NOTICE

The information in this document has been funded by the United States Environmental Protection Agency under contract No. EPA 68-02-3750 to Aerocomp, Inc. It has been subject to the Agency's peer and administrative review, and it has been approved for publication as an EPA document.

Mention of trade names or commercial products does not constitute endorsement or recommendation for use.

AFFILIATION

Mr. D. Bruce Turner is a meteorologist in the Meteorology and Assessment Division, Environmental Protection Agency, Research Triangle Park, North Carolina. He is on assignment from the National Oceanic and Atmospheric Administration, U. S. Department of Commerce. Mr. Joseph A. Catalano is the technical director of Aerocomp, Inc., Costa Mesa, California and Mr. Thomas Chico is a research meteorologist there.

PREFACE

One area of research within the Meteorology and Assessment Division is development, evaluation, validation, and application of models for air quality simulation, photochemistry, and meteorology. The models must be able to describe air quality and atmospheric processes affecting the dispersion of airborne pollutants on scales ranging from local to global. Within the Division, the Environmental Operations Branch adapts and evaluates new and existing meteorological dispersion models and statistical technique models, tailors effective models for recurring user application, and makes these models available through EPA's User's Network for Applied Modeling of Air Pollution (UNAMAP) system.

Although resembling previous Gaussian dispersion models, TUPOS introduces dispersion as functions of turbulence at plume level, layer by layer plume rise, and plume penetration above the mixing height. Multi-level meteorological information must be furnished by the user. Output is hourly concentrations written to an external file and optionally a second file with concentration contributions from each source.

The first four sections of this document are directed to managers and project directors who wish to evaluate the applicability of the model to their needs. Sections 5 and 6 are directed to engineers, meteorologists, and other scientists who are required to become familiar with the details of the model. Finally, Sections 7 through 9 are directed to persons responsible for implementing and executing the program.

Comments and suggestions regarding this publication should be directed to:

Chief, Environmental Operations Branch
Meteorology and Assessment Division (MD-80)
Environmental Protection Agency
Research Triangle Park, NC 27711.

Although attempts are made to thoroughly check computer programs with a wide variety of input data, errors are occasionally found. Revisions may be obtained as they are issued by completing and returning the form on the last page of this guide.

Technical questions regarding use of the model should be directed to (919) 541-4564. Users within the Federal Government may call FTS 629-4564. Copies of the user's guide are available from the National Technical Information Service (NTIS), Springfield, VA 22161.

The magnetic tape containing FORTRAN source code for TUPOS is contained (along with other dispersion models) in UNAMAP (Version 6), which will become available from Computer Products, NTIS, Springfield, VA 22161 (phone number: (703) 487-4763).

ABSTRACT

TUPOS and its postprocessor, TUPOS-P, form a Gaussian model which resembles MPTER but offers several technical improvements. TUPOS estimates dispersion directly from fluctuation statistics at plume level and calculates plume rise and partial penetration of the plume into stable layers using vertical profiles of wind and temperature. The model user is thus required to furnish meteorological information for several heights above-ground in a separate input file.

TUPOS can be used for short-term (hours to days) impact assessment of inert pollutants from single or multiple sources and can be expected to have greatest accuracy for locations within 10 km of the source. Although TUPOS will make computations for receptors having any ground-level elevation, it is not intended as a complex terrain model, but rather as a model for calculations over flat or gently rolling terrain. TUPOS will optionally treat buoyancy-induced dispersion but does not include building downwash, deposition, or fumigation.

The maximum number of point sources and the maximum number of receptor locations are easily adjusted at the time of program compilation and so have no specific limit. The program as listed in the appendix allows for 25 sources and 180 receptors.

Output from TUPOS consists principally of tape or disk concentration files which are then analyzed and summarized by the postprocessor, TUPOS-P. An hourly concentration file is automatically created by TUPOS; the user has the option of creating a partial concentration file.

SYMBOLS AND ABBREVIATIONS

Dimensions are abbreviated in terms of the International Standard (SI) for units:
Mass = grams (g), Length = meters (m), Time = seconds (s), and Temperature = Kelvin (K).

d	-- stack inside diameter (m)
d _z	-- the shortest distance between the effective plume height and a bounding surface (m)
E _R	-- ground level elevation of receptor (m)
E _S	-- ground level elevation of source (m)
f	-- stack-tip downwash correction factor
F	-- buoyancy flux parameter (m ⁴ /s ³)
F _b	-- residual buoyancy at bottom of layer (m ⁴ /s ³)
F _O	-- initial buoyancy flux (m ⁴ /s ³)
Fr	-- Froude Number
F _R	-- residual buoyancy (m ⁴ /s ³)
F _T	-- terrain adjustment factor (m)
f _y	-- nondimensional function of travel time for horizontal dispersion
f _z	-- nondimensional function of travel time for vertical dispersion
g	-- acceleration due to gravity (m/s ²)
H	-- effective height of plume (m)
h	-- stack height above ground (m)
H _a	-- adjusted effective height (m)
H _b	-- plume bottom (m)
H _t	-- plume top (m)
L	-- mixing layer depth (m)
Q	-- emission rate (g/s)
r	-- a ratio used to calculate the height level of maximum concentration
s	-- stability parameter (s ⁻²)
t	-- travel time (s)
T _a	-- ambient air temperature (K)

SYMBOLS AND ABBREVIATIONS (continued)

T_h	-- ambient air temperature at stack top (K)
T_s	-- stack gas temperature (K)
u_h	-- wind speed at stack top (m/s)
v_s	-- stack gas exit velocity (m/s)
x	-- downwind distance (m)
x_f	-- distance to final rise (m)
y	-- crosswind distance (m)
z	-- height above ground (m)
z_b	-- height of base of current layer (m)
z_t	-- height of top of current layer (m)
ΔH	-- plume rise (m)
ΔT	-- temperature difference between ambient air and stack gas (K)
x_p	-- pollutant concentration (g/m^3)
$\delta\theta/\delta z$	-- vertical potential temperature gradient of a layer of air (K/m)
π	-- pi, 3.14159
σ_a	-- standard deviation of the horizontal wind angle (dimensionless)
σ_e	-- standard deviation of the vertical wind angle (dimensionless)
σ_v	-- standard deviation of the horizontal crosswind component of the wind (m/s)
σ_w	-- standard deviation of the vertical component of the wind (m/s)
σ_y	-- lateral dispersion parameter (m)
σ_z	-- vertical dispersion parameter (m)
σ_{ze}	-- effective vertical dispersion (m)
σ_{z0}	-- initial vertical dispersion (m)

ACKNOWLEDGMENTS

The authors wish to express their appreciation to Mr. John S. Irwin and Mr. William B. Petersen for helpful comments regarding aspects of the work presented here. The authors are also indebted to Mr. Frank V. Hale III who designed the initial structure of TUPOS. Portions of this text were excerpted from the MPTER and PTPLU user's guides.

The secretarial assistance of Sylvia B. Coltrane is greatly appreciated.

In addition to the listed authors of the user's guide, other Aerocomp personnel made important contributions to the document. Ms. Sarah Cunningham prepared all technical illustrations and produced the final document. Editorial review was provided by Ms. Vicki Catalano.

Support of Aerocomp by the Environmental Protection Agency Contract No. 68-02-3750 is also gratefully acknowledged.

EXECUTIVE SUMMARY

TUPOS (Turbulence Profile Sigmata) is a Gaussian plume steady-state model which calculates dispersion using measured (or inferred) turbulence data (wind fluctuation standard deviations) at plume height. The model can be used to assess air pollutant impact from single or multiple sources over level or gently rolling terrain and can be expected to have greatest accuracy for locations within 10 km of the source. Gaussian assumptions and techniques are used to perform concentration estimates hour by hour, considering each hour as a steady-state period.

Information must be furnished by the user for each simulated hour at several levels for the five variables: ambient air temperature, wind direction, wind speed, standard deviation of wind azimuth, and standard deviation of wind elevation angle. These parameters are interpolated vertically for calculating plume rise, dilution, plume dispersion, and transport. This profile information must be provided in sufficient detail so that linear interpolation between levels is reasonable. One of the levels specified must be that of the mixing height.

Source parameters are physical stack height above ground, stack top inside diameter, stack gas temperature, stack gas exit velocity, and pollutant emission rate. Optionally, values for three variables: stack gas temperature, stack gas exit velocity, and emission rate can be entered hourly.

Optional features of the TUPOS computer code include:

- o Stack downwash, buoyancy-induced dispersion, and gradual plume rise;
- o Terrain adjustment as a function of stability category; and

- o An optional program-generated polar coordinate grid, with sector size and azimuth spacing entered as input.

To take advantage of the vertical profiles of temperature and wind speed provided by the input, a layer-by-layer plume rise algorithm (Turner, 1985) is used which also considers partial penetration of the plume into elevated stable layers. Dispersion is estimated from the wind fluctuations at plume height using the method of Irwin (1983).

The maximum number of point sources and the maximum number of receptor locations are easily adjusted at the time of program compilation and so have no specific limit. The program as listed in the appendix allows for 25 sources and 180 receptors.

Output from TUPOS consists principally of tape or disk concentration files which are then analyzed and summarized by the postprocessor, TUPOS-P. An hourly concentration file is automatically created by TUPOS; the user has the option of creating a partial concentration file.

By making the number of sources and receptors easily adjustable at time of compilation and removing functions that are largely bookkeeping to the post processor, the TUPOS system should be easily adaptable to computer systems with small core storage.

SECTION 1

INTRODUCTION

TUPOS is a multiple point source Gaussian dispersion algorithm which possesses many of the options and capabilities of MPTER. However, its differences from MPTER and other prior UNAMAP dispersion models are significant. For instance, TUPOS utilizes standard deviations of hourly wind fluctuations, in its dispersion algorithm, in the manner discussed by Irwin (1983). Also introduced in this model are layer-by-layer plume rise according to Turner (1985) and plume penetration above the mixing height (Briggs, 1975). A brief historical perspective on these new refinements is presented next.

Prior to the development of TUPOS, most UNAMAP dispersion algorithms utilized the σ -curves of the Pasquill-Gifford (P-G) scheme which are based on ground-level releases and short-range dispersion studies. Despite cautionary remarks from Pasquill (1976), the P-G dispersion estimates have been extrapolated to elevated sources and receptor distances far beyond their experimental basis.

Participants of an American Meteorological Society Workshop on stability classification schemes and sigma curves (Hanna et al., 1977) recommended refinement of methods for estimating the vertical and lateral dispersion parameters used in Gaussian plume models, especially for elevated releases. Draxler's (1976) and Cramer's (1976) dispersion characterizations employing wind turbulence data were mentioned as examples of available methods, but it was suggested that the scatter in the data precluded

recommending a particular scheme. A review panel (Randerson, 1979) stressed the usefulness of examining errors one might encounter using a particular dispersion characterization as compared to using other available schemes.

Irwin (1983, 1984) reviewed alternative dispersion schemes using data collected during 17 field tracer experiments conducted at 11 sites. From this review, Irwin synthesized a scheme from the characterizations of Cramer and Draxler which is robust and behaves well over a variety of dispersion conditions. This scheme requires specification of the variances of the vertical and lateral wind directions at plume height. TUPOS was designed to make use of on-site turbulence measurements according to these methods developed by Irwin.

Meteorological input to TUPOS consists of layer-by-layer values for five variables: wind direction, wind speed, temperature, standard deviation of wind azimuth, and standard deviation of wind elevation angle. It is assumed that layer heights are chosen so that linear interpolation of these five variables between levels will be appropriate. A meteorological processor, MPDA-1 (Paumier et al., 1986) produces information compatible with the input requirements for TUPOS. This processor is capable of using a variety of meteorological data sources to produce the resulting profiles.

Nearly all of the air quality simulation models, made available to date through the UNAMAP system (U.S. EPA, 1983), use plume rise methodology that depends upon only the wind speed estimated at the physical stack height and the surface-based Pasquill stability class and for the stable conditions, Pasquill stability classes E and F, set temperature gradients, $\delta\theta/\delta z$, of 0.02 K/m and 0.035 K/m, respectively. However, if available, it is more desirable to use vertical profiles of temperature and wind speed. TUPOS employs a layer-by-layer plume rise algorithm, developed by Turner (1985), that utilizes this profile data.

Full reflection or full penetration of plumes in the vicinity of the mixing height, used in previous models, is also overly simplistic. That is, if the plume centerline is above the mixing height, then there is no contribution of the plume to concentrations below the mixing height; or, if the plume centerline is below the mixing height, then the entire plume is eddy-reflected downward from the mixing height. TUPOS adopts a method suggested by Briggs (1975) and modified by Turner (1985) for treatment of partial plume penetration above the mixing height.

This user's guide is divided into three parts, with each part directed to a different audience: managers, dispersion meteorologists, and computer specialists. The first four sections are aimed at managers and project directors who wish to evaluate the applicability of TUPOS to their needs. Sections 5 and 6 are directed to dispersion meteorologists or engineers who are required to become familiar with the details of the model. Finally, Sections 7 through 9 are directed to persons responsible for implementing and executing the program. A listing of the FORTRAN source code is included in Appendix A.

The user's guide refers in various places to the features and limitations of MPTER. This is done for the benefit of users familiar with MPTER who now need some of the more refined features available in TUPOS.

SECTION 2

DATA-REQUIREMENTS CHECKLIST

To estimate concentrations for any simulated time period, data for program control, as well as information on emissions, meteorology, and receptors are required. These are mentioned briefly here; more detail on proper formatting for data entry to the program is covered in Section 8.

PROGRAM CONTROL DATA

The following control information is required for a simulation:

- Headings (for output),
- Meteorological data file identifier and creation date,
- Starting time (year, Julian day, and hour),
- Abbreviation for pollutant considered,
- Conversion for user units, and
- Pollutant half-life.

In addition, the user must indicate whether the following options are to be employed:

- Terrain adjustment,
- Stack downwash,
- Gradual plume rise, and
- Buoyancy-induced dispersion.

Output principally consists of tape or disk files which are then

analyzed and summarized by a separate postprocessor TUPOS-P (Turner, et al, 1985). An hourly concentration file is automatically created by TUPOS; the user has the option of creating a partial concentration file. For convenience, a brief summary of the simulation is printed; however, the user is encouraged to exercise the postprocessor, TUPOS-P (Turner et al., 1986), to obtain a detailed listing of the results.

EMISSION DATA

The following information is required for each point source:

- East and north coordinates of the point source (user units),
- Pollutant emission rate (g/s)
- Physical stack height (m),
- Stack gas temperature (K),
- Stack inside diameter (m), and
- Stack gas exit velocity (m/s).

The east-north coordinate system can be provided in any consistent units. Also, the stack ground-level elevation is required if the terrain adjustment option is used.

METEOROLOGICAL DATA

Hourly meteorological data are required for specific levels. The user may prepare the data in the format specified in Section 8 or data prepared by the Meteorological Processor for Dispersion Analyses, MPDA-1 (Paumier, et al, 1986), may be used. The hourly meteorological data needed for the computations are as follows:

- Year,
- Julian day,
- Hour,
- Number of vertical levels,

- Level number corresponding to the mixing height,
- Stability category,
- Height above ground of each level (m),
- Ambient air temperature at each level (K),
- Wind direction at each level (degrees),
- Wind speed at each level (m/s),
- Standard deviation of the azimuth angle (radians) at each level, and
- Standard deviation of the elevation angle (radians) at each level.

There are four stability categories in TUPOS: unstable, daytime neutral, nighttime neutral, and stable designated 1 to 4, respectively. These can be defined using the ratio of Monin-Obukhov length to mixing height. (The stability category is contained in the output from MPDA-1.)

It is assumed that the variation of meteorological parameters with height is provided in sufficient detail such that linear interpolation with height between levels yields reasonable values. Any information required for a height below the height of the lowest level is assigned the value of the lowest level. Similarly, any information required for a height above the height of the highest level is assigned the value of the highest level.

RECEPTOR DATA

The user has the option of designing his or her own receptor grid or instructing TUPOS to generate a polar coordinate receptor grid (see Section 8). In either case, the location (user length units) and, if the terrain adjustment option is used, the ground-level elevation (user height units) are required on input. Additionally, for the user-supplied receptors, the receptor height above ground (m) must be given.

SECTION 3

FEATURES AND LIMITATIONS

TUPOS is a Gaussian plume steady-state model using measured (or inferred) turbulence data (wind fluctuation standard deviations) as part of the meteorological input. It is a useful short-term (hours to days) algorithm to evaluate the effects of multiple point sources in the near-field (within 10 km). It is the intent of the authors that TUPOS be applied to sources whose effluent is dominated by buoyancy or momentum (not heavier than air releases). Only simple terrain adjustments are made; it is not expected that plume impaction be considered. The model includes the following optional computational features in common with MPTER:

- Stack downwash,
- Buoyancy-induced dispersion,
- Gradual plume rise, and
- Terrain adjustment as a function of stability category.

Modeling features unique to TUPOS include:

- Layer-by-layer plume rise according to Turner (1985), and
- Partial plume penetration above the mixing height
(Briggs, 1975 and Turner, 1985).

TUPOS retains limitations typical of Gaussian plume models including:

- No consideration of nonlinear pollutant removal or chemical reactions,
- No consideration of spatial variation in meteorology, and
- No consideration of increased horizontal dispersion due to wind direction shear through the vertical extent of plumes.

Also, TUPOS has no provision for calculating the effects from area or line source emissions or consideration of building downwash or fumigation.

Table 1 presents a comparison of TUPOS features with those of other air quality models. TUPOS has all the features of MPTER including terrain adjustment, stack downwash, gradual plume rise, buoyancy-induced dispersion, exponential removal mechanism, and a standard steady-state Gaussian plume dispersion algorithm. Air pollution concentrations are simulated for each one hour period using hourly average meteorology. During the calculation, steady-state conditions are assumed. The major improvements of TUPOS over MPTER are (1) TUPOS calculates dispersion parameters from on-site measured turbulence data instead of the Pasquill-Gifford (P-G) scheme (Pasquill, 1961) and (2) the multi-layer approach to plume rise, dilution, plume spreading, and transport considered by TUPOS. Moreover, TUPOS can simulate partial plume penetration. Table 2 summarizes the differences in approach between TUPOS and MPTER.

SECTION 4

BASIS FOR TUPOS

This section presents a brief narrative highlighting important aspects of the modeling approach. A detailed technical description, including equations, is provided in Section 5. Figure 1 illustrates the multi-layer approach incorporated in TUPOS. It should help the reader visualize some of the items discussed below. Although the structure of TUPOS resembles previous Gaussian models, such as MPTER (Pierce and Turner, 1980) it differs in several respects. Plume dispersion is estimated from fluctuation statistics at plume level. Multi-level meteorological information must be input. Plume rise and partial penetration of the plume into stable layers make use of the vertical profiles of wind and temperature.

METEOROLOGICAL PARAMETERS

Multi-level meteorological information for levels above ground must be furnished in a separate input file. Required parameters for each level include: ambient air temperature, wind speed and direction, the standard deviation of wind azimuth, σ_a , and the standard deviation of wind elevation angle, σ_e . It is assumed that this information is sufficiently detailed such that linear interpolation between levels characterizes the meteorology at any particular height. One of the levels specified must be that of the mixing height. Also, in order to properly specify the potential temperature change with height, it is good practice to specify at least one data level above the mixing height.

Figure 1. Schematic of multi-layer approach incorporated in TUPOS.

GAUSSIAN PLUME METHODOLOGY

Gaussian plume methodology assumes that pollutant concentrations from a continuously emitted plume are proportional to the emission rate, and are diluted by the wind at the point of emission at a rate inversely proportional to the wind speed. It also assumes that the time-averaged (over approximately one hour) pollutant concentrations crosswind and in the vertical near the source are closely described by Gaussian or normal distributions. The standard deviations of a plume concentration in these two directions are empirically related to the levels of turbulence in the atmosphere and increase with distance from the source.

Calculations are made for each simulated hour as if in steady-state conditions; that is, concentrations for a given hour are independent of those from previous hours. For receptors near the sources, this is a reasonable assumption.

Calculations for each hour are organized by source, such that all calculations are made for one source before proceeding to the next. In this regard, the total concentration for a given hour at a particular receptor is the sum of the estimated contributions from each source. This is also a reasonable assumption if there are no synergistic effects among different species from different sources. Emissions for only one pollutant are allowed for an individual run of TUPOS.

PLUME RISE

TUPOS employs a layer-by-layer plume rise algorithm developed by Turner (1985). In this approach, plume rise through each vertical layer is calculated taking into account the variation of temperature and wind speed with height.

Stack-tip downwash (optional) can be considered by applying a correction factor to the estimated plume rise (Bjorklund and

Bowers, 1982). This correction factor accounts for downwash in the lee of stacks during periods when the wind speed at the stack top is greater than or equal to 0.67 times the stack gas exit velocity.

Gradual plume rise is available as an optional calculation in TUPOS. Although the two-thirds dependence for rising plumes determines average plume height with distance quite well, the dispersive processes that occur during buoyant rise are thought to be different from those that occur during steady-state transport. The on-site dispersion parameters represent horizontal and vertical dispersion about a horizontal plume, which may or may not be appropriate for estimating dispersion during the plume rise phase. By making computations with and without gradual plume rise, potentially high concentrations can be identified. When gradual rise is not employed, computations use only the final effective plume height. Normal application of this model uses only the plume final rise. However, gradual rise is evaluated and used in determining buoyancy-induced dispersion.

Instead of the simplistic approach of either full reflection or complete penetration of a plume in the vicinity of the mixing height, TUPOS adopts the partial plume penetration technique suggested by Briggs (1975) and modified by Turner (1985). Assuming the initial vertical plume profile to be a "top hat" distribution, the plume top and bottom are compared with the mixing height. Then adjustments are made to the plume rise, and emission rate to account for the partial penetration of the plume above the mixing height.

DISPERSION

Dispersion is characterized by a scheme described by Irwin (1983), which utilizes on-site measured (or inferred) turbulence data. The method requires specification of the variances of the vertical and lateral wind directions at plume height and the

stability category (i.e., unstable, neutral-day, neutral-night, or stable). It should be emphasized that the turbulence data must be supplied in sufficient vertical detail such that linear interpolation between levels is appropriate.

Buoyancy-induced dispersion calculations (optional) are offered because emitted plumes undergo a certain amount of growth during the plume rise phase. This is due to the turbulent entrainment of ambient air. During the initial growth phases of release, the plume is assumed to be nearly symmetrical about its centerline; hence, the buoyancy-induced dispersion in the horizontal direction is modeled as equal to that in the vertical direction. The maximum effects on ground-level concentrations occur for short heights of release combined with large plume rise, but, in general, buoyancy-induced dispersion has only a small effect on maximum surface concentrations from elevated releases.

SECTION 5

TECHNICAL DESCRIPTION

TUPOS is a multiple point source, steady state Gaussian dispersion algorithm that estimates dispersion directly from turbulent fluctuation statistics at plume level and calculates plume rise and partial penetration of the plume into stable layers using vertical profiles of wind and temperature. TUPOS can be used for short term (hours to days) impact assessment of inert pollutants from single or multiple sources and can be expected to have greatest accuracy for locations within 10 km of the source.

METEOROLOGICAL PARAMETERS

In order to have turbulent fluctuations at plume level and to calculate plume rise and penetration, TUPOS requires values for five variables: wind direction (wind azimuth), wind speed, temperature, standard deviation of wind azimuth angle, and standard deviation of wind elevation angle for a number of heights above the ground. Sufficient heights should be used so that linear interpolation of these values in the vertical between levels will result in a reasonably accurate value for that height. One of the levels specified must be that of the mixing height. In order to properly specify the potential temperature change with height, it is good practice to specify at least one data level above the mixing height. The number of levels and the height above ground of each level can be changed on the data from hour to hour. A meteorological processor, MPDA-1 (Paumier, et al. 1986) can produce a data file that is compatible with the input requirements for TUPOS. This processor is capable of using a

variety of meteorological data sources to produce the required data. After calculating the height of the plume centerline, interpolated values of the meteorological parameters for plume centerline height are determined and used to determine plume transport direction and the plume dispersion.

GAUSSIAN PLUME EQUATIONS

Given a coordinate system with the origin at the ground, x upwind from the receptor, y crosswind, and z vertical (see Figure 2), the Gaussian equations for a continuous release are as follows:

$$x_p = Q/u \cdot g_1/(\sqrt{2\pi}\sigma_y) \cdot g_2/(\sqrt{2\pi}\sigma_z), \quad (1)$$

$$x_p = Q/u \cdot g_1/(\sqrt{2\pi}\sigma_y) \cdot 1/L \quad \text{and} \quad (2)$$

$$x_p = Q/u \cdot g_1/(\sqrt{2\pi}\sigma_y) \cdot g_3/(\sqrt{2\pi}\sigma_z). \quad (3)$$

g_1 , g_2 , and g_3 are defined as follows:

$$g_1 = \exp(-0.5y^2/\sigma_y^2), \quad (4)$$

$$g_2 = \exp[-0.5(z-H)^2/\sigma_z^2] + \exp[-0.5(z+H)^2/\sigma_z^2], \quad \text{and} \quad (5)$$

$$g_3 = \sum_{N=-\infty}^{\infty} \{ \exp[-0.5(z-H+2NL)^2/\sigma_z^2] + \exp[-0.5(z+H+2NL)^2/\sigma_z^2] \}. \quad (6)$$

For stable conditions or unlimited mixing, Eq. 1 should be used. For unstable and neutral conditions, where σ_z is equal to or greater than 1.6 L, Eq. 2 should be used. For unstable and neutral conditions where σ_z is less than 1.6 L, Eq. 3 should be used provided that both H and z are less than L.

Definitions and units of variables mentioned in this subsection are summarized in Table 3.

TABLE 3. DEFINITION OF VARIABLES USED IN GAUSSIAN PLUME EQUATIONS

Symbol	Definition	Units
x_p	concentration	g/m^3
Q	emission rate	g/sec
u	wind speed	m/sec
σ_y	standard deviation of plume concentration - horizontal distribution	m
σ_z	standard deviation of plume concentration - vertical distribution	m
L	mixing height	m
H	effective height	m
z	receptor height above ground	m
y	crosswind distance	m
g_1	horizontal dispersion function	--
g_2, g_3	vertical dispersion functions	--

PLUME RISE

Equations for estimating plume rise into neutral or unstable conditions above the stack were modified from techniques presented by Briggs (1983 and 1984). Equations for estimating plume rise within stable layers both for calm and windy conditions are from Briggs (1975).

These procedures are designed to take advantage of methods developed by Briggs to consider the vertical profiles of wind and temperature in estimating plume rise. It is assumed that temperature and wind speed are available for at least two levels above the ground. It is also assumed that the level of the mixing height is available. It is recommended that at least one data level above the mixing height be provided so that the potential temperature with height above the mixing height may be calculated.

Figure 2. Coordinate system showing Gaussian distribution in the horizontal and vertical.

The meteorological information given at different levels should be sufficiently dense in the vertical so that linear interpolation of the parameters between levels yields reasonable values.

Stack Tip Downwash

TUPOS considers the effects of stack downwash by applying a correction factor to the estimated plume rise. According to Bjorklund and Bowers (1982), the stack-tip downwash correction factor, f , (which is multiplied times the calculated plume rise) is defined by

$$f = \left\{ \begin{array}{ll} 1 & \text{for } u_h \leq v_s/1.5 \\ (3v_s - 3u_h)/v & \text{for } v_s/1.5 < u_h < v_s \\ 0 & \text{for } u_h > v_s \end{array} \right\} . \quad (7)$$

This correction factor accounts for the effects of downwash in the lee of stacks during periods when the wind speed at the stack height is greater than or equal to 0.67 times the stack gas exit velocity. It is not used (i.e., $f = 1$) for stacks with Froude numbers less than 3.0. The Froude number, Fr , is the ratio of the inertial force to the force of gravity for a given fluid flow. Briggs (1969) defines the Froude number for stack gas releases as

$$Fr = v_s^2 / [g d (T_s - T_a) / T_a], \quad (8)$$

where v_s is stack gas exit velocity, d is stack diameter, g is acceleration of gravity (9.806 m sec^{-2}), and T_s and T_a are temperatures of the stack gas and ambient air, respectively.

Determination of Stable or Neutral-Unstable Conditions

In order to calculate plume rise, TUPOS must determine the atmospheric thermal structure and decide whether the plume is dominated by buoyancy or momentum. The skeletal outline for calculating the plume rise is illustrated in Figure 3.

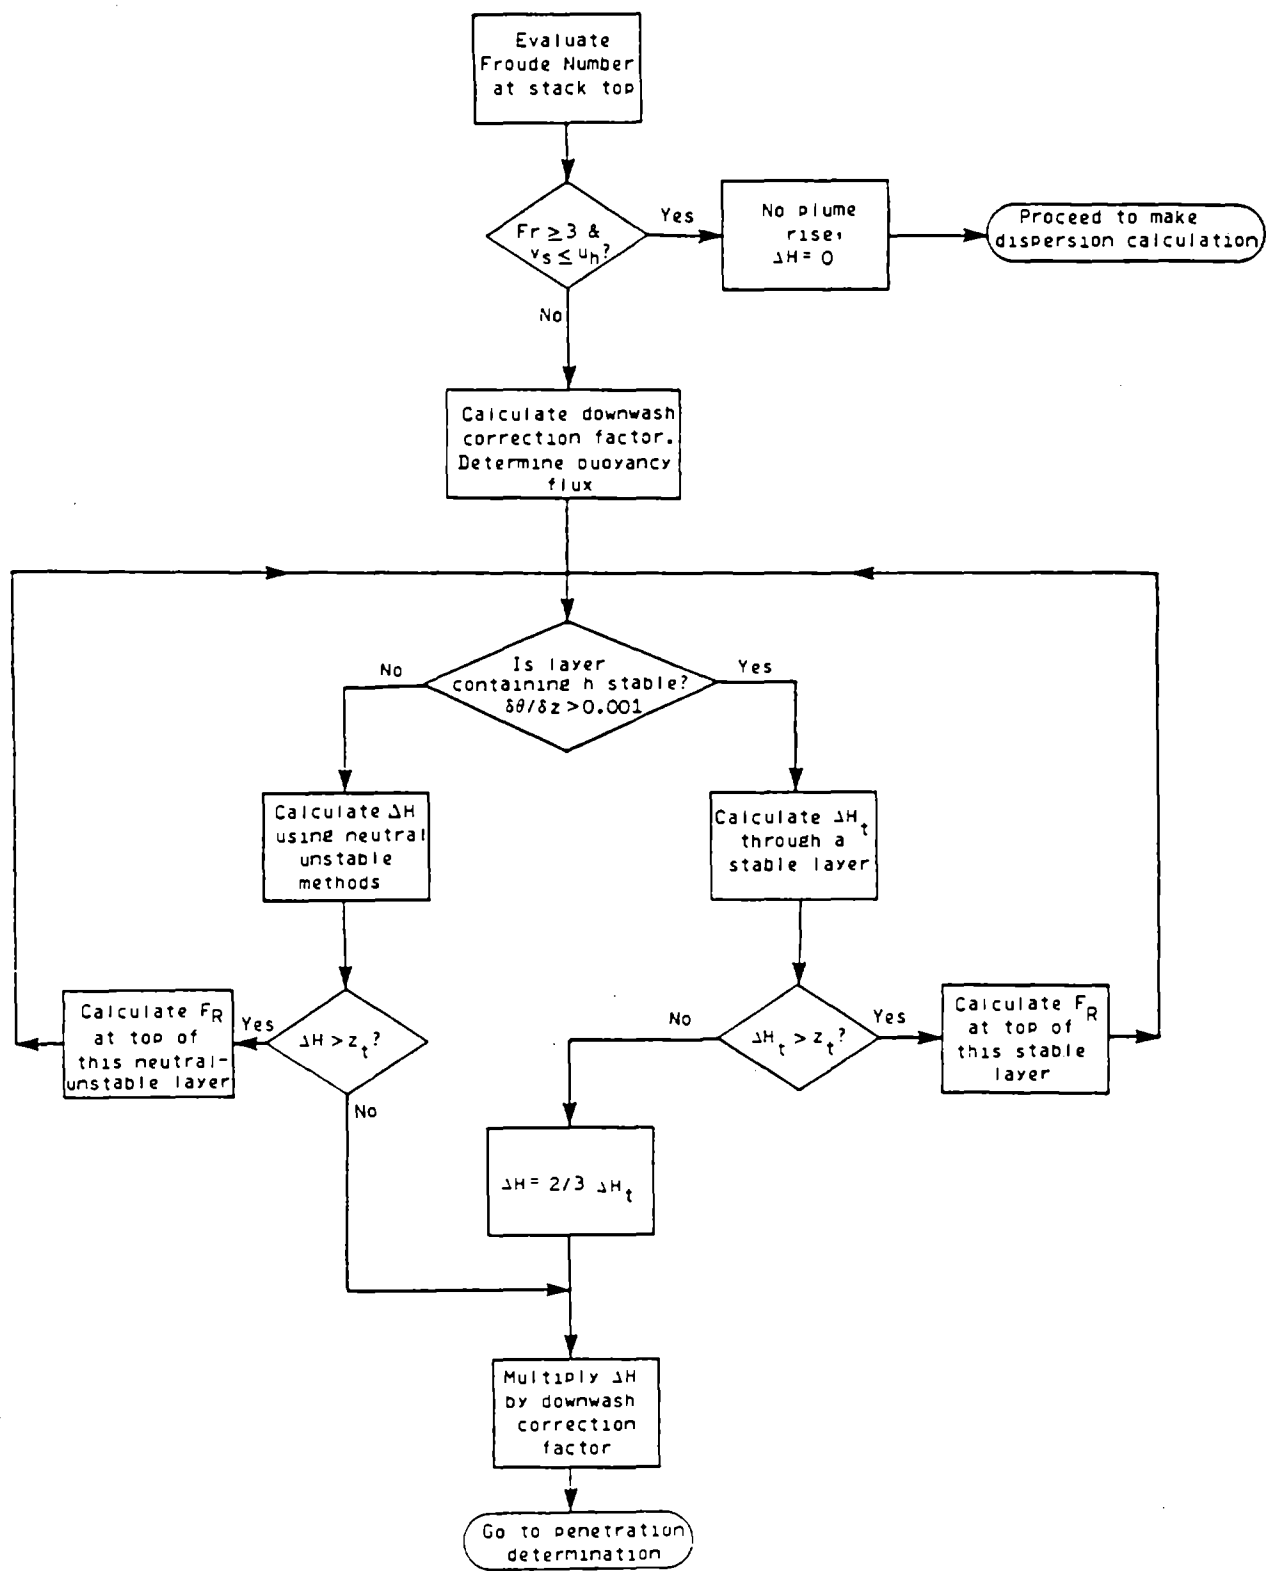

Figure 3. Flow diagram for the plume rise algorithm.

Regardless of the thermal stability of the layer containing the stack, a value for the neutral-unstable momentum rise is needed. It is determined from

$$\Delta H_{um} = 3 d v_s / u_h. \quad (9)$$

The subscript um is for unstable momentum. The initial buoyancy flux, F_0 , is also required. For stacks of circular cross section,

$$F_0 = g v_s d^2 \Delta T / (4 T_s), \quad (10)$$

where $\Delta T = T_s - T_h$ and T_h is the ambient air temperature at stack top.

The rate of potential temperature change with height for the layer containing the stack top is used to select the plume rise calculation method to be used initially. If $\delta\theta/\delta z$ is greater than 0.001 km^{-1} , the layer is considered stable, and the stable plume rise methods are used (see page 26). Otherwise, neutral-unstable methods are used.

Plume Rise Calculation for Neutral-Unstable Conditions

For neutral-unstable conditions, buoyancy rise is calculated with two different equations and the lower value from these two is compared with the previously calculated momentum rise (Eq. 9). These equations were modified from techniques presented by Briggs (1983 and 1984). The two equations are

$$\Delta H = 30 (F/u)^{0.6} + z_b \quad (11)$$

and

$$\Delta H = 24 (F/u^3)^{0.6} [h + 200 (F/u^3)]^{0.4} + z_b \quad (12)$$

Eq. 11 gives the lower value for low wind speeds, whereas Eq. 12 gives the lower value for high wind speeds. Both equations

are evaluated and the lower value is used. For the initial evaluation at the stack top, $F = F_0$, h is the physical stack height, $u = u_h$, and z_b , the height of the base of the layer above stack top, is zero. The equation that produced the value selected is noted for use later. If the neutral-unstable momentum rise (previously calculated from Eq. 9) is higher than the value selected, momentum rise applies and the final plume rise is the value from Eq. 9. Since momentum rise takes place near the stack top, the distance to final rise is set equal to zero.

If the buoyancy rise is higher than the momentum rise, buoyancy rise applies. If the plume rise is below the top of the layer containing the stack, the calculated value is the final plume rise. However, if the plume rise is greater than the top of the layer considered, the procedures in this sub-section are reapplied, using the mean wind speed between stack top and the top of the layer instead of the wind speed at the stack top. If the rise still exceeds the top of this layer, then the subsequent residual buoyancy is calculated (see next sub-section).

Residual Buoyancy Calculation for Neutral-Unstable Conditions

If the buoyancy plume rise is higher than the layer under consideration, the residual buoyancy at the top of this layer is computed. The residual buoyancy F_R is that buoyancy at the top of the layer that will give the same plume height as previously calculated. For example, the buoyant plume rise from a 60 m stack is calculated to be 330 m and the top of the layer containing the stack top is 80 m above the stack top. The residual buoyancy at this level 80 m above the stack is that required to yield 250 m plume rise. If Eq. 11 determined the buoyant plume rise, then

$$F_R = u \left[(\Delta H - z_t) / 30 \right]^{5/3} \quad (13)$$

is used to determine the residual buoyancy, where z_t is the height

of the top of the layer above stack top. If the layer considered is the one containing the stack, u is the mean wind speed between the stack top and the top of the layer. If the layer is a higher layer, u is the mean wind speed through that higher layer. If Eq. 12 was used, then the residual buoyancy is determined from

$$F_R = 0.0055 m u^3 / [1 + (h/m)]^{2/3}, \quad (14)$$

where $m = \Delta H - z_t$. Here, also, if the layer considered is the one containing the stack, the mean wind speed between stack top and the top of the layer is used for u . However, if the layer is a higher layer, the mean wind speed through the higher layer is used.

Plume Rise Calculation for Neutral-Unstable Layers Above the Stack

After computing residual buoyancy at the layer top, thermal stability is determined for the next layer. If $\delta\theta/\delta z$ is greater than 0.001 Km^{-1} , then the layer is considered stable. Otherwise, the layer is considered neutral-unstable and Eqs. 11 and 12 are both evaluated using $F = F_R$, the mean wind speed for the layer, and the proper value for z_b . The lower plume rise value is used and compared with the top of the current layer, z_t . If plume rise terminates in this layer or if this is the last level for which data were furnished, then final plume rise has been found. If not, the iterative process described in the previous subsection is repeated until the final plume rise is obtained. For heights above the last data level, wind speeds are assumed constant and equal to that of the top data level and $\delta\theta/\delta z$ is assumed to be the same as the topmost layer.

Plume Rise Calculation for Stable Layers

For determination of plume rise through stable layers, the equation for stable momentum rise,

$$\Delta H_{sm} = 0.646 [v_s^2 d^2 / (T_s u_h)]^{1/3} T^{1/2} / ((\delta\theta/\delta z)^{1/6}) \quad (15)$$

is first evaluated. The subscript sm is for stable momentum. This value is compared with the buoyancy momentum rise (Eq. 9), and the lower of these two values is set aside as representing the momentum rise under stable conditions.

Stable buoyancy rise is evaluated using

$$\Delta H_t = [(1.8 F_b T / (u \delta\theta / \delta z)) + z_b^3]^{1/3} \quad (16)$$

where ΔH_t is the height above h of the plume top. For the layer containing the stack, $F_b = F_o$, T is the ambient air temperature at the level of the stack top, u is the stack top wind speed, and z_b is zero. This equation may give excessively high values for low wind speeds. Thus stable rise for calm conditions, as given by

$$\Delta H_t = [(4.1 F_b T / (F_o^{1/3} \delta\theta / \delta z)) + z_b^{8/3}]^{3/8} \quad (17)$$

is also evaluated and the lowest value used. The equation used is also noted. Assuming a "top hat" plume with the plume thickness equal to the rise, the plume rise and the plume centerline are $2/3 \Delta H_t$, and the height of the plume bottom is $1/3 \Delta H_t$. The plume rise is compared with the value selected for momentum rise. If the momentum rise is higher, momentum rise is used for the final plume rise. If the buoyancy rise is higher, the plume top is compared with the height of the top of the layer being considered. If it exceeds the top of the layer, then Eqs. 16 and 17 are re-evaluated, using mean values between the physical stack height (h) and the top of the layer for air temperature (T) and wind speed (u). If the resulting plume top is below the top of the layer, the final plume top height has been found. However, if the plume top still exceeds the top of the layer, the stable residual buoyancy must be determined.

For the situation of a stable layer above the one containing the stack, F_b is the residual buoyancy at the bottom of this

layer, that is, the residual buoyancy at the top of the previous layer; T is the mean temperature of the layer; u is the mean wind speed of the layer; and z_b is the height above h of the base of the layer under consideration.

Residual Buoyancy Calculation for Stable Conditions

If Eq. 16 is used for the plume top determination, then

$$F_R = F_b - (0.56 \delta\theta/\delta z u/T) (z_t^3 - z_b^3) \quad (18)$$

is used to calculate the residual buoyancy at the top of a stable layer. If the layer considered is the one containing the stack, F_b is F_0 , u and T are the mean wind speed and mean temperature between stack top and the top of the layer, and z_b is zero. If it is a higher layer, F_b is the residual buoyancy at the bottom of the layer, that is, the top of the previous layer; u and T are the mean wind speed and temperature for the layer; and z_t and z_b are the heights of the top and bottom, respectively, of the layer.

If the value from Eq. 17 is used to estimate plume rise, then

$$F_R = F_b - (0.24 \delta\theta/\delta z F_0^{1/3}/T) (z_t^{8/3} - z_b^{8/3}) \quad (19)$$

is used to calculate the residual buoyancy at the top of the layer.

Final Plume Rise

The calculation of plume rise continues layer by layer (see Figure 3) using appropriate equations for stable or neutral-unstable layers until the plume rise height remains within a given layer. This is then taken as the final plume rise.

PLUME PENETRATION ABOVE THE MIXING HEIGHT

Methods have been suggested by Briggs (1975) and others (Weil and Brower, 1982) to consider partial penetration of the plume into the more stable layer above the mixing height. A modification of these methods is used in TUPOS.

To account for partial plume penetration, TUPOS uses the "top hat" distribution recommended by Briggs (1975). This assumes a uniform distribution of the plume with height about the centerline as shown in Figure 4. The plume depth is assumed to be the same as the rise of the centerline above the stack top.

With this simple picture of plume rise, the following situations are considered. If the plume bottom ($H_b = H - 0.5\Delta H$) is above the mixing height (i.e., $H_b > L$), the dispersion calculation is skipped and no impact of the plume at ground level is assumed. If the plume top ($H_t = H + 0.5\Delta H$) is below the mixing height (i.e., $H_t < L$), the entire plume is available for dispersion in the mixing layer. If the mixing height is between plume top and plume bottom, i.e.,

$$H_b < L < H_t,$$

partial penetration is considered; that is, only the plume beneath the mixing height is considered for dispersion. The following parameters are used for the portion of the plume remaining within the mixed layer:

$$Q' = Q[L - H_b]/\Delta H, \quad (20)$$

$$H' = [L + H_b]/2, \text{ and} \quad (21)$$

$$\Delta H' = H' - h, \quad (22)$$

where Q and Q' are the source strength of the original plume and the remaining plume (beneath the mixing height), respectively; H' and $\Delta H'$ are the height and plume rise of the remaining plume.

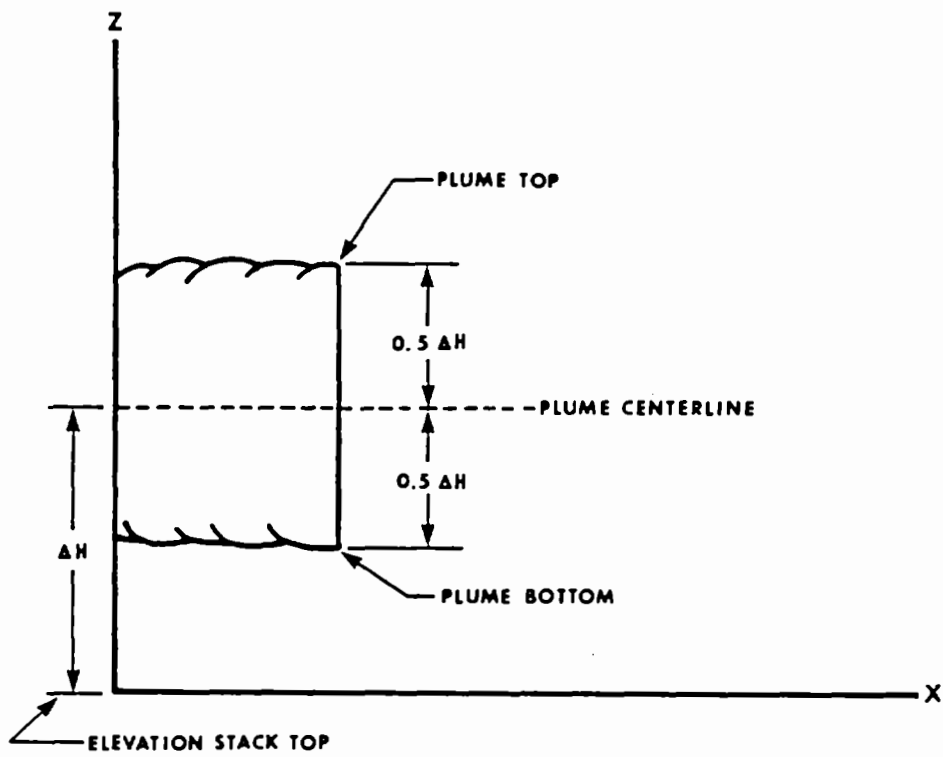

Figure 4. "Top hat" distribution for plume penetration.

Subsequently, $\Delta H'$ is used in calculating distance to final rise and buoyancy-induced dispersion. The plume penetration algorithm is summarized in Figure 5.

DISTANCE TO FINAL RISE

Except for the situation of the plume rise being due to momentum, in which case the distance to final rise is taken to be zero, the plume is assumed to rise to its final height using the 2/3 rule (Briggs, 1971, p. 1030). For any of the buoyant rise situations, the distance to final rise is calculated from

$$x_f = [u_h \Delta H' / (160 F_o^{1/3})]^{1.5} \quad (23)$$

GRADUAL PLUME RISE

If the distance between the source and the receptor, x (in kilometers), is less than the distance to final rise, the equivalent of Briggs' (1971, p. 1030), Eq. 2 is used to determine plume height, that is,

$$H = h + (160 F_o^{1/3} x^{2/3}) / u_h. \quad (24)$$

Although gradual rise might be calculated layer-by-layer, the approximation in Eq. 24 using stack top conditions is sufficient. The results of this equation are used only to calculate the buoyancy-induced dispersion. Should it exceed the final rise for the appropriate condition, the final rise is substituted instead.

DISPERSION PARAMETERS

TUPOS uses hour-by-hour turbulence data, according to methods recommended by Irwin (1983), to determine the dispersion parameters. Irwin proposed characterizing σ_y and σ_z in a manner similar to Cramer (1976) and Draxler (1976). It was suggested that the standard deviations of the crosswind and vertical concentration

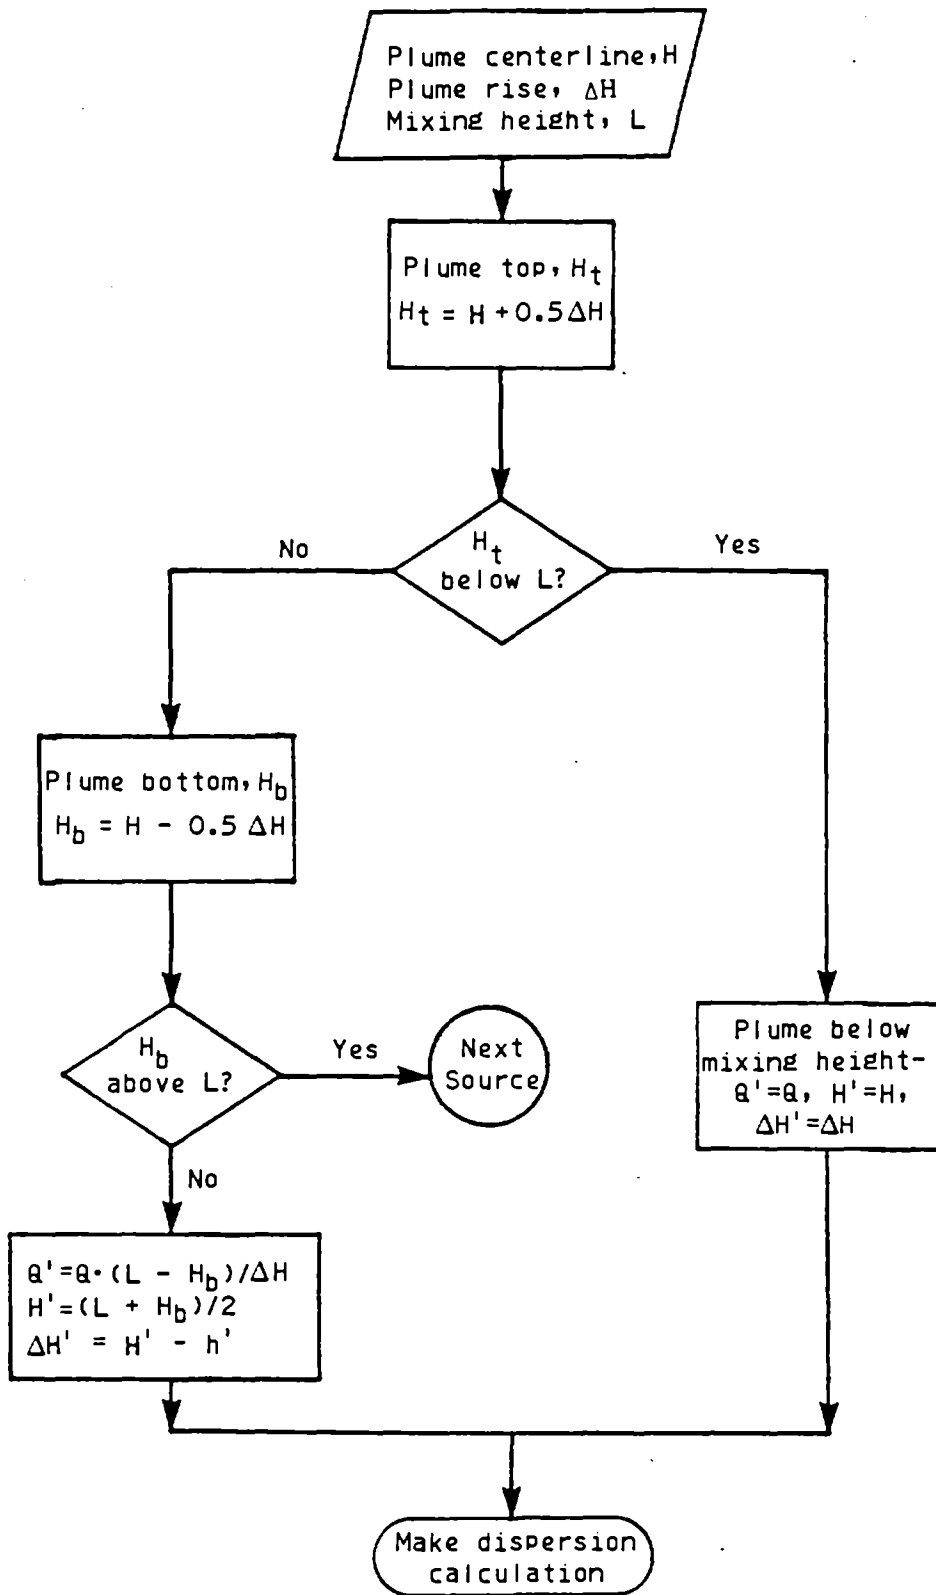

Figure 5. Flow diagram for calculating penetration of plume in relation to mixing height.

distributions, σ_y and σ_z be viewed as:

$$\sigma_y = \sigma_v t f_y \quad (25)$$

and

$$\sigma_z = \sigma_w t f_z, \quad (26)$$

where σ_v and σ_w are the standard deviations of the horizontal and vertical components of the wind, t is the downstream travel time of the pollutant, and f_y and f_z are nondimensional functions of travel time.

For small angles, the following approximations are made:

$$\sigma_v = \sigma_a u, \quad (27)$$

$$\sigma_w = \sigma_e u, \quad (28)$$

where σ_a and σ_e are the standard deviation of horizontal (azimuth) and vertical (elevation) wind angles (in radians), respectively. Substituting Eqs. 27 and 28 and $t = x/u$ into Eqs. 25 and 26 yields,

$$\sigma_y = \sigma_a x f_y \quad (29)$$

and

$$\sigma_z = \sigma_e x f_z. \quad (30)$$

Irwin (1983) summarized the performance of various characteristics of f_y and f_z over a variety of conditions and recommended the following expression:

$$f_y, f_z = 1/[1 + 0.9(t/t_0)^{1/2}], \quad (31)$$

For f_y , $t_0 = 1000$ seconds for all stability conditions. For f_z , $t_0 = 500$ seconds for unstable and daytime neutral conditions, and $t_0 = 50$ seconds for stable and nighttime neutral conditions.

OTHER CONSIDERATIONS

Removal or Chemical Reactions

Transformations of a pollutant resulting in its loss throughout the entire depth of each plume can be accomplished by an exponential decrease with travel time. The input parameter is the length of time expected for loss of 50% (half-life) of the emitted pollutant. TUPOS does not have the capability to change this parameter value during a given run. If the loss to be simulated occurs throughout the whole plume, without dependence upon concentration, then the exponential loss may provide a reasonable simulation if the loss rate is realistic. However, if the loss mechanism is selective, the loss rate will not be adequately modeled. Selective loss mechanisms include impaction with features on the ground surface, reactions with materials on the ground, or dependence on the concentration in a given small parcel of air (requiring consideration of contributions from all sources to this parcel). Simulation of dry deposition by exponential decay is quite reasonable if the plume is pretty well mixed vertically (unstable conditions), so that material is removed from the entire depth of the plume. When the plume is not well mixed, material deposits from the lowest layers of the plume and it becomes less Gaussian in shape with time.

Terrain Adjustments

A method is optionally included to treat terrain variations between source and receptor. For each source-receptor pair, two calculations are made and compared.

The first calculation is similar to that in MPTER. The relation of the plume to the topography can be varied by the user according to stability category from a completely level plume (which does not respond at all to topographic changes) to a plume which responds completely to changes in the terrain (terrain

following). Terrain adjustment factors are entered by the user for each of the four stability categories (unstable, daytime neutral, nighttime neutral, and stable). These factors can be any real number between 0 (represents plumes which level off and remain at the same mean-sea-level elevation) and 1 (represents plumes which completely respond to terrain). The author's current choice for these values is 0.5 for unstable and daytime neutral and 0.0 for nighttime neutral and stable conditions. (These values are used if both the terrain option and default option are employed.) Calculations are made by subtracting the adjusted difference, defined as the elevation of receptor ground level minus the elevation of the source ground level, from the effective plume height.

The equation used for the inclusion of the terrain adjustment is

$$H_A = H - (1 - F_T) \Delta E, \quad (32)$$

where

- H_A = adjusted effective height,
- H = effective height,
- $\Delta E = E_R - E_S$,
- E_R = ground-level elevation of receptor,
- E_S = ground-level elevation of source, and
- F_T = terrain adjustment factor.

Shown below are the adjusted effective heights for four example values of the terrain factor:

$H_A = H$	for $F_T = 1$
$H_A = H - \Delta E$	for $F_T = 0$
$H_A = H - 0.7 \Delta E$	for $F_T = 0.3$
$H_A = H - 0.1 \Delta E$	for $F_T = 0.9$

The manner in which the terrain adjustment is simulated is depicted in Figure 6 for three values of the terrain adjustment factor.

The second calculation is made to insure that the concentration resulting from the first (terrain) calculation is not used if it exceeds the maximum concentration that is expected anywhere in the plume at this distance from the source without terrain. The calculation uses the fact that the concentration in an elevated plume is a maximum at the effective stack height until sufficient growth occurs so that significant eddy reflection results from a bounding surface (the ground or a stable layer aloft). The concentration maximum in the plume then shifts toward that surface with increased distance from the source. Once the maximum concentration reaches the bounding surface, it remains there with increasing downwind distances. The distance d_z , equal to H or $L-H$, whichever is smaller, is compared with the value of σ_z at this distance. If the ratio σ_z/d_z is less than or equal to 0.71, the concentration calculation is made with $z = H$, that is, plume level. If this ratio is 1.0 or greater, the calculation is made with $z = 0$. The following four equations (which were determined empirically) are used to approximate the transition zone when σ_z/d_z is between 0.71 and 1.0:

$$\begin{aligned} r &= 2.01428 - 1.42857 (\sigma_z/d_z) && \text{for } 0.71 < \sigma_z/d_z \leq 0.85; && (33a) \\ r &= 2.925 - 2.5 (\sigma_z/d_z) && \text{for } 0.85 < \sigma_z/d_z \leq 0.93; && (33b) \\ r &= 5.25 - 5.0 (\sigma_z/d_z) && \text{for } 0.93 < \sigma_z/d_z \leq 0.97; && (33c) \\ r &= 13.3333 - 13.3333 (\sigma_z/d_z) && \text{for } 0.97 < \sigma_z/d_z < 1.00. && (33d) \end{aligned}$$

The calculation is then made for $z = r d_z$.

The lower of the two calculations is taken as the value of the concentration for the terrain situation.

Buoyancy-Induced Dispersion

Emitted plumes undergo a certain amount of growth during the plume rise phase. This is due to the turbulent motions associated

Figure 6. Adjustment of plume height due to terrain.

with conditions of plume release and the turbulent entrainment of ambient air. Pasquill (1976) suggests that this induced dispersion, σ_{z0} , can be approximated by $\Delta H/3.5$, and the effective dispersion can be determined by adding variances, i.e.,

$$\sigma_{ze} = \sqrt{\sigma_{z0}^2 + \sigma_z^2}, \quad (34)$$

where σ_{ze} is the effective dispersion and σ_z is the dispersion due to ambient turbulence levels. At the distance of final rise and beyond, σ_{z0} is a constant using ΔH of final rise. At distances closer to the source, the ΔH used to determine σ_{z0} is determined using the gradual rise formulation as follows:

$$\Delta H = 160 F_0^{1/3} x^{2/3}/u_h, \quad (35)$$

where x is distance in km.

Since in the initial growth phases of release, the plume is nearly symmetrical about its centerline, buoyancy-induced dispersion in the horizontal direction is considered equal to that in the vertical, i.e., $\sigma_{y0} = \Delta H/3.5$. Although buoyancy-induced dispersion is normally employed by TUPOS, it is optional and may be omitted.

SECTION 6

EXAMPLE PROBLEM

In this section, a hypothetical problem is provided to illustrate the use of TUPOS and the type of information it provides. Details concerning input and output for this example are discussed in Section 9 after the reader has become familiar with TUPOS input data preparation.

The problem is illustrated in Figure 7. All pertinent meteorological parameters are provided in Table 4. Sampling is to be performed along 30° arcs 1 and 5 kilometers downwind of the sources (see Figure 7). The point source emission inventory is summarized in Table 5.

This hypothetical problem forms the basis for the sample test discussed in Section 9. The input data and TUPOS generated output are provided there.

Figure 7. Source/receptor geometry for the example problem.

SECTION 7

COMPUTER ASPECTS OF THE MODEL

The general framework of TUPOS is discussed in this section. It is intended to give the reader a general knowledge of the computer program, rather than a detailed description of each subroutine. The overall structure of the program, the general processing flow, and a brief description of each subroutine is given in this section. Also provided is the overall system flow, which includes TUPOS, the input and output media, data flow, and preprocessor and postprocessor programs.

SYSTEM FLOW

Figure 8 outlines the overall system flow. Note that TUPOS is one of three programs required in the system. The Meteorological Processor for Dispersion Analyses, MPDA-1 (1986) and subsequent versions can be used to prepare meteorological data for input to TUPOS using unit 9. TUPOS-P can be used to obtain a detailed concentration summary. Optional input consists of hourly emissions data which includes emission rate, stack gas temperature, and stack gas exit velocity. The hourly emission data are expected on FORTRAN unit 10 and may be either a tape or disk file. If hourly emission data are entered, there must be a record of emission data for each hour of the simulation. Optional output includes hourly partial concentrations to FORTRAN unit 14. Hourly concentrations are automatically saved on FORTRAN unit 12. Units 12 and 14 can be either tape or disk media.

The input/output units used by TUPOS are summarized in Table 6.

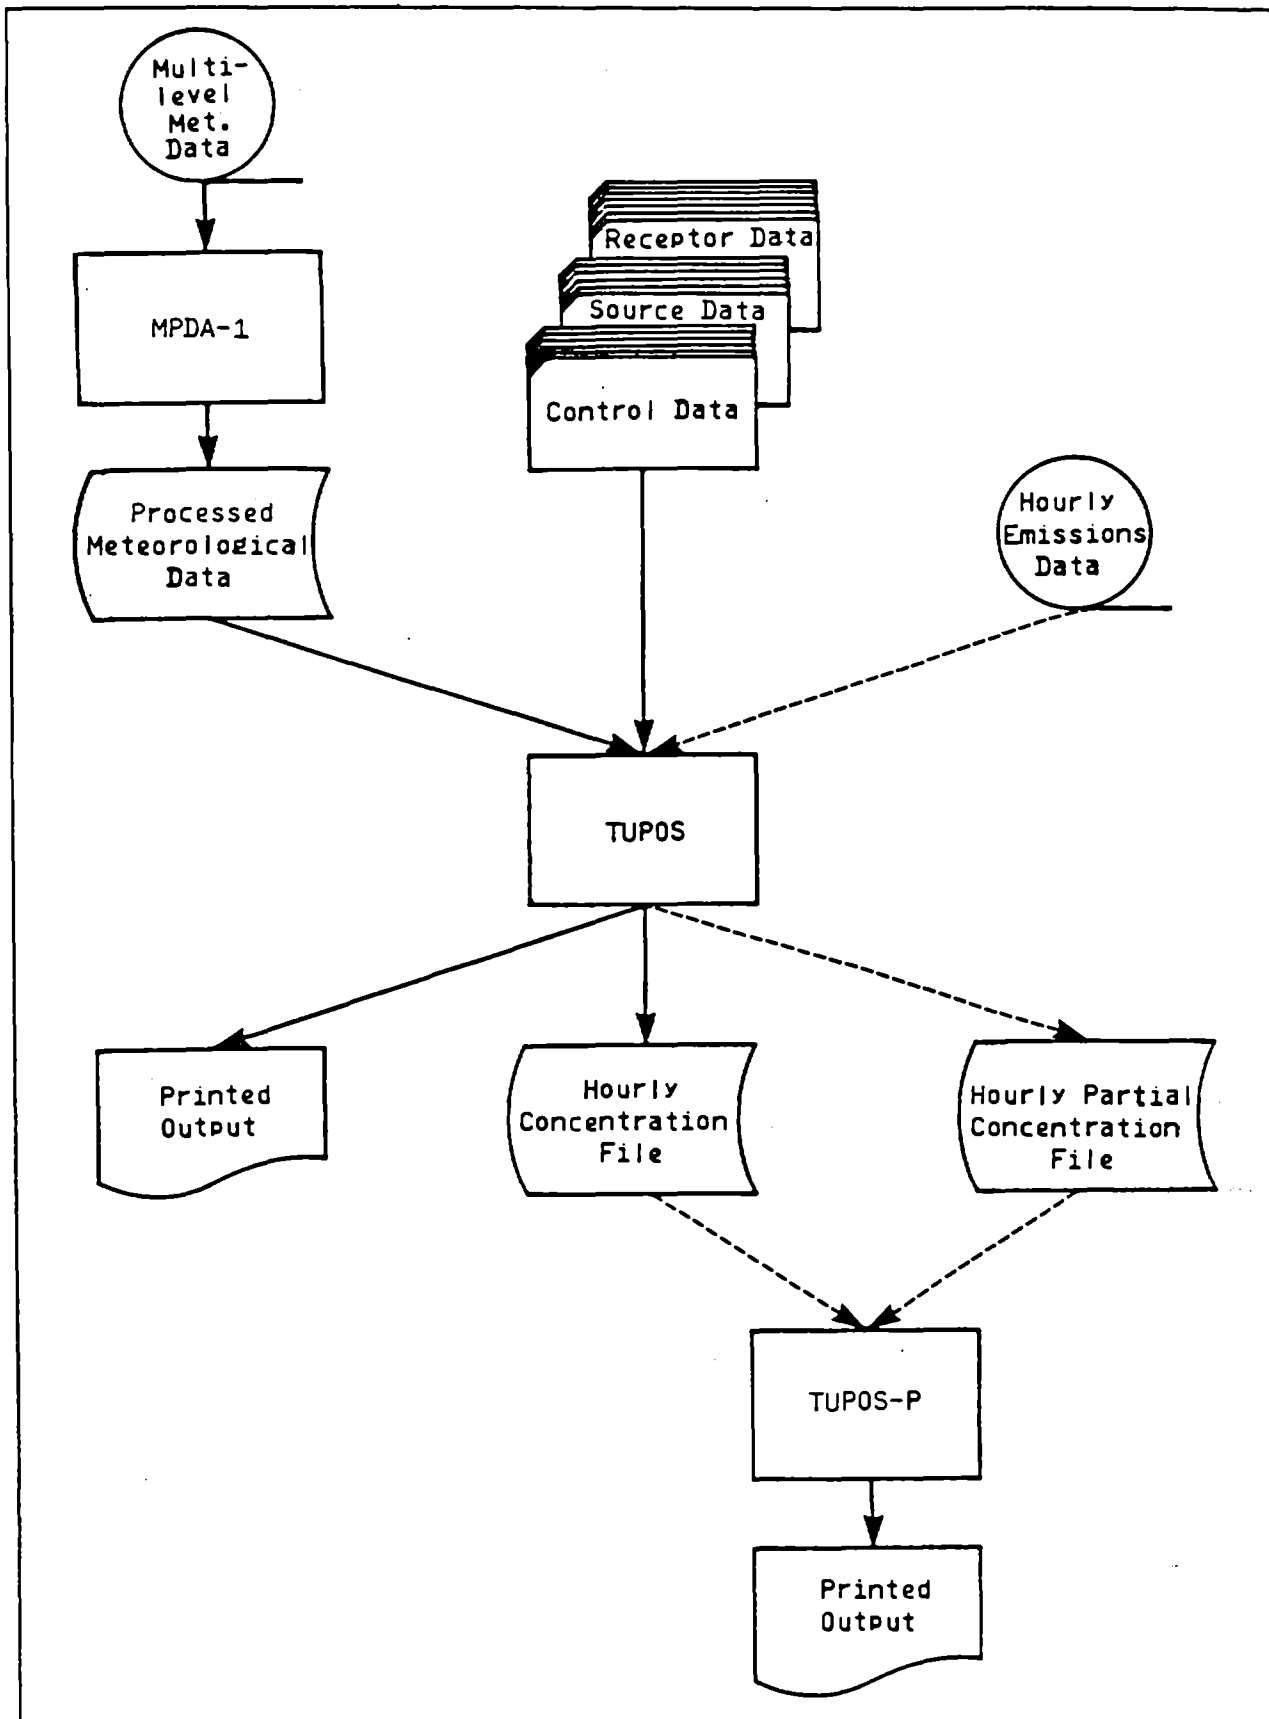

Figure 8. System flow for TUPOS. A dashed line indicates optional flow.

TABLE 6. INPUT/OUTPUT UNITS USED BY TUPOS.

STRUCTURE OF TUPOS

The program has a hierarchical static structure which also represents the dynamic structure as closely as possible. Thus, subprograms at higher levels perform coordinating tasks, and those at lower levels perform calculations; also, the order of subprograms at the same level represents the order of their execution. Subprograms are named according to the following convention:

TUlnn where TU represents TUPOS,
 l is the level number, and
 nn is the sequence number of
 the module on level l.

Figure 9 shows the program structure. Brief descriptions of the main program and subprograms follow.

TU100 -- This is the main program. It begins with introductory comments including the program abstract, authorship, and program structure. Following these introductory

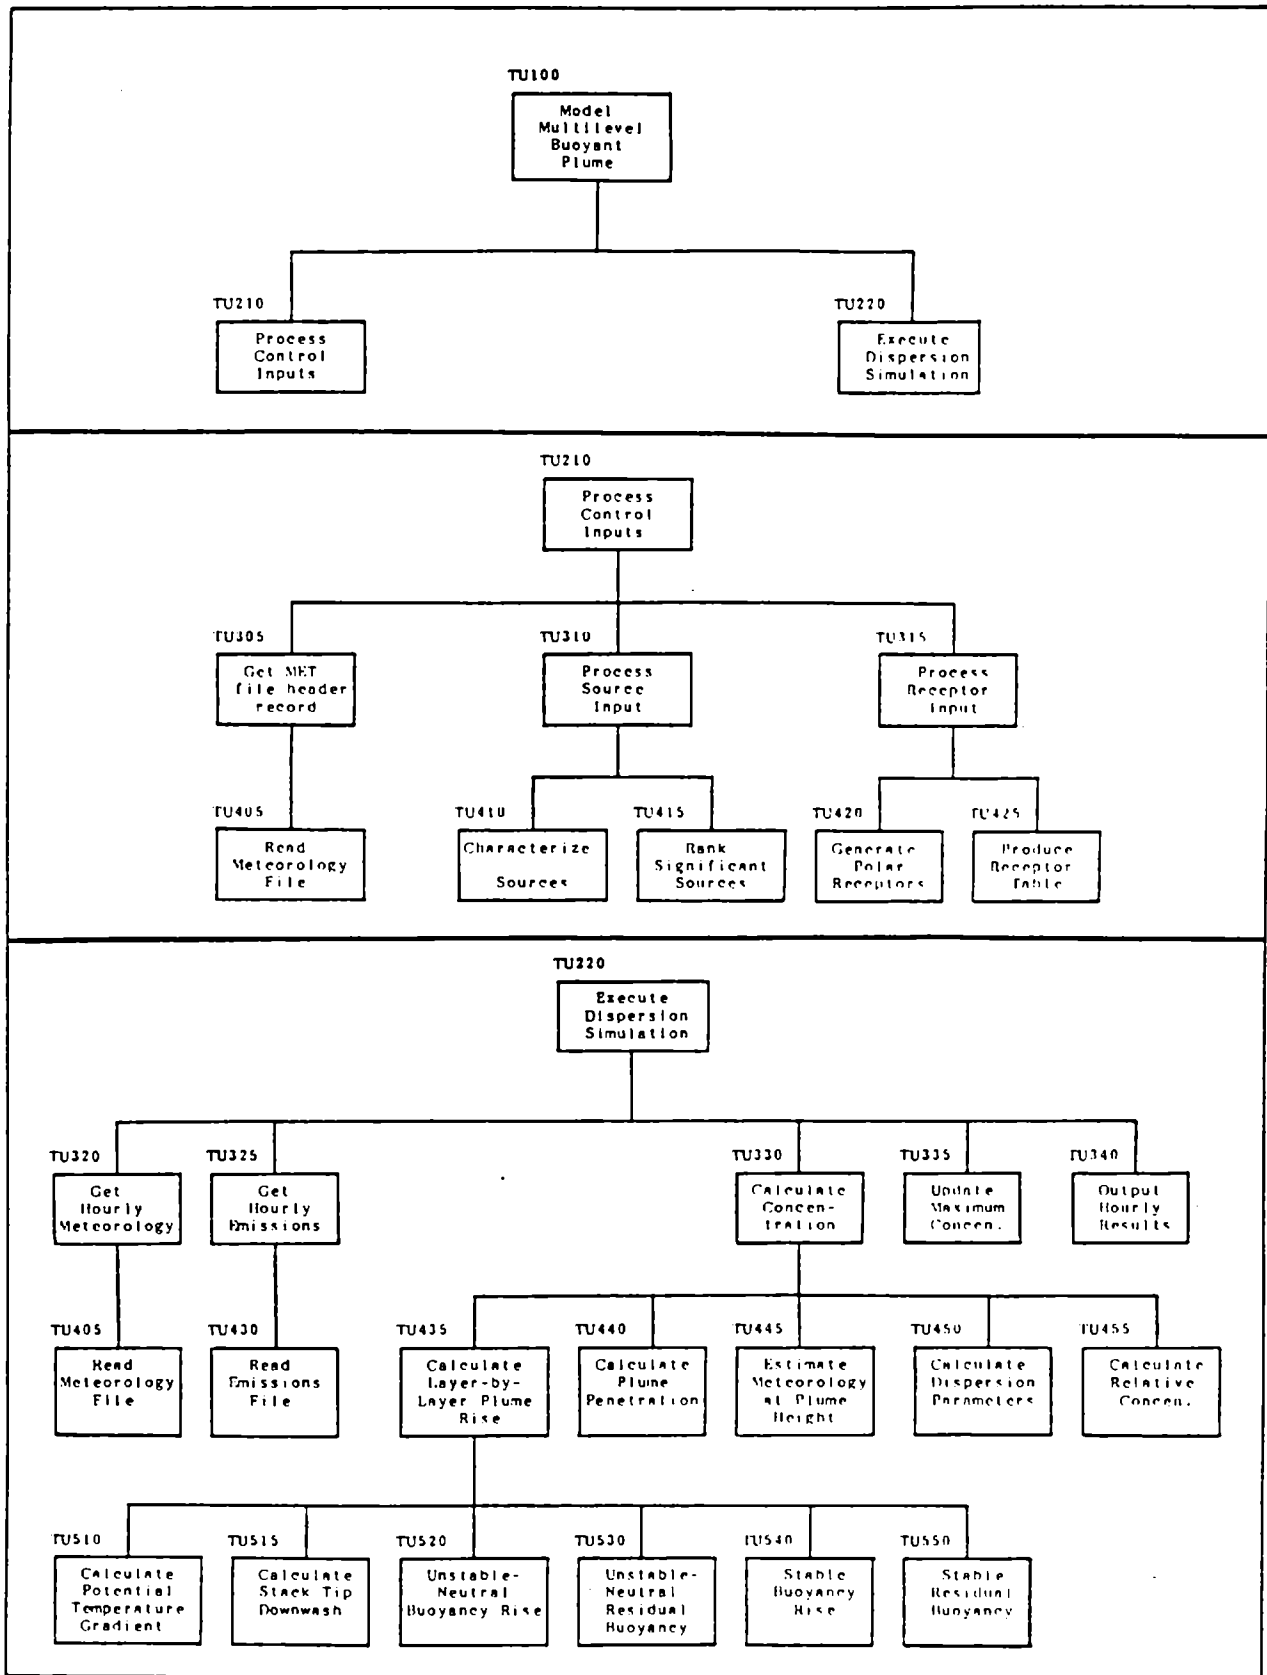

Figure 9. TUPOS program structure.

comments, subroutine TU210 is called to process the run control data. If the data are acceptable, subroutine TU220 is called to perform the run simulation. Program termination occurs exclusively in this subroutine.

TU210 -- Called by TU100, this module performs all input operations to unit 5 (control input file) and calls a number of subroutines (TU305, TU310, and TU315) to process the input. The subroutine begins with comments describing the control input file (unit 5).

TU220 -- This subroutine is called by TU100 and accomplishes the actual simulation. It includes the loop over hours. Comments describing the optional output files on units 12 and 14 are provided at the beginning of the subroutine.

TU305 -- This subroutine is called by TU210 and processes the header record of the sequential meteorology file (unit 9). TU305 calls subroutine TU405 to perform the actual I/O to the meteorology file.

TU310 -- Called by subroutine TU210, this subroutine coordinates all of the calculations related to source input. It calls subroutines TU410 and TU415 to characterize the point sources and rank significant sources, respectively. TU310 is executed once after all the source records have been read by subroutine TU210.

TU315 -- This subroutine is called by TU210 after all the receptor input has been read. It coordinates the generation of polar receptors and the printing of the receptor table by calling subroutines TU420 and TU425, respectively.

- TU320 -- This subroutine is called by TU220 and gets the hourly meteorology for the current hour of simulation. TU320 calls subroutine TU405 to perform the actual I/O to the meteorology file.
- TU325 -- This subroutine is called by TU220 if the hourly emissions option is exercised (i.e., IOPQ = 1). TU325 retrieves source data (emission rate, exit velocity, and stack gas temperature) for the current hour of simulation. TU325 calls subroutine TU430 to perform the actual I/O to the emissions file (unit 10).
- TU330 -- Subroutine called by TU220 to calculate the point source contribution to each receptor. Subroutines TU435, TU440, TU445, TU450, and TU455 are called by TU330.
- TU335 -- Subroutine called by TU220 to update the maximum hourly concentration.
- TU340 -- This subroutine is called by TU220 to print hourly concentration results for the number of hours desired.
- TU405 -- This subroutine, referenced by both TU305 and TU320, performs all input from the meteorology file (unit 9). It begins with comments describing the meteorology file.
- TU410 -- Subroutine called by TU310 to characterize each point source based on estimates of potential impacts.
- TU415 -- Subroutine called by TU310 to rank significant sources and print a table of ranked sources.
- TU420 -- This subroutine is called by TU315 to generate a polar receptor grid in terms of cartesian coordinates.

- TU425 -- This subroutine compiles and prints the receptor table which includes the receptor location, ground-level elevation, and height above ground level. It is called by TU315.
- TU430 -- Subroutine called by TU325 to read the emissions file. It begins with comments describing the emissions file (unit 10).
- TU435 -- Subroutine called by TU330 to perform layer-by-layer plume rise. This subroutine calls the following subroutines: TU510, TU515, TU520, TU530, TU540, and TU550.
- TU440 -- Subroutine referenced by TU330 to calculate plume penetration through the mixing layer.
- TU445 -- This subroutine is called by TU330 and estimates the meteorology at the plume level.
- TU450 -- Subroutine called by TU330 to calculate the lateral and vertical dispersion parameters for a particular receptor.
- TU455 -- Called by TU330 to compute the relative concentrations at a particular receptor.
- TU510 -- Subroutine called by TU435 to calculate the potential temperature gradient between two adjacent layers.
- TU515 -- Called by TU435 to compute the stack-tip downwash correction factor.
- TU520 -- This module is called by TU435 to compute unstable-neutral buoyancy rise.

TU530 -- This subroutine is called by TU435 to calculate unstable-neutral residual buoyancy.

TU540 -- Module called by TU435 to compute stable buoyancy rise.

TU550 -- Subroutine called by TU435 to calculate stable residual buoyancy.

ZF -- This function calculates a normalized height of peak concentration and is referenced only by subroutine TU330.

CHRON -- This subroutine is referenced in several places (subroutines TU220, TU320, and TU325). It converts dates between 1960 and 1999 to a common sequential hour.

ICHRON -- Subroutine called by TU220 to convert a common sequential hour to a year, Julian day, and hour.

Figure 10 is an abbreviated flow diagram of TUPOS showing its major loops and the relationships of the subroutines to each other. Only the 300 and 400 level subroutines are shown in this diagram since they perform most of the calculations and processing.

NON-STANDARD FEATURES

The PARAMETER statement, which is used in the TUPOS source code, is considered a non-standard FORTRAN feature. It allows constants to be referenced by symbolic names. This facilitates the updating of programs in which the only changes between compilations are in the values of certain constants. In TUPOS, the PARAMETER statement initializes constants NLMAX, NPTMAX, and NREMAX (i.e., the maximum number of vertical levels, point sources, and receptors, respectively). Also initialized by PARAMETER statements are the constants NDMAX and NRL. All these constants in turn are used to dimension numerous arrays. If the user's

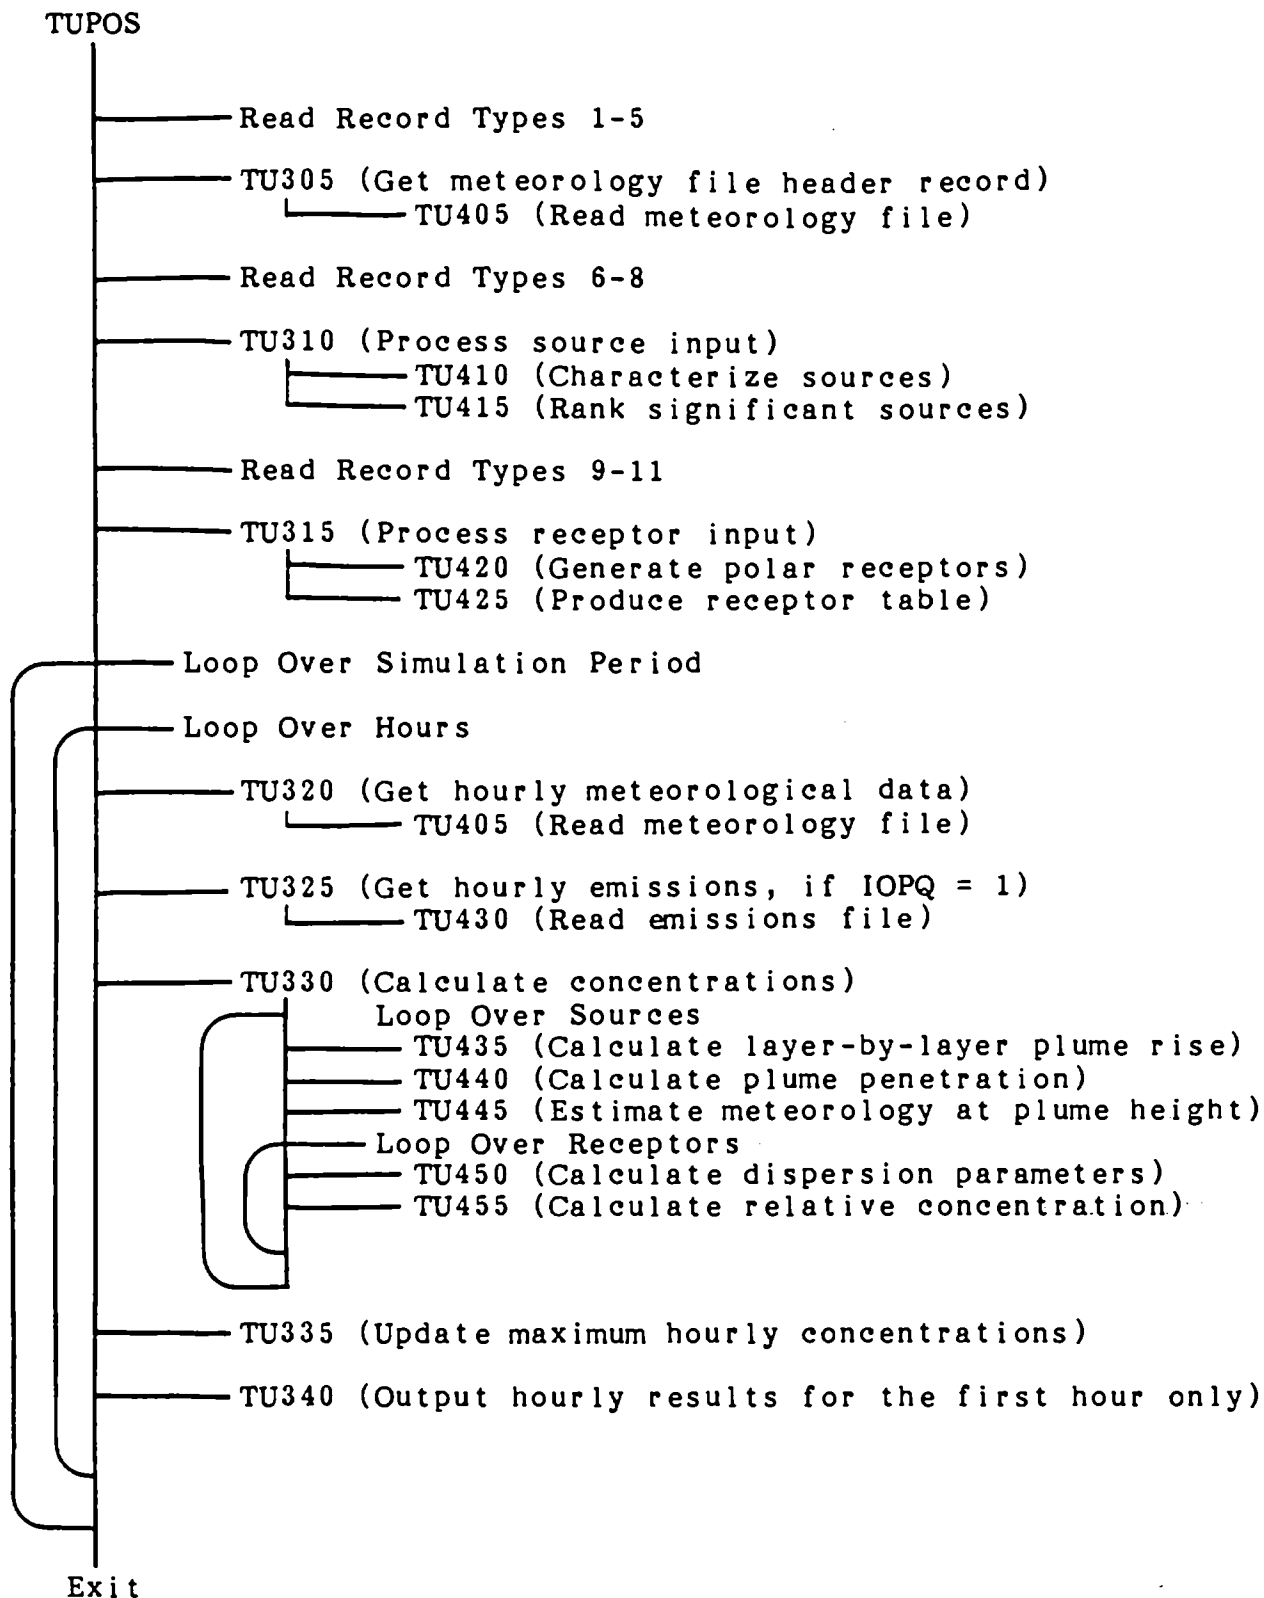

Figure 10. TUPOS Flow Diagram.

compiler does not support PARAMETER, the desired value of NLMAX, NPTMAX, NREMAX, NDMAX, and NRL must be hardcoded. The best way to do this is through global changes with an editor.

The ENCODE statement is also considered a non-standard FORTRAN feature. It is similar to formatted WRITE statements, however rather than transferring data between a peripheral unit and main storage, data is transferred between areas of main storage. In TUPOS, the ENCODE statement is used in labeling the polar coordinate receptors (subroutine TU420). If the user's compiler does not support ENCODE the code containing it should be eliminated. The result is that polar coordinate receptor names will be blank on output.

SECTION 8

INPUT DATA PREPARATION

RECORD INPUT SEQUENCE

There are 12 record types read by TUPOS; six of these are free format input. While the free format is simple to use, care should be taken to ensure that every variable is given a value in the correct order. Each variable should be separated by a comma and should conform to the variable name type. Three of the twelve record types are optional, depending on the options exercised on record type 5. A brief description of each input parameter is given in Table 7 with the appropriate units. The unit abbreviations are standard with the exception of "uu" and "uhu" which represent user length units and user height units, respectively. Under the "Format" column of Table 7, FF represents free format.

IDYS	---	FF	Starting Julian day for this simulation	day
IHRS	---	FF	Starting hour for this simulation	hr
IHLIM	---	FF	Total number of hours to be simulated	hr

=====
 * There are as many of this record type as there are sources.

INTRICACIES OF THE DATA

Most of the input data listed above are straightforward and typical of information required for Gaussian models. However, there are some input variables which require additional explanation to ensure proper assignment of values.

Record Type 4

The starting date must be within the period January 1, 1960 to December 31, 1999. Dates outside this range result in program termination. IYRS is a 2-digit year, that is, if the starting year is 1984 then IYRS = 84. IDYS is a Julian day between 1 and 366. IHRS is a 2-digit starting hour between 1 and 24.

Record Type 5

NPOL is a 4-character pollutant name for the pollutant whose dispersion is being simulated. METID, MDATAAC, and MDATBC are compared with variables METNAM, MDATA, and MDATB, respectively, which are read from the first record of the meteorology file (FORTRAN unit 9). This is done to assure that the proper meteorological data is used for the simulation. If the variables do not match, then execution is terminated.

Record Type 6

To employ a particular option, a 1 is entered on input; otherwise a zero is entered. Some of the options are described briefly next.

IOPT -- Terrain adjustment is made if the option is employed. The use of this option requires input of source ground-level elevations on record type 8 and receptor ground-level elevations on record type 11. If polar coordinate receptors are generated (i.e., IOPR = 1), then record type 10 with elevations for the

polar coordinate receptors is also read. Additionally, this option requires that four terrain adjustment factors, one for each stability category be entered on record type 7.

IOPD -- With IOPD = 0, stack downwash is used if applicable (see Section 5). With IOPD = 1, stack downwash is not estimated.

IOPG -- With IOPG = 0, gradual plume rise from stack top to the distance of final rise is determined using procedures outlined in Section 5.

IOPM -- With IOPM = 0, calculations are made in the usual way; IOPM = 1 represents a special case to save calculation time for elevated plumes during the nighttime. The purpose of this special case is so that if the simulation is only for extremely tall stacks, calculations can be avoided for nighttime situations when the plume can be expected to grow vertically very slowly and have no impact at the ground. With IOPM = 1 for nighttime conditions, if the plume bottom is below the height of the turbulent boundary layer (represented by the mixing height) the calculation is made in the usual way. However, if the plume bottom is above this height, this source is assumed not to contribute to receptor concentrations and no calculations of concentration are made.

IOPQ -- If IOPQ = 1, hourly emissions for each point source are read from unit 10 in subroutine TU430. A record with valid emissions must exist for each hour of the simulation.

IOPR -- For the user's convenience, implementing this option (IOPR = 1) provides a means of generating an array of receptors that are positioned about a specific source or some other point. If IOPR = 1, then the user must supply the necessary information on record type 9. If both IOPT = 1 and IOPR = 1, then elevations of the polar coordinate receptors must be given on record type 10. Receptor information may also be read in on record type 11 as well as generating polar coordinate receptors. The total

number of receptors is restricted to that set by the parameter statement.

IOPWPC -- When IOPWPC = 1, an hourly partial concentration file is written to FORTRAN unit 14. Output can become quite lengthy since so much information is possible, as the contribution from each source to each receptor is written. Therefore, care should be taken to ensure the allocated storage space can accommodate the amount of data generated.

Record Type 7

If IOPT = 1, then four terrain adjustment factors, one for each stability category, should be entered on this record. The values must be real numbers between zero and one. Terrain adjustment factors outside this range result in program termination. See Section 5 for a description of the effects of the terrain adjustment factors. In general, the authors feel that the terrain adjustment factor should be 0.5 for unstable or daytime neutral conditions and 0.0 for stable or nighttime neutral conditions.

Record Type 8

The point source information is similar to that required by most dispersion models. If the option to enter hourly emission data is not used (i.e., IOPQ = 0), the emission data should be the best estimate to suit the purposes of the modeler. (May be average emissions; may be maximum possible emissions.) If the terrain adjustment option is employed (i.e., IOPT = 1), the ground-level elevation of each point source must be provided.

A record containing 'ENDP' in the first 4 columns must follow the last source record.

Record Type 9

By using the radial grid option, the user can construct a complete radial grid system or only a portion (i.e., sector) of it. Two examples of how this option might be used are provided in Figure 11.

Record Type 10

If IOPT = 1 and IOPR = 1, then TUPOS expects a record type 10. The elevations are ordered so that all elevations for the first radial distance are entered first, then all elevations for each succeeding radial. There should be NAZ times NRAD elevations.

Record Type 11

An additional method of entering receptors is to specify their locations on individual records for each receptor. Note that the receptor height above ground level must be in meters. In many applications the height may be zero, other situations may occur where determining concentrations above ground is desirable, such as at plume centerline. Although no restriction on this height exists, careful thought should be given to the assignment of receptor heights far removed from the ground surface.

Values for ELR are required only if the terrain adjustment option is employed (i.e., IOPT = 1). Note that elevations are entered in user height units. A receptor whose elevation is below the lowest stack base elevation or above the lowest stack top value is flagged in the receptor table.

A record containing 'ENDR' in the first 4 columns must follow the last receptor record. If no receptors are read in using card type 11, the record containing 'ENDR' must be read following the last record type 10 entry or record type 9 if record type 10 is not used.

Figure 11. Two examples of the polar coordinate grid option.

Record Type 12

Additional time periods may be analyzed on a particular run by including one of these record types for each additional simulation period. It should be noted that all other control information remains fixed. An example might be helpful.

Suppose IYRS, IDYS, IHRS, and IHLIM on record type 4 are initialized as follows: 85, 1, 1, and 24. Thus the first simulation is for the first day of 1985. If the user also wants to analyze the 30th day of 1985, then a record type 12 must be included with the variables IYRS, IDYS, IHRS, and IHLIM on record type 12 defined as follows: 85, 30, 1, and 24. It is important to note that the additional simulation periods cannot go backward in time.

MULTI-LEVEL METEOROLOGICAL DATA FILE

It is recommended that the EPA-developed meteorological processor, MPDA-1 (1986), be used to generate the sequential meteorology file; however, information on the file layout is presented here for those users wishing to generate a TUPOS-compatible meteorology file. The file should be unformatted with the record layout shown in Table 8. The date in each record must be within the period January 1, 1960 to December 31, 1999.

TABLE 8. RECORD LAYOUT FOR THE METEOROLOGICAL DATA FILE

Variable	Description	Units
Record type 1 (occurs once at top of file)		
METNAM(2)	An 8 character alphanumeric identifier for the data	--
MDATA	Date-time of data creation (6 digits)	mo/day/yr
MDATB	Date-time of data creation (6 digits)	hr/min/sec
ND	Number of 72 character alphanumeric description records	--
DESC(18,ND)	ND lines of alphanumeric information that describe the file	--
Record type 2 (one for each hour)		
MYR	Year (2 digits)	yr
MJD	Julian day (3 digits)	day
MHR	Hour (2 digits)	hr
NLLIM	Number of data levels	--
LMX	Level number of mixing height	--
KLASS	Stability category (1 to 4)	--
ZL(NLLIM)	Height of each level	m
TL(NLLIM)	Temperature for each level	K
WDL(NLLIM)	Wind direction for each level	deg
UL(NLLIM)	Wind speed for each level	m/sec
SAL(NLLIM)	σ_a for each level	radians
SEL(NLLIM)	σ_e for each level	radians

OPTIONAL HOURLY EMISSION DATA FILE

If the hourly emissions option is employed (i.e., IOPQ = 1), TUPOS reads hourly values of emission rate, stack gas temperature, and stack gas exit velocity from FORTRAN unit 10. The emission file should be unformatted with the record layout shown in Table 9. The date in each record must be within the period January 1, 1960 to December 31, 1999. If IOPQ = 1 and the emission data for any hour in the simulation are missing, execution is terminated.

SECTION 9

EXECUTION OF THE MODEL AND SAMPLE TEST

EXECUTION

TUPOS produces an error-free compile on UNIVAC EXEC 8 and IBM MVS computers. A sample job stream is presented below.

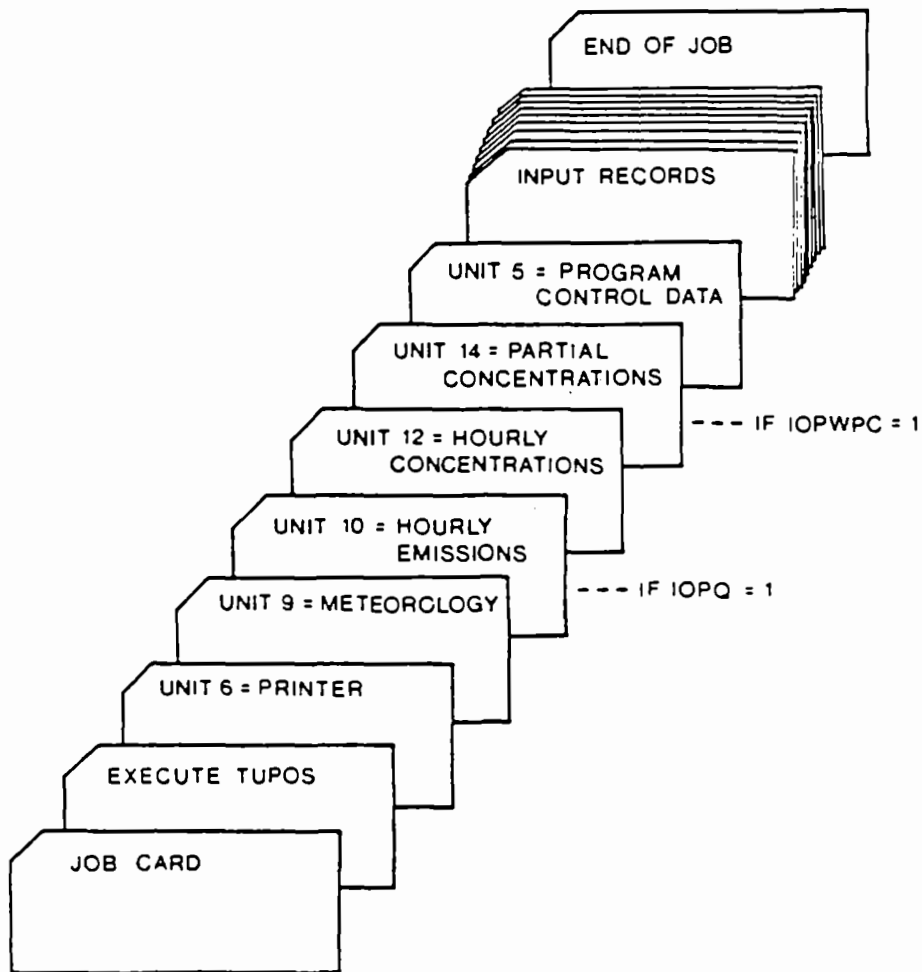

Figure 12. Sample job stream for TUPOS.

A job stream for a UNIVAC EXEC 8 system might have the following form:

```
@RUN,R/R JOB-ID,ETC
@ASG,A MODELS*LOAD.
@ASG,A MET.
@USE 9,MET.
@ASG,A EMIS.
@USE 10,EMIS. }
@ASG,R HCON. }  if IOPQ = 1
@USE 12,HCON.
@ASG,R PCON. }
@USE 14,PCON. }  if IOPWPC = 1
@XQT MODELS*LOAD.TUPOS
(input records shown in Table 10)
@FIN
```

The following is a sample job stream for an IBM system under OS or MVS. Units 9, 10, 12, and 14 are assumed to have been preallocated.

```
//JOBID JOB (PROJ,ACCT,OTHER),CLASS=A,TIME=1
//XTUPOS EXEC PGM=TUPOS,TIME=(,30)
//STEPLIB DD DSN=USER.MODELS.LOAD,DISP=SHR
//FT09F001 DD DSN=USER.MET.DATA,DISP=SHR
//FT10F001 DD DSN=USER.EMIS.DATA,DISP=SHR if IOPQ = 1
//FT12F001 DD DSN=USER.HCON.DATA,DISP=SHR
//FT14F001 DD DSN=USER.PCON.DATA,DISP=SHR if IOPWPC = 1
//FT06F001 DD SYSOUT=A
//FT05F001 DD *
(input records shown in Table 10)
/*
//
```

SAMPLE TEST

The example problem discussed in Section 6 is used for model verification. The meteorological file is generated by executing the auxiliary FORTRAN program, METVER, provided in Appendix B. The input data for model verification are given in Table 10. Annotated output for the example problem is shown in Figure 13. Users may verify the proper execution of the program by comparing their results with those given in the figure.

As listed in the Appendix, TUPOS requires just under 8,000 words of core storage for instructions and just under 20,000 words of core storage for data.

The relative potential impact given as part of the point source information is the emission over the square of the effective height for unstable conditions with a 3 m/s stack top wind speed.

TITLE: TUPOS TEST 9.
THREE SOURCES WITH BID.
USES 24-HOUR SYNTHETIC DATA SET.

*** SIMULATION SUMMARY ***

MAXIMUM SO2 CONCENTRATION FOR THE PERIOD (YR, DAY, HR) 83-365-15 TO 84- 1-14
CONCENTRATION: 4364.74
DATE: 83-365-15
RECEPTOR NUMBER: 23

↑ ↑
Julian day

} *Maximum concentration for the simulation provided along with where it occurred and at what time.*

NUMBER OF HOURLY MET RECORDS MISSING: 11
NUMBER OF HOURLY MET RECORDS INCOMPLETE: 2
CONCENTRATION ESTIMATES WERE MADE FOR: 11 HRS

} *The number of missing and incomplete records printed along with the number of successful calculations.*

*** NORMAL TERMINATION ***

↙
Indicates successful completion.

Figure 13. (continued)

CONCENTRATION FILES

As mentioned earlier, the principal output consists of tape or disk files. An hourly concentration file is automatically created by TUPOS; the user has the option of creating a partial concentration file. Hourly concentrations are written to FORTRAN unit 12 and hourly partial concentrations to unit 14. The user is encouraged to use the EPA-developed postprocessor, TUPOS-P (Turner et al., 1986), to analyze the hourly and partial concentration files. However, the record layouts for both unformatted files are provided in Tables 11 and 12.

TABLE 11. RECORD LAYOUT FOR THE HOURLY CONCENTRATION FILE

Variable	Description	Units
Record type 1 (occurs once at top of file)		
IFLAGH	Flag to indicate hourly concentration file. A value of 12 is output to represent unit 12.	--
Record type 2 (occurs once at top of file)		
LINE1(20)	80-character title	--
LINE2(20)	80-character title	--
LINE3(20)	80-character title	--
Record type 3 (occurs once at top of file)		
METNAM(2)	8-character identifier of the meteorological data	--
MDATA	Month/day/year of data creation (6 digits)	mo/day/yr
MDATB	Hour/minute/second of data creation (6 digits)	hr/min/sec
ND	Number of 72-character lines of description	--
DESC(18,ND)	ND 72-character lines to describe the meteorological file	--
Record type 4 (occurs once at top of file)		
NPOL	4-character pollutant name	--
CONTWO	Multiplier to convert user length units to kilometers	km/uu
CELM	Multiplier to convert user height units to meters	m/uhu

(continued)

TABLE 11 (continued)

Variable	Description	Units
HAFL	Pollutant half-life. If zero, produced no pollutant loss	sec
NPTLIM	Number of point sources in this simulation	--
NRELIM	Number of receptors in this simulation	--
Record type 5 (occurs once at top of file)		
IOPT	Terrain adjustment option	--
IOPB	Buoyancy-induced dispersion option	--
IOPD	Stack-tip downwash option	--
IOPG	Gradual plume rise option	--
IOPM	Test against mixing at night	--
IOPQ	Hourly emissions input option	--
IOPR	Polar coordinate receptor option	--
Record type 6 (occurs once at top of file if IOPT = 1)		
CONTER(4)	Terrain adjustment factors	--
Record type 7 (NPTLIM records, one for each source, at top of file)		
PNAME	12-character (3A4) source identifier	--
QEAST	East coordinate of source	uu
QNORD	North coordinate of source	uu
QJ	Emission rate for pollutant NPOL	g/sec
PSH	Physical stack height	m
TS	Stack gas temperature	K
D	Stack diameter	m
VS	Stack gas exit velocity	g/sec
QLEEV	Stack base ground-level elevation	uhu
IMPS	Significance rank of this source	--

(continued)

TABLE 11 (continued)

```

=====
Variable          Description          Units
=====
Record type 8 (occurs once at top of file; one for each receptor,
                that is, NRELIM records,)
RNAME            8-character (2A4) receptor identifier  --
RREC            East coordinate of receptor          uu
SREC            North coordinate of receptor         uu
ZR              Receptor height above ground-level    m
ELR             Receptor ground-level elevation      uu
STAR           Flag (2A1) to indicate receptor status,--
                * receptor elevation is below
                lowest stack base elevation
                ** receptor elevation is above
                lowest stack top elevation
    
```

(Note: Records 9, 10, and 11 are repeated in sequence for each hour.)

Record type 9 (one for each hour)

```

IYR            2-digit year          yr
IDY            Julian day          day
LH            Hour            hr
    
```

Record type 10 (one for each hour)

```

HSAV          NPTLIM values of effective plume      m
                heights for each source followed by
DSAV          NPTLIM values of distance to final    km
                rise for each source
    
```

Record type 11 (one for each hour)

```

PHCHI         Hourly concentrations at each      g/m3
                receptor (NRELIM values)
    
```

TABLE 12. RECORD LAYOUT FOR THE PARTIAL CONCENTRATION FILE

```
=====
Variable                Description                Units
=====
```

Record type 1 (occurs once at top of file)

```
IFLAGP                Flag to indicate partial concen-    --
                    tration file. A value of 14
                    output to represent unit 14.
```

Record types 2 through 8 are identical to those given in Table 11

Record type 9 (one for each hour)

```
IYR                2-digit year                yr
IDY                Julian day                day
LH                Hour                hr
```

Record type 10 (one for each source for each hour, that is NPTLIM records per hour.)

```
HSAV                Effective plume height for this source  m
DSAV                Distance to final rise for this source km
PARTC                Concentrations from this source at    g/m3
                    each receptor (NRELIM values)
```

(Note: Records 9, 10, and 11 are repeated in sequence for each hour.)

=====

Record types 1 through 8 are not repeated when the user requests additional simulation periods analyzed (i.e., record type 12 of Table 7 included in the input stream), since all other control information remains unchanged. Only hourly concentration results for each additional simulation period are written according to the specifications outlined in Tables 11 and 12. For instance, for all additional simulation periods only record types 9 through 11 are written to the hourly concentration file and

only record types 9 and 10 are written to the partial concentration file. Record types 1 through 8 occur once at the top of the files.

ERROR MESSAGES AND REMEDIAL ACTION

TUPOS can generate 31 error messages. Each of these terminates program execution. Table 13 lists each error message, along with its description and suggested corrective action. The table is ordered on the condition code indicator, ICOND.

ICOND is used to indicate if an error is detected in the input data which would preclude model execution. A nonzero value is assigned to ICOND when an input error is detected. The first 3 digits of ICOND indicate the subprogram in which the error occurred; the last 2 digits indicate the relative position within the subprogram. For instance, if ICOND = 21003 then the error occurred in subroutine TU210 at assignment 3 of ICOND.

TABLE 13. ERROR MESSAGES AND REMEDIAL ACTION.

```
=====
ICOND:          21002
MESSAGE:        *** CHECK OPTION LIST (I.E., RECORD TYPE 6).
                ***OPTION INPUT VARIABLES SHOULD BE EITHER 0 OR 1.
                ***EXECUTION TERMINATED, CONDITION CODE = 21002
DESCRIPTION:    User input value other than 0 or 1 for options.
ACTION:         Modify values on record type 6 to 0 or 1.
-----
ICOND:          21003
MESSAGE:        *** CONTER VALUE IS OUTSIDE OF RANGE: ZERO TO ONE.
                *** EXECUTION TERMINATED, CONDITION CODE = 21003
DESCRIPTION:    One of the terrain adjustment factors is outside
                the acceptable range of between 0.0 to 1.0.
```

(continued)

TABLE 13 (continued)

=====

ACTION: Change the offending value(s) of CONTER on record type 7. Values that were entered are printed prior to the error message.

ICOND: 21004

MESSAGE: *** USER TRIED TO INPUT MORE THAN xxxx POINT SOURCES.
*** EXECUTION TERMINATED, CONDITION CODE = 21004

DESCRIPTION: The user either entered more than the maximum number of point sources or forgot to place an 'ENDP' following the last point source.

ACTION: Reduce the number of point sources and/or place an 'ENDP' following the last point source.

ICOND: 21005

MESSAGE: *** INPUT DATA INDICATES THAT THERE ARE xxx POINT SOURCES FOR THIS SIMULATION.
*** EXECUTION TERMINATED, CONDITION CODE = 21005

DESCRIPTION: No sources were specified for this simulation.

ACTION: Revise the run stream so that it includes data for at least one point source.

ICOND: 21006

MESSAGE: *** TRYING TO GENERATE xxxxx RECEPTORS, BUT ARE ONLY ALLOWED xxxxx.
*** EXECUTION TERMINATED, CONDITION CODE = 21006

DESCRIPTION: The user is trying to generate more polar coordinate receptors than allowed.

(continued)

TABLE 13 (continued)

=====
ACTION: Modify NAZ and NRAD on record type 9 so that their
 product does not exceed maximum number of receptors
 specified.

ICOND: 21007
MESSAGE: *** USER EITHER TRIED TO INPUT MORE THAN xxxxx
 RECEPTORS OR 'ENDR' WAS NOT PLACED AFTER THE LAST
 RECEPTOR RECORD.
 *** EXECUTION TERMINATED, CONDITION CODE = 21007
DESCRIPTION: More receptors than maximum number specified
 (including polar coordinate receptors) were entered
 or an 'ENDR' was not placed after the last receptor
 record.
ACTION: Reduce the receptors input (including polar
 coordinate receptors) and/or place an 'ENDR' after
 the last receptor record.

ICOND: 210008
MESSAGE: *** NO RECEPTORS HAVE BEEN CHOSEN.
 *** EXECUTION TERMINATED, CONDITION CODE = 21008
DESCRIPTION: No receptors have been generated or read in.
ACTION: Restructure the input stream so that receptors are
 generated and/or read.

ICOND: 22001
MESSAGE: *** YEAR INPUT (yyyy) IS NOT WITHIN RANGE OF 60-99.
 *** EXECUTION TERMINATED, CONDITION CODE = 22001
DESCRIPTION: The year must be within the period 1960-1999.
ACTION: Modify starting year within input stream.

(continued)

TABLE 13 (continued)

```

=====

APPENDIX A

LISTING OF FORTRAN SOURCE CODE FOR TUPOS

The source code listing of TUPOS follows. The program consists of a main module, 29 subroutines, and 1 function.

TUPOS-1.0 (VERSION 85091) TUP00010
 AN AIR QUALITY DISPERSION MODEL IN TUP00020
 SECTION 2. NON-GUIDELINE MODELS, TUP00030
 IN UNAMAP (VERSION 6) JUL 86. TUP00040
 SOURCE: UNAMAP FILE ON EPA'S UNIVAC 1110, RTP, NC. TUP00050

* * * PROGRAM ABSTRACT -- TUPOS TUP00060

THIS DISPERSION MODELING TECHNIQUE FOR ESTIMATING CONCEN- TUP00090
 TRATIONS FROM BUOYANT POINT SOURCES IS BASED UPON GAUSSIAN TUP00100
 ASSUMPTIONS AND CALCULATES THE GAUSSIAN PLUME SPREADING, TUP00110
 SIGMA-Y AND SIGMA-Z, UTILIZING HOURLY WIND FLUCTUATION STANDARD TUP00120
 DEVIATIONS AT PLUME HEIGHT DESCRIBED BY IRWIN (1983). TUP00130
 MULTI-LEVEL METEOROLOGICAL INFORMATION FOR LEVELS ABOVE GROUND TUP00140
 MUST BE FURNISHED IN A SEPARATE INPUT FILE. METEOROLOGICAL TUP00150
 INPUT FILES COMPATIBLE WITH TUPOS INPUT REQUIREMENTS TUP00160
 CAN BE CREATED USING THE METEOROLOGICAL PROCESSOR MPDA-1 TUP00170
 (PAUMIER, ET AL, 1986). WIND SPEED TUP00180
 (INTERPOLATED VERTICALLY FROM THE INPUT DATA) IS USED BOTH FOR TUP00190
 ESTIMATION OF PLUME RISE AND FOR DILUTION. WIND DIRECTION AT TUP00200
 THE PLUME HEIGHT IS USED AS THE TRANSPORT DIRECTION. PLUME TUP00210
 RISE IS CALCULATED IN A LAYER-BY-LAYER MANNER USING THE INPUT TUP00220
 TEMPERATURE AND WIND SPEED PROFILES (TURNER, 1985). TO ACCOUNT TUP00230
 FOR PLUME PENETRATION ABOVE THE MIXING HEIGHT, TUPOS USES THE TUP00240
 "TOP HAT" DISTRIBUTION RECOMMENDED BY BRIGGS (1975). TUP00250
 DISPERSION IS CALCULATED FROM, TUP00260

$$\text{SIGY} = X * \text{SIGA} * \text{FY}$$

$$\text{SIGZ} = X * \text{SIGE} * \text{FZ}$$

WHERE SIGY AND SIGZ ARE THE STANDARD DEVIATION OF THE HORIZON- TUP00320
 TAL AND VERTICAL WIND ANGLES, RESPECTIVELY; AND FY AND FZ ARE TUP00330
 FUNCTIONS OF TRAVEL TIME AND STABILITY. OPTIONS ARE AVAILABLE TUP00340
 FOR TERRAIN ADJUSTMENT, STACK DOWNWASH, GRADUAL PLUME RISE, AND TUP00350
 BUOYANCY-INDUCED DISPERSION. COMPUTATIONS CAN BE MADE FOR ANY TUP00360
 NUMBER OF POINT SOURCES AT ANY NUMBER OF RECEPTOR LOCATIONS; TUP00370
 THE MAXIMUM NUMBER OF EACH IS SET AT THE TIME OF PROGRAM TUP00380
 COMPILATION. TUP00390

OUTPUT PRINCIPALLY CONSISTS OF TAPE OR DISK CONCENTRATION TUP00400
 FILES WHICH ARE THEN ANALYZED AND SUMMARIZED BY A POSTPRO- TUP00410
 CESSOR, SUCH AS TUPOS-P (TURNER ET AL., 1985). AN HOURLY TUP00420
 CONCENTRATION FILE IS AUTOMATICALLY CREATED BY TUPOS; THE USER TUP00430
 HAS THE OPTION OF CREATING A PARTIAL CONCENTRATION FILE. FOR TUP00440
 CONVENIENCE, A BRIEF SUMMARY OF THE SIMULATION IS PRINTED; TUP00450
 HOWEVER, THE USER IS ENCOURAGED TO EXERCISE THE POSTPROCESSOR TUP00460
 TO OBTAIN A DETAILED LISTING OF THE RESULTS. TUP00470
 TUP00480
 TUP00490

MAIN
 SUBPROGRAMS CALLED:
 TU305, TU310, TU315

DESCRIPTION:
 THIS MODULE PERFORMS ALL INPUT OPERATIONS TO UNIT 5, THE
 CONTROL INPUT FILE AND CALLS A NUMBER OF MODULES TO PROCESS
 THE INPUT. IF AN ERROR IS DETECTED IN THE DATA WHICH
 PRECLUDES MODEL EXECUTION, A NONZERO VALUE IS ASSIGNED TO
 ICOND.

***** CONTROL INPUT DATA (UNIT 5) *****

*** RECORD TYPES 1-3: ALPHANUMERIC DATA FOR TITLES. FORMAT(20A4)

LINE1 - 80 ALPHANUMERIC CHARACTERS.
 LINE2 - 80 ALPHANUMERIC CHARACTERS.
 LINE3 - 80 ALPHANUMERIC CHARACTERS.

*** RECORD TYPE 4: CONTROL. FORMAT (FREE)

IYRS - 2-DIGIT YEAR FOR THIS SIMULATION.
 IDYS - STARTING JULIAN DAY FOR THIS SIMULATION.
 IHRS - STARTING HOUR FOR THIS SIMULATION.
 IHLM - THE TOTAL NUMBER OF HOURS TO BE SIMULATED.
 CONTWO - MULTIPLIER TO CONVERT USER UNITS TO KILOMETERS.
 EXAMPLE MULTIPLIERS:
 FEET TO KM 3.048E-04
 MILES TO KM 1.609344
 METERS TO KM 1.0E-03
 CELM - MULTIPLIER TO CONVERT USER HEIGHT UNITS TO METERS.
 EXAMPLE MULTIPLIER:
 FEET TO METERS 0.3048
 HAFL - POLLUTANT HALF-LIFE (SECONDS); AN ENTRY OF ZERO
 WILL CAUSE NO POLLUTANT LOSS.

*** RECORD TYPE 5: MET DATA IDENTIFIERS. FORMAT (3A4,2I6)

METID, MDATA, MDATEC WILL BE USED TO COMPARE
 WITH INFO IN FIRST RECORD OF MET FILE TO INSURE
 PROPER DATA USED.

NPOL - 4 CHARACTER POLLUTANT NAME.
 METID - 8 CHARACTER IDENTIFIER.
 MDATA - MO DAY YR OF DATA CREATION (6 DIGITS).
 MDATEC - HR MIN SEC OF DATA CREATION (6 DIGITS).

*** RECORD TYPE 6: TECHNICAL & EXTERNAL FILE OPTIONS. FORMAT (FREE)

NPRNT - NO. HRS PRINTED OUTPUT
 1 = EMPLOY OPTION; 0 = DON'T USE OPTION.

TECHNICAL OPTIONS:

IOPT - USE TERRAIN ADJUSTMENTS.
 IOPB - USE BUOYANCY INDUCED DISPERSION.
 IOPD - NO STACK TIP DOWNWASH.
 IOPG - NO GRADUAL PLUME RISE.
 IOPM - TEST FOR PLUME WITHIN TURBULENT BOUNDARY
 LAYER (NIGHTTIME).
 IDFLT - OPTION FOR DEFAULT VALUES.
 EMPLOYING DEFAULT OPTION USES MODEL FEATURES
 ACCORDING TO AUTHOR'S PREFERENCE.

INPUT OPTIONS:

IOPQ - READ HOURLY EMISSIONS.(UNIT 10)
 IOPR - INPUT RADIAL DISTANCES AND GENERATE POLAR
 COORDINATE RECEPTORS.

```

C      VS(NPT)    61-68 F8.2 STACK GAS EXIT VELOCITY (M/SEC)
C      QELEV(NPT) 69-72 F4.0 STACK BASE GROUND-LEVEL ELEVATION
C              (USER HEIGHT UNITS)
C
C      !!! IMPORTANT !!!
C      RECORD WITH ENDP IN COLS 1-4 IS USED TO SIGNIFY END OF POINT
C      SOURCE INPUT.
C
C*** RECORD TYPE 9: POLAR COORDINATE RECEPTORS.  FORMAT (FREE)
C      (USED IF IOPR = 1)
C      CEST      EAST COORDINATE ABOUT WHICH POLAR COORD GRID IS
C              CENTERED (USER UNITS).
C      CNOR      NORTH COORDINATE ABOUT WHICH POLAR COORD GRID IS
C              CENTERED (USER UNITS).
C      NAZ       NUMBER OF AZIMUTHS.
C      AZBEG     BEGINNING AZIMUTH (DEGREES, CLOCKWISE FROM NORTH).
C      AZINT     AZIMUTH INTERVAL (DEGREES).
C      NRAD      NUMBER OF RADIALS.
C      RADIL     RADIAL DISTANCES (USER UNITS; NRAD OF THESE).
C
C      NOTE THAT IF NO TERRAIN AND NO RECEPTOR COORD TO BE
C      READ IN, MUST HAVE AN 'ENDR' RECORD HERE!!
C
C*** RECORD TYPE 10: POLAR COORDINATE RECEPTOR ELEV. FORMAT (FREE)
C      INPUT ONLY IF BOTH IOPT = 1 AND IOPR = 1.
C
C      ELR - POLAR COORDINATE RECEPTOR ELEVATION (USER HT UNITS)
C      READ IN RECEPTOR ELEVATIONS (USER HEIGHT UNITS) ORDERING
C      SO THAT ALL AZIMUTHS FOR THE FIRST RADIAL DISTANCE ARE ENTERED
C      FIRST, THEN ALL AZIMUTHS FOR EACH SUCCEEDING RADIAL.
C
C      NOTE THAT IF NO RECEPTOR COORDINATES TO BE READ IN,
C      MUST HAVE AN 'ENDR' RECORD HERE!!
C
C*** RECORD TYPE 11: RECEPTORS.  FORMAT(2A4,2F10.3,2F10.0)
C      (UP TO NREMAX RECEPTORS MAY BE GENERATED INCLUDING POLAR
C      COORDINATE ONES IF IOPR = 1.)
C      RNAME(I),I=1,2 ( 1- 8) 2A4 8 DIGIT ALPHANUMERIC STATION
C      IDENTIFICATION.
C      RREC (9-18) F10.3 EAST COORDINATE OF RECEPTOR (USER UNITS)
C      SREC (19-28) F10.3 NORTH COORDINATE OF RECEPTOR (USER UNITS)
C      ZR (29-38) F10.0 RECEPTOR HEIGHT ABV LOCAL GROUND-LEVEL (M)
C      ELR (39-48) F10.0 RECEPTOR GRD-LVL ELEVATION (USER HT UNITS)
C
C      !!! IMPORTANT !!!
C      RECORD WITH 'ENDR' IN COLS 1-4 IS USED TO SIGNIFY THE END OF
C      THE RECEPTOR RECORDS.
C

DESCRIPTION: TUP07540
THIS MODULE PERFORMS ALL I/O TO THE METEOROLOGY FILE, TUP07550
UNIT 9. METEOROLOGY DATA IS READ INTO COMMON METCOM. TUP07560
ERRORS ARE INDICATED BY PASSING A NONZERO VALUE THROUGH TUP07570
ICOND. END OF FILE IS INDICATED BY PASSING A VALUE OF ONE TUP07580
THROUGH IEOF. KMET IS USED TO RECORD BOTH THE NUMBER OF TUP07590
RECORDS READ AND TO INDICATE THE TYPE OF RECORD BEING READ TUP07600
(HEADER OR HOURLY). TUP07610
* * * INPUT FILE (UNIT 9) - METEOROLOGICAL DATA MUST BE ENTERED VIA TUP07620
THIS FILE. TUP07630

SUBROUTINE TU435(NPT,HL,H,TEMPST,UST,THZST,FO,DELH,DISTF,HE,MISG)
435-LAYER-BY-LAYER-PLUME-RISE

ARGUMENT LIST:
INPUT:  NPT   - SOURCE NUMBER
OUTPUT: HL    - MIXING HEIGHT (METERS)
        H     - PHYSICAL STACK HEIGHT (METERS)
TEMPST - AMBIENT AIR TEMPERATURE AT STACK TOP (K)
UST     - WIND SPEED AT STACK TOP (M/SEC)
THZST  - POTENTIAL TEMPERATURE OF LAYER CONTAINING
        STACK
FO      - INITIAL BUOYANCY FLUX (M**4/S**3)
DELH   - PLUME RISE (METERS)
DISTF  - DISTANCE TO FINAL RISE
HE     - EFFECTIVE PLUME HEIGHT (METERS)
MISG   - MISSING CODE (IF MISG > 0 THEN MISSING)

CALLING ROUTINES:
TU330

SUBPROGRAMS CALLED:
TU510, TU515, TU520, TU530, TU540, TU550

DESCRIPTION:
PLUME RISE IS CALCULATED THROUGH EACH VERTICAL LAYER TAKING
INTO ACCOUNT THE VARIATION OF METEOROLOGICAL INFORMATION
WITH HEIGHT (SPECIFICALLY, TEMPERATURE AND WIND SPEED). IT
IS ASSUMED THAT THE METEOROLOGICAL INFORMATION IS SUFFI-
CIENTLY DENSE IN THE VERTICAL SO THAT LINEAR INTERPOLATION
OF THE PARAMETERS BETWEEN LEVELS YIELDS REASONABLE VALUES.

APPENDIX C

LSTMET is a program to list data from any meteorological files prepared for input to TUPOS. There are two types of input to the program: A line of identifiers to compare with those on the input file, and a line of data consisting of two date-time groups, a start date-time and an ending date-time. Data with date-times inclusive between these two date-times will be printed. Each date-time consists of a year, Julian day and hour. Upon completion of printing the data included between the two date-times, an additional line of data is read expecting two more date-time groups. If the input data ends without a second line of date, the program will terminate normally. However, if a second line or subsequent lines are present, the data between each pair of date-time groups will be printed. For example, if a met file exists having 31 days' data from 85,001,01 through 85,031,24 and two data lines as

```
85, 017, 15, 85, 018, 14
85, 023, 10, 85, 023, 12
```

are included in the run stream, the first line will cause print out of 24 hours' met data beginning on Julian day 17 at hour 15 and the second line will cause print out of 3 hours' met data beginning on Julian day 23 at hour 10. As can be seen by this example, meteorological data can be skipped to get to those data desired. It is necessary to have the data portions in chronological order. If the two data lines above were reversed, the second data group would not be written.

The data print out is organized so that the printed lines appear as the layers in the atmosphere do with the lower heights above ground at the bottom. In order to make the data display of greatest use, the potential temperature change with height, $\sigma\theta/\sigma_z$, for each layer is calculated and included in the data display.

APPENDIX D

INMET is a program that will allow creation of a meteorological data file compatible with the input requirements of TUPOS. This program would be of greatest use, when it is desirable to create a file for a short period of record, such as, for just several hours.

Data type 1 consists of the indentifiers to be used on the header record on the meteorological file plus ND, the number of lines of the description. Data type 2 is a line of alphanumeric description of the met file. Lines of data type 2 are repeated ND times in the run stream. The header record in the meteorological file is created from type 1 and type 2 inputs.

Data type 3 contains values for six variables. The first three are year, Julian day and hour. The fourth is the number of levels in the vertical for which data will be furnished. The fifth is the number of the level that corresponds to the mixing height or the top of the nocturnal boundary layer height. The sixth is the stability classification: 1 = unstable, 2 = daytime neutral, 3 = nighttime neutral, and 4 = stable.

There is a data type 4 line of input for each of the number of levels given in data type 3. A value is given for each of the following six or seven (see following) variables: height above ground of the level, temperature for this height, wind direction for this height, wind speed for this height, standard deviation of wind azimuth angle, standard deviation of wind elevation angle, and the change of potential temperature with height between this level and the next.

It should be noted that although the change of potential temperature with height, $\delta\theta/\delta z$, is not a data parameter to be placed in the meteorological file, it may be a parameter that the user may want to adjust. Therefore, the user has the choice of providing temperatures for each level, in which case, the DTHDZ may be left off on the data input; or providing a temperature for only the lowest level and a value for $\delta\theta/\delta z$ for that level and each subsequent level except the last, and allowing the temperatures for the data file to be calculated from the first level temperature and the $\delta\theta/\delta z$ for each layer. For the latter case, zero is supplied for all temperatures except that for the first level and $\delta\theta/\delta z$ is given in the input data for all but the last layer.

```

15. SUPPLEMENTARY NOTES				
<p>16. ABSTRACT TUPOS and its postprocessor, TUPOS-P, form a Gaussian model which resembles MPTER but offers several technical improvements. TUPOS estimates dispersion directly from fluctuation statistics at plume level and calculates plume rise and partial penetration of the plume into stable layers using vertical profiles of wind and temperature. The model user is thus required to furnish meteorological information for several heights above-ground in a separate input file.</p> <p>TUPOS can be used for short-term (hours to days) impact assessment of inert pollutants from single or multiple sources and can be expected to have greatest accuracy for locations within 10 km of the source. Although TUPOIS will make computations for receptors having any ground-level elevation, it is not intended as a complex terrain model, but rather as a model for calculations over flat or gently rolling terrain. TUPOs will optionally treat buoyancy-induced dispersion but does not include building downwash, deposition, or fumigation.</p> <p>The maximum number of point sources and the maximum number of receptor locations are easily adjusted at the time of program compilation and so have no specific limit. The program as listed in the appendix allows for 25 sources and 180 receptors.</p> <p>Output from TUPOS consists principally of tape or disk concentration files which are then analyzed and summarized by the postprocessor, TUPOS-P. An hourly concentration file is automatically created by TUPOS; the user has the option of creating a partial concentration file.</p>
