## DISCLAIMER

This report has been reviewed by the Risk Reduction Engineering Laboratory, U.S. Environmental Protection Agency, and approved for publication. Approval does not signify that the contents necessarily reflect the views and policies of the U.S. Environmental Protection Agency, nor does mention of trade names or commercial products constitute endorsement or recommendation for use.

## FOREWORD

Today's rapidly developing and changing technologies and industrial products and practices frequently carry with them the increased generation of materials that, if improperly dealt with, can threaten both public health and the environment. The U.S. Environmental Protection Agency is charged by Congress with protecting the Nation's land, air, and water resources. Under a mandate of national environmental laws, the agency strives to formulate and implement actions leading to a compatible balance between human activities and the ability of natural systems to support and nurture life. These laws direct the EPA to perform research to define our environmental problems, measure the impacts, and search for solutions.

The Risk Reduction Engineering Laboratory is responsible for planning, implementing, and managing research, development, and demonstration programs to provide an authoritative, defensible engineering basis in support of the policies, programs, and regulations of the EPA with respect to drinking water, wastewater, pesticides, toxic substances, solid and hazardous wastes, and Superfund-related activities. This publication is one of the products of that research and provides a vital communication link between the researcher and the user community.

The Waste Minimization Branch of the Risk Reduction Engineering Laboratory has instituted the Waste Reduction Assessment Program to identify, evaluate and demonstrate waste minimization opportunities in industrial and commercial operations. This report is a waste minimization assessment of a truck assembly plant.

---

E. Timothy Oppelt, Director  
Risk Reduction Engineering Laboratory

## ABSTRACT

This report summarizes work conducted at a truck assembly plant under the U.S. Environmental Protection Agency's (EPA) Waste Reduction Assessment Program (WRAP) Program. This project was funded by EPA and conducted in cooperation with the truck assembly plant.

The purposes of the WRAP Program are to identify new technologies and techniques for reducing wastes from industrial processes used by selected sites and to enhance the adoption of pollution prevention/waste minimization through technology transfer. New techniques and technologies for reducing waste generation are identified through waste minimization opportunity assessments and may be further evaluated through joint research, development, and demonstration projects.

A waste minimization opportunity assessment was performed which identified areas for waste reduction at a truck assembly plant. The study followed procedures in the EPA Waste Minimization Opportunity Assessment Manual. Although the facility has made substantial progress to date, opportunities were identified for further action. This report identifies potential options to achieve further waste minimization progress.

A number of waste generating processes were initially screened. Detailed technical evaluations were performed on wastes associated with degreasing of frame rails (chassis); spray painting; and phosphating of miscellaneous parts (E-Coat). Options identified were as follows: Option 1 – Paint Solids Dewatering and Water Recycle, Option 2 – Improve Transfer Efficiency, Option 3 – Procedural and Small-Equipment Changes, Option 4 – Reduce Paint Mix Volume, Option 5 – Minimize Contamination of Degreasing Solvent, Option 6 – Ion Exchange Recycle of Rinse Waters and Option 7 – E-Coat Line Bath Maintenance. All were evaluated during the feasibility analysis phase except for Option 3. The study concludes that the best options appear to be Option 4, Option 5, and Option 2.

## ACKNOWLEDGEMENTS

We acknowledge information provided to us by vendors of equipment and services, and the useful project guidance and review comments of the EPA Project Officer, Mary Ann Curran. Review comments were also provided by Lisa M. Brown and James S. Bridges of the EPA's Risk Reduction Engineering Laboratory, Cincinnati, Ohio.

This report was prepared for EPA's Pollution Prevention Research Branch by George Cushnie and Susan Roman of Science Applications International Corporation for the U.S. Environmental Protection Agency Contract No. 68-C8-0061.

## SECTION 1

### PROJECT OVERVIEW

#### PURPOSE

The purpose of this project was to develop waste minimization (WM) plans for a truck assembly facility using the Environmental Protection Agency's (EPA) Waste Minimization Opportunity Assessment Manual (625/7-88/003). This manual provides a systematic planned procedure for identifying ways to reduce or eliminate waste.

#### PROCEDURES

The project was initiated with a survey of the facility. This survey was also used as a starting point for applying the waste minimization assessment procedures. These procedures consist of four major steps (Figure 1): 1) Planning and Organization – organization and goal setting; 2) Assessment – careful review of a facility's operations and wastestreams and the identification and screening of potential options to minimize waste; 3) Feasibility Analysis – evaluation of the technical and economic feasibility of the options selected and subsequent ranking of options; and 4) Implementation – procurement, installation, implementation, and evaluation. This project completed the first three steps of the procedures for various manufacturing processes used at the facility.

The waste minimization opportunity assessment manual contains a set of 19 worksheets which are designed to facilitate the WM assessment procedure. Table 1 lists the worksheets, according to the particular phase of the program in which they are employed, and a brief description of the purpose of the worksheets. A selected combination of Worksheets 1 through 16 were completed for the wastestreams during this project and are contained in Appendices A, B and C.

The focus of the waste minimization procedures for this project was on spray painting, degreasing and phosphating operations.

A waste minimization opportunity assessment was conducted at the truck assembly plant by an assessment team composed of staff from the facility, EPA personnel, and EPA's contractor, Science Applications International Corporation (SAIC). The assessment phase of the project was initiated with a two-day survey conducted by engineers from SAIC. The survey focused on the collection of process and waste data and the identification of procedures for waste management. This time period was also used to interview operators and to solicit waste minimization ideas through brain storming exercises. During the survey, the assessment team completed many sections for Worksheets 2 through 11.

After completion of the survey, the SAIC team continued to collect data and information from the facility through telephone contacts. This time period was also used to verify data and to resolve any informational discrepancies. SAIC then completed the assessment and feasibility analysis phases of the WM assessment (Worksheets 10 through 16).

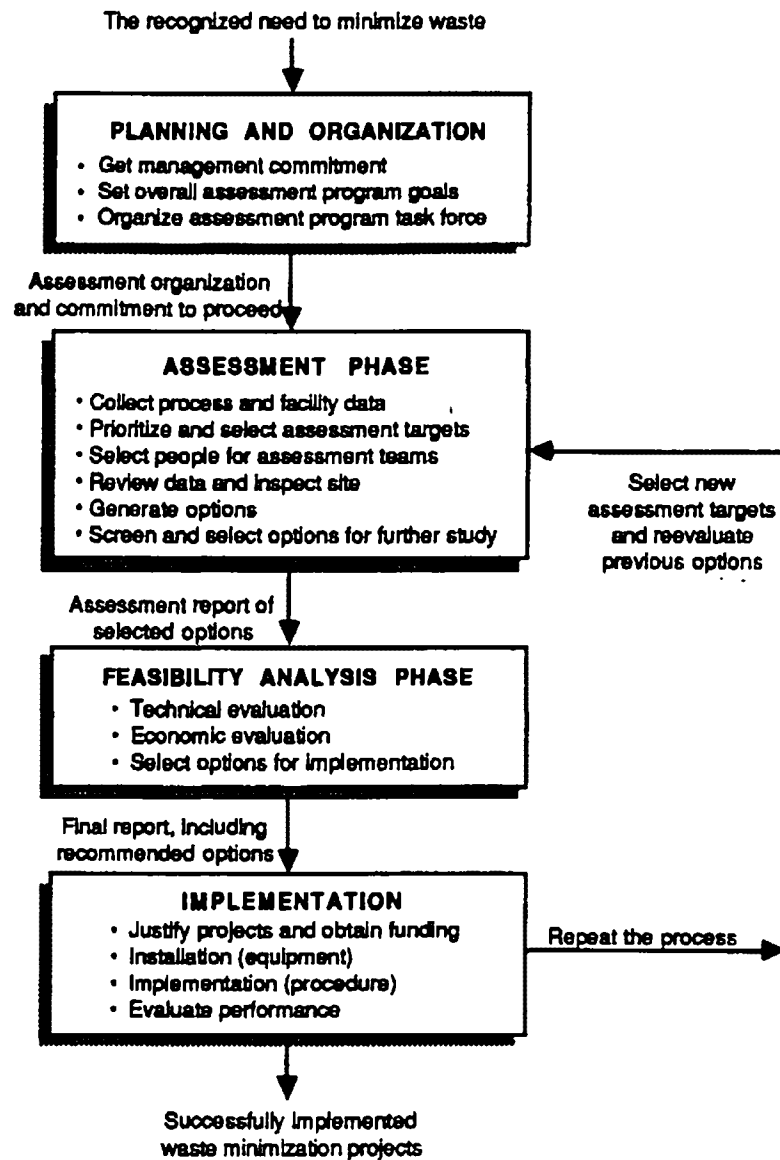

Figure 1. The Waste Minimization Assessment Procedure

**TABLE 1. LIST OF WASTE MINIMIZATION ASSESSMENT WORKSHEETS**

Phase	Number and Title	Purpose/Remarks
<b>Step 1 - Planning and Organization (Section 2)</b>	1. Assessment Overview	Summarizes the overall procedure.
	2. Program Organization	Records key members in the WMA program task force and the WM assessment teams. Also records the relevant organization.
	3. Assessment Team Make-up	Lists names of assessment team members as well as duties. Includes a list of potential departments to consider when selecting the teams.
<b>Step 2 - Assessment Phase</b>	4. Site Description	Lists background information about the facility, including location, products and operations.
	5. Personnel	Records information about the personnel who work in the area to be assessed.
	6. Process Information	This is a checklist of useful process information to look for before starting the assessment.
	7. Input Materials Summary	Records input material information for a specific production or process area. This includes name, supplier, hazardous component or properties, cost, delivery and shelf-life information, and possible substitutes.
	8. Products Summary	Identifies hazardous components, production rate, revenues, and other information about products.
	9. Individual Wastestream Characterization	Records source, hazard, generation rate, disposal cost, and method of treatment or disposal for each wastestream.

(continued)

**TABLE 1. (Continued)**

<b>Phase</b>	<b>Number and Title</b>	<b>Purpose/Remarks</b>
<b>Step 2 - Assessment Phase (continued)</b>	10. Wastestream Summary	Summarizes all of the information collected for each wastestream. This sheet is also used to prioritize wastestreams to assess.
	11. Option Generation	Records options proposed during brainstorming or nominal group technique sessions. Includes the rationale for proposing each option.
	12. Option Description	Describes and summarizes information about a proposed option. Also notes approval of promising options.
	13. Options Evaluation by Weighted Sum Method	Used for screening options using the weighted sum method.
<b>Step 3 - Feasibility Analysis Phase</b>	14. Technical Feasibility	Detailed checklist for performing a technical evaluation of a WM option. This worksheet is divided into sections for equipment-related options, personnel/procedural-related options, and materials-related options.
	15. Cost Information	Detailed list of capital and operating cost information for use in the economic evaluation of an option.
	16. Profitability Worksheet #1 Payback Period	Based on the capital and operating cost information developed from Worksheet 15, this worksheet is used to calculate the payback period.
	17. Profitability Worksheet #2 Cash Flow for NPV and IRR	This worksheet is used to develop cash flows for calculating net present value (NPV) or internal rate of return (IRR).
<b>Step 4 - Implementation</b>	18. Project Summary	Summarizes important tasks to be performed during the implementation of an option. This includes deliverable, responsible person, budget, and schedule.
	19. Option Performance	Records material balance information for evaluating the performance of an implemented option.

## ORGANIZATION OF REPORT

This report contains four sections and three appendices. Section 1 provides an overview of the project. Section 2 describes the processes surveyed during this project, and the waste management procedures employed at the facility. Section 3 presents the results of the assessment phase, including the selection of WM options. Section 4 contains the results of the feasibility analysis phase, including recommendations. Appendices A, B, and C present the WM worksheets completed for the facility. The planning and organizational worksheets (2 and 3) are contained in Appendix A. The worksheets applicable to the assessment phase (4 through 13) are presented in Appendix B. The feasibility analysis worksheets (14, 15 and 16) are contained in Appendix C.

## SECTION 2

### SITE DESCRIPTION

#### GENERAL DESCRIPTION OF THE TRUCK ASSEMBLY PLANT

This section contains a description of the site selected for this waste minimization project.

##### Facilities and Operating Procedures

The facility produces trucks and specializes in custom paint colors and designs. This facility assembles five different models. The production processes are primarily related to assembly and painting while the majority of the components of the vehicles are manufactured at other sites.

Production is done on one main assembly line which begins with the chassis (frame rails) and ends with a ready-to-start truck. Associated assembly/finishing procedures such as cab painting, door assembly, phosphating of small parts, etc., are done on small assembly lines which incorporate their finished work into the main assembly line. The assembly line is continuously moving and a tight schedule is required to produce the specified number of trucks in one 8-hour period.

##### Management and Personnel

The plant employs over 1,000 people. Production is primarily done on one shift.

#### PRODUCTION PROCESSES

The various manufacturing activities are located in a concentric manner around the main assembly line. At the outer ring, raw materials are stored outside of the building near the basic fabrication processes in which they are used. These processes in turn deliver parts to the assembly lines. The fabrication processes include cab building, trimming and painting, chassis or frame production, machining, engine preparation, and hydraulic/pneumatic line preparation (air piping). These lines feed the final assembly line.

The remainder of this section describes the production processes selected for this assessment.

##### Degreasing of Frame Rails (Chassis)

The Chassis is degreased in a booth just prior to entering the chassis paint booth. Chlorinated solvent is sprayed on using a hand held spray wand which enables workers to remove oil and grease from hard to reach areas. Solvent is also wiped onto easily accessible portions of the chassis using rags dipped into a bucket of solvent. The solvent along with the oil and grease drips off of the chassis or is blown off and evaporates from the floor. The chassis then moves into the chassis paint booth. Figure 2 is a work flow diagram of the degreasing operation.

Figure 2. Work Flow Diagram—Chassis Degreasing

Prior to 1989, the solvent used in the degreasing operation was nonhazardous and no disposal records were kept. Currently, the solvent used for chassis degreasing is formulated with 90 percent 1,1,1-trichloroethane and 10 percent methylene chloride. Early in 1989, the facility used 100 percent 1,1,1-trichloroethane. The switch in solvents was made for quality reasons.

### Spray Painting

The facility has paint booths dedicated to the painting of cabs, chassis, and for touch-up. The touch-up booths were not included in this assessment. The other booths are semi-enclosed rooms with downdraft water pit systems for capturing paint overspray.

The cab paint booths operate with painters working in each booth. Cabs are wheeled into the paint booths on carts that are moved by the automatic mechanism in the floor. They are then painted with two coats of paint. Cabs are automatically wheeled out of the booth and dried in a paint booth oven where the temperature is controlled to protect the fiberglass and plastic.

The chassis paint booth operates with painters. The frame rails (chassis) are wheeled into the paint booth. They are then painted on all sides. The chassis is then dried in a paint booth oven where the temperature is controlled to protect the fiberglass and plastic.

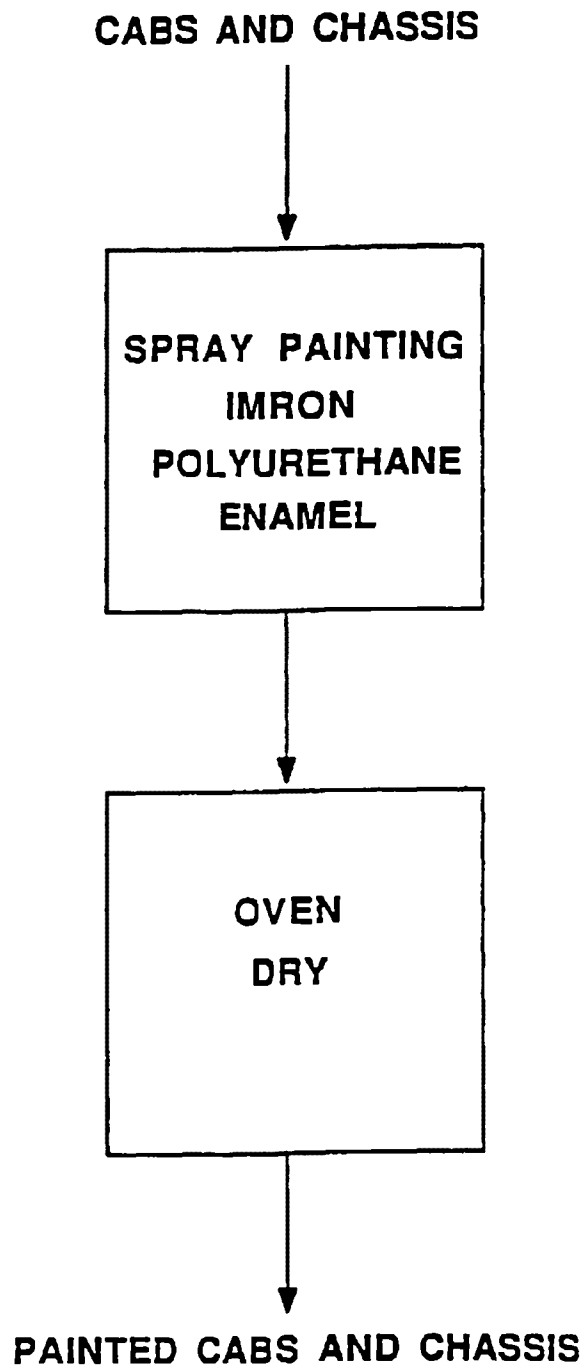

Figure 3 is a work flow diagram of the spray painting process.

The facility converted from conventional solvent paints to high solid paints on all trucks in 1989. This includes most primers and top coats for cabs and chassis paints. The decision to use high solids paints was based on the need to meet standards for volatile organic carbon (VOC) air emissions. The present permit limits the plant to 154 tons of VOC emissions per year.

Most of the paints used at this facility are solvent-based plural (two component) systems (an exception is the interior cab booth which uses a non-solvent paint). Single component solvent paints cannot be used on most of the truck assemblies because of the high usage of plastics and fiberglass in fabrication of the parts (mainly cabs). The single component paints, which are used widely in the automotive industry, require greater application temperatures which can damage the fiberglass and plastic parts.

The facility is in the process of converting from the "hot potting" method of component mixing (i.e., the two paint components are premixed in the spray painting pot) to use of equipment which allows the catalyst component to be injected and mixed at the gun during application. Paints mixed with the hot potting method have a pot life of approximately 3 hours at 72°F. With the catalyst injection system the paints have an indefinite lifespan. The leftover paint can therefore be used at a later time for touchup work. At present, the chassis booth and two cab booths are using the injection mixing.

All spray painting equipment used at the facility is the air assisted airless type. The guns in the chassis booth have been converted to high volume-low pressure guns. They operate at approximately 11 psi. Locks have been placed on the air regulators to prevent operators from using a higher pressure. The result of using lower pressures is a smaller quantity of paint overspray. The guns used in cab painting also have been modified. The painting pressures were reduced from 60 psi to 40 psi by installing new air caps. All paints are heated to reduce viscosity, which also allows for use of lower air pressures.

**Figure 3. Work Flow Diagram—Spray Painting**

### Phosphating of Miscellaneous Parts (E-Coat)

An automated phosphating (conversion coating) process and electro-coat painting (E-Coat) is employed for small and medium sized steel parts. This line consists of several processing and rinsing steps. Parts are attached to an overhead conveyor belt with hooks. They are then positioned above the process tanks by the operator who manually controls the movement of the conveyor belt. The tanks are then lifted up to the parts to immerse them in solutions. The parts are immersed for several minutes and then the tanks are lowered. Parts are allowed to drip over the tanks for several minutes and then are moved on to the next process tank. After the last step (E-Coat) the conveyor moves the parts through a drying oven and then returns the parts to the beginning of the line where the operator removes them and they are taken to the assembly areas. Figure 4 is a work flow diagram of the phosphating process. Tank 1 is an initial cleaning step which removes oil and grease and other surface contaminants from the parts. Cleaning improves paint adhesion and corrosion protection. Tank 2 is a hot rinse. Tank 3 contains disodium phosphate with titanium added as a surface activator. Tank 4 contains the zinc phosphating solution. A fluoride based chemical is added to this solution to precipitate aluminum and prevent spoiling of the phosphate bath. A pH adjustment chemical (phosphoric acid) is also added to tank 4. Tank 5 is an ambient temperature rinse. Tank 6 is a nonchromium sealer. Tank 7 is a deionized water rinse. Tanks 8, 9, and 10 contain the E-coat solution.

### WASTE GENERATION AND CHARACTERIZATION

The facility closely tracks the generation of wastes at its facility. Waste data for the years 1987 to 1989 are shown in Table 2. The facility has seen a significant decrease in the overall volume of waste generated and the associated disposal and transportation costs. The purpose of this project was to develop waste minimization options that can further reduce the volume of waste generated. This project has focused on the wastes generated during spray painting, degreasing (chassis) and phosphating (E-Coat) operations.

Table 2 lists eight industrial wastes generated at the plant, five of which are hazardous by EPA standards.

The production processes and wastestreams were coded during the project to provide a means of identification throughout the WM assessment. Table 3 provides a description of the code system. Processes are coded 01 through 03. Wastestreams are coded A through H. Process codes are combined with waste codes to identify specific wastestreams. The wastes selected for this assessment are listed in Table 4 and described in the following subsections.

### Degreasing of Frame Rails (Chassis) Wastes

The chassis is degreased in a booth prior to entering the chassis paint booth. A chlorinated solvent is used because of the immediate drying action and VOC emissions. The solvent is both sprayed and wiped on the chassis. The waste generated during degreasing comes from the wiping process. The rags are dipped into a bucket of solvent and used to wipe down the chassis. When not in use, the rags are left soaking in the solvent, which becomes contaminated with oil and grease from the dirty rags and is dumped into a drum to await disposal. The dirty rags are sent to an industrial laundry (Simco) and are reused at the facility.

Early in 1989, 100 % 1,1,1-trichloroethane was used as the degreasing solvent. During the course of 1989 a switch to 90 % 1,1,1-trichloroethane/ 10 % methylene chloride solvent was made for quality reasons. The switch to a combined solvent has increased the disposal cost by a factor of four, while the quantity of waste solvent generated has increased by a factor of 1.4.

\* Onsite pretreatment produces a sludge which is sent to a hazardous waste landfill. The treated water is discharged to a publicly owned treatment works (POTW).

### Spray Painting Wastes

The two major spray painting processes include the painting of cabs and frame rails (chassis). The wastes generated during spray painting operations include: paint waste (liquid and solid), detackified paint, and paint booth water. A description of each waste follows.

Paint wastes include: 1) unused spray paint (approximately one-third of total), and 2) still bottoms from the distillation of cleanout solvent (approximately two-thirds of total). Paint is prepared daily in the paint mix room, where colors are added, and then taken to the cab paint booths for use. Unused spray paint is returned to the paint mix room and placed into drums to which 5 gal of ethyl alcohol was previously added. The ethyl alcohol neutralizes the paint catalyst. The solution is constantly agitated to prevent solidification of the paint solids. This material is shipped offsite to a fuel blending operation at a cost of \$20 per drum. Previously, the unused spray paint was allowed to harden in the drum. This material was incinerated at a cost of \$450 per drum. This change in disposal practice is reflected in the annual costs of disposal.

The still bottoms are generated from the operation of a recovery still. Wash solvent (Solvent 2506) is used to clean out the paint guns and lines when switching from one paint color to another. The dirty wash solvent is pumped to an onsite distillation unit to be distilled for reuse. Generally, 350 to 400 gal of dirty solvent is distilled each day. This generates still bottoms at a rate of 1 to 2 drums per day. The volume of waste solvent generated has decreased during the past several years. This is due primarily to a change in the cleanout process. Previously the paint line was placed into the solvent container and pumped through at 14 oz/min. With the new system, solvent is introduced at 60 psi and air is injected. The air improves the efficiency of the cleanout process and reduces the volume of solvent required. From 1987 to 1989 the cost of disposal of paint wastes and still bottoms has decreased 82% (Table 2), although the quantity of these wastes during that time period actually increased.

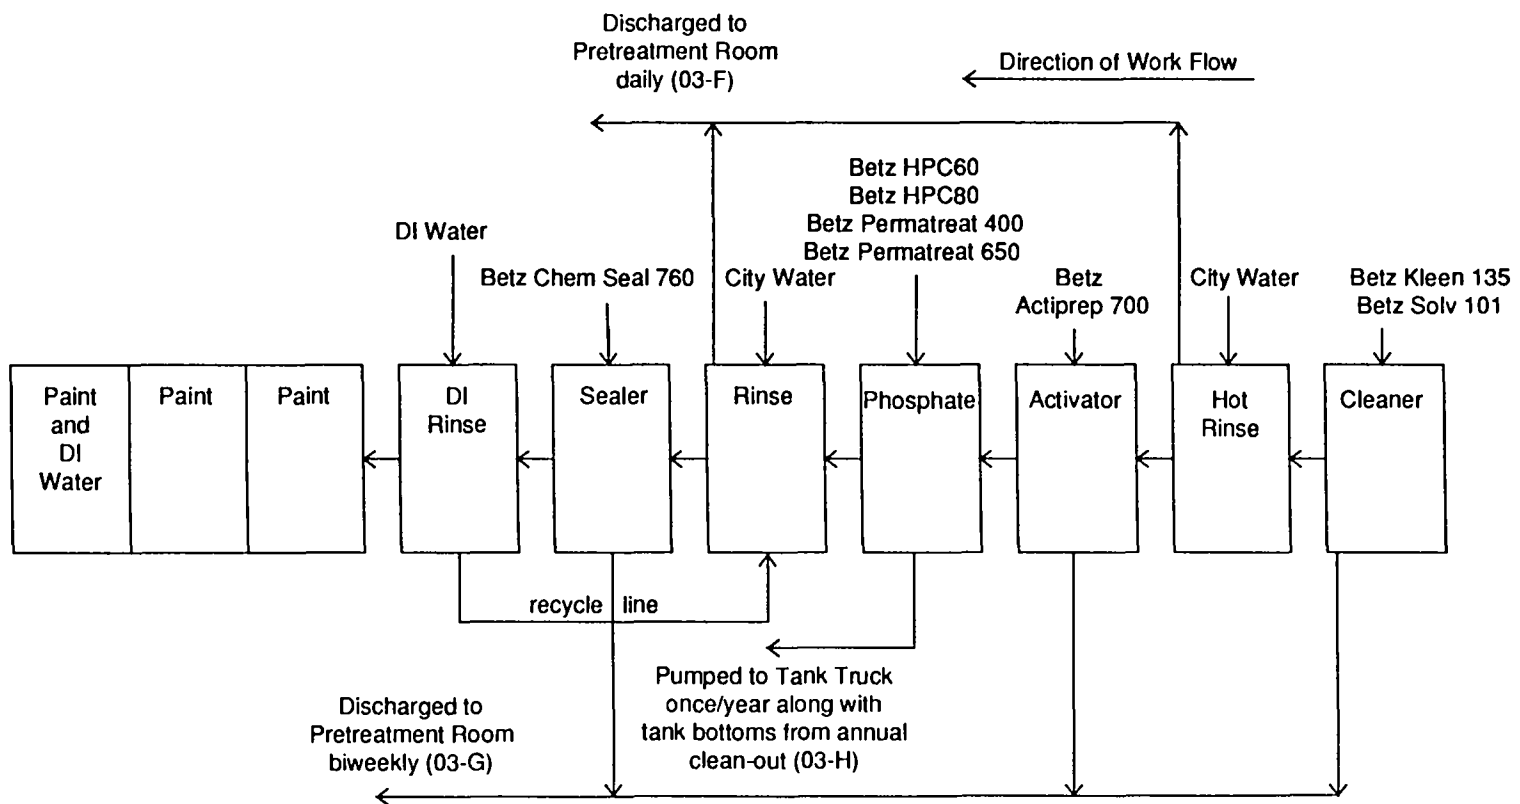

The detackified paint waste is the residual paint overspray which accumulates in the water reservoirs of the downdraft water booths. The paint booths are equipped with water curtains to collect paint overspray. Hydrocyclones are used at several of the booths to remove a portion of the paint solids each day. Each hydrocyclone generates 1/4 to 1 drum of detackified paint waste (20% solids) each day. A portion of the paint booth water (3,000 gal) is discharged daily to the onsite pretreatment system. Approximately every 4 to 6 weeks the detackified paint that has accumulated in the pits of each paint booth is pumped to a tank truck. These cleanouts generate a relatively wet (10% solids) paint sludge.

The water in the paint booth reservoirs is treated chemically to cause the detackification of the paint and to improve the operation of the system. The chemical treatment includes: 1) pH control (9.0 to 9.5), 2) addition of a cationic polymer and aluminum chloride to detackify the paint, 3) a foam controlling agent containing mineral oil to prevent foam from reaching electrical connections at the system pumps, and 4) a biocide to prevent the growth of bacteria which cause odors.

### Phosphating of Miscellaneous Parts (E-Coat) Wastes

The E-Coat process generates wastes in the form of spent process solutions, contaminated rinse waters and tank bottoms. Figure 5 illustrates the wastestreams generated and their disposal frequency for the E-Coat process.

**Figure 5. Wastestream Diagram of Phosphating (E-Coat) Operation**

Contaminated rinse waters from tanks 2, 5, and 7 are discharged continuously during use to the pretreatment unit. Spent process solutions (Cleaner, Activator and Sealer) are drained and discharged to pretreatment every two weeks. Annually, all of the tanks in the E-Coat line are cleaned. This is done by pumping the tanks to temporary storage and removing the tank bottoms to a tank truck. The phosphate bath is hauled away with the tank bottoms during the annual cleaning.

Pretreatment sludge is generated by operation of the wastewater treatment system which treats wastewater from the paint booths and the phosphating/E-coat line. The system is a ferric chloride/caustic soda flocculation/precipitation process. Sludge from the clarification step is dewatered on a filter press to approximately 35% solids. The sludge (F019 RCRA waste) is sent to a hazardous waste landfill for disposal in bulk shipments. The treatment system generates approximately 10 to 12 tons of sludge every 90 days.

## WASTE MINIMIZATION

The processes selected for this assessment, along with their wastestreams are summarized in Table 4. Current waste minimization techniques and waste disposal practices have enabled them to decrease both the volume of wastes and costs of waste disposal (Table 2) for their facility. The present methods of waste management used are presented in this section.

The quantities of wastes generated in 1989 for the spray painting, degreasing and phosphating operations are listed in Table 5 along with their associated disposal costs. Where the facility was unable to supply specific numbers, quantities were estimated on the basis of waste generation data collected during this assessment. In general, this facility sends smaller quantities of hazardous waste off-site than many other facilities with similar production levels. The waste disposal cost per truck produced in 1989 was approximately \$7.03 which is a significant reduction from the cost of \$31.05 per truck in 1987.

This facility has made major strides in waste minimization over the past two years. These efforts have focused on the following areas:

- Changes in paint formulation
- Changes in spray painting equipment
- Implementing operator controls and training
- Changing painting system cleanup procedures and equipment
- Adding dewatering units to spray paint booths
- Improving paint booth reservoir chemistry for detackifying overspray
- Reducing waste paint generation by minimizing the volumes mixed.

The next section of this report will focus on ways that waste generation can be further reduced.

**TABLE 5. WASTES GENERATED IN 1989 FROM SPRAY PAINTING, DEGREASING  
AND PHOSPHATING PROCESSES**

Wastestream	Stream Code	Annual Generation	Unit Cost for Disposal	Disposal Cost*
Waste Paint - Liquid (includes still bottoms from distillation unit)	01-A	213,142 lb	\$ .027/lb	\$5,821
Waste Paint - Solid	01-B	11,218 lb	\$ .778	\$8,731
Detackified Paint	01-C	523,000 lb	\$ .032/lb	\$16,647
Paint Booth Water	01-D	780,000 gal	\$2.20/1,000 gal <sup>†</sup>	\$1,716
Degreasing Solvent	02-E		\$0.53/lb	\$10,731
Rinse Waters	03-F	20,210 lb	\$2.20/1,000 gal <sup>†</sup>	\$1,122
Spent Process Solutions (Cleaner, Activator and Sealer)	03-G	510,000 gal	\$2.20/1,000 gal <sup>†</sup>	\$96
		43,680 gal		
Phosphate Bath and Tank Bottoms	03-H	2,780 gal	\$ .24/gal	\$667
Total Disposal Cost for Selected Wastes				\$45,531

\* Disposal costs include, where applicable, the onsite chemical treatment costs, transportation costs, and offsite treatment/disposal costs.

<sup>†</sup> These wastewaters are sent to the pretreatment system and then discharged to the POTW. The pretreatment process also generates a sludge from the treatment of these waters that is sent to a hazardous waste landfill.

## SECTION 3

### SUMMARY OF ASSESSMENT PHASE

The assessment phase of the waste minimization procedure includes data collection, selection of target areas, data review, and options generation and screening. The applicable worksheets are 4 through 13 (Appendix B). Table 6 lists the 8 wastestreams that were included in this assessment. The volume, characteristics, raw material costs and applicable waste minimization options are shown for each wastestream. The waste minimization options were developed jointly by the assessment team.

The WM screening process consists of a relative comparison of WM options using standard criteria presented in the WM Assessment Manual. This screening exercise is presented on Worksheet 13 and the results are summarized on Table 7. The criteria include various measures of waste minimization impacts relating to safety, cost, ease of implementation, and other relevant factors. Scores for individual WM options are determined by multiplying a weight factor, W, (1 to 10) for each criteria by a score (1 to 10) or measure (termed R-value) for how well each WM option satisfies each criteria ( $\text{Score} = R \times W$ ). Then, the scores for each WM option are summed over all criteria to produce a single score for each WM option. As indicated in Table 7, the scores for the identified options range from 348 to 487.

The weighted values (W) for each criteria were based on the goals of the waste minimization program. The measures for each option (R-value) were estimated by the assessment team. Where possible, these estimates were quantified (e.g., costs) and converted to R-values. For other measures, which could not be quantified, the R-values were estimated by the assessment team members through data review and discussion.

The result of the assessment phase was the selection of seven waste minimization options for further evaluation in the feasibility analysis phase (Section 4).

This section contains general descriptions of waste minimization technologies that are applicable to most truck assembly facilities. It also contains a description of the specific waste minimization options that were identified and evaluated during the assessment phase.

#### WASTE MINIMIZATION OPTIONS

The option generation step of the project (Worksheet 11) identified seven options that were considered to be potentially applicable. Options 1 and 6 relate to the use of water conservation measures with respect to paint booth water and rinse waters. Options 2 through 4 involve the reduction of waste paint generation using specialized equipment and monitoring procedures. Option 5 involves the reduction of waste solvent by avoiding contamination of fresh solvent. Option 7 involves the recycling of process solutions. Each of the seven options is briefly described in this section.

**TABLE 6. SUMMARY OF WASTE MINIMIZATION ASSESSMENT PHASE**

<b>Process/Wastestream Name/ID</b>	<b>Annual Waste Quantity</b>	<b>Value of Input Materials, \$/yr.</b>	<b>WM Options</b>
Spray Painting/Waste Paint - Liquid/01-A	213,142 lb	\$929,360	2, 3,4
Spray Painting/Waste Paint - Solid/01-B	12,280 lb	\$58,897	2, 3, 4
Spray Painting/Detackified Paint/01-C	523,100 lb	\$125,444	1, 2
Spray Painting/Paint Booth Water/01-D	780,000 gal	\$939	1, 2
Degreasing/Degreasing Solvent/02-E	20,210 lb	\$12,116	5
Phosphating/Rinse Waters/03-F	510,000 gal	\$614	6
Spent Process Solutions (Cleaner, Activator and Sealer)/03-G	43,680 gal	\$6383	7
Phosphating/Phosphate Bath and Tank Bottoms/03-H	2,780 gal	\$2,333	--

**TABLE 7. SUMMARY OF WASTE MINIMIZATION OPTIONS**

<b>Waste Minimization Option</b>	<b>Waste Option</b>	<b>Applicable Wastestreams</b>	<b>WM Option Screening Score</b>
Belt Filter	1	01-C, 01-D	348
Transfer Efficiency	2	01-C, 01-D	423
Procedural/Small Equipment Changes	3	01-A, 01-B	377
Reduce Paint Mix Volumes	4	01-A, 01-B	462
Maintain Solvent Segregation	5	02-E	487
Ion Exchange/Recycle of Rinse Waters	6	03-F	387
E-Coat Line - Bath Maintenance	7	03-G	373

### Option 1 - Paint Solids Dewatering and Water Recycle

Detackified paint that has built-up in the paint booth reservoirs over a period of four to six weeks is pumped directly to a tank truck and hauled to a disposal site. The detackified paint has a high water content (up to 95%) which increases disposal costs that are based solely on volume. The dewatering of this detackified paint can significantly reduce the cost of disposal by reducing the volume of waste sent to disposal. Further, recycling of the booth water will reduce water usage and extend the period between required draining and cleaning of the booths, thus reducing production downtime and booth chemical usage.

The dewatering process can be accomplished with the use of a belt filter (see Appendix C for cost information). The belt filter is an automatic gravity filtration system that typically uses a disposable fabric as the filter media. The detackified paint will be pumped from the paint booth to the belt filter. The fabric media filters out the paint solids and other debris while the water passing through is recycled to the paint booth reservoir. The detackified paint is rolled off of the filter into a drum to await disposal.

Belt filters are available with different filter areas to obtain the desired flow rate. Fabric media is chosen according to the type of filtration desired.

### Option 2 - Improve Transfer Efficiency

Transfer efficiency refers to the percentage of paint that leaves the paint gun and is actually deposited on the part's surface. A higher transfer efficiency means more paint is reaching the finished part. Two types of spray painting equipment that have high transfer efficiencies are high volume-low pressure (HVLP) (up to 90% efficiency) and electrostatic (up to 75% efficiency). The facility currently uses HVLP in their chassis paint booth (11 psi) and have obtained a transfer efficiency of approximately 50%. The cab painting equipment is air assisted airless. Previously, it was operated at 60 psi. By modifying the air caps, the facility has reduced operating pressure to 40 psi and have achieved improved transfer efficiency. It is unclear whether further increases in efficiency are technically feasible for cab painting. It may, however, be possible to further increase chassis painting efficiency by installing electrostatic spray painting. The facility has done some preliminary tests at the plant with electrostatic spray painting and achieved positive results. This change was therefore evaluated under this option. An improved transfer efficiency would decrease raw material costs, decrease the volume of paint solids resulting from overspray, decrease paint booth maintenance, and reduce VOC emissions.

### Option 3 - Procedural and Small-Equipment Changes

The facility is currently investigating a variety of procedural and small-equipment changes which will improve their waste minimization efforts for the spray painting operations. The following is a discussion of each change.

#### **Shipping Unused Paint With the Finished Truck--**

Small volumes (<1 gal) of unused paint are generated from the cab painting operation. Many of the cabs are custom painted and the unused paint is usually not immediately reusable and therefore is discarded. This change involves packaging the unused paint in a suitable container and shipping it with the truck for later use by the customer for needed touch-ups. Before implementation, regulatory constraints governing this option will be evaluated.

#### Adjusting the Production Schedules to Reduce Color Changes--

After painting each truck cab, the painting system must be cleaned out unless the same color is used for the subsequent truck. At present, some consideration is given to the painting sequence when the overall production schedule is developed. However, some improvement is still possible. This change involves giving greater consideration to the painting sequence. This change is considered valid since the waste generation rate from painting is so closely tied to the number of clean-outs. Further, this is the only process whose waste generation rate is related to the production sequence.

#### Installation of Control and Monitoring Devices and Alarms on Painting Systems--

The transfer efficiencies of the spray painting operations are operator dependent and are partly related to the air pressures used. High pressures generally reduce the transfer efficiency and therefore increase waste generation. Operators of spray painting equipment often use higher than necessary air pressures because the higher pressures reduce painting time. This change involves the use of: 1) controls on the painting system to reduce the maximum air pressure level, 2) digital displays of the air pressure being used which are visible by the foremen, and 3) high pressure alarms. These equipment changes will provide greater control over the painting operation.

Another device that could be used is a microprocessor control for paint flow. These devices closely control the flow rate of paint and can be expected to increase transfer efficiency.

One alternative to these changes is the use of robot painting systems. Such systems are used extensively by automobile manufacturers. However, their application is questionable because of the lower production rate and the wide range of cab designs. Also robot systems are relatively expensive and their use cannot be economically justified by the savings from potential waste generation.

#### Painting Details Over Background Colors--

Many of the trucks produced are custom painted. The painting designs often include details such as stripes. Currently, when stripes are ordered, the cab is entirely painted with the color of the stripe. The stripe is then masked and the cab is repainted with the general or "background" color. This procedure is used because it requires less masking, which is labor intensive.

Changing this procedure by reversing the sequence would significantly reduce the volume of paint sprayed and therefore the waste produced by overspray. The higher masking costs may be justified when considering both the raw material costs for paint and the disposal costs for related wastes.

#### Option 4 - Reduce Paint Mix Volume

Paints for cab painting are custom mixed using an automated device in the paint mix room and given to the painters prior to the painting of each cab. The volume of paint mixed is recorded in a computer data base by the operator in the paint mix room. The volume of paint mixed depends on: 1) the truck models which vary in painted area, and 2) the type of paint, since coverage varies between paints. After painting is completed, the painters return the unused paint to the mix room where it is discharged into drums. The unused volume is recorded in the data base. A review of the data base indicates that the average unused portion of paint can be reduced.

Option 4 involves more extensive use of the painting data base to reduce paint mix volumes and resultant waste paint volumes. This can be accomplished by using the computer software to generate statistical analyses of paint mix and waste volumes for different truck models and paint types.

Implementation of this option is expected to reduce raw material costs (paint) and waste disposal costs (unused paint).

#### Option 5 - Minimize Contamination of Degreasing Solvent

This option involves a minor equipment and a procedural change to prevent the contamination of solvent during the wiping process used to degrease frame rails (chassis). Currently, operators use solvent soaked rags which are rinsed and stored in the solvent container (bucket). When the solvent in the bucket becomes overly contaminated with oil, grease, and dirt, it is discarded into a drum to await disposal.

To reduce the volume of solvent discarded, the solvent bucket should be eliminated. The bucket should be replaced with a container that delivers a volume of solvent by hand pumping and has a secure lid to prevent the operators from rinsing rags in the fresh solvent. Once used, the rags should be wrung-out over a waste solvent container and fresh solvent would then be pumped onto the rag.

This option may require that the rags are changed more frequently, because the rinsing step currently used would no longer be available. These rags are currently recycled through an industrial laundry, and therefore additional wastes are not expected from this practice.

#### Option 6 - Ion Exchange with Recycle of Rinse Waters

The zinc phosphate/E-Coat line consists of several processing and rinsing steps. There are three rinse tanks: one hot rinse, one ambient temperature rinse, and one distilled water (DI water) rinse. The rinse tanks are fed on a continuous basis and discharged to a sewer line that conveys the wastewater to the pretreatment system. At the pretreatment system, the wastewater is combined with paint booth water and is chemically treated. The resultant sludge is considered a listed hazardous waste (FO19 - waste water treatment sludge from chemical conversion coating) by the State regulatory agency. Spent chemicals from the phosphate line are also discharged to the pretreatment system, with the exception of the phosphate solution which is hauled to disposal.

This option involves the use of an ion exchange (anion and cation columns) recycle system. The rinse waters discharged to the sewer would be treated by the system and recycled to the phosphating line on a continuous basis.

The system would reduce water use by recycling. The system may also reduce the volume of sludge generated by the pretreatment system. The pretreatment process currently includes the use of ferric chloride in the flocculation/precipitation system. Ferric chloride is occasionally used in systems where metal complexes are present as a result of phosphating chemicals. It is also applicable to oily wastes such as those discharged from paint booth reservoirs. Use of the ferric chloride results in high sludge volumes since the iron is precipitated as hydroxide. The ion exchange system may reduce the use of ferric chloride by 1) breaking the phosphate complex and 2) by reducing the hydraulic loading of the pretreatment system. The heavy metals, such as zinc, will be retained on the cation column and the anions such as phosphate, will be retained on the anion column. The regenerant from the cation column will contain regulated metals and would require pretreatment before discharge. The regenerant from the anion column may not contain any regulated pollutants and it may be possible to discharge it following simple neutralization, thus eliminating it from the treatment process.

Prior to implementing this option, the facility should conduct treatability tests to select the optimal ion exchange resins and to determine its impact on the ferric chloride requirements.

#### Option 7 - E-Coat Line Bath Maintenance

The process solutions contained in tanks 1 (cleaner), 3 (surface activator), and 6 (non-chromium sealer) are discarded approximately every two weeks and reformulated with fresh chemicals. The discarded solutions are drained to the treatment system. Concentrated wastewaters such as these can be expected to require a significant volume of chemical reagents for treatment and result in high sludge volumes. This option involves the use of filtration devices to remove undissolved contaminants and maintain the solution in working condition for an extended time period.

## SECTION 4

### FEASIBILITY ANALYSIS RESULTS

#### SUMMARY OF FEASIBILITY ANALYSIS PHASE

The purpose of the feasibility analysis phase is to prepare a technical and economic evaluation of the WM options and to select options for implementation.

The technical feasibility evaluation initially determines the nature of the WM options, either equipment-related, personnel/procedure-related, or materials-related. For each of the three types of WM options, specific information and data are required. For equipment-related options, the information requirements relate to the state of the technology, availability of equipment, performance specifications, testing, space and utilities, production effects, and training. For personnel/ procedure-related options the required information relates to training and operating instruction changes. For materials-related options, the required information relates to production impacts, storage and handling, training and testing.

The WM options evaluated during this project include five equipment-related options, one personnel/procedure-related option, and one materials-related option. The technical evaluation for each option is detailed on Worksheet 14.

The economic feasibility evaluation includes a cost analysis of both capital and operating costs. Capital costs include equipment, materials, utility connections, site preparation, installation, engineering, start-up, and training.

The operating costs include increases and decreases (cost savings) of utilities, disposal fees, raw materials, labor, and revenues from recovered products. Insurance and liabilities costs were not included in the operating cost calculation, since these costs were undetermined during the project. Also, onsite handling costs which are usually very significant were not included. Therefore, the projected savings that were calculated during this project, understate the actual potential savings.

#### RECOMMENDATIONS

The technical and economic results of the feasibility analysis phase are summarized in Table 8. This table indicates for each option, the total capital investment, the net operating cost savings and the payback period (total capital investment/net operating cost savings).

To further evaluate the relative benefits of each option, the options have been ranked (1 for the best to 7 for the worst) with respect to the net operating cost savings and the payback period. These rankings were then summed for each option and compared among all options and a final ranking was determined (1 for the best to 7 for the worst). These comparisons are shown in the final column in Table 8. Using these two criteria heavily weights the evaluation in terms of annual cost savings since both criteria contain annual costs factors. Other techniques for comparing options may also be valid. Worksheet 17 (Appendix C) is an alternative method, which calculates profitability based on cash flow.

**TABLE 8. SUMMARY OF WASTE MINIMIZATION FEASIBILITY ANALYSIS PHASE**

Process & Wastestream	Waste Minimization Option	Nature of WM Option	Capital Investment (\$)	Net Op. Cost Savings (\$/yr)	Payback Period (yr)	Rank Low to High (1-6)
<b>Spray painting:</b>						
Waste paint (01-A, 01-B)	2	Improve transfer efficiency	27,456	152,698	0.2	2
	3	Procedural/small-equip.	Unk.*	Unk.*	Unk.*	NA
	4	Reduce paint mix volumes	2,725	26,315	0.1	1
Detackified paint (01-C)	1	Paint solids dewatering	11,151	14,998	0.7	4
	2	Improve transfer efficiency				---
Paint booth water (01-D)	1	Paint solids dewatering				---
	2	Improve transfer efficiency	---	---	---	---
<b>Degreasing of frame rails (Chassis):</b>						
Degreasing solvent (02E)	5	Minimize solvent contamination	466	17,219	<0.1	2
<b>Phosphating of misc. parts (E-Coat)</b>						
Rinse waters (03F)	6	Ion exchange recycle	45,500	19,311	2.4	4
Spent process solutions (cleaner, activator and sealer)(03-G)	7	Bath maintenance	13,200	3,332	4.0	6

- \* The investment and projected savings for the procedural/small-equipment changes (Option 3) were not determined during the feasibility analysis phase. However, the majority of minimization techniques which make up this option are expected to be implemented by the facility.

The relative comparison used in this study indicates that the best options appear to be: Option 4—reducing paint mix volumes through closer control, Option 5—minimizing solvent contamination by using a different working container and procedures and Option 2—improving transfer efficiency by installing electrostatic painting in the chassis booth. Two options ranked with moderately good scores: Option 1—dewatering paint solids and recycling the booth waters and chemicals and Option 6—using ion exchange to recycle the phosphate/E-coat rinse waters. Option 7—bath maintenance on the phosphate/E-coat line ranked last; however, it is still within a reasonable range. Option 3—procedural and small equipment changes for painting was not evaluated during the feasibility analysis phase because the costs and savings could not be projected at this time. The Option 3 waste minimization techniques however appear to be technically and economically viable.

Some testing is needed before implementation of several of the options. For Option 1, testing should focus on determining if recycle can significantly reduce booth chemical use. A conservative assumption was made during the analysis that a 10% reduction is possible. For Option 2, the facility should contact electrostatic paint equipment suppliers and request an on-site demonstration. For Option 6, bench scale testing and possibly pilot scale testing is needed to determine the most suitable ion exchange resins. Testing is also needed to evaluate the impact of recycle on the current pretreatment process since a significant portion of the savings projected for this option relate to a reduction of treatment reagent use and sludge generation. Bath maintenance (Option 7) can be evaluated using simple cartridge filtration devices to remove solids from one of the process tanks (e.g., tank 1).

INDIVIDUAL WASTE STREAM  
CHARACTERIZATION

(continued)

Waste Stream Waste Paint-Liquid

6. Waste Origins/Sources

Fill out this worksheet to identify the origin of the waste. If the waste is a mixture of waste streams, fill out a sheet for each of the individual waste streams.

Is the waste mixed with other wastes? ☐ Yes ☒ No

Describe how the waste is generated.

Paint is prepared daily in the paint mix room and taken to the cab paint booths. Any leftover paint from the cab paint booths is returned to the paint mix room and placed in a drum for waste paint. The frame rail (chassis) paint booth has a bulk spray system for black paint which should produce no waste paint. However, when a chassis is painted any other color the paint is prepared in the paint mix room and any left over paint is put in a drum in the chassis paint booth. The paint is kept liquid with the addition of ethanol which neutralizes the catalyst in the paint.

Example: Formation and removal of an undesirable compound, removal of an unconverted input material, depletion of a key component (e.g., drag-out), equipment cleaning waste, obsolete input material, spoiled batch and production run, spill or leak cleanup, evaporative loss, breathing or venting losses, etc.

6. Waste Origins/Sources

Fill out this worksheet to identify the origin of the waste. If the waste is a mixture of waste streams, fill out a sheet for each of the individual waste streams.

Is the waste mixed with other wastes? ☐ Yes ☒ No

Describe how the waste is generated.

Waste paint from the cab paint booths and the chassis paint booth is stored in 55 gal. drums to await disposal. These drums are pumped into a tank truck. Any solidified paint in the bottom of the drums is scrapped out and consolidated into another 55 gal. drum for disposal.

Example: Formation and removal of an undesirable compound, removal of an unconverted input material, depletion of a key component (e.g., drag-out), equipment cleaning waste, obsolete input material, spoiled batch and production run, spill or leak cleanup, evaporative loss, breathing or venting losses, etc.

6. Waste Origins/Sources

Fill out this worksheet to identify the origin of the waste. If the waste is a mixture of waste streams, fill out a sheet for each of the individual waste streams.

Is the waste mixed with other wastes? ☐ Yes ☒ No

Describe how the waste is generated.

The cab paint booths and the chassis paint booth have a water curtain to collect paint overspray. Each booth has its own pit for the collection of the water, and detackification of the paint. A paint sludge builds up in the pits and is collected on an as is needed basis.

Example: Formation and removal of an undesirable compound, removal of an unconverted input material, depletion of a key component (e.g., drag-out), equipment cleaning waste, obsolete input material, spoiled batch and production run, spill or leak cleanup, evaporative loss, breathing or venting losses, etc.

Waste Stream Paint Booth Water

6. Waste Origins/Sources

Fill out this worksheet to identify the origin of the waste. If the waste is a mixture of waste streams, fill out a sheet for each of the individual waste streams.

Is the waste mixed with other wastes? ☒ Yes ☐ No

Describe how the waste is generated.

The cab paint booths and the chassis paint booth each have a water curtain to collect paint overspray. The water becomes contaminated with the oversprayed paint and solvent.

Example: Formation and removal of an undesirable compound, removal of an unconverted input material, depletion of a key component (e.g., drag-out), equipment cleaning waste, obsolete input material, spoiled batch and production run, spill or leak cleanup, evaporative loss, breathing or venting losses, etc.

INDIVIDUAL WASTE STREAM  
CHARACTERIZATION

(continued)

Waste Stream Degreasing Solvent

6. Waste Origins/Sources

Fill out this worksheet to identify the origin of the waste. If the waste is a mixture of waste streams, fill out a sheet for each of the individual waste streams.

Is the waste mixed with other wastes? ☐ Yes ☒ No

Describe how the waste is generated.

The chassis is degreased in a booth just prior to entering the chassis paint booth. A chlorinated solvent is used because of the immediate drying action and VOCs. The solvent is both sprayed and wiped on to the chassis. The waste comes from the wiping process. Rags are dipped into buckets of solvent and used to wipe down the chassis. The solvent in the bucket becomes contaminated with the dirty rags that are dipped repeatedly into the bucket.

Example: Formation and removal of an undesirable compound, removal of an unconverted input material, depletion of a key component (e.g., drag-out), equipment cleaning waste, obsolete input material, spoiled batch and production run, spill or leak cleanup, evaporative loss, breathing or venting losses, etc.

6. Waste Origins/Sources

Fill out this worksheet to identify the origin of the waste. If the waste is a mixture of waste streams, fill out a sheet for each of the individual waste streams.

Is the waste mixed with other wastes? ☒ Yes ☐ No

Describe how the waste is generated.

The E-Coat process is a series of 10 dip tanks. Tanks 2, 5 and 7 contain rinsewaters. Tank 7 is made up of DI water and is recycled to tank 5 which is made up of city water and DI water. Tank 2 contains only city water. Tanks 2 and 5 are continuous overflow rinses and are discharged to the plants waste treatment system.

Example: Formation and removal of an undesirable compound, removal of an unconverted input material, depletion of a key component (e.g., drag-out), equipment cleaning waste, obsolete input material, spoiled batch and production run, spill or leak cleanup, evaporative loss, breathing or venting losses, etc.

6. Waste Origins/Sources

Fill out this worksheet to identify the origin of the waste. If the waste is a mixture of waste streams, fill out a sheet for each of the individual waste streams.

Is the waste mixed with other wastes? ☒ Yes ☐ No

Describe how the waste is generated.

The solution in the process tanks 1,3, and 6 becomes contaminated with oil & dirt from parts being dipped in them. Dragout from intermediate rinses dilutes the solutions and they need to be replenished.

Example: Formation and removal of an undesirable compound, removal of an unconverted input material, depletion of a key component (e.g., drag-out), equipment cleaning waste, obsolete input material, spoiled batch and production run, spill or leak cleanup, evaporative loss, breathing or venting losses, etc.

6. Waste Origins/Sources

Fill out this worksheet to identify the origin of the waste. If the waste is a mixture of waste streams, fill out a sheet for each of the individual waste streams.

Is the waste mixed with other wastes? ☐ Yes ☒ No

Describe how the waste is generated.

The quality of the phosphate bath is maintained throughout the year with the addition of chemicals. The entire bath is replaced every one to two years or as needed at the operators discretion. This waste is usually mixed with the sludge from the tank bottoms in the E-Coat System. All of the tanks in the E-Coat system are cleaned once per year.

Example: Formation and removal of an undesirable compound, removal of an unconverted input material, depletion of a key component (e.g., drag-out), equipment cleaning waste, obsolete input material, spoiled batch and production run, spill or leak cleanup, evaporative loss, breathing or venting losses, etc.

OPTION GENERATION

Meeting format (e.g., brainstorming, nominal group technique): Informal

Meeting Coordinator: G. Cushnie

Meeting Participants:

The Truck Assembly Plant - EPA Contractor - SAIC, Chemical Supplier - Betz Metchem

LIST SUGGESTED OPTIONS	RATIONALE / REMARKS ON OPTION
1. In-house dewatering of the dewatered paint with recycle of the water;	1. Reduces volume of sludge sent to the landfill
2. Sludge dryers	2. Reduces volume of sludge sent to the landfill
3. Inject paint catalyst as paint is sprayed	3. Recently implemented in one of the cab paint booths, keeps unused paint liquid so it can be used later
4. Ship leftover paint (custom colors) with the finished truck	4. Customers often request touch-up paint/must meet DOT regulations for shipping
5. Electrostatic Spray System	5. Increases transfer efficiency and reduces over-spray/Preliminary testing of this type of equipment has already been done increases price of spray guns and requires a power pack for each painter
6. Vapor-Injection-Curing	
7. Change painting procedures so that custom	7. Reduces VOCs, reduces amount of paint used/

OPTION GENERATION

Meeting format (e.g., brainstorming, nominal group technique): Informal

Meeting Coordinator: G. Cushnie

Meeting Participants:  
The Truck Assembly Plant - EPA Contractor - SAIC, Chemical Supplier - Betz Metchem

LIST SUGGESTED OPTIONS	RATIONALE / REMARKS ON OPTION
designs don't require the entire part to be painted the color of a stripe or design first before the maincab color is painted over it	Increase masking time
9. Install lock regulators on spray painting guns-	9. Lower air pressure reduces the amount of paint overspray/Spray guns in the Chassis Paint Booth currently have lock regulators
10. Closer regulation of paint mixed versus paint sprayed	10. the paint mixed in the paint mix room is returned unsprayed/closer tracking and careful estimating can reduce this
11. Monitor painting schedule to minimize wash sprayed	11. Painting has some control over its schedule and further monitoring can decrease washout
12. Robotics	12. Problems with "Orange Peel" on finished paint coat
13. Belt filter to dewater paint sludge and recycle water back to the paint booth

OPTION GENERATION

Meeting format (e.g., brainstorming, nominal group technique): Informal

Meeting Coordinator: G. Cushnie

Meeting Participants:

The Truck Assembly Plant - EPA Contractor - SAIC

LIST SUGGESTED OPTIONS	RATIONALE / REMARKS ON OPTION
1. Use Spray system to degrease entire chassis and omit wiping with rags	1. Produces no waste solvent or dirty rags/increases VOC emissions and the amount of solvent used increases.
2. Segregate rags and solvent	2. Solvent will remain uncontaminated and won't need to be disposed of as frequently thus decreasing the amount of solvent sent to disposal and the amount used.
3. Install a still to recover the spent solvent	3. Expensive; would require labor permits; etc. and volume of solvent generated doesn't warrant its installation.
4. Change type of solvent used	4. Current solvent produces the desired cleaning quality.
5. New rail washer	5. Reduces the amount of oil & grease on the chassis thus reducing the amount of solvent used.

WORKSHEET  
12

OPTION DESCRIPTION

Option Name: Belt Filter (OP-1)

Briefly Describe the Option:

This option involves the dewatering of detackified paint with the use of a belt filter. The detackified paint will be pumped from the pit and the paint sludge is deposited in a drum for disposal while the water is recycled to the paint booth.

OPTION DESCRIPTION

Option Name: Improved Transfer Efficiency (OP-2)

Briefly Describe the Option:

Currently the cab paint booths have a transfer efficiency of approximately 35% and the chassis paint booth has a transfer efficiency of approximately 50%. The transfer efficiency can be increased up to 75-90% by switching to HVLP or electrostatic spray painting.

WORKSHEET  
12

OPTION DESCRIPTION

Option Name: Procedural/Small Equipment Changes (OP-3)

Briefly Describe the Option:

The facility is currently investigating a variety of procedural and small equipment changes which will streamline their waste minimization procedures. These include:

- o shipping unused paint with the finished truck
- o adjusting the painting schedule
- o installing high/low pressure alarms
- o installing a digital display of air pressure
- o paint stripes and designs over the background color
- o installing mini-computers to check fluid flow

OPTION DESCRIPTION

Option Name: Paint Mix Volumes (OP-4)

Briefly Describe the Option:

Paint is prepared daily in the paint mix room and is taken to the cab paint booths. Any left over paint is returned to the paint mix room for use at a later date. The facility has developed a tracking system to determine reliable estimates on the amount of paint required to paint a particular model. This is done by measuring the volumes of paint mixed as well as the volume of paint returned to the mix room. This estimating process can be refined with careful monitoring of these tracking records which will reduce costs for raw materials and disposal.

OPTION DESCRIPTION

Option Name: Ion Exchange/Recycle of Rinse Waters (OP-6)

Briefly Describe the Option:

This option involves the installation of ion exchange equipment to recycle the rinse waters generated on the phosphate/E-Coat line. The recycle of these waters will reduce water use and reduce the hydraulic loading of the pretreatment system. A smaller flow rate to the treatment system may reduce chemical use and sludge production.

Feasibility Analysis Phase  
Worksheets 14 to 17

Firm <u>SAIC</u>	Waste Minimization Assessment	Prepared By <u>S. Roman</u>
Site <u>1</u>	Proc. Unit/Oper. _____	Checked By <u>G. Cushnie</u>
Date <u>1/3/90</u>	Proj. No. <u>1-832-03-942-02</u>	Sheet <u>1</u> of <u>6</u> Page <u>1</u> of <u>6</u>

WORKSHEET  
**14a**

**TECHNICAL FEASIBILITY**

WM Option Description Belt Filter (OP-1)

1. Nature of WM Option
- ☒ Equipment-Related
- ☐ Personnel/Procedure-Related
- ☐ Materials-Related

2. If the option appears technically feasible, state your rationale for this. Belt filters have been used in similar applications to dewater detackified paint that has accumulated in the paint booth.

Is further analysis required? ☒ Yes ☐ No. If yes, continue with this worksheet. If not, skip to worksheet 15.

3. Equipment - Related Option

	YES	NO	
Equipment available commercially?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	_____
Demonstrated commercially?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	_____
In similar application?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	_____
Successfully?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	_____
Describe closest industrial analog	<u>Similar spray painting operations.</u>		
_____			
_____			
Describe status of development	<u>Fully Developed and Commercialized.</u>		
_____			
_____			

Prospective Vendor	Working Installation(s)	Contact Person(s)	Date Contacted
Serfilco		Dan Cooper	2-6-90
Hydro-Seperation Systmes		Roy Lister	2-6-90

1. Also attach filled out phone conversation notes, installation visit report, etc.

**TECHNICAL FEASIBILITY**

(continued)

WM Option Description Belt Filter (OP-1)

**3. Equipment-Related Option (continued)**

Performance information required (describe parameters): The following information is required:  
minimum and maximum flow rates and percent solids achievable. This data can be  
generated by sending a representative sample of the wet sludge to an experiment  
vendor for testing.

Scaleup information required (describe): NONE

Testing Required: ☐ yes ☒ no

Scale: ☐ bench ☐ pilot

Test unit available? ☐ yes ☐ no

Test Parameters (list)

Number of test runs:

Amount of material(s) required:

Testing to be conducted: ☐ in-plant  
☐

**Facility/Product Constraints:**

Space Requirements Approximately 20 ft<sup>2</sup> (5.5' X 3.5')

Possible locations within facility Unit will be used every 4 to 6 weeks when the  
detackified paint is pumped out of the paint booth. During use it should be located  
where the paint sludge is being pumped from the booth. When not in use it can be  
stored on-site, wherever space is available or left in place if convenient.

Firm <u>SAIC</u>	Waste Minimization Assessment	Prepared By <u>S. Roman</u>

**TECHNICAL FEASIBILITY**  
(continued)

WM Option Description Belt Filter (OP-1)

2. Equipment-Related Option (continued)

Utility Requirements:

Electric Power      Volts (AC or DC) 115/1/60 kW 23

Process Water      Flow 10-45gpm      Pressure \_\_\_\_\_  
(Detackified Paint)      Quality (tap, demin, etc.) \_\_\_\_\_

Cooling Water      Flow \_\_\_\_\_      Pressure \_\_\_\_\_  
                                 Temp. In \_\_\_\_\_      Temp. Out \_\_\_\_\_

Coolant/Heat Transfer Fluid \_\_\_\_\_  
                                 Temp. In \_\_\_\_\_      Temp. Out \_\_\_\_\_  
                                 Duty \_\_\_\_\_

Steam      Pressure \_\_\_\_\_      Temp. \_\_\_\_\_  
                                 Duty \_\_\_\_\_      Flow \_\_\_\_\_

Fuel      Type \_\_\_\_\_      Flow \_\_\_\_\_  
                                      Duty \_\_\_\_\_

Plant Air \_\_\_\_\_      Flow \_\_\_\_\_

Inert Gas \_\_\_\_\_      Flow \_\_\_\_\_

Estimated delivery time (after award of contract) 4 to 6 weeks

Estimated installation time 8 hours

Installation dates \_\_\_\_\_

Estimated production downtime none- production can continue during installation

Will production be otherwise affected? Explain the effect and impact on production. no

\_\_\_\_\_  
\_\_\_\_\_  
\_\_\_\_\_

Will product quality be affected? Explain the effect on quality. no

\_\_\_\_\_

Date <u>1/3/90</u>	Proj. No. <u>1-832-03-942-02</u>	Sheet <u>4</u> of <u>6</u> Page <u>   </u> of <u>   </u>

WORKSHEET  
**14d**

**TECHNICAL FEASIBILITY**

(continued)

WM Option Description Belt Filter (OP-1)

**3. Equipment-Related Option (continued)**

Will modifications to work flow or production procedures be required? Explain. Detackified paint would need to be pumped to the belt filter instead of directly to a tank truck. Then water would be pumped back to the paint booth and reused.

Operator and maintenance training requirements

Number of people to be trained \_\_\_\_\_

☐ Onsite

☐ Offsite

Duration of training \_\_\_\_\_

Describe catalyst, chemicals, replacement parts, or other supplies required.

Item	Rate or Frequency of Replacement	Supplier, Address
Disposa-Fabric Media	3-4-times per year	Serfilco, Glenview, IL

Does the option meet government and company safety and health requirements?

☐ Yes ☐ No Explain To be determined

How is service handled (maintenance and technical assistance)? Explain Service through local authorized repair centers or handles through the Serfilco office.

What warranties are offered? Serfilco - 1 year repair or replacement of defective parts.

WORKSHEET  
**14a**

**TECHNICAL FEASIBILITY**

WM Option Description Paint Mix Volume (OP-4)

1. Nature of WM Option
- ☐ Equipment-Related
- ☒ Personnel/Procedure-Related
- ☐ Materials-Related

2. If the option appears technically feasible, state your rationale for this. The facility is current tracking paint mixed volumes versus paint sprayed volumes and has achieved an average of 1.3 quarts of paint wasted per truck due to over mixing. Continued monitoring should be able to decrease this to less than one quart.

Is further analysis required? ☒ Yes ☐ No. If yes, continue with this worksheet. If not, skip to worksheet 15.

3. Equipment - Related Option (Not applicable-skip to worksheet 14e)

	YES	NO	
Equipment available commercially?	<input type="checkbox"/>	<input type="checkbox"/>	_____

# TECHNICAL FEASIBILITY

WM Option Description ION Exchange with Recycle of Rinse Water (OP-6)

1. Nature of WM Option
- ☒ Equipment-Related
- ☐ Personnel/Procedure-Related
- ☐ Materials-Related

2. If the option appears technically feasible, state your rationale for this. Ion Exchange is a  
technology that is commonly used on metal finishing lines for recycling  
rinse waters.

Is further analysis required? ☒ Yes ☐ No. If yes, continue with this worksheet. If not, skip to worksheet 15.

## 3. Equipment - Related Option

	YES	NO	
Equipment available commercially?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	_____
Demonstrated commercially?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	_____
In similar application?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	_____
Successfully?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	_____
Describe closest industrial analog applications.	<u>Working systems are in place for the same</u>		

Describe status of development Fully developed and commercialized

Prospective Vendor	Working Installation(s)	Contact Person(s)	Date Contacted 1.
Numerous manufacturers/vendors			

1. Also attach filled out phone conversation notes, installation visit report, etc.

**TECHNICAL FEASIBILITY**

(continued)

WM Option Description Ion Exchange with Recycle of Rinse Water (DP-6)

**3. Equipment-Related Option (continued)**

Performance Information required (describe parameters): Bench scale testing is needed to select the proper ion exchange resin and to determine approximate resin capacity. Also testing is needed to reevaluate the existing chemical precipitation process to determine if the iron salts dosage could be reduced.

Scaleup Information required (describe): Described above.

Testing Required: ☒ yes ☐ no

Scale: ☒ bench ☐ pilot

Test unit available? ☒ yes ☐ no Generally performed by vendor.

Test Parameters (list) Major anion and cations of concern.

Number of test runs: As needed.

Amount of material(s) required: As needed

Testing to be conducted:

☐ In-plant

☒ At vendor's facility

**Facility/Product Constraints:**

Space Requirements \_\_\_\_\_

Possible locations within facility Near existing ion exchange equipment in waste treatment room.

- Adjust table as necessary if the anticipated project life is less than or more than 8 years.
- Salvage value includes scrap value of equipment plus sale of working capital minus demolition costs.
- The worksheet is used for calculating an aftertax cash flow. For pretax cash flow, use an income tax rate of 0%.
- The present value of the cash flow is equal to the cash flow multiplied by the present worth factor.
- The net present value is the sum of the present value of the cash flow for that year and all of the preceding years.
- The formula for the present worth factor is  $\frac{1}{(1+r)^n}$  where  $n$  is years and  $r$  is the discount rate.
- The internal rate of return (IRR) is the discount rate ( $r$ ) that results in a net present value of zero over the life of the project.

16. ABSTRACT <p>EPA has developed a systematic approach to identify and implement options to reduce or eliminate hazardous waste. The approach is presented in a report entitled, "Waste Minimization Opportunity Assessment Manual" (EPA/625/7-88/003). This report describes the application of the waste minimization assessment procedures to a truck assembly facility in Chillicothe, Ohio. This facility volunteered to participate in the project and provided technical support during the study.</p> <p>The relative comparison used in this study indicates that the best options appear to be: 1) reducing paint mix volumes through closer control, 2) minimizing solvent contamination by using a different working container and procedures and 3) improving transfer efficiency by installing electrostatic painting in the chassis booth. Two options ranked with moderately good scores: 1) dewatering paint solids and recycling the booth waters and chemicals and 2) using ion exchange to recycle the phosphate/E-coat rinse water. The option for bath maintenance on the phosphate/E-coat line ranked last, however still within a reasonable range. One option which recommended procedural and small equipment changes for painting was not evaluated during the feasibility analysis phase, because the costs and savings could not be projected at this time. The associated waste minimization techniques however appear to be technically and economically viable.</p>
