## SUMMARY

A preliminary evaluation was conducted at a 1.0 mgd trickling filter treatment plant owned by the New Holland Borough Authority. Administrative procedures at the plant were found to be satisfactory. The treatment plant currently employs two full-time operators. Employment of an additional operator for maintenance purposes is recommended.

Three areas of operation were identified as needing some improvement or modification. The recommendations include:

1. Initiate a primitive maintenance schedule to eliminate equipment breakdowns.
2. Institute proper housekeeping procedures to achieve a cleaner and better functioning plant.
3. Authorize the preparation of an operation and maintenance manual for the plant.

## INTRODUCTION

This report sets forth the findings and recommendations from a preliminary evaluation of a biological wastewater treatment facility at New Holland, Pennsylvania. The evaluation was conducted under the U. S. Environmental Protection Agency (EPA) Contract No. 68-03-2223 by Gannett Fleming Corddry and Carpenter, Inc., Harrisburg, Pennsylvania. The New Holland plant is one of a number of biological wastewater treatment plants being studied under this contract. It is anticipated that this sampling of treatment facilities will help to identify operational and maintenance program improvements which will enable the performance of some treatment plants to be upgraded with minimal capital expenditures.

The evaluation program discussed in this report consisted of field inspection, discussions with supervisory and administrative personnel, process sampling and analysis, and collection of past operating and performance data. Operational procedures and problems encountered in the past were discussed with the treatment plant staff. Treatment efficiency during the study was evaluated from grab samples of influent, effluent, and intermediate flows collected daily. Past performance was assessed by analysis of one year's operating records supplied by the plant superintendent. Administrative, staffing, and budgetary information were also obtained during this preliminary evaluation.

## DESCRIPTION OF FACILITY

New Holland is located approximately 15 miles northeast of Lancaster, Pennsylvania. The Borough's wastewater treatment plant presently provides sanitary sewage services for a population of 4000. In addition to domestic wastewater, approximately 10 percent of the total flow to the plant is industrial wastewater. Cheese processing and paint manufacturing represent the major industries served by the treatment facility.

Constructed in 1940, the original plant consisted of primary clarification, trickling filtration, secondary clarification, and chlorination. Additional primary and secondary clarifiers, and a sludge digester were added in 1959. The plant has been designed to accommodate an average flow of 1.0 mgd. Separate stormwater and sewage collection systems are provided at New Holland.

Infiltration/inflow problems with the sewage system have been experienced in the past; however, repairs to the system to correct the problems are gradually being made.

Treated effluent from the New Holland plant is discharged to Mill Creek. Mill Creek is a tributary of Conestoga Creek which, in turn, is a tributary of the Susquehanna River. The National Pollutant Discharge Elimination System (NPDES) permit program sets forth the various effluent

requirements for the New Holland plant for discharging to Mill Creek.

These requirements are divided into interim and final limitations. Interim requirements are in effect until July 1, 1977, and final requirements are to be met after that date. The permit requirements are as follows:

Interim

<u>Parameter</u>	<u>30-day requirement</u>	<u>7-day requirement</u>
BOD <sub>5</sub>	30 mg/l	45 mg/l
suspended solids	30 mg/l	45 mg/l
Fecal coliform	200 colonies/100 ml	400 colonies/100 ml
pH	6.0 to 9.0	6.0 to 9.0

Final

BOD <sub>5</sub>	6 mg/l	6 mg/l
suspended solids	25 mg/l	25 mg/l
Fecal coliform	200 colonies/100 ml	400 colonies/100 ml
pH	6.0 to 9.0	6.0 to 9.0
Ammonia-Nitrogen	2.0 mg/l	2.0 mg/l
PO <sub>4</sub> as P	2.0 mg/l	2.0 mg/l
Dissolved oxygen	5.0 mg/l	5.0 mg/l

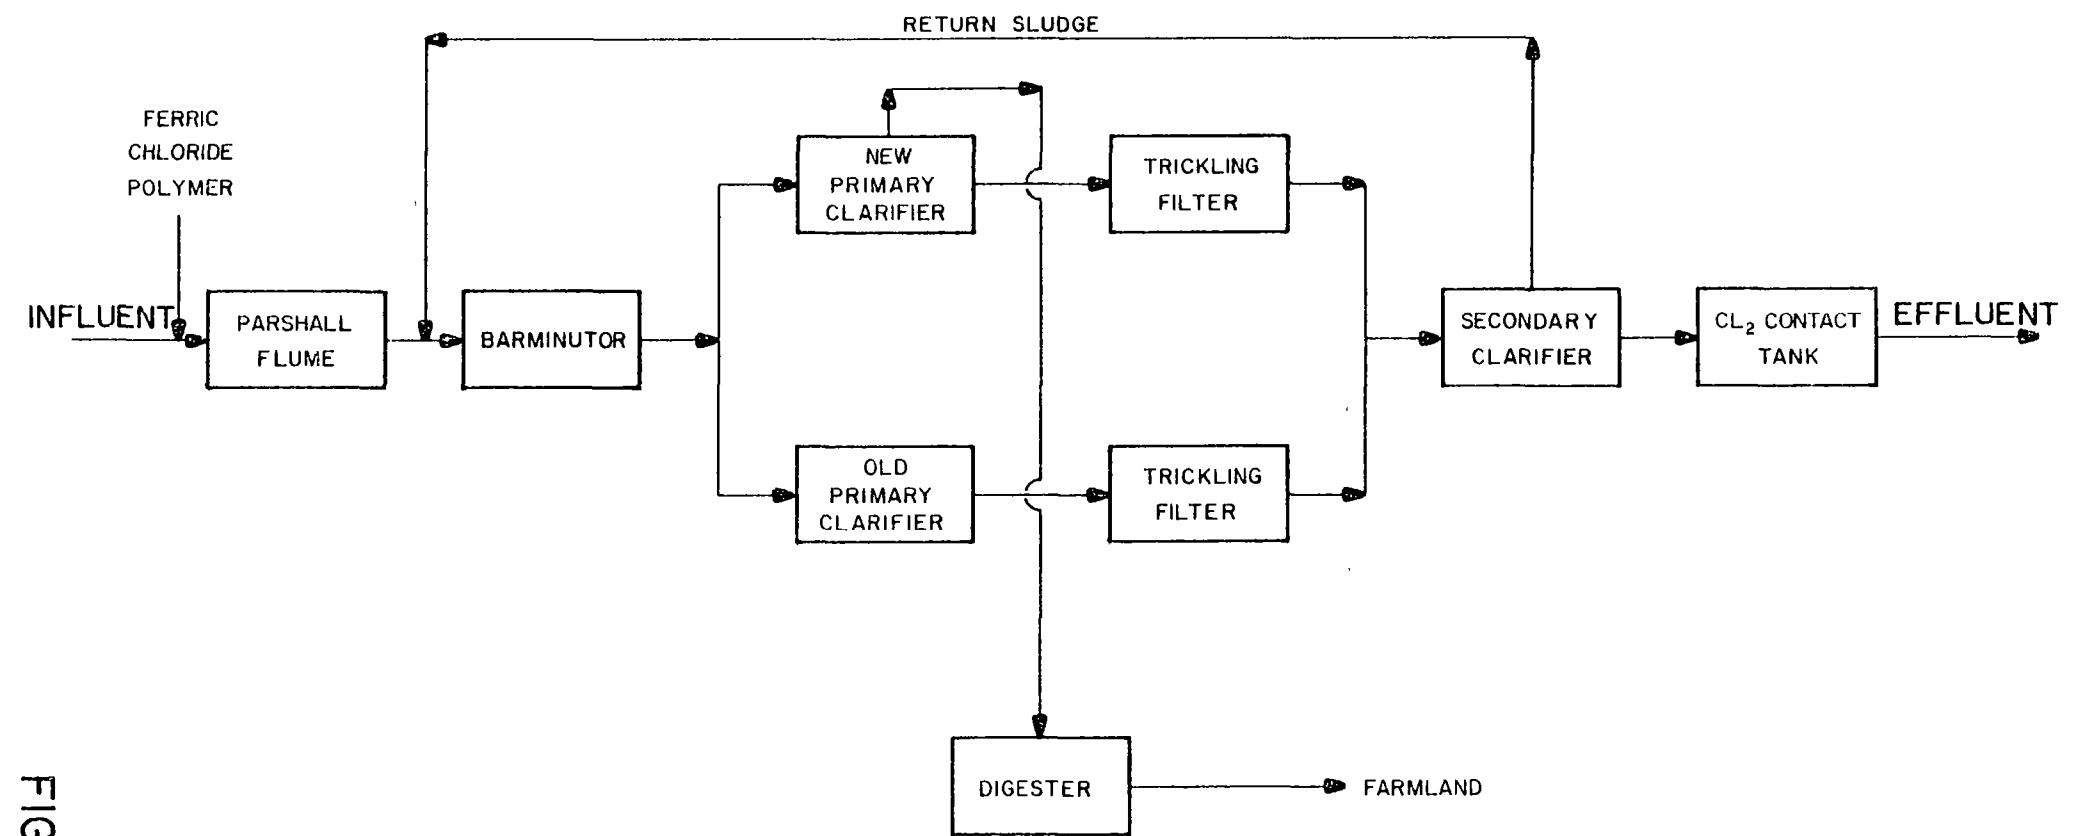

Additional effluent requirements for the plant are provided under a permit issued by the Pennsylvania Department of Environmental Resources (DER). The requirements under this permit, however, either parallel or are less stringent than those set forth by the NPDES.

DER has established water quality criteria for the section of Mill Creek at the point of discharge. The principal uses of the stream include water supplies for domestic and industrial concerns, water-contact recreation, irrigation and propagation of wildlife, fish, and other aquatic

life including cold-water fishes. In addition, the region has been designated as a conservation area.

The New Holland facility utilizes the trickling filtration process to accomplish secondary treatment. Ferric chloride and polymer are initially added to the influent wastewater for increased primary solids removal. Two barminutors then each receive half of the flow. Following preliminary treatment, the wastewater enters the primary sedimentation stage, consisting of two rectangular settling tanks and one circular clarifier. The effluent from the primary stage is then biologically treated by two high-rate trickling filters. Following the biological step, final settling is provided by one circular clarifier. Disinfection occurs in the chlorine contact tanks, which comprise both the original rectangular settling tanks and the original chlorine contact tanks. The final effluent is discharged to Mill Creek. Settled sludge is anaerobically digested and hauled to nearby farms for disposal. Design characteristics for the individual unit processes within the facility are summarized in Appendix A. Figure I provides a process flow schematic of the facility.

WASTEWATER TREATMENT FACILITIES  
NEW HOLLAND, PA.

## TREATMENT PLANT EVALUATION

### General Performance

The New Holland treatment facility was evaluated to determine whether its performance conforms with the design intent and permit requirements. Data regarding performance were compiled from three sources. The first, EPA Form 7500-5, "Report on Operation and Maintenance of Wastewater Treatment Plant," was completed during the field investigations conducted by Gannett Fleming Corddry and Carpenter, Inc. personnel. This document is presented herein as Appendix B. The available operating records maintained by treatment plant personnel served as a second source. This information as well as important operational parameters, is set forth in Appendix C. The final source included a sampling and analysis program of the influent and effluent wastewater flows and characteristics for each major plant unit process. This program was the major activity during a three-day field study conducted at the plant as part of the preliminary evaluation. The results of the survey sampling and analysis program are shown in Table I. Table II presents a summary comparison of recent operating records, survey data, design parameters, and permit requirements.

As indicated in Table II, wastewater parameters such as flow,  $BOD_5$ , settleable solids, suspended solids, fecal coliform, chlorine residual, and pH are monitored regularly at the New Holland plant. From January 1976 through December 1976, the average daily wastewater flow was 0.645 million

gallons. Influent  $BOD_5$  and suspended solids concentrations for the same period were 263 mg/l and 228 mg/l, respectively. The final effluent  $BOD_5$  concentration was reported to average 38 mg/l, and the suspended solids concentration, 23 mg/l.  $BOD_5$  and suspended solids removals of 84 percent and 89 percent respectively, were obtained. Throughout the 12-month period, the chlorine residual was maintained at an average 0.6 mg/l, while effluent fecal coliform counts averaged 6.4 colonies/100 ml. It should be noted that plant personnel indicated that problems were experienced with the chlorination equipment during the past severe winter. This resulted in deviations from the reported average coliform count.

A comprehensive sampling program was performed during the preliminary evaluation. However, the data obtained were the result of a three-day study and may not be representative of average conditions on a long-term basis. Columns 3 and 4 of Table I summarize the major operating parameters investigated. Presented together with the influent and effluent data are sampling data for the individual unit processes and the intermediate stream. Sampling points included the primary clarifier effluent, trickling filter effluent, and final clarifier effluent. Analyses conducted on samples from the major process streams included temperature,  $BOD_5$ , suspended solids, volatile solids, settleable solids, pH, and dissolved oxygen. The various sludge handling process streams were also evaluated. Specifically, primary sludge, secondary sludge and digester contents were examined for volatile and suspended solids. Digester supernatent was analyzed for  $BOD_5$  and volatile suspended and suspended solids.

The results of the three-day sampling program indicated that during that period the plant was not in conformance with the NPDES effluent limitations. However, it was noted that at the time of the study the plant was experiencing problems resulting from what were believed to be wastes from a local cheese processing industry. This industrial waste caused extremely high influent  $BOD_5$  and suspended solids concentrations. The  $BOD_5$  concentration was 2.8 times the normal level, while the suspended solids concentration was 1.4 times the previous year's average.  $BOD_5$  and suspended solids removal for the preliminary study period differed substantially from the year's operating data, probably as a result of the sudden overload condition. Removal for the study period averaged 54 percent and 66 percent respectively. For the previous year's operating data, similar averages were 84% and 89%. Effluent dissolved oxygen concentrations during the evaluation averaged 5.3 mg/l. In order to compare the plant effluent quality with NPDES requirements, 7-day and 30-day average concentrations were computed using actual plant operating data. This information, presented in Table III, indicates that the maximum 7-day average  $BOD_5$  and suspended solids concentrations were 66 mg/l and 102 mg/l, respectively, exceeding the respective interim permit limitations 30 percent and 14 percent of the time. Similarly, the maximum 30-day average  $BOD_5$  and suspended solids concentrations were found to be 66 mg/l and 49 mg/l, respectively, while the limitations as defined by secondary treatment were exceeded 92 percent and 50% of the time. The 7-day and 30-day average performance parameters are summarized in Table IV.

## Process Performance

For a thorough evaluation of the treatment performance, the operational efficiency of key unit processes within the plant must be examined. In this section, therefore, the analytical data and design parameters compiled for these processes are compared with corresponding data for properly designed and operated facilities. For comparison, sources of reference include the EPA process design manual for "Upgrading Existing Wastewater Treatment Plant," and various wastewater treatment texts.

The original primary settling tanks at the New Holland plant were designed to accommodate an overflow rate of 1,100 gallons per day per square foot ( $\text{gpd}/\text{ft}^2$ ) at an average influent flow of 1.0 mgd. The new primary clarifier was designed for an overflow rate of 700  $\text{gpd}/\text{ft}^2$  at the same 1.0-mgd flow. These figures assume an equal distribution of flow between the old and new clarifiers. At these surface loading rates, detention times are approximately 2.5 hours for the original settling tanks and 2 hours for the new clarifier. As indicated, the average flow to the facility is currently 0.65 mgd. Therefore, the present actual overflow rates are 460  $\text{gpd}/\text{ft}^2$  for the new, and 720  $\text{gpd}/\text{ft}^2$  for the old clarifiers. Actual detention times are 3.1 hours for the new, and 4.0 hours for the old clarifiers. The EPA process design literature recommends that overflow rates range from 800 to 1200  $\text{gpd}/\text{ft}^2$ .

During the three-day study, raw waste  $\text{BOD}_5$  and suspended solids concentration averaged 1,018 mg/l and 542 mg/l, respectively.  $\text{BOD}_5$  and

suspended solids concentration in the new primary clarifier effluent were approximately 641 mg/l and 234 mg/l. Similarly, BOD<sub>5</sub> and suspended solids concentrations for the original primary clarifier effluent were 814 mg/l and 468 mg/l, respectively. Therefore, the respective BOD<sub>5</sub> and suspended solids primary removal efficiencies were 37 percent and 57 percent for the new clarifier, while the old primary clarifier removal efficiencies were 20 percent and 14 percent for the same pollutants. The effluent settleable solids removal efficiency for the new primary clarifier averaged 99 percent. Effluent settleable solids concentrations for the original primary clarifier were higher than those of the raw waste. Plant operating records do not indicate the unbalanced primary clarifier performance shown during the survey. According to operating records, the new primary clarifier averaged an 82 percent removal of settleable solids, and the original primary settling tanks, an 89 percent removal.

The secondary treatment stage of the New Holland plant consists of biofiltration and final clarification. The trickling filters were designed to accommodate hydraulic and organic loads of 5.0 mgd/acre and 19.5 lb BOD<sub>5</sub>/1000 ft<sup>3</sup>/day, respectively. An examination of the operating data shows that hydraulic and organic loads averaged 3.07 mgd/acre, excluding recirculation, and 17.4 lb BOD<sub>5</sub>/1000 ft<sup>3</sup>/day, respectively. Because primary effluent BOD<sub>5</sub> data were not available, a reduction of 25 percent in the raw waste BOD<sub>5</sub> load through the primary clarifiers was assumed for calculating the organic load on the biological system. In

addition, the recirculation ratio for the same period was determined to be 0.7. The EPA process design manual recommends that high-rate trickling filters provide for hydraulic loads of 10 to 30 mgd/acre and organic loads of 30 to 60 lb BOD<sub>5</sub>/1000 ft<sup>3</sup>/day. Including recirculation, hydraulic loads of 5.2 mgd/acre are experienced at New Holland. Therefore, the design of the trickling filters would be classified as conservative.

The final clarifier at New Holland was designed to provide approximately 1.9 hours of detention time at 1.4 mgd (0.7 recirculation ratio). Final clarifier overflow rates currently average 330 gpd/ft<sup>2</sup>. The design overflow rate is 560 gpd/ft<sup>2</sup>, including recirculation. The EPA process design manual suggests that overflow rates for secondary clarifiers following trickling filters range from 400 to 600 gpd/ft<sup>2</sup>. A review of the three-day evaluation data indicates that the final clarifier effluent suspended solids concentrations averaged 196 mg/l, an obviously excessive concentration. However, this was under the previously described condition of extremely high load due to industrial wastes. Under normal operating conditions, secondary clarifier effluent is not monitored, so unit performance is unknown. However, the process load and design figures would indicate that any performance problems in secondary clarification during normal loading would be a result of poor sludge characteristics, rather than clarifier design.

The chlorination facilities at the New Holland plant were examined with regard to design and performance. At an average flow of

1.0 mgd, the chlorine contact tanks provide approximately 20 minutes, detention. The chlorine residual is usually maintained at about 0.6 mg/l, although during the three-day study a 0.1-mg/l residual was reported. At present flows, secondary effluent undergoes a 23-minute contact time prior to final discharge. The "Recommended Standards for Sewage Works-Great Lakes-Upper Mississippi River Board of Sanitary Engineer," commonly referred to as the Ten-State Standards, suggests a contact time of at least 15 minutes during peak flow periods. Chlorine residuals commonly range from 0.2 to 0.5 mg/l in properly operated facilities. Inasmuch as the fecal coliform analyses indicated that no colonies were present in the evaluation study samples, and the average fecal coliform count during the 12-month period prior to the evaluation was 6.4 cells per 100 ml, it appears that disinfection facilities at the New Holland plant are adequate and are performing satisfactorily.

According to plant operating records, the primary clarifiers, both old and new, are not performing adequately. Although settleable solids analysis is the only one regularly performed on primary effluent, indications are that the percent removals are not sufficient. Settleable solids should be almost completely removed, allowing only suspended matter to pass into the primary effluent. The additional settleable solids place an increased burden on the trickling filters and final clarifier.

During the three-day study, settleable and suspended solids analyses were performed on both primary effluents. As indicated, the new primary clarifier far exceeded the performance of the old primary

clarifiers, a condition which was apparently related to the unusually high influent pollutant concentrations observed. The inordinately high suspended solids loads were due, according to the plant personnel, to effluent from a cheese processing plant. Although the cheese processing plant has pretreatment facilities, New Holland personnel believed that those facilities were not operating properly at the time of the high  $BOD_5$  and suspended solids loads in the plant. This had been documented by the plant's consulting engineer. Unequal loads on the primary clarifiers caused by blockages of their respective bar screens may have caused the unbalanced performance of the new primary clarifier in relation to the old.

At the time of the study, both barminutors were observed to be inoperative and awaiting parts for repairs. During such times the bypass bar screens must be manually cleaned several times per day. Failure to do so results in clogging of the bar screens and an extremely unbalanced flow distribution to the clarifiers. Such an unbalance can overload one clarifier, causing high solids carry-over for that unit. Poor primary clarification will naturally interfere with the efficiency of the trickling filters.

The sludge treatment facilities at the New Holland plant were also evaluated. Sludge from the primary clarifiers is pumped directly to the anaerobic digester. Sludge from the secondary clarifier is returned to the head of the plant and settled in the primary clarifier. After digestion in the unheated digester, sludge is trucked as a liquid to nearby farms.

A mass balance study was performed to compare the pounds of solids removed from the wastewater with that removed from the digester. For the recorded 12-month period, an average 2,720 gallons per day were hauled from the digester, at an average concentration of 39,900 mg/l. Thus, for the year, the average rate of removal of solids from the digester was 910 lbs/day. The average influent suspended solids concentration was 228 mg/l, which is equivalent to a daily influent suspended solids load of 1,230 pounds. Effluent suspended solids concentrations averaged 23 mg/l for the same period. Thus, solids leaving the plant in the effluent amounted to approximately 120 lbs/day. Net solids removal through treatment averaged 1,010 lbs/day. This value is reasonably close to the above solids removal rate from the digester of 910 lbs/day.

The above analysis also compares well with published data. For example, according to EPA figures, approximately 1,500 pounds of solids are typically generated per million gallons of wastewater treated in a plant such as New Holland. Therefore, under average flow conditions, (approximately 0.645) at New Holland, one would expect about 1,000 lbs/day of solids to be produced for disposal.

## OPERATION AND MAINTENANCE

During the three-day study, various characteristics of the facility operation and maintenance were evaluated. Table V presents a summary evaluation of plant performance indicators at New Holland. As shown, the overall operation of the plant is adequate, though some areas of maintenance are marginally adequate or inadequate. In general, many items of equipment are worn excessively, are old, or are obsolete. This is due, in part, to the original plant being almost 40 years old.

There is no preventive maintenance program at the plant. Maintenance intervals for the equipment are excessively long, and treatment reliability due to equipment downtime is inadequate. Various pieces of equipment including both barminutors, were inoperative at the time of the survey. This necessitates the frequent manual cleaning of the bar screens. If left unattended, as during weekend operation, the blocked screens cause improper flow proportioning to the primary clarifiers. Another equipment malfunction noted was the inoperative distributor arm on one of the trickling filters. According to plant personnel, this arm periodically ceases operation and causes poor bacterial growth on the rock media. Under such a condition, the performance of the trickling filter is inadequate.

Plant housekeeping was also less than adequate. The control room, office, and work room appeared excessively cluttered. It appears

that there is no system for the storage of equipment, and as a result, equipment is left lying around haphazardly.

No emergency maintenance program has been established at New Holland. Although backup equipment, such as portable pumps, generators and spare chlorinators, are not available for use throughout the plant, emergency units and most parts are readily accessible. Also, major units and equipment, except secondary clarifiers, have been provided in parallel configuration, allowing one unit to handle the entire hydraulic load temporarily, if necessary, during maintenance or repair. In general, emergencies are handled satisfactorily at New Holland. Records of repairs and corrective maintenance are filed at the plant and appear satisfactory.

The laboratory at the New Holland plant contains the necessary equipment for performing the analysis required under the NPDES permit and the process control testing. Analyses of primary clarifier effluent settleable solids and pH are normally conducted twice weekly. Also analyzed twice weekly is the trickling filter effluent dissolved oxygen. Percent total and volatile solids and pH tests are analyzed from samples of wet sludge when it is pumped from the digester. Effluent  $BOD_5$  determinations are performed on final clarifier samples, and all other effluent parameters, on the chlorine contact tank effluent samples. Records of laboratory analyses appear complete and copies are filed and maintained systematically.

The personnel operated and maintain the facility without the aid of an operations manual. The lack of a complete reference manual has apparently

not had deleterious effect on the management of the facility.

Although process control is an important factor in the operation of any biological plant, a biofiltration plant is less amenable to such control than are the suspended growth systems. Nevertheless, the plant personnel are familiar with biological process fundamentals, and they apply these principles where applicable at New Holland. The staff is capable of identifying and developing solutions to process upsets as they occur within the system. In addition, the staff has demonstrated the ability to determine the system's response to various control measures.

## ADMINISTRATION

Operations at the New Holland facility are conducted during one shift, 8 hours daily, 5 days weekly. One- to two-hour inspections are made on weekends for pumping operations and routine maintenance. A superintendent, plant operator, and laborer make up the three man staff. Section E of Appendix B presents the estimated labor efforts devoted to the various work areas within the operation of the facility. These estimates represent the actual manpower expenditures as determined through interviews with the plant superintendent.

For comparison, a study of staffing requirements was performed in accordance with the EPA publication "Estimating Staffing for Municipal Wastewater Treatment Facilities." Appendix F sets forth the results of this investigation. As shown, approximately 3.6 persons should be employed to operate and maintain the treatment facility properly. This estimate indicates that the staff size at the facility is deficient by approximately one person. The areas where a need for more manpower is indicated include operation and maintenance. In both of these categories, the present manpower is approximately one-half the amount recommended. All other categories compare favorably with the recommended level of effort. As previously discussed, certain areas of operation and maintenance were found to be in need of improvement. It would appear that an additional person should be employed at the treatment facility. Because the areas of concern require qualified personnel, it would be recommended that any new employee be certified by

the State of Pennsylvania to insure proper operation of the New Holland plant.

The operating budget for the New Holland treatment facility is summarized in Table VI. Total expenses for the year 1976, were approximately \$48,000. Based on the average annual influent flow of 0.645 mgd, the total cost of treatment is approximately 20.4¢ per 1000 gallons treated. This unit cost appears representative of the cost associated with operating and maintaining a facility of the size and type of New Holland. Using the EPA technical report "A Guide to the Selection of Cost-Effective Wastewater Treatment Systems," an estimate of operation and maintenance costs was made for purposes of rough comparison. According to the publication, approximately 18.6¢ per thousand gallons should cover the costs of operation and maintenance at the New Holland plant. However, these estimates do not include the cost of hauling digested liquid sludge to farmlands for ultimate disposal. This cost would increase the estimate so that it would very closely coincide with the actual cost of treatment at New Holland.

An analysis of the budget indicates that approximately 60 percent of the annual expenditures are allocated to operation, while about 40 percent are set aside for maintenance. Although nearly equal, the distribution of funds should be more carefully scrutinized because of the age of the facility. With increasing age, the cost of maintaining the present facility will almost certainly increase, thus requiring more stringent management of expenditures to insure proper maintenance.

TABLE VI

ANNUAL BUDGET  
WASTEWATER TREATMENT FACILITIES  
NEW HOLLAND, PENNSYLVANIA

Salaries and Wages	\$ 10,700
Maintenance and Repairs	
Machinery and Equipment	\$ 6,800
Contracted Supplies	800
Subtotal	\$ 7,600
Supplies	
Materials	\$ 6,900
Gas, Grease and Oil	1,700
Major and Minor	
Equipment Replacement	1,800
Subtotal	\$ 10,400
Fuel and Electric	\$ 4,100
Chemicals	\$ 10,600
Contracted Services	\$ 1,500
Sludge Hauling	\$ 3,100
Total	\$ 48,000

## CONCLUSIONS AND RECOMMENDATIONS

The results of the preliminary evaluation presented in this report indicate that the New Holland wastewater treatment facility is not producing an acceptable effluent and is not consistently meeting regulatory agency permit requirements. Generally, the treatment problems observed at the plant are a result of inadequate maintenance, excessive age of certain items of equipment, and process upset due to equipment failure.

While operational procedures at the plant are adequate, maintenance procedures for many equipment items must be improved. For example, at the time of the survey, the barminutors, trickling filter bearings, and chlorinators were operating improperly and were in need of repair. Poor performance of the plant is attributed by plant personnel, to food processing wastes from local industries, resulting in fluctuating and unreasonable loads. However, analysis of operating data and design parameters indicate that the facility has the capacity to assimilate the wastes it normally receives. If all equipment were properly maintained, and full use of the plant thereby allowed, the occasional shock loads could be better controlled. To allow for improved maintenance programs, an increase in the operating staff size appears necessary. As stated, the EPA staffing estimate indicates that at least one more person should be employed at the treatment plant. According to that estimate, this person is most critically needed in operation and maintenance.

Analysis of budgetary information indicates that funds currently allotted for operation and maintenance of the facility are adequate. In addition to the recommendations discussed, several specific improvements are needed in the operation of the treatment facility. The New Holland plant is currently operated and maintained without the aid of an operations manual. Although the plant performance currently appears to be unaffected by this deficiency, a complete manual should be kept at the facility. Such a reference may prove useful in readily solving future problems at the plant as well as in training future personnel. It should be prepared by a consulting engineering or a similarly qualified firm retained by the Borough of New Holland. As a further improvement, ferric chloride and polymer should be added to the influent waste stream only when necessary, rather than continuously. This would decrease operating costs and reduce the amount of operator attention needed to attend to this system.

## APPENDICES

## APPENDIX A

APPENDIX A  
GENERAL DESCRIPTION OF SEWAGE TREATMENT PLANT UNIT PROCESSES  
WASTEWATER TREATMENT FACILITY  
NEW HOLLAND, PENNSYLVANIA

Process Component	Type of Unit	Number of Units	Dimensions (ft)				Remarks
			Diameter	Length	Width	SWD Depth	
Preliminary Treatment							
Flow Measurement							
Screening

## **APPENDIX D**

## APPENDIX D

**LABORATORY TESTING CAPABILITY AND PERFORMANCE**  
**WASTEWATER TREATMENT FACILITY**  
**NEW HOLLAND, PENNSYLVANIA**

<u>Parameter</u>	<u>Capability</u>	<u>Testing Method</u>	<u>Frequency</u>	<u>Sampling Location</u>	<u>Type of Sample (1)</u>
Flow	Yes	Parshall Flume	Continuous	Influent	G
BOD <sub>5</sub>	Yes	D.O. Meter	1/week	Influent, Effluent	G
Suspended Solids	Yes		Daily	Influent, Effluent	G
Fecal Coliform	Yes	Millipore	Weekly	Effluent	G
pH	Yes	pH Meter	Daily	Raw, Primary Clarifier, Effluent, Secondary Ef- fluent, Final Effluent	G
Phosphorus					
Ammonia Nitrogen					
Nitrate Nitrogen					
Total Kjeldahl					
Dissolved Oxygen	Yes	Dissolved Oxygen Meter	Daily	Trickling Filter Effluent, Final Effluent	G
Chlorine Residual	Yes	Orthotolodine	Daily	Final Effluent	G
COD					
Other					

(1) C-8 = Composite, 8-hour  
 G = Grab

## APPENDIX E

## APPENDIX E

STAFFING ESTIMATE FOR MUNICIPAL WASTEWATER TREATMENT FACILITY ACCORDING TO EPA OEM PROCEDURE, MARCH 1973, CONTRACT 68-01-0328.  
 BOROUGH OF NEW HOLLAND WASTEWATER TREATMENT PLANT  
 DESIGN FLOW 1,000 MGD

## I. ADJUSTMENT FOR LOCAL CONDITIONS (TABULATED VALUES ARE ADDED TO OBTAIN OVERALL PERCENTAGE ADJUSTMENT TO TABLE II TOTALS)

LOCAL CONDITION	COMMENT	OPERATION	MAINTENANCE	SUPERVISORY	CLERICAL	LABORATORY	YARDWORK
PLANT LAYOUT	AVERAGE	0	0	0	0	0	0
UNIT PROCESSES	STD, EQP, DIF, MANF	0	0	0	0	0	0
