Executive Summary

EPA's Office of Research and Development's (ORD) National Research Programs (Air, Climate, and Energy; Safe and Sustainable Water Resources; Sustainable and Healthy Communities; Chemical Safety for Sustainability; Human Health Risk Assessment; and Homeland Security) are aligned on the core principle of sustainability and are designed to provide the solutions the Agency and the nation need to meet today's complex environmental and human health challenges. Inevitably, important scientific issues will arise that cut across these six programs. Rather than create additional research programs for every cross-cutting issue, ORD is developing Research Roadmaps to clearly identify the science questions and associated research efforts that are ongoing in the six programs. These Roadmaps identify scientific gaps that inform the National Research Programs in the development of their Strategic Research Action Plans. As new high-priority, cross-cutting issues emerge, ORD expects to use this approach to integrate existing research efforts and to identify needed work. Specific research products/deliverables are not included in the Roadmap, as these may change as a result of ORD's planning and budgeting each year. However, ORD will use the EPA website to provide details regarding research products associated with implementation of this Roadmap. This Roadmap is devoted specifically to the issue of children's environmental health (CEH).

Sustainable decisions and actions are those that improve the well-being of individuals and communities today without compromising the health and welfare of future generations. The current EPA Administrator has committed *"to engaging closely with states, tribes, local partners, federal agencies and business and industry leaders in the most pragmatic, collaborative and flexible way possible to achieve environmental benefits for our children and future generations."* (U.S. EPA, 2014h). To meet this commitment, the Agency and stakeholders require information and tools to incorporate consideration of early life stage sensitivity, susceptibility, and vulnerability to support sustainable decisions and actions.

Today, there is increasing public awareness and concern around the prevalence of children's health outcomes in the United States, and a desire to understand the potential role of environmental factors on those outcomes. Recent high visibility research publications have identified associations between environmental factors and risk of diseases, including asthma, autism spectrum disorder, and childhood obesity. To date, research in this area has been limited and the complexity of exposures, disease etiology, and health outcomes make it difficult to evaluate and interpret associations between exposures and environmental factors. However, as a result of high-profile reports of links between CEH and environmental factors, including air pollution and chemicals in consumer products, the public is looking to the Agency to address or mitigate these environmental factors. While evidence is building of important links between CEH and environmental factors, the science in many cases is still far from actionable. More efficient and effective approaches are needed to develop an understanding of the biological basis of complex environmental disease to support intervention and prevent effects.

The challenge facing the Agency is to evaluate emerging scientific evidence and to fill in gaps requiring the identification of key environmental factors related to CEH, where the Agency can take action. Specifically, what modifiable environmental factors are amenable to practical change using

available technologies, policies, and preventive and public health measures? Within this context, CEH research is conducted by ORD to inform, support, and evaluate regulatory decisions protective of children’s health now and in the future; community decisions that protect and promote children’s health across generations; and, ecological decisions that provide sustainable healthy environments for children. The goal is to enable and extend the Agency’s ability to take actions that minimize early-life exposures for optimal well-being across all developmental lifestages, from preconception through puberty and into adulthood, recognizing that adverse consequences of exposure may not manifest until later in life.

ORD is investing heavily in CEH research – intramural, extramural, and through strategic partnerships. Through its National Research Programs, (Air, Climate, and Energy; Safe and Sustainable Water Resources; Sustainable and Healthy Communities; Chemical Safety for Sustainability; Human Health Risk Assessment; and Homeland Security) ORD is collecting and compiling data on children’s exposures and providing access to information on exposure factors, human behavior, chemical use, and developmental toxicity. Complex systems models of tissues and multi-organ development are being constructed, as well as studies that combine epidemiologic and laboratory-based approaches to provide a holistic understanding of the relationship between early-life environmental exposures and well-being during the lifespan. ORD is developing tools and models that can be used to access data, forecast exposures for thousands of chemicals, and evaluate dosimetry of chemicals in the developing organism. ORD is also developing decision-support tools to help States, local governments, and community organizations consider potential impacts of environmental exposures in the context of decisions designed to protect and promote children’s health.

Despite the many contributions to CEH research by ORD over the last decade, important gaps remain in actionable science and information required to understand, prevent, and mitigate impacts to children from real-world exposures to potentially harmful air, water, and chemicals. ORD leadership is required to bring together science generated inside and outside the Agency to build predictive capacity to evaluate alternative actions and anticipate outcomes.

Working in conjunction with its partners in the EPA regulatory program and other EPA stakeholders, we identified four cross-cutting research areas required to address the critical science challenges in CEH facing the Agency:

- (1) Knowledge infrastructure to address the problem that information and data are distributed and difficult to access;
- (2) Systems understanding of the relationship between environmental exposures and health outcomes across development;
- (3) Methods and models to evaluate early lifestage-specific risks and to support decisions protective of all lifestages; and
- (4) Translational research and tools to support community actions and decisions.

Transforming the Agency’s capacity for considering child-specific vulnerabilities requires that ORD apply advanced systems science and integrate diverse emerging data and knowledge in exposure, toxicology, and epidemiology to improve understanding of the role of environmental exposure during early life on health impacts that may occur at any point over the life course.

This *Children's Environmental Health Research Roadmap* helps connect the dots among research activities being implemented across the National Research Programs. Additionally, the vision articulated in this roadmap serves to focus ORD investment in CEH research on areas where EPA can play a significant leadership role and ensure that this cross-cutting research is integrated and impactful.

The impact of integrated ORD research in CEH will be that the:

- Agency has the necessary data to evaluate risks;
Information on early lifestage exposure and hazard is collated and organized to provide accessible data that can be used to estimate important CEH factors and to support evaluation of risks.
- Agency has scientific basis for action;
Systems understanding of early life exposures and associated health outcomes is used to build predictive models that enable effective Agency actions to protect the health of children.
- Agency has tools to evaluate benefits of alternatives and to support decisions;
Evaluated and accessible tools enhance agency capacity to adequately consider children's unique susceptibilities and vulnerabilities in Agency risk-based evaluations and sustainable public health decisions.
- Agency can enable communities to take action;
Information and translation tools are developed to support agency, state, tribal, and local decision makers with the knowledge needed to manage risks and to protect and promote CEH.

EPA has a unique mandate to understand the role of exposure to modifiable exogenous environmental factors during early life in the context of important modifying factors (i.e., non-chemical stressors) on health impacts during development. This roadmap presents ORD's vision for providing integrated and cutting-edge science on CEH to inform Agency decisions. This roadmap will build stronger bridges to EPA partners and stakeholders who care about CEH issues. Resulting research will provide the science required for EPA actions to promote children's environmental health and well-being.

Introduction

Background

The mission of the EPA is to protect human health and the environment. In addressing health risks, the goal is not only to provide protection for the general population, but specifically for vulnerable individuals and groups, including children. In addition, the Agency expects that decisions and actions designed to promote and protect children's health should do so sustainably. That is, today's public policy for improving the health of individuals and communities should provide effective solutions without compromising the health and welfare of future generations.

In the *Fiscal Year 2014-2018 EPA Strategic Plan*, the Agency "recognizes [that] environmental justice, children's health, and sustainable development are all at the intersection of people and place. These goals are not mutually exclusive. Throughout all our work to achieve more livable communities, EPA is committed to ensuring we focus on children's health and environmental justice." (U.S. EPA, 2014h). As such, ORD has identified children's health as a cross-cutting research area.

Over the last few decades, there have been a number of key legislative and policy initiatives that have been crucial to EPA's mission to protect children's health. In response to concern about the potential vulnerability of children to dietary exposure of pesticides, the U.S. Congress requested that the National Academy of Sciences (NAS) study this critical public health issue. In 1993, the NAS released a report titled *Pesticides in the Diets of Infants and Children*, which described significant differences in toxicity and exposure of pesticides between children and adults (National Academy of Sciences, 1993). The NAS report recommended that changes be made in regulatory practice: "Most importantly, estimates of expected total exposure to pesticide residues should reflect the unique characteristics of the diets of infants and children and should account also for all non-dietary intakes of pesticides. ... Determinations of safe levels of exposure should take into consideration the physiological factors that can place infants and children at greater risk of harm than adults."

The NAS report led Congress to enact the Food Quality Protection Act (FQPA) in 1996, which significantly amended the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) and the Federal Food, Drug, and Cosmetic Act (FFDCA) and set a new risk standard of ensuring "reasonable certainty of no harm." Effective protection of children was emphasized through EPA's use of an extra ten-fold children's safety factor when establishing tolerances unless data were available to show that a different factor was protective. The NAS report also provided the impetus for a series of actions to address the importance of assessing CEH within EPA and across the federal government.

Since the 1990s, EPA has enacted a number of policies and strategies to protect children's health. In 1995 (and reaffirmed in 2013), EPA released its [Policy on Evaluating Health Risks to Children](#) (U.S. EPA, 1995) to consider the risks to infants and children consistently and explicitly as a part of assessments generated during the decision making process, including the setting of standards to protect public health and the environment. In 2000, ORD released its [Strategy for Research on Environmental Risks to Children](#) (U.S. EPA, 2000) to strengthen the scientific foundation of EPA risk-based assessments and risk management decisions that support children's health and welfare.

In 2006, EPA prepared its *Guide to Considering Children’s Health When Developing EPA Actions: Implementing Executive Order 13045 and EPA’s Policy on Evaluating Health Risks to Children* (U.S. EPA, 2006). This guidance outlines the key steps to be considered when developing actions concerning children’s health.

Table 1 presents a summary of the major laws, policies, and guidance on the protection of children’s health from environmental hazards. Policies of the U.S. government (executive and legislative branches); U.S. EPA and other federal agencies; U.S. States; and international organizations are considered.

Table 1. Key governmental and international actions on children’s environmental health

Organization	Year	Title	Content
U.S. Government			
Presidential Task Force (co-chaired by HHS and EPA)	1997	Presidential Executive Order 13045 – Protection of Children from Environmental Health Risks and Safety Risks and establishment of the Presidential Task Force on Environmental Health and Safety Risks to Children (http://www.gpo.gov/fdsys/pkg/FR-1997-04-23/pdf/97-10695.pdf)	Requires all federal agencies to assign a high priority to addressing health and safety risks to children, coordinate research priorities on children’s health, and ensure that their standards take into account the special risks to children.
	2001	HUD Announces \$67 Million in Grants to Fight Childhood Lead Poisoning (http://archive.hhs.gov/news/press/2001pres/20011024a.html)	The task force’s priority is to examine programs that combat childhood lead poisoning.
	2012	Released the Coordinated Federal National Action Plan to Reduce Racial and Ethnic Asthma Disparities (http://www.epa.gov/childrenstaskforce)	The goal is to reduce disparities in the burden caused by asthma, particularly among children.
	2013	Established a Federal Healthy Homes Workgroup and released “Advanced Healthy Housing – A Strategy for Action.” (http://www2.epa.gov/children/presidential-task-force-environmental-health-and-safety-risks-children)	The goal is to support research that informs and advances healthy housing in a cost-effective manner.
	2014	Established a Subcommittee on Climate Change, co-chaired by NIEHS, EPA, and DHS. (http://www2.epa.gov/children/presidential-task-force-environmental-health-and-safety-risks-children)	In July 2014, the Subcommittee hosted an Expert Consultation on the Effects of Climate Change on Children’s Health to explore these issues and to help inform the ongoing U.S. Global Change Research Program.
106th U.S. Congress	2000	Children’s Health Act (Public Law 106-310) (http://www.gpo.gov/fdsys/pkg/PLAW-106publ310/pdf/PLAW-106publ310.pdf)	Directed NIH, NIEHS, CDC, and EPA to conduct a National Children’s Study.
110th U.S. Congress	2007	Energy Independence and Security Act of 2007 (http://www2.epa.gov/laws-regulations/summary-energy-independence-and-security-act)	Required EPA to develop school siting guidelines and environmental health guidelines.

Table 1. (continued) Key governmental and international actions on children’s environmental health

Organization	Year	Title	Content
EPA			
	1995	<i>Policy on Evaluating Health Risks to Children</i> (U.S. EPA, 1995) (http://www2.epa.gov/children/epas-policy-evaluating-risk-children)	The risks to infants and children should be considered consistently and explicitly as part of risk assessments, including the setting of standards to protect public health and the environment.
	1996	<i>National Agenda to Protect Children’s Health from Environmental Threats</i> (http://www2.epa.gov/children/epas-national-agenda-protect-childrens-health-environmental-threats)	All standards should be protective of heightened risks faced by children; develop a scientific research strategy regarding child-specific environmental threats; develop new policies regarding exposures faced by children.
	1996	Enactment of The Food Quality Protection Act (http://www.epa.gov/pesticides/health/children-standards.html)	Improved the safety standards that EPA uses in evaluating pesticide risks, especially risks to children.
	1997	Creation of the Office of Children’s Health Protection (OCHP) (http://www2.epa.gov/children/history-childrens-environmental-health-protection-epa)	Mission is to make the health protection of children a fundamental goal of public health and environmental protection.
	1997	Creation of the Pediatric Environmental Health Specialty Units (PEHSUs) with ATSDR	PEHSUs translate research into public health and clinical practice, educate health providers, and consult on pediatric environmental health issues.
	1998	Children’s Environmental Health and Disease Research Centers (CEHCs) (Jointly funded with NIEHS) (http://epa.gov/ncer/childrenscenters/)	Explores ways to reduce children’s health risks from environmental contaminants.
	2005 - 2008	New risk assessment guidance: <i>Guidance on Selecting Age Groups for Monitoring and Assessing Childhood Exposures to Environmental Contaminants</i> (U.S. EPA, 2005a) (http://www.epa.gov/raf/publications/guidance-on-selecting-age-groups.htm); <i>Supplemental Guidance for Assessing Susceptibility from Early-Life Exposure to Carcinogens</i> (U.S. EPA, 2005b)(http://www.epa.gov/raf/publications/cancer-guidelines/sup-guidance-early-life-exp-carcinogens.htm); <i>A Framework for Assessing Health Risk of Environmental Exposures to Children</i> (U.S. EPA, 2006b) (http://cfpub.epa.gov/ncea/risk/recorddisplay.cfm?id=158363); <i>Child-Specific Exposure Factors Handbook</i> (U.S. EPA, 2008) (http://cfpub.epa.gov/ncea/risk/recorddisplay.cfm?deid=199243) (The latest information on child-specific exposure factors can be found in the 2011 <i>Exposure Factors Handbook</i>)	Risk assessment guidance for assessing CEH issues.

Table 1. (continued) Key governmental and international actions on children’s environmental health

Organization	Year	Title	Content
EPA			
	2010	“Working for Environmental Justice and Children’s Health” (part of EPA’s <i>Strategic Plan, 2011-15</i>) (http://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P1008YOS.PDF)	Emphasis on development and use of the latest science on children’s unique vulnerabilities.
	2013	<i>Protections for Subjects in Human Subjects Research with Pesticides</i> (http://www.epa.gov/oppfead1/guidance/human-test.htm)	Provides for additional protection of susceptible subpopulations and prohibits EPA-sponsored research involving intentional exposures of pregnant women or children to any environmental substance. Implementation of this guidance has broad implications for CEH research.
	2013	ORD establishes six integrated, transdisciplinary National Research Programs: Air, Climate, and Energy (ACE); Safe and Sustainable Water Resources (SSWR); Sustainable and Healthy Communities (SHC); Chemical Safety for Sustainability (CSS); Human Health Risk Assessment (HHRA); and Homeland Security (HS) (http://www2.epa.gov/aboutepa/about-office-research-and-development-ord)	Provides the scientific foundation, methods, and tools that EPA needs to fulfill its mission of protecting human health and the environment.
	2013	EPA’s 1995 Policy on Evaluating Health Risks to Children is reaffirmed by the EPA Administrator (http://www2.epa.gov/sites/production/files/2013-11/documents/childrens_environmental_health_risk_2013_reaffirmation_memorandum.pdf)	“This reaffirmation strengthens EPA’s commitment to leadership in children’s environmental health as well as the leadership of the Office of Children’s Health Protection ... and continues to encourage much needed research.”
	2014	<i>EPA’s Report on the Environment</i> (http://www.epa.gov/roe/)	Provides the best available indicators of national trends in the environment and human health and includes CEH metrics.
Other Federal Agencies, Countries, and International Organizations			
NIH	2014	NIH announces a notice of intent to fund the Children’s Health Exposure Analysis Resource (CHEAR): a National Exposure Assessment Laboratory Network (http://grants2.nih.gov/grants/guide/notice-files/NOT-ES-15-007.html)	Laboratories will provide a comprehensive suite of laboratory-based analytical services for samples from children’s health studies.
FDA	2010	<i>Advancing Regulatory Science for Public Health</i> (http://www.fda.gov/downloads/scienceresearch/specialtopics/regulatoryscience/ucm228444.pdf)	Identifies improving child health as one of the major areas in which advancement in the field can improve public health.
HUD	2009	<i>The Healthy Homes Strategic Plan</i> (http://portal.hud.gov/hudportal/HUD?src=/program_offices/healthy_homes)	Roadmap for the protection of the health of children and other sensitive populations in a comprehensive and cost-effective manner.

Table 1. (continued) Key governmental and international actions on children’s environmental health

Organization	Year	Title	Content
Other Federal Agencies, Countries, and International Organizations			
Canada	2010	<i>National Strategic Framework on Children’s Environmental Health</i> (http://www.hc-sc.gc.ca/ewh-semt/pubs/contaminants/framework_children-cadre_enfants/index-eng.php#a0)	Guides the development of action plans for the protection of children living in Canada from exposure to environmental hazards.
European Union	2013	The Helix Project (http://www.projecthelix.eu/)	A collaborative project using novel tools and methods to characterize early life exposure to a wide range of environmental hazards and which will be integrated and linked with data on major child health outcomes.
World Health Organization (WHO)	2004	<i>Children’s Environment and Action Plan for Europe</i> (http://www.euro.who.int/_data/assets/pdf_file/0006/78639/E83338.pdf)	Developed four regional priority goals and committed the member states to develop and implement national children’s environment and health action plans.
	2012	<i>State of the Science of Endocrine Disrupting Chemicals</i> (http://www.who.int/ceh/publications/endocrine/en/)	Presents scientific knowledge on exposure to and effects of endocrine disrupting chemicals.
	2013	Guidance on identifying important lifestages for monitoring and assessing risks from exposures to environmental contaminants (http://www.who.int/ceh/publications/exposures_environmental_contaminants/en/)	Presents a harmonized set of age bins for monitoring and assessing risks from exposures to chemicals for global use that focuses on preconception through adolescence.
States			
California	2001	<i>Prioritization of Toxic Air Contaminants - Children’s Environmental Health Protection Act</i> (http://oehha.ca.gov/air/toxic_contaminants/SB25finalreport.html)	Presents information on chemicals that are identified as toxic air contaminants that may cause infants and children to be particularly susceptible to illness.
Washington	2008	<i>Chemicals of High Concern to Children - Children’s Safe Product Act</i> (http://www.ecy.wa.gov/programs/swfa/cspa/)	Presents information on chemicals that are toxic and have either been found in children’s products or have been documented to be present in human tissues.
Minnesota	2014	<i>Chemicals of Special Concern to Children’s Health</i> (http://www.health.state.mn.us/divs/eh/children/chemicals.html)	Presents information on chemicals that may adversely affect children’s health.

Current Drivers for CEH Research

There are three key drivers that define the need for, and focus of, EPA-led CEH research:

- 1) *EPA's 2014-2018 Strategic Plan*,
- 2) EPA program office mandates, and
- 3) Recent and emerging scientific findings related to CEH issues.

(1) EPA's 2014-2018 Strategic Plan

The *EPA Strategic Plan* released in early 2014 calls specifically for applied research in CEH in two of the five strategic goals: Goal 3 (Cleaning Up Communities and Advancing Sustainable Development) and Goal 4 (Ensuring Safety of Chemicals and Preventing Pollution).

In the area of cleaning up communities, research to enhance the ability to adequately consider children's unique susceptibilities and vulnerabilities will provide the Agency, State, Tribal, and local decision makers with the knowledge needed to make smart, systems-based decisions that will inform a balanced approach to their cleanup and development needs. EPA's chemical safety research will provide the scientific foundation to support safe and sustainable use of chemicals, including the systems understanding needed to adequately protect the health of children and other vulnerable groups.

Although there is no direct call for applied research in CEH under Goal 1 (Addressing Climate Change and Improving Air Quality) or Goal 2 (Protecting America's Waters), Agency decisions and actions to meet these strategic goals require the information and tools to consider child-specific vulnerabilities.

In addition, the EPA Strategic Plan emphasizes the importance of leveraging and building on existing partnerships to achieve strategic objectives. This includes partnering "with research organizations and academic institutions to focus and advance basic research and create models and measures to expand the conversation on environmental and human health concerns to address priority-focused, locally based problems, specifically including ... children's environmental health issues" (U.S. EPA, 2014h).

(2) EPA Program Office Drivers

EPA program offices have a variety of different mandates to protect children from environmental health risks. These mandates are based on authorities established under the environmental statutes and on guidance specific to each program office.

Office of Children's Health Protection (OCHP):

EPA established OCHP in May 1997 to make the protection of children's health a fundamental goal of public health and environmental protection in the United States. OCHP supports and facilitates Agency efforts to protect children's health from environmental threats through participation in: regulation and standards development; risk assessment guidance and policy development; research planning; and outreach and partnerships with health care professionals, youth groups, and community groups. Important OCHP projects have included: EPA's Clean, Green, and Healthy

Schools Initiative (<http://www.epa.gov/schools/>); increasing environmental health literacy of students and educators; support of Pediatric Environmental Health Specialty Units (<http://aoec.org/pehsu/index.html>); and publication, in partnership with the Office of Policy, of *America's Children and the Environment* (<http://www.epa.gov/ace/>), which evaluates and communicates trends in environmental contaminants that may contribute to childhood disease.

OCHP also provides children's health expertise in Agency rulemakings and other actions, including the Integrated Risk Information System (IRIS) and many other programs across the Agency. Data and analytical tools from ORD are valuable to OCHP's cross-cutting involvement in these priority actions for children's health.

Office of Chemical Safety and Pollution Prevention (OCSPP):

The Toxic Substances Control Act (TSCA) provides EPA with the authority to require reporting, record-keeping and testing requirements, and restrictions related to chemical substances and/or mixtures. OCSPP carries out these requirements by reviewing new and existing chemicals; evaluating chemical hazards, including hazards relevant to developmental and reproductive toxicological endpoints; and exposure, including exposures of children to environmental chemicals. EPA is currently working with Congress, members of the public, the environmental community, and industry to reauthorize TSCA. EPA is working with these groups to modernize and strengthen the tools available under TSCA to prevent harmful chemicals from entering the marketplace and to increase confidence that remaining chemicals are safe and do not endanger the environment or human health, especially for consumers, workers, and children.

Recently, as part of EPA's approach to enhance the Agency's existing chemicals management program, OCSPP identified 83 chemicals (TSCA Work Plan Chemicals) for further assessment under TSCA (<http://www.epa.gov/oppt/existingchemicals/pubs/workplans.html>). The chemicals were selected based on five criteria: hazard, exposure, persistence, bioaccumulation, and use, including use in children's products.

OCSPP also regulates all use of pesticides in the U.S. based on legislative authority provided under FIFRA. EPA's current pesticide review processes also focus on ensuring that pesticide registrations comply with the Endangered Species Act and achieve broader Agency objectives for water quality protection. The review processes place emphasis on the protection of potentially sensitive populations, such as children, by reducing exposures from pesticides used in and around homes, schools, and other public areas.

The 1996 Food Quality Protection Act directs EPA to develop a screening program, using appropriate validated test systems and other scientifically relevant information, to determine whether certain substances including pesticides may have hormonal effects in humans. At the same time, the 1996 amendments to the Safe Drinking Water Act authorize EPA to screen substances that may be found in sources of drinking water for endocrine disruption potential. To carry out this directive, OCSPP established the Endocrine Disruptor Screening Program (EDSP), which uses a two-tiered screening and testing process to gather information needed to identify endocrine-active substances and take appropriate action, as mandated by Congress. In 2005, EPA began screening priority chemicals under this program including: pesticide active ingredients and high production volume chemicals used as inert ingredients in pesticide formulation; drinking water contaminants,

such as halogenated organic chemicals; persistent chemicals such as dioxins and flame retardants; and chemicals found in plastics, pharmaceuticals and personal care products (<http://www.epa.gov/endo/pubs/prioritysetting/index.htm>). In 2010, OCSPP announced plans to make better use of computational toxicology tools in the EDSP and developed the *EDSP21 Work Plan*. This work plan outlines an approach for using computational or in silico models and molecular-based high-throughput assays to prioritize and screen chemicals to determine their potential to interact with the estrogen, androgen, or thyroid hormonal systems. (http://www.epa.gov/endo/pubs/edsp21_work_plan_summary%20overview_final.pdf).

Office of Water (OW):

In the standard setting process for chemicals in drinking water, OW is required, under [Section 103 of the 1996 Amendments](#) to the Safe Drinking Water Act, to determine “the effects of the contaminant on the general population and on groups within the general population such as infants, children, pregnant women, the elderly, individuals with a history of serious illness, or other sub-populations that are identified as likely to be at greater risk of adverse health effects due to exposure to contaminants in drinking water than the general population.”

OW considers the effect of contaminants on children’s health in the standard setting process by following EPA’s guidance on children’s health issues: *Supplemental Guidance for Assessing Susceptibility from Early Life Exposure to Carcinogens* (http://www.epa.gov/raf/publications/cancer_guidelines/sup-guidance-early-life-exp-carcinogens.htm) and *A Framework for Assessing Health Risks of Environmental Exposures to Children* (<http://cfpub.epa.gov/ncea/risk/recordisplay.cfm?deid=158363>). OW uses these guidances in its qualitative assessment of the adverse health effects of contaminants. For carcinogens, OW factors in age-dependent susceptibility in its dose-response assessment.

Office of Air and Radiation (OAR):

In conducting risk assessments for air toxics, OAR routinely seeks to identify groups, such as children, whose vulnerability to certain environmental contaminants may be higher than that of adults. Such assessments are conducted for all air toxics rulemakings, including National Emissions Standards for Hazardous Air Pollutants (NESHAPS, otherwise known as Maximum Achievable Control Technology, or MACT, standards) and Residual Risk rules. During these assessments, OAR specifically estimates risks to children and/or determines if children are disproportionately affected by their exposures and/or behavioral patterns. OAR uses dose-response values which specifically account for the differential sensitivity of children as compared to adults and has developed exposure estimates for mutagenic carcinogens (e.g., vinyl chloride and polycyclic aromatic hydrocarbons), which specifically account for the greater vulnerability of children to these compounds during their developmental years, based on EPA’s *Supplemental Guidance for Assessing Susceptibility from Early Life Exposure to Carcinogens*.

OAR also carefully considers impacts on children’s health as part of its periodic reviews of the National Ambient Air Quality Standard (NAAQS), in which the Agency must consider whether the standards are requisite to protect public health, including the health of at-risk subgroups, with an adequate margin of safety. Evaluating the effects of criteria air pollutants in children has been a central focus in several recent NAAQS reviews, including reviews of the lead, ozone, and particulate matter standards, which resulted in revised standards to strengthen public health protection.

Office of Solid Waste and Emergency Response (OSWER):

OSWER provides policy, guidance, and direction for the Agency's waste and clean-up programs, emergency response, management of hazardous substances and waste, and redevelopment of contaminated sites. OSWER implements its mission under a variety of mandates, including the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), the Resource Conservation and Recovery Act (RCRA), and the Small Business Liability Relief and Brownfields Revitalization Act. In addressing its mission, OSWER works to understand and protect the health of populations, taking into account the unique susceptibilities and vulnerabilities of children.

OSWER directly considers potential impacts to sensitive subpopulations, including children, in its risk assessment and risk management actions. Consistent with the National Contingency Plan [40 CFR 430(e)(2)(i)(A)(10)], OSWER's cleanup under Superfund actions ensures that exposures to the human population, including sensitive groups, are without adverse effect during a lifetime or part of a lifetime, and incorporate an adequate margin of safety. The Risk Assessment Guidance for Superfund (RAGS) documents provide specific guidance on the incorporation of child-specific factors, including body weight, timing of exposure, and unique exposure pathway considerations, such as dust and soil intake rates.

Regional Offices: Each Regional Office has a Children's Environmental Health Coordinator who is responsible for leading the CEH Program in their region, and to engage with other regional coordinators, including Regional School Coordinators and risk assessors. These programs are based on national and regional strategies to protect CEH through a number of regulations and voluntary programs. While exposures can occur in any number or variety of locations, the regions work with decision makers to understand and reduce exposures in home, learning, and play environments.

(3) Scientific Drivers Related to Adverse Health Outcomes

Recent and emerging research findings on the relationship of environmental contributions to children's health outcomes are important drivers for EPA's CEH research. Evidence points to associations between early life exposure to environmental contaminants and a wide range of children's health outcomes, including adverse birth outcomes, asthma, neurodevelopmental disorders, metabolic disease, and childhood cancer.

Adverse birth outcomes: These include preterm birth, low birth weight, neonatal mortality, and birth defects. Birth defects are seen in approximately 3% of births in this country and low birth weights are observed in 11% of births. In 2012, black non-Hispanic women had the highest rate of preterm birth of all racial groups (16.8%). Adverse birth outcomes are leading causes of infant mortality and may presage long-term problems including motor, cognitive, visual, hearing, behavioral, and social-emotional problems.

Birth outcomes have been associated with exposure to a variety of environmental contaminants in utero and early in life, including fine particulate matter (Dadvand et al., 2013; Fleischer et al., 2014; Stieb et al., 2012) and chemicals such as arsenic (Boekelheide et al., 2012), organochlorine pesticides, organic solvents, and other air pollutants (Gorini et al., 2014).

Asthma: The incidence and severity of childhood asthma continues to rise. In 2009, asthma affected 7.1 million children (about 10% of children) in the United States. Asthma disproportionately impacts minority children, especially in urban communities typified by low income, high levels of air pollution, and poor indoor air quality (Akinbami et al., 2012). 12.2% of children in families below the poverty line were reported to have asthma, compared to 8.7% of children in families above the poverty line. A higher percentage of black non-Hispanic children (16%) and children of “all other races” (12.4%) were reported to have asthma, compared to white non-Hispanic children (8.2%).

More is known about environmental factors that exacerbate asthma severity than those that cause asthma, but recent evidence implicates air pollution as a causative factor. Substantial evidence has associated *in utero* or early life exposures to environmental tobacco smoke, ambient and indoor air pollutants, and inhaled allergens (dust mites, pets and pollens) with asthma incidence and/or severity in children (Dick et al., 2014; Selgrade et al., 2013). Genetic factors and gene-environment interactions also play a role in asthma causation (Rigoli et al., 2011). Children with specific gene variants were shown to be at increased rates of asthma associated with air pollution (Macintyre et al., 2014). Environmental exposures may also impact asthma risk through epigenetic mechanisms, an emerging area of study (Kabesch, 2014; Salam et al., 2012).

Neurodevelopmental disorders: Developmental disabilities (DDs), including lower IQ, learning deficits and other indicators of poor cognitive function, and adverse effects on behavior, are common; about 1 in 6 children in the United States are affected. Between 1997 and 2008, the prevalence of DDs increased 17.1%, impacting about 1.8 million more children. The prevalence of autism increased 289% while attention deficit hyperactivity disorder (ADHD) increased 33%. Again, lower income children are disproportionately impacted by DDs. Children insured by Medicaid had nearly two-fold higher prevalence compared to those with private insurance.

Neurotoxicants that have been associated with developmental effects include lead, methylmercury, PCBs, arsenic, toluene, manganese, fluoride, chlorpyrifos, and tetrachloroethylene (Grandjean and Landrigan, 2014). Limited evidence is emerging to suggest an association between exposure to a range of environmental contaminants including air pollutants, organophosphate pesticides, brominated flame retardants, phthalates, bisphenol A, and perfluorinated compounds and adverse neurodevelopmental effects (Bellinger, 2013; Choi et al., 2012; Rodriguez-Barranco et al., 2013; Yim et al., 2014).

Recent children’s cohort studies implicate prenatal exposure to polycyclic aromatic hydrocarbons (PAHs) from air pollution and bisphenol-A with attention problems, anxiety and aggressive behavior in boys (F. Perera et al., 2012; F. P. Perera et al., 2011). The possible link between environmental contaminants and increasing prevalence of ADHD and autism is an area of active investigation. In addition, potential for gene-environment interactions are being studied (Hu, 2012).

Metabolic Syndrome: Metabolic syndrome, a cluster of adverse health effects including obesity, altered lipid levels, and other metabolic abnormalities, is increasing globally. Prevalence of childhood obesity in the U.S. has recently stabilized at approximately 16%. 22% of Mexican-American and 20% of black non-Hispanic children are obese, compared with 14% of white non-Hispanic children. Prevalence of obesity is greater in children with family incomes below poverty level than in

those above. The rise in obesity and related metabolic disease is of particular concern because the risk of life-threatening diseases, such as diabetes, cardiovascular disease, and cancer, is increased in persons with metabolic disease.

The possibility that environmental chemicals can influence childhood obesity is currently an area of significant study. Chemicals that are under investigation include dioxins, PCBs, DDT, DDE, per-fluoroalkyls, PBDEs, phthalates, bisphenol A, organotins, lead, air pollutants, polycyclic aromatic hydrocarbons (PAHs), naphthalene, diethylstilbestrol, thiazolidinediones. Some of these chemicals have been shown to increase obesity in laboratory animals and *in vitro* studies have shown cell differentiation that may indicate an association between certain chemicals and obesity (Karoutsou and Polymeris, 2012; La Merrill and Birnbaum, 2011; Scinicariello and Buser, 2014). Epigenetic reprogramming is hypothesized to be a contributing factor in childhood obesity and metabolic syndrome, and is an area of intense study (Janesick and Blumberg, 2011).

Developmental Origins of Disease: More generally, an increasing number of studies are addressing the hypothesis that exposure in early life to environmental stressors may influence development that impacts later health and disease risk. An area of intense interest involves epigenetic modification resulting from exposures during critical windows of development. The support for epigenetic change in early life comes from a large number of animal studies and a small number of observational studies in humans (Saffery and Novakovic, 2014). Evidence has been published for epigenetic changes including DNA methylation, histone modifications, and miRNAs in developmental programming, leading to an increased risk of disease (Bernal and Jirtle, 2010; Hou et al., 2012; Vaiserman, 2014). Environmental compounds being studied for their ability to cause epigenetic changes include asbestos, benzene, endocrine-disrupting compounds, and metals (Kim et al., 2012; Vaiserman, 2014).

Purpose

Protecting children's health from environmental risks remains a critical and enduring part of EPA's mission. EPA conducts and supports CEH research to inform regulatory decisions and to support community decision making to promote sustainable healthy environments for children. Given recent advances in the science of risk assessment, it has now become an opportune time to re-examine and update EPA's path forward for critical CEH research.

The purpose of this CEH Roadmap is to describe EPA's strategic vision for CEH research, building on and extending the problems and needs identified in EPA's 2000 research strategy. This new vision aims to use all science, particularly 21st century science and systems approaches to improve our understanding of how environmental factors affect children's health and contribute to the most prevalent diseases and disorders; incorporate basic human health research into the development of innovative new approaches for assessing risks associated with early lifestyle exposures, including prenatal and lactational exposures; and translate basic and applied research findings to inform new ways by which the Agency and others can take action to prevent or reduce adverse CEH outcomes and promote sustainably healthy environments in communities where children live, play, and learn.

The ORD cross-cutting Research Roadmaps are not intended to be new research strategies for Strategic Research Action Plans (StRAPs). Rather, they take a cross-cutting look at existing and imminent ORD research portfolios and emerging StRAPs for each National Research Program (NRP) and describe the focus of ongoing research and the direction of the planned research. They also inform future research planning in relevant NRPs. As such, this cross-cutting Research Roadmap has two important attributes: (1) the research needs described are “owned” by an NRP and articulated as either existing or planned (definitively or aspirationally) in a near-term timeframe; and (2) research needs described are those for which EPA/ORD needs to play a transformative leadership role.

This Roadmap is focused specifically on CEH research. There is a separate Roadmap for research on environmental justice which will articulate research and needs specific to all lifestages, and highlight research that addresses both CEH and environmental justice (health disparity) concerns.

The lifestage scope of the research described in this Roadmap specifically considers impacts associated with exposure during or across developmentally sensitive windows. Although many references are made to children as a “subpopulation” (e.g., 1996 SDWA amendments uses the term “subpopulation” to describe groups with unique attributes, including those defined by age or lifestage), since 2005 EPA has recognized the importance of distinguishing between population groups that form a relatively fixed portion of the population (e.g., groups based on ethnicity) and lifestages or age groups that are inclusive of the entire population. The term “lifestage” refers to a distinguishable time frame in an individual’s life characterized by unique and relatively stable behavioral and/or physiological characteristics that are associated with development and growth. Thus, childhood should be viewed as a sequence of lifestages, from birth, through infancy and adolescence. EPA has official guidance defining early lifestage specific age bins which has been affirmed by WHO (Cohen Hubal et al., 2013; U.S. EPA, 2005).

The purpose of this roadmap is to describe and facilitate integrated ORD CEH research that will provide the Agency and stakeholders with scientific understanding, information, and tools required to address early lifestage sensitivity, susceptibility, and vulnerability for sustainable decisions and actions.

Figure 1 outlines these lifestages which are the specific focus for this Roadmap and cross-cutting CEH research. Note that while exposures from preconception through adolescence are of primary interest, impacts may extend throughout the lifecourse into adult lifestages and across generations. Here, the lifecourse is depicted as a circle to convey the concept of intergenerational impacts from environmental exposures.

Research Scope

Expanded Problem Statement

Sustainable decisions and actions are those that improve the health of individuals and communities today without compromising the health and welfare of future generations. **The U.S. EPA and stakeholders require scientific understanding, information, and tools to incorporate consideration of early lifestage sensitivity, susceptibility and vulnerability for sustainable decisions and actions.**

Within the broad sphere of CEH, EPA has a unique mandate to focus on understanding the role of exposure to modifiable xenobiotic environmental factors during early life, in the context of important modifying factors (i.e., non-chemical stressors), on health impacts over the course of a lifetime. Specifically, applied research is required to enable and extend the Agency's ability to take action. The science challenges associated with filling this unique niche in CEH research are significant.

The Agency and stakeholders make decisions at several levels of organization, from the individual to community level all the way to the state and national level. ORD research will provide required information and tools by considering the different types of decisions and actions required to support CEH. The CEH research translation framework presented in Figure 2 captures the important science challenges addressed by ORD CEH research within this context. Two general translation routes are depicted: one focused on providing cutting-edge science for effective public health policy and efficient risk management at the national level; the second at the community level.

Understanding of developmental biology, impacts to biological pathways resulting from perturbations at critical windows of development, and genetic and environmental factors that may produce and/or modify these perturbations form the scientific basis for both translation routes. In the first, identification of toxicity pathways coupled with identification of important environmental factors (exposures) provides new opportunities to anticipate impacts by considering early indicators of adversity and monitoring for emerging environmental contaminants. Information and tools along this translation route will inform decision making and public health protection at the population level. Decision support tools developed along this route may include: (1) biomarkers, metrics, and indicators for measuring and monitoring environmental exposures as well as providing early indication of toxicological impacts; and (2) models for risk-based decision making, informed by detailed understanding of relevant environmental stressors and associated perturbations to toxicity pathways. In the second translational route, knowledge of individual patterns of exposure and disease predisposition resulting from the full range of community-level determinants provides opportunities to develop community-based approaches to health promotion and risk management. Here, information and decision support tools are developed to inform and support actions by communities to manage risks and promote health by providing a clear understanding of important exposures and how these can be locally controlled.

Considerations of individual variation based on genetic susceptibility, lifestage, timing of exposures, and interaction of non-chemical stressors is required context for both routes and for holistic assessment of risk factors associated with complex environmental disease. By capturing the science challenges of characterizing biologically relevant exposure, the framework presented in Figure 2 facilitates translation of advances and findings in computational toxicology to information that can be directly used to support risk-based decisions to improve public health. In addition, this framework captures the challenge of addressing data gaps along all levels of biological organization (i.e., from molecular through population levels) in a systems-based fashion to optimize design of future exposure and epidemiology studies. Such a strategic implementation of toxicology, exposure and epidemiology research is required to ensure efficient use of resources committed to children’s health studies.

Figure 2. Children’s environmental health research translation framework (Adapted from Cohen Hubal et al., 2010).

ORD research is designed and implemented through case examples that allow for demonstration and evaluation of research products. ORD works with EPA program partners and regions through its six National Research Programs to identify useful case examples, to develop and demonstrate the research products fit-for-purpose, and to evaluate the value added of ORD information and tools to both inform decisions and to support measurement of impact resulting from those decisions.

Children's Environmental Health Research Areas

Working in conjunction with its partners in the EPA regulatory program and other EPA stakeholders, EPA identified four cross-cutting research areas required to address the critical science challenges in CEH facing the Agency. To provide the science, information and decision support tools required to promote and protect children's health and well-being, EPA's CEH research is designed to address the following four priority research areas:

- (1) Knowledge infrastructure** to address the problem that information and data are distributed and difficult to access;
- (2) Systems understanding** of the relationship between environmental exposures and health outcomes across development;
- (3) Methods and models** to evaluate early lifestage-specific risks and to support decisions protective of all lifestages; and,
- (4) Translational research and tools** to support community actions and decisions

For each of these research areas, this Roadmap provides the general scope of the area, key research questions, and specific research needed to provide the answers.

Research Area 1: Knowledge infrastructure to address the problem that information and data are distributed and difficult to access

Information and data required to support Agency and stakeholder decisions and actions to promote and protect children are distributed and may be difficult to access. Much of these data are generated outside the Agency but are critical for evaluating emerging scientific evidence for role of key environmental factors in CEH, identifying data gaps required to reduce uncertainties in model predictions, and providing effective decision support tools. In all cases, the knowledge systems to facilitate integration and analysis of CEH data are required to identify and protect susceptible lifestages.

Key research questions addressed in this research area:

- What data and information are most critical for characterizing early lifestage vulnerabilities and susceptibility in the areas of exposure, toxicokinetics, toxicodynamics, and disease etiology?
- What data and information are most critical for evaluating linkages between early life environmental exposures and health outcomes, including those that may appear later in life?

- What data and information are most critical for reducing early lifestage-related uncertainties in exposure and risk characterization to provide the basis for EPA’s policy decisions?

Anticipated integrated impact:

The Agency has data it needs to evaluate risks. Information on early lifestage exposure and hazard is collated and organized to provide accessible data that can be used to estimate important CEH factors and to support evaluation of risks.

Research Area 2: Systems understanding of the relationship between environmental exposures and health outcomes across development

A holistic understanding of the factors that impact children’s health, specific to each stage of development, is needed in order to attribute, reduce, and eliminate risks specific to the environmental exposures over which EPA has regulatory authority. Systems-level understanding of the relationship between environmental exposures and health outcomes across development is required to develop predictive models that enable effective Agency decisions and actions that protect susceptible lifestages. EPA CEH research is designed to develop this understanding by considering exposures to chemicals and chemical classes of concern as well as the influence of non-chemical stressors and the built environment on children’s health outcomes. Toxicological and epidemiological studies on exposure to chemical and non-chemical stressors are included in this research area.

Key research questions addressed in this research area:

- By what common biological pathways do environmental contaminants contribute toward early origins of disease and to important childhood health outcomes, such as adverse birth outcomes, asthma, neurological disorders and metabolic syndrome?
- What are the key perturbations and biological targets associated with developmentally relevant adverse outcome pathways (AOPs)?
- What are the systems-level influences of the chemical and natural and built environments on these biological pathways and health outcomes?
- How can we evaluate the individual and community risk profiles associated with exposures to chemical mixtures including the contribution of non-chemical stressors across the course of development?

Anticipated integrated impact:

Agency has scientific basis for action.

Systems understanding of early life exposures and associated health outcomes is used to build predictive models that enable effective Agency actions to protect the health of children.

Specific research to provide biological systems understanding of the relationship between environmental exposures and health outcomes across development:

- Identification of AOPS for chemicals that disrupt specific developmental processes.
- Evaluation of relevance/concordance of lab animal models for human health.
- Linkage of environmental exposures to health outcomes via AOPs including outcomes apparent at birth and those which contribute to later onset of disease in childhood or adulthood.
- Development and evaluation of systems models to understand and predict developmental toxicity.
- Systems level understanding of the complex interactions between multiple chemical stressors and how these interact with non-chemical stressors (other environmental and socioeconomic factors), and genetics, including informing how those interactions may affect children’s health.

Research Area 3: Methods and models to evaluate early lifestage-specific risks and to support decisions protective of all lifestages

Risk assessors and risk managers need methods to measure lifestage specific exposure, toxicity and health endpoints as well as models and tools to analyze and integrate the information to adequately consider lifestage specific factors in sustainable decisions.

Key research questions:

- What methods, models, and decision support tools are needed to allow the Agency to use all available data to inform risk-based decisions?
- What methods, models, and decision support tools are needed to evaluate how and to what extent pregnant women and children are exposed to environmental stressors?
- What methods, models, and decision support tools are needed to evaluate how associated health outcomes vary by specific early lifestages and exposure patterns?
- What methods, models, and decision support tools are needed to support analysis of potential risks associated with exposures to multiple chemicals in the context of other important environmental stressors across development?

Anticipated integrated impact:

Agency has tools to evaluate benefits of alternatives and support decisions. Evaluated, accessible tools enhance agency capacity to adequately consider children’s unique susceptibilities and vulnerabilities in Agency risk-based evaluations and sustainable public health decisions.

Specific models and methods to evaluate early lifestage specific risks and support regulatory decisions including:

- Efficient, cost-effective methods for monitoring children’s exposures.

- Tools for assessing exposure (timing and duration)-dose-response relationships in children including physiologically-based pharmacokinetic (PBPK) models that incorporate early life-stage specific parameters.
- Novel computational tools to incorporate estimates of developmental toxicity into risk assessments.
- Risk assessment tools for incorporating multiple exposures across multiple vulnerable stages to estimate risks that may accrue over time.
- Web-based tools that incorporate early lifestage-specific factors for predicting source-to-effects.
- Extend models and methods to estimate children’s exposures at spatial and temporal scales relevant to the pollutant and health endpoint of concern.

Research Area 4: Translational research and tools to support community actions and decisions

Federal, State, Tribal and local governments make decisions at multiple scales (national to local) that impact children’s health and well-being. Decision support tools that incorporate multiple factors about the built and natural environments that contribute to children’s health, along with child-specific exposure and risk factors (including non-chemical stressors), can support informed decisions that protect and promote children’s health in the communities where they live, learn, and play. Ideally, these tools should be developed through partnerships and active engagement with affected communities and suitable for use across geographic scales.

Key research questions:

- What are the real-world environmental exposures to children in their homes, schools, and communities, and how do they contribute to children’s health risks?
- How do social and economic factors, including those specific to place, influence lifestage-specific exposure and risk?
- What tools can provide communities with the lifestage-specific information needed to support local decisions and actions?
- How can information regarding real-world environmental exposures to children inform community-based decisions in key sectors (e.g., land use; buildings and infrastructure; transportation; waste and materials management) to meet community needs?
- What are the most effective actions to prevent adverse environmental exposures and promote child well-being, how effective are these, and how can these be best communicated to communities and parents?

Anticipated integrated impact:

Agency can enable communities to take action. Information and translation tools are developed to support Agency, State, Tribal, and local decision makers with the knowledge needed to manage risks and to protect and promote CEH.

Specific research and tools to inform community decisions designed to protect and promote CEH:

- Methods and models for measuring or estimating exposures in pregnant women and children to environmental contaminants and potentially harmful substances in air, water, house dust, soil, and products encountered in their day-to-day lives.
- Models for estimating cumulative exposures and how they may vary in indoor vs. outdoor environments.
- Methods for measuring the sustainable benefits and costs of community decisions designed to promote CEH such as increasing green space or access to healthy foods.
- Community assessment tools (e.g., geographic information system (GIS) models) that identify sources of exposures as well as health-promoting factors with respect to specific places where children live, attend school, or recreate.
- Approaches for incorporating CEH into Health Impact Assessments.
- Approaches and guidance for optimizing the built environment to sustainably protect and foster CEH.

Research Alignment and Coordination

The four CEH Research Areas are cross-cutting to ORD's six National Research Programs. Currently, one or more of the four Research Areas is contained within each of the following NRPs: Air, Climate, and Energy (ACE); Chemical Safety for Sustainability (CSS); Human Health Risk Assessment (HHRA); Sustainable and Healthy Communities (SHC); and Safe and Sustainable Water Resources (SSWR). Several of the NRPs conduct research in all four areas. Details of the research are described in the individual NRP Strategic Research Action Plans.

Modifiable environmental factors addressed by ORD research include chemicals/classes of current and emerging focus where the Agency has a role in setting policy or in developing regulatory actions. These include manufactured chemicals and materials (pesticides, solvents, industrial chemicals, nanomaterials); hazardous chemicals released to the environment through improper waste disposal or accidental releases to the environment; environmental contaminants resulting from human activities such as energy generation (air pollutants); and water disinfection. Across the NRPs, research is focused on providing systems understanding of the role of modifiable environmental factors to the childhood diseases and disorders prevalent today, including adverse birth

outcomes, asthma, neurodevelopmental disorders, and metabolic outcomes. Table 2 summarizes the individual NRP contributions to the 4 research areas in the context of these prevalent CEH health outcomes.

In addition, to meet the Agency’s mandate for protecting children, ORD relies heavily on strategic partnerships with dozens of organizations ranging from other federal agencies, state governments and international organizations, to academia, nongovernmental organizations and industry. All of the strategic partners have an interest in promoting and protecting children’s health. Strategic partnerships are finalized through numerous types of agreements including STAR Grants, Cooperative Research and Development Agreements, Materials Transfer Agreements, and Memoranda of Understanding.

One of ORD’s leading partners in CEH research is the National Institute of Environmental Health Sciences (NIEHS). EPA, through its STAR Grants, and NIEHS jointly fund the Children’s Environmental Health and Disease Research Centers. Currently, there are 16 active centers conducting research to increase understanding of how environmental factors affect children’s health, and to promote translation of basic research findings into intervention and prevention methods to prevent adverse health outcomes. Other important partnerships include those of the Association of Toxic Substances and Disease Registry (ATSDR), the Centers for Disease Control (CDC), the Department of Health and Human Services (DHHS), the Food and Drug Administration (FDA), the Department of Housing and Urban Development (HUD), and several institutes at the National Institutes of Health (NIH). These partnerships are critical for conducting basic research on children’s health as well as for implementing research focused on interventions that support CEH.

Cross-Cutting ORD Research

Current ORD Research

This section summarizes ORD's current and recently completed research activities (2012-15) as they are aligned with the four CEH research areas described in Section III. These research activities are implemented by ORD's NRPs according to their respective StRAPs (<http://www.epa.gov/research/research-programs.htm>). Each activity addresses NRP-specific outputs and at the same time contributes to achieving the CEH Roadmap objectives. The NRP with key responsibility for each of the activities is provided in parentheses after the project name in this section.

See Appendix A for further details on the research activities outlined below, as well as information on additional ORD research activities; Appendix B for a summary of ORD published research on CEH outcomes from 2008 – 2014; and Appendix C for databases and tools that ORD has developed that include CEH information.

Current ORD activities in Research Area 1 (knowledge infrastructure) include the compilation of data on exposure factors; human behavior; chemical usage; and childhood physiological parameters, and the development of databases that provide the results of high-throughput *in vitro* assays and *in vivo* studies. Under Research Area 2 (systems understanding), ORD is developing bioinformatics-based, adverse outcome pathway, and simulation models to evaluate the toxicity of environmental chemicals. In addition, Children's Research Centers and place-based studies are evaluating the relationship between exposure and a variety of health outcomes in children and adolescents, leading to an increased understanding of how interactions among complex stressors may increase the sensitivity of children. Research Area 3 (methods and models) includes the development of exposure assessment tools and human exposure models for environmental chemicals. ORD is developing dosimetry models and using new approaches to categorize lifestages and to evaluate chemical mixtures. Under Research Area 4 (translational research), ORD is developing decision support tools to enable communities to provide healthy environments for children. ORD is also translating research findings on children's health to inform communities and other local groups as they develop environmental health related strategies that are sustainable.

Research Area 1: Knowledge infrastructure to address the problem that information and data are distributed and difficult to access

Currently, knowledge resources are being developed under Research Area 1 in the following three areas: (1) exposure information, (2) early lifestage pharmacokinetic parameters, and (3) developmentally relevant hazard data. ORD's relevant research in each of these areas is summarized as follows:

(1) Exposure Information

Exposure data are critical for characterizing children's environments and for evaluating interactions of children with the environment across development.

Exposure Factors Handbook (HHRA)

Data about children's exposures and exposure factors, such as lifestage specific modeled estimates of soil and dust ingestion, is incorporated into EPA's *Exposure Factors Handbook* (U.S. EPA, 2011); available at <http://cfpub.epa.gov/ncea/risk/recordisplay.cfm?deid=236252>. The exposure factors include: drinking water consumption; soil and dust ingestion; inhalation rates; dermal factors including skin area and soil adherence factors; consumption of fruits and vegetables, fish, meats, dairy products, and homegrown foods; human milk intake; human activity factors; consumer product use; and building characteristics.

Consolidated Human Activity Database (CHAD)

ORD's Consolidated Human Activity Database (CHAD) is a compilation of data on human behavior from 24 individual studies (U.S. EPA, 2014d); available at: <http://www.epa.gov/heasd/chad.html>. This resource includes more than 50,000 individual data days of detailed location and activity data and corresponding demographic data including age, sex, employment, and education level. Data are included for all ages, including infants and children.

ExpoCast Database (CSS)

ExpoCast Database (ExpoCastDB) was developed to improve access to human exposure data from observational studies, including those funded by ORD. ExpoCastDB consolidates measurements of chemicals of interest in environmental and biological media collected from homes and child care centers. ExpoCastDB is available as a searchable database (U.S. EPA, 2014g); available at: <http://actor.epa.gov/actor/faces/ExpoCastDB/Home.jsp> on EPA's Aggregated Computational Resource (ACToR) system, an online data warehouse that collects data on over 500,000 chemicals from over 1000 public sources (U.S. EPA, 2014a); available at: <http://actor.epa.gov/actor/faces/ACToRHome.jsp>.

Chemical and Product Categories (CSS)

Chemical and Product Categories (CPCat) is a database of information on how chemicals are used (U.S. EPA, 2014b); available at: <http://actor.epa.gov/actor/faces/CPCatLaunch.jsp>. CPCat contains information on the uses of chemicals (including use by children), products that contain chemicals, manufacturers of the products, and a hierarchy of consumer product "use" categories. It also contains information on any regulations or studies in which the chemical has been considered hazardous to children.

(2) Early Lifestage Pharmacokinetic Parameters

Pharmacokinetic and pharmacodynamic parameters for all lifestages are required to predict the potential for health effects from exposures to environmental chemicals. Child-specific parameters are used to characterize dose to the developing child in utero, after birth through lactational exposure, and during early infancy through prepubertal ages.

Enzyme Ontogeny Database (CSS)

Chemicals are often biotransformed in the body by activating and/or detoxifying enzymes whose expression changes over time from the developing embryo to adulthood. Thus, metabolic capacity based on the spectrum and relative quantity of critical enzymes at different lifestages can play

an important role in determining childhood susceptibility to environmental chemicals. ORD has developed an enzyme ontogeny database that is useful for the development of PBPK models to explore metabolism-based variability during early lifestages.

(3) Developmentally Relevant Hazard Data

Data from *in vivo* animal studies, screening assays, and other study types are needed in order to carry out risk and hazard assessments on environmental chemicals. ORD has developed databases that allow easy access to developmental hazard data that is being used to link environmental exposures at early lifestages with health outcomes in children and later in life.

ToxCast Database (CSS)

ToxCastDB provides results of high-throughput *in vitro* assays. Biology covered in the large set of assays include endpoints related to endocrine, reproductive, and developmental toxicity. A major proportion of the assays are human-based cells or proteins. ToxCastDB is available as a searchable database through the ACToR system (U.S. EPA, 2014i); available at: <http://actor.epa.gov/actor/faces/ToxCastDB/Home.jsp>.

Toxicity Reference Database (CSS)

Toxicity Reference Database (ToxRefDB) contains data from thousands of *in vivo* animal studies and is available as a searchable database through the ACToR system (U.S. EPA, 2014j); available at: <http://actor.epa.gov/toxrefdb/faces/Home.jsp>. Developmental toxicity data includes results from studies on more than 380 chemicals with 18 endpoints for both the rat and rabbit, while the reproductive toxicity information is based on the results from multigenerational reproductive studies on 316 chemicals, with 19 parental, reproductive, and offspring endpoints.

Adverse Outcome Pathway Wiki (CSS)

An Adverse Outcome Pathway (AOP) is a conceptual framework that portrays existing knowledge concerning the linkage between a direct molecular initiating event and an adverse outcome. The goal of an AOP is to provide the framework to connect the two events. AOP Wiki is a wiki-based tool that provides an interface for collaborative sharing of established AOPs and building new AOPs (Anonymous, 2014); available at: http://aopkb.org/aopwiki/index.php/Main_Page. AOP Wiki uses templates to make it easier for users to include the information needed for proper evaluation of an AOP. Developmentally relevant AOPs are being incorporated. Currently, endocrine pathways are well represented.

Research Area 2: Systems understanding of the relationship between environmental exposures and health outcomes across development

Research Area 2 has been divided into the following two subgroups: (1) systems biology to predict developmentally relevant outcomes, and (2) systems understanding of complex stressors. ORD's relevant research in each of these areas is summarized as follows:

(1) Systems Biology to Predict Developmentally Relevant Outcomes

Systems models for tissues and multi-organ pathways specific to embryo-fetal and neonatal development are being developed. These models increase the Agency's understanding of the biologic mechanisms of chemical stressors that contribute to childhood health outcomes.

Bioinformatics-Based Models (CSS)

As discussed on page 27, ToxCastDB uses high-throughput biochemical and cellular *in vitro* assays to evaluate the toxicity of environmental chemicals. The development of predictive models is being carried out in phases, with the development and publication of first-generation (Phase I) ToxCast predictive models for reproductive toxicity (M. T. Martin et al., 2011) and developmental toxicity (Sipes et al., 2011). Pathways for endocrine disruption (Reif et al., 2010), embryonic stem cell differentiation (Chandler et al., 2011) and disruption of blood vessel development (Kleinstreuer et al., 2011) have been linked to the Phase I ToxCast *in vitro* data. For the next approximately 700 compounds in Phase II, where animal toxicology is less well-characterized, ORD is developing plausible model structures that deal with the possibility of additional relevant interactions and components beyond those represented in the first-generation predictive models.

AOP Models (CSS)

ORD is developing AOP models, such as the vascular AOP model, with the aim of establishing the predictive value of chemical disruption of blood vessel development (vasculogenesis) during critical windows of embryonic and fetal development. A vasculogenesis model is being tested in zebra fish embryos and in embryonic stem cells. As additional individual AOPs are developed, they can be assembled into AOP networks that may aid the prediction of more complex interactions and outcomes resulting from exposure to complex mixtures and/or chemicals with multiple modes of actions.

Simulation Models (CSS)

Simulation models predict chemical toxicity using relevant biologic information, such as the influence of subcellular pathways and networks on the development of tissues and organs. ORD is developing the Virtual Embryo model, a simulation model of predictive toxicology of children's health and development, which can be applied to prenatal or postnatal (including lactational) exposures.

(2) Systems Understanding of Complex Stressors

Epidemiologic, animal studies, and *in vitro* assays are being used to develop a systems understanding of the relationship between environmental exposures as stressors and lifestage-specific susceptibility and vulnerability.

Laboratory-Based Studies (CSS and SHC)

Intramural ORD research has used a variety of *in vitro* models to evaluate the effects of chemical exposure in developmentally relevant systems. Cell (e.g., human multipotent neuroprogenitors, rodent embryonic stem cells, specific pathway-responsive modified hepatocytes), organ (e.g., human and rodent palatal shelves), and whole rodent embryo cultures, as well as whole organisms (developing zebrafish) have been used to address issues of toxic response. Many of these models have been developed, characterized, and refined to answer specific research questions. Several model systems have been used to evaluate the effects of chemicals to aid in the translation of high-throughput data in the ToxCast assays. *In vitro* approaches using adipocyte stem cells are also being developed as potential predictors of obesity and to explore cellular mechanisms of action of specific chemicals.

Experimental research is also addressing causality in (longitudinal) lifecourse rodent studies where effects of early life exposures on postnatal development and multiple health outcomes can be evaluated under controlled laboratory conditions. These studies are also being used to examine the extent to which modifying factors such as diet, exercise, and stress may alter sensitivity to chemical stressors, a question relevant to diverse community settings and conditions.

Epidemiological Studies (SHC and ACE)

EPA-NIEHS Children’s Environmental Health and Disease Prevention Research Centers (CEHC)

The EPA-NIEHS jointly funded Children’s Environmental Health and Disease Prevention Research Centers (CEHCs, or “Children’s Centers”) Program, ongoing since 1998, continues to generate exposure and biomarker data in pregnant women and children, along with mechanistic data in experimental models, in order to show relationships between exposure to chemical contaminants and a variety of children’s health outcomes, and to identify critical windows of susceptibility (U.S. EPA, 2014e); available at: www.epa.gov/ncer/childrenscenters; http://cfpub.epa.gov/ncer_abstracts/index.cfm/fuseaction/recipient.display/rfa_id/560/records_per_page/ALL. The long-range goals of this STAR Program include understanding how environmental factors affect children’s health, and promoting translation of basic research findings into intervention and prevention methods to prevent adverse health outcomes (Table 3).

Table 3. Current EPA/NIEHS Children’s Environmental Health and Disease Prevention Research Centers exploring associations between exposures and health outcomes in children

Institution – P.I.	Chemical Exposures and Other Stressors	Outcomes	Underlying Mechanisms (molecular, genetic, social factors)
Brown University – Boekelheide	Arsenic, EDCs (estrad- iol, BPA, genistein), dietary restriction	Fetal liver, lung and prostate development; prostate cancer in later life	Endocrine disruption; Epigenetic changes in organ development
Columbia University – Perera	Endocrine Disrupting Compounds (BPA), PAHs,	Neurodevelopmental disorders such as problems with learning and behavior; obesity and metabolic disorders	Endocrine disruption; Epigenetic reprogramming and metabolic syndrome
Dartmouth College – Karagas	Arsenic in drinking water and food	Growth and development; immune response	Epigenetic changes and influence of gut microbiome
Duke University/ University of Michigan – Miranda	Environmental, social and individual susceptibility factors, PM, Ozone	Disparities in birth outcomes, respiratory health in infants	Social determinants of childhood disease
Duke University – Murphy	Environmental tobacco smoke	ADHD, neurobehavioral dysfunction	Epigenetic modulation in fetal and child development
Johns Hopkins University – Diette	Airborne pollutants (particulate matter, nitrogen dioxide), allergens, urban diets	Asthma	Dietary contributions to asthma, based on anti-oxidant and anti-inflammatory impacts on immune function and inflammation
National Jewish Health – Schwartz, Szeffler	Air pollution (ozone, PM, NO ₂), ambient bacterial endotoxin	Asthma, immune system function, determinants of host defense	Host-immune responses and TL4 receptor function; interactions between ozone and endotoxin

Table 3. (continued) Current EPA/NIEHS Children’s Environmental Health and Disease Prevention Research Centers exploring associations between exposures and health outcomes in children

Institution – P.I.	Chemical Exposures and Other Stressors	Outcomes	Underlying Mechanisms (molecular, genetic, social factors)
University of California at Berkeley - Buffler, Metayer	Pesticides, tobacco-related contaminants, chemicals in house dust (PCBs, PBDEs)	Childhood leukemia	Epigenetic and genetic influences
University of California at Berkeley – Eskenazi	Pesticides (DDT, manganese), flame retardants	Neurodevelopment, growth and timing of puberty, obesity	Epigenetic reprogramming, altered endocrine status
University of California at Berkeley – Hammond, Balmes, Shaw	Ambient air pollutants (airborne PAHs), in utero exposure to traffic-related pollutants, endotoxin	Birth defects/preterm birth, immune system dysfunction (asthma/allergies), obesity/glucose dysregulation	Gene variants in biotransformation enzymes; molecular mechanisms e.g., altered T-cell function; neighborhood factors
University of California at Davis – Van de Water	BPDEs, pyrethroid insecticides, perfluorinated compounds, POPs	Autism spectrum disorder (ASD)	Immune dysfunction and autoimmunity, genetic/epigenetic contributions
University of California at San Francisco – Woodruff	EDCs, PBDEs (BDE-47), PFCs (PFOA), psychosocial stress	Placental and fetal development, adverse birth outcomes	Gene expression changes via epigenetic mechanism, contribution of psychosocial stress
University of Illinois at Urbana-Champaign – Schantz	EDCs (phthalates, BPB), high fat diet	Neurological and reproductive development	Endocrine disruption, oxidative stress
University of Michigan – Peterson, Padmanabhan	BPA, phthalates, lead, cadmium	Birth outcomes, child weight gain, body composition, activity patterns, hormonal levels, sexual maturation, metabolomics and risk of metabolic syndrome	Dietary influences; epigenetics and gene expression changes; oxidative stress
University of Southern California – McConnell	Near-roadway air pollution including elemental carbon, PM 2.5	Obesity, fat distribution, metabolic phenotypes, systemic inflammation	Expression of genes in metabolic pathways, beta cell function, oxidative stress;
University of Washington – Faustman	Agricultural pesticides	Altered neurodevelopment	Genetic susceptibility, neurotoxicity, oxidative stress, cellular pathways underlying neurodevelopment

Clean Air Research Centers (ACE)

ORD's Clean Air Research Centers Program includes a number of epidemiologic projects directly relevant to CEH. Two currently active Children's Centers are producing new data and knowledge on the relationship between air pollution and children's health, with final reports expected in 2015. The Children's Center at Emory University is generating "Novel estimates of pollutant mixtures and pediatric health in two birth cohorts," and the Children's Center at Harvard University is evaluating "Longitudinal effects of multiple pollutants on child growth, blood pressure and cognition." (U.S. EPA, 2012); available at: <http://www.epa.gov/ncer/quickfinder/airquality.html>.

Place-Based Studies (ACE and SHC)

ORD recognizes that combinations of stressors are often unique to a particular community setting and that interventions to improve children's health must take this complexity into account. For example, a STAR grant and ORD in-house project, *The Near-Road Exposures and Effects of Urban Air Pollutants Study (NEXUS)* (ACE), examined the influence of traffic related air-pollutants on respiratory outcomes in a cohort of 139 asthmatic children (ages 6-14) who lived close to major roadways in Detroit, MI. Another place-based study, *The Mechanistic Indicators of Childhood Asthma (MICA) Study* (SHC), was designed to pilot an integrative approach in children's health research. MICA incorporates exposure metrics, internal dose measures, and clinical indicators to decipher the biological complexity inherent in diseases such as asthma and cardiovascular disease with etiology related to gene-environment interactions. Additionally, grantees are conducting place-based research exploring interactions among stress and air pollution in community settings; how school conditions influence academic performance (SHC); and how to predict exposures for children living near a Superfund site (ACE).

Research Area 3: Methods and models to evaluate early lifestage-specific risks and to support decisions protective of all lifestages

Research Area 3 has been divided into the following two subgroups: (1) exposure, and (2) dosimetry models. ORD's relevant research in each of these areas is summarized as follows:

(1) Exposure

ORD has developed tools to increase the usability and access to exposure data, models to predict exposure by a variety of pathways and routes, and approaches for categorizing lifestage changes and prioritizing chemical mixtures.

EPA ExpoBox (HHRA)

EPA ExpoBox is a web-based compendium of over 800 exposure assessment tools that provides links to exposure assessment databases, models, and references (U.S. EPA, 2013c); available at: http://www.epa.gov/ncea/risk/expobox/docs/archive/Expobox_Fact-Sheet_Nov13.pdf. It includes approaches for exposure assessments; tiers and types of exposure assessments; chemical classes; routes of exposure to chemicals, lifestages and populations; and exposure media. It also includes, in a searchable and downloadable format, the full list of exposure factors from the *Exposure Factors Handbook* (see page 26).

SHEDS-HT Model (CSS)

The Stochastic Human Exposure and Dose Simulation–HT (SHEDS-HT) model is a screening-level human exposure model for chemicals. Exposure results can also be estimated for individual age-gender cohorts. Exposure-relevant information specific to children included in SHEDS-HT includes age-specific behaviors (such as hand-to-mouth contact and use of consumer products), time spent in microenvironments, and food intakes.

ExpoCast (CSS)

ExpoCast is a rapid, high-throughput model using off-the-shelf technology that predicts exposures for thousands of chemicals (U.S. EPA, 2014f); available at: <http://epa.gov/ncct/expocast/>. ORD research is generating and incorporating new information about age-dependent exposures (e.g., product use) into ExpoCast to support risk-based decisions. This model can be more specifically applied to capture children’s unique vulnerabilities.

(2) Dosimetry Models

ORD has developed a number of dosimetry models that assess exposure, predict dose, and describe the kinetics of environmental chemicals as related to children’s health.

Empirical Models (CSS)

Persistent Bioaccumulative Toxicants

A statistical model was developed for predicting levels of polybrominated diphenyl ethers (PBDEs) in breast milk, based on serum data from the National Health and Nutrition Examination Survey (NHANES) (Marchitti et al., 2013). In this research, congener-specific linear regression partitioning models were developed and applied to 2003-2004 NHANES serum data for U.S. women. These models provide a sustainable method for estimating population-level concentrations of PBDEs in U.S. breast milk and should improve exposure estimates in breastfeeding infants.

ORD is now applying this approach to other environmental chemicals (dioxins, perfluorinated compounds (PFCs), polychlorinated biphenyls (PCBs), and organochlorine pesticides). ORD is also working on developing a comprehensive quantitative structure-activity relationship (QSAR)-based model for predicting milk:serum partitioning ratios for classes of chemicals where serum and milk data are not available to construct regression models.

In vitro to In vivo Extrapolation

ORD has proposed an approach to link results from *in vitro* high-throughput studies with population group-specific dosimetry for neonates, children, and adults, and exposure estimates (Wetmore et al., 2014). For nine ToxCast chemicals, pharmacokinetic models for multiple population groups were constructed that predicted chemical concentrations in the blood at steady state. These models have potential application to estimate chemical-specific pharmacokinetic uncertainty factors and to estimate population group-specific oral equivalent dose values to aid in chemical prioritization and identifying population groups with greater susceptibility to potential pathway perturbations.

PBPK Models

Virtual Embryo Project (CSS)

ORD has developed a life-stage PBPK model, which has been incorporated into the Virtual Embryo project. This model was developed to computationally investigate the relationship between chemical exposure, tissue dosimetry, and *in vitro* markers of critical events related to AOPs. The model includes time-changing physiological and biochemical descriptors related to a pregnant mother, fetal growth, and child exposure through lactation.

Ethanol (ACE)

To supplement and complete PBPK models in the literature, ORD developed PBPK models to describe the kinetics of ethanol in adult, pregnant, and neonatal rats for the inhalation, oral, and intravenous routes of exposure (S. A. Martin et al., 2012).

Research Area 4: Translational research and tools to support community actions and decisions

Research Area 4 has been divided into the following four subgroups: (1) decision support tools, (2) problem driven research, (3) translational research, and (4) social determinants of health. ORD's relevant research in each of these areas is summarized as follows:

(1) Decision Support Tools

ORD is developing decision support tools for State, Tribal, local governments, and other organizations in order to make sound decisions about both community development and healthful environments, and to avoid unintended consequences.

Community-Focused Exposure and Risk Screening Tool (SHC)

ORD has developed the Community-Focused Exposure and Risk Screening Tool (C-FERST) (U.S. EPA, 2013a); available at: <http://www.epa.gov/heasd/c-ferst/>, which has been developed as a “toolkit” for step-by-step community assessment guidance (e.g., Community Action for Renewed Environment (CARE) roadmap), GIS maps, reports, fact sheets, best practices, and potential solutions. Children's health issues in C-FERST currently include childhood lead exposure, childhood asthma, and schools. Recently, C-FERST was used, along with other tools, to inform a Health Impact Assessment (HIA) related to school renovation decisions in Springfield, Massachusetts.

EnviroAtlas (SHC)

EnviroAtlas, publicly released in May 2014, includes, at least for selected urban areas, such indicators as the locations of schools, recreational areas, factors relevant to health outcomes (demographics, income), access to transportation routes, and indicators of ecosystem services such as tree cover (related to heat, recreation, green-space accessibility). This tool also includes an Eco-Health Relationship Browser (U.S. EPA, 2013b); available at: http://enviroatlas.epa.gov/enviroatlas/Tools/EcoHealth_RelationshipBrowser/introduction.html. Health outcomes currently searchable in the browser of direct relevance to CEH include low birth weight and preterm birth; asthma; ADHD; and obesity.

(2) Problem-Driven Research

Studies are being conducted to further the understanding of linkages between human health and environmental exposures. Communities are using results of these analyses to make decisions concerning renovation of schools, location of recreational areas, and future development.

EPA Pilot Study Add-On to the Third Study Site of the Green Housing Study (SHC)

The Green Housing Study is a collaborative effort between HUD and CDC. In partnership with HUD and CDC, ORD will collect additional multimedia measurements and questionnaire data from the index children and a sibling(s) actively participating in the Green Housing Study in order to characterize personal, housing, and community factors influencing children's potential exposures to indoor contaminants at various lifestages.

Dust and Soil Ingestion (SHC)

ORD is using models to estimate different exposure parameters, such soil and dust ingestion rates, in children. For example, ORD used the SHEDS-Soil/dust model to estimate soil and dust ingestion rates for young children at two Taiwanese locations, and for simulations pertinent to U.S. children in specific age categories (Glen et al., 2013).

Chemical and Non-chemical Stressors and Childhood Obesity (SHC)

ORD is currently completing a state-of-the-science literature review to identify chemical and non-chemical stressors related to childhood obesity. Numerous chemical and non-chemical stressors were identified and grouped into the following domains: individual, family, community, and chemical. Data shows that there is not always a positive association between a stressor and childhood obesity, and that there can be inconsistent correlations between the same stressors and obesity. However, there is sufficient evidence to suggest the interactions of multiple stressors may contribute to the childhood obesity epidemic.

Chemical and Non-chemical Stressors and Neurocognitive Health (SHC)

ORD is conducting research to examine stressors related to neurocognitive health in children, ages 3-6 years. Key exposure factors were identified for each developmental lifestage from pregnancy to 3-6 years old. These elements were incorporated into a model and the results suggest that some childhood exposures (e.g., socioeconomic status, parent-child interaction, diet, built environment) not only present as key factors, but act as effect modifiers of stressors experienced during pregnancy and infancy (e.g., lead, pesticides, prenatal stress).

Community Multi-scale Air Quality Model (ACE)

The EPA's Community Multi-scale Air Quality (CMAQ) Model is a powerful computational tool used by EPA and states for air quality management that gives detailed information about the concentrations of air pollutants in a given area. Comparison of data from the CMAQ model with birth outcomes or childhood hospital admissions for asthma has generated data on associations between pollutant exposure (i.e., particulate matter (PM) or ozone) and health outcomes (U.S. EPA, 2014c), available at: <http://www.epa.gov/AMD/Research/RIA/cmaq.html>.

See Appendix A for additional examples of problem-driven technical support and research on PCBs in Schools (HHRA) and Child-Specific Exposure Scenarios examples (HHRA).

(3) Translational Research

Translational research involves translating the results from research on children’s health into findings that are useful to communities, neighborhoods, health care providers, or other groups as they develop strategies to work on local environmental health issues.

EPA/NIEHS Children’s Center Program (SHC)

As discussed on page 29, the EPA-NIEHS co-funded Children’s Centers (CEHCs) Program is generating exposure and biomarker data in pregnant women and children, showing relationships between exposure and a variety of children’s health outcomes, and identifying critical windows of susceptibility (U.S. EPA, 2014e); available at: www.epa.gov/ncer/childrenscenters. A critical and unique component of the Children’s Centers Program is the inclusion of Community Outreach and Translation Cores. These cores use a variety of innovative approaches to translate research findings and intervention strategies to community stakeholders (see Table 4).

Table 4. EPA/NIEHS Children’s Centers community outreach and translation - community partners

Institution – P.I.	Study Site Location(s)	Community Outreach and Translation – with Community Partners
Brown University – Boekelheide	Providence, Rhode Island	Silent Spring Institute, Environmental Justice League of Rhode Island
Columbia University – Perera	New York City (Northern Manhattan and South Bronx), Poland, China	Bronx Borough Presidents Office, Bronx Health Link, Columbia Community Partnership for Health, Columbia University Head Start, Community Health Worker Network of NYC, Dominican Medical Association, New York, Harlem Children’s Zone Asthma Initiative, Harlem Health Promotion, Northern Manhattan Perinatal Partnership, Nos Quedamos, WE ACT for Environmental Justice
Dartmouth College – Karagas	Hanover, New Hampshire	Dartmouth-Hitchcock Concord Clinic, Concord Hospital Family Clinic, Concord Obstetrics and Gynecology Professional Associates, Concord Women’s Care, Family Tree Health Care (Warner, NH), Dartmouth Hitchcock Lebanon Clinic, Concord Hospital, The Family Place, Dartmouth-Hitchcock Medical Center, New Hampshire Department of Environmental Health Services, New Hampshire Birth Conditions Program, University of New Hampshire Department of Molecular, Cellular and Biomedical Sciences
Duke University/ University of Michigan – Miranda	Durham, North Carolina and Ann Arbor, Michigan	Durham Congregations, Associations, and Neighborhoods (CAN), Triangle Residential Options for Substance Abusers (TROSA), Durham Affordable Housing Coalition, Partnership Effort for the Advancement of Childrens Health/Clear Corps (PEACH), Durham People’s Alliance, Durham County Health Department, Lincoln Community Health Center, Duke University Nursing School Watts School of Nursing, City of Durham Department of Neighborhood Improvement Services, City of Durham Department of Community Development, Children’s Environmental Health Branch of NC Department of Environment and Natural Resources, North Carolina Asthma Alliance, East Coast Migrant Head Start, North Carolina Community Health Center Association, North Carolina Rural Communities Assistance Project
Duke University – Murphy	Durham, NC	DukeEngage Program, El Centro Hispano (local Latino community), Partnership for a Healthy Durham

Table 4. (continued) EPA/NIEHS Children’s Centers community outreach and translation - community partners

Institution – P.I.	Study Site Location(s)	Community Outreach and Translation – with Community Partners
Johns Hopkins University – Diette	Baltimore, MD	Baltimore City Head Start Program, Baltimore City Health Department Healthy Homes Program, Baltimore School Food Services Program, Healthy Stores Program, Maryland Asthma Control Program, Women Infants and Children (WIC) nutrition programs
National Jewish Health – Schwartz, Szefer	Denver, CO	Colorado Asthma Coalition, Colorado Clinical Guidelines Collaborative, Colorado Department of Public Health and Environment, Denver Public School System, Lung Association of Colorado, Rocky Mountain Prevention Research Center, EPA Region 8, Alamosa Public School, Denver Health, Colorado Public Health, Practice Based Research Network, Regional Air Quality Council, Colorado Air Quality Commission, Grand Junction Housing Authority, Western Colorado Math & Science Center, Region 8 Pediatric Environmental Health Specialty Unit (PEHSU)
University of California at Berkeley – Buffler, Metayer	Berkeley, CA	Network of 8 clinical institutions in northern and central California participating in the Northern California Childhood Leukemia Study (NCCLS), national community of pediatric health care professionals with an interest in environmental health issues; national community of persons interested in leukemia; California community of persons interested in childhood leukemia; Region 9 Pediatric Environmental Health Specialty Unit (PEHSU)
University of California at Berkeley – Eskenazi	Berkeley and Salinas, CA	Clinica de Salud del Valle de Salinas, Natividad Medical Center, South County Outreach Effort (SCORE), Monterey County Health Department, California Rural Legal Assistance (CRLA) Program, Grower/Shipper Association of Central California
University of California at Berkeley/Stanford University – Hammond, Balmes, Shaw	Berkeley, Palo Alto, Bakersfield and San Joaquin Valley, CA	Medical Advocates for Healthy Air; Fresno Metro Ministry; Center on Race, Poverty, and the Environment; San Joaquin Valley Latino Environmental Advancement Project (LEAP); El Comite para el Bienestar de Earlimart; Coalition for Clean Air; San Joaquin Valley Cumulative Health Impact Project (SJV-CHIP); Central California Environmental Justice Network; Central Valley Air Quality Coalition; Californians for Pesticide Reform
University of California at Davis – Van de Water	Davis, CA	Families for Early Autism Treatment, Learning Disabilities Association, Parents Helping Parents, San Francisco Bay Chapter of the Autism Society of America, Alameda County Developmental Disabilities Council, Cure Autism Now, State of California health/developmental service providers, California Departments of Developmental Services and Health Services, California Regional Centers and Office of Environmental Health Hazard Assessment
University of California at San Francisco – Woodruff	San Francisco, CA	American College of Obstetricians and Gynecologists (ACOG District IX), Association of Reproductive Health Professionals, Physicians for Social Responsibility (PSR) San Francisco Bay Area Chapter, WORKSAFE (California Coalition for Worker Occupational Safety & Health Protection), California Department of Health Occupational Health Branch
University of Illinois at Urbana-Champaign – Schantz	Urbana-Champaign, IL, and New Bedford, MA	Illinois Action for Children (IAFC), American Academy of Pediatrics (AAP), Just-In-Time Parenting, Champaign-Urbana Public Health Department, Great Lakes Center for Environmental Health, Cambridge Health Alliance, Carle Foundation Hospital, Provena Covenant Medical Center

Table 4. (continued) EPA/NIEHS Children’s Centers community outreach and translation - community partners

Institution – P.I.	Study Site Location(s)	Community Outreach and Translation – with Community Partners
University of Michigan – Peterson, Padmanabhan	Ann Arbor, MI, and Mexico City, Mexico	Early Life Exposures in Mexico to Environmental Toxicants (ELEMENT), National Institute of Public Health, Mexico City, Detroit Hispanic Development Corporation
University of Southern California – McConnell	Los Angeles, CA	The Children’s Clinic (Long Beach and South Bay), Asian and Pacific Islander Obesity Prevention Alliance, East Yard Communities for Environmental Justice, Digital Rain Factory, Los Angeles Parks Foundation, The Trust for Public Land Center for Park Excellence, Policies for Livable, Active Communities and Environments (PLACE) of Los Angeles, Trade, Health and Environment Impact Project, Center for Community Action & Environmental Justice (Riverside and San Bernardino), Coalition for a Safe Environment (Wilmington), East Yard Communities for Environmental Justice (Commerce and East L.A.), Long Beach Alliance for Children with Asthma, Outreach Program of Southern California Environmental Health Sciences Center Los Angeles (USC/UCLA), Urban & Environmental Policy Institute, Occidental College
University of Washington – Faustman	Yakima Valley, WA	Community members in the Yakima Valley, Farm Workers Union, Growers’ Association, Washington State Department of Health and Department of Agriculture, Farm Workers’ Union, Yakima Valley Farm Workers Clinics, Radio KDNA (Spanish language), Washington State Department of Labor and Industries, Columbia Legal Services, Washington State Migrant Council, EPA Region 10

(4) Social Determinants of Health (Place-Based Studies)

ORD is carrying out research on the biological, environmental, and social conditions that may contribute to disparities in health outcomes in children.

NIMHD Centers of Excellence on Environment and Health Disparities (SHC)

Social determinants of health are a focus of research in the *EPA and NIMHD Centers of Excellence on Environment and Health Disparities* (<http://www.epa.gov/ncer/ehs/disparities/health-disparities.html>). ORD, through an interagency agreement with the National Institute of Minority Health and Health Disparities (NIMHD) (<http://www.nih.gov/about/almanac/organization/NIMHD.htm>) is supporting the establishment of transdisciplinary networks of excellence in health disparities research to achieve a better understanding of the complex interactions of biological, social, and environmental determinants of population health.

One of these Center projects, “Analysis and Action on the Environmental Determinants of Health and Health Disparities” (University of South Carolina) is exploring six areas of health disparities that contribute disproportionately to premature death and morbidity found among poor and racial/ethnic minorities (e.g., infant mortality). Another project, “Environmental Health Disparities Research” (University of Texas) is exploring the individual- and neighborhood-level contributions to disparities in children’s pulmonary health.

Environmental and Community Factors Influence Effectiveness of Medical Treatments for Asthma (SHC)

An ORD study, in collaboration with the University of North Carolina, *Observational Assessment of Baseline Asthma Control as a Susceptibility Factor for Air Pollution Health Effects in African-American Children with Persistent Asthma*, is examining factors that contribute to asthma disparities in adolescents. The study is following a cohort of African-American youth with moderate-to-severe asthma and examining a variety of factors including air pollution, home environment, and community issues that may contribute to the high rate of asthma in this population and the relative effectiveness of medical treatments.

Integrated Approaches to Sustain the Built and Natural Environment and the Communities They Support (SHC)

In this study, researchers are using GIS tools and multi-layered mapping to examine relationships between access to green space and birth outcomes. Analyses focus on associations between birth measures across the greater Durham-Chapel Hill, North Carolina area and various measures of green space around the home, including tree cover along busy roadways.

Summary of ORD CEH Research Partnerships

ORD has partnered with a number of other Federal agencies and independent organizations to further CEH research. One example where EPA reached out to leverage expertise and capacity with partner federal agencies is on the topic of endocrine disruption. Evidence is mounting that some chemicals disrupt the endocrine system. The endocrine system regulates biological processes throughout the body and is sensitive to small changes in hormone concentrations. Some of this research has identified dose-response relationships that have nonmonotonic curves. Non-monotonic dose-response curves (NMDRs) are of concern because they do not follow the usual assumption made in toxicology that as dose decreases, the response also decreases. In addition, more complex interactions and outcomes resulting from exposure to complex mixtures and/or chemicals with multiple modes of action are not addressed well with existing models and assessment tools. Prenatal and early-life exposures are of particular concern and additional complexity is associated with the fact that these exposures may lead to health impacts across the lifespan. As a result, there is a need to shift thinking about how potential for adverse impacts and ultimately risks are evaluated. To comprehensively evaluate the evidence in this arena, EPA has formed a working group with experts from several EPA offices, FDA, NIEHS, and NICHD to explore this issue and to write a state-of-the-science paper.

Table 5 lists some of ORD's partner organizations and the CEH programs that are currently underway through these partnerships.

Table 5. ORD Partnerships and Activities

Partners	Research	Description
NTP/NIEHS	Children’s Environmental Health and Disease Research Centers (http://epa.gov/ncerchildrenscenters/)	Research to increase understanding how environmental factors affect children’s health and promote translation of basic research findings into intervention and prevention methods to prevent adverse health outcomes.
NTP/NIEHS	Systematic review of progestin use during pregnancy (http://dx.doi.org/10.1289/ehp.1306711)	Systematic review of progestin use during pregnancy with interest on the effects in the mother and offspring after exposure during pregnancy/gestation.
NTP/NIEHS & NICHD; CDC	National Children’s Study (http://www.nationalchildrensstudy.gov/Pages/default.aspx)	Multi-year research study examining the effects of environmental influences on the health and development of children.
ATSDR; Association of Occupational and Environmental Clinics	Pediatric Environmental Specialty Units (http://aoec.org/pehsu/aboutus.html)	Ten specialty units across the U.S. that are a source of medical information and advice on environmental conditions that influence children’s health.
HUD; CDC	EPA Pilot Study Add-On to the Green Housing Study	Study that is collecting additional multimedia measurements and questionnaire data from the index children in the Green Housing Study and a sibling(s) in order to characterize personal, housing, and community factors influencing children’s potential exposures to indoor contaminants at various lifestages.
CDC	National Birth Defects Prevention Study (http://www.nbdps.org/)	Population-based, case-control study examining the causes of birth defects.
NIH/National Institute of Minority Health and Health Disparities	STAR Centers of Excellence of Environment and Health Disparities (http://www.epa.gov/ncer/ehs/disparities/health-disparities.html)	Networks of excellence in health disparities research to achieve a better understanding of the complex interactions of biological, social and environmental determinants of population health.
DHHS, FDA, Health Resources and Services Administration, NIH, Office of the Assistant Secretary for Health, HUD, DOJ, and DOT	Interagency Asthma Disparities Workgroup (part of the President’s Task Force on Environmental Health Risks and Safety Risks to Children) (www.epa.gov/childrenstaskforce)	Workgroup with the goal of reducing the burden caused by asthma, particularly among minority children and children with family incomes below the poverty level.
CAAT DNT workshop 2014	Center for Alternatives to Animal Testing (CAAT) workshop on developmental neurotoxicity testing (http://caat.ihsph.edu/programs/workshops/DNT4/)	Presented information on cutting-edge technologies being used to develop alternative tests for developmental neurotoxicity testing.

Research Gaps and Priority Research Needs

In the context of Agency mandates for CEH information (Section IIA), the decision context as presented in the Translation Framework (Figure 2), and a set of high visibility child health outcomes (Appendix D) identified by ORD and Program Partner members of the CEH roadmap working group, a gap analysis was conducted to identify and prioritize needs for ORD research in CEH.

The ORD portfolio of active and planned CEH research as described in the evolving NRP Strategic Research Action Plans was reviewed. Here, a strong set of tools for addressing current regulatory mandates was identified. Gaps remain around specific needs for science and information to incorporate consideration of early lifestage sensitivity, susceptibility, and vulnerability into these tools. Building confidence that EPA decisions are fully considering lifestage specific issues will require incorporating extant data and developing targeted information to reduce uncertainties in model predictions and risk-based assessments.

Emerging scientific understanding of CEH and the potential role of modifiable exogenous environmental factors was reviewed for a set of high-visibility health outcomes. Prevalence and trends were summarized, as was evidence pointing to associations between early life exposure to environmental contaminants and the following children's health outcomes: adverse birth outcomes, asthma, neurodevelopmental disorders, metabolic syndrome, and childhood cancer. In addition, maturing scientific understanding of shared mechanisms for these complex environmental diseases (e.g., endocrine disruption) was considered. Building evidence in support of the Developmental Origins of Health and Disease hypothesis including implications of epigenetic effects (Saffery and Novakovic, 2014) was also identified as an important scientific driver for research in CEH as part of this gap analysis.

The scope of CEH research activities in other federal agencies was evaluated. NIH (including NIEHS and NICD) is making significant investments in research to increase the understanding of fundamentally shared mechanisms of complex disease, genetic susceptibility across the lifespan to environmental diseases, and a broad range of other modifying factors, including psychosocial stressors (NIEHS, 2012). Based on this gap analysis, it is clear that rather than duplicate these investments, ORD will need to leverage these efforts and identify pivotal leadership roles for EPA.

Clear gaps remain in actionable science and information required to understand, prevent, and mitigate impacts to children from real-world exposures to air, water, and chemicals. ORD leadership is required to bring together science generated inside and outside the Agency to build predictive capacity to evaluate alternative actions and anticipate outcomes. This section highlights priority research needs identified for each of the four CEH Roadmap research areas. The bullet points present the strategic research gaps and the discussion provides examples of research needs and potential approaches to begin to address these needs.

Research Area 1: Knowledge infrastructure to address the problem that information and data are distributed and difficult to access

Early lifestage-specific data that could support Agency decisions are being generated at an increasing pace both within EPA and across the wider children's health research community. However, significant barriers remain to effectively access and mine relevant information to understand and predict the role of exposures to environmental factors during early life on health impacts. Priority Agency needs in this research area are for:

- Accessible data on critical lifestage-specific factors that influence children's vulnerability and resilience to environmental insults, including efficient links to access/collate knowledge and data about such factors from research conducted across the wider CEH research community;
- Accessible information on lifestage-specific determinants of activities, behaviors, physiology and exposure;
- Accessible information on susceptibility to chemicals and other contaminants based on lifestage (absorption, distribution, metabolism, excretion (ADME), toxicity, and PBPK considerations);
- Associated data on genetic susceptibility and increased susceptibility due to health and nutritional status, including pre-existing diseases and disorders;
- Accessible lifestage-specific data for non-chemical stressors linked to the built and natural environments, and to social and economic factors; and,
- Accessible data and information that shows the inter-relationships between chemical exposures and factors modifying those exposures.

ORD can begin to address these gaps by leveraging current activities within the NRPs to apply advanced approaches for curating and providing access to data through high-interest use-cases (i.e., research focused on addressing a gap in one or more of the other three research areas described in this Roadmap). For example, ORD has multiple activities focused on providing web-based information resources and associated web services to efficiently access these data (e.g., dashboards) as inputs to design workflows and analysis tools.

ORD has also developed a novel semi-automated approach using bioinformatics and computational techniques to mine the literature and facilitate systematic review. Using MeSH terms, ORD can find articles of interest and search in a systematic way. First, articles of interest are captured into a set database using specific MeSH annotations. The MeSH terms for this first pass are generally related to chemicals, proteins, or adverse outcomes of interest, but may include any MeSH terms. Second, this set of publications are queried using additional terms (e.g., proteins, cell-processes, species) to find articles where these terms are co-annotated. The co-annotation of terms gives plausible hypotheses about their associations, as well as the publication reference, without having to manually search the literature. Once these relationships and articles are identified, the article can be manually evaluated for evidence of this association. This database and mining approach is useful for identifying global hypotheses about associations of interest such as chemical-protein, chemical-cell process, or chemical-adverse outcome at all levels of biological complexity. These

relationships can then be used to build AOPs, understand unappreciated connections, and identify current data gaps.

These approaches can be applied in the context of NRP-specific and cross-cutting ORD CEH research to amplify the impact of investments in studies, models, and decision support tools.

Research Area 2: Systems understanding of the relationship between environmental exposures and health outcomes across development

The NIH (including NIEHS and NICHD) is currently investing significant resources in research to increase the Agency's understanding of the fundamental shared mechanisms of complex disease, susceptibility across the life span to diseases resulting from environmental factors, and links between the totality of environmental exposures and biological pathways (NIEHS, 2012). EPA's Strategic Plan translates this fundamental knowledge to provide a systems understanding that is necessary to adequately protect the health of children. As such, ORD can provide leadership in addressing priority gaps associated with using systems-based understanding of biology (from the molecular, tissue, and organ level out to the individual and population) to predict the potential for adverse impacts associated with development, chemical use, and environmental contamination. To effectively provide this leadership will require strategic implementation of ORD's STAR extramural grants program and leveraging partnerships of other cross-agency partnerships. Priority gaps in this area are broad and include the need for:

- Improved understanding of critical environmental factors, and interactions, that impact children's growth and development at EPA-defined early lifestages (U.S. EPA, 2005) and across the lifecourse;
- Understanding of the extent to which environmental stressors contribute to the childhood diseases and disorders prevalent today, including: abnormal birth outcomes (neonatal mortality, premature birth, morbidity, birth defects), metabolic and endocrine imbalance (associated with obesity and neurological outcomes), cognitive disorders related to neurodevelopmental dysfunction (learning problems, attention deficit hyperactivity disorder (ADHD), autism), and respiratory dysfunction such as asthma; and,
- Complex systems models that integrate key determinants to predict potential outcomes and impacts.

The Adverse Outcome Pathway (AOP) framework currently gaining traction in the toxicology and risk assessment communities provides an opportunity to integrate ORD CEH research across NRPs to begin to address these key gaps in the context of high-priority assessment needs specific to early lifestages. An AOP portrays existing knowledge of linkage between a direct molecular initiating event and an adverse outcome at a biological level of organization relevant to risk assessment (i.e., actionable) (Ankley et al., 2010). These AOPs provide a framework for organizing and communicating existing knowledge concerning the linkages between molecular initiating events, intermediate key events along a toxicity pathway, and apical adverse outcomes traditionally considered relevant to risk assessment and/or regulatory decision making. When developed and evaluated in a rigorous manner, AOPs provide a scientifically-defensible foundation for extrapolating from

mechanistic data to predicted apical outcomes. Additionally, as individual AOPs are developed, they can be assembled into AOP networks that may aid the prediction of more complex interactions and outcomes resulting from exposure to complex mixtures and/or chemicals with multiple modes of action. These AOP networks then afford the opportunity to integrate and evaluate the potential for impacts associated with nonchemical stressors, in addition to chemical stressors. By considering AOPs and AOP networks associated with important developmental processes, as well as those associated with disease endpoints of concern, mechanistic toxicology information and epidemiology insights can be brought together for model development and analysis of critical knowledge gaps.

A major challenge is to translate AOP frameworks across scales of biological organization (molecules, cells, tissues, populations) and function, while incorporating critical windows of exposure, dose, pharmacodynamics, and pharmacokinetics. Multiscale modeling and simulation is a powerful approach for capturing and analyzing biological information that is inaccessible or unrealizable from traditional modeling and experimental techniques. For example, virtual tissue models (VTMs) afford the opportunity to develop science without conducting studies in children. By simulating a range of predicted effects, the earliest signs of adversity can be identified, and new testable hypotheses aimed at improving the accuracy of inferences from *in vitro* data. These same modeling approaches can be applied to capture the complexity of children's interactions with the environment in their home, school, and community as well as to postulate key environmental determinants of health.

ORD will continue to identify effective strategies for fostering emerging scientific understanding and encouraging application of the latest science to inform Agency decisions. For example, the importance of epigenetic changes, i.e., the alteration of birth outcomes and/or the reprogramming of cells to promote disease susceptibility and metabolic dysfunctions that could occur later in life, is just beginning to be understood. Some of the EPA/NIEHS Children's Centers are currently doing work in this area and further research is needed, using both experimental and epidemiological approaches, to help increase the understanding of the extent to which environmentally-induced epigenetic changes can contribute both to future disease status and future resilience.

Research Area 3: Methods and models to evaluate early lifestage-specific risks and to support decisions protective of all lifestages

As guidance for incorporating consideration of lifestage-specific risks into Agency decisions are implemented, the need to incorporate a wide range of lifestage-specific information into workflows and analytical tools to support assessments has increased. Methods and tools are needed to effectively address a growing range of considerations and factors where data may be limited. Priority needs are for:

- Rapid, efficient methods to characterize children's total environments, including the built and natural environments, where pregnant women and children live, learn, and play;
- Rapid, efficient methods for evaluating potential for developmental toxicity science-based tools to support consideration of critical child-specific vulnerabilities for environmental and health policy decisions that promote and protect children's health.

For example, there is currently only limited information on exposures and exposure factors for infants and children less than 6 years of age. In addition, even when there is information on exposure levels from biomonitoring or other sources, there is little knowledge on the pathways of exposure, i.e., whether the exposure is predominantly from air, food, water, or other sources. Such information remains a critical gap in EPA's *Exposure Factors Handbook* (U.S. EPA, 2011), a resource that is widely used across the Agency and by other organizations to conduct chemical risk assessments. Novel, ultra-low burden approaches are required to develop the exposure factor information and data required to support these Agency assessments of risks in early life. There are also important gaps in methods and approaches for characterizing potential exposures associated with the home, school, and community environment required to assess risks associated with real-world exposures to mixtures, as well as to characterize potential modifying factors for more holistic decisions and solutions.

Another high-priority Agency research need is for continued development and evaluation of assays and testing schemes to identify the potential for developmental toxicity and human-relevance across the full range of critical endpoints. Assays that can be implemented in rapid, cost-effective schemes are of particular priority to facilitate development of data for thousands of chemicals in commerce that have not been evaluated for potential impacts to developmental pathways.

Research Area 4: Translational research and tools to support community actions and decisions

A lifecourse approach to health considers how an individual's current and future health may be affected by the dynamic interaction among social, biological, and environmental influences over time. It underscores the importance of multiple risk and protective influences and considers how the presence or absence of these influences during critical and sensitive stages of development may affect the health of individuals or selected populations (National Research Council, 2011). There is expected to be significant investment by NIH to support public health in vulnerable populations and groups, including children. EPA leadership will be required to enable research that meets targeted needs for translational tools incorporating lifestage-specific considerations to provide local decision makers with the knowledge needed to inform a balanced approach to community cleanup and development. Priority needs are for:

- Translational tools that can be used by community decision makers to access and use quality data sources specific to promote children's healthy development,
- Research related to child-specific impacts of exposure to non-chemical and chemical stressors at the community level.

State, Tribal and local governments make decisions that impact children's health and well-being in communities and settings (e.g., schools, daycare facilities, homes) where they live, work, and play. In order to optimize child (lifestage)-specific settings, community decision makers need access to information on the health impacts of multiple factors in the built and natural environment that contribute, in positive or negative ways, to children's health, and their importance relative to each other. A lifecourse approach is needed to identify the types of decisions that focus on child- (or lifestage-) specific environments. By taking a lifecourse approach and building such information

into decision support tools, community decision makers can optimize features of the built and natural environments so as to reduce (eliminate, prevent) risk and actively promote healthy development and well-being.

Informing 2016-2019 ORD Research Planning

EPA's Office of Research and Development's National Research Programs (Air, Climate, and Energy; Safe and Sustainable Water Resources; Sustainable and Healthy Communities; Chemical Safety for Sustainability; Human Health Risk Assessment; and Homeland Security - <http://www2.epa.gov/epa-research/strategic-research-action-plans>) are aligned on the core principle of sustainability and are designed to provide the solutions the Agency and the nation need to meet today's complex environmental and human health challenges. Inevitably, important scientific issues arise that cut across these six programs. Rather than create additional research programs for every cross-cutting issue, ORD is developing Research Roadmaps to clearly identify the science questions and associated research efforts that are ongoing in the six programs. These Roadmaps identify scientific gaps that inform the National Research Programs in the development of their Strategic Research Action Plans. As new, high priority, cross-cutting issues emerge, ORD expects to use this approach to integrate existing research efforts and identify needed work. Specific research products/deliverables are not included in the Roadmap; these may change as a result of ORD's planning and budgeting each year. However, ORD will use the EPA's website to provide details regarding research products associated with implementation of this Roadmap. Here, we elaborate on the objectives of integrated ORD research in CEH and on the approach for enabling this research through the National Research Programs.

Objective: Apply advanced and emerging science to understand and predict the role of exposure to xenobiotic environmental factors during early life, in the context of important non-chemical stressors, on health impacts across the course of development. Develop tools to address the complexity of CEH and support decisions that promote health and well-being of children.

Conceptual Framework

Systems theory provides the required framework for linking exposure science, toxicology, and epidemiology to study, characterize, and make predictions about the complex interactions between children and environmental stressors (both chemical and nonchemical) across the course of development (Figure 3). Multifactorial exposures to individuals, communities, and populations are captured horizontally from left to right (source-to-dose response with feedback), while outcome hierarchy is captured vertically from bottom to top (adverse outcome pathway). Kinetics and dynamics of these complex systems processes are not depicted, but are critical to meet the objective of moving toward development of predictive tools for supporting risk-based decisions.

The science developed will support consideration of multiple vulnerability and susceptibility factors for risk-based decisions. Exposure assessment and risk assessment require population and community-specific information or exposure factors that may vary significantly based on geography and cultural practices. These factors have been reviewed and a framework has been described to facilitate systematic consideration of these contextual factors for exposure and risk assessment (see Table 6) (DeFur et al., 2007).

Figure 3. Concept for integrated CEH research in ORD.

Conceptual Approach

EPA CEH Research will apply complex systems science to integrate the rapidly expanding body of information on children’s environments with advancing insights on developmental processes to inform the understanding of key factors contributing to health outcomes. This understanding will be translated and tools provided to support Agency decisions that promote and protect children’s health and well-being.

Studies will be model-driven to direct resources toward filling priority scientific gaps and to facilitate advancement of Agency capacity to be predictive of potential risks. This approach iteratively measures, mines, models, and manipulates (4M’s) to extract maximum understanding from extant data and to provide tools that support holistic evaluation of the complex interactions that determine health impacts of early life exposures. To ensure short term impact in support of Agency needs, the scope of the research will be targeted by implementing studies through case examples focused on priority health outcomes and exposures as identified by ORD Program Office Partners through the NRPs.

Table 6. Examples of specific vulnerability factors (Defur et al., 2007)

Environmental Conditions (habitat quality)	Receptor Characteristics (individual or group quality)

Measurement includes obtaining multi-dimensional information of the system through a variety of methods including high-throughput data capture. This involves much of the same data capture approaches that have been traditionally performed, but broadens the space through increasing system complexity (e.g., cellular processes, metabolism, protein location, receptor binding, enzyme activation/inhibition, biomarkers of exposure, environmental concentrations) and efficiency (e.g., rapid screening methods requiring fewer materials and increasing output).

Mining includes the organized compilation of the multi-dimensional data into usable databases, and bioinformatics approaches which mine the database to develop plausible relationships providing systems-based hypotheses, including, for example, putative AOPs.

Modeling includes developing statistically-based signatures (i.e., metrics) and computational-mechanistic models from the relevant information. These models are complex, nonlinear, and interconnected, integrating the data beyond a linear process.

Manipulation includes functional studies to predict system-level behaviors *in silico* and to evaluate model performance. An iterative process of prediction-validation is necessary to refine models in order to adequately represent the human-environment system at important levels of organization, whether the consequences result in normal development and well-being or adverse consequences to development and health.

This approach calls for knowledgebase-driven methods to incorporate information from past and current research, compilation of plausible pathways and mechanism of exposure and toxicity, models that can predict whether or not a chemical will elicit an adverse outcome, simulations that can incorporate these models, validation models for checks and balances, and acceptance and integration into current risk assessment paradigms, as well as integrating these data in new ways to evaluate risk.

Application of this common approach to identify the most important environmental factors driving early-life exposures and associated health outcome over the lifecourse will address key scientific gaps required to support the Agency's mission and strategic goals for protecting and promoting children's well-being.

Example 1: Birth Outcomes (Vascular VTMs)

The Virtual Tissue Modeling (VTM) project focuses on biologically-driven assembly to enable (*in vitro*) and simulate (*in silico*) key events in an AOP framework with respect to spatio-temporal dynamics in human development. The overall goal is to advance the mechanistic understanding of how chemical disruption of cell lineage, fate, and behavior propagates to higher levels of biological organization and adverse developmental outcomes. Genomic and environmental signals act cohesively during successive windows of development. When disrupted, these changes can impact aspects of maternal or filial development, leading to an array of adverse birth outcomes (e.g., malformations, low birth weight).

Embryonic vascular network assembly is a complex process characterized by the formation of geometric tubular networks (vasculogenesis). The early pattern is based on differential cell growth, migration and survival along a growth factor (VEGF-A) gradient as well as differential cell adhesion

and cell folding that connect the endothelial cell network and create a patent luminal channel, respectively. Subsequent growth and remodeling of the primitive capillary network (angiogenesis) is mediated by invasive angiogenic sprouting induced by local growth factors linked to oxygen tension as well as shear-stress signals following establishment of blood flow (Perfahl et al., 2011; Shirinifard et al., 2009). To understand and predict impacts of chemical exposures on this system, computational systems models have been built that incorporate all of the systems biology framework components (measurement, mining, modeling, manipulation). This provides a good example for how the systems biology approach can be applied to a particular developmental system.

Measurement: Data of chemical-biology perturbations came from the EPA's ToxCast program, as well as from text mining the public literature. A number of ToxCast assays specifically related to the vascular system were selected for incorporation into AOPs and computational simulation models. These assays and targets came from a human primary co-culture cell system with eight cell lineages (e.g., endothelial, peripheral blood, coronary artery smooth muscle, fibroblasts) evaluating protein secretion readouts (e.g., tissue factor, VCAM-1, MCP-1, uPAR, MMPs, TGFb, collagen); cell-free assays evaluating protein binding (e.g., VEGF, endothelin) and enzyme activity (e.g., caspase, ephrin, MMPs, Tie2); and cell-based assays evaluating transcriptional regulation (e.g., RAR, VDR, TGFb). A litany of MeSH terms was developed based on annotated genes, canonical pathways and cellular processes that could be linked to normal and abnormal vasculogenesis and angiogenesis to identify relevant vasculature-related articles and co-annotated concepts and principles.

Mining: Mining techniques combined literature mining integration tools (eLibrary) and bioinformatics approaches for making predictions about putative Vascular Disrupting Compounds (pVDCs). Using the MeSH terms indicated above on the public literature domain limited the articles to 100,000. These articles were organized in a way to assist in finding relevant relationships described in the articles and annotated in the MeSH terms. In the case of angiogenesis, for instance, the relationship between angiogenesis and proteins is captured by extracting co-annotations for neovascularization and proteins. Similarly, chemicals co-annotated with neovascularization are extracted into another sheet and organized by whether the chemical appears from the MeSH annotations to have an adverse effect on neovascularization or to have a therapeutic effect on neovascularization. The protein annotations are further processed to look at co-annotations in the literature, which coarsely indicates a biological relationship. Although the exact nature of the relationship is not identifiable from the annotations, the knowledge that two proteins are co-annotated is a helpful starting point for more in-depth exploration and further research. These associations are helpful in elucidating AOPs within the modeling section.

Chemicals were identified to be potential vascular disruptors, pVDCs, through identifying and prioritizing the ToxCast HTS assays relevant to vascular development. Six broad classes of assay targets (24 in total) were identified from the HTS assays, including receptor tyrosine kinases (VEGFR2, TIE2), GPCR-based chemokine signals (CXCL10, CCL2), and the GPI-anchored signals from matrix remodeling (PAI1, uPAR), among others. Next, the chemical-assay target activities for each chemical were used to rank the chemicals as least to most likely to affect the developing vasculature system. This provided a list of potential chemicals to pursue in follow-up modeling and confirmation steps across 1060 chemicals in the ToxCast library.

Modeling: AOPs delineate the documented, plausible, and testable processes by which a chemical induces molecular perturbations and the associated biological responses that describe how the molecular perturbations cause effects at the subcellular, cellular, tissue, organ, whole animal, and population levels of observation. This concept identifies the pathway linking a molecular initiating event (MIE) to an adverse outcome. To identify potential MIEs, the gene ontology (GO) and mammalian phenotype (MP) browsers of the Mouse Genome Informatics database (<http://www.informatics.jax.org/>) were searched for terms affiliated with the disruption of vascular development. Terms for abnormal vasculogenesis [MP:0001622; 72 genotypes, 73 annotations] and abnormal angiogenesis [MP:0000260; 610 genotypes, 894 annotations] were captured into a table as well as the gene and protein and then both were linked to ToxCast assays. This list had 65 target genes with bona fide roles in vasculogenesis or angiogenesis, 50 of which had evidence of abnormal embryonic vascular development based on genetic mouse models (Knudsen and Kleinstreuer, 2011). The proposed AOP for embryonic vascular disruption is shown in Figure 4.

Figure 4. Proposed AOP for embryonic vascular disruption.

An integrated understanding of the mechanisms and key events underlying embryonic vascular disruption requires a modeling framework to link relevant information about molecular pathways and cellular processes with the kinetics and dynamics of the system that describe the interactions and functioning of those elements. A systems biology approach is required to extend traditional conceptual linear models into computational models that are, ideally, quantitative or predictive. In building a simulation model of this process, each simulated cell in the model, like a biological cell, has an inherent capacity to process local information from the microenvironment and respond according to its own genetic blueprint or history. The key molecular players and cellular behaviors of concern were identified via the eLibrary, AOP framework, and ToxCast assay data. By incorporating these data and critical pathways and processes (e.g., extracellular matrix remodeling, chemokine pathways, growth factor signaling), the model can test certain hypotheses on cell signaling interactions and emergent vessel network topologies following chemical disturbance of specified growth factors, cell-surface receptors, and breakdown of the extracellular matrix. Discrete cellular behaviors (growth, adhesion, proliferation, apoptosis, chemotaxis) and parameters (growth factor diffusion, decay, secretion and uptake rates and cell size, motility, growth rate) were programmed into the simulation. Model outputs (cell number, angiogenic index, average vessel length/diameter, number of branching points) were compared to histological data for accurate representation.

Manipulation: Confirmation studies for the AOP and simulation model on vascular development included several anti-angiogenic reference compounds: 5HPP-33 (thalidomide analogue), TNP-470 (Wnt inhibitor), PTK787 (VEGFR2 inhibitor), and AG1478 (EGFR inhibitor). The 5HPP-33 reference compound was confirmed active in ToxCast Phase II assays across the AOP signature. In collaboration with scientists at the DOW Chemical Company, 5HPP-33 and TNP-470 were shown to interfere with microvessel outgrowth in aortic explant assay and caused lethality (5HPP-33 $\geq 15\mu\text{M}$) and malformations (TNP-470 $\geq 0.25\mu\text{M}$) in rat whole embryo culture. Computer simulation with 5HPP-33 predicted similar exposure-related morphological effects. RNA-Seq analyses were proposed to aid in understanding the specificity of the vasculogenesis-disruption mechanisms and allow identification of novel gene targets perturbed following chemical exposure. RNA-Seq analysis conducted on rat embryos (GD10) exposed to 5HPP-33 and TNP-470 in vitro revealed concentration-dependent effects on vasculogenesis genes (i.e., VCAM1, TNF, CASP8, HIF1A, AHR). These studies provide evidence that the science is correctly understood within the context of this research and that the predictions are plausible.

Example 2: Asthma (MICA Study)

Despite recent evidence suggesting that the very large increase in asthma incidence and prevalence observed in recent years may be slowing (Akinbami et al., 2011), the global burden of this complex disease remains at an all-time high. More than 20 million Americans have asthma, including approximately 7 million children under the age of 18. The cost of treating asthma in children under 18 in the U.S. is estimated at \$3.2 billion per year. Prevalence of asthma in low-income and minority children in the United States is disproportionately higher (Akinbami et al., 2011; von Mutius and Hartert, 2013).

The *Mechanistic Indicators of Asthma (MICA) Study* was designed to investigate whether genomic data (blood gene expression), viewed together with a spectrum of exposure, effects, and clinical and susceptibility markers, can increase the sensitivity required to define exposure-response-effects relationships and provide mechanistic insight for further hypothesis generation and testing.

As such, this study provides an example of how a systems biology approach can support a more holistic understanding of the multifactorial etiology of environmental disease (Gallagher et al., 2011; George et al., 2015).

Measurement: A nested case-control cohort of 205 non-asthmatic and asthmatic children (9-12 years of age) from Detroit, MI, were recruited. The integrated study design and framework for MICA is shown in Figure 5. The MICA design focuses on environmental exposures, susceptibility, asthma, and other health measures, including risk factors associated with obesity and cardiovascular disease. Information on a wide range of risk factors relevant to asthma and asthma exacerbations were characterized through collection of exposure metrics, lung function tests, and biological and clinical indicators measured in blood, urine, and fingernails. The study includes environmental measures (indoor and outdoor air, vacuum dust), biomarkers of exposure (cotinine, metals, total and allergen specific Immunoglobulin E, polycyclic aromatic hydrocarbons, volatile organic carbon metabolites) and clinical indicators of health outcome (immunological, cardiovascular and respiratory). In addition, blood gene expression and candidate SNP analyses were conducted. Selected measurements are highlighted in Figure 5.

Figure 5. The overall MICA Study design includes exposure, biomarkers of exposure, clinical indicators, genomic data (blood gene expression and SNP) and health status indicators.

Mining: Traditional analysis of complex disease considers one domain of data at a time to identify associations between biomarkers or bioindicators and disease outcomes. The commonly employed methodologies used require a clearly defined phenotype representative of multiple underlying disease processes for traditional supervised methods or a disease clearly identifiable by genomic or clinical data for traditional unsupervised methods, neither of which is true of complex disease. The large data sets that are now widely available can be mined to define novel, mechanistically distinct disease subtypes (endotypes) in a completely data-driven manner. Approaches for maximizing the discovery potential of these data sets are still an area of significant research. Alternative approaches for mining the MICA data were evaluated (e.g., Student's t-test, single data domain clustering and the Modk-prototypes algorithm). To best exploit strengths and limitations of the MICA data, a novel multi-step decision tree-based method was developed to define endotypes. This new method gave the best segregation of asthmatics and non-asthmatics, and it provided easy access to all genes and clinical covariates that distinguish the groups (Williams-DeVane et al., 2013).

Modeling: As noted above, gene expression data were combined with hematologic, immunologic, and cardiopulmonary covariates to define mechanistically distinct subtypes (or endotypes). A novel method was used to integrate the clinical covariate data with gene expression, resulting in a recursive partitioning tree that segregated individuals according to their asthma status. The resulting tree model assembled asthmatic subjects into purely data driven endotypes. These endotypes were consistent with previous classifications, though the data suggest multiple mechanistically distinct neutrophilic subtypes. Functional characterization of the genes and associated covariates revealed a complex interaction among Th2 mediated lung inflammation, heightened systemic innate immune response, and potentially metabolic syndrome in discriminating asthma endotypes. These findings support a prominent role for systemic inflammation due to heightened innate immune responsiveness across the asthma syndrome and suggest that new biomarkers are needed to better classify mechanistically distinct neutrophilic endotypes.

Manipulation: Characteristics of the data-driven derived endotypes from this study are consistent with previously published endotypes based solely on clinical diagnostic criteria, but this data-driven method provides mechanistic understanding that is not possible when using established clinical markers alone. One theme that emerges from this analysis is the interplay between innate and adaptive immune responses across endotypes. Results also suggest a role for broad systemic inflammation in addition to the localized hyperreactivity in the lung as a major driver for asthma. The findings of this data-driven mining and modeling approach are consistent with studies demonstrating that weight loss improves asthma symptoms without significant changes in markers of airway inflammation. Of note, body mass index (BMI) alone is not a predictor of asthma in the MICA Study, in contrast with other recent studies; this may be because MICA looks at asthma prevalence in children rather than correlates of asthma onset. The MICA Study, among others, putatively identifies underlying mechanisms linking obesity and asthma through systemic inflammation related to metabolic syndrome and increases the relevance and understanding of clinical findings.

The result of applying this holistic approach to the study of asthma in children is a better understanding of the various asthma endotypes and a scientifically defensible foundation for the evaluation of the many environmental factors influencing each mechanistically distinct endotype. Non-eosinophilic asthmatics likely fall into multiple mechanistically distinct subgroups or endo-

types. Exacerbation of asthma by obesity and metabolic syndrome likely occurs through enhanced systemic inflammation, which will not be detected by biomarkers reliant on airway inflammation.

Asthma biomarkers reliant on airway inflammation may miss endotypes driven by systemic inflammation. The increasing incidence of asthma due to the rise in obesity will expand the proportion of these endotypes.

Example 3: The Future of Cross-Cutting CEH Research

The traditional risk-based assessment paradigm supports decisions to minimize adverse impacts associated with environmental exposures. Clearly, removing chemical/pollution stressors is a necessary and essential component of children's health protection. Community planning and development decisions are designed from the holistic perspective of both minimizing risks while at the same time providing an environment that supports and promotes healthy (optimal) child development. Such a goal is an inherent property of sustainability. To support this goal, novel methods are required to incorporate and consider the complexity associated with these decisions and to compare alternatives and evaluate outcomes.

For example, the same agent-based modeling tools used by the ORD Virtual Tissues Modeling project to simulate how chemical perturbations at the cellular level propagate to higher levels of biological organization can potentially be applied to simulate population level interactions of children in a community. It has been suggested that health behavior research is a candidate for application of complex systems modeling approaches to address empirical questions that cannot be addressed using the regression approaches common to the field of social epidemiology (Galea et al., 2009). Similarly, these approaches could provide the capacity to integrate the vast array of information required to computationally test and evaluate community-level interventions and public-policy decisions designed to improve CEH. By designing cross-cutting ORD research to extend these approaches across all levels of organization, important gaps in data and understanding can be efficiently identified for targeted study and data collection. The conceptual research framework and approach described in these three examples, implemented through case examples of high priority to ORD program office and regional partners, will facilitate integrated research required to support holistic and sustainable decisions in support of CEH.

Summary

CEH research is conducted by the EPA to improve the scientific understanding required to support: regulatory decisions protective of children’s health now and in the future; community decisions that protect and promote children’s health across generations; and, ecological decisions that provide sustainable healthy environments for children. The overarching goal for EPA’s CEH research program is to provide the Agency and others with the information needed to incorporate consideration of early lifestage susceptibility and vulnerability into decision making.

EPA’s CEH research is designed to address four priority research areas: (1) knowledge infrastructure to provide early lifestage-specific data and information; (2) systems (biological) understanding of the relationship between environmental exposures and health outcomes across development; (3) methods and models fit for purpose to evaluate early lifestage-specific risks and to support decisions protective of all susceptible and vulnerable early lifestages; and (4) translational research and tools fit for purpose to support community actions and decisions.

EPA is currently carrying out research in each of these four areas and plans to build on this research as it plans for the future. EPA will continue to partner with other Federal agencies and independent organizations to further CEH research. Future research will apply complex systems science to integrate the rapidly expanding body of information on children’s health. This information will be translated into tools and databases that will support Agency decisions that promote and protect children’s health and well-being. Model-driven studies will be used to direct resources toward filling priority scientific research gaps and to advance the Agency goals of protecting human health and the environment.

Appendix A: ORD's Current Research Activities

This Appendix presents more information on the research activities that are presented in Section IV of the document as well as information on additional research activities. The NRP with key responsibility for each of the activities is provided in parentheses after the project name in this section.

- ACE = Air, Climate, and Energy Research
- CSS = Chemical Safety for Sustainability Research
- HHRA = Human Health Risk Assessment Research
- SHC = Sustainable and Healthy Communities Research
- SSWR = Safe and Sustainable Water Resources Research

See Table A1 for a summary of these research activities.

Table A1. ORD's current research activities

Research Area 1. Knowledge Infrastructure to Provide Early Lifestage-Specific Data and Information		
Title	Research Program	Description
Exposure Information		
Exposure Factors Handbook	HHRA	Databases and handbook with information on children's exposures and exposure factors; human behavior; amounts of chemicals currently found in food, drinking water, air, dust, indoor surfaces, and urine; and chemical usage.
Consolidated Human Activity Database	CSS	
ExpoCast Database	CSS	
Chemical and Product Categories Database	CSS	
Early Lifestage Pharmacokinetic Parameters		
Enzyme Ontogeny Database	CSS	Database that can be used as a screening tool to explore metabolism-based variability, based on enzyme differences, during early lifestages.
Developmentally Relevant Hazard Data		
ToxCast Database	CSS	Data from <i>in vivo</i> animal studies, screening assays and other study types are included in these databases.
Toxicity Reference Database	CSS	
Adverse Outcome Pathway (AOP) Wiki	CSS	A wiki-based tool that provides an interface for collaborative sharing of established AOPs and building new AOPs.

Table A1. (continued) ORD’s current research activities

Research Area 2. Systems Understanding of the Relationship Between Environmental Exposures and Health Outcomes Across Development		
Title	Research Program	Description
Systems Biology to Predict Developmentally Relevant Outcomes		
Bioinformatics-Based Models	CSS	System models for tissues and multi-organ pathways specific to embryo-fetal and neonatal development. Examples include: First-generation ToxCast predictive models for reproductive and development toxicity, the Vascular AOP model, and the Virtual Embryo model.
AOP Models	CSS	
Simulation Models	CSS	
Systems Understanding of Complex Stressors		
Laboratory Based Studies	CSS, SHC, and SSWR	Includes <i>in vitro</i> models to evaluate the effects of chemical exposure in developmentally relevant systems, and <i>in vivo</i> models with rodents studying issues such as alterations in endocrine function during fetal and early childhood and its effect during and after puberty.
Epidemiologic Studies		
EPA-NIEHS Children’s Environmental Health and Disease Research Centers (CEHC Program)	SHC and ACE	Jointly funded by EPA and NIEHS through the STAR grant program, the CEHC program explores ways to reduce children’s health risks from environmental contaminants. Health outcomes under investigation include adverse birth outcomes, asthma, autism, obesity, altered immune function, and cancer.
Clean Air Research Centers	ACE	Studies investigating the relationship between air pollutants and children’s health.
Place-Based Studies	ACE, SHC and SSWR	Includes studies investigating housing quality, traffic-related air pollutants, indoor air pollutants, and water-related exposures and their effect on children’s health outcomes.
Co-Exposure to Multiple Stressors	SHC and ACE	New methods for modeling and assessing cumulative exposure and risk.
MICA Study	CSS and SHC	Study incorporates exposure metrics, internal dose measures, and clinical indicators to investigate gene-environment interactions in asthma and cardiovascular disease.

Table A1. (continued) ORD’s current research activities

Research Area 3. Methods and Models Fit for Purpose to Evaluate Early and Lifestage-Specific Risks and to Support Decisions Protective of all Susceptible and Vulnerable		
Title	Research Program	Description
Exposure		
EPA ExpoBox	HHRA	Tools to increase the usability and access to exposure data, models to predict exposure by a variety of pathways and routes, and approaches for categorizing lifestage changes and prioritizing chemical mixtures.
SHEDS-HT Model	CSS	
ExpoCast	CSS	
Lifestage Categories for Monitoring and Assessing Exposures to Children	SHC	
Biogeographical Approach for Prioritizing Chemical Mixtures	CSS	
Dosimetry Models		
Empirical Models		
Persistent Bioaccumulative Toxicants	CSS	Models that assess exposure and predict dose based on measurements of biomarkers and kinetic parameters.
<i>In vitro</i> to <i>in vivo</i> Extrapolation	CSS	
Community Multi-scale Air Quality Model	CSS	
Pesticide Biomarker Measurements in Children	CSS	
PBPK Models		
Virtual Embryo Project	CSS	PBPK models that investigate the relationship between exposure, tissue dosimetry, and kinetics of environmental chemicals.
Ethanol	CSS	

Research Area 4. Translational Research and Tools Fit for Purpose to Support Community Actions and Decisions		
Title	Research Program	Description
Decision Support Tools		
Community-Focused Exposure and Risk Screening Tool	SHC	Tools that enhance access to information for environmental health decision making.
EnviroAtlas	SHC	

Table A1. (continued) ORD’s current research activities

Research Area 4. (continued) Translational Research and Tools Fit for Purpose to Support Community Actions and Decisions		
Title	Research Program	Description
Problem-Driven Research		
EPA Pilot Study Add-On to the Third Study Site of the Green Housing Study	SHC	Studies that increase the understanding of the linkages between human health and environmental exposures that will be useful for community decision-making.
Dust and Soil Ingestion	CSS and SHC	
Chemical and Non-Chemical Stressors and Childhood Obesity	SHC	
Chemical and Non-Chemical Stressors and Neurocognitive Health	SHC	
Community Multi-Scale Air Quality Model	ACE	
PCBs in School	HHRA	
Child-Specific Scenarios Examples	HHRA	
Translational Research		
EPA-NIEHS Children’s Environmental Health and Disease Research Centers (CEHC Program)	SHC	Includes a Community Outreach and Translation Core that use a variety of approaches to translate research findings and intervention strategies to the community.
Social Determinants of Health		
STAR Centers of Excellence on Environment and Health Disparities	SHC	Studies investigating the complex interactions of biological, social, and environmental determinants of population health.
Environmental and Community Factors Influence Effectiveness of Medical Treatments for Asthma	SHC

Research Area 1. Knowledge infrastructure to provide early lifestage-specific data and information

Currently knowledge resources are being developed under Research Area 1 in the following three areas: (1) Exposure Information, (2) Early Lifestage Pharmacokinetic Parameters, and (3) Developmentally Relevant Hazard Data. ORD's relevant research in each of these areas is summarized as follows:

(1) Exposure Information

Exposure data are critical for characterizing children's environments and for evaluating interactions of the child with that environment across development.

Exposure Factors Handbook (HHRA)

Data about children's exposures and exposure factors, such as lifestage specific modeled estimates of soil and dust ingestion is incorporated into EPA's Exposure Factors Handbook (U.S. EPA, 2011); available at <http://cfpub.epa.gov/ncea/risk/recordisplay.cfm?deid=236252>. This important resource is used by exposure assessors both inside and outside the Agency to obtain data on lifestage specific exposure factors to calculate human exposure to environmental agents. These factors include: drinking water consumption, soil and dust ingestion, inhalation rates, dermal factors including skin area and soil adherence factors, consumption of fruits and vegetables, fish, meats, dairy products, homegrown foods, human milk intake, human activity factors, consumer product use, and building characteristics.

Consolidated Human Activity Database (CHAD)

ORD's Consolidated Human Activity Database (CHAD) is a compilation of data on human behavior from 24 individual studies (U.S. EPA, 2014d); available at: <http://www.epa.gov/heasd/chad.html>. This resource includes more than 50,000 individual data days of detailed location and activity data and corresponding demographic data including age, sex, employment, and education level. These data are used in human exposure and health studies and models used for exposure and risk assessment. Data are included for all ages, including children as young as infants. Recent information added to CHAD for children includes data from the 2008 phase of the Child Development Supplement of the University of Michigan's Panel Study for Income Dynamics (PSID).

ExpoCast Database (CSS)

ExpoCast Database (ExpoCastDB) was developed to improve access to human exposure data from observational studies, including those funded by ORD. ExpoCastDB consolidates measurements of chemicals of interest in environmental and biological media collected from homes and child care centers. Data currently include the amounts of these chemicals found in food, drinking water, air, dust, indoor surfaces, and urine. The current publicly released version of ExpoCastDB includes data for 99 unique chemicals primarily consisting of active ingredients in pesticide products. Chemical concentrations measured in samples collected for three observational studies are included: the American Healthy Homes Survey (AHHS), the First National Environmental Health Survey of Child Care Centers (CCC), and the Children's Total Exposure to Persistent Pesticides and Other Persistent Organic Pollutants (both CTEPP NC and CTEPP OH) studies.

ExpoCastDB is available as a searchable database (U.S. EPA, 2014g); available at the link <http://actor.epa.gov/actor/faces/ExpoCastDB/Home.jsp> on EPA's Aggregated Computational Resource (ACToR) system, an online data warehouse that collects data on over 500,000 chemicals from over 1000 public sources (U.S. EPA, 2014a); available at: <http://actor.epa.gov/actor/faces/ACToRHome.jsp>. Controlled vocabularies are used to facilitate searching and analyses across datasets and to encourage standardized reporting of observational exposure information. ExpoCastDB provides a separate interface within ACToR to facilitate linkage of exposure measurement data with data on toxicity, environmental fate, and chemical manufacturing and usage information.

Chemical and Product Categories (CSS)

Chemical and Product Categories (CPCat) is a database of information on how chemicals are used (U.S. EPA, 2014b); available at: <http://actor.epa.gov/actor/faces/CPCatLaunch.jsp>. As with ExpoCast, CPCat is available as a searchable database within ACToR. CPCat contains information on the uses of chemicals; products that contain chemicals; manufacturers of the products; and a hierarchy of consumer product "use" categories. Examples of the types of uses in this database include uses in: consumer products; automotive products; agricultural chemicals; and pesticides. It also contains information on use by children and lists any regulations or studies in which the chemical has been considered hazardous to children.

(2) Early Lifestage Pharmacokinetic Parameters

Pharmacokinetic and pharmacodynamic parameters for all lifestages are required to predict the potential for health effects from exposures to environmental chemicals. Child-specific parameters are used to characterize dose to the developing child *in utero*, after birth through lactational exposure, and during early infancy through prepubertal ages.

Enzyme Ontogeny Database (CSS)

Chemicals are typically metabolized in the body sequentially by activating and detoxifying enzymes that change over time from the developing embryo to adulthood. Therefore, the availability of certain enzymes at different lifestages could play an important role in determining the susceptibility of children, compared to adults, to environmental chemicals. ORD has developed an enzyme ontogeny database that can be used as a screening tool to explore metabolism-based variability, based on enzyme differences, during early lifestages.

(3) Developmentally Relevant Hazard Data

Data from *in vivo* animal studies, screening assays, and other study types are needed in order to carry out risk and hazard assessments on environmental chemicals. ORD has developed databases that allow for easy access to developmental hazard data that is being used to link environmental exposures at early lifestages with health outcomes in children and later in life.

ToxCast Database (CSS)

ToxCastDB provides results of high-throughput *in vitro* assays. Biology covered in the large set of assays include endpoints related to endocrine, reproductive, and developmental toxicity and a major proportion of the assays are human-based cells or proteins. Information about the assay design, chemical dose, and experimental set-up are also provided in the database. ToxCastDB is available as a searchable database through the ACToR system (U.S. EPA, 2014h); available at: <http://actor.epa.gov/actor/faces/ToxCastDB/Home.jsp>.

Toxicity Reference Database (CSS)

Toxicity Reference Database (ToxRefDB) contains data from thousands of *in vivo* animal studies and is available as a searchable database through the ACToR system (U.S. EPA, 2014i); available at: <http://actor.epa.gov/toxrefdb/faces/Home.jsp>. Information on study design, dosing, and treatment-related effects from subchronic, chronic, cancer, developmental, and reproductive studies are included in the database. The developmental toxicity information includes results from studies on more than 380 chemicals with 18 endpoints for both the rat and rabbit, while the reproductive toxicity information is based on the results from multigenerational reproductive studies on 316 chemicals, with 19 parental, reproductive, and offspring endpoints.

Adverse Outcome Pathway Wiki (CSS)

An Adverse Outcome Pathway (AOP) is a conceptual framework that portrays existing knowledge concerning the linkage between a direct molecular initiating event and an adverse outcome. The goal of an AOP is to provide the framework to connect the two events. In developing information on early lifestage toxicity, ToxCast provides the infrastructure to predict pathways of toxicity by probing the fundamental nature of chemical interaction(s) with their potential molecular targets and cellular consequences. However, since toxicity is an expression of lesion propagation to higher levels of biological organization, AOP models are needed to provide weight-of-evidence for biological plausibility across the developmental linkages leading to observable endpoints in the newborn or child. Multi-cellular interactions, such as between immune cells and endothelial cells during angiogenesis for example, play important roles in utero-placental development, embryogenesis, and other AOPs linked to childhood development. These AOPs can be used to integrate multi-dimensional data with vast biological knowledge.

AOP Wiki is a wiki-based tool that provides an interface for collaborative sharing of established AOPs and building new AOPs (Anonymous, 2014); available at: http://aopkb.org/aopwiki/index.php/Main_Page. AOP Wiki uses templates to make it easier for users to include the information needed for proper evaluation of an AOP.

Research Area 2. Systems understanding of the relationship between environmental exposures and health outcomes across development

Research Area 2 has been divided into the following two subgroups: (1) Systems Biology to Predict Developmentally Relevant Outcomes and (2) Systems Understanding of Complex Stressors. ORD's relevant research in each of these areas is summarized as follows:

(1) Systems Biology to Predict Developmentally Relevant Outcomes

Systems models for tissues and multi-organ pathways specific to embryo-fetal and neonatal development are being developed. These models increase our understanding of the biologic mechanisms of chemical stressors that contribute to childhood health outcomes.

Bioinformatics-Based Models (CSS)

As discussed on page 65, ToxCastDB uses high-throughput biochemical and cellular *in vitro* assays to evaluate the toxicity of environmental chemicals. ORD has developed bioinformatics-based models using ToxCastDB in a two-step process: (1) examining which assays were associated with

chemicals having certain toxicity profiles, such as developmental or reproductive toxicity, and (2) developing predictive models using these assay associations to predict the likelihood of reproductive, developmental, or other types of toxicity of chemicals that had not been tested *in vivo*. The development of predictive models is being carried out in phases, with the development and publication of first-generation (Phase I) ToxCast predictive models for reproductive toxicity (M. T. Martin et al., 2011) and developmental toxicity (Sipes et al., 2011). These models anchored *in vitro* data to *in vivo* endpoints for a set of approximately 300 data-rich chemicals. Pathways for endocrine disruption (Reif et al., 2010), embryonic stem cell differentiation (Chandler et al., 2011) and disruption of blood vessel development (Kleinstreuer et al., 2011) have been linked to the Phase I ToxCast *in vitro* data. For the next approximately 700 compounds in Phase II, where animal toxicology is less well characterized, ORD is developing plausible model structures that deal with the possibility of additional relevant interactions and components beyond those represented in the first-generation predictive models.

AOP Models (CSS)

ORD is developing AOP models, such as the vascular AOP model, with the aim of establishing the predictive value of chemical disruption of blood vessel development (vasculogenesis) during critical windows of embryonic and fetal development. Using computer-based simulation tools, vasculogenesis and its disruption can be visualized in the virtual absence and presence of specific chemicals across a given dose range. This model is being tested in zebrafish embryos and in embryonic stem cells and provides information for individual chemicals and chemical families on potential reproductive and developmental toxicity and susceptibility by developmental stage. As additional individual AOPs are developed, they can be assembled into AOP networks that may aid the prediction of more complex interactions and outcomes resulting from exposure to complex mixtures and/or chemicals with multiple modes of actions.

Simulation Models (CSS)

Simulation models predict chemical toxicity using relevant biologic information, such as the influence of subcellular pathways and networks on the development of tissues and organs. ORD is developing the Virtual Embryo model, a simulation model of predictive toxicology of children's health and development, which can be applied to prenatal or postnatal (including lactational) exposures. This model uses cell-based systems and knowledge databases to generate and integrate chemical, biological and toxicological information at all levels of biologic organization (molecular, cell, tissue, organ, and organism) in order to enhance the predictive power to evaluate potential chemical toxicity. The virtual model uses AOP models, such as the model for vasculogenesis (see section above) and endocrine system models, as modules in the model. Additional models for palate formation (predicting cleft palate), limb formation (predicting limb defects), eye development (predicting retinal disease) and phallus development (predicting hypospadias) are under active development.

(2) Systems Understanding of Complex Stressors

Epidemiologic, animal studies, and *in vitro* assays are being used to develop a systems understanding of the relationship between environmental exposures as stressors and lifestage-specific susceptibility and vulnerability. A critical component of a systems approach is determining how interactions among complex stressors – chemical and non-chemical (social, physical) – may increase the sensitivity of children.

Laboratory Based Studies (CSS, SHC, and SSWR)

Intramural ORD research has used a variety of *in vitro* models to evaluate the effects of chemical exposure in developmentally relevant systems (CSS). Cell (e.g., human multipotent neuroprogenitors, rodent embryonic stem cells, specific pathway-responsive modified hepatocytes), organ (e.g. human and rodent palatal shelves), and whole rodent embryo cultures, as well as whole organisms (developing zebrafish) have been used to address issues of toxic response. Many of these models have been developed, characterized, and refined to answer specific research questions. Several model systems have been used to evaluate the effects of chemicals to aid in the translation of high-throughput data in the ToxCast assays.

Intramural ORD research is also using *in vivo*, longitudinal study designs with rodents to explore causation and characterize how *in utero* and neonatal environmental stressors may alter development and thereby contribute to adverse health outcomes in adulthood (SHC). For example, ongoing work is examining how alterations in endocrine function during fetal and early childhood may impair adrenal and reproductive function during and after puberty. Researchers are also exploring lifelong changes in physiology that may result from fetal and neonatal exposures and predispose an individual to metabolic syndrome (obesity, hypertension, diabetes), impaired neurological function, and altered immune responses. Molecular and epigenetic mechanisms are being explored in these studies and companion *in vitro* models designed to identify toxicity pathways. Intramural researchers are designing studies to address hypotheses generated by epidemiologic studies, such as those being conducted by the Children's Centers (see next section below), in order to elucidate mechanisms and characterize modifying factors such as prenatal stress.

Laboratory based studies are also examining the cumulative risk of mixtures of chemicals. For example, ongoing studies are examining dose- and effect-additivity models for considering combined impacts of endocrine disruptors that perturb reproductive tract development after *in utero* exposures (SHC). Similarly, the combined impact of disinfection byproducts in drinking water on developmental processes and children is being examined (SSWR). *In vitro* and *in vivo* studies are investigating the effects of cumulative exposure to disinfection byproducts in drinking water, comparing two common disinfection methods (chlorination and chloramination). These mixtures are also being evaluated in mouse embryonic stem cells.

Epidemiologic Studies (SHC and ACE)

EPA-NIEHS Children's Environmental Health and Disease Prevention Research Centers (SHC)

The EPA-National Institute of Environmental Health Sciences (NIEHS) co-funded Children's Environmental Health and Disease Prevention Research Centers (CEHCs, or "Children's Centers") Program, ongoing since 1998, continues to generate exposure and biomarker data in pregnant women and children in order to show relationships between exposure and a variety of children's health outcomes, and to identify critical windows of susceptibility (U.S. EPA, 2014e); available at: www.epa.gov/ncer/childrenscenters; http://cfpub.epa.gov/ncer/abstracts/index.cfm/fuseaction/recipient.display/rfa_id/560/records_per_page/ALL. Jointly funded by EPA and NIEHS through the STAR grant program, the long-range goals include understanding how environmental factors affect children's health, and promoting translation of basic research findings into intervention and prevention methods to prevent adverse health outcomes. To achieve these goals, the program fosters research collaborations among basic, clinical, and behavioral scientists with participation

from local communities. The Children’s Centers Program celebrated its 15th anniversary in 2013 with a meeting in Washington, D.C., including comments from EPA Administrator Gina McCarthy.

The Children’s Centers are currently collecting exposure data on pesticides, bisphenol A (BPA), phthalates, brominated flame retardants, metals such as arsenic, lead and manganese, and air pollutants including polyaromatic hydrocarbons (PAHs) and environmental tobacco smoke. Collectively, they are examining a wide range of health outcomes in cohorts of children including adverse birth outcomes, asthma and respiratory dysfunction, autism and other neurobehavioral problems including ADHD, obesity and metabolic syndrome, altered immune function and childhood cancer (Table A2). Increasingly, they are focused on potential epigenetic mechanisms by which exposures during gestation and early life may reprogram gene expression and set the stage for a variety of health conditions later in life. Furthermore, several Centers maintain or have access to longitudinal birth cohorts whose members are now entering puberty, making it possible to address multifactorial environmental public health questions relevant to adolescents.

Several Centers focus on childhood asthma as a common health outcome for which racial and ethnic disparities exist. These studies approach asthma from multiple fronts including air pollution from near-road exposures (as both causative and exacerbating), and the effectiveness of medical and dietary interventions. These studies and other STAR and ORD in-house studies on asthma causation and intervention described later address place-based community scenarios and are contributing to meeting EPA commitments in the *Coordinated Federal Action Plan to Reduce Racial and Ethnic Asthma Disparities* (President’s Taskforce on Environmental Health Risks and Safety Risks to Children, 2012).

Table A2. Current children’s environmental health and disease prevention research centers exploring associations between exposures and health outcomes in children

Institution – P.I.	Chemical Exposures and Other Stressors	Outcomes	Underlying Mechanisms (molecular, genetic, social factors)
Brown University – Boekelheide	Arsenic, EDCs (estradiol, BPA, genistein), dietary restriction	Fetal liver, lung and prostate development; prostate cancer in later life	Endocrine disruption; Epigenetic changes in organ development
Columbia University – Perera	Endocrine Disrupting Compounds (BPA), PAHs,	Neurodevelopmental disorders such as problems with learning and behavior; obesity and metabolic disorders	Endocrine disruption; Epigenetic reprogramming and metabolic syndrome
Dartmouth College – Karagas	Arsenic in drinking water and food	Growth and development; immune response	Epigenetic changes and influence of gut microbiome
Duke University/ University of Michigan – Miranda	Environmental, social and individual susceptibility factors, PM, Ozone	Disparities in birth outcomes; respiratory health in infants	Social determinants of childhood disease
Duke University – Murphy	Environmental tobacco smoke	ADHD; neurobehavioral dysfunction	Epigenetic modulation in fetal and child development

Table A2. (continued) Current children’s environmental health and disease prevention research centers exploring associations between exposures and health outcomes in children

Institution – P.I.	Chemical Exposures and Other Stressors	Outcomes	Underlying Mechanisms (molecular, genetic, social factors)
Johns Hopkins University – Diette	Airborne pollutants (particulate matter, nitrogen dioxide), allergens, urban diets	Asthma	Dietary contributions to asthma, based on anti-oxidant and anti-inflammatory impacts on immune function and inflammation
National Jewish Health – Schwartz, Szefer	Air pollution (ozone, PM, NO ₂), ambient bacterial endotoxin	Asthma; immune system function; determinants of host defense	Host-immune responses and TL4 receptor function; interactions between ozone and endotoxin
University of California, Berkeley - Buffler, Metayer	Pesticides, tobacco-related contaminants, chemicals in house dust (PCBs, PBDEs)	Childhood leukemia	Epigenetic and genetic influences
University of California, Berkeley – Eskenazi	Pesticides (DDT, manganese), flame retardants	Neurodevelopment; growth and timing of puberty; obesity	Epigenetic reprogramming; altered endocrine status
University of California, Berkeley – Hammond, Balmes, Shaw	Ambient air pollutants (airborne PAHs), in utero exposure to traffic-related pollutants, endotoxin	Birth defects/preterm birth, immune system dysfunction (asthma/allergies), obesity/glucose dysregulation	Gene variants in bio-transformation enzymes; molecular mechanisms e.g., altered T-cell function; neighborhood factors
University of California at Davis – Van de Water	BPDEs, pyrethroid insecticides, perfluorinated compounds, POPs	Autism spectrum disorder (ASD)	Immune dysfunction and autoimmunity; genetic/epigenetic contributions
University of California, San Francisco – Woodruff	EDCs, PBDEs (BDE-47), PFCs (PFOA), psychosocial stress	Placental and fetal development, adverse birth outcomes	Gene expression changes via epigenetic mechanism; contribution of psychosocial stress
University of Illinois, Urbana-Champaign – Schantz	EDCs (phthalates, BPB), high fat diet	Neurological and reproductive development	Endocrine disruption; oxidative stress
University of Michigan – Peterson, Padmanabhan	BPA, phthalates, lead, cadmium	Birth outcomes; child weight gain; body composition; activity patterns; hormonal levels; sexual maturation; metabolomics and risk of metabolic syndrome	Dietary influences; epigenetics and gene expression changes; oxidative stress
University of Southern California – McConnell	Near-roadway air pollution including elemental carbon, PM 2.5	Obesity; fat distribution; metabolic phenotypes; systemic inflammation	Expression of genes in metabolic pathways; beta cell function; oxidative stress
University of Washington – Faustman	Agricultural pesticides	Altered neurodevelopment	Genetic susceptibility; neurotoxicity; oxidative stress; cellular pathways underlying neurodevelopment

Clean Air Research Centers (ACE)

ORD's Clean Air Research Centers Program (STAR) includes a number of epidemiologic projects directly relevant to children's environmental health. Two currently active Centers are producing new data and knowledge on the relationship between air pollution and children's health, with final reports expected in 2015. The Center at Emory University is generating "Novel estimates of pollutant mixtures and pediatric health in two birth cohorts," and the Center at Harvard University is evaluating "Longitudinal effects of multiple pollutants on child growth, blood pressure and cognition." (U.S. EPA, 2012); available at: <http://www.epa.gov/ncer/quickfinder/airquality.html>.

Place-Based Studies (ACE, SHC, and SSWR)

ORD recognizes that combinations of stressors are often unique to a particular community setting and that interventions to improve children's health must take this complexity into account. For example, ongoing place-based studies are examining the contributions of housing quality and mold to the severity of childhood asthma in children exposed to near-road air pollution (ACE). Other studies are showing that the social-economic status of a community can significantly alter the response of resident asthmatics to wood smoke from nearby wildfires (SHC). These studies are designed to inform community intervention decisions and benefit community sustainability.

A STAR grant and ORD in-house project, "The Near-Road Exposures and Effects of Urban Air Pollutants Study (NEXUS)" examined the influence of traffic related air-pollutants on respiratory outcomes in a cohort of 139 asthmatic children (ages 6-14) who lived close to major roadways in Detroit, Michigan (ACE). An integrated measurement and modeling approach was used to quantitatively determine the contribution of traffic sources to near-roadway air pollution and predictive models were used to estimate air quality and exposures for the children (Vette et al., 2013).

A STAR grant project, "Effects of Stress and Traffic Pollutants on Childhood Asthma in an Urban Community," (SHC and University of Medicine and Dentistry of New Jersey) is assessing young study participants (ages 9-14) with persistent asthma to correlate changes in asthma status with changes in air pollution measures and incorporate the influence of stress (evaluated with behavioral and biological indicators). In another STAR project, "Community Stressors and Susceptibility to Air Pollution in Urban Asthma" (SHC and University of Pittsburgh), researchers are exploring the interdependent and synergistic effects of community stressors and traffic-related air pollution on asthma exacerbation among children (ages 5-17). They are applying variants of spatial poisson regression and multi-level time-series modeling using syndromic surveillance and hospitalization databases by accessing emergency department visits and hospitalization records to examine the association between exposure to air pollution and increases in asthma in children.

Geospatial tools are also being developed and deployed in place-based children's health research to improve characterization of complex built and natural environments at various scales. For example, STAR grantees from Texas State University, Texas A&M University, Texas Department of State Health Services, and University of North Carolina-Charlotte are collaborating on a project called "Air Pollution-Exposure-Health Effect Indicators: Mining Massive Geographically-Referenced Environmental Health Data to Identify Risk Factors for Birth Defects" (SHC). Using air pollution exposure assessment methods, visual data mining tools, and epidemiological analysis procedures, they are defining new environmental public health indicators linking exposure metrics and birth defects.

Additional new knowledge about how the built environment, especially learning environments, influence children's health and performance, potentially in both positive and negative ways, is also being generated by STAR grantees. Currently, grantees from the New York Department of Health are exploring linkages between school-related environments, children's school performance, and environmental policies (report due in 2015) (SHC). More recently, a 2013 RFA solicited research on "Healthy Schools: Environmental Factors, Children's Health and Performance, and Sustainable Building Practices" (SHC) (U.S. EPA, 2013d); available at: http://epa.gov/ncer/rfa/2013/2013_star_healthy_schools.html. This research will investigate the impact of indoor pollutants, as well as outdoor pollutants being drawn indoors in schools, on children's health and ability to learn. These grants will be announced in 2014.

An ORD and EPA Region 6 study (SSWR) is examining water-related exposures and birth defects, in a five-county area surrounding Corpus Christi, Texas. Previous studies noted an elevated rate of birth defects in and around the Corpus Christi area. In this study, ORD is conducting analyses to determine the extent and locations of clusters of birth defects and is examining the relationship between these clusters to water and other environmental exposures.

Evaluating Impact of Co-Exposure to Multiple Stressors

Research is ongoing on new methods for modeling and assessing cumulative exposure and risk. For example, "Estimation of Childhood Lead Exposure at the Census Tract Level Based on Aggregate Sources" (SHC) was a multi-factor analysis of cumulative lead exposure that increased the knowledge base concerning lead exposure in children.

A STAR grant project called "Effects-Based Cumulative Risk Assessment in a Low-Income Urban Community near a Superfund Site" (ACE and Harvard School of Public Health) is leveraging data from an ongoing birth cohort study and public databases to predict exposures as a function of all chemical stressors of interest. The resulting health risk characterization will include geospatial and demographic variability and trends over time.

MICA Study (CSS and SHC)

The Mechanistic Indicators of Childhood Asthma (MICA) study was designed to pilot an integrative approach in children's health research. MICA incorporates exposure metrics, internal dose measures, and clinical indicators to decipher the biological complexity inherent in diseases such as asthma and cardiovascular disease with etiology related to gene-environment interactions. A cohort of 205 non-asthmatic and asthmatic children (ages 9 to 12) from Detroit, Michigan, was recruited. The study includes environmental measures (indoor and outdoor air, vacuum dust), biomarkers of exposure (cotinine, metals, allergen specific IgE, PAH and volatile organic carbon (VOC) metabolites) and clinical indicators of health outcome (immunological, cardiovascular and respiratory). In addition, blood gene expression and candidate single nucleotide polymorphism (SNP) analyses were conducted. Based on an integrative design, the MICA study provides an opportunity to evaluate complex relationships between environmental factors, physiological biomarkers, genetic susceptibility and health outcomes (Gallagher et al., 2011).

Research Area 3. Methods and models fit for purpose to evaluate early lifestage-specific risks and to support decisions protective of all susceptible and vulnerable early lifestages

Research Area 3 has been divided into the following two subgroups: (1) Exposure, and (2) Dosimetry Models. ORD's relevant research in each of these areas is summarized as follows:

(1) Exposure

Exposure factors and exposure data (page 64) need to be easily accessible to risk assessors in order to assess the effects of environmental chemicals on children. ORD has developed tools to increase the usability and access to exposure data, models to predict exposure by a variety of pathways and routes, and approaches for categorizing lifestage changes and prioritizing chemical mixtures.

EPA-Expo-Box (HHRA)

EPA-Expo-Box is a web-based compendium of over 800 exposure assessment tools that provides links to exposure assessment databases, models, and references (U.S. EPA, 2013c); available at: http://www.epa.gov/ncea/risk/expobox/docs/archive/Expobox_Fact-Sheet_Nov13.pdf. It includes approaches for exposure assessments, tiers and types of exposure assessments, chemical classes, routes of exposure to chemicals, lifestages and populations, and exposure media. It also includes, in a searchable and downloadable format, the full list of exposure factors from the Exposure Factors Handbook (see page 64).

SHEDS-HT Model (CSS)

The Stochastic Human Exposure and Dose Simulations–HT (SHEDS-HT) model is a screening-level human exposure model for chemicals. Pathways included in the model include near-field direct and indirect use of chemicals in the home (e.g., use of personal care products, cleaning products, and pesticides), emission of chemicals from building materials, and dietary consumption of contaminated foods. SHEDS-HT is a probabilistic model that produces population-level distributions of exposures by the dermal, inhalation, and ingestion routes. Exposure results can also be estimated for individual age-gender cohorts. Exposure-relevant information specific to children included in SHEDS-HT includes age-specific behaviors (such as hand-to-mouth contact and use of consumer products), times spent in microenvironments, and food intakes.

ExpoCast (CSS)

ExpoCast is a rapid, high-throughput model using off the shelf technology that predicts exposures for thousands of chemicals (U.S. EPA, 2014f), available at: <http://epa.gov/ncct/expocast/>. ExpoCast evaluated 1,763 chemicals for estimating exposure due to industrial releases and a simple indicator of consumer product use. ORD research is generating and incorporating new information about age-dependent exposures (e.g., product use) into ExpoCast so that this model can be more specifically applied to capture children's unique vulnerabilities to support risk-based decisions.

Lifestage Categories for Monitoring and Assessing Exposures to Children (SHC)

ORD has developed a consistent set of childhood lifestage categories for researchers to use when assessing childhood exposure and potential dose to environmental contaminants (Firestone et al.,

2007). The standard lifestage categories are: birth to <1 month; 1 to <3 months; 3 to <6 months; 6 to <11 years; 11 to <16 years; and 16 to <21 years. These categories consider developmental changes in various behavioral, anatomical, and physiological characteristics that impact exposure and potential dose. These lifestage categories were recommended by EPA to be used as standard age groups in exposure and risk assessments in the report titled “Guidance on Selecting Age Groups for Monitoring and Assessing Childhood Exposures to Environmental Contaminants” (U.S. EPA, 2005); available at: <http://www.epa.gov/raf/publications/pdfs/AGEGROUPS.PDF>.

In order to harmonize lifestage categories for monitoring and assessing risks from exposures to chemicals for global use, the World Health Organization (WHO) recommended adapting ORD’s lifestage categories, as presented above (Cohen Hubal et al., 2013).

Biogeographical Approach for Prioritizing Chemical Mixtures (CSS)

In a study of the co-occurrence pattern of pesticides in child care centers (Tornerio-Velez et al., 2012). ORD used methods from the field of biogeography to investigate co-occurrence patterns in chemicals. The results showed that the co-occurrence of pesticides in the child care centers was not random but was highly structured, leading to the co-occurrence of specific combinations of pesticides. ORD concluded that chemical mixtures arise, in part through nonrandom processes such as economic factors, engineered formulations, and differential degradation such that the observed number of combinations tends to be less than the theoretical random number of combinations. The biogeographical approach will be highly useful for prioritizing chemical mixtures in risk assessment and to calculate co-occurrence probabilities of mixtures of chemicals.

(2) Dosimetry Models

ORD has developed a number of dosimetry models that assess exposure, predict dose, and describe the kinetics of environmental chemicals as related to children’s health.

Empirical Models

Persistent Bioaccumulative Toxicants (CSS)

A statistical model was developed for predicting levels of polybrominated diphenyl ethers (PBDEs) in breast milk, based on serum data from the National Health and Nutrition Examination Survey (NHANES) (Marchitti et al., 2013). In this research, congener-specific linear regression partitioning models were developed and applied to 2003-2004 NHANES serum data for U.S. women. The predictions of PBDE levels in breast milk were consistent with reported concentrations in 11 U.S. studies.

ORD is now applying this approach to other environmental chemicals (dioxins, perfluorinated compounds (PFCs), polychlorinated biphenyls (PCBs), and organochlorine pesticides); it is expected that these models will facilitate the use of available biomonitoring serum data (e.g., NHANES) to better characterize infant exposures. ORD is also working on developing a comprehensive quantitative structure-activity relationship (QSAR)-based model for predicting milk:serum partitioning ratios for classes of chemicals where serum and milk data are not available to construct regression models. This QSAR model will predict the potential of an environmental chemical to partition into breast milk and can be used to improve exposure and risk estimates for breast-feeding infants.

In vitro to In vivo Extrapolation (CSS)

ORD has proposed an approach to link results from *in vitro* high throughput studies with population group specific-dosimetry for neonates, children, and adults, and exposure estimates. For nine ToxCast chemicals, pharmacokinetic models for multiple subpopulations were constructed that predicted chemical concentrations in the blood at steady state. These models have potential application to estimate chemical-specific pharmacokinetic uncertainty factors and to estimate subpopulation-specific oral equivalent dose values to aid in chemical prioritization and identifying subpopulations with greater susceptibility to potential pathway perturbations (Wetmore et al., 2014).

Community Multi-scale Air Quality Model (CMAQ)

The EPA's Community Multi-scale Air Quality (CMAQ) Model is a powerful computational tool used by EPA and states for air quality management that gives detailed information about the concentrations of air pollutants in a given area. Comparison of data from the CMAQ model with birth outcomes or childhood hospital admissions for asthma has generated data on associations between pollutant exposure (i.e., particulate matter (PM) or ozone) and health outcomes (U.S. EPA, 2014c), available at: <http://www.epa.gov/AMD/Research/RIA/cmaq.html>.

Pesticide Biomarker Measurements in Children (CSS)

ORD is investigating the utility of various biomarkers for determining exposure to environmental chemicals in children. In a study consolidating the results from several large- and small-scale observational studies on children's exposure to pesticides, ORD compared measurements of urinary metabolites of select pesticides with the kinetic parameters of the pesticides (Egeghy et al., 2011). The temporal variability of the metabolites detected, based on time of pesticide application, as well as the relative importance of dietary exposure compared to the indirect ingestion, dermal, and inhalation routes were examined. The results showed that urinary biomarker levels provided only limited evidence of pesticide application and appeared to be affected by differences in the contribution of each exposure route to total intake.

PBPK Models (CSS)

Virtual Embryo Project

ORD has developed a life-stage PBPK model, as part of the Virtual Embryo project in the predictive toxicology of children's health and development following prenatal or lactational exposure to environmental chemicals. This model was developed to computationally investigate the relationship between chemical exposure, tissue dosimetry and *in vitro* markers of critical events related to AOPs. The model includes time-changing physiological and biochemical descriptors related to a pregnant mother, fetal growth, and child exposure through lactation.

Ethanol

To supplement and complete PBPK models in the literature, ORD developed PBPK models to describe the kinetics of ethanol in adult, pregnant, and neonatal rats for the inhalation, oral, and intravenous routes of exposure. The three models accurately predicted the kinetics of ethanol, including the absorption, peak concentration, and clearance across multiple datasets. This work provides comprehensive lifestage models of ethanol pharmacokinetics and represents the first

step in developing models for use with blends of ethanol and gasoline that are commonly used in the United States. (S. A. Martin et al., 2012).

Research Area 4. Translational research and tools fit for purpose to support community actions and decisions

Research Area 4 has been divided into the following four subgroups: (1) Decision Support Tools, (2) Problem Driven Research, (3) Translational Research, and (4) Social Determinants of Health. ORD's relevant research in each of these areas is summarized as follows:

(1) Decision Support Tools

ORD is developing decision support tools for state, tribal and local governments in order to make sound decisions about both community development and healthful environments, and to avoid unintended consequences.

Community-Focused Exposure and Risk Screening Tool (SHC)

ORD has developed the Community Focused Exposure and Risk Screening Tool (C-FERST) (U.S. EPA, 2013a); available at: <http://www.epa.gov/heasd/c-ferst/> to enhance access to information for environmental health decision making. Developed in collaboration with several pilot communities, and scheduled for public release in 2014 following external peer review, this Web-based tool provides a repository of information for >40 environmental issues. Children's health issues in C-FERST currently include childhood lead exposure, childhood asthma, and schools. By providing a public venue for communicating ORD science and EPA guidance and solutions, C-FERST can empower communities with information for prioritizing and addressing environmental issues. C-FERST will soon provide data and maps of modeled childhood lead exposures for local impact estimates and targeting enforcement activities. Future versions of C-FERST will incorporate additional research results and features to help address children's environmental and cumulative risk issues.

Health Impact Assessment

Recently, C-FERST was used, along with other tools, to inform a Health Impact Assessment (HIA) related to school renovation decisions in an environmental justice community. The HIA for the Gerena Elementary School in Springfield, Massachusetts—one of EPA's first HIAs, and the first school building focused HIA in the field—is a collaboration between EPA and stakeholders including the Massachusetts Departments of Public Health and Environmental Protection, city, school, and community groups. The purpose of this HIA is to provide and help process information to help the City of Springfield narrow down options for renovation and improvement at the Gerena School to those that will best address environmental problems, reduce potential negative health impacts such as asthma exacerbations, and enhance well-being of the school community. The school is directly under a highway and adjacent to roadways and a railway, so the project is considering transportation-related indoor air exposures as well as those from flooding, moisture, mold and other indoor environmental issues in the school.

In the process, EPA is learning how its science can be used in the HIA process and incorporating HIA into its decision-support tools. A new HIA roadmap is being incorporated into C-FERST to facilitate broad access to information, guidance, and best practices in conducting future HIAs. ORD

led the assessment phase of the HIA for this elementary school, including indoor and outdoor air monitoring, building systems evaluation, and data analysis.

EnviroAtlas (SHC)

EnviroAtlas, scheduled for public release in 2014 will include, at least for selected urban areas, such indicators as the locations of schools, recreational areas and factors relevant to health outcomes (demographics, income) and access to transportation routes and indicators of ecosystem services such as tree cover (related to heat, recreation, green-space accessibility). This tool also includes an Eco-Health Relationship Browser (U.S. EPA, 2013b), available at: <http://www.epa.gov/research/healthscience/browser/introduction.html> (launched in 2012). It is a user-friendly Web-based browser which illustrates linkages between human health and ecosystem services, i.e., the benefits supplied by nature. Health outcomes currently searchable in the browser of direct relevance to CEH include low birth weight and preterm birth, asthma, ADHD, and obesity. Expansion of the browser to more completely address children's health is being considered.

(2) Problem-Driven Research

Studies have been conducted to further the understanding of linkages between human health and environmental exposures. Communities are using results of these analyses to make decisions concerning renovation of schools, location of recreational areas, and future development.

EPA Pilot Study Add-On to the Third Study Site of the Green Housing Study (SHC)

The Green Housing Study is a collaborative effort between the U.S. Department of Housing and Urban Development (HUD) and the Centers for Disease Control and Prevention (CDC). Three main goals of the Green Housing Study are to: (1) compare levels of certain chemical and biological agents and non-chemical stressors in green versus traditional, multi-family, low-income housing; (2) ascertain differences in the health of the residents in these homes; and (3) assess the economic impacts of the "greening" of housing—particularly those related to health. These goals will be accomplished in ongoing building renovation programs sponsored by HUD. Green housing includes strategies to reduce exposure to environmental contaminants, including but not limited to the use of integrated pest management practices, the use of low/no volatile organic compound (VOC) materials (e.g., paints, carpets), and improved insulation and ventilation practices. Briefly, both the green-renovated and comparison (no renovation) homes will be from the same housing development or neighborhood to ensure homogeneity with regard to housing type and other socioeconomic factors. Changes in environmental measurements (pesticides, VOCs, particulate matter [i.e., PM_{2.5} and 1.0], indoor allergens, and fungi) over a one-year post-renovation period will be compared to pre-renovation measurements, such that each home's measurements will be compared with its own baseline measurements. This study design enables both a pre- and post-renovation comparison as well as a comparison between green-renovated and control homes in order to detect differences in exposure levels and asthma outcomes. Residents will participate for one month prior to renovation, the time required for renovation of their home, and 12 months after completion of the renovation. The duration of participation for residents of comparison homes is the same.

In partnership with HUD and CDC, ORD will leverage this opportunity to collect additional multi-media measurements and questionnaire data from the index children actively participating in the Green Housing Study and a sibling(s) in order to characterize personal, housing, and community factors influencing children's potential exposures to indoor contaminants at various lifestyles. Additionally, by recruiting siblings of the index children, ORD will begin to examine how lifestyle affects children's exposures when children have the potential to be exposed to the same chemicals in consumer products found in their environment.

Dust and soil ingestion (CSS and SHC)

ORD is using models to estimate different exposure parameters, such as soil and dust ingestion rates, in children. These parameters are used in exposure and risk assessments to evaluate the health outcomes of environmental chemicals in children. For example, ORD used the SHEDS-Soil/dust model to estimate soil and dust ingestion rates for young children at two Taiwanese locations. One site was designated as the control, since the village in which the homes were located was thought to be less likely impacted by the pollutants under investigation. The other site was designated as a near road exposure site. Inputs were developed for both types of sites. In addition, similar SHEDS-Soil/dust simulations were conducted for U.S. children. The ages of the children simulated ranged from 6 months up to (but less than) 36 months. The children were divided into three age categories: 6 months to <12 months; 12 months to <24 months; 24 months to <36 months and soil and dust ingestion rates were estimated through model simulation (Glen et al., 2013).

Chemical and Non-Chemical Stressors and Childhood Obesity (SHC)

Childhood obesity has tripled in the last three decades and now affects 17% of children in the U.S. In 2010, the percentage of obese children in the U.S. was nearly 18% for both 6-11 and 12-19 years of age. Recent evidence in the literature suggests that exposure to selected environmental chemicals may impact obesity. Socioeconomic status, ethnicity, and the built environment may also impact obesity. Recent studies have also shown that poor quality food outlets in close proximity to neighborhoods or schools increased the likelihood of poor quality food purchases. While much research has focused on individual stressors impacting obesity, little research has emphasized the complex interactions of numerous chemical and non-chemical stressors affecting a child's health and well-being.

ORD is conducting research in this area to (1) identify and characterize chemical and non-chemical stressors that impact childhood obesity; (2) identify key stressors across a range of stressor domains; and (3) characterize the interactions of these key stressors on children's health.

ORD is currently completing a state-of-the-science literature review to identify chemical and non-chemical stressors related to childhood obesity. Using this information, a searchable database was created and analyzed to identify key stressors. Numerous chemical and non-chemical stressors were identified and grouped into the following domains: individual, family, community, and chemical. Stressors were related to the child and their everyday environments (home and community) and used to characterize child health and well-being. Data shows that there is not always a positive association with a stressor and childhood obesity, and that there can be inconsistent correlations between the same stressors and obesity. However, there is sufficient evidence to suggest the interactions of multiple stressors may be the cause of the childhood obesity epidemic.

Chemical and Non-Chemical Stressors and Neurocognitive Health (SHC)

Early childhood (0-6 years old) is a time of significant brain growth and foundational skills development essential for school readiness and academic achievement. Maximizing a child's learning potential can be achieved only with complete knowledge of stressors that impact learning. Many studies attempt to identify associations between individual exposure factors and neurocognitive development. However, extending from pregnancy to a child's first day of school, numerous stressors (e.g., chemicals, prenatal stress, behaviors, family violence) may influence children's neurocognitive development and health and well-being. Additionally, community-level decisions related to land use, transportation, buildings and infrastructure, and waste and materials management may also influence a child's health and well-being by impacting their home and learning environments.

ORD is conducting research to examine stressors related to neurocognitive health in children ages 3-6 years to (1) identify and characterize individual stressors associated with neurocognitive development and (2) develop a conceptual model that identifies key stressors and their possible interactions.

ORD completed a literature review across multiple databases (e.g., PubMed, Web of Science, PsychInfo) utilizing the search strings: neurodevelopment or cognition and children. Assessment of the quality of the study and its applicability to the general population was conducted to identify key stressors associated with neurocognitive health and to develop a conceptual model using a multi-level systems approach.

Key exposure factors were identified for each developmental lifestage from pregnancy to 3-6 years old. These factors were grouped three different ways according to (1) the type of occurrence (e.g., individual, home, school, community); (2) characterization as an individual health, social, environmental or economic determinant; and (3) how decisions regarding land use, buildings and infrastructure, waste and materials management, and transportation have impacted them. These elements were incorporated into the model and the results suggest that some childhood exposures (e.g., SES, parent-child interaction, diet, built environment) not only present as key factors, but act as effect modifiers of stressors experienced during pregnancy and infancy (e.g., lead, pesticides, prenatal stress).

Community Multi-scale Air Quality Model (ACE)

The EPA's Community Multi-scale Air Quality (CMAQ) Model is a powerful computational tool used by EPA and states for air quality management that gives detailed information about the concentrations of air pollutants in a given area. Comparison of data from the CMAQ model with birth outcomes or childhood hospital admissions for asthma has generated data on associations between pollutant exposure (i.e., particulate matter (PM) or ozone) and health outcomes (U.S. EPA, 2014c), available at: <http://www.epa.gov/AMD/Research/RIA/cmaq.html>.

PCBs in Schools (HHRA)

ORD research characterized sources of exposure to PCBs in school environments, showing that both window caulking and light ballasts have contributed to exposures in older schools. Findings from this research showed that caulk put in place between 1950 and 1979 can contain as much as 30% PCBs and can contaminate adjacent material such as masonry or wood. Fluorescent light fixtures that still contain their original PCB-containing light ballasts may rupture and emit PCBs. En-

capsulation, a PCB containment method, was shown to be effective only when the PCB content in the source was low. EPA used the results of this research to update its guidance to building owners and school administrators on how to reduce exposures to PCBs that may be found in schools (U.S. EPA, 2013e); available at: <http://www.epa.gov/pcbsincaulk/caulkresearch.htm>.

Child-Specific Exposure Scenarios Examples (HHRA)

The “Child Specific Exposure Scenarios Examples” is a companion document to the “Exposure Factors Handbook: 2011 Edition” (EFH) (see page 64). The purpose of the “Child Specific Exposure Scenarios Examples” is to present childhood exposure scenarios using data from the “Child Specific Exposure Factors Handbook” (U.S. EPA, 2008); available at <http://cfpub.epa.gov/ncea/risk/recordisplay.cfm?deid=199243> and updated children’s data from the EFH (U.S. EPA, 2011); available at: <http://cfpub.epa.gov/ncea/risk/recordisplay.cfm?deid=236252>. These scenarios are not meant to be inclusive of every possible scenario, but they are intended to provide a range of scenarios that show how to apply exposure factors data to characterize childhood exposures. The example scenarios were compiled from questions and inquiries received from users of the earlier versions of the EFH on how to select data from the Handbook. The scenarios presented in the report promote the use of the standard set of age groups recommended by EPA in the report titled “Guidance on Selecting Age Groups for Monitoring and Assessing Childhood Exposures to Environmental Contaminants” (U.S. EPA, 2005) (see page 73); available at <http://www.epa.gov/raf/publications/pdfs/AGEGROUPS.PDF>.

(3) Translational Research

Translational research involves translating the results from research on children’s health into findings that are useful to communities, neighborhoods, or other groups as they develop strategies to work on local environmental health issues. Many of the studies discussed on page 68 include translational components, involving environmental health communication, community outreach, and collaboration with local community groups.

CEHC Program (SHC)

As discussed on page 68, the EPA-NIEHS co-funded CEHC Program is generating exposure and biomarker data in pregnant women and children, showing relationships between exposure and a variety of children’s health outcomes, and identifying critical windows of susceptibility (U.S. EPA, 2014e); available at: www.epa.gov/ncer/childrenscenters. Collectively they are examining a wide range of health outcomes in cohorts of children including adverse birth outcomes, asthma and respiratory dysfunction, and other diseases.

A critical and unique component of the Children’s Centers Program is the inclusion of a Community Outreach and Translation Core. These cores use a variety of innovative approaches to translate research findings and intervention strategies to the community. As summarized in Table A3, outreach and translation involves a wide variety of community partners, including community advocacy and environmental justice organizations, state and city health departments, state and city environmental protection and natural resources departments, city governments, health care providers, schools and educational advocacy groups, and various programs in universities. Thus, research translation benefits environmental health broadly by influencing decisions at all levels, from health policy to personal choices.

Table A3. EPA/NIEHS Children’s Centers community outreach and translation – community partners

Institution – P.I.	Study Site Location(s)	Community Outreach and Translation – with Community Partners
Brown University – Boekelheide	Providence, RI	Silent Spring Institute, Environmental Justice League of Rhode Island
Columbia University – Perera	New York City (Northern Manhattan and South Bronx), Poland, China	Bronx Borough Presidents Office, Bronx Health Link, Columbia Community Partnership for Health, Columbia University Head Start, Community Health Worker Network of NYC, Dominican Medical Association, New York, Harlem Children’s Zone Asthma Initiative, Harlem Health Promotion, Northern Manhattan Perinatal Partnership, Nos Quedamos, WE ACT for Environmental Justice
Dartmouth College – Karagas	Hanover, NH	Dartmouth-Hitchcock Concord Clinic, Concord Hospital Family Clinic, Concord Obstetrics and Gynecology Professional Associates, Concord Women’s Care, Family Tree Health Care (Warner, NH), Dartmouth Hitchcock Lebanon Clinic, Concord Hospital, The Family Place, Dartmouth-Hitchcock Medical Center, New Hampshire Department of Environmental Health Services, New Hampshire Birth Conditions Program, University of New Hampshire Department of Molecular, Cellular and Biomedical Sciences
Duke University/ University of Michigan – Miranda	Durham, NC and Ann Arbor, MI	Durham Congregations, Associations, and Neighborhoods (CAN), Triangle Residential Options for Substance Abusers (TROSA), Durham Affordable Housing Coalition, Partnership Effort for the Advancement of Childrens Health/Clear Corps (PEACH), Durham People’s Alliance, Durham County Health Department, Lincoln Community Health Center, Duke University Nursing School Watts School of Nursing, City of Durham Department of Neighborhood Improvement Services, City of Durham Department of Community Development, Children’s Environmental Health Branch of NC Department of Environment and Natural Resources, North Carolina Asthma Alliance, East Coast Migrant Head Start, North Carolina Community Health Center Association, North Carolina Rural Communities Assistance Project
Duke University – Murphy	Durham, NC	DukeEngage Program, El Centro Hispano (local Latino community), Partnership for a Healthy Durham
Johns Hopkins University – Diette	Baltimore, MD	Baltimore City Head Start Program, Baltimore City Health Department Healthy Homes Program, Baltimore School Food Services Program, Healthy Stores Program, Maryland Asthma Control Program, Women Infants and Children (WIC) nutrition programs
National Jewish Health – Schwartz, Szeffler	Denver, CO	Colorado Asthma Coalition, Colorado Clinical Guidelines Collaborative, Colorado Department of Public Health and Environment, Denver Public School System, Lung Association of Colorado, Rocky Mountain Prevention Research Center, EPA Region 8, Alamosa Public School, Denver Health, Colorado Public Health, Practice Based Research Network, Regional Air Quality Council, Colorado Air Quality Commission, Grand Junction Housing Authority, Western Colorado Math & Science Center, Region 8 Pediatric Environmental Health Specialty Unit (PEHSU)
University of California at Berkeley – Buffler, Metayer	Berkeley, CA	Network of 8 clinical institutions in northern and central California participating in the Northern California Childhood Leukemia Study (NCCLS), national community of pediatric health care professionals with an interest in environmental health issues; national community of persons interested in leukemia; California community of persons interested in childhood leukemia; Region 9 Pediatric Environmental Health Specialty Unit (PEHSU)

Table A3. (continued) EPA/NIEHS Children’s Centers community outreach and translation – community partners

Institution – P.I.	Study Site Location(s)	Community Outreach and Translation – with Community Partners
University of California at Berkeley – Eskenazi	Berkeley and Salinas, CA	Clinica de Salud del Valle de Salinas, Natividad Medical Center, South County Outreach Effort (SCORE), Monterey County Health Department, California Rural Legal Assistance (CRLA) Program, Grower/ Shipper
University of California at Berkeley/Stanford University – Hammond, Balmes, Shaw	Berkeley, Palo Alto, Bakersfield and San Joaquin Valley, CA	Medical Advocates for Healthy Air, Fresno Metro Ministry, Center on Race, Poverty, and the Environment, San Joaquin Valley Latino Environmental Advancement Project (LEAP), El Comit�e para el Bienestar de Earlimart, Coalition for Clean Air, San Joaquin Valley Cumulative Health Impact Project (SJV-CHIP), Central California Environmental Justice Network, Central Valley Air Quality Coalition, Californians for Pesticide Reform
University of California at Davis – Van de Water	Davis, CA	Families for Early Autism Treatment, Learning Disabilities Association, Parents Helping Parents, San Francisco Bay Chapter of the Autism Society of America, Alameda County Developmental Disabilities Council, Cure Autism Now, State of California health/developmental service providers, California Departments of Developmental Services and Health Services, California Regional Centers and Office of Environmental Health Hazard Assessment
University of California, San Francisco – Woodruff	San Francisco, CA	American College of Obstetricians and Gynecologists (ACOG District IX), Association of Reproductive Health Professionals, Physicians for Social Responsibility (PSR) San Francisco Bay Area Chapter, WORKSAFE (California Coalition for Worker Occupational Safety & Health Protection), California Department of Health Occupational Health Branch
University of Illinois at Urbana-Champaign – Schantz	Urbana-Champaign, IL and New Bedford, MA	Illinois Action for Children (IAFC), American Academy of Pediatrics (AAP), Just-In-Time Parenting, Champaign-Urbana Public Health Department, Great Lakes Center for Environmental Health, Cambridge Health Alliance, Carle Foundation Hospital, Provena Covenant Medical Center
University of Michigan – Peterson, Padmanabhan	Ann Arbor, MI and Mexico City, Mexico	Early Life Exposures in Mexico to Environmental Toxicants (ELEMENT), National Institute of Public Health, Mexico City, Detroit Hispanic Development Corporation
University of Southern California – McConnell	Los Angeles, CA	The Children’s Clinic (Long Beach and South Bay), Asian and Pacific Islander Obesity Prevention Alliance, East Yard Communities for Environmental Justice, Digital Rain Factory, Los Angeles Parks Foundation, The Trust for Public Land Center for Park Excellence, Policies for Livable, Active Communities and Environments (PLACE) of Los Angeles, Trade, Health and Environment Impact Project, Center for Community Action & Environmental Justice (Riverside and San Bernardino), Coalition for a Safe Environment (Wilmington), East Yard Communities for Environmental Justice (Commerce and East L.A.), Long Beach Alliance for Children with Asthma, Outreach Program of Southern California Environmental Health Sciences Center Los Angeles (USC/UCLA), Urban & Environmental Policy Institute, Occidental College
University of Washington – Faustman	Yakima Valley, WA	Community members in the Yakima Valley, Farm Workers Union, Growers’ Association, Washington State Department of Health and Department of Agriculture, Farm Workers’ Union, Yakima Valley Farm Workers Clinics, Radio KDNA (Spanish language), Washington State Department of Labor and Industries, Columbia Legal Services, Washington State Migrant Council, EPA Region 10

(4) Social Determinants of Health

ORD is carrying out research on the biological, environmental, and social conditions that may contribute to disparities in health outcomes in children. Although the scope of this research extends well beyond a lifestage-specific focus, some specific activities are targeting children's environmental health.

STAR Centers of Excellence on Environment and Health Disparities (SHC)

Social determinants of health are a focus of research in the STAR Centers of Excellence on Environment and Health Disparities (<http://www.epa.gov/ncer/ehs/disparities/health-disparities.html>). ORD, in collaboration with the National Institute of Minority Health and Health Disparities (NIMHD) (<http://www.nih.gov/about/almanac/organization/NIMHD.htm>), through an Interagency Agreement, is supporting the establishment of transdisciplinary networks of excellence in health disparities research to achieve a better understanding of the complex interactions of biological, social and environmental determinants of population health. The collaboration promotes coordination efforts within the NIMHD Centers for Excellence in health disparities research, addressing racial and socioeconomic disparities in environmentally mediated health outcomes and access to healthy community environments.

One of these Center projects, "Analysis and Action on the Environmental Determinants of Health and Health Disparities" (University of South Carolina) will explore six areas of health disparities that contribute disproportionately to premature death and morbidity found among poor and racial/ethnic minorities (e.g., infant mortality). This project is developing a relational database and web portal for integration of data on health outcomes, natural and built environment and social environment. Another, "Environmental Health Disparities Research" (University of Texas) will explore the individual- and neighborhood-level contributions to disparities in children's lung health.

Environmental and Community Factors Influence Effectiveness of Medical Treatments for Asthma (SHC)

An ORD study, in collaboration with the University of North Carolina, "Observational Assessment of Baseline Asthma Control as a Susceptibility Factor for Air Pollution Health Effects in African-American Children with Persistent Asthma," is examining factors that contribute to asthma disparities in adolescents. The study is following a cohort of African American youth with moderate-to-severe asthma and examining a variety of factors including air pollution, home environment, and community issues that may contribute to the high rate of asthma in this population and the relative effectiveness of medical treatments.

Integrated Approaches to Sustain the Built and Natural Environment and the Communities They Support: Children's Health Example (SHC)

In this study, researchers are using GIS tools and multi-layered mapping to examine relationships between access to green space and birth outcomes. Analyses focus on associations between birth measures across the greater Durham-Chapel Hill, North Carolina area and various measures of green space around the home, including tree cover along busy roadways.

Climate change (ACE)

Young children may be disproportionately affected by climate change and would require specific adaptations to respond to climate-related stressors. Research is using a multidisciplinary assessment approach to identify those aspects of climate change to which vulnerable populations are most sensitive, most likely to be exposed, and most able to adapt, and determine how vulnerability to climate change may interact with non-climate environmental stressors.

Current research is evaluating health effects associated with events expected to increase in frequency during climate change, incorporating age-category-specific effect estimates. Where possible, child-specific effects will be reported. Related research on climate change, relevant although not necessarily specific to children's health, includes impacts of increased ground level ozone and weather events influencing allergic, chronic, waterborne and infectious disease risks. EPA recently awarded grants to six groups and institutions to study the health effects of climate change on tribes. These grants will fund research on: improving air quality and reducing environmental factors that trigger asthma; threats to food sustainability; coastal climate impacts to traditional foods, cultural sites, and tribal community health and well-being; and food security and tribal health.

(<http://indiancountrytodaymedianetwork.com/2014/07/23/epa-awards-5-million-research-climate-change-and-tribal-health-156029>).

Appendix B. Literature Search of ORD CEH Activities

A literature search of EPA-ORD children’s environmental health activities was performed in [EPA Science Inventory](#) using the following search conditions. The table lists individual hyperlinks to the Science Inventory, where more information on each of the manuscripts may be found.

Search Boundaries	Peer Reviewed Journals; Jan. 1, 2008 – March 25, 2015
Search Terms	adolescence, adolescent, child, childhood, children, developmental, daycare, early life, epigenetic, fetal, in utero, infant, maternal, paternal, perinatal, postnatal, pregnancy, pregnant, prenatal, school, young adult
Total Results	341

Appendix C. CEH Tools and Databases

Name & Type	Acronym	Brief Description
Databases		
Consolidated Human Activity Database	CHAD	Compiled, detailed data on human behavior from 19 separate studies
Exposure Forecaster Database	ExpoCast	Automated model to predict exposures for thousands of chemicals
Aggregated Computational Toxicology Resource	ACToR	Data warehouse of all publicly available chemical toxicity data, including chemical structure, physico-chemical values, <i>in vitro</i> assay data and <i>in vivo</i> toxicology data.
Physiological Parameters Database for PBPK Modeling	-	Includes physiological parameters such as alveolar ventilation, blood flow, tissue volumes, and glomerular filtration rate used for Physiologically-Based Pharmacokinetic (PBPK) modeling
Chemical and Product Categories Database	CPCat	Database containing information on the uses of chemicals, products that contain chemicals and manufacturers of the products
Ontogeny Database on Enzymes	-	Database that can be used as a screening tool to explore metabolism-based variability, based on enzyme differences, during early lifestages
Toxicity Forecaster Database	ToxCast	Builds computational models from HTS data to forecast the potential human toxicity of chemicals
Toxicity Reference Database	ToxRef	Captures thousands of <i>in vivo</i> animal toxicity studies on hundreds of chemicals
Adverse Outcome Pathway Wiki	AOP Wiki	Provides an open-source interface for rapid and collaborative sharing of established AOPs and building new AOPs
Virtual Tissues Knowledgebase	VT-KB	A human and machine readable knowledgebase developed by extracting and organizing relevant facts from the scientific literature and other sources of information in to central database
Exposure Toolbox	Expo-Box	Web-based compendium of over 800 exposure assessment tools that provides links to exposure assessment databases, models, and references
Handbooks		
Exposure Factors Handbook	EFH	Summary of the available statistical data on various factors used in assessing human exposure

Name & Type	Acronym	Brief Description
Models		
<u>Stochastic Human Exposure and Dose Simulations–HT Model</u>	SHEDS-HT	A probabilistic human exposure model that produces population-level distributions of exposures by the dermal, inhalation, and ingestion routes
<u>Stochastic Human Exposure and Dose Simulation Model for Multimedia</u>	SHEDS-Multimedia	A physically-based, probabilistic model, that can simulate multiple- or single-chemical exposures over time for a population via residential and dietary exposure routes for a variety of multimedia, multipathway environmental chemicals
<u>Community-Focused Exposure and Risk Screening Tool</u>	C-FERST	A community mapping, information access, and assessment tool designed to help assess risk and assist in decision making with communities
<u>EnviroAtlas</u>	-	Collection of tools and resources that provides geospatial data, maps, research, and analysis on the relationships between nature, people, health, and the economy
<u>Eco-Health Relationship Browser</u>	-	Interactive tool that illustrates scientific evidence for linkages between human health and ecosystem services
Environmental Quality Index	EQI	Estimates environmental quality at the county level used to assess effects on health outcomes

Appendix D: Environmental Stressors and Childhood Disorders

The following is a summary of information on five childhood disorders: childhood cancer, asthma, adverse birth outcomes, autism, and metabolic syndrome, including the current state of scientific knowledge on the contribution of environmental stressors to the causation of the disorders. Information on prevalence, trends, and research activities across the Federal Government on each of the five disorders is also presented.

Childhood Cancer

Definition

- Childhood cancer is not a single disease but a variety of malignancies in which abnormal cells divide in an uncontrolled manner (U.S. EPA, 2013).
- The most common childhood cancers are leukemias (cancers of the white blood cells) and cancers of the brain or central nervous system (U.S. EPA, 2013).
- Other less common childhood cancers include neuroblastoma, Wilms tumor, rhabdomyosarcoma and osteosarcoma (Congressional Childhood Cancer Caucus, 2014).

Prevalence

- Childhood cancer is the leading cause of death (other than injuries) in U.S. children ages 1 to 14 (U.S. EPA, 2013).
- It is estimated that 15,780 children (up to 19 years of age) will be diagnosed with cancer, and 1,960 will die of the disease in 2014 (NCI, 2014).
- As of 2010, there were approximately 380,000 survivors of childhood cancer in the U.S (NCI, 2014).

Trends

- Over the past 20 years, there has been some increase in the incidence of children diagnosed with all forms of cancer, from 11.5 cases per 100,000 children in 1975 to 14.8 cases per 100,000 children in 2004 (Congressional Childhood Cancer Caucus, 2014).
- Death rates from childhood cancer have declined in the past 20 years, with the 5-year survival rate increasing; for all childhood cancers combined the survival rate increased from 58.1% in 1975-77 to 79.7% in 1996 – 2003 (Congressional Childhood Cancer Caucus, 2014).
- Increased survival rates have been especially dramatic for acute lymphoblastic leukemia (ALL), which is the most common childhood cancer, from a 5-year survival rate of <10% in the 1960's to about 90% in 2003-2009 (NCI, 2014).

Causes

- Genetic syndromes such as Down Syndrome, exposure to high levels of ionizing radiation, and certain pharmaceutical agents used in chemotherapy are known risk factors for childhood cancer, but these explain only a small percentage of childhood cancer cases (NCI, 2014).
- Critical genes and processes regulating development are being studied for their association with childhood cancer, with certain genes associated with an increased risk of ALL and other types of childhood cancer (Evans et al., 2014).
- Different types of cancer affect children at different ages, and recent studies suggest that susceptibility to some cancers in adulthood may be determined by prenatal exposures (U.S. EPA, 2013).
- Environmental factors are under investigation for their association with childhood cancer (U.S. EPA, 2013).
- Research suggests that childhood cancer may be caused by a combination of genetic predisposition and environmental exposure (U.S. EPA, 2013).

Evidence for Environmental Risk Factors

- Pesticides
 - *A meta-analysis of 31 studies reported a significant association between prenatal maternal occupational pesticide exposure (but not paternal occupational pesticide exposure) and childhood leukemia (Wigle et al., 2009).*
 - *In a meta-analysis of 13 case-control studies, Bailey et al. (2014a) reported a significantly increased risk of acute myeloid leukemia (AML) in children with maternal exposure to pesticides during pregnancy and a slightly increased risk of ALL in children with paternal exposure around conception.*
 - *Research suggests that parental, prenatal, and childhood exposure to pesticides may be associated with a higher risk of brain tumors in children (U.S. EPA, 2013).*
- Hazardous air pollutants (HAPs)
 - *Reynolds et al. (2003) found an increased risk for childhood leukemia in census tracts where children were exposed to a group of 25 potentially carcinogenic HAPs.*
 - *A meta-analysis of 9 studies (Boothe et al., 2014) on residential traffic exposure and childhood leukemia reported that childhood leukemia is associated with residential exposure during the postnatal period, but not during the prenatal period.*
 - *Some studies have found an association between leukemia and traffic density and vehicle density (surrogate measures of exposure to motor vehicle exhaust) while others did not find an association, with review studies concluding that the overall evidence is inconclusive (U.S. EPA, 2013).*
- Environmental Tobacco Smoke
 - *The U.S. Surgeon General concluded that there is suggestive evidence that prenatal and postnatal exposure to environmental tobacco smoke can lead to leukemia and brain tumors in children (U.S. DHHS, 2006).*

- Paint
 - *Bailey et al. (2014b), a meta-analysis of 13 studies, did not report an association between parental occupational exposure to paint and childhood leukemia.*
- Indoor Air Pollution
 - *Gao et al. (2014) found an increased risk for ALL with indoor air pollution consisting of nitrogen dioxide and 17 types of VOCs.*
 - *Deziel et al. (2014) reported an increased risk for ALL with increasing concentrations of polycyclic aromatic hydrocarbons (PAHs) in household dust.*
- Power Lines
 - *Some studies have found an association between exposure to power lines and childhood cancer and other studies have not found an association (U.S. EPA, 2013).*
 - *A variety of national and international organizations have concluded that the link between exposure to very low frequency electromagnetic fields and cancer is controversial or weak (U.S. EPA, 2013).*
- Radiation and Radon
 - *Some studies have reported an association between radon and childhood leukemia, while others have not reported an association (U.S. EPA, 2013).*
 - *Kendall et al. (2012) reported an association between naturally occurring gamma radiation and childhood leukemia.*

Research Activities Across the Federal Government

- EPA-NIEHS Children’s Environmental Health and Disease Prevention Research Centers
www.epa.gov/ncer/childrenscenters
- *A study at the University of California at Berkeley is investigating the association of pesticides, tobacco-related contaminants, and chemicals in house dust and childhood leukemia.*

Asthma

Definition

- Asthma is a disease of the lungs in which the airways become blocked and cause breathing difficulties (Asthma and Allergy Foundation of America, 2014).
- Asthma is commonly divided into two types: allergic (extrinsic) asthma and non-allergic (intrinsic) asthma (Asthma and Allergy Foundation of America, 2014).
- Asthma triggers are substances or conditions that cause asthma symptoms to appear (Asthma and Allergy Foundation of America, 2014).

Prevalence

- In the year 2009, asthma affected 7.1 million (about 10%) of children in the U.S (U.S. EPA, 2013).
- 10.7% of boys, compared to 8.0% of girls, were reported to have asthma in 2009 (a statistically significant difference) (U.S. EPA, 2013).

- In 2009, children living in families below the poverty line, 12.2% were reported to have asthma compared to 8.7% of children living in families above the poverty line (a statistically significant difference) (U.S. EPA, 2013).
- In 2007-2010, a higher percentage of black non-Hispanic children (16%) and children of “all other races” (12.4%) were reported to have asthma, compared to white non-Hispanic children (8.2%) (U.S. EPA, 2013).

Trends

- The percentage of children with asthma increased substantially from 1980 to 1996 and remains at high rates today (U.S. EPA, 2013).
- The proportion of children reported to have asthma increased from 8.7% in 2001 to 9.4% in 2010 (U.S. EPA, 2013).
- In 2010, 5.7% of all children were reported to have had one or more asthma attacks in the previous 12 months (U.S. EPA, 2013).

Causes

- Researchers believe genetic and environmental factors may interact to cause asthma, probably early in life. These factors include: inherited factors that increase the risk of developing allergies; parents who have asthma; certain respiratory infections during childhood; and contact with airborne allergens or viruses during early childhood (NIH, 2014).
- Known asthma triggers include: exercise; weather; secondhand smoke; dust mites; molds; cockroaches and pests; pets; nitrogen dioxide; chemical irritants; outdoor air pollution; and wood smoke (U.S. EPA, 2014).
- Recent research suggests that epigenetic mechanisms may play a role in the development of asthma (Kabesch, 2014).

Evidence for Environmental Risk Factors

- Outdoor air pollutants
 - *Particulate matter, ozone, nitrogen dioxide, carbon monoxide, and sulfur dioxide have been associated with increased asthma symptoms in children (U.S. EPA, 2013).*
 - *Long-term ozone exposure may be a contributing factor in the development of asthma, particularly among children who frequently exercise outdoors (McConnell et al., 2012).*
 - *Hazardous air pollutants being studied for their possible association with asthma include acrolein, formaldehyde, nickel, and chromium (Leikauf, 2002).*
 - *Prenatal exposure to polycyclic aromatic hydrocarbons (PAHs) (hazardous air pollutants found in diesel exhaust, secondhand smoke, and wood smoke), has been associated with the development of asthma in children (Rosa et al., 2011).*
 - *Many studies have found an association between traffic-related air pollution (i.e., living close to busy roads) and the occurrence of new cases of asthma or exacerbation of existing asthma symptoms (U.S. EPA, 2013).*

- Indoor air pollutants
 - McGwin et al. (2010), a meta-analysis of 7 studies, concluded that there was a significant association between exposure to formaldehyde (a chemical released from carpet and furniture) and increased asthma symptoms in children.
 - Volatile organic compounds (VOCs) released in the home have been associated with the onset and exacerbation of asthma (Chin et al., 2014).
 - Biological sources such as pets, mold, dust mites, cockroaches, and other pests have been shown to increase existing asthma symptoms in children (Dales et al., 2008; Apelberg et al., 2001; Breyse et al., 2010; Portnoy et al., 2008; Douwes and Pearce 2003; Fisk et al., 2007).
 - The Institute of Medicine (2000) concluded that exposure to dust mites can cause asthma in susceptible children, and exposure to cockroaches may cause asthma in young children.
- Environmental Tobacco Smoke
 - The U.S. Surgeon General concluded that exposure to environmental tobacco smoke results in more severe asthma symptoms in children (U.S. DHHS, 2006).
- Green infrastructure
 - Urban tree cover was shown to significantly reduce ambient concentrations of particulate matter, ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide (Nowak et al., 2006).
 - Lovasi et al. (2008) reported that asthma was negatively correlated with urban street trees in New York City; an increase in tree density of 343 trees/km² was associated with a 29% lower asthma prevalence in 4- and 5-year-old children.
 - Dadvand et al. (2014) reported that proximity to forest land, percent tree cover and percent green space around the home were linked to reduced asthma, while proximity to parks was correlated with increased asthma and allergies. The authors hypothesized that trees generally buffer air pollutants that can exacerbate asthma, but there may be more exotic species planted in parkland that produce airway irritants.
 - Dales et al. (1991) reported that the odds of asthma for children were increased 29% when dampness and/or mold were present in the home. Green infrastructure can mitigate asthma risk in low-lying neighborhoods, because trees, wetlands, and other vegetated land cover absorb stormwater, reducing the extent and duration of floods.

Research Activities Across the Federal Government

- Coordinated Federal Action Plan to Reduce Racial and Ethnic Asthma Disparities – HHS, EPA, HUD. www.epa.gov/childrenstaskforce
 - Presents a framework across the federal government to accelerate actions to reduce disparities in asthma.
- EPA-Funded Research
 - A study at the University of North Carolina is examining factors that contribute to asthma disparities in children.
 - A study at the University of Medicine and Dentistry of New Jersey is correlating changes in asthma status with air pollution and stress in children with persistent asthma.

- *A study at the University of Pittsburgh is exploring the effects of community stressors and traffic-related air pollution on asthma in children.*
- EPA-NIEHS Children’s Environmental Health and Disease Prevention Research Centers
www.epa.gov/ncer/childrenscenters
- *A study at Johns Hopkins University is investigating the association between outdoor air pollutants, including particulate matter and nitrogen dioxide, and asthma in children.*
- *A study at the National Jewish Health Center is investigating the relationship between air pollution and the development of asthma in children.*
- NIEHS Funded Research
<http://www.niehs.nih.gov/research/supported/recovery/critical/childhealth/>
- *A study at Johns Hopkins University is investigating the impact of indoor air pollutants and the incidence of asthma in children.*
- *A study at Children’s Hospital Medication Center, Cincinnati, OH, is studying diesel exhaust and its role in the development of asthma in children.*
- NIH - National Asthma Control Initiative
<http://www.nhlbi.nih.gov/health-pro/resources/lung/naci/>
- *Multi-component, mobilizing and action-oriented effort to engage diverse stakeholders who are concerned about or involved in improving asthma control with the ultimate aim of bringing the asthma care that patients receive in line with evidence-based recommendations.*
- *NIH - National Asthma Education and Prevention Program*
<http://www.nhlbi.nih.gov/about/org/naepp/index.htm>
- *Ultimate goal of the program is to enhance the quality of life for patients with asthma and decrease asthma-related morbidity and mortality.*

Adverse Birth Outcomes

Definition

- Adverse birth outcomes include preterm birth (births before 37 weeks of pregnancy), low birth weight, neonatal mortality, and birth defects (U.S. EPA, 2013).
- Preterm and low birth weight infants are at a greater risk for infant death and complications involving effects on the respiratory, gastrointestinal, immune, and central nervous systems (U.S. EPA, 2013).
- Longer-term problems of preterm birth include motor, cognitive, visual, hearing, behavioral, and social-emotional problems (U.S. EPA, 2013).
- Birth defects consist of a range of structural and chromosomal abnormalities that occur before birth (U.S. EPA, 2013).

Prevalence

- Birth defects are the leading cause of infant death in the first year of life in the U.S. (U.S. EPA, 2013).
- From 2004 to 2006, approximately 3% of births in the U.S. were affected by birth defects, with the highest number of cases reported for Down Syndrome, cleft lip, and cleft palate (CDC, 2014).
- Effects from preterm birth and low birth weight are the second leading cause of infant death in the U.S (U.S. EPA, 2013).
- The preterm birth rate varies depending on the age of the mother, with women ages 20 to 39 having the lowest rate of preterm birth, compared to women under 20 years old and women 40 years and older (U.S. EPA, 2013).
- Multiple birth babies are five times more likely to be born preterm than singleton babies (U.S. EPA, 2013).

Trends

- The rate of preterm birth showed an increasing trend between 1993 and 2006, ranging from 11% in 1993 to its highest value of 12.8% in 2006. Since that time, the rate has declined to 11.5% in 2012 (U.S. EPA, 2013; March of Dimes, 2014).
- In 2012, black non-Hispanic women had the highest rate of preterm birth of all racial groups (16.8%), although it decreased from a high of 18.5% in 2006 (U.S. EPA, 2013).
- It is difficult to identify national trends for birth defects, since there is no unified national monitoring system; available information comes from state birth defects monitoring systems and birth certificates (U.S. EPA, 2013).

Causes

- Increases in maternal age, rates of multiple births, use of early Cesarean sections and labor inductions, changes in neonatal technology, assisted reproductive technologies, chronic maternal health problems, maternal smoking, use of alcohol or illicit drugs, maternal and fetal infections, placental problems, inadequate maternal weight gain, and socioeconomic factors have been associated with preterm birth and low birth weight (U.S. EPA, 2013).
- Some birth defects are inherited. In addition, alcohol use, smoking, and insufficient folate in a woman's diet are known causes of birth defects (U.S. EPA, 2013).
- A variety of environmental factors are under investigation for their association with adverse birth outcomes (U.S. EPA, 2013).

Evidence for Environmental Risk Factors

- Outdoor air pollutants
 - *Stieb et al. (2012), a meta-analysis of 62 studies, concluded that particulate matter, nitrogen dioxide, and carbon monoxide are associated with adverse birth outcomes, including low birth weight and preterm birth.*

- *A number of studies have reported associations between airborne polycyclic aromatic hydrocarbons (PAHs) and reduced birth weight and fetal growth restriction (U.S. EPA, 2013).*
- *Several studies have reported associations between residential proximity to traffic during pregnancy and an increased risk of preterm birth; however the Health Effects Institute (2010) reviewed the existing studies and concluded that there is inadequate and insufficient evidence to infer a causal relationship.*
- *Wigle et al. (2008), a literature review, concluded that nitrogen dioxide, sulfur dioxide, and particulate matter are associated with certain cardiac birth defects.*
- **Indoor air pollutants**
 - *Smoke from traditional cookstoves, fueled by wood, coal, or dung, has been associated with an increase in low birth weight and other adverse health effects (NIEHS, 2014).*
- **Hazardous Waste Sites**
 - *Multiple studies have reported an association between residence near hazardous waste sites and an increased risk of birth defects, particularly neural tube defects and congenital heart disease (U.S. EPA, 2013).*
 - *Yauck et al. (2004) and Brender et al. (2008) reported an association between hazardous waste sites that emit heavy metals or solvents and birth defects.*
 - *Currie et al. (2011) reviewed birth records of children born to mothers living near any of the 154 Superfund sites and reported an overall reduced incidence of birth defects.*
- **Environmental Tobacco Smoke**
 - *The U.S. Surgeon General concluded that exposure of pregnant women to environmental tobacco smoke causes a small reduction in mean birth weight, and that the evidence is suggestive (but not sufficient to infer causation) of a relationship between maternal exposure to environmental tobacco smoke during pregnancy and preterm delivery (U.S. DHHS, 2006).*
- **Pesticides**
 - *Many studies have reported an association between maternal and paternal exposure to pesticides and an increased risk of birth defects in children; however Wigle et al. (2008), in a review of the literature, concluded that the data are inadequate to confirm an association between pesticide exposure and the risk of birth defects.*
- **Endocrine Disrupting Chemicals**
 - *Several studies have reported an association between endocrine disrupting chemicals and urogenital malformations in newborn boys, such as cryptorchidism and hypospadias (U.S. EPA, 2013).*
- **Solvents**
 - *McMartin et al. (1998), a meta-analysis of a number of studies of women's occupational exposure to organic solvents, reported an increased risk of birth defects and oral cleft palates in children born to women exposed to these solvents.*
 - *Wigle et al. (2008), in a review of the literature, concluded that the evidence linking paternal exposure to solvents to neural tube defects was suggestive of an association, but not strong enough to make conclusions about a causal relationship.*

- Phthalates
 - *Several studies have reported associations between prenatal exposure to some phthalates and preterm birth, shorter gestational length, and low birth weight; however one study reported that longer gestational length and increased risk of Cesarean section delivery were associated with phthalate exposure (U.S. EPA, 2013).*
- Disinfection By-Products
 - *Several studies have reported associations between disinfection by-products and an increased risk of birth defects, particularly neural tube defects and oral clefts; however Wigle et al. (2008), in a review of the literature, concluded that the evidence is too limited to make conclusions about an association between disinfection by-products and birth defects.*
 - *Studies on disinfection by-products and preterm birth have shown conflicting results (U.S. EPA, 2013).*
- Polychlorinated biphenyls (PCBs)
 - *Baibergenova et al. (2003) reported that increased exposure to PCBs from fatty fish consumption was associated with lower birth weights, while Longnecker et al. (2005) did not observe an association between PCB exposure and low birth weight or preterm delivery.*
- Perfluorinated compounds
 - *Some studies have reported an association between perfluorinated compounds, particularly perfluorooctane sulfonic acid (PFOS) and perfluorooctanoic acid (PFOA) and adverse birth outcomes including low birth weight, decreased head circumference, reduced birth weight, and smaller abdominal circumference (U.S. EPA, 2013).*
- Health Promotion: engagement with nature
 - *Increasing tree cover near a mother's home by 10% can have a marginal decrease on small-for-gestational-age births, lowering them by 1.42 per 1,000 births. Potential causal mechanisms include increased physical activity, stress reduction as a result of contact with green space, and improved social contacts (Donovan et al., 2011).*
 - *Dadvand et al. (2012) reported that higher levels of greenness near maternal residences were associated with higher birth weight and infant head circumference, particularly in participants with low/moderate education levels. Potential mechanisms include decreased personal exposure to air pollution and increased physical activity.*

Research Activities Across the Federal Government

- EPA-Funded Research
 - *A joint study between Texas State University, Texas A & M University, Texas Dept. of State Health Services, and the University of North Carolina at Charlotte is defining new public health indicators linking exposure metrics and birth defects.*
 - *EPA is examining water-related exposures and birth defects in a five-county area in Texas.*
- EPA-NIEHS Children's Environmental Health and Disease Prevention Research Centers
www.epa.gov/ncer/childrenscenters

- A study at the University of California at Berkeley is investigating the association between air pollutants, including airborne PAHs, and birth defects and preterm birth.
- A study at the University of California at San Francisco is studying the role of endocrine disrupting compounds, perfluorinated compounds, and other chemicals in fetal development and adverse birth outcomes.
- A study at the University of Michigan is investigating the association between phthalates, lead, cadmium, and other compounds and adverse birth outcomes.
- Pregnancy Health Interview Study/Birth Defects Study – NIH, FDA, Private companies, others <http://www.bu.edu/slone/research/studies/phis/>
- Multicenter case control study began in 1976 and is investigating a wide range of environmental exposures in pregnancy that may be associated with birth defects and other adverse birth outcomes.
- NIEHS Research on Cookstoves <http://www.niehs.nih.gov/research/programs/geh/cookstoves/>
- NIEHS funded research in Guatemala, Ecuador, Nepal, Pakistan, Ghana and the U.S. on the health effects, including low birth weight, of smoke from cookstoves.
- CDC Birth defects research and tracking <http://www.cdc.gov/ncbddd/birthdefects/research.html>
- CDC tracks birth defects, researches factors that might increase or decrease the risk of birth defects, and identifies community or environmental concerns or other factors that need more study.

Autism

Definition

- Autism spectrum disorder (ASD) is a group of developmental disabilities that can cause significant social, communication and behavioral challenges (Landrigan et al., 2012; NIEHS, 2014).
- A diagnosis of ASD now includes several conditions that used to be diagnosed separately: autistic disorder, pervasive developmental disorder not otherwise specified (PDD-NOS), and Asperger syndrome (NIEHS, 2014).

Trends

- Change in percentage of children ages 5 to 17 years old in the U.S. reported to have ever been diagnosed with autism has increased from 0.1 percent in 1977 to 1.0 percent in 2010 (U.S. EPA, 2013).
- Globally, after accounting for methodological variations, there is no clear evidence of a change in prevalence for ASD between 1990 and 2010. (Baxter et al., 2014).

Prevalence

- The CDC estimates ASD affects roughly 1 in 68 children in the U.S. (8 years-of-age, during the year 2010) (CDC, 2014).
- ASD is almost 5 times more common among boys (1 in 42) than among girls (1 in 189) (CDC, 2014)
- Globally, the prevalence of ASD is estimated to be 1 in 132 persons (Baxter et al, 2014).

Causes

- Emerging understanding suggests a complex, dynamic system of metabolic and immune anomalies involving many organ systems, including the brain, in association with environmental exposures (U.S. EPA, 2013).
- Evidence points to pregnancy and the early postnatal period as critical windows of vulnerability (IACC, 2013).
- Understanding of the role of genes has been significantly refined in recent years. Data suggest that approximately 40-60% of ASD risk can be attributed to inherited, common variation (SNPs) (Sandin et al., 2014).

Evidence for Environmental Risk Factors

- Outdoor Air Pollutants
 - *Several studies suggest that there is an increased risk of ASD from air pollution exposure during gestation and/or early infancy (Becerra et al., 2013; Volk et al; 2013; Von Ehrenstein et al., 2014).*
 - *Volk et al. (2014) reported that children with both a specific genotype and high air pollutant exposures were at increased risk of ASD compared to children who had the same genotype and lower pollutant exposures.*
 - *Allen et al. (2014) investigated the mechanism by which exposure to ultrafine particulate matter from air pollution adversely affects central nervous system development in mice.*
- Pesticides
 - *Shelton et al. (2014) showed an increased risk of ASD for children of mothers that lived within 1.5 km of an agricultural pesticide application during pregnancy.*
 - *Roberts et al. (2007) reported an increased risk for developing ASD with increasing poundage of organochlorine pesticide applied and decreased with distance from the pesticide application sites.*
- Brominated Flame Retardents
 - *In a literature review, Messer (2010) suggests that polybrominated diphenyl ethers) PBDEs may be a risk factor for ASD, while a case-control study that measured 11 PBDE congeners showed no difference in PBDE levels congeners in children with ASD compared to controls (Hertz-Picciotto et al., 2011).*

Research Activities Across the Federal Government

- Interagency Autism Coordinating Committee (IACC)
 - *Established in accordance with the Combating Autism Act of 2006, reauthorized 2011 (Public Law 112-32)*
 - *Federal Members of IACC include Director NIH, Director NIEHS, Director NICHD, FDA, DOD, HHS, DOfEd*
 - *Strategic Plan, 2009, updated April 2014, objectives associated with elucidating causes of ASD emphasize:*
 - *Understanding how environmental risks may differ in vulnerable subgroups*
 - *Applying emerging science in epigenetics, the microbiome, animal models of ASD, and bioinformatics*
- GAO report May 20, 2014, on coordination of federal autism activities
 - *The GAO found that apart from federal agencies' participation on the IACC, there were limited instances of agency coordination.*
 - *1,206 autism research projects funded by 12 federal agencies.*
 - *Five Agencies fund a total of 159 research activities focused on elucidating causes of autism. Primarily NIH followed by DOD and CDC. EPA included under category "other agencies" with one activity.*
- BRAIN Initiative
 - *June 5, 2014 NIH released a scientific vision for \$4.5 billion investment over 10 years beginning in 2016.*
 - *Early results include application of 3-D map collating activity of genes in 300 brain regions during mid-prenatal development to demonstrate relationship between genetic risk factors for ASD and early brain development.*

Metabolic Syndrome

Definition

- Metabolic syndrome incorporates a cluster of adverse health effects, including obesity, hypertension, altered lipid levels, and other metabolic abnormalities, that appear to be caused by common biological mechanisms (U.S. EPA, 2013).
- Obesity, defined as a high range of weight for an individual of given height that is associated with adverse health effects, is measured based on set cutoff points directly related to an individual's body mass index (BMI) (U.S. EPA, 2013).
- Obesity has been associated with cardiovascular disease, cancer, psychological stress, asthma, and diabetes in childhood and later in life (U.S. EPA, 2013).

Prevalence

- The prevalence of childhood obesity in the U.S. has been increasing for several decades, although it has stabilized at approximately 16% over the past few years (U.S. EPA, 2013).

- In 2005–2008, 22% of Mexican-American and 20% of black non-Hispanic children were obese, compared with 14% of white non-Hispanic children and 14% of children of “Other Races/Ethnicities” (U.S. EPA, 2013).
- Among children in the U.S., the prevalence of obesity is greater in children with family incomes below poverty level than in those above poverty level (U.S. EPA, 2013).

Trends

- In 1976 – 1980, 5% of children in the U.S. were identified as obese; this rate rose until it reached a high of 16% in 2007 -2008 (U.S. EPA, 2013).

Causes

- Obesity is primarily due to an imbalance between caloric intake and activity (U.S. EPA, 2013).
- A number of animal and cellular studies suggest that environmental chemical exposures may contribute to obesity and diabetes (U.S. EPA, 2013).
- Studies show that obesity is largely programmed during early life, including the prenatal period (Janesick and Blumberg, 2011).

Evidence for Environmental Risk Factors

- Outdoor air pollutants
 - *Several studies have reported that obesity may result in greater susceptibility to the adverse effects of air pollutants, such as particulate matter and ozone, including airway inflammation, cardiovascular effects and increased particle deposition in the lungs (U.S. EPA, 2013).*
- Endocrine Disrupting Chemicals
 - *Studies suggest that some endocrine disrupting chemicals, such as bisphenol A, phthalates, diethylstilbestrol, and endogenous steroids may be associated with obesity in children (Choi et al., 2014; Karoutsou and Polymeris, 2012).*
 - *Janesick and Blumberg (2011) hypothesized that individuals exposed to certain endocrine disrupting chemicals early in life might be predisposed to increased fat mass and obesity.*
- Other Chemicals
 - *Smink et al. (2008) reported that prenatal exposure to high levels of hexachlorobenzene was associated with increased weight and BMI in children at 6.5 years old.*
 - *Verhulst et al. (2009) reported that prenatal exposure to DDE (the main metabolite of DDT) was associated with increased BMI and exposure to PCBs was associated with increased BMI in early childhood.*
 - *Scinicariello and Muser (2014) found an association between total urinary PAH metabolites and naphthalene metabolites and higher BMI, obesity, and waist circumference in children ages 6-11 years of age.*
- Health Promotion: Physical Activity
 - *Children who lived in greener neighborhoods were less likely to increase their BMI scores over 2 years compared to those who lived in less-green neighborhoods. The lower BMI scores were likely due to increased physical activity or time spent outdoors (Bell et al 2008).*

- Wolch et al. (2011) reported that children who had parks and/or recreation programs close to their homes had lower measured BMIs at age 18 than those without such programs. The authors concluded that this may be because children with better access to parks and recreation programs spend more time in physical activity and thus have reduced BMIs.
- Models based on the results from Wolch et al. (2011) suggest that if all children in the sample were to have average access to parkland and recreation programs near their homes, over 9.5% of boys and 8.3% of girls would move from overweight to normal BMIs, and approximately 2% of obese children would move down to overweight.

Research Activities Across the Federal Government

- EPA Funded Research
 - EPA is conducting a state-of-the-science literature review to identify chemical and nonchemical stressors related to childhood obesity.
- EPA-NIEHS Children’s Environmental Health and Disease Prevention Research Centers www.epa.gov/ncer/childrenscenters
 - A study at the University of California at Berkeley is investigating the association between pesticides and flame retardants and obesity.
 - Another study at the University of California at Berkeley is studying the effects of air pollutants on obesity and glucose dysregulation.
 - A study at the University of Michigan is investigating bisphenol A, phthalates, lead, and cadmium and the risk of metabolic syndrome.
 - A study at the University of Southern California is studying near-roadway air pollution and its contribution to obesity and metabolic phenotypes.
- NIH Obesity Research <http://www.obesityresearch.nih.gov/>
 - NIH seeks to identify genetic, behavioral, and environmental causes of obesity; to understand how obesity leads to type 2 diabetes, cardiovascular disease, and other serious health problems; and to build on basic and clinical research findings to develop and study innovative prevention and treatment strategies.
- CDC – Overweight and Obesity: Childhood Obesity Facts <http://www.cdc.gov/obesity/data/childhood.html>
 - Presents facts about the prevalence of childhood obesity in the U.S.
- CDC - National Collaborative on Childhood Obesity Research (NCCOR) <http://www.cdc.gov/obesity/data/surveillance.html>
 - CDC’s [Catalogue of Surveillance Systems](#) reviews, sorts, and compares more than 75 surveillance systems with data related to childhood obesity research.
 - CDC’s [National Collaborative on Childhood Obesity Research \(NCCOR\) Measures Registry](#) is a database of diet and physical activity measures used in childhood obesity research.
