INITIAL SCREENING OF THERMAL DESORPTION FOR SOIL REMEDIATION

James J. Yezzi, Jr. and Anthony N. Tafuri U.S. Environmental Protection Agency Edison, NJ

> Seymour Rosenthal Foster Wheeler Enviresponse, Inc. Edison, NJ

> > William L. Troxler Focus Environmental, Inc. Knoxville, TN

INTRODUCTION

Petroleum contaminated soils—caused by spills, leaks, and accidental dischargesexist at many sites throughout the United States. Thermal desorption technologies which are increasingly being employed to treat these soils, have met soil cleanup criteria for a variety of petroleum products.

Currently the United States Environmental Protection Agency is finalizing a technical report entitled *Use of Thermal Desorption for Treating Petroleum-Contaminated Soils* to assist remedial project managers, site owners, remediation contractors, and equipment vendors in evaluating the use of thermal desorption technologies for petroleum contaminated soil applications. The completed report will be available from the Center for Environmental Research Information (CERI) by June 1992.

136 Thermal Description

CONTENTS OF TECHNICAL REPORT

The report will discuss the following areas:

- Thermal desorption theory.
- The relationship of thermal desorption applicability, operations, and
 efficiency to site, contaminant and soil characteristics, as well as the effects
 of regulatory requirements.
- Commercial thermal desorption systems.
- Operating costs for thermal desorption systems.

Comprehensive appendices to the report serve as an encyclopedic source with detailed discussions on related topics; for example:

- Thermal desorption theory.
- Site, contaminant, and soil characteristics, and their impact on thermal desorption applicability.
- Regulatory issues affecting the permitting and operation of thermal desorption systems.
- Commercially available thermal desorption systems.
- Project task lists for use of mobile and fixed-based systems.
- Estimation of costs for using mobile or fixed-based thermal desorption systems.
- Comparison of thermal desorbers to incinerators.

THREE-LEVEL SCREENING METHOD

The report will also present a three-level screening method to help a reader predict the success of applying thermal desorption at a specific site. This method utilizes a series of worksheets that will assist the reader in accomplishing the following activities:

- Performing an initial assessment, based on limited data, to determine the applicability of thermal desorption for a given application.
- Identifying thermal desorption and off-gas treatment system requirements.
- Developing an overall cost estimate for treating a site using thermal desorption.

The objective of screening level one is to determine the likelihood of success in a specific application of thermal desorption. It will take into account procedures for collecting and evaluating data on site characteristics, contaminant characteristics, soil characteristics, and regulatory requirements. This level will establish whether or not thermal desorption should be evaluated further for site remediation, whether treatment should occur on-site or off-site, and if on-site is a viable option, what system size will be most cost-effective.

Screening level two will evaluate alternative thermal desorption technologies and factors such as the type of unit operations and operating conditions that are required to achieve specific cleanup criteria. It will also identify the most viable equipment alternatives.

Screening level three will guide in the preparation of an economic evaluation of the treatment alternatives selected in the first two levels. It identifies project tasks that must be conducted and provides typical cost factors for treating petroleum contaminated soils by thermal desorption technologies.

The scope of this paper addresses only screening level one which provides a preliminary assessment of the applicability of thermal desorption to a particular site. This topic encompasses worksheets that are an integral part of the "user friendly" screening process. Level one screening provides a foundation for the subsequent two levels which follow a similar "user friendly" worksheet approach to evaluating thermal desorption technologies and establishing costs for thermal desorption in an overall remediation project.

Figure 1 illustrates the three-level screening method presented in the report.

The screening level one worksheets are developed to simplify the evaluation of thermal description effectiveness and are based on the collection of limited data. The worksheets do not constitute a design manual, nor a final basis for choosing thermal description as a remedy. They provide a pre-selection screening method to determine if the utilization of thermal description to a particular site warrants further consideration.

LEVEL ONE SCREENING

The first level of screening describes six steps for collecting and evaluating key data that will affect the application of thermal desorption at a specific site. These data are defined as "critical success factors."

The worksheets in the report guide the reader through the six steps:

- 1. Data collection.
- 2. Waste classification.
- 3. On-site versus off-site treatment selection.
- 4. Critical success factor evaluation.
- 5. Contingency planning.
- 6. Treatment system selection.

The initial screening accomplished by these six steps limits the number of alternatives that will be subjected to further screening levels.

STEP 1: DATA COLLECTION

This first step in screening level one involves the collection of data in four major categories:

138 Thermal Desorption

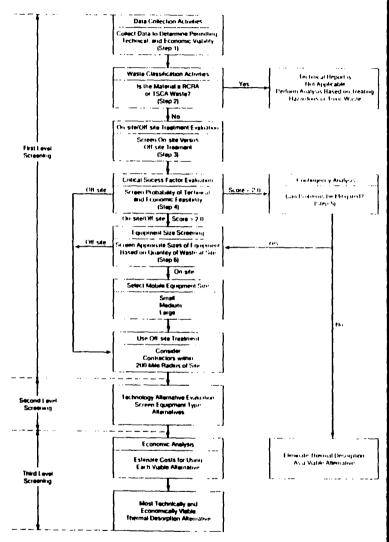

Figure 1 Thermal desorption evaluation decision diagram.

- Contaminant characteristics
- Regulatory requirements
- Site characteristics
- Soil characteristics

Table 1 details these types of data. The method limits the number of parameters in the screening analysis in order to minimize the time and cost of the evaluation. The source of these data, required to complete the critical success factor evaluation, generally include limited field investigations, standard analytical tests, or published sources. The report appendices contain detailed information regarding the potential impact of each item presented.

STEP 2: WASTE CLASSIFICATION

This second step in level one screening uses the data collected in the first step to confirm that the site is appropriate for further evaluation. The report focuses on the cleanup of petroleum-contaminated soil as a non-RCRA and non-TSCA waste. The flow chart in Figure 2 provides a decision tree for classifying the contaminated soil and confirming the applicability of the report. The appendices in the report contain detailed explanations of each element in the flow chart.

STEP 3: ON-SITE VERSUS OFF-SITE TREATMENT SELECTION

Figure 3 presents a decision diagram to compare the economic effectiveness of onsite or off-site treatment. This figure is only a screening tool; it is not a substitute for a detailed economic analysis of alternatives. The report discusses economic analysis in depth as a separate topic.

STEP 4: CRITICAL SUCCESS FACTOR EVALUATION

In this fourth step, worksheets address each critical success factor. Completing these worksheets employs simple qualitative and/or quantitative methods for rating each factor according to the probability for the successful application of thermal desorption. The form ranks each factor as having a least, average, or highest probability for successful use of thermal desorption.

Example - Calculation of the Probability of Success

Table 2 contains an example of a completed critical success factor screening evaluation for an on-site application. The remedial manager first defined the critical contaminant as well as the site, regulatory, and soil characteristics. The manager assumed that an on-site cleanup of 800 tons of soil contaminated with No. 6 fuel oil will occur at a 1.25 acre commercial retail facility in a state having the assumed criteria presented in the example. The contamination at this site resulted from a leaking underground storage tank. The TPH concentration is 12,000 mg/kg and metal concentrations do not exceed state or local criteria.

Table 1 Thermal Description Data Requirements Critical Success Factors

	Da	ata Collection	
Characteristic	Rationale	Source	Method
Contaminant Characteristics			1
Petroleum product type	Selection of required soil treatment temperature	Owner's knowledge of tank usage	Site owner interview
Concentration of TPH in contaminated soil	Determination of treatment and disposal requirements under state and local regulations, selection of required soil treatment temperature and residence time, potential to exceed lower explosive concentration limits in thermal desorption device.	Analytical data from soil boring samples	EPA 418.1 is most common method, state and local requirements may vary
TCLP extract concentration of metals or organics tlead from leaded gasotine is most likely contaminant)	Material may be classified as a RCRA hazardous waste if TCLP extract concentrations exceed values listed in 40 CFR 251. Excusions apply for wastes from underground storage tanks that are subject to the RCRA Corrective Action requirements in 40 CFR 280. See flow chart in Figure 2. If material is a hazardous waste, this Technical Report is not applicable.	Analytical data from soil boring samples	EPA 1311 (extraction) EPA 6010 (metals) EPA 8260 (volatile organics) EPA 8080 (semivolatile organics)
Concentration of PCBs in contaminated soil	If PCBs are present at a concentration of greater than 50 ppm, the waste is subject to TSCA regulations and this Technical Report is not applicable.	Analytical data from soil boring samples	EPA 8080

Table 1 Thermal Desorption Data Requirements Critical Success Factors (Continued)

	Data Collection				
Characteristic	Rationale	Source	Method ^(a,b)		
Data Requirements Critical Success Factors Total metals concentration (As. Bs. Cd. Cr. Pb. Hg. Se. Ag)	State and local regulatory requirements for treatment or disposal of contaminated soil. Analytical data from soil boring samples		EPA 3050 (acid digestion) EPA 6010 (metals), meet with regulatory agencies		
Site Characteristics					
Contaminant source	Exemptions apply for wastes that exhibit the RCRA characteristic of toxicity codes D018-D043 if the waste is from a leaking underground storage tank that is subject to the Corrective Action Requirements in 40 CFR 280. See flow chart in Figure 2.	Identification of communicate source	Site review		
Contaminated soil quantity (tons)	Selection of on-site versus off-site treatment.	Soil borings, concentration of contaminants, soil cleanup criteria	Use approved analytical methods from SW-846		
Site usage	Project cost estimate abould include revenue Revenue loss each day that site is out of service		Site owner's cost estimate		
Operational area available	Must be sufficient to set up and operate process equipment and maintain field and treated soils stockpile (on-site treatment only).	Plot pian drawing of area available for operations	Site survey

R. Total Mander of Parameters Raind					17	
					2.23	
The date in this work doest compiled a next score of 38 from 17 rated parameters, with an everage come of 2.23. This store warrants further necessarian of the earl discontine. The messages should continue through the two oblitional contenting fevels.						

Benzene concentrations in the leachate exceed the TCLP standard. Moderate regulatory considerations require three permits, little or no performance testing, and residual target levels of 50 mg/kg TPH and <2 mg/kg BTEX. The soil is fine-grained inorganic clay with a moisture content of 22%.

Using the site values recorded on the example worksheet, the reader calculates the appropriate score for each critical success factor. A score of 3 has a "highest" probability of success; 2 indicates "average"; and 1 is the "least likely to succeed." In some instances a particular success factor may not be applicable to an alternative, or data may not be available. Duplicate evaluations must consider on-site and off-site treatment separately, since several data factors apply to only one of these alternatives.

An evaluation summary appears at the bottom of the worksheet. By calculating the total score for all categories and dividing by the number of factors that were rated, the reader can compile an overall composite score. This score indicates the probability for success in this application of thermal desorption.

The composite score is a relative indicator of technical difficulty and treatment cost. Sites that receive a composite score greater than 2.0 are the most technically and economically viable candidates. Treatment costs for these applications will generally range from \$35 to \$65 per ton. A score below 2.0 indicates lower viability and higher costs (\$65 to \$125 per ton).

The data in this worksheet compiled a total score of 38 from 17 rated parameters, with an average score of 2.23. This score warrants further consideration of thermal desorption. The manager should continue through the two additional screening levels.

STEP 5: CONTINGENCY PLANNING

The reader can use Table 3 to prepare contingency plans for any critical success factors with a "least" probability for success. In many cases, engineering or administrative procedures can mitigate the possible effects of a parameter with a "least" probability rating.

STEP 6: TREATMENT SYSTEM SELECTION

Figure 4 contains a diagram for determining the most cost-effective size of thermal desorption equipment as a function of contaminated soil volume at a site. A vertical line drawn from the site size value on the x axis will intersect with one or more horizontal operating range bars that represent various sizes of treatment equipment. The systems identified (by the intersection of the line with bars representing them) should continue on to second and third level screening.

Table 3 Critical Success Factor Contingency Analysis.

Table 3 Critical Success Pactor Contingency Analysis.					
Characteristic	Reason for impact	Contingency plan			
Contaminant Characteristics Petroleum product type	Petroleum product requires high treatment temperature.	Selection of thermal desorption devices with appropriate			
		operating temperature range.			
Concentration of TPH in contaminated soil	High (>2-3%) concentration of TPH in contaminated soil may cause concentration of organics in thermal desorption offgas to be above lower explosive limit for directly heated thermal desorption devices.	Blend highly contaminated soil with lower TPH concentration soils to reduce overall average concentration or use indirectly heated thermal desorption device.			
TCLP extract concentration of metals or organics	Concentration of parameter in TCLP extract exceeds criteria.	Material must be handled as a RCRA hazardous waste. Technical Report does not apply.			
Total metals concentration (As, Ba, Cd, Ph, Hg, Se, Ag)	Exceeds state regulatory criteria for preferred treated soil disposal alternative.	Use alternative treated soil disposal option or stabilize treated material.			
Concentration of PCBs in contaminated soil	PCB concentration greater than 50 ppm.	Material must be handled as a TSCA toxic waste. Technical Report does not apply.			

Table 3 Critical Success Factor Contingency Analysis (Continued)

Characteristic	Reason for impact	Contingency plan
Site Characteristics		
Contaminanted soil quantity	Small quantity of soil (< 500 tons).	Use off-site treatment.
	Large quantity of soil (> 10,000 tons).	Use on-site treatment.
Site usage	Revenue lost from site's normal commercial operations because site is out of service.	Use off-site treatment.
Operational area avaitable	Insufficient operational area available for on- site treatment (Note: area required depends on capacity of mobile thermal treatment system).	Use off-site treatment.
Surrounding land use	Adjoining land uses such as schools, parks, health care facilities, or dense urban development.	Use off-site treatment.
Distance to stationary thermal desorption facility	Transportation cost to ship soils.	Use on-site treatment.
Ambient temperature	Low ambient temperature may cause soit to freeze and be difficult to screen and difficult to thaw in thermal desorber.	Perform project during warmer weather. Crush material before processing in thermal desorption device.

16 ABSTRACT

The purpose of this paper is to present procedures for collecting and evaluating key data that affect the potential application of thermal desorption for a specific site. These data are defined as "critical success factors". The screening procedure can be used to perform an initial assessment, based on

timited data, to determine if thermal desorption may be a viable technology for a given application.

The critical success factor screening methodology is executed in six steps: 1) Data collection, 2) Waste classification, 3) On-Site versus off-site treatment evaluation, 4) Critical success factor evaluation, 5) Contingency planning and 6) Treatment system size evaluation.

Procedures for performing and summarizing the Results of each of these screening steps are presented. The screening procedures were developed to simplify the evaluation of thermal desorption effectiveness and are based on the collection of limited data. The screening steps do not constitute a design manual, nor a final basis for choosing thermal desorption as a remedy. They provide a pre-selection screening method to determine if the utilization of thermal desorption to a particular site warrants further consideration.

If the results of the critical success factor screening evaluation are positive, the user should perform additional analyses to evaluate equipment alternatives. Alternatives that are considered include the use of specific types of thermal desorber technologies or offgas treatment systems and the selection of the appropriate size of thermal desorption system for mobile applications
