FOREWORD

The National Eutrophication Survey was initiated in 1972 in response to an Administration commitment to investigate the nation-wide threat of accelerated eutrophication to fresh water lakes and reservoirs.

OBJECTIVES

The Survey was designed to develop, in conjunction with state environmental agencies, information on nutrient sources, concentrations, and impact on selected freshwater lakes as a basis for formulating comprehensive and coordinated national, regional, and state management practices relating to point-source discharge reduction and non-point source pollution abatement in lake watersheds.

ANALYTIC APPROACH

The mathematical and statistical procedures selected for the Survey's eutrophication analysis are based on related concepts that:

- a. A generalized representation or model relating sources, concentrations, and impacts can be constructed.
- b. By applying measurements of relevant parameters associated with lake degradation, the generalized model can be transformed into an operational representation of a lake, its drainage basin, and related nutrients.
- c. With such a transformation, an assessment of the potential for eutrophication control can be made.

LAKE ANALYSIS

In this report, the first stage of evaluation of lake and water-shed data collected from the study lake and its drainage basin is documented. The report is formatted to provide state environmental agencies with specific information for basin planning [§303(e)], water quality criteria/standards review [§303(c)], clean lakes [§314(a,b)], and water quality monitoring [§106 and §305(b)] activities mandated by the Federal Water Pollution Control Act Amendments of 1972.

Beyond the single lake analysis, broader based correlations between nutrient concentrations (and loading) and trophic condition are being made to advance the rationale and data base for refinement of nutrient water quality criteria for the Nation's fresh water lakes. Likewise, multivariate evaluations for the relationships between land use, nutrient export, and trophic condition, by lake class or use, are being developed to assist in the formulation of planning guidelines and policies by EPA and to augment plans implementation by the states.

ACKNOWLEDGMENT

The staff of the National Eutrophication Survey (Office of Research & Development, U. S. Environmental Protection Agency) expresses sincere appreciation to the Wisconsin Department of Natural Resources for professional involvement and to the Wisconsin National Guard for conduct of the tributary sampling phase of the Survey.

Francis H. Schraufnagel, Acting Assistant Director, and Joseph R. Ball of the Bureau of Water Quality, and Donald R. Winter, Lake Rehabilitation Program, provided invaluable lake documentation and counsel during the Survey. Central Office and District Office personnel of the Department of Natural Resources reviewed the preliminary reports and provided critiques most useful in the preparation of this Working Paper series.

Major General James J. Lison, Jr., the Adjutant General of Wisconsin, and Project Officer CW-4 Donald D. Erickson, who directed the volunteer efforts of the Wisconsin National Guardsmen, are also gratefully acknowledged for their assistance to the Survey.

WATERFORD IMPOUNDMENT-TICHIGAN LAKE STORET NO. 5559

I. CONCLUSIONS

A. Trophic Condition:

Survey data and the records of others show that the Tichigan Lake basin and the rest of the Waterford Impoundment are highly eutrophic waters.

B. Rate-Limiting Nutrient:

The algal assay results show that the composited assay sample was nitrogen limited. The lake data show nitrogen limitation at all sampling times in Tichigan Lake and in the Widespread.

C. Nutrient Controllability:

1. Point sources--During the sampling year, the Waterford Impoundment-Tichigan Lake system received a phosphorus load at a rate far in excess of that proposed by Vollenweider (in press) as "dangerous"; i.e., a eutrophic rate (see page 17). Of this load, it is calculated that the communities of Waukesha and Mukwonago contributed nearly 84%.

In the following table, the total phosphorus loading rates that can be achieved by specified levels of phosphorus removal at Waukesha and Mukwonago are shown and compared to Vollenweider's suggested loading rates.

% P Removal	Total P L lbs/acre/yr	.oading g/m²/yr
Existing 50 70 80 90	183.0 106.5 75.9 60.6 45.3 30.0	20.51 11.94 8.51 6.79 5.07 3.36
Vollenweider: "Dangerous" (eutrophic rate) "Permissible" (oligotrophic rate)	e)	1.16 0.58

It will be noted that none of the removal options would reduce the phosphorus loading rate to an acceptable level, if it is assumed that all of the phosphorus from the indicated point sources reaches the water body. Note that the non-point source load attributed to the Fox River provided a loading rate of 28 lbs P/lake acre/yr or 3.14 $g/m^2/yr$, and thus non-point source loading rates alone would exceed the "dangerous" rate.

The Wisconsin Department of Natural Resources is now requiring phosphorus control at all of the municipal point sources in the Fox (Illinois) River basin. It would be expected that such control would at least result in a reduction in the incidence of nuisance algal blooms in the Waterford Impoundment-Tichigan Lake complex. However, since only 8% of the complex area is more than 20 feet deep (Poff, et al., 1970), rooted aquatic vegetation probably will continue to be a problem.

2. Non-point sources (see page 17)--It is estimated that non-point sources contributed about 16% of the total phosphorus load during the sampling year. Nutrient loads in the tributaries of other study lakes in the Fox (Illinois) River drainage were not determined, but the Fox River phosphorus export estimated using the dolomitic mean (see page 13) compares quite well to exports measured in other stream systems in Wisconsin.

The very high phosphorus export of the Fox River measured at station A-4 in Waukesha is believed to be due to the contributions of three point sources beyond the 25-mile limit of the Survey.

II. INTRODUCTION

The Waterford Impoundment-Tichigan Lake complex was formed by the impoundment of the Fox (Illinois) River at the Village of Waterford. The rise in water level due to the 8-foot-head dam submerged the outlet of naturally occurring Tichigan Lake, and the lake basin is now broadly joined with the rest of the system.

The complex now includes three more or less distinct parts: (1) The Tichigan Lake basin--268 acres, maximum depth 63 (68?*) feet; (2) the "Widespread" (of the Fox River)--623 acres, maximum depth ca. 5 feet; and (3) Buena Lake--241 acres, maximum depth 8 feet. The approximate limits of the three parts are indicated by the dotted lines on the map (page vi).

Apparently, the Widespread and the lake basin are now considered to be "Tichigan Lake" (several publications state that the area of the lake is 891 acres; i.e., the sum of the two areas; and Buena Lake is listed separately). However, this report is concerned with the entire complex, although it is noted that lake sampling was limited to the Tichigan basin and the Widespread.

Although the Waterford dam was originally constructed to provide for flood control and low-flow augmentation, reportedly the structure is no longer capable of water level regulation. Present uses of the impoundment are recreational and include swimming, boating, and fishing. Game fish present are northern pike, walleyes, largemouth bass, white bass, channel

^{*} Survey limnologists reported sampling at depths of 64 and 65 feet and a total depth of 68 feet.

catfish, and panfish. Reportedly, the system provides one of the most versatile warmwater fisheries in southeastern Wisconsin, although carp are abundant and cause management problems (Poff, et al., 1970).

Except for the Tichigan basin, public access is good; public access to Tichigan is afforded only by way of the navigable former lake outlet (Poff and Threinen, 1961).

III. LAKE AND DRAINAGE BASIN CHARACTERISTICS

- A. Lake Morphometry*:
 - 1. Surface area: 1,133 acres.
 - 2. Mean depth: 6.3 feet.
 - 3. Maximum depth: 63 feet.
 - 4. Volume: 7,113 acre/feet.
 - 5. Mean hydraulic retention time: 19 days.
- B. Tributary and Outlet: (See Appendix A for flow data)
 - 1. Tributaries -

	Name	Drainage area ^T	Mean flow ^T
	Fox River	334.0 mi ²	179.2 cfs
	Mukwonago River**	(80.0 mi ²)	(48.0 cfs)
	Minor tributaries & immediate drainage -	20.2 mi ²	11.2 cfs
	Totals	354.2 mi ²	190.4 cfs
2	Outlot		

2. Outlet -

Fox River 356.0 mi^{2††} 190.4 cfs

- C. Precipitation^{†††}:
 - 1. Year of sampling: 38.7 inches.
 - 2. Mean annual: 31.5 inches.

^{*} Poff, et al., 1970.

 $[\]pm$ Drainage areas are accurate within $\pm 0.5\%$; mean daily flows are accurate within $\pm 40\%$; mean monthly flows are accurate within $\pm 35\%$; and normalized monthly flows are accurate within $\pm 35\%$.

^{**} Included in Fox River area and flow.

tt Includes area of lake.

ttt See Working Paper No. 1. "Survey Methods".

IV. LAKE WATER QUALITY SUMMARY

Tichigan Lake and the Widespread were sampled three times during the open-water season of 1972. Each time, samples for physical and chemical parameters were collected from one or more depths at one station on the lake and one on the Widespread (see map, page vi). During each visit, a single depth-integrated (15 feet or near bottom to surface) sample was composited from the two stations for phytoplankton identification and enumeration; and during the last visit, a single five-gallon depth-integrated sample was composited for algal assays. Also each time, a depth-integrated sample was collected from each of the stations for chlorophyll <u>a</u> analysis. Maximum depths sampled were 65 feet at station l and 4 feet at station 2.

The results obtained are presented in full in Appendix B, and the data for the fall sampling are summarized below. Note, however, the Secchi disc summary is based on all values. A comparison of the data obtained at the two stations during the November sampling, when Tichigan Lake was well mixed, demonstrates that there were significant differences in all parameters except for the phosphorus species. Similar differences are evident in surface samples taken in June and in August. Water quality in the Widespread obviously reflects the quality of the incoming Fox River, but Tichigan Lake apparently is much less affected. Possibly ground water recharge is a more important factor in the quality of the lake.

In any case, separate summaries of the fall data are presented below for the two stations. For differences in the various parameters at the other sampling times, refer to Appendix B.

0.060 P	0.186	0.890	22.0
0.060 P + 10.0 N	0.186	10.890	95.7
10.0 N	0.126	10.890	69.3

2. Discussion -

The control yield of the assay alga, <u>Selenastrum capri-cornutum</u>, indicates that the potential primary productivity was at a very high level at the time the composite sample was collected.

The assay also shows that the sample was nitrogen limited.

Note that the addition of increments of phosphorus did not

result in an increase in yield, but the addition of only nitrogen or nitrogen with phosphorus resulted in significantly greater yields than the control yield.

The data obtained at the two stations also indicate nitrogen limitation at the other sampling times as well.

D. Trophic Condition:

Survey data and the records of others show that the entire Waterford complex is highly eutrophic.

Of the 46 Wisconsin water bodies studied, none had a higher mean total phosphorus, none had a higher mean inorganic nitrogen, only one had more mean chlorophyll <u>a</u>, and only two lakes had a higher algal assay control yield.

V. NUTRIENT LOADINGS (See Appendix C for data)

For the determination of nutrient loadings, the Wisconsin National Guard collected monthly near-surface grab samples from each of the tributary sites indicated on the map (page vii), except for the high runoff months of April and May when two samples were collected. Sampling was begun in September, 1972, and was completed in August, 1973.

Through an interagency agreement, stream flow estimates for the year of sampling and a "normalized" or average year for the Fox River sites nearest the lake and the mean Mukwonago River flow were provided by the Wisconsin District Office of the U.S. Geological Survey.

In this report, nutrient loads in the Fox and Mukwonago rivers were calculated using mean concentrations and mean flows. Nutrient loadings for unsampled "minor tributaries and immediate drainage" ("ZZ" of U.S.G.S.) were estimated by determining the nutrient loads, in $lbs/mi^2/year$, in the Mukwonago River at station B-2 and multiplying by the ZZ area in mi^2 .

The operator of the Waukesha wastewater treatment plant provided monthly effluent samples and corresponding flow data. The Village of Mukwonago declined participation in the Survey, and loads from there were estimated using nutrient and flow data obtained by the Department of Natural Resources in August, 1970 (McKersie, et al., 1972).

Three other municipalities--Brookfield, Pewaukee, and Sussex--are located upstream from the Waterford-Tichigan system beyond the 25-mile

limit of the Survey*. While nutrient loads from these sources are not included in the following tables, they are evident in the nutrient export loads of the Fox River at station A-4 in Waukesha (see page 17).

In the following loading tables, all of the nutrient loads measured at Waukesha and estimated for Mukwonago are assumed to have reached the Waterford complex during the sampling year. However, the amount of effluent phosphorus measured at the Waukesha STP alone exceeded that measured at the Fox River at the inlet station (A-2); and the areal or non-point phosphorus load indicated for the Fox River was calculated with mean flows and the regional dolomitic mean total phosphorus concentration as determined by the Department of Natural Resources (Poff, et al., 1970; page 7).

The nitrogen load attributed to the Fox River is the amount measured at station A-2 minus the loads attributed to the Waukesha and Mukwonago treatment plants.

A. Waste Sources:

Known municipal -

<u>Name</u>	Pop. <u>Served</u> **	<u>Treatment</u>	Mean <u>Flow (mgd</u>)	Receiving <u>Water</u>	
Waukesha	40,258	Trickling filter	10.080	Fox River	
Mukwonago	2,367	Trickling filter	0.156***	Mukwonago	River

^{*} See Working Paper No. 1.

^{** 1970} Census.

^{***} McKersie, et al., 1972.

2. Industrial* - Only two industries of nutrient significance are located in the drainage. One of these, the Mammoth Springs Canning Corporation, disposes of wastes by a lagoon-spray irrigation system with no discharge; the other is a small ice-cream factory, Keystone Farms, with a septic tank-stabilization pond system discharging to Pebble Creek about 35 stream miles upstream from Tichigan Lake.

^{*} McKersie, et al., 1972.

	Fox River	514,080	55.7
b.	Minor tributaries & immediate drainage (non-point load) -		4.6
с.	Known municipal -		
	Waukesha Mukwonago	330,140 11,740	35.8 1.3
d.	Septic tanks* -	13,080	1.4
e.	Industrial - Unknown	?	-
f.	Direct precipitation** -	10,920	1.2
	Total	922,330	100.0
Out	puts -		
Lak	e outlet - Fox River	835,860	

^{3.} Net annual N accumulation - 86,470 pounds

2.

^{*} Estimated 550 dwellings and 2 parks on lakeshore; see Working Paper No. 1. ** See Working Paper No. 1.

D. Mean Annual Non-point Nutrient Export by Subdrainage Area:

Tributary	lbs P/mi ² /yr	lbs N/mi ² /yr
Fox River at A-2* Fox River at Waukesha**	95	1,539
(station A-4 above STP)	304	2,709
Mukwonago River	76	1,926

E. Yearly Loading Rates:

In the following table, the existing phosphorus loading rates are compared to those proposed by Vollenweider (in press). Essentially, his "dangerous" rate is the rate at which the receiving waters would become eutrophic or remain eutrophic; his "permissible" rate is that which would result in the receiving water remaining oligotrophic or becoming oligotrophic if morphometry permitted. A mesotrophic rate would be considered one between "dangerous" and "permissible".

	Total	Phosphorus	Total Nitrogen		
<u>Units</u>	Total	Accumulated	Total	Accumulated	
lbs/acre/yr grams/m ² /yr	183.0	76.5	814.1	76.3	
grains/in-/yr	20.51	8.57	91.2	8.6	

Vollenweider loading rates for phosphorus (g/m²/yr) based on mean depth and mean hydraulic retention time of Waterford-Tichigan Lake:

"Dangerous" (eutrophic rate) 1.16
"Permissible" (oligotrophic rate) 0.58

^{*} Dolomitic mean x A-2 flow.

^{**} Nine-year mean flow at U.S.G.S. gage (Anonymous, 1974; page 151) x A-4 concentrations.
