluded because they have limited bearing on the current and future pollution situation; only a few references predate 1950. Selections from research reports were restricted to those directly concerning changes in groundwater quality. Chapters II and III contain annotated listings of bibliographies and important general references. Thereafter the literature is reviewed in essay form on a subject basis, including: urban pollution, industrial pollution, agricultural pollution, pollution from wells, salt water and surface water, pollutants and effects, and evaluating pollution. LIQUID MANURE, POSSIBILITIES OF DECOMPOSITION BY MEANS OF AEROBIC WASTE WATER CLEANSING METHODS,

H. Liebmann and K. Scherb
Wasser-und Abwasser-Forschung, Number 1, p. 8-11, January, 1971. 5 tab, 6 ref.

Descriptors: Liquid wastes, Aerobic treatment, Activated sludge, Ammonia, Drying, Nitrification, Waste water treatment.
Identifiers: Detention time, Toxicity.

Aerobic biological treatment of liquid manure can be accomplished by special activated sludge plants. For this treatment, manure has to be diluted in a 1 to 1 ratio with water. The plant should be operated with sludge loadings below 50 BOD per kg MLSS per day and detention times of more than 20 to 30 days. Liquid manure has a high percentage of ammonium hydroxide which has to be oxidized, since it is toxic to fish. Tests show that ammonium can be nearly completely nitrified, if the oxygen content and the reaction time in the activated sludge plants is sufficient. However, biological treatment demands areas in which the excess sludge can be deposited. Excess sludge has a very good drying property. After 1 to 2 days, it is reduced to half the volume without developing odors. After a short drying time, the water content was 91 to 93 percent, and after 3 months, only 87 to 88 percent. (Text in German) (Solid Waste Information Retrieval System)

FROM AGRICULTURAL WASTES TO FEED OR FUEL,

Chemical Engineering News, Vol. 50, No. 22, p. 14-15, May 29, 1972. 1 fig.

Descriptors: Recycling, Feeds, Fuels, Farm wastes, Hydrogenation.
Identifiers: Bureau of Mines, Pyrolysis, Refeeding.

Studies were conducted by the Bureau of Mines to determine the use of agricultural wastes for feed or fuel. Two processes were explored for converting such waste to fuel. One was a pyrolysis method, in which the feed was heated in a closed system at atmospheric pressure without the addition of air or other gas. In the second method, hydrogenation, the feed was heated under pressure in the presence of carbon monoxide, steam, and a catalyst, also in a closed system. Hydrogenation offers the most commercial promise. The reason is that it yields a single produce (oil), which would be simpler and more economical to produce, store, and market than would the 3 products formed by pyrolysis. An alternative use for bovine manure is as a raw material for making cattle feed. Bovine manure may be anaerobically fermented to convert it to a more usable form. The method not only produces an animal feed but also a fuel gas (methane), which can be burned to supply the heat and indirectly the electrical power needed for the process. The single most important question yet to be answered is the actual nutritional value of the feed ingredient when fed to ruminants. (Rowe-East Central)

THE ANAEROBIC DIGESTION OF LIVESTOCK WASTES TO PRODUCE METHANE: 1946-June 1975; A BIBLIOGRAPHY WITH ABSTRACTS,

Center for Studies of Physical Environment, Institute of Technology, University of Minnesota, St. Paul 55108
G. Shadduck and J. A. Moore
The Anaerobic Digestion of Livestock Wastes to Produce Methane, 1946-June 1975; A Bibliography with Abstracts, University of Minnesota, December, 1975, 103 p.

Descriptors: Bibliographies, Anaerobic digestion, Methane, Farm wastes, Fertilizers, Effluents.

This bibliography of 416 entries and abstracts covers materials published from 1946 to June, 1975, concerning anaerobic digestion of livestock wastes to produce methane. Sources from which the entries were first identified include: Bibliography of Agriculture, Bibliography of Agriculture computer search, Chemical Abstracts, Water Pollution Abstracts, Commonwealth Bureau of Soils annotated bibliography no. 874; Manure Gas. London Science Museum Science Library bibliographical series no. 794; Some Post-War References to "Bio-Gas", Dokumentation Lantechnik, Braunschweig-Volkenrode, bibliography; Biogas, Commission Internationale des Industries Agricules bibliography 2650; Bibliographie Sur La Production Du Gas De Methane Par Fermentation Du Fumier Et Des Residus Agricoles, En Vue De Son Utilisation A La Ferme. In addition to these, there were other articles which the authors identified and abstracted themselves. Recent popular articles were generally excluded. Four appendices give the following information: (1) Bibliographic entries for publications concerning anaerobic digestion of farm-generated cellulosic materials. (2) Bibliographic entries for publications concerning fertilizing qualities of digester effluent, (3) Search methodology and limitations, and (4) A tabular summary of recent literature pertaining to continuous fed digesters. (Merryman-East Central)

ANIMAL WASTE - A PROBLEM OR AN OPPORTUNITY,

United States Environmental Protection Agency, Robert S. Kerr Environmental Research Laboratory, Ada, Oklahoma 74820
W. C. Galegar and L. R. Shuyler
Water — 1972, AIChE Symposium Series, New York, American Institute of Chemical Engineers, 1973, p. 167-171. 12 ref.

Descriptors: Farm wastes, Agricultural runoff, Feedlots, Economics, Recycling, By-product recovery, Pathogenic bacteria.
Identifiers: Environmental Protection Agency, Research, Land disposal, Fish kills.

During the last 15 years, modernizing animal productions has resulted in the concentration of large feeding operations. This concentration of animals has eliminated the natural capacity of the environment to assimilate waste at the point of excretion. There are three major problem areas in animal waste management: (1) beef cattle feedlot waste, (2) dairy waste, and (3) swine waste. In the mid 1960's, over 80 percent of the fish kills and a number of disease transmissions were caused by rainfall runoff from concentrated feeding operations. Some purification methods for rainfall runoff are treatment, reuse, and land disposal. EPA emphasized the land disposal method. Because of the economy of commercial fertilizers, land disposal methods have been neglected. Properly applied waste can provide an economic return and waste must be disposed of in some manner. In many locations sufficient land for waste disposal is becoming scarce. So, EPA has been researching methods of gas production from animal waste and refeeding of animal waste back to animals. The type of feed rations and collection methods used may be dictated by type of by-product recovered. (Cannon-East Central)

BIOGENIC SEDIMENTATION AND ALTERATION OF ARGILLACEOUS SEDIMENTS IN SHALLOW MARINE ENVIRONMENTS,

H. N. Fisk Laboratory of Sedimentology, University of Cincinnati, Cincinnati, Ohio 45221
W. A. Pryor
Geological Society of America Bulletin, Vol. 86, No. 9, p. 1244-1254, September, 1975. 12 fig, 3 tab, 44 ref.

Descriptors: Marine animals, Sedimentation, Digestion.
Identifiers: Callinassa major Say, Onaphis microcephala Hartman, Fecal pellets, Argillaceous sediments.

The feeding activities and excretory products of the marine decapod Callinassa major Say and the marine anaelid Onuphis microcephala Hartman were studied in shallow marine environments of the southern Atlantic and eastern Gulf of Mexico coasts of the U.S. These filter-eating organisms produce significant quantities of argillaceous fecal pellets which are transported and deposited as granular clay with hydraulically equivalent quartz and grains. At average population densities observed in shallow marine environments, these organisms are able to remove and pelletize approximately 12 metric tons of suspended materials per square kilometer per year. The digestive processes of these organisms wholly or partly destroy chlorite, partly destroy mixed-layer clay minerals, and disorder kaolinite and illite. The fecal pellets rich in organic matter, result in the development of biogenic muds of relatively concentrated high organic content. These organic-rich fecal pellets may serve as progenitors of glauconite pellets, furnishing sites for the microreducing environments necessary for the glauconitization processes. Whereas flocculation is the important process in the deposition of argillaceous sediments in deltaic environments, biogenic pelletization may be the most important process in depositing argillaceous sediments in shallow marine interdeltaic environments. DAIRY MANURE MANAGEMENT FOR POLLUTION CONTROL,

Delta Engineering, Inc., Sumner, Washington
W. Dalrymple
Dairy Science Handbook 5, p. 142-143, 1972.

Descriptors: Daily industry, Air pollution, Water pollution, Anaerobic lagoons, Waste storage, Irrigation, Crop response, Nitrogen, Phosphorus, Biochemical oxygen demand.
Identifiers: Field application.

Animal wastes are a significant problem in air and water pollution. Many attempts have been made with different systems to meet requirements that are presently established by regulatory agencies. Often these develop as a result of the one-step-at-a-time approach imposed without warning by regulatory agencies. Because of the expense and general poor treatment of the resulting management practice an extensive research project was undertaken in More, Washington, to demonstrate the practicality of seasonal application to fields, together with storage. Criteria which must be taken into consideration are climate, land values, soil conditions, etc. A roof was built over the area where the cows were kept to reduce rainfall addition to wastes. All the wastes (about 20 gal/animal—10 excrement and 10 for flushing) was pumped into anaerobic lagoons which provided 8 months storage. The lagoons quickly developed surface crust which eliminated odors and flies. Little treatment occurred because the waste was stored during the winter. Effluent from the lagoons was approximately 3000 ppm BOD, total nitrogen about 1,000 ppm, and total phosphorus about 110 ppm. This was applied to the fields at 40,000 gal/acre 4 times per growing season. A 150,000 gal/acre rate proved to be in excess and killed all the clover in the green chop. Tests conducted on phosphorus, nitrogen, and bacterial movement through the soil revealed that bacteria (coliform) moved less than a few inches and a buildup of movement of nitrogen and phosphorus was not detected past the root zone of the grass. When the spraying occurred during the wet season, nitrogen moved readily through the soil. Green chop was cut and fed to the cattle with no ill effects or rejection. Compared to any other scheme, manure management by this method seems to be the best solution available. (Ott-East Central)

THE DISPOSAL OF COW SLURRY ON ARABLE LAND. PART I. APPLICATION AND INITIAL EFFECTS,

Trawscoed E.H.F.
H. T. H. Cromack and D. O'Connell
Experimental Husbandry, Vol. 28, p. 69-80, 1975.

Descriptors: Potatoes, Slurries, Dairy industry, Waste disposal, Crop response, Nutrients.
Identifiers: Land disposal, Application rates.

An experiment was started at Bridget's Experimental Husbandry Farm in 1969 to investigate the effect of applying large quantities of cow slurry to arable land. The experiment was carried out on four sites in four successive years 1969-72. On all sites the soil was Andover series, a well/structured calcareous silty loam with upper chalk at 30-46 cm below the surface with an organic carbon content of 1.9 percent. Drainage was natural and very good. The slurry contained feces and urine from dairy cattle. It also contained a small quantity of sawdust which had spilled from the housed dairy cubicle beds. Slurry disposal is described in terms of cow-equivalents. A cow-equivalent is the quantity of slurry produced by one cow housed for 364 days. It was found that the application of more than 8 cow-equivalents caused serious runoff problems and made it difficult to plant potatoes in the spring. Cultivating the soil and applying slurry in smaller but more frequent applications reduced but did not eliminate surface runoff. Large quantities of nutrients were applied with the slurry; these raised the soil nutrient status in proportion to the quantity of slurry applied. Slurry application increased the yield of potatoes compared with an inorganically fertilized treatment. Potato yields were little affected by the quantity of slurry applied. (Cameron-East Central)

EFFECT OF FARM YARD MANURE ON THE AVAILABILITY OF CA FROM $CA^{45}CO_3$ IN A SODIC SOIL (ESP 77.7),

Department of Soils, Haryana Agricultural University, Hissar, India
S. R. Poonia and D. R. Bhumbla
Plant and Soil, Vol. 38, No. 3, p. 679-682, 1973. 4 tab, 8 ref.

Descriptors: Calcium, Calcium carbonate, Crop response.
Identifiers: Land application, Sodic soil, Fary yard manure, Dhaincha,

An evaluation was made of the effect of farm yard manure (FYM) on the availability of Ca from Calcium carbonate in a non-saline sodic soil, using $Ca^{45}CO_3$. Three and a half kg of a non-saline sodic soil were separately weighed for 12 polyethylene lined earthern pots. Four levels of FYM, 0, 3, 6 and 9 percent on dry-weight basis, were thoroughly mixed into the soil, keeping 3 replications. Five me of tagged $CaCO_3$ per 100 g soil was thoroughly mixed in the soil at all levels of FYM and treated soil was watered, equilibrated for 7 days, remixed, and planted with 20 dhaincha seeds. Nitrogen, phosphorus, and potassium were applied at a rate of 50, 20, and 20 mg/kg soil respectively. Ten plants of dhaincha were allowed to grow in each pot for 50 days, harvested, washed, dried, weighed, ground and analyzed for Ca, Mg, Na, K, P, N, and Ca^{45}. Results showed: (1) even with the use of FYM, the contribution of Ca from $CA^{45}CO_3$ is less than 6 percent of the total Ca in plant, (2) dry matter yield of plant tops is negatively related with Na content and positively with Ca:Na ratio, (3) apart from increased availability of Ca from Ca Co_3 with the application of FYM, other factors—(a) improvement in soil physical conditions, (b) supply of nutrients, and (c) probable decrease in the activity of Na in the growth medium, also seem to be the probable reasons for increased dry matter yield, and (4) the increase in the total uptake of Ca from the soil as well as applied $Ca^{45}CO_3$ in response to FYM seems to be because of an increased root growth and increased availability of Ca. (Rowe-East Central)

THE EFFECT OF FUMIGATION WITH METHYL BROMIDE OR FORMALDEHYDE ON THE INFECTIVITY OF POULTRY HOUSE LITTER NATURALLY CONTAMINATED WITH SALMONELLA VIRCHOW,

Houghton Poultry Research Station, Houghton, Huntingdon, England
J. F. Tucker, E. G. Harry and H. E. Wainman
British Veterinary Journal, Vol. 131, No. 4, p. 474-485, 1975. 1 fig, 21 ref.

Descriptors: Litters, Salmonella, Chemical treatment, Poultry, Fumigants.
Identifiers: Infectivity, Methyl bromide, Formaldehyde.

The purpose of this investigation was to determine the effectiveness of methyl bromide (MeBr) fumigation in rendering litter naturally contaminated with Salmonella virchow, noninfectious to chicks in experimental animal accommodation, a comparison being made with the use of formaldehyde (HCHO) for this purpose. S. virchow was used as a test organism because it has been implicated in cases of food poisoning originating from infected poultry carcasses. The effectiveness of the fumigation process was also determined by measuring the reduction in Salmonella contamination in the treated litter. Application of methyl bromide at 2 dosage rates and at various temperatures resulted in widely varying treatments, in terms of the measured concentration-time products, in the approximately 20-hour exposure period allowed. However, in no case was the litter rendered noninfectious to chicks. A single trial with formaldehyde was also ineffective. In some of the tests where relatively small amounts of MeBr were used, fumigation seemed to enhance litter infectivity. In 3 of the 4 tests in which MeBr fumigation was carried out with concentration-time products of 430 mg h/litre and less at floor level, and in the test using HCHO fumigation, the incidence of salmonellosis was higher in the chicks on the fumigated litter, than in those on the unfumigated litter. The apparent lack of effect of formaldehyde fumigation on the Salmonella content of the litter was considered to have resulted from the method of sampling the litter, in which both subsurface and surface layers were included. EFFECT OF GYPSUM AND MANURE ON THE GROWTH OF WHEAT IRRIGATED WITH BICARBONATE RICH WATER,

Rajasthan Salinity Laboratory, Jodhpur, Rajasthan, India
S. S. Puntamkar, P. C. Mehta, and S. P. Seth
Journal of the Indian Society of Soil Science, Vol. 20, No. 3, p. 281-285, 1972. 2 tab, 17 ref.

Descriptors: Crop response, Gypsum, Irrigation, Wheat, Sodium, Calcium, Magnesium, Potassium.
Identifiers: Manure, Land application.

A field experiment was conducted to study the effect of gypsum and manure on soil properties and crop yield. Gypsum was applied at 5, 10, and 20 tons/ha and manure at 15 and 30 tons/ha alone or in combination with one another. Wheat (Sonora 64) was grown as a test crop. The crop was irrigated with bicarbonate rich water. Gypsum and manure was found to increase wheat yield when they were applied separately or in combination. The highest yield was recorded when 20 tons of gypsum was applied alone. The application of manure with gypsum was found to enhance the replacement of exchangeable sodium. The decrease in exchangeable sodium ranged from 1.6 to 10.9 percent by the addition of gypsum and manure; whereas, exchangeable calcium was found to increase up to 17.7 percent. Exchangeable magnesium was found to decrease from 0.3 to 11.4 percent; whereas, potassium increased 0.8-3.6 percent. (Merryman-East Central)

EFFECT OF ORGANIC AMENDMENTS ON CERTAIN SOIL ENZYMES,

Microbiological Laboratory, Department of Biology, Tamil Nadu, Agricultural University, Coimbatore - 641003, Tamil Nadu, India
D. Purushothaman and R. Kesavan
Indian Journal of Microbiology, Vol. 14, No. 3, p. 137-138, 1974. 1 tab, 9 ref.

Descriptors: Fertilizers, Farm wastes.
Identifiers: Soil amendments, Soil enzymes, Land disposal.

The effect of certain soil amendments on soil enzymes is examined. Ten kg each of read loam and black cotton soils of Coimbatore tract were taken in circular cement pots. Well powdered groundnut cake (GNC) and farm yard manure (FYM) were separately mixed with the soil in calculated quantities to obtain 40 kg level of nitrogen/ha. The treatments were sufficiently replicated with appropriate controls. The soils were maintained at 50 percent moisture holding capacity throughout the study and samples were collected on the 1st, 5th, 10th, 20th, 30th, and 45th days. One g quantities of soil samples were incubated with the appropriate substrates for 24 hr. at 37 degrees C. The reaction mixture was clarified by centrifugation at 2100 x g for 15 min. and the end products formed were determined in a Spectronic-20 colorimeter. Results showed that the black and red loamy soils when amended with FYM and GNC exhibited increased enzyme activities. α-Amylase and invertase were found to be relatively more active in the 2 soils than glucosidase and cellulase. GNC amended soils increased amylase activity; FYM enhanced invertase activity. FYM amendment enhanced B-glucosidase activity only in black soil. GNC amendment increased the same in red soil. α-Amylase activity of soil was positively correlated with organic matter content. The FYM and GNC soil amendments increased α-amylase activity. Cultivated neutral soils were characterised by greater activity of invertase; whereas, sandy soils exhibited poor activity. The black soil exhibited more invertase activity than did red loam. Addition of organic amendments slightly increased B-glucosidase activity. Cellulase was found to have a feeble activity in soil, possibly because cellulose is not an obligatory carbon source to soil microorganisms since the microorganisms have a broad nutritional base. THE EFFECT OF STORAGE IN SLURRY ON THE VIRULENCE OF SALMONELLA DUBLIN,

Agricultural Research Council, Institute for Research on Animal Diseases, Compton, Newbury, Berkshire
P. W. Jones
Journal of Hygiene, Vol. 74, p. 65-70, 1975. 3 tab, 6 ref.

Descriptors: Waste storage, Slurries, Pathogenic bacteria.
Identifiers: Virulence, Salmonella dublin, Mice, Bacto-tryptose (BT), Animal health.

Research was done to determine whether storage of Salmonella dublin in slurry and in broth reduces the virulence of the organism. An aerogenic smooth strain of S. dublin isolated by M. H. Hinton from a case of abortion in a dairy cow was used. White BSVS male mice were used at an average weight of 21 g. All mice, housed one animal per cage, received 0-25 ml. of inoculum delivered into the stomach from a syringe needle with a 'pear drop' end. Bacto-tryptose (BT) broth was prepared according to the formula: bactotryptose (Difco), 20 g., sodium chloride 5 g., sodium glycerophosphate 2 g., glucose 1 g., distilled water 1000 ml., and had a pH of 7.4. Slurry, collected from a dairy farm lagoon, was centrifuged at 1000 g for 2 min. to remove fiber. Slurry and BT were stored in 200 ml. volumes in a water bath at 10± 0.1 degrees C. No apparent reduction in virulence was noted in S. dublin stored either in slurry for up to 36 days or BT for up to 70 days. Mortality was slightly higher in groups of mice which had received stored rather than freshly prepared S. dublin. It appears that S. dublin survives in slurry for up to a month without loss of virulence. The disease risk associated with infected slurry is presumably related to the number of pathogenic organisms present rather than to their virulence. Although S. dublin will remain capable of causing disease, the risk to other animals of contaminated slurry will depend on other factors including the number of animals in a herd-excreting the organism, the dilution of infected excreta with non-infected excreta, the period for which the slurry is stored prior to spreading on pasture and the time elapsing before infected pasture is grazed. (Cameron-East Central)

ENHANCED TREATMENT OF LIVESTOCK WASTEWATER. III. ENHANCED AEROBIC TREATMENT OF SWINE WASTE BY ANAEROBIC PRE-CONDITIONING,

Assistant Professor, Agricultural Pollution Control Laboratory, Department of Agricultural Engineering, Michigan State University, East Lansing, 48823.
J. B. Gerrish, J. P. Harper, and P. O. Ngoddy
Journal of Agricultural Engineering Research, Vol. 20, p. 13-23, 1975. 11 fig, 5 tab, 12 ref.

Descriptors: Biological treatment, Aerobic conditions, Anaerobic conditions, Slurries, Chemical properties, Physical properties, Odor, Temperature.
Identifiers: Swine wastes, Holding times, Foaming.

A slurry of screened hog waste, diluted fivefold, was pre-treated anaerobically and then it was aerobically treated. Four anaerobic holding times were tested to determine which one would minimize subsequent aerobic treatment time. The holding times were 0, 3, 7, and 10 days. Air was admitted to those systems after the respective holding times and aeration was continued for a period of not less than 10 days in any case. It was found that: (1) reductions in the order of 60-80 percent in chemical oxygen demand, total solids, volatile solids, and suspended solids can be obtained for strong hog wastes, (2) these reductions can be achieved in reasonable times, i.e. of the order of 10 days, (3) anaerobic pre-conditioning can reduce the aeration requirements for a prescribed degree of treatment; 40 percent reduction in aeration energy was realized after 10 days' pre-conditioning, and (4) the test for total solids is unreliable for liquors containing high concentrations of volatiles such as the volatile fatty acids. The success of the anaerobic preconditioning depends on maintaining the anaerobic stage at an elevated temperature. Whatever supplemental energy is expended in heating the anaerobic stage can probably be more than compensated by the saving in aeration energy. The odors emanating from the batch processes were unacceptable. Some foaming was observed shortly after the onset of aeration. (Rowe-East Central)

ABSORPTION OF AMMONIA BY AQUEOUS SOLUTIONS IN A DAIRY AREA,

R. E. Luebs
Summaries of Papers, Statewide Conference on Crises and Conflicts in Agro-Ecosystems, University of California (Division of Agricultural Sciences), Berkeley, December 21-22, 1970, p. 42-43.

Descriptors: Ammonia, Absorption, Dairy industry, California, Air pollution, Water pollution, Soil pollution.
Identifiers: Acid traps, Water traps.

Three hundred sixty dairies are located in a 55-square mile area west of Riverside and southeast of Pomona, California. Preliminary sampling of ammonia absorption by dilute acid and water was made ½ mile from this area's densest accumulation of dairies. Over a 10-day period in November before the winter rainfall season, ammonia absorption by dilute acid in the dairy area exceeded that at a control site by a factor of 50. The control site was located at an airport, 6 miles from the dairy area. Urban residences and business areas lay between the dairy area and the control site. Absorption in an agricultural area devoted to crops and with widely scattered chicken ranches was 6 percent of that in the dairy area. Drying of wet dairy corrals markedly increased volatilization of ammonia. Ammonia concentration outside the most densely populated dairy area decreased with distance. Absorption of ammonia by water in traps over periods of 3-4 days was from 55 to 75 percent that absorbed in dilute acid. Ammonia content of rainfall collected over a 3-week period was 5 times greater than at the control site. Open water and soils around dairies or feedlots are likely to be enriched in nitrogen by absorption of ammonia and through its solution in rainfall. (Merryman-East Central)

EXAMINATION OF SLURRY FROM CATTLE FOR PATHOGENIC BACTERIA,

Agricultural Research Council, Institute for Research on Animal Diseases, Compton, Newbury, Berkshire
P. W. Jones and P. R. J. Matthews
Journal of Hygiene, Vol. 74, p. 57-64, 1975. 2 fig, 1 tab, 18 ref.

Descriptors: Slurries, Cattle, Pathogenic bacteria, Salmonella.
Identifiers: Brucellas, Leptospires.

A number of slurry systems were examined to assess the degree to which they were contaminated with pathogenic microorganisms. Since many pathogenic microorganisms may be excreted in the feces of infected animals, slurry could be a potential hazard to farm animals when applied to pasture. One hundred and eighty-seven samples of slurry from cattle were examined for the presence of salmonellas, pathogenic leptospires and brucellas. Twenty strains of Salmonella identified as S. dublin, 4 as S. Typhimurium and 4 as other serotypes. These were S. indiana, S. bredeney, S. cerro and S. 4, 12:d:—. All strains produced gas in 1 percent glucose peptone water and none were agglutinable in 1/500 neutral acriflavine. Sixty-four suspected leptospire colonies from 56 slurry samples were examined and confirmed as treponemas by dark-field microscopy. Sixty-four hamsters inoculated with these organisms survived up to 21 days when they were killed. No brucellas were isolated. The total colony count per sample of slurry ranged widely, with a maximum at 10^9 organisms/g. The coliform count ranged from less than 10^3/g. to more than 10^6/g. with most samples containing between 10^5 and 10^6 coliforms/g. The total solids concentration of the samples ranged from less than 1 percent (one sample) to 19 percent with a mean of 11.3 percent. There were two samples outside the range at 26 percent and 34 percent. (Cameron-East Central)

EXPERIMENTS OF SLURRY HANDLING, TREATMENT, AND LAND APPLICATION AT THE N.I.A.E., 1968-1974,

National Institute of Agricultural Engineering, Wrest Park, Silsoe, Bedford, MK45 4HS
R. Q. Hepherd
Report No. 15, National Institute of Agricultural Engineering, Wrest Park, Silsoe, Bedford, MK45 4hS, February, 1975, 24 p. 3 fig, 10 tab, 27 ref.

Descriptors: Slurries, Separating techniques, Waste storage, Solid wastes, Liquid wastes, Biological treatment, De-watering, Economics, Flocculation, Anaerobic conditions, Air pollution, Water pollution.
Identifiers: Land spreading, Great Britain.

This report reviews the applied research carried out at the National Institute of Agricultural Engineering between 1968 and 1974 to overcome farm problems, and in particular, to investigate slurry separation, biological treatment and sludge de-watering. The main conclusions from the work to-date are as follows: Separating (1) The separation of slurries before storage and land spreading produces smell-free solids that are easy to stack and spread on land and liquids that are also easy to store and to spread, (2) The liquid and solid products of separation appear easier to apply and better for the crops than slurries, (3) Studies of the economic viability of separation systems require farm measurements, and (4) The capital cost incurred in slurry separation may well be outweighed by the benefits. Treatment—(1) Treatment of animal manures to produce an effluent meeting Royal Commission standards is very difficult, (2) A high proportion of the output of effluent liquid plants must be applied to land, (3) De-watering is important if the wet sludges produced by treating slurries are to be converted to easily stored and handled solids, (4) If virtually all the slurry is converted into solids which can be easily transported, stored and spread elsewhere, the problems of farms which are short of land for spreading are greatly reduced, (5) Improvement separation and treatment stages of a complete slurry treatment process to reduce de-watering costs, may be possible by means of flocculation or other sludge de-watering aids, (6) The processes used to date have been satisfactory with slurries which have been stored under anaerobic conditions, and (7) The fibrous solids, de-watered sludge, and filtrate, are unlikely to cause air or water pollution problems. FACTORS AFFECTING THE RELEASE OF GASES FROM BOVINE WASTE,

Oregon State University, Corvallis
R. O. Kellems, D. C. Church and J. R. Miner
Proceedings, Western Section, American Society of Animal Science, Vol. 27, 1976, 5 p. 7 tab, 17 ref.

Descriptors: Gases, Diets, Waste storage, Crude protein, Urea, Specific gravity.
Identifiers: Volatilization, pH, Dry matter, Storage period.

The effect of different sources of grains (corn, barley, and Milo) and levels of supplementation (25, 50, 75 percent) on the initial volatilization of volatile gases from animal wastes and several variables that are associated with animal wastes (crude protein content, urea content of urine, specific gravity of urine, pH of feces, storage period, and dry matter content) were studied through the implementation of 4 separate experiments. Results of the experiments indicated that cereal grain source and level in a ration affects the initial volatilization of hydrogen sulfide and volatile nitrogenous gases. This change in relative amounts of hydrogen sulfide and ammonia was thought to be due to changes in the pH of the wastes; this is especially important with respect to ammonia release due to a direct relationship between pH and ammonia volatilization. Increasing the moisture content of the waste reduced the evolution rate of ammonia and amines during the initial storage period. Of the variables measured, it was found that the urea, specific gravity and moisture content of the waste were the most highly correlated with volatilization of nitrogenous gases. Further research must be done to determine how practical this approach would be in predicting and controlling the production of volatile gases from bovine waste. (Rowe-East Central)

GROWTH OF BROILERS FED ON DIETS CONTAINING DRIED POULTRY MANURE,

Agricultural Research Council's Poultry Research Centre, King's Buildings, West Mains Road, Edinburgh EH9 3 S, Scotland
D.J.W. Lee and R. Blair
British Poultry Science, Vol. 14, No. 4, p. 379-388, 1973.

Descriptors: Diets, Poultry, Performance.
Identifiers: Broilers, Refeeding, Dried poultry manure, Food conversion efficiency.

One experiment, using purified diets, tested whether autoclaving had any effect on the utilization of dried poultry manure (DPM) and whether the essential amino acid content of DPM explained the greater growth rate compared with the basal diet. A second experiment studied the effect on performance of feeding diets, which had been formulated to include DPM, to broilers for periods up to 8 weeks under commercial conditions. In the first experiment, 60 7-day-old male broiler chicks housed in individual metabolism cages were offered 1 of 6 purified diets for 14 days. These basal diets, formulated to have the same ME contents, had different nitrogenous supplements. Diet A contained PRC essential amino acid mixture equivalent to 15 g N/kg; B, basal+12 percent glutamic acid; C, basal plus essential amino acid mixture equivalent to essential amino acid content of 20-09 percent DPM; D, basal + essential amino acid + 12 percent glutamic acid; E, basal + 20-09 autoclaved DPM; F, basal + 20-09 percent unautoclaved DPM. The rank order of final body weights at 21 days of chicks fed on these diets were: D(292g)>B(258 g)>F(254 g) > E(253 g)>A(180 g), >(P 0.05). Chicks fed diet C had better food conversion efficiency than those fed diet A, and D was better than B. In the second experiment, 24 groups of broiler chicks were given commercial-type diets containing 0 percent of 5 percent DPM from 1 day of age for 4 weeks. From 4-8 weeks of age, one of the three diets with 0 percent, 5 percent or 10 percent DPM was fed according to a 2 (sexes) x2x3 factorial design. Between 0 and 4 weeks, feeding DPM had no significant effect on body weight or food consumption, but birds receiving 5 percent DPM had an improved food conversion efficiency. Between 4 and 8 weeks, birds fed 5 and 10 percent DPM were heavier than the controls at 6 weeks, but this increase was not significant at 8 weeks. Food consumption was not affected, but the food conversion efficiency improved with the increasing inclusion of DPM. At 8 weeks, birds fed 5 percent DPM were heavier than birds fed none. INFLUENCE OF FARMYARD MANURE ON SOIL STRUCTURE AND SOME RELATED SOIL PROPERTIES,

Department of Soils, Haryana Agricultural University, Hissar, India
M. C. Sarkar, M. Singh, and J. Nath
Journal of the Indian Society of Soil Science, Vol. 21, No. 2, p. 227-229, June, 1973. 1 tab, 10 ref.

Descriptors: Soil amendments, Organic matter, Sampling, Hydraulic conductivity, Saturation.
Identifiers: Farmyard manure.

An investigation was undertaken to study the role of farmyard manure in improving soil physical properties. Soil samples were collected in 1970-1971 from surface and subsurface soil layers of a permanent manurial experimental field at Haryana Agricultural University Research Farm. The study data indicated a significant increase in percentage aggregate for samples collected after 57 and 104 days of manure application which declined thereafter, and over a period of 340 days no significant change was noticed. Likewise, there was some initial lowering of bulk density after manure application, but this improvement was also temporary. Increased doses of farmyard manure caused significant increase in organic matter. However, the increased organic matter started declining from 97 percent to 77 percent and further to 57 percent in samples collected after 57, 104, and 185 days, respectively. Organic matter content did not change thereafter, showing the constancy with the climate and ecological conditions. From these data, it was determined that adequate addition of farmyard manure must be made every 6 months in order to maintain the level of increased organic matter. Benefits to be found in this increased organic matter are increased hydraulic conductivity and increased saturation percentage. Also, the physical condition of the surface soils is improved. (Rowe-East Central)

THREE-YEAR DPW PRODUCER SURVEY SHOWS BULK PRICE $5-9 PER TON,

Feedstuffs, Vol. 48, No. 50, p. 28, December 6, 1976.

Descriptors: Economics, Recycling, Fertilizers, Feeds, Performance.
Identifiers: Dried poultry wastes, Refeeding, Application rates.

A survey of dried poultry waste (DPW) producers showed bulk sales from farms ranged in price from $5-9/ton from 1973-1976. Stage one sales of DPW by 8 producers totaled 14,200 tons for a three-year period, and the average price was $5.95/ton at the farm where it was produced. Another 14,000 tons of DPW were used on local fields owned or leased by producers. Stage two sales totaled 24,000 tons for the first-year period. Average price for all stage two DPW was $62.62/ton. The DPW producers surveyed made these observations: (1) Cost of stage one is about $20/ton for the final product (2) Cost of stage 2 is usually over $60/ton for the final product. (3) There is a need to develop markets or uses for DPW that don't involve fertilizer or organic supplements. (4) Stage two product at 9 percent moisture was fed back to growing pullets at levels up to 10 percent of total ration from 8-18 weeks with no adverse effect on laying house performance. (5) Stage one drying reduces moisture to 25-60 percent while stage two reduces moisture 7-10 percent moisture. At 7 percent moisture over half of the total nitrogen is usually lost. (6) Manure out to the house must be below 60 percent moisture when entering dehydrator to be dried readily with minimum use of fuel. (7) The best application rates of stage one manure are 2 tons/acre for hay and small grains/year, while corn ground may take up to 8 tons/acre/year. (Merryman-East Central)

LIVESTOCK WASTE DISPOSAL - A MOUNTING PROBLEM,

Research Officer, New Zealand Agricultural Engineering Institute
D. J. Hills
Soil and Water, Vol. 10, No. 3, p. 32-36, March, 1974. 4 fig.

Descriptors: Waste disposal, Regulation, Confinement pens, Liquid wastes, Livestock, Poultry, Aeration, Irrigation, Lagoons, Agricultural runoff, Drying, Design, Water pollution.
Identifiers: Land disposal, Waste management, New Zealand.

Factors which have led to increasing use of confinement pens in New Zealand animal production are: competition for land, better control of animal health and nutrition, production of a consistent, high-grade product, requirement for less labor, and better adaptability to the development of the integrated operation. Confinement pen production of animals has changed the waste generation pattern from diffused to point-source, the waste transport form from solid to liquid handling, the waste processing from simple storage to rigorous treatment, the waste utilization from crop fertilizer to soil conditioner, and the waste disposal from a chore to a vexing problem. It has become almost imperative to treat animal wastes to stabilise them so they do not create an environmental nuisance or health hazard. Thus new waste management techniques have evolved. Management methods for piggeries, milking sheds, beef cattle feedlots and poultry houses are discussed. Projected trends for animal waste management in New Zealand are: (1) Piggery wastes will be mechanically aerated before land spreading. Some existing operations will utilize surface aerators floating in ponds. New operations will begin incorporation in-the-building oxidation ditches or external tanks with surface aeration. (2) Dairy shed wastes will continue to be disposed of by spray irrigation or anaerobic lagoons. Eventually, as water becomes a scarcer commodity, mechanical aeration will be required to treat the wastes. (3) Beef cattle feedlots are inevitable. Location of these must take into account runoff pollution following rain storms. (4) Poultry waste treatment will tend towards in-the-building drying techniques. (5) The ultimate disposal of wastes from all treatment systems will be to the land. (6) Waste disposal systems will be carefully integrated in the design stages of new livestock operations. MICROBIOLOGICAL AND CHEMICAL SURVEY OF BEEF CATTLE WASTE FROM A NONSURFACED FEEDLOT,

Department of Biology, Texas Tech University, Lubbock, Texas 79409
D. W. Thayer, P. Lewter, J. Barker, and J. J. J. Chen
Bulletin of Environmental Contamination and Toxicology, Vol. 11, No. 1, p. 26-32, January, 1974. 2 tab, 7 ref.

Descriptors: Feedlots, Cattle, Chemical properties, Physical properties, Biological properties, Sampling, Microorganisms, Reclamation, Proteins, Microbiology.
Identifiers: Nonsurfaced feedlots, Climate.

This article discusses a study which was carried out on the average microbiological properties and selected chemical and physical properties of waste from a large nonsurfaced beef cattle feedlot in a semiarid climate. The purpose of the research was to define some of the major properties of the stockpiled manure prior to its potential use as a substrate for the production of single-cell protein. Under the discussion of materials and methods the following are covered collection on samples; media and culture conditions; chemical analysis; and sampling periods. Tabular results are presented on: viable microorganisms in feedlot manure and the chemical composition of feedlot manure. Another topic which is considered is the stockpile method of manure disposal, which is prevalent in the Southwest, and the attendant disposal and sanitation problems created thereby. MILK PRODUCTION FROM A RATION CONTAINING DRIED POULTRY WASTE,

Great House Experimental Husbandry Farm
W. A. Kneale and J. R. Garstang
Experimental Husbandry, Vol. 28, p. 18-24, 1975. 8 tab, 9 ref.

Descriptors: Dairy industry, Feeds.
Identifiers: Refeeding, Dried poultry waste, Milk production.

Dried poultry waste was tested in rations fed to dairy cows during lactation. Autumn calving Friesian cattle were used in these experiments. Seven heifers were allocated per treatment in the first, 8 cows per treatment in the second and 16 cows per treatment in the third experiment. Roughage was supplied as hay and this was fed in an amount calculated to provide 85 percent of maintenance. It was found that the complete replacement of soya bean meal and groundnut meal by dried poultry waste tended to reduce milk output from cows fed this ration. The energy value of a ration containing 20 percent poultry waste was lower than that of a ration containing conventional vegetable protein. A 10 percent inclusion of poultry waste appeared to be acceptable in terms of milk production. When considering the use of poultry waste, the ash content of that waste should be determined before an inclusion rate is decided upon. The inclusion of poultry waste in a dairy feed was not a health hazard to those consuming the milk, neither did it produce tainted milk. (Cameron-East Central)

A NOVEL CONTINUOUS PYROLYZER — THE TTU REPORT,

Department of Chemical Engineering, Texas Tech University, Lubbock 79409
H. W. Parker
Presented at the Rocky Mountain Regional American Chemical Society Meeting, Laramie, Wyoming, June 17-19, 31 p. 2 tab, 7 fig, 19 ref.

Descriptors: Pyrolysis, Pilot studies, Recycling, Oil.
Identifiers: Manure.

A variation of the Bureau of Mines Gas-Combustion Retort for oil shale has been developed which omits the troublesome internal gas distributor. This is accomplished by intermittent addition of air to the gas being recycled through the retort or by continuous small additions of air to the recycle gas. The 16 cm. diameter pilot retort has been operated at processing rates of 940 kg/m^2 hr on 0.64 to 1.9 cm. manure particles containing 55 percent ash and 12.6 percent water. Results have shown that this retort can be operated to pyrolyze manure in both the cyclic and the continuous air injection modes. Capacity of the retort was established for continous air injection as 940 kilograms of feedlot waste/hour/square meter of retort cross section. The limited capacity of the recycle compressor prevented establishment of maximum processing for the cyclic mode of air injection, but it is assumed to be about the same. The continuous air injection mode of operation yielded less oil, and lower BTU product gas was observed for the cyclic air injection mode. The manure employed during the continuous air injection tests contained much more ash but less moisture than that used in the cyclic air injection tests. When the data were converted to yields based on moisture and ash free manure, the continuous air injection mode still produced much lower gas and liquid yields but higher char yields. Another factor which contributed to reduced yields of combustible gases in the continuous air injection mode was that the mixture of recycle gas and air which was injected into the retort was always fuel rich. (Rowe-East Central)

POWER PLANT BOILERS TO BE FUELED BY COW MANURE,

Oklahoma Rural News, Vol. 27, No. 4, p. 7, November, 1976.

Descriptors: Recycling, Fuels, Methane, Feed, Fertilizers, Oklahoma, Legislation, Grants.
Identifiers: Anaerobic digesters.

Legislation under consideration by both the House and Senate in Washington, D.C. will,if successful, establish a study of anaerobic digesters for converting animal and vegetable wastes into methane gas and fertilizer. The legislation provides for a study of anaerobic digesters by the Soil Conservation Service in consultation with the National Bureau of Standards and the National Science Foundation. More than 100 farms of 640 acres or less throughout the U.S. would then participate in field performance tests. Those models rated most effective and safe would be "certified" and farmers would be eligible for grants for the installation of certified models. An Oklahoma City based firm isn't waiting for the legislation. Calorific Recovery Anaerobic Process, Inc., is building a plant in the Oklahoma Panhandle to convert cattle manure from 3 feedlots with a total capacity of 110,000 head, is scheduled to start in December, 1977. Approximately 600 million cubic feet of methane will be produced annually and will be sold to Natural Gas Pipeline Company of America for use in Chicago. Animal feed and fertilizer expected to be used locally by farmers will also be produced at the plant. (Merryman-East Central)

POULTRY WASTES AS A FEEDSTUFF FOR SHEEP,

Research Station, Agriculture Canada, P.O. Box 90, Lennoxville, Quebec J1M 1Z3
P. Flipot, M. McNiven and J. D. Summers
Canadian Journal of Animal Science, Vol. 55, No. 3, p. 291-296, 1975. 5 tab, 17 ref.

Descriptors: Feeds, Waste treatment, Performance.
Identifiers: Refeeding, Sheep, Poultry manure.

A study was conducted to provide information concerning the acceptability and potential nutritive value of wet caged hen excreta when fed to mature sheep. Six wethers averaging 37 kg were used in a double 3 x 3 latin square design and were fed diets which contained approximately 64 percent (wet weight) poultry excreta. The excreta had been treated with tannic acid (3 percent) or with paraformaldehyde (2 percent). Soybean meal and water were used in the control diet. Dry matter and water intake of sheep fed this diet consumed less water and had correspondingly lower water excretion and percentage retention of water. Dry matter, total nitrogen, and energy digestibilities were significantly decreased in diets containing poultry excreta. Paraformaldehyde treatment significantly reduced the apparent digestibilities of dry matter and energy of the diet compared to the tannic-acid-treated diet. Nitrogen retained as a percent of total nitrogen intake was not significantly different for the control and the tannic-acid treated poultry excreta diet. Ensiling characteristics were not adversely affected by poultry excreta. The study data suggest that wet poultry excreta treated with tannic acid can be successfully used for the feeding of sheep. More work is required to find the most suitable additive to stabilize the chicken feces, and thus reduce odor and make the product more palatable. Work is also required on the risk of pathogenic organisms. (Rowe-East Central)

PRESENT SITUATION AND PROBLEMS ON ENVIRONMENTAL PROTECTION AND CONSOLIDATION IN JAPAN,

Chemistry Laboratory, Tokyo University of Agriculture, Japan
K. Ishimaru
Reprinted from the Proceedings of the Symposium on Animal Research, Tropical Agriculture Research Center, Ministry of Agriculture and Forestry 2-2-1, Nishigahara, Kita-Ku, Tokyo 114, Japan, 1973, p. 147-162. 25 tab.

Descriptors: Water pollution control, Waste treatment, Legal aspects.
Identifiers: Japan, Odor control.

Increased livestock production has inevitably brought more stringent environmental protection laws in Japan. The Basic Law Environmental Pollution Control (Enacted in 1967, Law No. 132) regulates air pollution, water pollution, soil pollution, noises, osillation, land subsidence, mold and offensive odors. Of primary importance to animal husbandry are odors and water pollution. In Japan, odor intensities are measured and are required to meet certain standards. Odor control measures that may be utilized by livestock owners are: (1) Closure of barn and deodorization of enclosed odors, (2) Rinsing — Deodorization by channeling odor through a smoke duct or tower and then film-spraying with water, (3) Chemical treatment, (4) Oxidation, (5) Absorption, (6) Thermal decomposition, (7) Microorganism treatment by placing offensive smelling substance in microorganism growth culture, and (8) Soil treatment. Water must also be safeguarded. The Water Pollution Control Law requires that the purity of water in Japanese streams must comply with stipulated levels established for pH, BOD, COD, SS, and Coli. Treatment processes for animal wastes are discussed. Primary treatment methods outlined include: a storage tank, a solids removal apparatus, a sedimentation tank and settling tank, a simple digestion tank, and a sterilized tank. Secondary treatment processes outlined include: the activated sludge process and the trickling filtration process. While animal wastes make good fertilizers, the following must be considered when electing to use animal wastes in that manner: (1) farm size, (2) soil quality and composition, (3) kind of crops, (4) form and decay-rate of the fertilizer, (5) collection and treatment, (6) transportation and distribution, and (7) environmental and sanitation problems. RESIDUAL VALUE OF SLURRIES (CATTLE, PIG AND POULTRY),

N.A.A.S., Bristol
C. Berryman
Presented at NAAS Soil Scientists Open Conference, Paper SS/1/116, 1968, p. 326-332. 3 tab, 11 ref.

Descriptors: Slurries, Cattle, Poultry, Nitrogen, Potash, Phosphate, Crop response.
Identifiers: Land disposal, Land application, Swine, Residual values.

The lack of experimental work to measure the residual value of slurry gives rise to much difficulty when suggesting residual values of this type of manure. Factors which can influence the residual value are reviewed and an estimate of the residual value of nitrogen, phosphate, and potash in cattle, pig, and poultry slurries is given. There can be no finality about estimates of residual values because so much depends upon the farmer's skill in management and his particular method of farming. (Rowe-East Central)

ROTATING DISC PROCESS TREATS SLAUGHTERHOUSE WASTE,

Oklahoma State University, Stillwater
E. L. Stover and D. F. Kincannon
Industrial Wastes, Vol. 22, No. 3, p. 33-35, May/June, 1976. 5 fig.

Descriptors: Waste water treatment, Recycling, Aeration, Chemical oxygen demand, Temperature, Dissolved oxygen, Effluents.
Identifiers: Slaughterhouse wastes, Rotating biological reactor, Paunch manure.

The rotating biological reactor can successfully treat slaughterhouse-meatpacking wastes. Blood, grease, and paunch manure constitute the major problems. Recovery of these three products greatly reduces undesirable contents of the waste-water and can also be profitable in large slaughterhouses. Dried blood can be used for livestock feed, plywood adhesive, fertilizer ingredients, or as a protective colloid. In most of the smaller slaughterhouses, recovery practices are not incorporated, therefore, the wastewater consists of a mixture of blood, grease, paunch manure, and washwater. The rotating biological reactor requires a minimum amout of space. The rotating polystyrene disc system is noiseless, easy to operate, and requires a minimum of maintenance and power. The rotating discs are partially submerged, and the microbial population is alternately passed through the air and the wastewater. The discs provide media for the support of a fixed microbial growth, contact the growth with the wastewater, and aerate the wastewater to provide the dissolved oxygen necessary to maintain aerobic biological activity. The rotating disc used in this study was a four-ft. long, ten-gallon capacity unit built specifically for experimental purposes. Some experiments were carried out at a hydraulic loading of 0.5 gpd/ft. and varying organic loadings of slaughterhouse wastewater. Approximately 50 percent of the total COD removed occurred in the first stage of the unit. The substrate removal rates decreased and approached a constant minimum value as the applied organic loading was increased. A COD removal efficiency of 80 percent was achieved at a loading of 0.004 lb COD /day/ft. As the organic loading increased, the removal efficiency decreased and approached a constant minimum value. At loadings of 0.039 lb COD /day/ft. and greater, only ten percent COD removal was obtained by the unit. As the wastewater passed through the unit it increased in pH. A temperature drop of 25 degrees F was noted between the influent and effluent wastewater. There was an oxygen utilization of approximately 1 mg/l above that supplied by the unit. Therefore, oxygen utilization did not restrict the removal efficiency of the unit. (Rowe-East Central)

EFFECTIVE MANURE HANDLING: TIME-MOTION FOCUS ON FEEDLOT WASTE EFFICIENCY,

Texas A&M University
J. M. Sweeten
Feedlot Management, Vol. 18, No. 5, p. 22-25, 28, May, 1976. 8 fig, 1 tab.

Descriptors: Efficiencies, Solid wastes, Management, Feedlots, Equipment, Costs, Productivity, Texas.
Identifiers: Time-motion studies, Manure collection, Elevating scraper, Wheel loader, Energy consumption.

A time-motion study of manure collection was conducted at 4 feedlots (ranging from 28,000 to 100,000 head capacity) in the Texas Panhandle. Collection systems included elevating scraper, wheel loader, and wheel loader plus plowing or rototilling. Major objectives were to compare machine productivity (tons manure/hour), energy consumption (tons/hp/hour) and cost (dollars/ton) for both collection and loading phases of solid manure handling. It was found that the elevating scraper had a lower energy requirement and slightly lower cost than wheel loaders operated with or without the benefit of pre-plowing or rototilling of the manure pack. In addition, the elevating scraper and the wheel loader chisel plow combination yielded the highest productivity (175 tons/hour). (Merryman-East Central)

POULTRY MANURE: WASTE OR RESOURCE,

S. R. Wilkinson
Contribution from Soil, Water, and Air Sciences, Southern Region, Agricultural Research Service, U. S. Department of Agriculture, in cooperation with the University of Georgia Agricultural Experiment Stations, 1974, 4 p. 2 tab.

Descriptors: Litters, Fertilizers, Crop response.
Identifiers: Poultry waste, Land application, Application rates, Animal health, Pollution.

The value of poultry manure as a fertilizer and the use of land for litter disposal are examined. Plant nutrient content of poultry litter is variable and depends on its water content, the circumstances of flock management and production, and length and type of storage. Plant responses to nutrients present in high water content manures have been disappointing. Nitrogen in manures is generally not as readily available as nitrogen from commercial fertilizers. Utilization of poultry manure and litters as fertilizers or merely as a waste to be disposed of upon the land must be done under the constraints of maintaining a quality environment. Wise application of manure recycles nutrients to the soil, increases productivity, improves the soil, doesn't hurt the quality of water leaving the soil, and enhances a quality environment. Safe levels of broiler litter fertilization of fescue cut only for hay are about 8-10 tons acre. Four to five tons of broiler litter/acre/year is recommended for grazed pastures in order to prevent animal health problems of fat necrosis, grass tetany, nitrate toxicity and difficulty in fully using the grass grown. SOIL AND CROP RESPONSE TO APPLIED ANIMAL WASTE,

Research Assistant, Plant Science Department, South Dakota State University, Brookings
M. L. Horton, R. R. Schnabel, and J. N. Wiersma
Journal Paper No. 1431, South Dakota Agricultural Experiment Station, Brookings, 1975, 14 p. 2 fig, 6 tab, 11 ref.

Descriptors: Crop response, Salts, Diets, Infiltration rates, Soil properties, Cattle, Confinement pens, Feedlots.
Identifiers: Land application.

Research was initiated in August, 1973, which included feeding trials, field disposal plots, and laboratory analysis. The research was conducted to investigate the effects of various rates of applied wastes produced by animals on different rations upon soil properties and crop production under sub-humid conditions where minimum amounts of leaching water are available. Beef steers from confinement pens (11 head/pen) and 8 pens in the open with no shelter (11 head/pen) were fed a common basic ration with 4 levels of added salt — 0.00, 0.25, 0.50, and 0.75 percent of the ration on a dry-weight basis. All wastes were collected, stored until time of application, and applied to field disposal plots at 4 rates (44.8, 89.6, 139.4 and 179.2 MT/ha). The applied wastes consisted of 2 salinity levels — low (combined wastes from pens receiving 0.50 and 0.75 percent added salt). Laboratory analyses were performed on waste samples collected at the time of field application, on soil samples collected at planting and harvest, and on plant samples collected at tasseling stage. An infiltration study was conducted on half of the plots during the period July 6 to July 18, 1975. Results confirmed that application of animal waste to certain soils under conditions of minimal leaching can increase the salinity to levels harmful to the growth of many plants of agronomic importance. Applications of animal waste in excess of 90 MT/ha caused reduced infiltration. The cause of decreased water infiltration appeared to be increased sodium levels and dissolution of organic matter. RHEOLOGY OF LIVESTOCK WASTE SLURRIES,

Research Leader, U. S. Meat Animal Research Center, Clay Center, Nebraska
A. G. Hashimoto and Y. R. Chen.
Transactions of the ASAE, Vol. 19, No. 5, p. 930-934, September-October, 1976. 1 fig, 7 tab, 10 ref.

Descriptors: Rheology, Slurries, Equations, Aeration, Pumping, Mixing.

Study objectives were: (1) to identify a parameter that would mathematically describe the rheological properties of aerated and fresh dairy, poultry and swine waste slurries and that could be easily and precisely measured experimentally; and (2) to describe the procedures to estimate the effect of rheological properties on pumping, mixing, and aerating livestock waste slurries. The study showed that the rheological consistency index (k) and rheological behavior index (n) of livestock waste slurries can be expressed in terms of the equilibrium sludge volume fraction (ϕL) as: $K=b_1\phi L^{b_2}$ and $n=b_3+b_4\ln\phi L$ where b_1 to b_4 were determined for aerated and fresh dairy, poultry and swine waste slurries, and were found to be different depending on the range of ϕL. The relationships between K and n to the effective viscosity (μe) and generalized Reynolds number (N_{Re}) have been described along with the effect of μe and N_{Re} on mixed power characteristics, oxygen transfer efficiency, and pressure headloss in pipeline transport of slurries. The centrifugation method to determine ϕL is also described. (Merryman-East Central)

REMOVAL OF GASEOUS AMMONIA AND METHYLAMINE USING OZONE,

Assistant Professor, Agricultural Engineering Department, University of Florida, Gainesville
D. T. Hill and C. L. Barth
Transactions of the ASAE, Vol. 19, No. 5, p. 935-938, 944, September-October, 1976. 4 fig, 2 tab, 12 ref.

Descriptors: Ammonia, Ozone.
Identifiers: Odor control, Methylamine, Animal health.

Some of the basic properties of ozone-ammonia and ozone-methylamine reactions were investigated when using ozone as an oxidant for odor removal. Specific objectives were: (1) to determine whether ozone requirements for reduction of odorant concentration can be predicted by stoichiometric relationships and (b) to determine the ozone dose-contact time relationship for effective ammonia methylamine removal. Ozone was found to be an effective oxidant for both compounds studied, if given enough time. However, the relatively long contact times that are needed for ammonia and methylamine removal from odorous atmospheres in animal production facilities make the process appear to be of questionable value. The fact that these atmospheres contain many more diverse and chemically active compounds that would compete with the ammonia and methylamine for the ozone suggests that the contact time for effective ammonia and methylamine removal would be longer than observed in the investigation. The physiological effect on the animals by the ozone would prohibit this. One solution to the problem would be to exhaust the atmosphere of the production unit with a fan. If odor problems occurred because of close proximity to neighbors, ozone could then be employed to abate the problem. (Merryman-East Central)

NETWORK ANALYSIS FOR DAIRY WASTE MANAGEMENT ALTERNATIVES,

Agricultural Engineering Department, Cornell University, Ithaca New York
L. M. Safley, Jr., D. R. Price, and D. C. Ludington
Transactions of the ASAE, Vol. 19, No. 5, p. 920-924, September-October, 1976. 3 fig, 2 tab, 17 ref.

Descriptors: Computer programs, Management, Dairy industry, Waste treatment, Waste disposal, Economics.
Identifiers: Network analysis.

Network analysis was applied effectively to the problem of determining the economic cost of dairy waste handling. Eleven freestall waste handling systems were defined and compared on the basis of a given set of input parameters. The network developed was analyzed on the basis of initial construction cost and yearly operational cost. A computer program was written to facilitate the computation. The program was constructed so that it might be easily adapted to new systems. It is felt that providing analysis for decision making on waste management alternatives has been partially met with the network analysis tool. The analysis tool was developed for use by extension personnel to assist farmers in selecting a system best suited to their specific farm operation and location. Additional inputs are needed to improve the usefulness of network analysis, such as benefits from manures for fertilizers, labor requirements, and odor control. (Merryman-East Central)

QUANTITATIVE PREDICTION OF ODOR INTENSITY,

Assistant Professor, Agricultural Engineering Department, University of Florida, Gainesville
D. T. Hill and C. L. Barth
Transactions of the ASAE, Vol. 19, No. 5, p. 939-944, September-October, 1976. 2 fig, 6 tab, 12 ref.

Descriptors: Equations, Ammonia, Hydrogen sulfide.
Identifiers: Odor control, Odorant concentration, Odor intensity, Methylamine.

An investigation was made of the relationship of odor intensity, of odorant mixtures and individual odorant concentration using hydrogen sulfide, ammonia, and methylamine, common odorants in animal production facilities. Mathematical equations were developed to measure three, two-odorant mixtures and one, three-odorant mixture and it was found that they sufficiently quantified the relationship between pure odor components. The empirically derived prediction equations all contained a linear term and an exponential term, and extremely complex coefficients. The complexity of these equations would increase when greater numbers of odorants are involved. It was felt that controlling one odorant emitted in waste treatment process could provide significant odor reduction by limiting the odorant interactions of addition of synergism. Controlling one odorant would be easier than controlling all or most of the significant odorants present. (Merryman-East Central)

3489 - A8, B1, C2, E2
AMMONIA VOLATILIZATION AND NITROGEN TRANSFORMATIONS IN SOILS USED FOR BEEF MANURE DISPOSAL,

Research Agricultural Engineer, Environmental Effects Laboratory, Waterways Experiment Station, U.S. Army Corps of Engineers, Vicksburg, Mississippi
R. E. Peters and D. L. Reddell
Transactions of the ASAE, Vol. 19, No. 5, p. 945-952, September-October, 1976. 5 fig, 6 tab, 24 ref.

Descriptors: Waste disposal, Ammonia, Nitrogen, Soil chemical properties.
Identifiers: Land disposal, Volatilization, Cattle manure.

A soil column installation was used in studying ammonia volatilization and nitrogen transformations when a large application of beef manure is incorporated into the soil. Limed (pH ≈ 12) and unlimed (pH = 7.5) soil columns were incubated for 30, 60 and 90 day periods. Ammonia volatilization was found to be much greater from the high pH treatment while carbon dioxide evolution was much lighter from the low pH treatment. Approximately 10 percent of the total nitrogen from the low pH treatment was lost while a 20 percent loss occurred in the high pH treatment. (Merryman-East Central)

MANURE-METHANE CONVERSION BEING STUDIED IN WEST,

Feedstuffs, Vol. 48, No. 47, p. 16, November 15, 1976.

Descriptors: Recycling, Fuels, Methane, Feedlots, Anaerobic digestion, California.
Identifiers: Cattle manure, Sanitary landfill.

Pacific Gas & Electric Co. and Southern California Gas Co. are spending \$50,000 to study the potential conversion of cattle manure into methane. The study should take 6 months. It is expected that an estimated 30 million cubic feet of methane a day could be produced in Imperial, Fresno, and Kern counties. The main methane conversion process being examined involved anaerobic digestion. Also, Pacific Gas is working with Mountain View, California, and the Environmental Protection Agency in a joint project to see if methane can be extracted from the 544-acre Mountain View sanitary landfill. (Merryman-East Central)

PIPELINE TRANSPORT OF LIVESTOCK WASTE SLURRIES,

Agricultural Engineering Department, Cornell University, Ithaca, New York
Y. R. Chen, and A. G. Hashimoto
Transactions of the ASAE, Vol. 19, No. 5, p. 898-906, September-October, 1976. 7 fig, 7 ref.

Descriptors: Slurries, Equations, Rheology, Reynolds number.
Identifiers: Pipeline transport, Fanning friction coefficient.

A study was undertaken to find the correlation between the Fanning friction coefficient (f) of slurries flowing through 7.42 and 4.80 cm ID aluminum irrigation pipes. The N'_{Re} (Reynolds number) were based on the rheological properties of the slurries measured by a capillary tube viscometer. The applicability of using rotation viscometer data in calculating N'_{Re} was also discussed. In the laminar flow region, the experimental results closely followed $f = 16\ N'_{Re}$. For livestock waste slurries, the laminar flow region ended at $N'_{Re} = 3100$ and the fully developed turbulent region began at $N'_{Re} = 4300$. The f - N'_{Re} correlation for livestock waste slurries with n' between 0.4 and 1 and $4300 < N'_{Re} < 10^5$ was $f = 0.0306\ (N'_{Re})$ - 0.18. In these equations, f = fanning friction coefficient, dimensionless; N'_{Re} = generalized Reynolds number for non-Newtonian liquids, dimensionless; n' = rheological behavior index from capillary viscometer, dimensionless. (Merryman-East Central)

OHIO SWINE WASTE SYSTEM SHOWS LESS POLLUTION ODOR,

J. D. Kendall, ed.
Feedstuffs, Vol. 47, No. 12, p. 13-14, 27, March 24, 1975.

Descriptors: Waste treatment, Waste disposal, Waste storage, Physical treatment, Chemical treatment, Biological treatment, Chlorine.
Identifiers: Odor control, Land disposal, Application rates, Hydrogen peroxide, Sodium hypochlorite, Potassium permanganate.

E. P. Taiganides of Ohio State University discussed a three-year test of a complete automated waste treatment system on a pig farm in Botkins, Ohio, in which there was no water pollution and a minimum of odor nuisance. The treatment system included (1) hydraulic removal of wastes in the building by flushing gutters with liquids from overhead siphon tanks and tipping buckets; (2) primary treatments consisting of a stabilization of solids, solids storage tanks and final disposal of settled solids on farm land; (3) secondary treatment, consisting of an oxidation ditch, final clarifier and re-use of clarifier effluent as flushing liquid in the building, and (4) tertiary treatment, consisting of a laboratory evaluation of the use of high-pressure-driven membranes for the removal of chemical nutrients from the clarifier effluent. Control of odor from stored liquid swine wastes by means of various chemical and biological compounds was also discussed in terms of the work undertaken by Pennsylvania State scientists C. A. Cole, H. D. Bartlett, D. H. Buckner, and D. E. Younkin. In short-term experiments, hydrogen peroxide, sodium hypochlorite, chlorine, and potassium permanganate, dosed at 500 ppm, greatly reduced sulfide and odor level in liquid swine manure. However, activated carbon dosed at even 5000 ppm was not as effective. In another study, Bartlett studied the effects of injecting waste slurry directly into crop land, thus avoiding the "lingering pungent odor" of slurry spread on top of the ground. Subsurface applications of liquid manure were shown to give complete control of odor problems at the spreading site; however, manure application rates should be limited to supply nitrogen not much in excess of the amount that the crops can assimilate. DEQ DEVELOPS RULES TO CONTROL ODORS,

J. Wiebel
Wallaces Farmer, Vol. 101, No. 20, p. 54, October 23, 1976.

Descriptors: Regulations, Legal aspects, Iowa, Feedlots.
Identifiers: Department of Environmental Quality, Odor control.

The Iowa Department of Environmental Quality's Air Quality Commission is evaluating proposed odor control regulations which may be passed, may be slightly modified, or which may be modified to such an extent that they have to once again be brought before a public hearing. According to the new regulations, when an odor complaint is filed, it would first be discussed before the local county board of health in hopes of circumventing legal action. Also, 2 types of permit programs were proposed for the new regulations. The first was a mandatory permit program in which anyone putting up a livestock facility that has a potential for odor problems has to have a permit. The other was that an optional permit program in which permits would not be required, but such permits would help in defense in event of complaints. Unless there are some hangups, some or all of the regulations being considered could go into effect this year. (Merryman-East Central)

GOOD NEWS AND BAD IN FEEDLOT RUNOFF RULES,

J. Wiebel
Wallaces Farmer, Vol. 101, No. 20, p. 15, October 23, 1976.

Descriptors: Regulations, Legal aspects, Feedlots, Agricultural runoff, Water pollution.
Identifiers: Permits.

Iowa's new feedlot runoff regulations go into effect October 25, 1976. Sizes (minimum capacity) of open feedlots required to have permits are: beef cattle - 1000, dairy cattle - 700, swine (butcher and breeding over 55 lb) - 2500; sheep and lambs - 10,000, and turkeys - 55,000. Multipliers are given for computing animal units for feedlots of more than one species. A permit is needed by feedlots having more than 1000 animal units. Open feedlots as small as 100 beef cattle or the equivalent may need a permit if runoff enters a stream. The stream must be large enough to drain more than 3200 acres above the feedlot. Deciding factor is how far the runoff must travel to reach the stream in relation to feedlot size. For confinement feedlots, those where livestock are kept under roof and wastes are handled in liquid or semi-liquid form, capacity requirements for obtaining a permit depend upon the type of waste handling system used. A permit must also be obtained if wastes are discharged into a stream through a manmade drainage system such as a ditch, tile, or flushing system. Same capacities apply if a stream runs through the feedlot. Operations requiring permits under these circumstances have the following minimum capacities: beef cattle - 100, dairy cattle - 70, swine - 250, sheep - 1000, turkeys - 5000, and chickens - 9000. Feedlot owners may also be required to secure permits if they don't meet minimum control measures or they are polluting state-waterways. Feedlots requiring permits must apply for them by April 1, 1977. (Merryman-East Central)

EFFECT ON SOIL AND PLANT MINERAL LEVELS FOLLOWING APPLICATION OF MANURE FROM SWINE FED HIGH DIETARY COPPER,

Department of Animal Science, Virginia Polytechnic Institute and State University, Blacksburg 24061
R. T. Kornegay, J. D. Hedges, D. C. Martens, and C. Y. Kramer
1973-1974 Livestock Research Report, Research Division Report 158, Virginia Polytechnic Institute and State University, Blacksburg, July, 1974, p. 129-134. 5 tab.

Descriptors: Diets, Copper, Fertilizers, Soil contamination, Crop response, Zinc, Potassium, Phosphorus, Calcium, Magnesium.
Identifiers: Land application, Swine manure, Corn, Minerals.

Manure from pigs fed high dietary levels of copper was incorporated into a silty loam soil for 2 consecutive years to study its effects on soil and plant mineral levels. Average composition of the manure for both years on a dry basis was 3.66 percent nitrogen, 3.13 percent calcium, 0.94 percent magnesium, 2.53 percent phosphorus, 1.31 percent potassium, 763 ppm zinc, 2135 ppm iron. Wet manure each year contained about 22 percent dry matter. Results revealed that in general copper, zinc, potassium, calcium and magnesium accumulate in the surface layer of the soil until the soil is plowed, after which there is some increase in the layers. On the other hand, phosphorus moves downward, although the surface 4 inches retained the highest level. The copper content of the

corn plant (ear leaf) was increased for corn grown on the plots receiving high copper manure;, however, there was no increase in the copper content of the grain. (Merryman-East Central)

RESEARCH ON ORGANIC INDUSTRIAL BYPRODUCTS, RECYCLED MANURE FOR FEED REPORTED AT ANRC,

Feedstuffs, Vol. 44, p. 6, November 27, 1972.

Descriptors: Recycling, Feeds, Additives, Performances, Arsenic compounds, Cattle, Wood wastes.
Identifiers: Refeeding, Dairy cattle, Sheep, Liver abcess.

Five presentations to the 1972 annual meeting of the Animal Nutrition Research Council are reported. Dr. C. C. Calvert noted that one of the problems associated with the refeeding of animal manures is their contamination with feed additive residues. Animal waste research was done at Beltsville on arsenicals to determine whether the amount of arsenic from arsanilic acid and 3-nitro-4-hydroxphenylarsonic acid found in poultry manure and litter has any effect on the performance of sheep and dairy cows consuming them and whether residues are deposited in various tissues and milk. Such arsenic was fed to dairy cows at levels up to 32 mg As/kg of body weight for 5 days. Milk production and general health of the cows was not significantly affected. In experiments with sheep, results showed that 83-91 percent of the total ingested arsenic was excreted in urine and feces. Aresenic fed to sheep at levels of 30, 150, and 300 mg kg of diet for 28 days resulted in no clinical symptoms of arsenic toxicity in the sheep. Dr. L. B. Carew, Jr., reported on the subcommittee for metabolizable energy standards which divided the task of establishing standards into 4 categories: (1) analytical methods, (2) direct methods, (3) indirect methods, and (4) biological and environmental variables. Dr. Terry Klopfenstein and Bill Schneider reported that bovine hepatic necrobacillosis (liver abcess) is a frequently occurring condition in cattle fed high concentrate finishing rations. Several trials have indicated that rations which produce acidosis, such as those containing high levels of wheat, increase incidence of liver abcesses. Dr. M. R. Spivey-Fox, Food and Drug Adminstration, reported on programs for determination of key elements in U.S. foods and routes of some elements of the foods. Dr. David Dinius, noted that wood wastes are receiving increasing interest as a feedstuff for ruminants. The higher the digestibility, the greater the dietary percentage of wood residue that can be fed without adversely affecting animal performance. Energy is essentially the only available nutrient. NUTRITIVE VALUE OF AEROBICALLY TREATED LIVESTOCK AND MUNICIPAL WASTES,

Department of Agricultural Engineering, University of Illinois, Urbana-Champaign
D. L. Day and B. G. Harmon
Environmental Protection Agency Report EPA-660/2-74-041, Wastewater Use in the Production of Food and Fiber — Proceedings, Oklahoma City, March 5-7, 1974, p. 240-255. 3 fig, 11 tab, 27 ref.

Descriptors: Aerobic treatment, Nutrients, Feeds, Amino acids, Performance.
Identifiers: Refeeding, Oxidation ditch mixed liquor, Crude protein, Lysine.

This paper reviews some of the major projects of analyzing the amino-acid content of aerobically treated sewage and livestock wastes and of evaluating the product as a protein supplement in the diets of livestock. Although the amino-acid content is similar for aerobically treated municipal wastes and livestock wastes, extraneous materials can be more closely controlled in livestock wastes than in municipal sewage. A method developed at the University of Illinois in recent years utilizes oxidation-ditch mixed liquor (ODML) in situ, supplying drinking water as well as protein and other nutrients. Crude protein in the ODML varies from 30 to 46 percent, the latter value is as high as in soybean meal. Also lysine and other amino acids essential to growth can be as high in concentrated ODML as in soybean meal. This method avoids the ordinary expenses generally associated with recycling. It also offers 2 obvious advantages: minimizing pollution and realizing a new source of nutrients. The present costs of soybean meal make the method economically feasible and energetically attractive. However, a more efficient method of oxidation is needed. Even so, the aerobic process offers possibilities for a least-cost method of waste management that has several advantages over alternate methods. Obviously, the acceptance of the use of this monocellular protein product in the diets of livestock will require some explanation and education. (Day-University of Illinois; Merryman, ed.)

EFFECTS OF INTENSIVE APPLICATIONS OF LIVESTOCK MANURE ON SOIL AND CROPS,

Department of Agricultural Engineering, University of Minnesota
P. R. Goodrich, E. C. Miller, J. J. Boedicker, S. D. Evans, G. W. Randall, and A. E. Hanson .
1973 Minnesota Cattle Feeder's Report, 1973 Research Report B-193, Department of Animal Science, University of Minnesota, p. 99-115. 18 tab.

Descriptors: Crop response, Soil dynamics, Nutrients.
Identifiers: Land application, Application rates, Corn, Livestock wastes.

In the summer of 1970, an interdisciplinary project was initiated involving many agricultural scientists within the Institute of Agriculture, University of Minnesota. Cooperating in the project were personnel from the experiment stations at Cookston, Grand Rapids, Morris, Rosemount, and Waseca. Objectives of the main project were to investigate problems associated with: (1) The heavy annual application and incorporation of manure. (2) The downward movement of nutrients following the application of manure. (3) The capacity of land to serve as a disposal medium for manure. (4) The response of corn to manure applications. The manure rate study was implemented after information was gained from several pilot studies started in 1970. Annual applications of manure at 3 rates were made to soil cropped each year to corn. Results are given for the ongoing experiments which are taking place at the 5 experiment stations listed. (Merryman-East Central)

THAT MANURE PIT: IS IT A GOLDMINE?,

Managing Editor, Agricultural Engineering
M. Pratt
Agricultural Engineering, Vol. 56, No. 6, p. 19, June, 1975

Descriptors: Recycling, Liquid wastes, Fertilizers, Fuels, Methane, Nutrients, Economics, Cattle.
Identifiers: Oxidation ditch mixed liquor, Refeeding Swine, Dairy cattle.

Five experts discussed practical manure handling and utilization techniques at an open forum session moderated by WGN-TV farm service director Orion Samuelson. Jim Converse, University of Wisconsin, stressed the need to look at the net energy retrieved from a manure utilization system rather than to look at gross energy possibilities only. This may make such recycling into energy less attractive. While converting animal wastes into energy seems impractical now, when our fossil fuel supplies start to dwindle, it may become a viable alternative. Bill Kline, owner of Agrilabs, Inc. described his firm's program to sell deodorized liquid manure as a soil additive. There is even a possibility of shipping the liquid manure to developing nations in the tankers that bring petroleum to U.S. ports. John Eldon and Rodney Bisnich described the system used at Eldon Farms, where hogs in the finishing house are brought to market weight consuming liquid from their own wastes as their only water source. Eldon Farms presently recycles oxidation ditch mixed liquor to about 180 hogs of the 450 kept in the finishing house at one time. Don Jedele, University of Illinois, described the feedlot operation of Larsen & Taylor Feedlots in DeKalb County, Illinois, where manager Ray Larsen handles 1340 cattle at a time, with 2¼ herds a year — which adds up to about 2.5 million gallons of manure a year. This manure is spread on the land to utilize its fertilizer value. Larsen estimates the manure value as fertilizer is $9.56 per animal raised. At least 400 head would be required to justify the expense of the tankwagon and pump. Larsen figures 34 man-days are needed yearly in the spreading operation. (Merryman-East Central)

PLANNING LAND FOR REDUCTION OF NON-POINT SOURCES OF WATER POLLUTION,

Associate Professor, Agricultural Engineering Department, Purdue University, West Lafayette, Indiana 47907
R. Z. Wheaton
Presented at the 1976 Annual Meeting, American Society of Agricultural Engineers, University of Nebraska, June 27-30, Paper No. 76-2078, 6 p.

Descriptors: Legal aspects, Planning, Agricultural runoff, Economics.
Identifiers: Water Pollution control, Land planning, Non-point sources.

Planning to achieve land treatment is reviewed based on experiences resulting from a project in northeastern Indiana whose major objective was to reduce sediments and related pollutants in agricultural runoff for improvement in water quality. As a result of these experiences, the following conclusions were drawn: (1) Non-point pollution control will involve treating private land for public benefit. (2) Public information programs should be started early. (3) The public should be kept informed throughout all phases of planning. (4) Planning should be kept as close to the people as possible. (5) It is necessary to work through community leaders. (6) Planning to achieve adequate land treatment will require several times the technical assistance now available. (7) Some type of cost share and other incentive programs will be needed. (8) The planner must be flexible to adapt his technology to the needs. (9) Many practices will involve groups instead of individual land owners. (10) Acceptance of certain practices may be slow but once accepted, their application may proceed rapidly. (11) Some individuals who are reluctant at first may become willing cooperators after a year or two. (12) Demonstrations are effective selling tools. (13) A program for maintenance should be built into the plan. (14) The land owner must have assurances that he is in compliance regardless of the occurence of major hydrologic events. (15) Cost share and similar incentives will not achieve complete land treatment. (16) The goals must be practible, obtainable and at a cost that society is willing to pay. (Merryman-East Central)

SUCCESSFUL RECYCLING CALLS FOR COMBINATION OF GOOD MANAGEMENT, CARE AND PROCESSING OF WASTE,

Director of Engineering, Agpro, Inc.
D. J. Gribble
Beef, Vol. 12, No. 9, p. 32-35, May, 1976. 6 fig.

Descriptors: Recycling, Separation techniques, Solid wastes, Liquid wastes, Irrigation, Fertilizers, Economics, Performance.
Identifiers: Refeeding, Land disposal, Flushing.

Cattle waste reclamation has potential for solving several current pressing problems and for showing substantial return on the investment while doing it. A system that helps improve sanitation and cleanliness, reduces the labor required to clean up, store and dispose of manure, meets current and projected EPA requirements, and provides enough reclaimed feed to pay its own way, is certainly timely in light of current regulations and feed costs. An example of such a system may be found in a recent research study at the University of North Carolina where solids reclaimed from manure slurry were refed to Jersey steers in a ration consisting of one part reclaimed solids to two parts silage concentrate mix. The calves maintained an average gain of 1.9 pounds/day on the ration. The analysis of the total ration indicated the silage and concentrate mix could be expected to support an average daily gain of 0.8 pounds. The difference (1.1 pounds/day) was attributed to the presence of screened manure solids in the ration. It was found that remaining liquid wastes could be applied to croplands by means of sprinkler irrigation or could be reused as flush water within the livestock facility. (Merryman-East Central)

TOTAL WASTE HANDLING FROM 100 COWS IN FREE STALL,

Associate Professor, Agricultural Engineering Department, Cornell University, Ithaca, New York
R. W. Guest and W. W. Irish
Presented at the 1972 Annual Meeting, North Atlantic Region, American Society of Agricultural Engineers, University of Maryland, August 13-15, 1972, Paper No. NA72-402, 6 p. 1 fig.

Descriptors: Dairy industry, Management, Liquid wastes, Solid wastes, Waste storage, Waste disposal.
Identifiers: Land spreading, Waste collection.

Basic components of waste handling systems are collection, transfer, storage, processing and disposal. Basic criteria for dairy waste management are: (1) All waste must be removed from dairy housing units daily. (2) Spreading during the snow season and intense rainy periods should be minimal. (3) Interference with peak labor periods should be minimal, (4) Labor must be minimized (Automation maximized). (5) Waste utilization by crops should be maximized. (6) Air and water pollution must be minimal. (7) Conservation of water should be practiced. A dual system with liquid and dry waste handling is proposed and alternative management methods are given. (Merryman-East Central)

"SINK" "ZIG-ZAG WATERWAY" FOR FEEDLOT RUNOFF CONTROL,

Nebraska Farmer, Vol. 117, No. 13, p. 29, July 5, 1975.

Descriptors: Agricultural runoffs, Feedlots, Water pollution, Nebraska.
Identifiers: Runoff control, Field sink, Switchback waterway, Debris basin.

Three U.S. Department of Agriculture, Agricultural Research Service Engineers at the University of Nebraska have come up with 2 systems for handling feedlot runoff without holding ponds. One is the "field sink", a flat disposal area adjacent to the feedlot, where the sink can remain under cultivation. This system, which is being tried at a feedlot near Springfield, Nebraska, is 160 by 325 feet, an area about 85 percent as large as the feedlot from which the runoff is received. The runoff is first accumulated in a debris basin in the feedlot with many of the solids settling out in the basin as the liquid flows out through an intake riser and into a buried tile line. The other system is the "switchback waterway", a zig-zagging grassed waterway with a gradual grade, providing a long runoff flow-route within a small area. This system is being tested at a 3-acre feedlot near Gretna, Nebraska. Runoff from the feedlot first passes through debris basins before entering the serpentine grassed waterway. Within an area that separates the feedlot and a stream by a distance of about 400 feet, this meandering waterway with its 8 hairpin turns carries runoff over a 2,600-foot route. It is estimated that the waterway will control feedlot runoff during about 80 percent of the rainstorms in Eastern Nebraska. (Rowe-East Central)

USE OF POULTRY MANURES IN STEER FINISHING RATIONS,

Director of Feed Research, Gold Kist Research Farm, Talmo, Georgia
A. E. Cullison, H. C. McCampbell, A. C. Cunningham, R. S. Lowrey, E. P. Warren, B. D. McLendon, and D. H. Sherwood
Journal of Animal Science, Vol. 42, No. 1, p. 219-228, January, 1976. 8 tab, 16 ref.

Descriptors: Performance, Recycling.
Identifiers: Refeeding, Poultry wastes, Steer finishing rations, Crude protein.

Two feeding trials involving 70 and 110 steers, respectively, were carried out. The first trial was to study the use of different levels of pure dried broiler excreta as a protein source in steer rations. The second trial was conducted to compare broiler manure with a wood shavings base, broiler manure with a peanut hulls base and dried layer hen manure as steer ration components. The dried broiler excreta contained 34.5 percent crude protein (dry basis). The other 3 diets contained, in respective order, 22.5, 24.9, and 40.4 percent crude protein. When dried broiler excreta was fed to provide either one-half or all of the supplemental protein in steer finishing rations, weight gains were not significantly different from those obtained with the control ration; however, there was a tendency for daily weight gains to decrease as the level of broiler excreta in the ration increased. Steers receiving 20 percent broiler manure/wood shavings and 2 percent cane molasses in place of the control ration (containing 12.5 percent peanut hulls and 1.5 percent minerals) performed in every parameter studied, including taste panel evaluations, as well as or better than steers on the control ration. In a similar experiment, broiler manure/peanut hulls did not give a comparable performance until additional roughage was provided. Rations containing dried caged layer hen manure yielded lower rates of gain than rations containing broiler manure. Steers receiving a negative control ration containing no protein supplement were found to gain faster than steers receiving supplemental protein in the form of dried hen manure. (Rowe-East Central)

SAMPLING PROCEDURES FOR NITROGEN AND PHOSPHORUS IN RUNOFF,

Soil Scientists, U. S. Department of Agriculture, Columbia, Missouri
R. E. Burwell, G. E. Schuman, R. F. Priest, W. E. Larson, and E. E. Alberts
Transactions of the ASAE, Vol. 18, No. 5, p. 913-917, 1975. 2 fig, 5 tab, 10 ref.

Descriptors: Agricultural runoff, Sampling, Nitrogen, Phosphorus.
Identifiers: Storm nutrient discharges.

Surface runoff data collected from 2 corn-cropped watersheds in southwestern Iowa during a 5-year period were analyzed to evaluate sampling methods needed to determine storm discharges of NO_3-N, NH_4-N, inorganic P, sediment N (total kjeldahl N) and sediment P ($NaHCO_3$-extractable P). Three methods of averaging sample nutrient concentrations were described for calculating storm nutrient discharges, and these were compared with a standard integrated method. The arithmetic mean of nutrient concentrations for samples collected during major runoff multiplied by the quantity of water or sediment was superior to the all-sample mean and the three-sample methods for determining NO_3-N, and $NaHCO_3$-extractable P discharges. The three-sample mean method of calculation which involved only 3 samples collected at runoff rates greater than 0.28 m^3/sec (24 percent of total samples collected) was more favorable than the all-sample mean method for determining storm discharges of NO_3-N, NH_4-N, and sediment N. The three-sample mean method would probably give satisfactory accuracy for most surveys, with savings in field work and laboratory time. A storm-to-storm decrease of NO_3-N concentration was observed, indicating that each storm should be sampled or an accounting made for this decrease to quantify cropping season discharges of NO_3-N. Since this storm-to-storm effect was not evident for NH_4-N inorganic P, sediment N, and sediment P, sampling of each event would not be required for these parameters. Unsampled events could be estimated. (Rowe-East Central)

PIPELINE TRANSPORT OF LIVESTOCK WASTE SLURRIES,

Agricultural Research Service, USDA, Department of Agricultural Engineering, Cornell University, Ithaca, New York 14853
Y. R. Chen, and A. G. Hashimoto
Presented at the 1975 Winter Meeting, American Society of Agricultural Engineers, Chicago, Illinois, Dec. 15-18, 1975, Paper No. 75-4552, 19 p. 6 fig, 1 tab, 16 ref.

Descriptors: Slurries, Pipelines, Equations, Design, Density.
Identifiers: Rheological data, Livestock wastes, Total solids.

The friction coefficient for pipeline flow of livestock waste slurries was correlated to the generalized Reynolds number (N'_{Re}). The rheological property indicates K' and n', of the slurry were from the capillary viscometer. In the laminar flow region, the experimental results closely follow $f = 16/N'_{Re}$. For livestock waste slurries, the laminar flow region ended at $N'_{Re} \cong 3100$ and the fully developed turbulent region began at $N'_{Re} \cong 4300$. The f - N'_{Re} correlation for livestock waste slurries with $4300 < N'_{Re} < 10^5$ was $f = 0.0306\ (N'_{Re})^{-0.18}$. It was also found that the rheological data from rotational viscometer were useful in calculating N'_{Re}. For the slurry with low solids concentration and low flow rates, the solid particles could settle in the pipe. This could greatly increase the friction coefficient. It was found that the slurry density depended linearly on its solids concentration, for less than 10 percent total solids concentration. (Rowe-East Central)

TWENTY-EIGHT PERCENT SAFE PROTEIN FROM BROILER LITTER,

R. Whipple
Broiler Industry, Vol. 34, No. 1, p. 38, 42-43, January, 1971.

Descriptors: Recycling, Diets, Proteins, Nutrients, Fertilizers, Cattle, Feedlots, Public health, Safety.
Identifiers: Refeeding, Broiler litter, Cattle wastes, Turkeys, Swine.

Research is being conducted at Busse-Hillstrom Research Farm at Cokato, Minneapolis, in which poultry litter is ensiled and refed to cattle and cattle manure is composted and refed to hogs. The poultry litter (wood shavings plus turkey broiler excreta) is ensiled in a sealed silo. After ensiling, the product is found to have 28 percent protein, 30 percent moisture, 36 percent fiber, 2 percent fat, 8½ percent ash and 1 percent phosphorus. The ensiled litter is fed to steers at a ratio of two-thirds poultry silage, one-third high moisture corn, plus a mineral supplement. The mineral supplement contains dicalcium phosphate, a trace of mineralized salt, and vitamins A and D. Wastes from the steers then go through a separation process in which solids are composted for a year for refeeding to hogs and the liquids are forwarded to a storage well for use on fields as fertilizer. Thus far, the refeeding of the poultry and cattle wastes has been found entirely safe. The elimination of a drying process for the wastes eliminates packaging, storage, and handling costs, thus increasing the economic benefits of such recycling. (Rowe-East Central)

URINE AND FECES EFFECT ON NH_3 AND ODORS FROM BOVINE WASTE,

Department of Animal Science, University of Hawaii, Honolulu, Hawaii 96822
R. O. Kellems, D. C. Church, and J. R. Miner
Proceedings, Western Section, American Society of Animal Science, Vol. 27, 1976, 3 p. 4 tab.

Descriptors: Odor, Ammonia, Urine, Sampling.
Identifiers: Feces, Cattle wastes, Olfactory panel.

Experiments were conducted to evaluate: (1) the relationship between ammonia generation rates and objectionable odors and (2) the effect of urine, feces, and length of storage on ammonia production from bovine waste. Feces and urine samples were collected from 5 Holstein heifers that were fed a ration of 25 percent barley and 75 percent alfalfa hay. From the composite samples of urine and feces, the following samples were prepared: 100 g urine, 50 g feces + 50 g water, 50 g feces + 50 g urine, and 25 g feces + 75 g water. The samples were incubated at 30°C for 24 hours prior to being evaluated by an olfactory panel. Rates of ammonia release for each of the various samples were determined prior to presentation to the olfactory panel. The initial numerical rating and ranking values for relative offensiveness were not found to be noticeably different for the samples evaluated. This would indicate that the relative portions of feces, urine, and water have little effect upon the initial release of odoriferous compounds. A negative correlation for the fecal content and a positive correlation for urine with respect to ranking were observed. Ammonia release rates were positively correlated with urine content of the samples. The water and fecal content were negatively correlated with the initial release of ammonia. Samples containing urine generated more ammonia than samples containing only feces and water. In a second experiment, fresh feces and urine were collected from Holstein heifers fed 25 percent barley and 75 percent alfalfa hay. Samples prepared from the composite samples of feces and urine were: 100 percent feces, 100 percent urine, 50 percent feces + 50 percent urine, 75 percent feces + 25 percent urine, 75 percent feces + 25 percent water, 50 percent feces +50 percent water, 25 percent feces +75 percent water, and 5 percent feces +95 percent water. The samples were maintained in a water bath at 30°C for 25 days. Ammonia evolution rates of the samples were determined. Urine was found to be primarily responsible for the initial release of ammonia. Feces had little effect. (Rowe-East Central)

3510 - A8, B2, E2
NEW IRRIGATION SYSTEM MAY ELIMINATE PROBLEM OF LIVESTOCK WASTE DISPOSAL,

Beef, Vol. 13, No. 3, p. 12, 14-15, November, 1976. 2 fig.

Descriptors: Irrigation, Equipment, Design, Economics, Costs, Slurries, Fertilizers, Liquid wastes.
Identifiers: Land application.

Valmont Industries has come up with a new livestock waste irrigation system which alleviates past problems of clogged lines and nozzles and uneven distribution. Their new irrigation system utilizes a one wheel-and-support unit with a boom that is only 185 feet long. When the boom rotates, it covers a 10-acre area with liquid manure. The waste system has far more capacity than is needed by most operations for just manure handling. The leftover capacity may be used to provide standby and supplemental irrigation — a practice which can pay big dividends even in the usually-moist Cornbelt. The unit will cost between $9,000 and $10,000. To that must be added the cost of a gas-driven power generator, plus the cost of pipe and the pump. Purdue Agricultural engineer John Nye estimates that the system takes about one man-hour per 10 acres to handle the center pivot. Besides reduction in labor, two other advantages of the system are that manure may be spread in any weather and the system may be used to apply irrigation water on top of the spread slurries to carry the fertilizer down into the ground. Nye does not recommend applying the wastes to growing crops. (Merryman-East Central)

PROCESS FEASIBILITY STUDY: THE ANAEROBIC DIGESTION OF DAIRY COW MANURE AT THE STATE REFORMATORY HONOR FARM, MONROE, WASHINGTON,

Ecotope Group (Research Consultants)
Process Feasibility Study: The Anaerobic Digestion of Dairy Cow Manure at the State Reformatory Honor Farm, Monroe, Washington, Ecotope Group, January, 1975, 119 p. 25 fig, 23 ref, 6 appendices.

Descriptors: Feasibility studies, Anaerobic digestion, Recycling, Costs, Washington, Gases, Fertilizers, Fuels, Design, Confinement pens, Management.
Identifiers: Dairy manure.

A feasibility study has been completed. Manure from 350 cattle units (one cattle unit=1000 pound animal) dairy operation will be scraped from loafing shed and deposited into the digestor to produce a combustible gas and ammoniated nitrogen fertilizer. Digestor tanks will be an existing product which can be purchased at a reasonable cost. Digestion technique will utilize high rate gas recirculation mixing. Net production (after heating needs) of bio-gas (600BTU/cu ft) was estimated to be 7500 to 9500 cu. ft./day in cold and warm seasons respectively. Bio-gas will be used to reduce consumption of #2 fuel oil. BTU replacement savings is estimated to be $4488.00/year. Fertilizer earnings are based on transformation of organically bound nitrogen to the ammoniated form. This was estimated to be 8 tons/year for earnings of $6344.00/year to reduce consumption of ammoniated nitrogen fertilizer. Total direct cost of system was estimated to be $56,700.00. Evaluation of scale of project shows the amortized cost per cattle unit is near the break-even point for investment payback from bio-gas earnings alone. (Ecotope Group)

WASTE WATER IRRIGATION,

Feedlot Management
Lamp, staff editor
Feedlot Management, Vol. 18, No. 8, p. 7-8, 10, 13, 14, August, 1976. 5 fig.

Descriptors: Agricultural runoff, Water pollution, Feedlots, Grants, Irrigation, Liquid wastes, Crop response, Fertilizers.
Identifiers: Runoff control, Holding ponds. Debris basins, Land application.

L. P. Schram Feedlot, Inc., Papillion, Nebraska, was thought to pose a threat to the purity of Walnut Creek which runs through the feedlot. Consequently, an Environmental Protection Agency grant was established in which the Environmental Protection Agency picked up 70 percent of the bill and Schram paid the other 30 percent in instigating a system to solve the problem. With the assistance of personnel from the University of Nebraska, the Agricultural Research Service and the Soil Conservation Service, a system was developed for runoff control. In the system that was developed, ten debris basins were located at the base of the feedlot pens to catch the initial runoff. A small orifice inside each riser screened out sediments from the liquids, allowing them to flow into holding ponds via underground PVC tiles. From the holding ponds, the liquid manure was fed into a center pivot irrigation system for disposal on croplands. Optimal disposal times were found to be prior to planting or after the crops were up 4-6 inches. This posed the problem of maintaining runoff holding capacity for a 10-year, 24-hour storm, but avoiding applying runoff to crops when they were vulnerable. Other problems that occurred were plugging of the orifices in the risers and deepening of the debris basins within the feedlot caused by cattle walking through them. Also, one year, a steer lay down on ice covering a debris basin. The ice melted and the steer drowned. While the system may not be problem free, at least it permits Mr. Schram to stay in business. (Merryman-East Central)

WHAT'S MANURE WORTH?,

Successful Farming, Vol. 74, No. 11, p. 28-29, 47, October, 1976. 3 fig. 1 tab.

Descriptors: Nutrients, Chemical analysis, Economics, Costs.
Identifiers: Livestock wastes.

Successful Farming cautions against taking anyone else's figures in trying to figure out how much nutrient value is in livestock wastes for any particular feedlot. While livestock wastes have a monetary value, they also have wide variability in their nutrient content. This was exemplified by a study in which Successful Farming compared nitrogen, phosphorus, potassium, and percent solids in manure samples from 6 different farms. To get a good average sample, the lagoon or pit from which the sample is drawn should be agitated long enough to get all solids in suspension. The sample can be personally delivered to a laboratory for examination or it can be delivered by mail (preferably well-packed in a plastic container). Cost of securing such lab analysis varies. Labs checked by Successful Farming ranged from $12 to $22. Laboratories which provide such analysis are listed. (Merryman-East Central)

SOLVING THE FARM WASTE PROBLEM,

Veterinary Record, Vol. 95, No. 17, p. 399, 1974.

Descriptors: Waste treatment, Waste disposal, Diseases, Solid wastes, Liquid wastes, Slurries, Fertilizers, Recycling.
Identifiers: Carcass disposal.

At a meeting held by the British Veterinary Association Congress on September 18, 1974, Mr. A. F. Baldry reported on traditional methods of waste disposal, on the factors affecting choice of waste disposal systems, and on the transfer of disease by animal wastes. He stated that use of liquid slurry systems is on the increase and offers advantages of saving labor costs, reducing straw costs, and eliminating "mucking out". Factors affecting choice of a waste disposal system are: size of the enterprise, housing and feeding systems, type of land, annual rainfall, cropping policy, the possibility of water course pollution, health hazards, capital and running costs, labor requirements, nuisance value of odor, pipe moving in cold weather, and legal aspects. After discussing methods of disposal and treatment, Mr. Baldry went into the question of diseases which might be transferred by slurry, namely, salmonellosis, tetanus, anthrax, Q fever, Johne's disease, viral diseases, parasitic diseases, brucellosis, tuberculosis, leptospira and metabolic disorders. Most study has been done on the spread of salmonellosis. The case for the spreading of viruses has not been proved and requires more investigation. Mr. Baldry also discussed slurry as a fertilizer, slurry as a source of energy, manure as a feed, silage effluent, and carcass disposal. (Merryman-East Central)

AGRICULTURAL WASTES AND ENVIRONMENTAL POLLUTION,

Chief Soil Chemist, Soil and Water Conservation Research Division, U. S. Department of Agriculture, Beltsville, Maryland
J. Lunin
Advances in Environmental Science and Technology, Vol. 2, New York, Wiley, 1971, p. 215-261. 91 ref.

Descriptors: Pollution, Technology, Agricultural runoff, Erosion, Fertilizers, Insecticides, Herbicides, Salts, Minerals, Phosphorus, Nitrogen, Watersheds, Sediments, Salts, Minerals.
Identifiers: Pollution control, Livestock wastes.

We have adopted more intensified systems of livestock production, increased our use of agricultural chemicals, and expanded mechanization at a rapid rate, but only in recent years have we given consideration to the impact of this technology on environmental quality. Consequently, research to date has neither enabled us to assess adequately the effect of agricultural wastes on overall environmental quality nor to efficiently develop or modify technology to minimize pollution hazards. It is necessary to identify, quantify, and evaluate the significance of agricultural wastes in environmental pollution before efficient management practices can be developed for control and abatement. We need specific definitions of what constitutes a hazard in soils, water, plants, animals, or air from the various agricultural sources. Once criteria are established, management practices can be developed to achieve desired levels of pollution control and abatement. Existing management practices may be improved and new ones developed. Many problems can be solved by curbing runoff and soil loss. Existing erosion control practices, if universally adopted, would be quite effective, but these must be constantly modified to meet intensification of agricultural operations. Technology is needed for increasing fertilizer use efficiency. New technology is needed for safer and more economic disposal of animal wastes. Alternatives for use of persistent insecticides are being investigated. Use of herbicides will increase and new compounds developed must be evaluated for safety. New and improved methods for pesticides applications would help decrease pollution hazards. (Merryman-East Central)

PUMPING, MIXING, AND FLOW CHARACTERISTICS OF ANIMAL WASTES,

Agricultural Engineering Department, The University of Tennessee, Knoxville
J. I. Sewell, H. D. Bartlett and R. J. Smith
Presented at the 1974 Winter Meeting, American Society of Agricultural Engineers, Chicago, Illinois, December, 1974, Paper No. 74-4542, 14 p. 6 fig, 11 ref.

Descriptors: Liquid wastes, Slurries, Pumping, Mixing, Flow characteristics, Management, Design, Recycling, Irrigation, Equipment, Cattle, Poultry, Separation techniques.
Identifiers: Flushing, Agitation, Swine.

Equipment and procedures for pumping and mixing liquid slurries of dairy, beef, swine and poultry manure are reported by 3 different authors representing the University of Tennessee, Pennsylvania State University, and Iowa State University. Topics under study by the University of Tennessee include: agitation and slurry irrigation of animal wastes, flow characteristics of poultry wastes, agitation of liquid beef wastes, agitation of liquid dairy wastes, and a liquid swine waste system. Pennsylvania State University is studying manure slurry pumping. Under study are: manure pit pumps, manure irrigation pumps, extrusion pumping, and solids-liquid separation. Iowa State University is studying liquid swine waste management. Under study are: recycling of lagoon liquor, coarse screening of lagoon liquors, hydraulic handling of poultry wastes, dewatering lagoons by pumping, and slurries flowing by gravity in pipes. Performance of the systems and design changes are discussed. (Rowe-East Central)

RHEOLOGY OF AERATED LIVESTOCK WASTE SLURRIES,

Agricultural Research Service, U.S. Department of Agriculture, Department of Agricultural Engineering, Cornell University, Ithaca, New York 14853
A. G. Hashimoto and Y. R. Chen
Presented at the 1975 Annual Meeting, American Society of Agricultural Engineers, University of California, Davis, June 22-25, 1975, Paper No. 75-4038, 12 p. 6 fig, 9 ref.

Descriptors: Rheology, Slurries, Pumping, Mixing, Aeration, Equations, Centrifugation.

The objectives of this study were: (1) to identify a parameter that would mathematically describe the rheological properties of aerated dairy, poultry and swine waste slurries and that could be easily and precisely measured experimentally; and (2) to describe procedures to estimate the effect of rheological properties on pumping, mixing, and aerating livestock waste slurries. The study showed that the rheological consistency index (K) and rheological behavior index (n) of livestock waste slurries can be expressed in terms of the equilibrium sludge volume fraction (Φ_L) as: $K = b_1 \Phi_L^{b_2}$ and $n = b_3 + b_4 \ln \Phi_L$ where b_1 to b_4 are constants. Values of b_1 and b_4 were determined for aerated dairy, poultry and swine waste slurries, and were found to be different depending on whether ΦL was greater or less than 20 percent. The relationships between K and n to the effective viscosity (μe) and generalized Reynolds number ($N_{Re'}$) were described along with the effect of μe and $N_{Re'}$ on mixer power characteristics, oxygen transfer efficiency and pressure head loss in pipeline transport of slurries. Also described was a centrifugation method to determine ΦL. This method is more precise, less time consuming, simpler and applicable over a wider total solids range than the previously reported quiescent settling method. (Rowe-East Central)

USING CATTLE FEEDLOT MANURE TO CONTROL WIND EROSION,

Agricultural Research Service, U. S. Department of Agriculture, Manhattan, Kansas 66506
N. P. Woodruff, L. Lyles, J. D. Dickerson, and D. V. Armbrust
Journal of Soil and Water Conservation, p. 127-129, May-June, 1974. 2 fig, 2 tab.

Descriptors: Wind erosion, Equations, Weathering.
Identifiers: Erosion control, Surface-applied manure, Tilled-in manure, Anchored wheat straw.

The effectiveness of surface-applied and tilled-in cattle feedlot manure was compared with that of anchored wheat straw in controlling wind erosion. Feedlot waste containing 66 percent water was obtained from Kansas State University beef-cattle research feedlots and applied to plots at 4 rates (2, 5, 10, and 15 tons/acre, wet-weight) for surface-applied manure and 3 rates — 15, 30, and 60 tons/acre of manure disked into the soil. Except for the 2-ton surface manure, all treatments significantly lowered soil loss 2 days after application, and the 30 and 60 tons of tilled manure, the 15 tons of surface-applied manure, and all straw treatments were significantly more effective than were the 2- and 10-ton surface-applied and 15-ton tilled-manure treatments. The data indicated that at least 15 tons/acre of surface-applied manure and 30 tons/acre of tilled manure were required to reduce soil loss to less than a half ton/acre. This was 88 percent reduction from no-treatment, and it approached the 92 percent reduction attained with a half ton/acre of anchored straw. Equations were developed for use in designing wind erosion control practices. Curves were drawn for converting different amounts of surface-applied and tilled-in manure to their flat, small-grain wind erosion control equivalents. Overwinter weathering losses of surface-applied manure averaged 50 percent; tilled-in manure losses averaged 40 percent. (Rowe-East Central)

RUNOFF CONTROL SYSTEMS FOR OPEN LIVESTOCK FEEDLOTS,

Extension Agricultural Engineer, Purdue University
J. C. Nye, D. D. Jones, and A. L. Sutton
Publication No. ID-114 (1976), Cooperative Extension Service, Purdue University, 1976. 8 p. 8 fig, 3 tab.

Descriptors: Agricultural runoff, Feedlots, Design, Settling basins, Infiltration, Indiana, Waste storage, Soils.
Identifiers: Runoff control, Holding ponds.

Runoff control can be accomplished on almost all livestock farms with settling basins, infiltration areas, or holding ponds. The size and type of components that are used can vary. This study has presented the basic design information needed to develop an effective system of runoff controls. To design a settling basins and infiltration channel area of the feedlot the soil type must be known. The settling basin is designed for the runoff from the 1-year, 1-hour storm which is 1.2 inches over most of Indiana. The infiltration area is designed to absorb the runoff from the 25-year, 48-hour storm which is 5.5 inches over most of Indiana. The holding pond cannot be emptied. The settling basin is designed to slow the runoff and allow the larger manure solids to settle. The runoff should be held in the basin for 15 to 30 minutes. The surface area of the basin is found by dividing the feedlot runoff rate by 4 cubic feet/hour/square foot. A surface settling rate of 4 cubic feet/hour/square foot has been found to be effective for settling the solids from feedlot runoff. The depth of the settling basin depends on how the basin is emptied. If liquid manure handling equipment is available, a wier notch would be used as the overflow. If the settling solids are to be handled with conventional solid manure handling equipment, a porous dam can be constructed of 2 x 6 lumber with a 1½" spacing between boards. The length of the dam should be about 2 feet. If long term storage of the settled solids is needed, surface area of the basin should be enlarged. If the settled solids will be handled with liquid manure equipment, the basin can be deeper than 2 feet. If a manure tanker will be driven next to the basin, the vertical sidewalls should be reinforced. (Rowe-East Central)

SALMONELLOSIS IN CATTLE,

Veterinary Investigation Officer in charge of the Ministry's Veterinary Investigation Centre at Norwich, England
E. A. Gibson
Agriculture, Vol. 73, p. 213-216, 1966.

Descriptors: Salmonella, Cattle, Pathogenic bacteria, Treatment.
Identifiers: Great Britain, Salmonella dublin, Salmonella typhimurium, Clinical signs, Diagnosis.

Of the many types of salmonella which have been found in cattle, only 2 have been discovered in Great Britain to be of practical day-to-day importance — Salmonella dublin and Salmonella typhimurium. These 2 organisms behave quite differently. Though occasionally found in other animals, S. dublin is essentially a pathogen of cattle. S. typhimurium seems able to infect practically all species of birds and animals — and man with equal facility. While S. dublin seems to establish itself in certain geographical areas, S. typhimurium infection occurs in adult cattle throughout Britain. The 2 infections produce similar clinical signs in adult cattle — dullness, lack of appetite, high temperature, and profuse diarrhea with fluid feces that may contain mucus and blood. Both infections can produce a 'carrier' state for spreading the infection, but S. typhimurium is usually "carried" for a much shorter time. Prevention of the infection may be achieved by use of a vaccine that has been developed against S. dublin. The vaccine also helps prevent S. typhimurium infection. Certain management practices also may be employed, including placement of newly-purchased calves into clean, disinfected, isolated premises upon arrival to the feedlot. If salmonellosis is suspected in a batch of calves, diagnosis and treatment are, of course, matters for the veterinary surgeon, especially as laboratory examinations may be necessary to confirm the diagnosis and to test the sensitivity of the organism to various drugs and antibiotics. RENAL FUNCTION CHANGES IN LAYING HENS FED ON DRIED POULTRY MANURE,

Agricultural Research Council's Poultry Research Centre, King's Buildings, West Mains Road, Edinburgh 3H9 3FS, Scotland
L. Martindale and D. J. W. Lee
British Poultry Science, Vol. 17, No. 2, p. 195-197, March, 1976.

Descriptors: Poultry, Diets, Chemical properties, Performance.
Identifiers: Dried poultry manure, Renal function, Refeeding.

Three groups of 8 laying hens of the Warren-SSL strain were housed individually in battery cages with food and water supplied ad libitum. The hens, which had been fed on diets containing 0, 10 or 20 percent DPM for one year from point-of-lay, were allowed to continue on the same diets. The diets were made up on a least-cost-basis to contain DPM, 0, 100, and 200 g/kg; metabolisable energy 11·30, 10·38, and 11·46 MJ/kg; crude protein 163, 157 and 151 g/kg respectively, the true protein content of the DPM being used in the formulation of the diets. Renal function was studied in each bird after overnight fasting and, whenever possible, immediately after oviposition. Birds fed on 20 percent DPM showed increased rates of effective renal plasma flow and increased renal tubular secretion of urate during the infusion of large amounts of urate. Renal hypertrophy was not detected in any group. (Edwards-East Central)

METHANE GAS PRODUCTION FROM ANIMAL WASTES,

Department of Agricultural Engineering, University of Manitoba, Canada
H. M. Lapp, D. D. Schulte, and L. C. Buchanan
Publication 1528, Canada Department of Agriculture, 1974, 9 p. 1 fig.

Descriptors: Recycling, Methane, Anaerobic digestion, Canada, Design.

A dual-stage digestion system was installed at Glenlea Research Station, University of Manitoba in 1973. The system consists of 2 fiberglass septic tanks, 8 feet in diameter and 10 feet high, equipped with mechanical stirrers and internal hot water coils (35°C). These tanks hold 5.13m^2 slurry which is fed at 1.6 g VS/1/day with 20 day detention. The digesters yield gas of 60-69 percent methane, but fall below the expectations of 7 cu ft/day/hog. Pilot plant operational studies are continuing at the University of Manitoba to evaluate the technical and economic feasibility of producing methane from animal wastes by anaerobic digestion under Canadian climatic conditions. UTILIZATION OF DRIED POULTRY WASTE IN CHICK STARTER RATIONS,

Department of Poultry Science, University of British Columbia, Vancouver, British Columbia V6T 1W5 Canada
P. Stapleton and J. Biely
Canadian Journal of Animal Science, Vol. 55, p. 595-607, December, 1975. 2 fig, 13 tab, 21 ref.

Descriptors: Rations, Performance, Poultry, Feed additive, Nutrients.
Identifiers: Dried poultry waste, Refeeding, Lysine, Methionine.

Dried poultry waste (DPW) from chicks fed a basal diet was formulated in chick starter rations, based on its chemical analysis, to ensure that all rations were equal in their true protein, fiber, calcium, phosphorus, and estimated caloric content. At 4 weeks of age, chicks fed rations containing 20 percent recycled DPW averaged 10 percent less weight than control chicks. Feed efficiency was found to decrease as DPW was refed. The addition of 20 percent lysine and 20 percent methionine increased the weights of chicks and improved feed efficiency by 6 percent when added to the DPW and control rations. The only important chemical changes that occurred in DPW recycled 5 times was the increase in fat level from 3.04 to 9.6 percent and the decrease in calcium and phosphorus levels from 1.94 and 1.88 percent to 0.88 and 1.10 percent, respectively. Amino acid composition remained the same. Twenty percent DPW rations elevated plasma uric acid levels to 5.7 mg percent, but no relationship between body weights and plasma uric acid was found. The mineral composition of the tibia of chicks was not affected by either the protein level or DPW in the ration. On the basis of results of the feeding trials and of the chemical analyses conducted, one cannot attribute the growth depressing effect of dietary DPW to a single factor. The lowered body weights may be due to a combination of factors or to a substance not revealed by the present analyses. Study results clearly indicate the need for further investigation of the nutritive and economical values of DPW in poultry rations. (Merryman-East Central)

SOIL INGESTION BY CATTLE ON SEMIARID RANGE AS REFLECTED BY TITANIUM ANALYSIS OF FECES,

Soil scientist, Snake River Conservation Research Center, Kimberly, Idaho 83341
H. F. Mayland, A. R. Florence, R. C. Rosenau, V. A. Lazar, and H. A. Turner
Journal of Range Management, Vol. 28, No. 6, p. 448-452, November, 1975. 5 fig, 1 tab, 8 ref.

Descriptors: Grazing, Cattle, Titanium, Analysis.
Identifiers: Soil ingestion, Feces.

Soil ingestion was determined for cattle grazing a Bromus tectorum range in southern Idaho by measuring titanium concentrations in animal feces collected at 2-week intervals during the droughty 1973 grazing season. The experiment was based on the premise that titanium, which is abundant in soils, is contained only in small quantities (less than 1 ppm) in plants not contaminated with soil. Soil attached to aboveground plant parts did not seem to contribute much to fecal soil concentrations in the study. Fecal-soil concentrations in excess of 2 percent probably originated from soil adhering to ingested stem bases and roots or from direct soil ingestion. Fecal-soil concentrations ranged from 3 to 30 percent during the droughty 1973 season and generally increased as the amount of available forage decreased. Muddying of forage was definitely not a contributing factor in the Idaho study since soils remained dry during the July to November period. It was felt that fecal-soil concentrations in this study were probably related to closeness of grazing, forage availability, and shallow rooted plants. Cattle easily pulled the shallow-rooted cheatgeass plants from the dry silty soils along with portions of roots and attached soil. It was felt that soil ingestion may be important in considering the uptake of such toxic elements as cadmium, lead, mercury, pesticides and radionucleides, which are concentrated in the upper few centimeters of soil. (Rowe-East Central)

EFFECTS OF SOLID AND LIQUID BEEF FEEDLOT WASTES ON SOIL CHARACTERISTICS AND ON GROWTH AND COMPOSITION OF CORN FORAGE,

G. Wallingford
Ph.D. Dissertation, Department of Agronomy, Kansas State University, 1974, 293 p. 44 fig, 27 tab, 38 ref.

Descriptors: Solid wastes, Liquid wastes, Feedlots, Crop response, Corn, Salinity, Nitrogen, Water pollution, Groundwater pollution.
Identifiers: Land disposal, Loading rates.

A research project was begun in the fall of 1969 to study the effects of solid and liquid beef feedlot wastes on soil properties and plant growth. Corn was the crop chosen for study due to the large acreage of corn growth in the study area and because of its large yield and nutrient recycling potential. Beef-feedlot manure and lagoon water were shown to improve soil productivity when applied at rates that do not greatly exceed the capacity of the growing crop to remove nutrients contained in the wastes. Large amounts of either the solid or liquid materials retard corn growth. Salt buildup on the soil was thought responsible for the retardation. Electrical conductivity measurement of surface soil saturation extracts was found a reliable method to monitor salt accumulation. Loading rates based on salt content should not be used on a long-term basis because excess nitrogen will be lost out of the soil profile as nitrate nitrogen. Loading rates based on nitrogen content can be made on a long-term basis and are the most practical in conserving nitrogen and protecting the quality of groundwater and surface waters. (Rowe-East Central)

EFFECTS OF FERTILIZER, BARNYARD MANURE, AND CROP RESIDUES ON IRRIGATED CROP YIELDS AND SOIL CHEMICAL PROPERTIES,

Research Station, Agriculture Canada, Lethbridge, Alberta T1J4B1
S. Dubetz, G. C. Kozub, and J. F. Dormaar
Canadian Journal of Soil Science, Vol. 55, No. 4, p. 481-490, November, 1975. 1 fig, 3 tab, 19 ref.

Descriptors: Fertilizers, Crop response, Soils, Chemical properties, Irrigation.
Identifiers: Barnyard manure, Crop residue.

Barnyard manure, N fertilizer, and crop residues (corn stovers and sugar beet tops) were incorporated into a Dark Brown Chernozemic soil singly and in combination in an irrigated four-course rotation (sweet corn, soft spring wheat, sugar beets, and sugar beets) that completed four cycles. Manure application at 27 t/ha every 4 years increased organic matter, nitrogen, phosphorus, and potassium of the soil and resulted in a 31 percent increase in the last-cycle yields of first-year sugar beets. When 66 kg N/ha were combined with the manure, the yields of first-year beets were increased 53 percent. Responses by second-year sugar beets were smaller. Each ton of manure used in the last 3 cycles of the experiment resulted in an average yield increase of 422 kg of sugar beets. Each application of 66 kg N/ha, as used in the last 3 cycles of the experiment, resulted in an average annual increase of 1.5 tons of sugar beets. The N fertilizer also increased the yields of corn during the third and fourth cycles, but corn did not respond to manure alone. The fertility treatments dd did not increase wheat yields. Incorporating sugar beet tops or corn stovers into the soil increased beet and corn yields but not wheat yields. The yields of sugar beets responded more to the residue treatments when grown without manure or N fertilizer than when the fertility treatments were included. (Merryman-East Central)

NUTRITIVE VALUE OF A SAMPLE OF DRIED POULTRY MANURE FOR THE LAYING HEN,

Agricultural Research Council's Poultry Research Centre, King's Buildings, West Mains Road, Edinburgh EH9 3FS, Scotland
J. M. McNab, D. W. F. Shannon, and R. Blair
British Poultry Science, Vol. 15, No. 2, p. 159-166, March, 1974, 6 tab, 27 ref.

Descriptors: Diets, Poultry, Nutrients, Performance, Phosphorus, Calcium, Nitrogen.
Identifiers: Refeeding, Dried poultry manure, Digestibility.

Two diets containing DPM as the sole source of nitrogen were prepared. Diet A contained 600 g/kg of DPM and diet B contained 995 g/kg. At the end of the experimental period for each diet, fecal and urine samples which had been taken from each bird were bulked, freeze-dried and weighed. The food, dried feces and urine were ground to pass through a 1 mm sieve and analyzed for total nitrogen by the Kjeldahl procedure. The composition of the DPM sample and the true digestibility coefficients of some of the components were determined. The true digestibility coefficients of the true protein, crude fat, uric acid, total organic matter and carbohydrate were found to be 64.2, 69.5, 91.2, 25.5 and 23.1 percent respectively by regression analysis of absorbed vs ingested nutrients. True digestibilities of some of the constituent amino acids ranged from 24.7 percent to 76.4 percent. The absorption of calcium and phosphorus was characterized of the individual bird and ranged from 1.2 to 45.3 percent for calcium and from 7.5 to 46.2 percent for phosphorus. It was found that ¼ to ⅓ of DPM was absorbed by the laying hen. (Rowe-East Central)

THE EFFECTS ON REARING AND SUBSEQUENT LAYING PERFORMANCE OF REARER DIETS CONTAINING TWO LEVELS OF PROTEIN AND DRIED POULTRY MANURE OR UREA,

Agricultural Research Council's Poultry Research Centre, King's Buildings, West Mains Road, Edinburgh EH9 3FS, Scotland
D. J. Lee, R. Blair and P. W. Teague
British Poultry Science, Vol. 17, No. 3, p. 261-268, May. 1976. 5 tab, 9 ref.

Descriptors: Performance, Diets, Urea, Energy Calcium, Phosphorus, Proteins.
Identifiers: Dried poultry manure.

An experiment was performed to determine whether 50 g dried poultry manure (DPM)/kg could be incorporated into rearer diets without adverse effects on subsequent laying performance. Two treatments were also included to test whether 10 g urea/kg added to rear diets would cause decreased food intake and could be used to regulate consumption. Six hundred and seventy-two light-hybrid, 6-week-old pullets were allocated to 8 experimental treatments and cage-reared to 18 weeks of age. In the 6-12 week period, 4 dietary treatments were applied. Diet 1 contained 160 g crude protein/kg. Diet 2 contained 160 g crude protein/kg with 50 g DPM. Diet 3 contained about 140 g crude protein/kg. Diet 4 contained about 140 g crude protein/kg with 50 g DPM. Two additional diets were also fed in which diets 1 and 3 were supplemented with 10 g urea/kg (diets 5 and 6). Diets containing DPM were formulated to utilize the crude protein, energy, calcium, and 50 percent of the phosphorus content of DPM. Pullets fed on high protein diets (1, 2, and 5) were significantly heavier at 18 weeks than those fed on low protein diets (3, 4 and 6). In the laying period, total estimated egg weight and food intake and conversion were significantly less. Dietary DPM had no significant effect on the 18-week body weight, but food consumption was significantly less and conversion was significantly improved. There were no significant effects on subsequent laying performance. Dietary urea caused no significant effects on rearing or laying performance. (Rowe-East Central)

MATHEMATICAL MODELLING OF ANIMAL WASTE TREATMENT,

Department of Agricultural Engineering, The University of Newcastle upon Tyne, England
J. L. Woods and J. R. O'Callaghan
Journal of Agricultural Engineering Research, Vol. 19, No. 3, p. 245-258, 1974.

Descriptors: Mathematical models, Waste treatment, Microorganisms, Separation techniques, Chemical properties.
Identifiers: Substrates.

Models that have been used to describe the dynamics of microorganism populations are surveyed. One model, that of Monod, is described in detail. The Monod model, a substrate model, is based on the assumption that the growth rate can be restricted by a shortage of any one substrate. This description, relating organism growth to a limiting substrate, appears to give greater insight into the physical situation than the alternative models, which tend to be more empirical and so limit extrapolation to treatment situations outside the specific test conditions. A comparison is made with experimental work, largely relating to pig slurry and leading to a formula for the prediction of the chemical oxygen demand of effluent supernatant. The effects of the feed concentration, the rate of flow, and the method of solids separation of the treatment process are discussed in light of the Monod model. (Merryman-East Central)

USING SWINE MANURE AS A FERTILIZER,

Department of Agricultural Engineering, University of Manitoba, Canada
D. D. Schulte and M. B. Tokarz
Presented at the Manitoba Hog Producer Meeting, Morris, Manitoba, March 1, 1976, 12 p. 2 fig, 5 tab.

Descriptors: Fertilizers, Nutrients, Economics, Nitrogen, Phosphorus, Potassium.
Identifiers: Land spreading, Swine manure.

The objective of this paper is to evaluate the relative costs of commercial fertilizers and manure fertilizers in a systematic and rational manner in an attempt to enable the pork producer to better assess the trade-offs between manure handling systems, the fertilizer value of the manure and the costs of commercial fertilizer. Results showed that a pig, from the time it is weaned until it is marketed produces about 7.2 pounds of nitrogen, 2 pounds of phosphorus, and 3 pounds of potassium in its manure. However, as much as 50 percent or more of the nitrogen contained in the manure is lost during storage and while spreading the manure. Additional nitrogen can be lost if the manure is not immediately incorporated into the soil. At today's fertilizer prices, and allowing a 50 percent loss of nitrogen, the nitrogen and phosphorus value of the manure is about $1.47 per hog marketed. The cost of using manure or fertilizer compares favorably with the cost of commercial fertilizer. A typical hog operation, growing and finishing 1,750 head per year and borrowing the capital to handle its manure, would have a net profit of approximately $0.24 to $.36 per hog by using the manure instead of by purchasing commercial fertilizer. Not taken into account in these figures are the facts that the manure would have to be handled anyway (even if it were not used as a fertilizer), and that manure has many beneficial effects on the soil which are not accountable in economic terms. CORNELL ATTEMPTS TO USE MANURE TO PRODUCE PROTEIN, REDUCE POLLUTION

Feedstuffs, Vol. 48, No. 49, p. 4, November 29, 1976.

Descriptors: Proteins, Fermentation, Aerobic conditions, Microorganisms, Bacteria, Yeasts, Feeds, Fertilizers, Energy.
Identifiers: Poultry wastes, Refeeding.

Professor Michael L. Shuler of Cornell's School of Chemical Engineering is principal investigator of a project, funded for 2 years with a $139,800 grant from the National Science Foundation, which will try to achieve the double objective of mass producing bacteria, and possibly yeasts, using manure as a growing medium. An aerobic fermentation process will be used in which air will be bubbled through the poultry wastes so that microorganisms can grow rapidly. The whole process should take about 6 hours with a continuous operation. It is anticipated that the microbial product would be fed to chickens as part of the regular diet, substituting for much of the conventional high-protein feed supplements. Energy value of the microbial feed product is yet to be determined. The solid residue that will be produced during the process can be utilized by spreading it on the land. (Merryman-East Central)

USING LIQUID POULTRY WASTES IN WOODLANDS,

The Connecticut Agricultural Experiment Station, Box 1106, New Haven, Connecticut 06504
G. R. Stephens, and D. E. Hill
Proceedings of the International Conference on Land for Waste Management, Ottawa, Canada, October, 1973, p. 234-242. 3 fig, 5 ref.

Descriptors: Liquid wastes, Poultry, Nitrogen, Pine trees.
Identifiers: Land application, Woodlands, Plant response.

Liquid poultry manure containing 260 to 2,250 kg/ha N was applied at rates of 25 to 225 t/ha to plantations of white pine on well-drained and poorly drained soils during 1970-1972. Groundwater under plots receiving up to 115 tons/ha manure always contained less than 10 ppm NO_3-N throughout the study period. Groundwater beneath the poorly drained plot that received 225 tons/ha in 1970 contained as much as 80 ppm NO_3-N within 8 months of application, and still contained as much as 12 ppm NO_3-N after 27 months had elapsed. Storage of nitrogen in pine needles increased with increasing manure application and was 58 percent greater in heavily manured plots. Needle fall from all trees contained about a third to a half of the nitrogen in live foliage. Although manured trees returned more nitrogen to the soil in needle fall, they also retained more nitrogen in their crowns. After 3 years, relative growth rates of manured trees on the well-drained site had doubled. Manured trees of the poorly drained side did not experience a growth increase. It would appear that, assuming that 1,000 hens annually produce about 64 tons of liquid manure, 1 ha of pine plantation could safely utilize this manure on a sustained basis. (Merryman-East Central)

VERTICAL DISPERSAL OF FECAL COLIFORMS IN SCRANTON FINE SAND,

Department of Microbiology, University of Florida, Gainesville 32601
F. Dazzo, P. Smith, and D. Hubbell
Proceedings, Soil and Crop Science Society of Florida, Vol. 32, p. 99-102, 1973. 1 fig, 1 tab, 17 ref.

Descriptors: Coliforms, Sands, Slurries, Groundwater pollution, Sprinkler irrigation, Percolation.

A 91 cm plexiglass column lysimeter was used to study removal of coliforms from cow manure slurry percolating through sandy soil to groundwater table depths. The column was packed with Scranton fine sand obtained from a field adjacent to forage crops receiving cow manure slurry. Deionized water was added to the packed column to saturate the soil. In the first experiment, soil solutions were withdrawn from various depths within the lysimeter in order to analyze fecal coliform populations. In the second experiment, the remaining waste water was allowed to drain in order to determine the potential for groundwater pollution in contaminated soil due to a rise in the water table. Ninety percent of the fecal coliforms were removed from the slurry by percolation in the first 13 cm of the soil. Fecal coliforms could no longer be detected in the precolating slurry at a soil depth of 48 cm. Under these conditions, groundwater could become polluted from a legal standpoint in terms of its bacteriological quality if it rose to a depth of 38 cm. It may be seen then that vertical dispersal of fecal bacteria is a problem which should be considered and controlled in the design and operation of a waste treatment process involving sprinkler irrigation on land. USE CAUTION WHEN SPREADING WITHOUT AMPLE MOISTURE,

Hoard's Dairyman, Vol. 121, No. 23, p. 1340, December 10 and 25, 1976.

Descriptors: Salinity, Soil water movement, Infiltration rates, Rainfall, Irrigation.
Identifiers: Land spreading, Application rates.

Maurice L. Horton of the Water Resources Institute at South Dakota State University advises against applying excess manure to soils that do not receive enough rainfall or irrigation water. In the research reported, application of beef feedlot wastes in excess of 20 tons of dry matter/acre in each of 2 consecutive years resulted in large increases of salts within the soil profile. With less than normal rainfall resulting in little or no leaching water, the effect of the increased salts was lower yields. Following 2 consecutive years of waste application, soils receiving more than 40 tons of waste/acre/year showed a substantial reduction in the ability to infiltrate water. Elimination of the waste treatment for one season resulted in increased water infiltration and reduced salinity due to rainfall and weather conditions. (Merryman-East Central)

SORTING OUT SLURRY SYSTEMS,

M. Looker
Pig Farming, Vol. 21, No. 8, p. 68-69, 73, August, 1973. 8 fig.

Descriptors: Slurries, Waste treatment, Separation techniques, Equipment, Design, Biological treatment, Aeration.

Mr. John Hawkins of the National Institute of Agricultural Engineering (NIAE), Silsoe, Bedfordshire, England, feels that farmers with intensive livestock units and a limited amount of land need some form of treatment plant to help them dispose of the large quantities of slurry produced. NIAE is studying 3 types of separators with the aim of producing a farm machine that will separate slurry, which is difficult to handle and store, into a solid that can be stacked and spread more easily than farmyard manure, and a liquid capable of being stored, pumped, and treated without difficulty. These first-stage separators are all basically screens, although 2 have an additional component which squeezes or presses the fibrous solids from the slurry. Depending on the machine and its setting, slurries containing 8-12 percent dry matter are converted into a solid of 16-25 percent dry matter. This can form up to 40 percent, by weight of the original slurry, and can be stacked and spread. The remaining liquid is free-flowing and only contains 5-7 percent dry matter. On some intensive units, the liquid will need further treatment. Basically, 2 types of aerobic treatment plants are being studied by NIAE — biological filters and an aeration tower. A description of these plants is given. (Merryman-East Central)

WHERE THERE'S MUCK THERE'S GAS,

Rowett Research Institute
S. Bousfield, P. N. Hobson, R. Summers, and A. M. Robertson
Pig Farming, Vol. 21, No. 11, p. 79, 81, 83, November 1973. 4 fig.

Descriptors: Anaerobic digestion, Recycling, Gases, Costs, Economics, Pilot plants, Methane.
Identifiers: Piggery wastes.

Work has been instigated to develop an anaerobic digestion process for breaking down piggery waste on the farm. Pilot-plant experiments were carried out in a 100-litre continuously loaded, stainless-steel digester, heated to 95°F. The anaerobic processes were monitored. Results obtained from the pilot plant provided the basis for constructing a farm-scale digester. Experiments with the farm-scale digester are only in their early stages, but these, combined with the pilot-plant experiments, suggest that anaerobic digestion of piggery waste is possible on a large scale. The commercial feasibility of making gas by this process is debatable. The cost of the experimental digester vessel was 1300 pounds; the gas holder, 1200 pounds, and the heat exchanger, 450 pounds. Ancillary equipment: pumps, pipe-work, electrical work, boiler house with gas and oil boilers, storage tank, etc, 2000 pounds. Running costs are not yet worked out. If the process is considered primarily as a waste treatment, then the costs of this have to be met and production of usable gas can offset some of these costs. Future experiments will consider adding crop wastes and silage liquid to the animal wastes for gas production on the farm. (Merryman-East Central)

NUTRIENT VALUE AND DIGESTIBILITY OF CATTLE MANURE AS A FEED INGREDIENT,

R. C. Hill
M.S. Thesis, Auburn University, December 10, 1975, 90 p. 21 tab, 154 ref.

Descriptors: Nutrients, Performance, Cattle.
Identifiers: Digestibility, Refeeding, Cattle manure, Ensiling.

Research was conducted to determine the feed replacement value of cattle manure when substituted into a balanced ration, to characterize the digestibilities of manure-containing rations, and to determine the effects of manure-containing rations on carcass quality. Forty-four steers were allotted by weight and breed to 4 treatment groups: (1) control — full fed basal mixture, (2) an ensiled mixture consisting of 80 percent basal and 20 percent wet manure collected from the feeding floor, (3) an ensiled mixture consisting of 60 percent basal and 40 percent manure, and (4) an ensiled mixture consisting of 40 percent basal and 60 percent manure. Animals were fed these rations for 112 days. Average daily gain (kg) and dry matter fed per unit of gain for rations 1-4 were: 1.21, 7.75; 1.29, 7.50; 1.33, 7.03; and 0.99, 7.45, respectively. Only at the 60 percent level of manure addition was daily gain significantly decreased. Feed intake was markedly reduced when 60 percent manure was added to the ration indicating a possible palatability or fill problem. The results of this study indicated that wet manure can be incorporated into a balanced ration at 40 percent and ensiled without decreasing gain, while improving feed efficiency. At this level of manure inclusion in the diet, 1 kg of dry manure was found to be equivalent to 1.5 kg of basal ration in respect to gain, and the calculated metabolizable energy of dry manure was 1.25 times that of corn. Thus, wet manure can be incorporated into a balanced ration, ensiled, and fed to finishing steers without any adverse effects on performance. There was also no adverse effect on carcass or flavor. DRY WEATHER MAY CAUSE LAGOON ODOR PROBLEMS,

Wallaces Farmer, Vol. 101, No. 21, p. 47, November 13, 1976

Descriptors: Lagoons, Odor, Pumping, Solids.

Many livestock producers with lagoons think 1976 was a great year for their operations because much of the liquid evaporated during the dry weather, allowing them to get by without pumping their lagoons down. However, Stu Melvin, Iowa State University extension agricultural engineer, fears that, because the lagoon solids became thicker, lagoon odors will be terrible in the spring. If lagoons are not properly diluted and then pumped down, solids will build up and shorten the lagoon's life. (Merryman-East Central)

SUPPRESSION OF SUPERPHOSPHATE-PHOSPHORUS FIXATION BY FARMYARD MANURE. II. SOME STUDIES ON THE MECHANISMS,

Nuclear Institute for Agriculture and Biology, Lyalpur, Pakistan
M. Sharif, F. M. Chaudhry, and A. G. Lakho
Soil Science and Plant Nutrition, Vol. 20, No. 4, p. 395-401, December, 1974. 1 tab, 2 fig, 25 ref.

Descriptors: Phosphorus, Soils, Sampling, Chemical analysis, Crop response.
Identifiers: Farmyard manure, Superphosphates, Application rates.

Superphosphate was applied to a calcareous loam soil at rates of 98, 245, 490, and 2453 kg P/ha. $NaHCO_3$ extractable phosphorus was determined in all treatments; whereas, phosphate and lime potentials and various fractions of soil phosphates were determined only in treatment of 98 kg P/ha. The fertilizer treatments in quadruplicate were imposed in 3 ways: (1) superphosphate alone, (2) superphosphate and farmyard manure premixed at a 1:4 ratio, 24 hours before their incorporation into soil (premixed treatment) and (3) superphosphate and farmyard manure at a 1:4 ratio applied to soil separately (unmixed treatment). Soil samples receiving various fertilizer treatments were incubated at different time intervals, dried, ground to pass through a sieve, and stored in plastic bottles before they were analyzed. At all the time intervals, $NaHCO_3$ extractable phosphorus remained at a higher level in the premixed treatments than in the unmixed or superphosphate treatment only. The soil solution in the premixed treatments contained calcium phosphates of higher solubility than those in the unmixed treatment. The premixed treatment increased the soluble and Fe-Al phosphate at the expense of calcium phosphates. Results suggest that the increased uptake of phosphorus by plants from the application of superphosphate premixed with farmyard manure may have resulted from increased solubility of phosphorus in the pre-mixed treatments. (Merryman-East Central)

THE LIPIDS OF FOUR UNUSUAL NON-PATHOGENIC HOST-ASSOCIATED SPIROCHETES,

Department of Microbiology, University of Minnesota, Minneapolis 55455
B. P. Livermore and R. C. Johnson
Canadian Journal of Microbiology, Vol. 21, No. 11, p. 1877-1880, 1975. 1 tab, 11 ref.

Descriptors: Lipids, Bacteria.
Identifiers: Swine wastes, Spirochetes.

Lipid compositions of 2 spirochetes isolated from the human oral cavity and 2 isolated from swine feces were examined. The isolates were unusual because they required isobutyric and valeric acids rather than long-chain fatty acids for growth. Consequently, mediums free of serum or fatty acid-albumin supplements could be utilized in culturing them. The major fatty acids synthesized were normal and iso fatty acids with 14 and 16 carbons. No chain lengths were longer than 16 carbons. No unsaturated fatty acids could be detected. The major complex lipids observed were phosphatidyl glycerol, mongalactosyl diglyceride, and bis-phosphatidyl glycerol. Nitrogenous phospholipids were not snythesized. The data indicated an intermediate position of these isolates between Treponema and free-living Spirochaeta. (Merryman-East Central)

SURVIVAL OF LEPTOSPIRES IN CATTLE MANURE,

Department of Veterinary Microbiology and Public Health, College of Veterinary Medicine, University of Minnesota, St. Paul, 55101
S. L. Diesch
Journal of the American Veterinary Medical Association, Vol. 159, No. 11, p. 1513-1517, December 1, 1971. 1 fig, 1 tab, 16 ref.

Descriptors: Pathogenic bacteria, Model studies, Public health.
Identifiers: Leptospires, Oxidation ditch, Survival time, Health effects.

Research objectives were to measure leptospiral survival time: to develop and improve bacteriologic methods of measurement for detection of pathogens and for measurement of their survival in beef cattle manure in a laboratory model oxidation ditch during simulated field environmental conditions at summer temperatures; and to evaluate potential health effects of pathogens in cattle manure. Leptospires survived in manure in Selas candles for 6 days, in effluent for 5 days, in settling chamber sludge for 4 days, and in manure of the oxidation ditch for 61 days (preliminary). The oxidation ditch study was still in progress. Leptospires survived in well and stream water studies for 3 days. Disposal of beef cattle manure in the oxidation ditch model did constitute a potential public health problem. (Rowe-East Central)

IRRIGATION SYSTEM DOES HIS MANURE DISPOSAL WORK,

R. Watkins, editor
Crops for Livestock, p. A-3-A-5, October, 1976. 4 figs.

Descriptors: Sprinkler irrigation, Liquid wastes, Lagoons, Aerobic conditions, Anaerobic conditions, Nutrients, Odor, Fertility.
Identifiers: Swine manure

Dave Streange, central Indiana volume corn hog producer, has developed a system for disposing of liquid hog manure through an irrigation system. A tractor PTO-mounted pump pulls liquid manure from a lagoon located next to slotted-floor hog confinement buildings with pits that empty into the lagoon. The liquid manure is pumped to irrigation sprinklers placed in an adjoining cornfield. Manure is disposed from 4,000 hogs with about 100 hours of labor a year. In winter the lagoon does not function. It simply becomes a manure holding pit from where full-strength waste is irrigated onto idle land. The irrigation system is capable of spreading 90 gallons per minute at 90 pounds pressure. The major benefit to the corn crop is the plant nutrients in the manure. There is quite a significant loss of nutrients through oxidation of the waste in the lagoon. About 80 percent of the fertility value is retained if pumped directly from the pit under the building to the land. Through the lagoon, only about 20 percent is retained. About the only problem with odor is in the spring when the lagoon changes from anaerobic to aerobic. At that time there are some gasses that are offensive, but it doesn't last long. (Rowe-East Central)

15. SUPPLEMENTARY NOTES

16. ABSTRACT

Management and research information on animal wastes has expanded rapidly in recent years. This material has appeared in such diverse sources as journal articles, conference papers, university publications, government publications, magazine articles, books or book chapters, and theses. This bibliography was compiled in order to speed the flow of information on findings in one segment of the livestock industry to other segments that could benefit from this technology.

Included in this publication are the following indexes: (1) author, (2) animal information categories. These indexes are followed by a section of abstracts of each reference entry found in the bibliography. Single copies of most articles can be obtained in hard copy or microfiche form at cost from the Animal Waste Technical Information Center, School of Environmental Science, East Central Oklahoma State University, Ada, Oklahoma 74820.
