### **Disclaimer Statement**

This report has been reviewed by Region VIII, EPA, and approved for publication. Approval does not signify that the contents necessarily reflect the views and policies of the Environmental Protection Agency, nor does mention of trade names or commercial products constitute endorsement or recommendation for use by the Environmental Protection Agency.

## **ABSTRACT**

This report describes the Northern Great Plains Wind Measurement Program as conducted by Aeronutronic Ford's Aero-Comm Engineering Services Division for the Environmental Protection Agency. The operation of the government furnished data collection system, which utilized Bendix-Friez Aerovane systems at Glendive, Montana; Gillette, Wyoming; and Bowman, North Dakota, is discussed with conclusions and recommendations provided. Data reduction techniques used to process the strip chart recordings into wind speed and direction information are described. One-hour averages of wind speed and direction, and monthly and annual wind rose data summaries are also included in the report.

# NORTHERN GREAT PLAINS WIND MEASUREMENT PROGRAM

## I.

### INTRODUCTION

#### A. Background

The Environmental Protection Agency (EPA) has need for detailed upper air data, viz., wind speed (ws) and direction (wd), in the rural areas of the Northern Great Plains. The area of eastern Montana, western North Dakota, and northeastern Wyoming is developing their coal resources in response to the nation's increased energy demands. EPA needs the upper air data for use in their mathematical atmospheric pollutant diffusion models to predict air quality impacts of potential large mine-mouth power plants and gasification plants located in these rural areas.

At the present time the National Weather Service Stations do not provide detailed, quality meteorological information of the wind speed and direction within about 50 or more miles from these areas of interest. This wind measurement program by Aeronutronic Ford was designed to meet this EPA need and provide upper air data for a period of twelve months at these three rural sites: Glendive, Montana; Gillette, Wyoming; and Bowman, North Dakota.

#### B. Work Objectives

Aeronutronic Ford's objective for this program was to install and operate a three site wind data acquisition network for continuously collecting wind speed and direction data at an altitude of thirty meters. The wind data, collected in analog form on strip chart recordings, required data reduction and conversion into a computer compatible format. The provision of a high quality of wind data ready for further computer processing by EPA was the prime object of Aeronutronic Ford's efforts. The methods employed to provide data quality are described in "Quality Control of the Three-Site Northern Great Plains Wind Measurement Program, report number 6732-75-03. This report has been included in the appendices (section V.A)

## II.

### SUMMARY

#### A. Conclusions

1. Operation of a wind data acquisition network using aged instrumentation will not allow a 90% data collection rate unless the operator is available for daily inspection of the recorder and is capable of implementing minor maintenance on the recorder.
2. The particular Aerovane recorders used during this program were in a worn condition. The

operation of one Aerovane Transmitter (Serial Number 3385) should be monitored closely during the initial period of its reuse.

3. The data reduction techniques including the computer processing programs developed for use on this project worked very well and should be considered for further use.

#### B. Recommendations

Should this type of wind-measurement program be required again for similar type locations we recommend the following comments be considered.

1. The choice of the Aerovane Recorder Operator is more important than is apparent. The attention to monitoring of the Aerovane system operation, the response to malfunctioning of the equipment, and the proper handling of the Aerovane chart recordings are necessary for successful data collection and recovery. The individual chosen must be aware and responsive to these tasks and must be given training in the operation of the system.
2. The choice of tower locations is, of course, limited to those inside the area of interest whose access is available to the government. However, unless absolutely essential, an unmanned location should not be selected. The reliability of these Aerovane systems is such that extended periods without operator attention can often result in loss of considerable data. Further, the contractor must have access to the towers. For example, the low data collection rate achieved at Bowman was in a large part due to the use of an unmanned site location and Aeronutronic Ford not having access to the tower. The Bowman tower and its equipment could only be serviced by a particular contractor of the North Dakota Highway Department.

### III. WIND MEASUREMENT PROGRAM

#### A. Schedule of Events

The activity associated with the performance of the Northern Great Plains Wind Measurement Program is shown in the schedule of events which follows:

Contract Signed, 14 NOV 74

Equipment Received, 13 DEC 74

Data Collection started at Glendive, 26 DEC 74

Data Collection started at Gillette, 30 DEC 74  
First Monthly Report (no data) submitted, 3 JAN 75  
Second Monthly Report (inc. data) submitted, 7 FEB 75  
Data Collection started at Bowman, 12 FEB 75  
Third Monthly Report (inc. data) submitted, 7 MAR 75  
Quality Control Report submitted, 10 MAR 75  
Fourth Monthly Report (inc. data) submitted, 14 APR 75  
Fifth Monthly Report (inc. data) submitted, 9 MAY 75  
Sixth Monthly Report (inc. data) submitted, 10 JUN 75  
Seventh Monthly Report (inc. data) submitted, 10 JUL 75  
Eighth Monthly Report (inc. data) submitted, 10 AUG 75  
Ninth Monthly Report (inc. data) submitted, 15 SEP 75  
Tenth Monthly Report (inc. data) submitted, 10 OCT 75  
Eleventh Monthly Report (inc. data) submitted, 11 NOV 75  
Twelfth Monthly Report (inc. data) submitted, 9 DEC 75  
Thirteenth Monthly Report (inc. data) submitted, 9 JAN 76  
Fourteenth Monthly Report (inc. data) submitted, 9 FEB 76  
Data collection ceased at all sites, 29 FEB 76  
Fifteenth Monthly Report (inc. data) submitted, 10 MAR 76  
Equipment removed from all sites, 10 MAR 76  
Draft Final Report submitted, 29 MAR 76  
Draft Final Report returned, 23 APR 76  
Equipment returned to EPA, 23 MAR 76  
Final Report distributed, 9 JUL 76

#### B. Data Collection System

The Government Furnished Equipment (GFE) supplied for this program consisted of four Wind Direction and Speed Recording Systems, each with approximately 100 feet of cable. Each of these systems, manufactured by Bendix-Friez, is composed of a Model 120 Aerovane Transmitter and a Model 141 Recorder.

The tower locations, selected and secured by EPA, for use as data collection points were at: Glendive, Montana; Gillette, Wyoming; and Bowman, North Dakota. For Glendive the KXGN-TV tower located in the Makoshika State Park at a former USAF gap-filler radar site a short distance south of town was selected. The tower has a height of 32 meters (105 ft) and is square with a taper such that at the 30-meter altitude of the Aerovane sensor the tower is about 0.90 meters (3 ft) square. The terrain around the tower can be described as "rough". The tower is situated at one of the highest levels in the area. The location drops off in the west into a large canyon and towards the north-northwest into a smaller canyon. Overall the area appears as "bad lands". A small building near the tower was used to house the recorder.

The Collins Communications, Inc. tower located about three miles south of Gillette and about a quarter mile off State Highway 59 was EPA's second site selection. Here a 0.61 meter (2 ft) triangular shaped tower with a height of 134 meters (440 ft) sets atop a hill about 60 meters higher than the neighboring hills; the closest to the north and another more distant to the south. The Aerovane was installed at 30 meters (100 ft). A heated and

air-conditioned building, approximately 2.4m x 3.7m (8 ft x 12 ft), near the tower was available for housing the recorder

For the third site the North Dakota State Highway Department tower about five miles north of Bowman and about one and one-half miles NE off US Highway 85 was chosen. This triangular shaped tower, 0.61 meters or 2 ft on a side, is 100 meters (330 ft) high and sets on top a 60-meter (200 ft) hill. The terrain may be described as "gentle" with the nearest hill about 0.8 Km ( $\frac{1}{2}$  mile). The Aerovane sensor was installed at 30 meters.

The well crated wind measurement systems were received at our maintenance shop in Miles City, Montana, on December 13, 1974. An inspection showed the equipment to be in good physical condition upon arrival. Pre-installation testing and calibration were performed on all units in a system configuration. Figure 1 identifies the pre-installation tests performed on each system. The tests made during the installation are indicated on another check sheet as shown in Figure 2. These tests indicated the systems were all functioning properly.

Installation methods and techniques were developed based on previous experience with similar type towers. A diagram of the installation of the Aerovane Transmitter and boom at Gillette is shown in Figure 3 to indicate a typical tower installation. The alignment to the prevailing wind direction was limited by the square-shaped tower at Glendive to one of four directions, viz., N, E, W, or S; west was selected. At both Gillette and Bowman the triangular-shaped tower orientation permitted six possibilities, E, W, SSW, SSE, NNW, and NNE. Since NW was the assumed prevailing wind direction at both sites, NNW or 330° was chosen for the boom mounting direction. The Aerovane Transmitters were positioned 1.2 meters (4 ft) from the tower. The boom mounting allowed the transmitter to be brought near to the technician for azimuth alignment then extended from the tower for operation outside the direct interference from the tower body.

Installation at the three towers was completed on the following dates: Glendive, December 26, 1974; Gillette, December 30, 1974 and, Bowman, February 12, 1975. The installations at Glendive and Gillette were made within approximately two weeks of the receipt of the GFE. The considerable delay, 40 days, in the installation at Bowman resulted from the requirements of the North Dakota Highway Department that only the Johnson Tower Company of Minot, N.D., do all the on-tower work. The date of February 12 was the first time the Johnson Tower Company was available for the job.

### C. Network Operation

The three-site network was in full operation starting from 1900 MST, 12 FEB 75 and ending 2400 MST, 29 FEB 76. The data collection statistics are shown in Table I which shows the data collection rate for the network as 87.9 percent.

Notes (1) Two measurement, WS and WD, are possible each hour.

(2) Data loss exceptions allowed for circumstances beyond the control of this contractor. See narrative in this section for explanation.

Operators were selected for each of the three stations out of those individuals who had employment at the tower site or in some relation to it. A KXGN-TV station operator who worked at the tower site was selected at Glendive and a Collins Communications Corp. employee who had daily duties at the Gillette tower was used at that location. No daily routine site visits by radio technicians were made at the North Dakota Highway Dept. tower but a North Dakota Highway employee working out of Bowman was contracted to handle the Bowman wind station operation.

Consequently, the Bowman tower system operated in a strictly unmanned situation. The Aerovane Recorder was housed in an old refrigerator modified especially for this project. This housing was placed in the open near to the radio building. Operator servicing of the recorder was scheduled weekly.

Each operator was given verbal instruction on the operation of the Aerovane System. A copy of the guidelines for the operators is shown in Figure 4. A supply of strip charts, ink, a pen cleaning and filling kit, and pre-addressed, postage paid mailers were provided to each operator.

A review of the operation of each station follows:

1. Glendive. Since December 26, 1974, the Glendive Station collected 9465 or 91.6% of the maximum number of one-hour wind speed and direction measurement pairs available. For one-hour wind speed averages, 9567 or 92.6% were measured while 9467 or 91.6% of one-hour wind direction averages were recorded. This site had the best data collection rate of the three locations.

The reasons for data loss included improper paper loading by the operator, a recorder paper take-up malfunction, and a damaged Aerovane caused by contact with a weather balloon. The damaged Aerovane resulted in the longest single outage viz., 359 data pairs from August 28 to September 12, 1975. During a weather balloon launching, one pilot balloon became entangled with the Aerovane. First the balloon string prevented the Aerovane from moving in azimuth, then (after breaking) the string wound behind the propeller and impeded its rotation with wind speed. Apparently the balloon launch operator (also a TV station operator) intended to free the Aerovane himself because we were not notified until September 12, the same day our maintenance crew made the repair.

A total of four visits were made to the Glendive site: one to coordinate the installation and select an operator, one to install the system,

## GUIDELINES FOR WIND RECORDER OPERATOR

1. The chart paper should be changed each week, preferably on Friday. At the start of each roll please write your initials, the date, and time.
2. Occassionally observe that the recorder is operating properly, that is, the ink is writing and the time is correct. At these times, as well as at the end of the chart, please note your initials, the date and the time. (As you know you cannot mark at the exact point in time where the pen is tracing, so select the nearest printed hour where marking is possible and mark that time. This verifies the time for data reduction. If the time is off from the printed time, then adjust the mechanism for the proper time).
3. Good operation is effected by a properly operating recorder. We appreciate your attention in the changing of paper, filling the ink tanks, filling and cleaning the pens, setting the time, oiling the recorder, and monitoring the recording.
4. Use the mailing envelopes to send the recorded charts and other notes or comments you may have. Please advise us when your ink bottle is only  $\frac{1}{2}$ -full.
5. In the event of recorder malfunction, please phone our Miles City office at (406)232-4350 collect for maintenance attention.

Figure 4 Guidelines for Wind Recorder Operator

one to repair the damaged Aerovane and one to remove the equipment.

2. Gillette: During the operation of Gillette Station 8555 or 83.6% of the maximum number of one-hour wind speed and direction measurement pairs available were collected. The wind speed data collection percentage exceeded that of wind direction at all three stations. At Gillette 9207 or 90.0% of the one-hour wind speed averages were measured while only 8923 or 87.2% of the one-hour wind direction averages were recovered.

The reasons for data loss included both equipment troubles and operator inattention. Problems occurred with recorders which included the paper take-up motor switch, the ink supply, and the ink flow through the pen. The most significant failure resulted from a lightning strike to the tower on May 31. This strike knocked out the power and caused an open rotor winding in the Aerovane Transmitter. Since the Aerovane wind direction synchro system can operate in this condition except that no reference is available to insure that the transmitter and receiver synchros are in phase and not locked-in 180 degrees out of phase, the failure was not detected until some time later. Careful analysis of the data between May 31 and August 28, 1975, resulted in the loss of only 62 data pairs during this period due to the failure. In the event of low wind speeds an Aerovane with an open rotor winding can drift somewhat and lock-in 180 degrees out of phase when the wind speed resumes. The 180° out of phase wind direction indications can occur when low wind speeds or calm periods precede a definite change in wind direction. During extended calm periods the wind direction indicator may drift somewhat so that when the wind speed "picks up" from a new azimuth the direction synchros may be physically positioned nearer to the 180° out of phase null than the proper one. With the reference provided by the rotor this condition could not occur. Identification of the incorrect wind directions which occurred during this period was difficult. The 180° reversals were detected by noting periods of calm proceeding dramatic changes in wind direction.

Eight visits were made to the Gillette tower, five for maintenance and repair of the wind measurement system.

3. Bowman. At the Bowman Station 7161 one-hour measurement pairs or 78.1% of the maximum possible during the operational period between February 12, 1975, and February 29, 1976. Wind speed only data averages totalled 7501 (81.8%) and direction only 7206 (78.6%). The Bowman tower system experienced several difficulties. Aerovane propellers were broken both during the installation and the removal of the system by the Johnson Tower Company, the only on-tower climbers authorized by the North Dakota Highway Department. Shortly after the installation the recorder housing blew over during a high wind condition and had to be relocated. Paper loading and jamming were the major sources of data loss but inking problems also resulted in more losses than expected.

Six trips were required to the Bowman tower. Four of these were necessary for maintenance purposes.

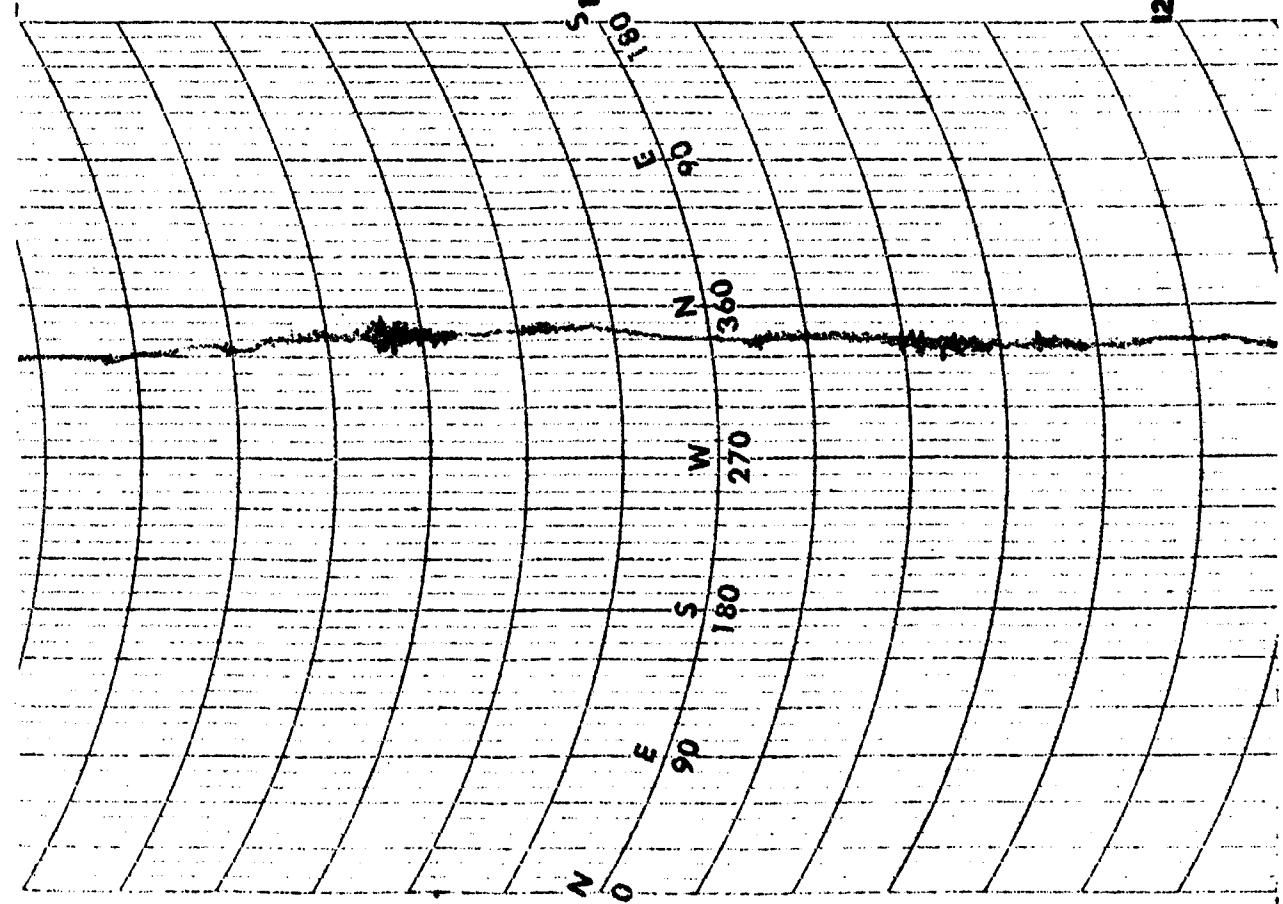

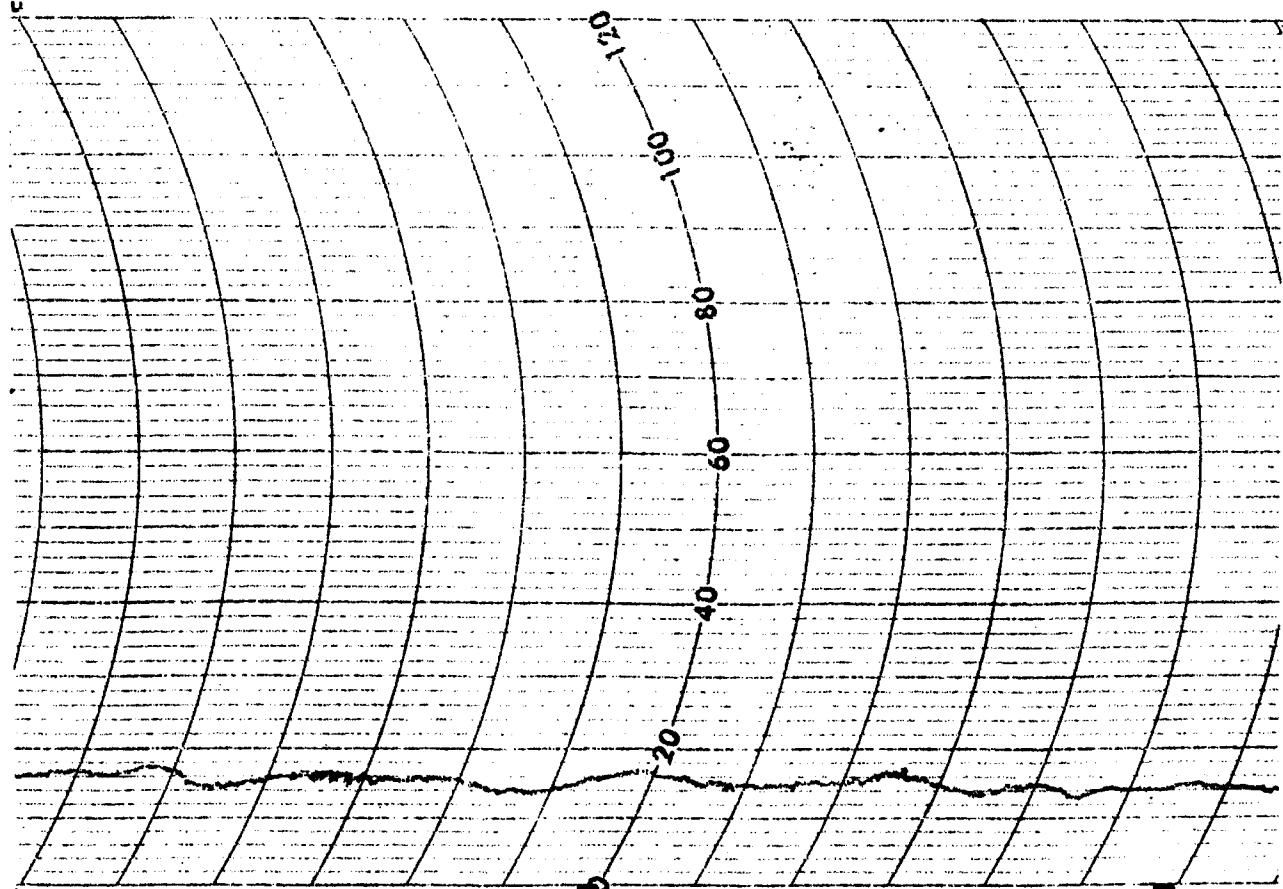

#### D. Data Reduction

The raw wind data from an Aerovane Recorder comes in strip chart form as shown by the sample in Figure 5. Each month 13.2 meters (43.4 ft) of these chart records from each site were reduced to a two-page report of hourly averages and formatted as shown in Figures 6A and 6B. Each hour average was determined manually by the data reduction technician from 8.62 cm (3 in) of trace length using a special reading table described below. This measurement is based on the technician's ability to accurately read, integrate, and average the short length of trace amplitude. The quality control check discussed on page 7 in Appendix A proved the validity of this manual technique. Figure 6A provides the wind direction averages from one tower site for one month and Figure 6B gives the wind speed averages in meters/second (m/s) for the same location and period.

Scale conversion of the analog wind speed trace was necessary. The government furnished recorder mechanisms produced a knots (nautical mile per hour) output, which as requested by EPA, had to be reported in meters/second. A special scale and chart reading device was constructed to accomodate the units conversion and facilitate accurate chart reading. The scale was based on this conversion relationship,

$$1 \text{ meter/second} = 0.514777 \text{ knots}$$

The wind direction measurement as made by the Aerovane System is a continuous trace on a chart scale of ten degrees per line. Reading of the hourly average over a three-inch trace length was made to the nearest ten-degree direction, i.e., to one

of 36 possible wind directions. The EPA Project Officer requested that these readings be reported using the notation of the 16 compass point directions referenced to true north. Figure 7 indicates the wind direction intervals in degrees covered by each of the 16 compass points.

After the manual reading of the analog wind measurement traces whereby the technician determines hourly average values for both wind speed and direction within each scale range over a three-inch chart length, the data are recorded on a computer coding form. The readings were then punched onto data cards for computer processing using a program called Wind Speed-Wind Direction. This program produced the data in the format ready for distribution to EPA. As shown in Figure 6A the wind speed data cards from one site and for one month were listed onto one sheet. The wind direction data cards containing the measurement values to the nearest 10-degree increment were computer processed for the compass point conversion and then listed in a format similar to the wind speed data as shown in Figure 6B.

The computer data cards were then rearranged into measurement pair order for processing by Program Wind-Rose. The Wind-Rose program sorted the wind speed data according to selected speed classes into the proper compass point direction. The six speed classes used were: 0-2, 3-4, 5-6, 7-8, 9-10, and above 10 meters/sec. After determining the number in each category, the program calculated the percentage of the total which each number represented. Figure 8 is a sample of the Wind Rose Program printout. The percentage figures make the preparation of an actual wind-rose diagram much easier.

The computer data cards, the Wind-Speed and Wind-Direction data sheets, and the Wind Rose printouts were all distributed to the EPA Project Officer each month.

In review, the data reduction process followed this sequence:

- 1) receive the chart roll by mail from the site operator;
- 2) review the complete strip chart to ascertain if any obvious problems with the recorder existed;
- 3) manually read the data using specially constructed, chart-reading aid to determine the hourly average of wind speed and direction;
- 4) record data on computer coding form;
- 5) punch data card;
- 6) process by computer using Program Wind Speed-Wind Direction;

- 7) proof read;
- 8) rearrange cards for wind rose data processing;
- 9) process by computer using Program Wind-Rose;
- 10) proof read;
- 11) duplicate computer cards.

#### E. Termination

The systems were removed from all of the tower sites and returned to the contractors maintenance shop by March 10, 1976. Each system was inspected and checked for operational condition. All systems, though worn, are operational. Aerovane transmitter, serial number 3385, was subjected to improper handling by non-contractor tower climbers during its removal; consequently, its operation should be monitored closely during the initial period of reuse.

The government furnished systems were repackaged in the original shipping containers and returned to the Denver EPA Regional office.

### IV. DATA PROVIDED

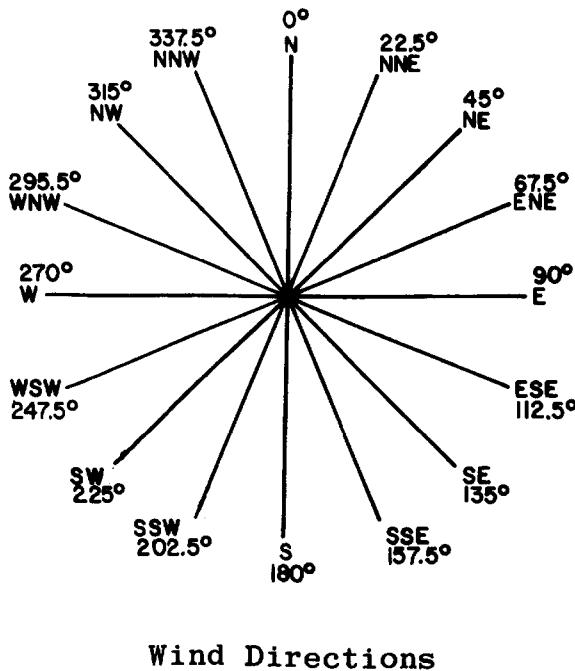

#### A. Reports

The monthly wind speed and direction data for each of the three stations was provided in the format shown in Figure 6 as attachments to the monthly reports. These data are listed in Section V.C. Punched cards with the data is a form for further computer processing were also provided to the Project Officer on a monthly basis:

#### B. Wind Roses

The monthly wind rose data sheets (see Fig. 8) covering each station have been combined to produce summary wind roses diagrams. Each of these diagrams show the wind speed and direction at 30 meters for the period March 1, 1975 to February 29, 1976. The wind roses for Glendive, Gillette, and Bowman are shown in Figures 9, 10 and 11 respectively. The number of measurements within the six speed classes and 16 compass directions are provided in Tables II, III and IV for the same order of stations. The first line shows the actual number of measurements within the 0-2 meter/second speed class and the second line indicates the percentage of the total the number represents. This sequence is repeated for the remaining five speed classes. Monthly wind rose data tabulations for each station appear in Section V.B.

The annual wind roses show the highest wind speeds at Bowman and the lowest at Glendive. At Bowman 25% of the wind

The data in the above table is arranged as follows: the first row associated with each wind speed class shows the number of measurements at each of the sixteen compass points and the second row gives the percentage of the total measurements which the number represents

speed measurements were in the highest speed class of over 10 meters/second. At Gillette 17% of the wind speed reading were over 10 meters/second; the largest number of WS measurements was in the 5 to 6 meter/second class. The wind speed exceeded 10 meters/second only 0.02% of the time at Glendive and most frequently was in the 3 to 4 meter/second class.

Further, the annual wind roses show the prevailing wind directions for the three locations. These indications are: Glendive, SSW; Gillette, WSW; and Bowman, W.

QUALITY CONTROL OF THE THREE-SITE  
NORTHERN GREAT PLAINS WIND MEASUREMENT PROGRAM

I. INTRODUCTION

Philco-Ford submits this document outlining the quality control practices to be employed during the performance of the Northern Great Plains Wind Measurement Program for the Environmental Protection Agency (EPA). The practices described in this report are intended to indicate the attention of Philco-Ford to the procedures necessary to provide the highest quality of data feasible from the wind measurement equipment provided by the government. However, the quality control and other measures to be used throughout the program will not be limited only to those discussed here. Philco-Ford Communication Systems Division (CSD) is committed to providing high quality in the performance of all of its programs.

This document first identifies the responsibility for the implementation of the program quality control (QC), then outlines the procedures to be used during (1) the system installation (including pre-installation testing), (2) the system operation, (3) the wind data reduction and handling, and (4) the program termination.

II. RESPONSIBILITY

The responsibility for the quality control exercised on this program is indicated below:

project overall - Robert Matkins

pre-installation checks - Andrew Christensen

installation & calibration tests - Andrew Christensen

data reduction - Daryl Gress

III. SYSTEM INSTALLATION

A. Pre-installation Checks

After the GFE is received at our Miles City maintenance center, each instrument and recorder will be inspected and checked for proper operation. Tests on the equipment operation help ensure dependable and continuous service from each of the systems.

The transmitter will be carefully unpacked as it is a precision instrument and must be treated accordingly. Care will be taken so that the transmitter is not damaged in handling. the

rotor and vane will not be used to lift the transmitter. The stationary center section will be used for lifting.

Each transmitter and recorder will be bench checked for proper operation and alignment as a system before field installation.

Normally, when the transmitter is shipped, the direction synchro is set (zeroed) so that when wired correctly, the vane will be parallel to the flat side of the connector housing (side opposite nameplate), and the tail will be on the same side as the threaded hole in the connector housing. Thus, when the transmitter is installed, it is only necessary to align the flat side of the connector housing with the "true" (not magnetic) north-south direction and with the threaded hole in the connector housing on the south side.

With the vane thus positioned, the recorder should register 0 degrees. Turn the vane through 360° and check to see if the recorder follows in the correct direction.

Turn the rotor in a counter-clockwise (when facing the rotor) direction and the recorder should indicate wind speed in a positive direction. When the rotor is stationary, the recorder should indicate zero.

Check the transmitter for excessive friction. To ascertain if the rotor turns freely, attach a one-cent coin to the flat side of the rotor blade at the tip, using "Scotch" tape. Place the transmitter in a vertical position. Turn the blade so that the coin is approximately 45 degrees from the vertical. When the rotor is released, the weight of the coin should be sufficient to carry the blade to the bottom.

To ascertain if the vane turns freely, attach a fifty-cent coin to the flat side of the vane at the trailing edge. Lay the vane on a bench or table so that the vane and rotor project over the edge. Position the vane so its centerline is horizontal. When the vane is released, the weight of the coin should be sufficient to carry the trailing edge of the vane downward.

Check the wind speed accuracy of the magneto. Connect the transmitter to the recorder. The load must be  $1150 \pm 6$  ohms. When only one recorder is used, it is necessary to simulate a second recorder by connecting a  $2300 \pm 12$  ohm resistor across terminals V1 and V2 of the recorder to obtain the 1050-ohm load.

Check the operation of the recorder ensuring that the correct speed gear is installed, the drive speed is correct, the chart paper moves properly, and the pens write smoothly on the paper.

Complete the Pre-installation Test Check Sheet and correct any discrepancies found in the system before repacking for

transporting to the installation site. Figure 1 shows a copy of this checksheet.

## B. System Installation

The Aerovane transmitter will be installed on an eight-foot boom placed upwind of the prevailing wind at a height of 30 meters on each of the specified towers.

The boom material will be galvanized iron pipe which will provide stable support with minimum vibration under strong wind conditions. It will be positioned and mounted with suitable hardware to permit easy accessibility for inspection, maintenance and recalibration. An Aerovane Mast Adapter #515331 will be mounted on the end of the boom to adapt the transmitter for mounting and to allow rotation of the transmitter for orientation purposes.

Philco-Ford will provide all necessary signal, power and ground cables to complete the interconnection of the transmitter, recorder and power source in accordance with the National Electric Code.

A shelter properly ventilated and weather-proofed will be installed at the base of the tower to house the strip chart recorder and power disconnect switch at locations where permanent structures are not available.

## C. System Calibration

After a bench-tested Aerovane system has been installed, the transmitter orientation and the system operation must be checked for proper calibration.

If a tower has a north mark, it must be transferred to the transmitter mount. If not, true north must be established. One method that has been used for Aerovane systems in the past utilizes a transmit mounted on a Jacob staff and a jig with scope site, as follows:

The connector housing must be positioned in the support adapter so that when the transmitter base is mounted on the connector housing, the null point is pointing at true north. Locate the K&E pocket transit and Jacob staff approximately 100 yards away from the tower area in a northerly direction. Take a sighting on the weather station pole and obtain the magnetic heading from the weather station pole to the Jacob staff.

At the tower, mount the Aerovane unit on the connector housing and transfer the scribe mark on the bottom flange of the transmitter base to the top flange of the connector housing. Remove the Aerovane unit and loosen the lock screws that hold the connector housing to the support adapter. Mount the azimuth alignment jig on the connector housing. Locate the scribe mark on the connector housing in relation to the protractor scale on the jig. Obtain the

declination for the particular location. Magnetic north is east of true north at all of the sites. Add the declination to the magnetic heading previously obtained for a true heading figure. Using the protractor scale, rotate the scope away from the scribe mark, in the proper direction, the number of degrees in the true heading figure and lock the scope. Using a pipe wrench, rotate the connector housing until the scope crosshairs are lined up with the Jacob staff. Tighten the lockscrews in the support adapter, remove the jig, and then install the Aerovane unit. The synchro should now be at the zero position when the Aerovane is pointing at true north.

Example: If the magnetic heading from the weather station pole to the Jacob staff is  $10^{\circ}$  magnetic and the declination is  $16^{\circ}$  east, then the true heading figure is  $26^{\circ}$  true. Lock the scope  $26^{\circ}$  clockwise from the scribe mark. Turn the connector housing until the crosshairs line up with the Jacob staff. The scribe mark will now be pointing at true north.

Another convenient method of aligning the transmitter to the north mark is by clamping a straight-edge to the flat side of the connector housing and orienting the transmitter until the straight-edge is in alignment with the north-south direction. After the transmitter has been properly positioned, it should be secured to the support.

After the transmitter has been properly installed and wired to the recorder, the vane and the rotor should be manually rotated to see that they are free.

Load the recorder with chart paper and ink. Start recorder and check for proper chart paper drive and inking of record. Adjust as necessary.

Turn the vane through  $360^{\circ}$  and check to see if recorder follows in the correct direction. With the rotor of the vane pointing with the north-south direction, check to see if the recorder indicates that direction. When the rotor is stationary, the recorder should indicate zero wind speed. When the rotor is turned by the wind, check to see that the recorder indicates a positive wind speed. Complete the Installation and Calibration Test Check Sheet shown in Figure 2.

#### IV. SYSTEM OPERATION

During the initial system alignment and calibration at the tower site, the local operator will be trained in the operation of the wind measurement system and in his responsibilities. These responsibilities will be: (1) to inspect the system and verify proper recorder operation periodically; (2) to remove the inked data record at least once each week, annotate the date and time, and mail the record to Billings for data reduction; (3) to place new paper in recorder periodically as required; and (4) to contact the system maintenance technician in the event of a recorder or

Figure 2

other system malfunction; and (5) to respond to the instructions of the system maintenance technician in the event a trouble is detected remotely from the data recordings.

Few problems are anticipated with the transmitter except possible physical damage. Chart recorder drive and inking problems are not uncommon. Proper and careful handling of chart paper loading and ink supply will eliminate most problems. This will be stressed when training an operator.

When a failure occurs, communication with the operator to determine the problem is very important. If possible, replacement parts will be on hand before a maintenance trip is scheduled. All efforts will be made to repair the systems on site.

If it is not possible to repair the system on site, both transmitter and recorder will be removed and returned for shop repair and a complete bench test before reinstallation. Timely repairs for a minimum out-of-service time will be stressed.

#### V. DATA REDUCTION AND HANDLING

The strip chart recordings containing the raw wind data will be carefully handled and read by the data reduction technicians. Upon receipt of the recordings, they will be logged and briefly scanned to detect any unusual recorded events which require further attention by the equipment technician or operator.

The strip charts will be carefully read to convert the two analog traces into hourly averages of wind direction and speed. An appropriate scale will be used in converting the knots per hour wind speed traces into the requested units of meters per second. The data will be collected using the form shown in Figure 3. Wind speeds will be read and recorded to the nearest one meter per second and wind directions readings will be to the nearest ten degrees. After the data has been read and given the quality control check, each strip chart recording will be labeled and stored.

The quality control check involves re-reading a sample of the hourly averages by another technician. From the 168 total readings each week a random sample of 50 are read again. The 50 readings are compared with the original and if any readings differ the week's chart recording is read again completely. The probability of finding at least one from the X erroneous original readings using a sample size of 50 is given by

$$P_x = 1 - \frac{\binom{168-x}{50} \binom{x}{0}}{\binom{168}{50}} = 1 - \frac{(168-x)!}{168!} \frac{(118)!}{(118-x)!}$$

Table I shows the probabilities  $P_x$  for several values of X.

TABLE

X	P <sub>X</sub>	X	P <sub>X</sub>	X	P <sub>X</sub>
0	0.0000	7	0.9212	14	0.9946
1	0.2976	8	0.9458	15	0.9964
2	2.5079	9	0.9629	16	0.9976
3	0.6570	10	0.9746	17	0.9984
4	0.7616	11	0.9827	18	0.9989
5	0.8347	12	0.9882	19	0.9993
6	0.8857	13	0.9920	20	0.9995

Then the data on the forms is punched on computer cards in preparation for electronic data processing (edp). the edp will convert the wind direction data into the proper 1/16th of the compass, viz., N, NNE, NE, etc., and printout the data in the format shown in Figure 4. Each measurement on the printout is verified with the handwritten value on the data collection form.

#### VI. PROGRAM TERMINATION

Following the completion of the 12-month recording period and with the confirmation of the Project Officer that sufficient data has been collected, the GFE will be removed from the tower sites. The towers will be inspected for damage and our tower contact's release will be obtained. The equipment will be returned to the Miles City maintenance shop and inspected before repacking into the original shipping cases. All GFE will then be shipped to a government designated location(s) according to the instructions of the Project Officer.
