APPENDIX A

CHEMICAL SUBSTANCE DEFINITIONS

Some Class 2 chemical substances listed on the Inventory have been marked by a dagger symbol (†). These substances are marked to indicate that their preferred names are not specific or complete enough to permit unambiguous identification of the substance or category of substances. This appendix lists these substances, in ascending Chemical Abstracts Service (CAS) Registry Number order, and provides for each a supplemental definition or descriptive phrase. Some definitions have been developed by EPA in conjunction with trade or technical associations; others were prepared using information submitted to EPA during the Initial Inventory reporting period.

Supplemental identification of chemical substances listed in this appendix takes three distinct forms. Many substances are identified by means of a definition. Others, in particular substances derived from botanical sources, are further identified by specifying the genus or genus/species of the source and by inclusion of a standard phrase "extractives and physically modified derivatives." Still others are identified in terms of The Soap and Detergent Association (SDA) Substance Identification Procedure. Each of these forms is discussed in greater detail below.

In general, definitions were prepared for substances whose preferred names were incomplete or potentially ambiguous because they contained:

1. Process terms that are not *chemically* descriptive (e.g., distillation residues, distillation overheads, by-product(s), low-boiling, catalytic reformed);
2. Trade jargon (e.g., slack wax, spelter, winterized, deodorized distillates, steep liquor, foots oil);
3. Unqualified or very broadly qualified substance class terms (e.g., pyridine bases, petroleum resins, phenols (petroleum));
4. Physical rather than chemical terms (e.g., microcrystalline, pulp, agglomerates, sinter, viscous).

Many of the definitions follow a standard format. The first sentence states that the substance is a combination of a certain

class of substances and the nature of the process by which it was derived. The next sentence (or sentences) usually identifies the *predominant* components and perhaps an approximate boiling range or other characterizing physical data. The definitions do not normally cite specific composition values.

Definitions were *not* prepared generally for Class 2 substances whose names simply include chemically descriptive reaction terms (e.g., chlorinated, epoxidized, ethoxylated, sulfated, polymerized, oxidized, hydrogenated), specific chemical derivative terms (e.g., 2-ethylhexyl esters; esters with diethylene glycol; polymer with...), or descriptions based on the reactants (e.g., reaction products with diethanolamine), even when the base materials have been defined based on the above criteria. For example, Castor oil has a definition; Castor oil, sulfated, sodium salt does *not* have a definition. Similarly, Tung oil has a definition; alkyd resins based on Tung oil are not defined.

Substances derived from botanical sources, including oils, extracts, and resins, are normally further identified by specifying the genus or genus/species of the source and by appending the phrase "extractives and their physically modified derivatives." In this context, the phrase applies to the source and includes *all* extracts and physically modified derivatives from that source. "Physically modified" means the application of certain processes usually not considered to involve chemical reactions, namely: distillation, expression, filtration, drying, heating, cooling, extraction and deodorization by adsorption.

Many Class 2 chemical substances derived from natural fats and oils and synthetic substitutes have been identified using the SDA Substance Identification Procedure. These substances are further identified by specifying their corresponding SDA Substance Names and SDA Reporting Numbers. The applicability and limitations of these identifiers is contained in the SDA Substance Identification Procedure which appears at the end of this appendix.

Glass, oxide
Synonym: Chemical substances manufactured in the production of inorganic glass
This category encompasses the various chemical substances manufactured in the production of inorganic glasses by the glass industry. For purposes of this category, "glass" is defined as an amorphous, inorganic, usually

transparent or translucent substance consisting of a mixture of silicates, or sometimes, borates or phosphates, formed by a fusion of silica, or of oxides of boron or phosphorus, with a flux and a stabilizer, into a mass that cools to a rigid condition without crystallization. This category consists of the various chemical substances, other than byproducts or impurities, which are formed in melting furnaces during the production of various glasses and concurrently incorporated into a glass mixture. Any glass contains one or more of these substances, but few, if any, contain all of them. The elements listed below are principally present as oxides but may also be present as halides or sulfides, in multiple oxidation states, or in more complex compounds. Trace amounts of other oxides or chemical compounds may be present. Oxides of the first seven elements listed* collectively comprise more than 95 percent, by weight, of the glass produced in the United States.

Ceramic materials and wares, chemicals

Synonym: Chemical substances manufactured in the production of ceramics

This category encompasses the various chemical substances manufactured in the production of ceramics. For purposes of this category, a ceramic is defined as a crystalline, inorganic, usually opaque substance consisting principally of combination of inorganic oxides of aluminum, calcium, chromium, iron, magnesium, silicon, or zirconium which is formed first by fusion or sintering at very high temperatures, then by cooling, resulting in a rigid, crystalline structure. Those ceramics which are produced by heating inorganic glass, thereby changing its physical structure from amorphous to crystalline but not its chemical identity are not included in this definition. This category consists of chemical substances other than by-products or impurities which are formed during the production of various ceramics and concurrently incorporated into a ceramic mixture. Its composition may contain any one or a combination of these substances. Trace amounts of oxides and other substances may be present. The following elements are principally present as oxides but may also be present as fluorides, chlorides, sulfides or carbides, in multiple oxidation states, or in more complex compounds.

SDA SUBSTANCE IDENTIFICATION PROCEDURE

FOR CLASS 2 CHEMICAL SUBSTANCES DERIVED FROM NATURAL FATS AND OILS AND SYNTHETIC SUBSTITUTES

The substance identification system presented here is an alternate and relatively simple method which was used to identify for the Inventory certain multicomponent Class 2 chemical substances derived from natural fats and oils and synthetic long-chain alkyl substitutes. The system was developed by The Soap and Detergent Association in conjunction with the EPA and is intended to standardize the identification of substances manufactured and used extensively in the soap and detergent industry. Accordingly, the system was used to identify multicomponent soaps and surface active agents (and also their precursors and derivatives) manufactured, imported, or processed for such uses as wetting agents, emulsifiers, dispersants, and penetrants. Its applicability, however, extended beyond the soap and detergent industry.

This system was not to be used to identify any single component Class 1 chemical substance (i.e., a substance whose composition may be represented by a definite chemical structure diagram) or any combination of such substances prepared by mixing without chemical reaction. Furthermore, it was not to be used in those cases where the person reporting considered its applicability to be marginal or in question.

The Class 2 chemical substances which were reported using this system are complex, multicomponent materials whose individual components have a common structural feature: one or more long-chain alkyl groups to which is attached a chemically functional group or groups. These components differ from one another with respect to one or more of the following long-chain alkyl group characteristics: length (carbon number), saturation, structure (linear or branched), and/or the position of functional group attachment(s).

Under the SDA Substance Identification Procedure, certain of these Class 2 chemical substances are identified by SDA Substance Names and by corresponding SDA Numbers and Substance Definitions.

SDA SUBSTANCE NAMES

SDA Substance Names are systematically-derived, and, within the limitations of the system, are as precisely descriptive of the chemical composition of a substance as possible.

SDA Substance Names consist of two or, in some cases, three parts. The two parts common to all SDA Substance Names are: (1) the Alkyl Descriptor, A, which describes the long-chain alkyl groups of the substance, and (2) the Functionality Descriptor, F, which identifies the functional group(s) of the substance. A third part, the Salt Descriptor, S, identifies the cation(s) of any salt.

SDA Substance Names are systematically constructed according to the following formats:

(A) alkyl (F),
or in the case of salts,
(A) alkyl (F) (S).

where A denotes the Alkyl Descriptor; F, the Functionality Descriptor; and S, the Salt Descriptor.

For example, the SDA Substance Name for a fatty amine which contains predominantly C_{10} - C_{16} saturated alkyl chain-length is:

C_{10} - C_{16} alkyl amine
where the phrase " C_{10} - C_{16} " corresponds to the Alkyl Descriptor (A), and "amine", to the Functionality Descriptor (F).

Similarly, the SDA Substance Name for the sodium salt of a fatty carboxylic acid comprised predominantly of C_{16} saturated and C_{18} unsaturated alkyl chains is:

C_{16} and C_{18} unsaturated alkyl carboxylic acid sodium salt

where the phrase " C_{16} and C_{18} unsaturated" corresponds to the Alkyl Descriptor (A); "carboxylic acid" to the Functionality Descriptor (F); and "sodium salt", to the Salt Descriptor (S).

The Class 2 chemical substances covered by this system are limited to those whose composition may be described using the Alkyl, Functionality, and Salt Descriptors listed below in Tables 1, 2, and 3, respectively. These descriptors, discussed in detail below, can be combined in the SDA Substance Name format to describe more than 5,000 multicomponent Class 2 chemical substances.

Alkyl Description

Table 1 lists the Alkyl Descriptors covered by this system of substance identification; assigned to each is a two-digit Alkyl Descriptor Code used in generating the SDA Reporting Numbers, described later. Each Descriptor identifies a distribution of alkyl groups in terms of carbon chain length, saturation and/or unsaturation, and linear or branched structure. Alkyl group distributions are inclusive of both even and odd alkyl chain lengths.

The Descriptors of Table 1 were chosen to cover the predominant long-chain alkyl group distributions actually present as of 1978, in most commercial multicomponent Class 2 substances of this type, and to provide for each as precise a description as practical. Use of this system is predicated on selecting the narrowest alkyl distribution (Alkyl Descriptor) which describes the predominant long-chain alkyl groups of the substance reported. In this context, the term "predominant" means that about 80 to 100 percent of all long-chain alkyl groups are included within the description.

In the Alkyl Descriptor, a saturated, linear long-chain alkyl group is denoted by " C_x " where the subscript x indicates the number of carbon atoms in the alkyl chain. Unsaturated and multiple branched alkyl groups are denoted by " C_x unsaturated" and " C_x branched", respectively.

By convention, the number of carbon atoms in a long-chain alkyl group includes all long-chain alkyl and functional group carbon atoms, other than those contained in an aromatic ring, which are connected to each other in an unbroken chain of carbon-carbon-bonds. For example, the alkyl chainlength, designated by "R" in the representative structural diagrams

found in Table 2, includes the acyl carbon of carboxylic acids and their derivatives, and the total number of carbon atoms in such structures as $R-CH_2-OH$ or $R-CH:CH_2$. The alkyl group does not include, however, functional group carbon atoms which are part of a phenyl ring, or are separated from the alkyl chain by a phenyl group or an atom other than carbon, e.g., $R-Ph$, $R-N(CH_3)_2$, or $R-O(CH_2)_3NH_2$.

Unless specified otherwise, the alkyl groups identified by each Alkyl Descriptor are linear, or essentially linear, hydrocarbon chains. The natural fats and oils listed below provide such alkyl groups:

Vegetable	Animal
Avocado	Grease
Babassu	Lard
Castor	Neatsfoot
Coconut	Poultry
Corn	Tallow
Cottonseed	
Crambe	Marine
Linseed	
Olive	Herring
Oiticica	Menhaden
Palm	Salmon
Palm-kernel	Sardine
Peanut	Sperm Body
Rapeseed	(whale)
Rice Bran	Sperm Head
Safflower	(whale)
Safflower (high oleic)	Whale
Sesame	
Sorghum	
Soybean	
Sunflower	
Tung	
Wheat Germ	

These sources provide both saturated and unsaturated alkyl groups; castor oil provides a C_{18} hydroxy substituted alkyl group. Alkyl groups derived from other natural sources are not covered by this system.

Synthetic sources can provide linear or essentially linear alkyl groups, i.e., chain branching, if any, is limited to no more than one secondary methyl (CH_3 -) or ethyl (C_2H_5 -) group per alkyl chain. For purposes of this system, the latter type of alkyl chain is included within the designation "linear". Multiple branched alkyl groups, derived exclusively from synthetic sources, have separate Alkyl Descriptors.

Some Class 2 chemical substances covered by this procedure are comprised of components which have two or more long-chain alkyl groups, e.g., (dialkyl) amine, or (dialkyl) dimethyl ammonium chloride. This system could be used to identify such substances provided that each long-chain alkyl group is describable, in its predominant composition, by an Alkyl Descriptor found in Table 1 and that none of these long-chain alkyl groups is a single component structure describable by a definite chemical structural diagram.

Functionality Description

Table 2 lists the Functionality Descriptors which could be used in this system of substance identification; assigned to each is a three-digit Functionality Descriptor Code used in generating SDA Reporting Numbers. The partial chemical substance nomenclature (Functionality Descriptors) for each identifies a specific functional group or groups. Different Descriptors are provided for salts, and for their corresponding acids.

Associated with each Functionality Descriptor in Table 2

is a representative structure diagram or diagrams. In many cases, these diagrams depict only one of several possible isomers of a substance identified by a given Functionality Descriptor. For example, a $C_{14}-C_{18}$ alkyl amine identified by this system may contain components which have the amine functional group ($-NH_2$) attached to a terminal alkyl carbon, as shown in Table 2 for Functionality Descriptor Code 029, or to any other carbon atom in the alkyl chain. The applicability and limitations of each representative structural diagram are defined by a Substance Definition. (See Substance Definition, below.)

Salt Description

Table 3 lists the Salt Descriptors covered by this system of substance identification; assigned to each is a two-digit Salt Descriptor Code used in generating the SDA Reporting Number. SDA Substance Names for Class 2 chemical substance which are not salts contain no Salt Descriptor part; the Salt Descriptor Code for such substances is 00.

Mixed salts of monovalent anions are considered mixtures of the individual salts, each of which were to be identified separately. Mixed salts of divalent anions, however could be identified as a single substance.

SDA REPORTING NUMBER

The SDA Reporting Number is derived using the two- or three-digit codes associated with each Alkyl, Functionality, or Salt Descriptor contained in Tables 1, 2, and 3. The SDA Reporting Number is generated by systematically combining these codes for a given substance in a manner similar to that used to derive the SDA Substance Name. SDA Reporting Numbers have the following formats:

SDA aa-fff-ss
or for mixed salts of divalent anions,
SDA aa-fff-ss,s's'

where "aa" denotes the appropriate Alkyl Descriptor Code; "fff", the appropriate Functionality Descriptor Code; and "ss" (and "s's'") the appropriate Salt Descriptor Code(s).

For example, the SDA Reporting Number for $C_{10}-C_{16}$ alkyl amine is:

SDA 15-029-00

This number was generated using the Descriptor Codes found in Tables 1 to 3. Table 1 identifies the Alkyl Descriptor Code for " $C_{10}-C_{16}$ ": 15. Table 2 identifies the Functionality Descriptor Code for "(alkyl) amine": 029. Table 3 identifies the Salt Descriptor Code to be used when the substance is not a salt: 00. Inserting these numbers in the standard format yields the correct SDA Reporting Number.

SUBSTANCE DEFINITION

Each Functionality Descriptor listed in Table 2 is assigned a Substance Definition Format number ranging from 1 to 6. Through this number, the SDA Substance Name is linked to one of six generalized Substance Definitions appearing in Table 4. For each substance reported by this procedure, a unique definition can be generated by inserting the Alkyl, Functionality, and Salt Descriptor parts of its SDA Substance Name, and the corresponding representative structural diagram found in Table 2 into the appropriate generalized Substance Definition. Examples contained in Table 4 illustrate how such definitions are generated. The Substance Definitions provide a chemical description of each substance identified by an SDA Substance Name and specify the applicability and limitation of the corresponding representative structure diagram.

[Note: In Table 4, the term "positional isomers", appearing

in some Substance Definitions refers to substances which are otherwise similar except for the position of functional group attachment(s) on the long-chain alkyl group(s).] A seven step method, described in Addendum III of the Toxic Substances Control Act Candidate List of Chemical

Substances (March 1978), was useful in applying the nomenclature of this system to the identification and reporting of particular chemical substances. Additional examples which further illustrate the applicability and limitations of the system are also presented there.

APPENDIX B CONFIDENTIAL CHEMICAL SUBSTANCE IDENTITIES

The following list contains generic chemical names for the substances included in the category "Chemical Substances with Confidential Identities," which appears in the Initial Inventory. These generic names were created according to the guideline procedures presented in the following pages. These guidelines were published and made available by EPA to assist persons who wished to claim the precise identity of a chemical substance as confidential for purposes of the Inventory. Such persons were required to submit a proposed generic name for the reported substance that was "only as generic as necessary to protect the confidential identity of the particular chemical substance." Persons who intend to manufacture or import for a commercial purpose a chemical substance that is not included on the Inventory by a specific

chemical name but falls within one of the generic names included in this list may ask EPA whether the specific chemical identity is included on the Inventory under the category of confidential chemical substance identities. EPA may disclose such information provided the person establishes a *bona fide* intent to manufacture or import the substance for commercial purposes, in accordance with the procedures outlined in section 710.7(g) of the inventory reporting regulations (40 CFR Part 710).

This list does not include generic names for all confidential chemical substance identities on the Inventory. EPA expects to include additional generic names in the first supplement to the Inventory, which will be published in July or August of 1979.

GUIDELINES FOR CREATING PROPOSED GENERIC NAMES FOR CONFIDENTIAL CHEMICAL SUBSTANCE IDENTITIES FOR THE TSCA INVENTORY

The procedures presented below were designed by EPA to provide guidance in developing proposed generic names for chemical substances whose specific identities were claimed as confidential for purposes of the Inventory. They are included in this Appendix to assist persons in interpreting the generic chemical names listed here.

These guideline procedures are based on the masking of selected, revealing parts of a specific substance name which most precisely describe the identity of a particular chemical substance. Although the guidelines address single masking, multiple masking was permitted provided the person reporting the substance justified in writing the need for such additional masking.

Because of differences inherent in naming Class 1 and Class 2 chemical substances, the guidelines address each separately. However, in certain instances the procedure for creating proposed generic names for Class 1 substances is applicable to the creation of generic names for Class 2 substances as well.

Class 1 Chemical Substances

The composition of a Class 1 chemical substance, except for impurities, can be represented by a definite chemical structure diagram. For reporting purposes, a substance of this type could be identified by three items of information: 1) its specific chemical name, 2) its molecular formula, and 3) its chemical structure diagram. The specific chemical name for a Class 1 substance is so precisely descriptive of the exact substance identity, however, that the other two items of information can be easily generated.

The names of Class 1 chemical substances normally disclose the following chemical structure information:

1. Identity of parent structure (i.e., a chain of carbon atoms, a ring system, or a coordinated metal)
2. Identity, number, and position of chemical group(s) which are attached to the parent structure(s) or to other chemical groups.
3. Identity and number of counter ions (for salts).
4. Stereochemical relationships.

Generic chemical names were created for Class 1 chemical substances by masking structurally descriptive parts of their specific chemical names. Masking could be accomplished by substituting non-descriptive terms (e.g., "substituted") for descriptive parts of the name. Proposed generic names created by eliminating stereochemical indicators (if appropriate) from the specific chemical name and by masking one other structure detail, as specified below, were, in most cases, acceptable to EPA for inclusion in this Appendix.

The structurally descriptive parts of a Class 1 chemical name, any one of which could be masked when creating a proposed generic name, are listed below:

1. A locant which specifies the placement of a single chemical group.
2. Locant and multiplicative prefixes (e.g., di-, tri-, tetra-) which together specify the number and placement of a given chemical group.
3. Identity (but not placement and number) of a given chemical group.
4. Identity of a given parent structure, and locants of substituent chemical groups.
5. Identity and multiplicative prefixes (specifying the number) of a given simple cation or anion of a salt.

Chemical Group Masking

Table 1 of this guideline procedure lists by name and molecular formula the type of chemical groups which could be masked to create a proposed generic name for a Class 1 chemical substance. As stated above, only one such group or multiple occurrence of the same group could be masked in the specific chemical name for the substance.

The groups of atoms found in Table 1 are common chemical structural units; a given group may be listed under more than one name. Each group includes at least one atom other than carbon or hydrogen.

A chemical group which includes a carbon atom having more than one single free valence (e.g., carbonyl -CO-) could not be masked if the carbon atom is directly attached to an acyclic carbon atom or is included within a ring system; in this circumstance, only the atom or group of atoms attached to the carbon atom could be masked. (See Example 2, below, where the oxo group is masked).

Certain chemical groups in Table 1 include hydrogen atoms which are often additionally substituted, e.g., an ethyl group could be substituted for a hydrogen of the sulfamyl group ($\text{H}_2\text{NSO}_2\text{-}$) to give $\text{C}_2\text{H}_5\text{NHSO}_2\text{-}$. If additionally substituted, only the chemical group listed in Table 1 could be masked, not the substituent.

Table 1 lists most of the common chemical functional groups which contain oxygen, e.g., $\text{H}_2\text{NCO-}$. While not always listed, the Group VIa element (sulfur, selenium, and tellurium) analogs of these functional groups, e.g., $\text{H}_2\text{NCS-}$, are considered included within Table 1 and, accordingly, could be used in masking.

Parent Masking

A parent structure which is a chain of carbon atoms or a ring system could be masked in the chemical name only by the following generic terms:

- alkyl or alkane
- alkenyl or alkene
- alkynyl or alkyne
- carbomonocyclic or carbomonocycle (e.g., benzene, cyclopentane)
- carbopolycyclic or carbopolycycle (e.g., naphthalene, spiroundecane)
- heteromonocyclic or heteromonocycle (e.g., pyrrole, *p*-dioxane)
- heteropolycyclic or heteropolycycle (e.g., indole, benzothiazole)

In the case of a coordinated metal compound, the identity of the metal atom could be masked by the term "metal" in the chemical name.

Only one such parent group or multiple occurrences of the same parent group could be masked.

The following examples show how several hypothetical compounds could be identified by names which mask only one structural detail (other than stereochemistry).

Class 2 Chemical Substances

The composition of a Class 2 chemical substance cannot be represented by a definite chemical structure diagram. The specific name used to describe such a substance on the Inventory was based, in whole or in part, on the supplemental information provided for each substance reported on Form C—information which further established the identity of the substance.

The composition of some Class 2 substances can be represented by a partial or incomplete chemical structure diagram. In other instances, the composition can only be described in terms of a complex combination of several different known or unknown components.

The method by which a Class 2 substance was manufactured can also serve to identify the substance. For a substance manufactured by chemical reaction, identification can be stated in terms of the immediate precursor substances and other reactants which participate in the final reaction sequence used to manufacture the substance, and the nature of the reaction, e.g., ethoxylation, or bromination. For a substance derived from a source without chemical reaction, processing

information identifies the source and method of derivation, e.g., distillation, or extraction with methylene chloride.

Because Class 2 chemical substance names may be based on such variable types of information, these guideline procedures for creating proposed Class 2 generic names are necessarily stated in only the most general terms. Nonetheless, in instances such as those described below, the guideline procedure presented earlier for creating generic names for Class 1 substances may be applicable.

The composition of a Class 2 chemical substance which can be represented by a partial or incomplete chemical structure diagram can generally be described by a specific chemical name which encompasses the variability or incompleteness in the structure, yet which is as descriptive as possible of the structure in other respects. EPA generally accepted a proposed generic name for such a substance if created by following the guideline procedure specified for masking Class 1 chemical substances.

In other instances, the specific name for a Class 2 chemical substance may identify, by specific chemical name, a pre-dominant component or components of its composition, an immediate precursor or precursors, and other reactants. EPA generally accepted a proposed generic name for such a substance if it was constructed by masking the chemical name of *one* such component, precursor, or reactant according to the guideline procedure specified for Class 1 substances.

The following example shows how one hypothetical substance could be identified by names which mask only *one* structural detail.
