ACKNOWLEDGEMENT

We sincerely appreciate the cooperation and support provided by the following; Mr R.J. Hebling and Mr Gus Rios of the Florida Department of Environmental Protection at Marathon, Florida, Mr Ed Castle of Operations Management International, Inc. and his staff who operate the City of Key West Wastewater treatment plant and, the United States Coast Guard Group - Key West. Their assistance and insight are greatly appreciated.

INTRODUCTION

The Environmental Protection Agency as part of their NPDES permit review process is evaluating the impacts of several municipal discharges to the coastal environment. This initiative includes a determination of appropriate measurement techniques for identification of effects to both the water column as well as the benthic communities.

As part of this process, the Water Management Division (WMD) requested the assistance of the Environmental Services Division (ESD) to identify the circulation/dilution patterns in the vicinity of the Key West outfall. The results of this study will be used to guide sampling protocols for further investigations of both the water column and the substrate in the vicinity of the wastewater plume migration.

In proceeding with this request, the ESD, in conjunction with the WMD planned and subsequently conducted a hydrographic study during the period of May 9 through May 16, 1994. The study focused on defining the dilution and dispersion patterns of the Key West POTW effluent as it mixes with the marine waters.

CONCLUSIONS

- ◆ The outfall line appears to have separated at approximately 1000 meters from shore. In its existing configuration the discharge is through a single port at the 6 meter contour as opposed to a reported design which featured a diffuser at the 10 meter contour.
- ◆ Currents measured north of the outfall are aligned with the navigation channel paralleling the western shore of Key West. South of the outfall the current regime is dominated by the easterly flowing Florida Current.
- ◆ Effluent from the Key West POTW was diluted 6:1 at the effluent boil, 93:1 750 meters from the boil and, to 1900:1 at 4300 meters from the boil.
- ◆ Flood tides carried the traced wastewaters along the western shore of Key West via the navigation channel and continued through Garrison Bite above Flemming Key.
- ◆ On the ebb tide, currents directed the plume southeasterly for approximately 1000 meters, then the Florida Current directed the flow in a more easterly direction paralleling the southern shoreline of Key West.
- ◆ Mathematical model simulations were in close agreement with the field tracer data.
- ◆ Simulation of the dilution afforded by use of a diffuser section indicates that levels of dilution at 200 meters from the outfall could be an order of magnitude greater than with

the existing single port configuration.

- ◆ Nutrient levels measured in the boil and within the plume reflected enrichment above background within the first 200 meters from the outfall.
- ◆ Algal growth potential tests indicate nutrient enrichment is moderate 200 meters from the boil. The limiting nutrient was nitrogen.
- ◆ Semi-diurnal tides with a mean range of 1.3 feet was recorded during the survey.
- ◆ Winds were from the east-southeast and averaged 5 knots.

STUDY AREA

The study area is located in the vicinity of Key West, Florida (Figure 1). Tides in this area are semi-diurnal with a mean range of 1.3 feet (NOS tide tables).

The City of Key West POTW discharges an average daily flow of 6 MGD through a submerged outfall which is directed southwesterly from the southern tip of Key West into the marine waters. The discharge line, extends from the shore near the southwest portion of the island southwesterly toward the navigation channel (Figure 1). Reportedly, the discharge line, originally extended to the 10 meter contour and included a diffuser section. Recent diver surveys (NOAA) as well as this EPA study however, indicate that the discharge line has separated and now discharges through a single port located approximately 1000 meters from shore at the 6 meter contour.

STUDY OBJECTIVES

The overall study objective was to define the dilution characteristics of the discharge as it mixes with the marine waters. In order to accomplish this objective, an intensive survey was conducted. The following were the specific objectives at the Key West site:

- ◆ Determine the dilution variability in the receiving waters during a tidal cycle.
- ◆ Estimate the build-up concentration of wastewater under long term conditions.
- ◆ Measure the characteristics of the currents in the vicinity of the outfall.
- ◆ Determine the nutrient enrichment in the discharge plume.

METHODS AND RESULTS

The basic strategy at the Key West site involved releasing a dye tracer (Rhodamine WT) into the POTW discharge line to the ocean in a continuous fashion for a full 25 hour tidal cycle. Boat mounted flow-through fluorometers were then used to measure the circulation and dilution of these traced waters in the oceanic system. Measurements of tracer concentration were made in these ambient waters during the initial 25 hour injection period as well as at 6 to 12 hour slack tide intervals for 2 to 3 days following the tracer injection.

Hydrographic Data

Prior to commencing the tracer study, marker buoys as well as three recording current meters were deployed in the vicinity of the outfall (Figure 2). In addition, a water level recorder and recording wind speed and direction instrumentation were deployed at the Trumble Point United States Coast Guard Station located on Key West.

The buoys, placed at a distance of 200 meters from the outfall, served to provide a high degree of position control in the near field zone of the waste plume. Placement of the three current meters deployed during this survey (Figure 2) was based primarily upon historic current data. These data sources include National Oceanic and Atmospheric Administration (NOAA) Tidal Current Table information (6 sites shown), short term information from an existing instrument deployed near the outfall by NOAA's Acoustical Laboratory in Miami and, data from two instruments deployed by ESD during a short term study conducted in February, 1994. As shown by the depiction of this historic data (Figure 3), ebb and flood currents generally align with the passages between the keys. However, currents seaward of the outfall are dominated by easterly currents associated with the Florida Current which traverses easterly from the Gulf of Mexico toward the Atlantic Ocean.

Based on this information, the current meters were deployed in locations (shown on Figure 2) anticipated to be within the path of the traced effluent. All the meters were deployed within 1000 meters from the outfall to provide information within the dynamic near field region of the plume. The meters deployed at mid-depth were programmed to collect temperature, conductivity, salinity and, current speed and direction at 5 minute intervals during the period of 5/11-14/94.

Winds were from the northeast during the early part of the study and then rotated to a east/southeast direction during the later portion of the study (Figure 4 and Appendix A). Wind speeds averaged 2.5 meters/second.

Results of the current meter deployments are shown on Figures 5 - 13 and in Appendix A. The current meter located near channel marker 13 north of the outfall as well as the meter located south of the outfall near channel marker 12 (Figure 2) revealed current patterns very similar to the historic trends shown earlier on

Figure 3. As depicted on Figures 5-7 for the south meter and Figures 8-10 for the north meter, currents aligned with the navigation channel in nearly a north-south pattern and featured a net displacement to the south (Figures 7 & 10). However, in the case of the current meter deployed near the front range marker east of the outfall, currents were in an east-west alignment in a fashion more representative of the Florida Current (Figures 11-13). The principal feature of the currents recorded by this east meter deployment was the dominance of the western component of the currents. Net displacement at this location as shown by Figure 13 was to the west. Apparently, a localized vortex is formed in the waters immediately southwest of Key West as the result of mixing of the north-south currents aligned with the navigation channel and the easterly bias of the Florida Current.

Tide record established at the USCG Station at Trumble Point is shown on Figure 14. The average tide range during the survey period was 1.3 feet with minimum and maximum excursions of 0.5 and 2.1 feet respectively. The mean range reported in the NOAA Tide Tables is 1.3 feet.

Dye Dilution Study

The 25 hour tracer injection period was planned to coincide with a high tide predicted to occur at 1110 on Thursday May 12. As shown on Figure 14, this high tide was followed by a low tide at 1800 and then by a weaker high and low before completing the cycle with a high tide occurring at 1215 on May 13. During this period, the Rhodamine WT tracer was introduced into the discharge line (after effluent dechlorination) in a continuous fashion by means of a precision metering pump. The tracer injection commenced 2 1/2 hours (0825 on 5/12) prior to the predicted occurrence of the high tide to compensate for residence time of the wastewater in the outfall line.

Effluent flow rate, which averaged 6.4 MGD, was monitored (at the parshall flume upstream of the chlorine contact chamber) at 30 minute intervals so that the tracer injection pump could be adjusted to pace effluent flow characteristics in attempt to develop a mixed tracer/effluent concentration in the discharge line of 1000 PPB. A total volume of 25.4 liters of Rhodamine WT dye was injected over this period. As shown on Figure 15 the effluent pump operates at a rate of 5735 GPM. When the pump is off, the effluent continues to discharge by means of siphoning through the effluent pump. During the "off" cycle the effluent flow rate is 1500 GPM.

The resultant tracer concentration in the effluent as measured from samples collected from a sampling port on the effluent line at the POTW was 925 ppb (Figure 16).

The tracer release into the effluent wet well commenced at 0825 on 5/12/94. Monitoring for these traced wastewaters in the ocean began at 0930 on 5/12 and was accomplished by two crews utilizing boat-mounted flow-through fluorometers with the pump intake positioned at the 1 meter depth. Monitoring locations were concentrated on transects established along Loran lines, as well as keyed to channel markers and other fixed navigational aids. Loran

instrumentation was verified/adjusted by taking position readings at fixed navigation locations so that TD grids could be adjusted to known positions. In the vicinity of the outfall, buoys placed at 200 meters from the outfall provided a higher degree of positioning control near the zone of initial dilution (ZID).

Figures 17-21 depict the dye tracer isopleths described by the monitoring. During the initial monitoring period and the subsequent low tide sampling period on the afternoon and evening of 5/12 the traced waters followed a south by southeast pattern within the first 1000 meters from the outfall and then turned more easterly in nearly a parallel fashion in respect to the southern shoreline of Key West (Figures 17 & 18). As shown on Figure 18 tracer levels of 150 ppb were recorded at the boil and the 10 ppb isopleth extended 750 meters from the boil. Effluent dilution then, based upon a tracer concentration of 925 ppb in the effluent line, was 6:1 at effluent boil (925 ppb in effluent/150 ppb in the boil) and reached 93:1 (925 ppb/10 ppb) within 750 meters from the outfall.

During the flood tide (0930-1330 5/13/94) the currents distributed the traced wastewaters northerly along the navigation channel boarding the western end of Key West (Figure 19). Traced effluent west detected along the western extent of Fleming Key and then northeasterly through Garrison Bite.

Figures 20 and 21 depict the results of the monitoring on the slack tides after completion of the tracer release and serve to indicate the level of traced waters remaining/returning to the vicinity of the outfall. As shown on Figure 20 very little traced effluent remained in the area 6 hours after secession of the tracer release. After 24 hours (1045-1400 5/14/94) only a very small dye patch remained above detection levels (Figure 21).

The single port discharge configuration made monitoring the traced effluent very difficult in the zone near the outfall. Within the first 50 - 100 meters from the outfall a traverse of 10 or 20 meters would often produce a fluctuation of 1 - 2 orders of magnitude in fluorometric readings. With distance from the outfall the mixing process became more complete.

Dilution Model Predictions

In an attempt to predict dilution levels of the Key West wastewater under existing conditions a plume model was applied. The model used was Cormix developed by G.H. Jirka and P.J. Akar of Cornell University (1991). Input data included effluent discharge characteristics, outfall design and geometric dimensions as well as, the receiving water density and velocity characteristics. The data base used and comparison period chosen was the first ebb tide occurring on 5/12/94 as shown on Figure 18.

Results of the modeling run with a listing of the input parameter values used are given in Appendix B. Comparisons of model predictions under existing conditions to the field data are provided in Figures 22,23 &,24. The model predictions compare favorably with the field tracer data. For example, dilution near the edge of the zone of initial dilution (ZID) where the plume is

experiencing dilution due to buoyancy and discharge velocities the model results, as depicted by the inflection point on Figure 22, is 6:1. This can be compared to a similar value obtained in the field measurements.

Figures 23 and 24 depict the extension of the predictions further away from the outfall. A comparison of far field dilution as shown in Figure 24, indicates that the tracer data describes a slightly lower degree of dilution with distance than does the model predictions. This disparity is small, as shown dilution measured at the limit (4300 meters) of the dye tracer transects was 1900:1 as compared to 2000:1 predicted by the model.

This calibrated model was then used to predict dilution that could occur; 1) under a different ambient velocity regime or, 2) if a diffuser section was added to the existing outfall configuration.

Figures 25 and 26 depict the dilution levels predicted by the model under ambient velocities ranging from 0.2 fps (0.06 m/s) to 0.7 fps (0.21 m/s). All other model input parameters were held the same as in the calibration phase. As shown on these figures, with increasing ambient currents, dilution increases. The magnitude of the differences becomes more pronounced with distance from the outfall. For example, at 200 meters from the outfall the model predicts dilutions ranging from 11:1 to 14:1 with these velocities, however at 2000 meters the dilutions predicted range from 100:1 to 370:1.

In order to provide an evaluation of dilution available with the discharge distributed over a greater area, the model was run with the calibration parameters (including velocity) but with a diffuser section added to the existing configuration. The simulated diffuser design selected for illustrative purposes consists of a 25 meter diffuser placed perpendicular to and attached to the end of the existing pipe. Six ports, each with a diameter of 0.25 meters are equally spaced along the diffuser section. The ports directed upward to the water surface are at 90° to the header pipe.

Results of the dilution predictions with the simulated diffuser are compared to the existing single port configuration in Figures 27 and 28 (model runs are in Appendix B). Readily apparent in the predictions is the improvement in dilution with the addition of the diffuser section. The inflection points shown on Figure 27 at approximately 100 meters for the diffuser design and at 10 meters for the existing configuration is the edge of the hydrodynamic mixing zone which is most sensitive to discharge configuration in the model. In this zone, the buoyancy of the effluent coupled with the distribution and velocity provided by the outfall design govern the dilution process. Outside this zone the dispersion characteristics of the receiving waters are prevalent in achieving further dilution. As shown in Figure 27, at 200 meters from the outfall the simulated diffuser section increased dilution levels ten fold (150:1 vs 13:1) over those obtained in the existing configuration. This simulation serves to illustrate the potential improvement in effluent dilution and dispersion obtainable through the use of a diffuser section. The design simulated is only one example of a variety of possible configurations.

Nutrient Enrichment

Samples were collected within the discharge plume for chemical analysis during two sampling events. These events coincided with a flooding and an ebbing tide during the tracer release. During each of the two sampling events, samples were collected in the discharge boil, in the plume, and upstream of the outfall. Samples were preserved in the field and returned to ESD laboratories for analysis of TOC, NO₂-NO₃, NH₃, TKN, and T-P.

Results of the analysis are given in Table 1.

* DENOTES SAMPLE TAKEN WITHIN DISCHARGE PLUME

As seen from the above table, nutrient levels within the boil, sample KW-1 and to a lesser extent KW-5, taken near the boil reflect the presence of the wastewaters. This is particularly true in the case of the nitrite-nitrate nitrogen and total phosphorus forms of the nutrients present. The two samples taken from within the plume at a distance of 200 meters from the boil (KW-3, KW-6) had nearly similar nutrient levels to those of the samples taken out of the plume (KW-2, KW-4).

Algal growth potential tests (AGPT) were performed on samples collected in conjunction with those for analytical analysis. These AGPT tests serve two functions. They measure maximum growth potential of marine algae based upon the available nutrients in the sample. Secondly, nutrients added to the sample in the laboratory serve to determine the limiting nutrients relative to growth potential of the test organism. Samples for AGPT analysis were shipped to ESD laboratories for testing.

Table 2 provides the results of the AGPT tests and, Appendix C contains the laboratory report.

*C+N = Control + Nitrogen

*C+P = Control + Phosphorus

Although there are no published marine AGPT dry weight levels which are indicative of enrichment, the Florida Department of Environmental Protection

considers a level of 10 mg/l as enriched. Laboratory results indicate that up-current stations KW-2 and KW-4 would be slightly enriched, boil stations KW-1 and KW-5 were grossly enriched (42.9 and 23.1 mg/l) and, down-current thin plume stations KW-3 and KW-6 are moderately enriched, but diluted (Table 2).

Nutrient limitation studies indicate that the samples collected from the boil or from within the plume were strongly nitrogen limited. The remaining stations were co-limiting to both nitrogen and phosphorus, meaning both nutrients were required to stimulate growths greater than the untreated samples.

QUALITY ASSURANCE

Field activities and sampling protocols followed ESD standard operating procedures (SOP) manuals.

*** CORMIX MODEL RUN ***

CORMIX SESSION REPORT:
XX

CORNELL MIXING ZONE EXPERT SYSTEM

I t system: CORMIX v.2.10 April 1993
...E NAME/LABEL: KEY WEST OUTFALL - MAY 1994
DESIGN CASE: NEAR FIELD
FILE NAME: NF5
Using subsystem CORMIX1: Submerged Single Port Discharges
(Version: CMX1 v.2.20 April 1993)
Start of session: 07/28/94--11:56:17

SUMMARY OF INPUT DATA:

AMBIENT PARAMETERS:

Cross-section	= unbounded
Average depth	HA = 6 m
Depth at discharge	HD = 6 m
Ambient velocity	UA = .2 m/s
Darcy-Weisbach friction factor	F = .0116
Wind velocity	UW = 3 m/s
Stratification Type	STRCND = U
Surface density	RHOAS = 1016.8 kg/m^3
Bottom density	RHOAB = 1016.8 kg/m^3

DISCHARGE PARAMETERS:

Nearest bank	Submerged Single Port Discharge = left
Distance to bank	DISTB = 900 m
Port diameter	D0 = .62 m
t cross-sectional area	A0 = 0.3018 m^2
charge velocity	U0 = 0.85 m/s
Discharge flowrate	Q0 = .257 m^3/s
Discharge port height	H0 = .5 m
Vertical discharge angle	THETA = 0 deg
Horizontal discharge angle	SIGMA = 0 deg
Discharge temperature (freshwater)	= 28 degC
Corresponding density	RHO0 = 996.2337 kg/m^3
Density difference	DRHO = 20.5662 kg/m^3
Buoyant acceleration	GPO = .1984 m/s^2
Discharge concentration	C0 = 925 PPB
Surface heat exchange coeff.	KS = 0 m/s
Coefficient of decay	KD = 0 /s

DISCHARGE/ENVIRONMENT LENGTH SCALES:

LQ = 0.54 m	Lm = 2.33 m	Lb = 6.37 m
LM = 1.41 m	Lm' = 99999.0 m	Lb' = 99999.0 m

NON-DIMENSIONAL PARAMETERS:

Port densimetric Froude number	FR0 = 2.42
Velocity ratio	R = 4.25

MIXING ZONE / TOXIC DILUTION ZONE / AREA OF INTEREST PARAMETERS:

Toxic discharge	= no
Water quality standard specified	= no
latory mixing zone	= no
on of interest	= 2000.00 m downstream

HYDRODYNAMIC CLASSIFICATION:

| FLOW CLASS = H3 |

-----*

This flow configuration applies to a layer corresponding to the full water depth at the discharge site.

Applicable layer depth = water depth = 6 m

* ***** M G ZONE EVALUATION (hydrodynamic and regulatory summary) :

X-Y-Z Coordinate system:

Origin is located at the bottom below the port center:
900 m from the left bank/shore.

NEAR-FIELD REGION (NFR) CONDITIONS :

Note: The NFR is the zone of strong initial mixing. It has no regulatory implication. However, this information may be useful for the discharge designer because the mixing in the NFR is usually sensitive to the discharge design conditions.

Pollutant concentration at edge of NFR = 136.1579 PPB
Dilution at edge of NFR = 6.7
NFR Location:
(centerline coordinates) x = 9.19 m
y = .00 m
z = 6.00 m
NFR plume dimensions: half-width = 7.50 m
thickness = .58 m

Buoyancy assessment:

The effluent density is less than the surrounding ambient water density at the discharge level.

Therefore, the effluent is POSITIVELY BUOYANT and will tend to rise towards the surface.

| EAM INTRUSION SUMMARY:

Plume exhibits upstream intrusion due to low ambient velocity or strong discharge buoyancy.

Intrusion length = 2.88 m
Intrusion stagnation point = 2.55 m
Intrusion thickness = .58 m
Intrusion half width at impingement = 7.50 m
Intrusion half thickness at impingement = .58 m

***** TOXIC DILUTION ZONE SUMMARY *****

No TDZ was specified for this simulation.

***** REGULATORY MIXING ZONE SUMMARY *****

No RMZ and no ambient water quality standard have been specified.

***** FINAL DESIGN ADVICE AND COMMENTS *****

REMINDER: The user must take note that HYDRODYNAMIC MODELING by any known technique is NOT AN EXACT SCIENCE.

Extensive comparison with field and laboratory data has shown that the CORMIX predictions on dilutions and concentrations (with associated plume geometries) are reliable for the majority of cases and are accurate to within about +-50% (standard deviation).

As a further safeguard, CORMIX will not give predictions whenever it judges the design configuration as highly complex and uncertain for prediction.

CORMIX SESSION REPORT:

XX

CORNELL MIXING ZONE EXPERT SYSTEM

at system: CORMIX v.2.10 April 1993
 - SITE NAME/LABEL: KEY WEST OUTFALL - MAY 1994
 ORIGINAL design case: FAR FIELD
 ORIGINAL file name: FF4
 Start of main session: 07/28/94--09:50:51

DESIGN ITERATION number: 2

NEW DESIGN CASE: FAR FIELD

NEW FILE NAME: FF6

Using subsystem CORMIX1: Submerged Single Port Discharges
 (Version: CMX1 v.2.20 April 1993)

Start of iteration session: 07/28/94--11:25:29

 SUMMARY OF INPUT DATA:

AMBIENT PARAMETERS:

Cross-section	= unbounded
Average depth	HA = 6 m
Depth at discharge	HD = 6 m
Ambient velocity	UA = .2 m/s
Darcy-Weisbach friction factor	F = .0116
Wind velocity	UW = 3 m/s
Stratification Type	STRCND = U
Surface density	RHOAS = 1016.8 kg/m^3
Bottom density	RHOAB = 1016.8 kg/m^3

DISCHARGE PARAMETERS:

Submerged Single Port Discharge

Nearest bank	= left
Distance to bank	DISTB = 900 m
Port diameter	D0 = .62 m
Port cross-sectional area	A0 = 0.3018 m^2
Discharge velocity	U0 = 0.85 m/s
Discharge flowrate	Q0 = .257 m^3/s
Discharge port height	H0 = .5 m
Vertical discharge angle	THETA = 0 deg
Horizontal discharge angle	SIGMA = 0 deg
Discharge temperature (freshwater)	= 28 degC
Corresponding density	RHO0 = 996.2337 kg/m^3
Density difference	DRHO = 20.5662 kg/m^3
Buoyant acceleration	GPO = .1984 m/s^2
Discharge concentration	C0 = 925 PPB
Surface heat exchange coeff.	KS = 0 m/s
Coefficient of decay	KD = 0 /s

DISCHARGE/ENVIRONMENT LENGTH SCALES:

LQ = 0.54 m	Lm = 2.33 m	Lb = 6.37 m
LM = 1.41 m	Lm' = 99999.0 m	Lb' = 99999.0 m

NON-DIMENSIONAL PARAMETERS:

Specific densimetric Froude number	FR0 = 2.42
Locity ratio	R = 4.25

MIXING ZONE / TOXIC DILUTION ZONE / AREA OF INTEREST PARAMETERS:

Toxic discharge	= no
Water quality standard specified	= no
Regulatory mixing zone	= no

Region of interest = 10000.00 m downstream

HYDRODYNAMIC CLASSIFICATION:

-----*
FLOW CLASS = H3 |
-----*

This flow configuration applies to a layer corresponding to the full water depth at the discharge site.

Applicable layer depth = water depth = 6 m

MIXING ZONE EVALUATION (hydrodynamic and regulatory summary) :

X-Y-Z Coordinate system:

Origin is located at the bottom below the port center:
900 m from the left bank/shore.

NEAR-FIELD REGION (NFR) CONDITIONS :

Note: The NFR is the zone of strong initial mixing. It has no regulatory implication. However, this information may be useful for the discharge designer because the mixing in the NFR is usually sensitive to the discharge design conditions.

Pollutant concentration at edge of NFR = 136.1576 PPB

Dilution at edge of NFR = 6.7

NFR Location: x = 9.19 m

(centerline coordinates) y = .00 m

z = 6.00 m

NFR plume dimensions: half-width = 7.49 m
thickness = .58 m

ancy assessment:

The effluent density is less than the surrounding ambient water density at the discharge level.

Therefore, the effluent is POSITIVELY BUOYANT and will tend to rise towards the surface.

UPSTREAM INTRUSION SUMMARY:

Plume exhibits upstream intrusion due to low ambient velocity or strong discharge buoyancy.

Intrusion length = 2.88 m

Intrusion stagnation point = 2.56 m

Intrusion thickness = .58 m

Intrusion half width at impingement = 7.49 m

Intrusion half thickness at impingement = .58 m

FAR-FIELD MIXING SUMMARY:

Plume becomes vertically fully mixed at 6203.16 m downstream.

***** TOXIC DILUTION ZONE SUMMARY *****

No TDZ was specified for this simulation.

***** REGULATORY MIXING ZONE SUMMARY *****

No RMZ and no ambient water quality standard have been specified.

***** FINAL DESIGN ADVICE AND COMMENTS *****

REMINDER: The user must take note that HYDRODYNAMIC MODELING by any known technique is NOT AN EXACT SCIENCE.

sive comparison with field and laboratory data has shown that the MIX predictions on dilutions and concentrations (with associated plume geometries) are reliable for the majority of cases and are accurate to within about +-50% (standard deviation).

As a further safeguard, CORMIX will not give predictions whenever it judges the design configuration as highly complex and uncertain for prediction.

Discharge (volume flux)	q0 =	0.010280 m ² /s
Momentum flux	m0 =	0.011212 m ³ /s ²
Oxygen flux	j0 =	0.002039 m ³ /s ³

DISCHARGE/ENVIRONMENT LENGTH SCALES :

lq = 0.00 m	lm = 0.28 m	lM = 0.69 m
lm' = 99999.0 m	lb' = 99999.0 m	la = 99999.0 m

(These refer to the actual discharge/environment length scales.)

NON-DIMENSIONAL PARAMETERS:

Slot Froude number	FRO	=	25.22
rt/nozzle Froude number	FRD0	=	4.89
locity ratio	R	=	5.45

MIXING ZONE / TOXIC DILUTION ZONE / AREA OF INTEREST PARAMETERS:

Toxic discharge	= no
Water quality standard specified	= no
Regulatory mixing zone	= no
Region of interest	= 2000.00 m downstream

HYDRODYNAMIC CLASSIFICATION:

| FLOW CLASS = MU1H |

This flow configuration applies to a layer corresponding to the full water depth at the discharge site.

Applicable layer depth = water depth = 6 m

MIXING ZONE EVALUATION (hydrodynamic and regulatory summary) :

X-Y-Z Coordinate system:

Origin is located at the bottom below the port center:
897.50 m from the left bank/shore.

NEAR-FIELD REGION (NFR) CONDITIONS :

Note: The NFR is the zone of strong initial mixing. It has no regulatory application. However, this information may be useful for the discharge designer because the mixing in the NFR is usually sensitive to the discharge design conditions.

Pollutant concentration at edge of NFR = 8.2932 PPB

Dilution at edge of NFR = 111.5

NFR Location:
(centerline coordinates) x = 31.43 m
 y = .00 m
 z = 6.00 m

NFR plume dimensions: half-width = 16.65 m
 thickness = 4.30 m

Buoyancy assessment:

The effluent density is less than the surrounding ambient water density at the discharge level.

Therefore, the effluent is POSITIVELY BUOYANT and will tend to rise towards the surface.

***** TOXIC DILUTION ZONE SUMMARY *****

No TDZ was specified for this simulation.

***** REGULATORY MIXING ZONE SUMMARY *****

No RMZ and no ambient water quality standard have been specified.

***** FINAL DESIGN ADVICE AND COMMENTS *****

CORMIX2 uses the TWO-DIMENSIONAL SLOT DIFFUSER CONCEPT to represent the actual three-dimensional diffuser geometry. Thus, it approximates the details of the merging process of the individual jets from each port/nozzle.

In the present design, the spacing between adjacent ports/nozzles (or riser assemblies) is of the order of, or less than, the local water depth so that the slot diffuser approximation holds well.

Nevertheless, if this is a final design, the user is advised to use a final CORMIX1 (single port discharge) analysis, with discharge data for an individual diffuser jet/plume, in order to compare to the present near-field prediction.

REMINDER: The user must take note that HYDRODYNAMIC MODELING by any known technique is NOT AN EXACT SCIENCE.

isive comparison with field and laboratory data has shown that the RMIX predictions on dilutions and concentrations (with associated assume geometries) are reliable for the majority of cases and are accurate to within about +-50% (standard deviation).

As a further safeguard, CORMIX will not give predictions whenever it judges the design configuration as highly complex and uncertain for prediction.

REGMZ = 0
XINT = 2000.00 XMAX = 2000.00

Z COORDINATE SYSTEM:

ORIGIN is located at the bottom and the diffuser mid-point:
897.50 m from the LEFT bank/shore.

X-axis points downstream, Y-axis points to left, Z-axis points upward.

NSTEP = 50 display intervals per module

*** AGPT LAB REPORT ***

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY

REGION IV

ENVIRONMENTAL SERVICES DIVISION
ATHENS, GEORGIA 30613

JUN 13 1994

4ES-ES

MEMORANDUM

SUBJECT: KEY WEST, FLORIDA ALGAL ASSAY

FROM: DON SCHULTZ *(Signature)*

TO: TOM CAVINDER, CHIEF
WATER QUALITY UNIT

Algal Growth Potential Tests (AGPT) were conducted with six salt water samples collected adjacent to the Key West municipal sewage treatment plant (STP) discharge on May 12, 1994. Sampling stations were located to provide an unimpacted control station 200 meters upcurrent from the discharge boil, a station from the STP discharge boil, and a station 200 meters down-current from the discharge boil. These stations were sampled on two separate tidal cycles and have been described as separate stations to identify them as separate time samples. Table 1. describes the separate station samples.

The AGPT were conducted with the marine test alga Dunaliella tertiolecta according to the method described in EPA's Marine Algal Assay Procedure (EPA, 1974), The test procedure consisted of utilizing non-treated samples to measure the productivity of the sample, plus separate treatments of the samples with nitrogen and phosphorus. The last treatments were to determine the algal nutrient limitation of samples. The salinity of the samples were all found to be uniformly 35 0/00. The test alga had been cultured to grow at this salinity prior to the tests.

While there are no published marine AGPT dry weight levels which are indicative of enriched conditions, personal communication with Florida Department of Environmental Regulation indicated that they consider a level of 10 mg/L as such. Accordingly, control stations KW-2 and KW-4 would be slightly enriched, boil stations Kw-1 and Kw-5 were grossly enriched and down-current stations KW-3 and KW-6 are moderately enriched, but being diluted (table 2).

Nutrient limitation of AGPT can normally provide an indication of the source of the sample since most STP discharges are nitrogen limited. However, most of Florida marine waters are naturally nitrogen limited (anonymous, 1976) and could confuse AGPT results. The AGPT nutrient limitation results indicated that the boil stations KW-1 and KW-5 and one down-current station, KW-6, were all strongly nitrogen limited (table 2). The remaining station nutrient limitation results were co-limiting to both nitrogen and phosphorus, meaning both nutrients were required to provide algal growths greater than the untreated samples.
