Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emission Standards:

Response to Comments

United States Environmental Protection Agency

Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emission Standards:

Response to Comments

Assessment and Standards Division
Office of Transportation and Air Quality
U.S. Environmental Protection Agency

United States Environmental Protection Agency

EPA-420-R-21-027
December 2021

This Response to Comments (RTC) document is a compilation of public comments that EPA received on the proposed rule "Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards" as well as EPA responses. This RTC also includes a few comments that we received after the close of the comment period on September 27, 2021, and that we have considered to the extent practicable. Additional responses appear in the preamble to the final rule. We have generally organized this RTC by category of comment topic and have included a list of commenters in each topic category. The original documents submitted by commenters, including any attachments, footnotes, tables, and figures, as well as public hearing transcripts are available in Docket ID No. EPA–HQ–OAR–2021–0208.

The responses presented in this document are intended to augment the responses to comments that appear in the preamble to the final rule and to address comments not discussed in the preamble to the final rule. To the extent there is any confusion or apparent inconsistency between this document and the preamble, the preamble itself remains the definitive statement of the rationale for the revisions to the standards adopted in the final rule. This document, together with the preamble to the final rule and the information contained in the RIA, and related technical support documents, should be considered collectively as EPA's response to all of the significant comments submitted on the proposal.

Table of Contents

1. General Comments in Support of or Opposing the Proposal

1.1. General Support for EPA's Rulemaking

Commenter: Advanced Engine Systems Institute (AESI)

AESI supports EPA's reconsideration of the light-duty GHG standards through MY 2026 and the Administration's commitment to promulgate standards for MY2027 and beyond. Suppliers rely on long term regulatory certainty to justify their investments that will allow the US to meet our national climate objectives and ensure the creation of high quality U.S. jobs. We agree with EPA's assessment that the majority of the improvements through MY 2026 are achievable through broader deployment of existing technologies already available for combustion engines and vehicles with hybrid and fully electrified powertrains. Performance based regulations are a proven method for meeting environmental goals through a diversity of technology solutions.

Commenter: Alliance For Automotive Innovation

Auto Innovators supports the goals of EPA's GHG program: to drastically reduce greenhouse gas emissions from light-duty vehicles and to encourage a transition to electric and net-zero emission vehicles, including plug-in hybrid electric vehicles, battery electric vehicles, and fuel cell electric vehicles. [EPA-HQ-OAR-2021-0208-0571-A1, p. 2]

Auto Innovators and our member companies are aligned with this Administration's goals and vision for addressing climate change and fostering a strong and competitive U.S. economy. We support the goals of EPA's GHG program: to reduce greenhouse gas emissions from light-duty vehicles and to encourage a transition to EVs, including battery electric, plug-in hybrid electric, and fuel cell electric vehicles.

Auto Innovators generally supports EPA's proposed GHG standards with appropriate and necessary flexibilities included in the program. [EPA-HQ-OAR-2021-0208-0571-A1, p. 7]

Commenter: Alliance for Vehicle Efficiency (AVE)

AVE is supportive of EPA's stated purpose to issue the Proposed Rule in response to President Biden's Executive Order 13990 'Protecting Public Health and the Environment and Restoring Science To Tackle the Climate Crisis' (Jan. 20, 2021). [EPA-HQ-OAR-2021-0208-0256-A1, p. 1]

The Proposed Rule's objective of restoring the standards to the level anticipated before the Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Years 2021–2026 Passenger Cars and Light Trucks re-establishes support for the long-term investments that technology suppliers made over a decade ago. The Proposed Rule will provide suppliers with the opportunity to obtain a return on these earlier investments which will in turn support the next generation of technology investments necessary to meet future emission standards. [EPA-HQ-OAR-2021-0208-0256-A1. p. 2]

Commenter: Alliance of Nurses for Health Environments

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 21.]

As the transportation sector is the leading source of harmful carbon pollution in the U.S., strong clean car standards are critical to providing meaningful pollution reductions and fuel savings.

Commenter: Aluminum Association

Broadly, the Association supports the continued prioritization of GHG tailpipe emission reductions in the light duty vehicle sector and believes that increasing the efficiency of mobility solutions will strengthen the United States' competitive advantage in the evolving global vehicle marketplace [EPA-HQ-OAR-2021-0208-0233-A1, pp. 2-3]

Whichever GHG gram/mile trajectory between MY 2023 and 2026 is ultimately selected by EPA, the U.S. aluminum industry will continue to work closely with automakers in innovating across the aluminum supply chain so the material continues to serve as a key enabler, helping automakers meet their specified emission reduction targets [EPA-HQ-OAR-2021-0208-0233-A1, p.3]

Commenter: American Honda Motor Company (Honda)

With the recent administration change comes, as expected, a new policy direction. Despite a whipsaw of federal environmental vehicle regulations over the past decade, Honda firmly believes the correct path forward is a robust program rooted in the tenets of the California Framework agreement. That is: challenging but achievable standards paired with meaningful policy flexibilities that accommodate a diverse array of compliance strategies. Based on our experience, not only is this a proven approach of good public policy, but it also provides opportunity for further investment in vehicle electrification, a critical technology necessary to meet future climate goals. Honda appreciates EPA's work on the August 2021 proposed rule, and the opportunity to comment on it. The proposal is, in many respects, consistent with the above approach, and we applaud the agency for proposing such action. At the same time, certain elements of the proposal could, in our view, benefit from additional agency consideration. Honda's views on those elements are shared below. We appreciate EPA's consideration of Honda's input,6 and are happy to answer any questions the agency may have. [EPA-HQ-OAR-2021-0208-0565-A1, p.3]

Honda commends the agency for its proposal to resume substantive GHG reductions in the light duty transportation sector. As a regulated party with strong views on corporate responsibility, we have long believed that challenging but achievable standards – paired with meaningful policy flexibilities that accommodate a diverse array of compliance strategies – is an appropriate approach for bringing continued environmental progress at a reasonable cost. [EPA-HQ-OAR-2021-0208-0565-A1, p.14]

The agency's proposed standards represent a brief but significant preface to a new chapter for the auto industry: accelerated decarbonization, higher levels of electrification and, ultimately, a step-function of further emissions reduction opportunities. Yet with that change come new challenges. Although these proposed standards cover just four years, they reflect a pivotal moment that will have lasting impact on both the auto industry and its readiness to face additional progress. As such, Honda supports the agency's proposed MY2023-2026 stringency, though we believe small modifications to certain program elements could improve industry's ability to comply with future regulations. We thank EPA again for its consideration of our input, and would be happy to have further discussion at the agency's convenience. [EPA-HQ-OAR-2021-0208-0565-A1, p.14]

Honda also generally supports comments to this docket submitted by our trade association, the Alliance for Automotive Innovation (AFAI).

Commenter: American Lung Association

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp.88-89]

Furthermore, the standards are very popular. I want to emphasize this important point. Americans want cleaner cars. In June the American Lung Association released a poll showing that 74 percent of American voters supported the Federal Government setting stronger standards on tailpipe emissions for passenger cars and trucks with the amount of emissions allowed declining over time.

Here's some more findings from that poll. 72 percent of voters agreed that the nation should make significant investments in zero emission vehicles as part of efforts to rebuild the economy, 74 percent of voters support the Federal Government advancing policies to encourage a nationwide transition to electric vehicles, and 70 percent of voters support the Federal Government requiring that by 2040 all new freight trucks, buses, and delivery vans sold in the U.S. must produce zero tailpipe emissions.

Commenter: Anderson, Laurie

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 103.]

Climate change and air pollution is a reality we must contend with and we must address pollution from all sectors. Therefore, I support this Administration's proposal to reduce greenhouse gas emissions from cars and light trucks.

Commenter: Asthma and Allergy Foundation of America (AAFA)

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 214.]

we support the Administration's proposal to strengthen greenhouse gas standards for passenger cars, SUVs, and light trucks.

Commenter: Bay Area Air Quality Management District

In this comment letter, the Bay Area Air District expresses our support for putting strong greenhouse gas standards back on the books: an important step towards rectifying the actions promulgated in SAFE Part Two. Greenhouse gas standards should reflect robust scientific and technical analyses, control emissions to the greatest extent feasible, and appropriately increase in stringency over time in order to maximize benefits. [EPA-HQ-OAR-2021-0208-0283-A1, p. 1]

Overall, the Bay Area Air District asks EPA to adopt greenhouse gas standards that achieve the greatest emission reductions feasible and encourage the deployment of zero emission technology. California and the Bay Area are hubs of technical and environmental progress. We have seen firsthand what can be achieved by government regulations that foster leadership, galvanize use of the best available technologies, and promote technological innovation. Together, the State and the Bay Area Air District have been at the forefront of air pollution control, designing programs and strategies to reduce air pollution for decades. These locally designed programs have been replicated around the country and indeed throughout the world, bringing pollution control solutions far beyond the Bay Area. [EPA-HQ-OAR-2021-0208-0283-A1, pp.2-3]

Ultimately, the Bay Area Air District supports EPA in this rulemaking, as it puts forward strong greenhouse gas standards and addresses the critical missteps from the greenhouse gas portion of the SAFE Vehicles Rule. [EPA-HQ-OAR-2021-0208-0283-A1, p.3]

Commenter: Blue Green Alliance

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 92-93.]

That's why it's critical that we use all the tools we have at our disposal to urgently reduce greenhouse gas emissions through policies and investments that engage and benefit all people, from the manufacturing workers who build the vehicles of the future to the people who drive them, from the communities where they're made to the communities where they're driven. Strong clean vehicle standards accompanied by policies to rebuild manufacturing are critical to achieving these aims. Returning to a strong trajectory of vehicle emissions reductions can put the U.S. back in the leadership role and clean vehicle deployment and manufacturing innovation.

Commenter: BorgWarner Inc.

BorgWarner is in favor of forward progress to consistently reduce CO2 and other emissions. We support the proposed rule with flexibilities to provide industry with a broader pathway forward to zero emission vehicles. The proposed rule represents an ambitious acceleration of the pace of improvement. [EPA-HQ-OAR-2021-0208-0260-A1, p. 1-2]

Commenter: Brandt, Peter

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 211.]

There are a lot of reasons I support EPA's proposal here.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 214.]

So I'm very heartened that the agency is considering this and I would urge you to not water things down in response to industry opposition.

Commenter: California Air Resources Board (CARB)

The California Air Resources Board (CARB) supports the proposal by the U.S. Environmental Protection Agency (U.S. EPA) to revise its 2023 and later model year light-duty vehicle greenhouse gas emissions standards. [EPA-HQ-OAR-2021-0208-0643-A6, p.6]

The proposed standards are squarely directed at reducing greenhouse gas emissions but contribute to meeting all these needs, as explained in detail below. CARB strongly supports this proposal. [EPA-HQ-OAR-2021-0208-0643-A6, p.6]

Commenter: California Attorney General Office, et al.

Our States and Cities1 hereby submit these comments in response to the United States Environmental Protection Agency's ('EPA') notice of proposed rulemaking: Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards, 86 Fed. Reg. 43,726 ('Proposal'). We welcome EPA's reconsideration of its Safer Affordable Fuel-Efficient Vehicles Rule for Model Years 2021-2026 Passenger Cars and Light Trucks ('SAFE 2') (85 Fed. Reg. 24,174 (April 30, 2020)), and we strongly support increasing the stringency of EPA's greenhouse gas ('GHG') emissions standards. [EPA-HQ-OAR-2021-0208-0245-A1, p.1]

We, thus, welcome EPA's proposal to implement more stringent GHG emissions standards for light-duty vehicles and urge the agency to continue actions to reduce these emissions from this sector. [EPA-HQ-OAR-2021-0208-0245-A1, p.10] There is no time to lose in acting to avoid the catastrophic impacts of the climate crisis. We, therefore, urge EPA to expeditiously adopt rigorous GHG standards for model years 2023 through 2026. The technologies to achieve significant reductions are available, well-understood, and cost-effective, so there is no need to wait to require further deployment of these technologies or to delay the massive economic and public health benefits of reducing these emissions. [EPA-HQ-OAR-2021-0208-0245-A1, p.34]

1 The States of California, Colorado, Connecticut, Delaware, Hawaii, Illinois, Maine, Maryland, Minnesota, Nevada, New Jersey, New Mexico, New York, North Carolina, Oregon, Rhode Island, Vermont, Washington, and Wisconsin; the Commonwealths of Massachusetts and Pennsylvania; the District of Columbia; the Cities and Counties of Denver and San Francisco; and the Cities of Los Angeles, New York, Oakland, and San Jose.

Commenter: Canaday, Woody

I'm writing in support of the EPA's proposed tightening of standards for GHG emissions by light duty trucks. First, it was disappointing that standards were loosened under the prior administration. This appeared to be a strictly political action for, as noted in the proposed regs, five manufacturers had already agreed to more stringent California standards. Second, there is obvious and increasing urgency to reduce GHGs and light duty trucks make up one-sixth of US emissions according to the EPA notes. Third, government regulation is required when markets are unable to take external costs into consideration. A prime example of this was the introduction of seat belt regulations over the objection of profit-seeking manufacturers. Much, much more is at stake in this particular case. [EPA-HQ-OAR-2021-0208-0490, p. 1]

Commenter: Cantley, Jennifer

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 272-273.]

I am a supporter of the Administration's proposal to the regulatory actions to reduce greenhouse gas emissions in this country.

Commenter: Center for Climate and Energy Solutions (C2ES)

Statement of Nathaniel Keohane, President, Center for Climate and Energy Solutions

'Dramatically reducing climate pollution from transportation, and ultimately moving to a zero-emissions fleet, are vital steps to achieving our climate goals and maintaining America's global competitiveness. The administration's draft proposed car standards are an important step in the right direction. They demonstrate that President Biden, the EPA, and NHTSA recognize the importance of eliminating harmful transportation pollution and point the way toward the increased ambition we will need through the end of the decade.

'Our success in cutting vehicle emissions and building an American clean energy economy will depend not only on the standards we set, but also on the investments we make. The 50 percent EV sales target reflects the direction that leading automakers are already going, with many committing to making 100 percent of new car sales electric by 2035. Congress must play its part and enact the policies needed to support those efforts, including rapid expansion of EV charging infrastructure, credits for EV sales, and offering rebates for consumers purchasing them.' [EPA-HQ-OAR-2021-0208-0287-A1, pp. 8-9] https://www.c2es.org/press-release/nat-keohane-on-proposed-vehicle-standards-and-ev-targets/

Commenter: Chicago Metropolitan Agency for Planning

While CMAP is able to play a role in mitigating climate change through the programming of federal transportation funds regionally, there is an urgent need for a national strategy to reduce emissions. This proposed rule would provide a critical piece of that strategy at the federal level. According to the U.S. EPA, light-duty vehicles are responsible for 58 percent of emissions within the transportation sector, which equates to 17 percent of total U.S. emissions. [EPA-HQ-OAR-2021-0208-0219-A1, p.1]

In the Chicago region, light-duty vehicles account for approximately 65 percent of transportation emissions. Since 2015, the composition of vehicle types registered in the region has changed significantly. Passenger cars have decreased from 66.5 percent of all registered vehicles to 51.5 percent while light-duty vehicles have increased from 30.2 percent to 43.8 percent. Addressing this growing source of emissions is critically important to not only the Chicago region, but the transportation sector overall. [EPA-HQ-OAR-2021-0208-0219-A1, p.2]

Once again, CMAP is encouraged by the federal government's efforts to reduce harmful emissions and increase national mitigation efforts against climate change. We urge the U.S. EPA and other federal departments such as the U.S. Department of Transportation to continue to develop comprehensive strategies that will move our nation toward a more resilient, sustainable, and healthier future. [EPA-HQ-OAR-2021-0208-0219-A1, p.2]

Commenter: City of Albuquerque, NM

AQP respectfully submits the following comments in support of the Environmental Protection Agency's ('EPA') recently proposed Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards ('Proposed Emission Standards'). [EPA-HQ-OAR-2021-0208-0535-A1, p.1]

Additionally, the Proposed Emission Standards are consistent with the City's Climate Action Plan. Under this plan, the City is committed to reducing greenhouse gas emissions from public transportation, increasing the City's fleet size for electric and hybrid vehicles, and expanding the number of public electric vehicle charging stations. Thus, AQP strongly supports EPA's Proposed Emission Standards. [EPA-HQ-OAR-2021-0208-0535-A1, p. 3]

Commenter: City of San Antonio, Texas

The City of San Antonio, Texas supports the Environmental Protection Agency's (EPA) proposed revision as included on Docket item EPA-HQ-OAR-2021-0208, 'Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards'. If approved, these revisions will strengthen the City's efforts to meet Ozone Attainment standards and implementation of our Climate Action and Adaption Plan (CAAP). [EPA-HQ-OAR-2021-0208-0236-A1, p.1]

Commenter: Connecticut Department of Energy and Environmental Protection

Connecticut DEEP appreciates the opportunity to comment on the proposal and encourages EPA to continue to adopt strong policies to curb GHG and criteria pollutant emissions from the mobile sources sector to reduce air pollution, protect public health especially in our most vulnerable communities. [EPA-HQ-OAR-2021-0208-0264-A1, p.3]

Commenter: Consumer Federation of America

We must begin by applauding the agency for taking the time to lay out a process to do it right. It would have been easier to say that the rule adopted by the previous administration made no sense, but much more challenging to reverse the rule in a manner that would withstand scrutiny by the courts under the Administrative Procedure Act. We believe that the Environmental Protection Agency has risen to the challenge placed before it. [EPA-HQ-OAR-2021-0208-0297-A1, p. 3]

Commenter: Consumer Reports (CR)

Consumer Reports supports EPA’s efforts to reverse the previous administration’s rollback and reinstate strong light duty vehicle greenhouse gas standards. [EPA-HQ-OAR-2021-0208-0602-A1, p.4]

Consumers want better fuel economy for their vehicles, and support stronger standards by a wide margin. Nationally representative surveys have repeatedly demonstrated overwhelming public, bipartisan support for continuing to strengthen federal standards that affect vehicle efficiency. CR’s most recent fuel economy survey continues to show this strong interest.12 Key results include:

— 94% of consumers consider fuel economy to be important when considering what vehicle to purchase or lease

— 89% of consumers agree that automakers should continue to improve fuel economy for all vehicle types

— 83% of consumers expect each new generation of vehicles available on the market to be more fuel-efficient than the last

— 73% of consumers agree that the U.S. government should continue to increase fuel efficiency standards [EPA-HQ-OAR-2021-0208-0602-A1, pp.6-7]

Further, when asked what attributes in their current vehicle had the most room for improvement, consumers selected fuel economy 42% of the time, significantly more than any other selection, and 3 times as often as they selected horsepower as shown in Figure 2.1. [EPA-HQ-OAR-2021-0208-0602-A1, p.7] [[See EPA-HQ-OAR-2021-0208-0602-A1, p.7 for Figure 2.1]]

In a separate survey Consumer Reports asked consumers about their interest in electric vehicles.13 It found that 71% of consumers had some interest in buying an electric vehicle, with 31% considering purchasing an EV for their next vehicle. Further analysis of these survey results uncovered a trend showing a significant increase in interest in purchasing an EV with direct experience with the vehicles. Survey respondents were given an “experience score” from 0-3 based on the answers to the following questions:

— Do you know someone who owns a plug-in electric vehicle?

— Have you ever been a passenger in a plug-in electric vehicle?

— Have you ever driven a plug-in electric vehicle? [EPA-HQ-OAR-2021-0208-0602-A1, p.8]

The results are shown in Figure 2.2. Consumers with an experience score of 1 or 2 were more than two times as likely to consider an EV for their next vehicle, while consumers with an experience score of 3 were three times more likely to consider an EV for their next vehicle. However, only 6% of consumers in the survey sample had an experience score of 3, while 63% had an experience score of 0. This shows that there is significant room for improvement in consumer interest in electric vehicles as they become more common, and consumers gain greater experience and comfort with them. [EPA-HQ-OAR-2021-0208-0602-A1, p.8] [[See EPA-HQ-OAR-2021-0208-0602-A1, p.8 for Figure 2.2]]

Despite consumers’ clear preference for vehicles with lower emissions and fuel costs, consumer choices are limited in the market, with 2/3 of car models getting within 5 mpg of the model average and nearly 2/3 (63%) of truck models getting within 3 mpg of the model average.14 Furthermore, a team of researchers from UC Davis analyzed auto advertisements and found that performance is mentioned three times as frequently as either fuel economy or safety.15 In 2017, a mere 7% of ads mentioned fuel economy.16 This is despite the fact that consumers have shown a willingness to pay two to three times more for improvements in fuel economy and safety than for improvements in acceleration, and their willingness to pay increases with information on fuel economy.17 [EPA-HQ-OAR-2021-0208-0602-A1,p.9]

Commenter: Corporate Electric Vehicle Alliance (CEVA)

As companies that represent over $1 trillion in annual revenue and collectively own, lease, or operate more than one million fleet or networked vehicles in the United States, we are writing to express our support for strong light duty vehicle standards [EPA-HQ-OAR-2021-0208-0276-A1, p.1]

We share a common goal of electrifying our fleets and networks as well as reducing our transportation carbon footprint, and we recognize that strong policies will be necessary to effect this critical transition. Our members see climate change as a significant risk, and reducing GHGs as a major economic opportunity. We recognize that clean vehicles, including zero emission vehicles (ZEVs) and efficient internal combustion engine vehicles, bring significant economic and environmental benefits, including operational cost savings and protection from fuel price volatility, as well as improved air quality and a reduced carbon footprint. [EPA-HQ-OAR-2021-0208-0276-A1, p.1]

Commenter: Cuny, Phillip

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 245.]

One thing we can do right now, though, is raise these mileage standards and emission standards for cars and light trucks. This is probably not going to be very popular in Texas where it seems everybody drives a truck, but it is the right thing to do.

For years, SUVs have been allowed to dodge the mileage standards because they are classified as light trucks which is really ridiculous. They are designed to carry passengers. They really are passenger vehicles and now many trucks have four doors and they are used more as passenger vehicles than trucks.

If we're not going to redesignate these vehicles as passenger vehicles, we need to at least raise the standards.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 246.]

What I want to impress upon you is that we need to act now.

Commenter: Davidson, William

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 207.]

Cleaner cars of all types are a win-win for everyone. Everyone wins with cleaner air. Everyone wins with less dependence on oil, and everyone wins by slowing and ultimately reversing climate change, and when I say everyone, I include automakers who will also win domestically and internationally by selling cleaner cars.

Commenter: DENSO International America, Inc. (DENSO)

DENSO supports the goals of the EPA program to strengthen federal GHG emissions standards for passenger cars and light trucks by setting stringent requirements for reductions through MY 2026. We also support a regulatory structure that promotes flexible and cost-effective compliance pathways, encourages investment in advanced technologies, and provides real world benefits. Finally, DENSO encourages a revised national program that is harmonized to the greatest extent possible between EPA, the National Highway Transportation Safety Agency (NHTSA), and includes the State of California. More details on these points and others are discussed below. [EPA-HQ-OAR-2021-0208-0282-A1, p. 2]

Commenter: E2 - Environmental Entrepreneurs

As outlined in our recent factsheet: The Need for Speed: The Economic Urgency for Bold Action on Clean Vehicles: Speeding the transition to electric and other zero-emissions vehicles (ZEVs) is critical to the future of America's auto industry. It will save jobs, save money for consumers and businesses, and keep the U.S. auto industry competitive with the rest of the world. As transportation is now the country's biggest source of carbon emissions, it is also key to addressing the economy's biggest threat - climate change. [EPA-HQ-OAR-2021-0208-0604-A1, p. 1]

Commenter: Electric Drive Transportation Association (EDTA)

EDTA Supports EPA's Proposed Standards for MYs 2023–2026, in combination with a comprehensive policy framework, which will reinforce industry efforts, buildout electric drive infrastructure and supply chain networks, and grow consumer markets.

Collaboration and cooperation across government and industry is critical to ensuring that the transition proceeds as rapidly and coherently as possible. In addition to advancing vehicle policies, a concerted policy effort will be needed to achieve the Administration's goals for deploying 500,000 charging stations across the country by 2030.

The U.S. can lead the development and adoption of innovative technologies, while also shaping supplychains, creating jobs, defining global standards, and reshaping the international marketplace. Together, we can establish the policies that will speed the transition to e-mobility, while reducing greenhouse gas emissions, expanding U.S. market leadership, and securing the transportation workforce of the future. [EPA-HQ-OAR-2021-0208-0569-A1, p. 3]

Commenter: Energy Innovation Policy and Technology LLC

In summary, we applaud the EPA for their work to update and revise the Safer Affordable Fuel-Efficient (SAFE)1 Vehicles Rule for Model Years (MY) 2021-2026 Passenger Cars and Light Trucks to better reflect real-world advances in clean vehicle technologies, changing market trends, and the urgent need to reduce greenhouse gas emissions (GHGs) and other pollutants from the transportation sector. [EPA-HQ-OAR-2021-0208-0605-A1, pp. 1]

Commenter: Energy Strategy Coalition

Meaningful standards on light-duty vehicles that lead to decreasing emissions through 2026, and beyond, are an appropriate, essential, and widely supported component of national efforts to reduce emissions. Such standards are critical to provide regulatory certainty and send a long-term investment signal to promote low-carbon, low-emitting transportation technologies necessary to achieve emissions reductions. We accordingly support EPA's Proposed Standards. [EPA-HQ-OAR-2021-0208-0533-A1, pp. 1-2]

Commenter: Environment America

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 237.]

I would like to thank this Administration for taking the first steps to roll back the attacks the previous Administration placed on clean car standards by reinstating limits on vehicle pollution.

Commenter: Environmental Defense Fund (EDF)

EDF supports the Agency's Proposal to strengthen the Clean Car standards that were weakened by the previous administration. These comments highlight the importance and urgency in finalizing this rulemaking for model years ('MY') 2023-2026 and in finalizing longer term standards for MYs 2027 and beyond. [EPA-HQ-OAR-2021-0208-0688-A1, p. 1]

Commenter: Environmental Law and Policy Center (ELPC)

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 287.]

It is critical to remember that the necessity for this NPRM and this hearing is because the auto industry, which agreed to the 2012 program, including letters of commitment, lost no time in pushing the Trump Administration to undermine it. As a result, we have lost years of emissions reductions as the urgency for action mounts daily.

Commenter: General Motors LLC (GM)

GM supports economy wide efforts to address climate change including a drive towards an all-electric future and improving the fuel efficiency of our fleet through one national regulatory program that supports and strengthens American jobs and enhances the wellbeing of American consumers. GM supports the emission reduction goals of this proposal. [EPA-HQ-OAR-2021-0208-0234-A1] [p.2]

Further, we believe the standards should drive American leadership in battery electric vehicles (EVs). America must take the lead in this effort or other nations will dominate in electric vehicles and set global regulatory and industrial standards. [EPA-HQ-OAR-2021-0208-0234-A1] [p.2]

GM supports the emission reduction goals of this proposal and believes that the environmental benefits can and should be achieved through high-volume electric vehicle sales that will set the industry on a stronger trajectory to greater GHG reductions in model year 2027 and later. The auto industry is embarking upon a profound transition as we do our part to achieve the country's climate commitments. [EPA-HQ-OAR-2021-0208-0234-A1][p.3]

Significant EV Investments Are Needed to Meet Climate Goals. These commitments towards an all-electric future demonstrate GM's seriousness in achieving the environmental benefits envisioned by the proposed standards. Accordingly, GM supports the proposal and is committed to working constructively to achieve those benefits. GM believes that industry compliance should primarily be met through increased sales of battery electric vehicles that will encourage mass adoption and help the U.S. claim a leadership position in auto electrification. We believe that focusing on a battery electric vehicle compliance pathway is a key component to setting the industry on an irreversible path towards a tailpipe-free light duty fleet. Concentrating industry on this pathway would also provide the necessary clarity for all stakeholders to make the critical investments in the nationwide charging infrastructure that will be required. Increasing battery electric vehicle volumes in the period of this rulemaking would provide a strong foundation for the industry to make the GHG reductions necessary to meet the Paris Climate objectives and provide a model for the next set of regulations targeting 2027-2035 which will need to focus on battery electric vehicle deployment. [EPA-HQ-OAR-2021-0208-0234-A1] [p.4]

GM supports one national program across all 50 states and urges the federal government to pursue a regulatory program that encourages holistic consideration of the most cost-effective means to decarbonize the transportation sector and transition to an all-electric vehicle future that benefits the industry, its workforce, the nation, and our global climate. [EPA-HQ-OAR-2021-0208-0234-A1] [p.7]

Commenter: Gillet, Victoria

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 287.] I'm strongly in favor of the new proposed light-duty vehicle greenhouse gas emission standards.

Commenter: Hawkins, Dodie

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 55-56]

What more can I say to convince the EPA to develop the standards requested by so many esteemed speakers? Anything I might say related to climate change, combustion engines, electric vehicles, or the like would only be redundant.

So, I would like to focus my few minutes on something else, our responsibility to be good stewards of God's creation: this world. I know there are people rolling their eyes and tuning me out as just some batty old lady but hear me out, please.

We can't all be at all places at all times. So responsible people are selected to be stewards or the persons who manage another person's property or affairs and that is what the EPA is, our steward of earth.

I believe the earth is speaking to us loud and clear. Earthquakes, floods, droughts, fires, and many other tragic consequences of our disregard for the earth are becoming all too frequent. Unfortunately, we have not heard the cries from the earth for far too long. Is it too late? I pray not. I am blessed with 15 grandchildren and five great-grandchildren so far. Will they feel that I betrayed them by not doing enough to stop the onslaught of climate change? Again, I pray not. But EPA stewards, you have the opportunity to be good stewards, good managers of this earth. Personally, at 84, I'm running out of time and energy to fight the fight but not so for you.

Commenter: Hewes, Celerah

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 106-107.]

The transportation sector is the largest source of carbon pollution in the U.S. Cleaning up vehicle pollution is one of the most important things we can do to fight climate change.

That is why I was glad to hear that the EPA is proposing to strengthen federal greenhouse gas emission standards for passenger cars and light trucks which accounts for 17 percent of U.S. climate pollution.

Commenter: Holiday, Thomas

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 81.]

I support the proposed EPA Greenhouse Gas Emissions Standards for Model Year 2026 and just to be conscious about that, that would be a 52-mile-per-gallon efficiency and a CO2 burn of a 171 grams per mile.

Commenter: Holmgren, Doug

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 95.]

You've heard many people speak about how it will lead to greater savings and eliminate unnecessary manufacturing loopholes. Those are wonderful achievements if they can come about.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 97.]

So, yes, it is imperative that we return to and improve upon the Obama/Biden Administration targets for vehicle greenhouse gas emissions. Tragically, we lost valuable time due to the malfeasance of the Trump Administration. We must get back on track.

Commenter: International Union, United Automobile, Aerospace & Agricultural Implement Workers of America (UAW)

It was an honor to stand with President Biden, you, other members of the Administration, members of Congress, and industry leaders in the Rose Garden when President Biden announced his Administration's proposed 2023-26 Model Year (MY) light-duty emission regulations. I believe that carbon emission and fuel efficiency standards can be good for the environment, American workers, U.S. manufacturing, and the economy. [EPA-HQ-OAR-2021-0208-0749-A1, p. 1]

We have learned from experience that strong standards based on broad input from key stakeholders can be good for the environment and autoworkers. Well-constructed regulations promote investment, establish certainty, create new jobs in vehicle production and advanced technology, and allow manufacturers the flexibility necessary to meet the standards. Our union is proud of the role we played in reaching a consensus on MY 2011-2025 light-duty vehicle standards. We worked with a wide variety of stakeholders, including the administration, state and federal regulators, the automobile industry, environmental advocates, elected officials, and many others throughout that process. The consensus was not easily obtained and required decades of hard work and compromise. Fortunately, the standards that resulted from this process led to significant reductions in greenhouse gases, increases in the average fuel economy of passenger vehicles sold in the United States, and the creation of the 'One National Program' that was implemented in 2012. [EPA-HQ-OAR-2021-0208-0749-A1, p. 1]

I believe that carbon emission and fuel efficiency standards can be good for the environment, American workers, U.S. manufacturing, and the economy. The Environmental Protection Agency's Revised 2023-26 Model Year (MY) Light-Duty Vehicle Greenhouse Gas (GHG) Emissions Standards by and large strike the right balance of continuing to reduce automotive GHG emissions and encourage automakers to invest in new technologies that will benefit autoworkers and the economy.

Commenter: Jaguar Land Rover North America, LLC (JLRNA)

JLRNA strongly supports efforts to reduce Greenhouse Gas (GhG) emissions from light-duty vehicles, improve their fuel economy and advance the transition to low emissions vehicles. Therefore, JLRNA would welcome the opportunity to continue its constructive dialogue with the relevant Government agencies in order to agree a balanced solution based on our unique position. [EPA-HQ-OAR-2021-0208-0269-A1, p.1]

Commenter: Kansas Senator Marci Francisco

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 293.]

My thanks to you, the EPA officials, for the opportunity to testify today in support of the EPA solidifying strong greenhouse gas emissions standards for light-duty vehicles to further fuel efficiency of automobiles and curb pollution.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 296.]

Please focus on reducing the emissions from both internal combustion engines as well as encourage electric vehicles and embrace the opportunities for the standard to be raised for all passenger vehicles and light-duty trucks so that we have fewer emissions and thus a lower negative impact to society's health and ecosystems.

Commenter: Keagle, Josh

I write in support of the “Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards.” Here in North Carolina, our farmers are suffering. Climate change is making wetter hurricanes which hurts the crops. More days of extreme heat degrades livestock productivity and fish farms. Please help our farmers!

Commenter: Kimmel, Julie

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 99.]

I support this Administration's proposal to strengthen federal greenhouse gas emissions standards for passenger cars and light trucks. This proposal is a step in the right direction for the health of our children and our climate.

Commenter: Klein, Stephanie

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 279-280.]

I strongly support EPA's proposal to strengthen federal greenhouse gas emissions standards for passenger cars and light trucks for Model Years 2023 to 2026.

Cleaning up vehicle pollution is one of the most important things we can do to clean up our air and fight climate change.

Commenter: Lucid USA, Inc. (Lucid)

The Biden Administration made its commitment to electrification clear when President Biden last month issued Executive Order 14037, Strengthening American Leadership in Clean Cars and Trucks, which set an ambitious new goal that 50% of all new cars and trucks sold in the United States be EVs or plug-in hybrid electric vehicles by 2030, and directed EPA and NHTSA to revise Trump-era GHG and Corporate Average Fuel Economy (CAFE) standards. Lucid supports this overall electrification goal, as well as EPA’s proposed increase in stringency of the GHG standards above the standards set by the Trump Administration. These steps will push the U.S.

automobile market towards faster electrification, but additional steps are needed to meet President Biden's goal. [EPA-HQ-OAR-2021-0208-0528-A1, p. 3]

Lucid supports the Biden Administration's goals to fight climate change through full electrification of transportation. We also support the Biden Administration's goals for manufacturing and production of EVs and components within the United States. Lucid is leading by example on both fronts with our new Arizona factory and longstanding research and development at our California facilities. Lucid looks forward to being a committed partner to EPA in achieving these goals. [EPA-HQ-OAR-2021-0208-0528-A1, p. 7]

Commenter: Marcot, Nicole

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 156-157.]

I'm deeply concerned about the effects air pollution and climate change have on the health of my community and on our children's future. So I support this Administration's proposal to strengthen greenhouse gas emissions standards for cars and light trucks.

Commenter: Maryland Department of Environment

MDE supports the proposal to revise the greenhouse gas (GHG) emission standards for model year (MY) 2023 through 2026 light-duty vehicles (LDVs). In 2020, there was a recission of the 2012 National Clean Car Standards under the Safe Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Years 2021-2026 Passenger Cars and Light Trucks (SAFE 2 Rule). That recission did not further the country's progress towards reductions of GHG and criteria pollutant emissions. [EPA-HQ-OAR-2021-0208-0241-A1, p.1]

Maryland is supportive of this proposed rulemaking and appreciates EPA's initiative on this issue. [EPA-HQ-OAR-2021-0208-0241-A1, p.2]

Commenter: Mass Comment Campaign sponsored by Evangelical Environmental Network (15,748)

We write to commend you on the EPA's proposed rule revision to strengthen federal greenhouse gas emissions standards for passenger cars and light trucks (EPA-HQ-OAR-2021-0208-0116). We offer not only our personal gratitude for this important step, but also the support of tens of thousands of our fellow pro-life Christians across the country. [EPA-HQ-OAR-2021-0208-0561-A1, p.1]

Commenter: Mass Comment Campaign sponsored by Environment America (11,080)

I write to you on behalf of Environment America, a national network comprised of 29 state environmental groups with members and supporters across the country who want clean air and a healthy climate. I want to first thank you for revisiting the 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards. Stronger emissions standards are better for our environment and for public health. [EPA-HQ-OAR-2021-0208-0557-A1, p.1]

Commenter: Mass Comment Campaign sponsored by Interfaith Power and Light et al. (1,599)

Therefore, we are united in our call for continuing to reduce vehicle emissions. As the United States builds a clean energy economy, we must focus on the sector that now generates the largest percentage of climate pollution: transportation. The clean car standards are the most effective policy currently available to contribute to climate solutions. [EPA-HQ-OAR-2021-0208-0192-A1, p.1]

In 2012, auto companies, federal agencies, and the state of California agreed to a long overdue new set of clean car standards to boost vehicles' fuel efficiency and reduce carbon pollution from tailpipes. Implementing these standards was a critical step in our moral obligation to address the climate crisis. However, this significant step forward was rolled back under the previous administration. Now, we are calling on the Biden Administration to move forward with stronger national clean car standards. [EPA-HQ-OAR-2021-0208-0192-A1,p.1]

We urge you to consider this moral opportunity and enact bold new standards that truly envision the best for our communities, our nation, and our world. [EPA-HQ-OAR-2021-0208-0192-A1,p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-9 (3,219)

As an American, concerned with the climate crisis and the harmful air pollution that afflicts our communities, I'm writing to express my support for EPA's proposed GHG emission standards for passenger cars and light trucks. [EPA-HQ-OAR-2021-0208-0640-A1, p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-11 (1,667)

Enacting more stringent clean car standards will provide numerous co-benefits for people and parks — from saving American's billions at the pump, to preventing unhealthy vehicle air pollution that severely harms public health and the wellbeing of park ecosystems. [EPA-HQ-OAR-2021-0208-0642-A1, p.1]

Commenter: McQuire, Terry

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 224.]

ask that EPA as quickly as possible move forward with cleaner car standards that bring us closer to zero emission vehicles that have zero greenhouse gas emissions as well as other dangerous air pollutants that we know harm our communities.

Commenter: Metropolitan Washington Air Quality Committee (MWAQC)

On behalf of the Metropolitan Washington Air Quality Committee (MWAQC), the Metropolitan Washington Council of Governments' (COG) Climate, Energy and Environment Policy Committee (CEEPC), and the National Capital Region Transportation Planning Board (TPB), we are writing to offer our support for the proposed rule to revise existing national greenhouse gas (GHG) emissions standards for passenger cars and light trucks through Model Year (MY) 2026. We support your efforts to revise these standards to be more stringent than the Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule standards, and the proposed rule aligns with our 2021 Legislative Priorities. [EPA-HQ-OAR-2021-0208-0208-A1][p.1]

The EPA's current proposal to strengthen federal GHG emissions standards for passenger cars and light trucks by setting stringent requirements for reductions through MY 2026 would provide the critical leadership needed for our region to work towards meeting adopted environmental goals and standards. We agree that this comprehensive federal program will achieve significant GHG emissions reductions and will result in substantial public health and welfare benefits, while providing consumers with savings from lower fuel costs. [EPA-HQ-OAR-2021-0208-0208-A1][p.2]

Commenter: MI Air MI Health

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 195.]

For the record, MI Air MI Health fully supports the U.S. EPA's proposal to tighten greenhouse gas standards for passenger cars, SUVs, and light trucks for Models 2023 to 2026, replacing the SAFE Vehicles Rule.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 197.]

Again, MI Air MI Health fully supports quickly finalizing today's proposal to move forward with strong ambitious greenhouse gas and fuel efficiency standards for cars, light trucks, and SUVs.

We encourage even more aggressive action. Our environment, public health, and our most vulnerable populations can't afford to be idle on this issue, and I hope that you feel the urgency that I feel. Everyone deserves to breathe clean and healthy air.

Commenter: Minnesota Pollution Control Agency (MPCA) and Minnesota Department of Transportation (MnDOT)

The MPCA and MnDOT continue to support strong and technically feasible vehicle GHG emissions standards that drive deep greenhouse gas (GHG) emission reductions and a healthy environment for all Minnesotans. [EPA-HQ-OAR-2021-0208-0211-A1, p,1]

The MPCA and MnDOT appreciate EPA making it a priority to address light-duty vehicle GHG emissions standards and quickly replace the unreasonable and damaging Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule. The SAFE rule rolled back the federal emissions standards adopted in 2012, which had been robustly analyzed and affirmed to be reasonable and achievable in the 2016 Midterm Review. As noted in our comments throughout the SAFE rulemaking process, the SAFE standards were unnecessary, based on bad analyses, and harmful to human health and the environment. [EPA-HQ-OAR-2021-0208-0211-A1, p.2]

Commenter: Moore, Cinthia

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 115.]

Today, I am calling in support of the EPA's proposal to strengthen greenhouse gas emissions standards for cars and light trucks.

Commenter: National Association of Clean Air Agencies (NACAA)

NACAA welcomes this EPA proposal to revise greenhouse gas (GHG) emission standards for model year (MY) 2023 through 2026 light-duty vehicles (LDVs) and commends the agency for placing a top priority on seeking to rectify the 2020 rollback, under the ‘Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Years 2021-2026 Passenger Cars and Light Trucks’ (‘SAFE 2’ Rule), of the 2012 National Clean Car Standards. This proposal has the potential to offer substantial benefits in the form of important emission reductions that state and local air agencies need to achieve and/or sustain public health, clean air (including attainment and maintenance of the health-based National Ambient Air Quality Standards, or NAAQS) and other environmental goals and address air quality impacts in disproportionally impacted communities. These standards would also contribute to domestic job growth, economic development and fuel security. [EPA-HQ-OAR-2021-0208-0255-A1, p.1]

Commenter: National Parks Conservation Association (NPCA)

A strong clean cars standard will provide clear benefits for these communities across the nation—from improving localized health outcomes in hot spot communities, to saving average American’s billions at the pump. [EPA-HQ-OAR-2021-0208-0291-A1, p. 2]

Commenter: New Mexico Environment Department

New Mexico Environment Department (NMED) applauds your leadership in addressing climate change consistent with Executive Order 13990 on Protecting Public Health and the Environment and Restoring Science to Tackle the Climate Crisis (January 20, 2021), including the recently proposed Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards. As light-duty vehicles (LDVs) contribute 17 percent of the US greenhouse gas emission (GHGe), these CO2 standards are urgently needed to address emissions from transportation. The EPA rule, modeled as average fleet-wide CO2 targets, will also assist New Mexico in achieving the targets laid out by New Mexico Governor Lujan Grisham to reduce the state's GHGe by 45 percent by the end of the decade. NMED respectfully submits these comments on the proposed standards for your consideration. [EPA-HQ-OAR-2021-0208-0205-A1] p.1]

NMED supports increasing stringency standards that best advance the needs of New Mexicans and would, at a minimum, achieve the same level of emission benefits as under the standards adopted in 2012. NMED's reasons for supporting the increased stringency are presented below. [EPA-HQ-OAR-2021-0208-0205-A1][pp.1-2]

Commenter: Newhouse, Richard

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 77.]

We must ensure that the voices in support of strong vehicle emissions standards are heard, especially since the industry lobbyists will use this hearing as an opportunity to submit misinformation in support of weaker standards.

Improving fuel economy is one of the ways U.S. automakers can reduce greenhouse gas emissions of their vehicles and nine of 10 U.S. adults agree that automakers would continue to improve fuel economy for all vehicles and large SUVs and pickup trucks.

Strong clean air standards can drive down vehicle pollution, support our economy with consumer savings and spur innovation in the development of new cleaner car technologies and electrification of the transportation sector which you've heard quite a bit about.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 78]

Setting strong federal clean air standards through 2026 can put us back on track to save consumers up to $80 billion in reduced gas, maintenance, and price costs over the lifetime of new vehicles purchased during the next five years while restoring clean air in our communities.

Commenter: NGVAmerica

NGVAmerica and its member companies support the efforts of President Biden and the Administration to accelerate the move to deep decarbonization of the U.S. economy. Therefore, we support the steps the U.S. EPA is taking in this rulemaking to accelerate the pace of change within the transportation sector and its efforts to reduce transportation related greenhouse gas emissions. NGVAmerica and its members are committed to supporting actions that will result in the decarbonization of the transportation sector through the increased use of low-carbon, gaseous-fuels including renewable, conventional natural gas, and, eventually, hydrogen [EPA-HQ-OAR-2021-0208-0214-A1, p.1]

Our members support the ultimate goal of the model year 2023 and later light-duty vehicle greenhouse gas emission standards – to decarbonize the transportation sector as quickly as possible while greatly reducing harmful criteria emissions that contribute to poor air quality and federal ambient air standards [EPA-HQ-OAR-2021-0208-0214-A1, p.1]

Commenter: Nissan North America, Inc.

Nissan strongly supports the long-term electrification, fuel efficiency, and carbon neutrality goals of the U.S. Environmental Protection Agency ("EPA") and the National Highway Traffic Safety Administration ("NHTSA"). Policy actions by federal, state, and local governments to invest in and accelerate electric vehicle ("EV") market expansion are vital to realizing these shared goals. Nissan encourages EPA and NHTSA to maintain support for expanded market measures such as purchase incentives and infrastructure development, which encourage adoption of zero-emission vehicles ("ZEVs"). Nissan further encourages EPA and NHTSA to continue to offer and expand incentives for the development, manufacture, and sale of EVs, including credit multipliers, A/C and off-cycle credits, as well as to expand CAFE credit trading and extend GHG credit life. Nissan also encourages the agencies to maintain and expand the compliance flexibilities built into the existing GHG and CAFE programs in order to allow the automotive industry to continue investing heavily in meeting and exceeding these goals. [EPA-HQ-OAR-2021-0208-0529-A1, p. 1-2]

Commenter: Oliver, Shaina

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 72.]

I support this Administration's proposal to strengthen protection for clean car standards that will protect all children's health and future.

I urge this Administration to move forward on setting ambitious federal clean car standards would be a step in the right direction. The transportation sector is the largest source of carbon pollution in the U.S. Cleaning up vehicle pollution is one of the most important things we can do to fight climate change.

Commenter: Program for Public Consultation

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 96-98.]

They were informed that this proposal would increase the cost of vehicles but save consumers more on gas in the long run. Similarly, increasing fuel efficiency standards for heavy-duty trucks, vans, tractors, and similar vehicles was supported by 71 percent, including 84 percent of Democrats, 68 percent of Independents, and 56 percent of Republicans, though they were told the increase would increase the cost of the vehicle, once again saving money on gas in the long run. These were also supported in Texas, despite its dependence on oil, as well as in Ohio and Florida. After the Trump Administration's replacement of the Clean Power Plan with the Affordable Clean Energy rule, which froze the fuel efficiency standards, a survey by Yale University and George Mason University asked respondents whether they would support the government setting stronger fuel efficiency standards for cars, trucks and SUVs, a large majority of 78 percent of voters were in support, including 91 percent of Democrats, 76 percent of Independents, and 62 percent of Republicans.

In conclusion, increasing fuel efficiency standards as a way to reduce air pollution is consistently supported by a large majority of the public, including majorities of Republicans, even after informed that it would raise the cost of vehicles.

At the Program for Public Consultation, we do not take a position on policy issues but believe that in a democracy it is important for government agencies to consult citizens on key public issues that the government faces. We encourage you to take the views of all of the public into account when deciding whether to change federal fuel efficiency standards.

Commenter: Pruitt, Katherine

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 156.]

I am grateful and relieved after so many rollbacks of critical public health and environmental protections under the previous Administration that President Biden and his Administration have acknowledged the importance of tackling pollution from the transportation sector that is contributing to climate change.

I appreciate that the Biden Administration is taking a small step in the right direction with this proposal and other broader actions on clean cars, climate change, and environmental justice which I support.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 158.]

Stronger standards for cleaner cars, if enacted now, will make a much-needed difference in my community and will protect my family.

The great thing about setting standards is that it works and the public supports it. It ensures equitable access to health and environmental benefits that cleaner technologies are making available now and into the future.

EPA must finalize the rule this year, 2021, to cover Model Years 2023 through 2026.

Commenter: Representative Padma Kuppa

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 144.]

I've always been conscious of the need to protect our planet for the future generations and a critical component of this is reducing vehicle emissions and having stringent clean air standards.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 145.]

We bring to our jobs a belief in science that empowers us to improve vehicle emissions. We have a work ethic that drives us also empowers innovation and support for clean car standards so that our automotive industry can deliver real-world emissions reductions and set standards for others to follow around the world.

Commenter: Sabetta, Tracy

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 99.]

In support of an EPA proposal to set the strongest possible federal clean car standards through 2026.

Commenter: Sainz, Columba

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 226.]

I support this Administration's proposal.

Commenter: Scholar, Reverend

As an American, concerned with the climate crisis and the harmful air pollution that afflicts our communities, I'm writing to express my support for EPA's proposed GHG emission standards for passenger cars and light trucks. I respectfully urge you to finalize them as soon as possible and move swiftly to establish the next set of standards that put us on the path to 100% sales of new zero-pollution cars and light trucks by 2035. With ambitious multi-pollutant standards, we can protect the health of our communities and achieve the President's goal of a zero-emission transportation future. [EPA-HQ-OAR-2021-0208-0724-A1, p. 1]

Commenter: Sierra Club

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 28-29.]

I cannot overstate the importance of strong clean car standards, for climate action, racial justice, and improving public health.

I'm calling on EPA to strengthen this proposed rule to deliver on our shared priorities.

President Biden and his Administration have promised to take action to reverse Donald Trump's illegal and dangerous attacks on cleaner cars and clean air.

I thank the Administration for the speed with which they have worked on new clean car standards to set us back on track.

Strong standards will protect communities across the country from harmful transportation pollution, set enforceable regulations that the auto industry must meet, and are critical to our nation slashing climate= disrupting emissions and meeting our Paris Agreement commitment by 2030.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 30.]

During the previous Administration, Sierra Club in coalition with the diverse set of advocacy groups worked to defend the clean car standards. Now is the moment for the Biden Administration to go further than ever before and establish the strongest rule possible.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 31.]

I'm here today to urge the EPA to set the strongest possible clean car standards to deliver real world emissions and reductions that match the urgency of the climate crisis that we're living right now.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 33-34.]

We appreciate President Biden and his Administration for following through on promises to address climate action and environmental justice by reversing the previous Administration's attacks on clean car standards, but by acting swiftly on these rules the Administration has acknowledged the importance of tackling climate pollution for transportation.

But we need the boldest and strongest possible clean car standards to truly make good of these commitments. We cannot afford a rule that locks in more climate pollution.

It's time for the Biden Administration to reinstate our strongest tool against climate change and go beyond the standards President Obama set nearly a decade ago.

Commenter: Smith, Arthur

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 315.]

I strongly support this Administration's swift action on clean cars.

Commenter: South Coast Air Quality Management District

The South Coast AQMD supports EPA regulatory action to correct as far as possible the unlawful, damaging course set by the 2020 SAFE rulemaking. [EPA-HQ-OAR-2021-0208-0215-A1, p.2]

Commenter: Stout, Linda

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 118-119.]

In 2020, the American Lung Association stamped us with an F for our failing air quality. This is why I support our Administration's proposal to allow states to adopt strong clean car standards.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 120.]

Infrastructure for cleaner options is available right now. That's why I wholeheartedly support the proposal allowing states to establish clean car standards that protect our children's health and their future.

Commenter: Thomas, JP

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 182-185.]

Overall, PPC finds that a large majority support the government taking action to reduce air pollution. In a September 2020 survey, 78 percent of voters assigned a very or somewhat high priority to the government working to reduce air pollution that causes negative health effects. This included 54 percent of Republicans, eight in 10 Independents, and 98 percent of Democrats.

A survey in 2016 on the clean power plans proposal to require all cars and trucks by 2025 to emit half the carbon dioxide of the 2010 model elicited support from 73 percent of voters, including 86 percent of Democrats, 71 percent of Independents, and 57 percent of Republicans.

They were informed that this proposal would increase the cost of the vehicle but save consumers more on gas in the long run. Similarly, increasing fuel efficiency standards for heavy-duty trucks, vans, tractors, and similar vehicles was supported by 71 percent of American voters, including 84 percent of Democrats, 68 percent of Independents, and 56 percent of Republicans, though they were told the proposal would increase the cost of the vehicle, again while saving money on gas in the 16 long run.

Both of these increases were supported also by bipartisan majorities of voters in Texas, despite its dependence on the oil industry.

After the Trump Administration replacement of the clean power plan with the Affordable Clean Energy Rules, which froze the fuel efficiency standards, a survey by Yale University and George Mason University asked respondents whether they would support the government setting stronger fuel efficiency standards for cars, trucks, and SUVs.

A large majority of 78 percent of voters were in support, including 91 percent of Democrats, 76 percent of Independents, and 62 percent of Republicans.

In conclusion, increasing fuel efficiency standards as a way to reduce air pollution is consistently supported by a large majority of the public, including majorities of Republicans, even after being informed that it would raise the cost of vehicles. At Voice of the People we do not take a position on policy issues but believe that democracy is important for government agencies to consult citizens on key policy issues that the government faces.

We encourage you to take the views of all of the public into account when deciding whether to change federal fuel efficiency standards.

Commenter: Trombetta, Nick

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 216.]

I wanted to voice my support for reinstating and strengthening the clean car standards that were rolled back by the Trump Administration.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 218-219.]

In conclusion, strengthening clean car standards are a win for all parties involved, not just the environment and not just for consumers. It's clearly in the best long-term interests of car manufacturers, the planet, and vulnerable communities. It is past time that the United States takes a strong stance on climate change.

Commenter: Uberuaga, Michelle

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 283.]

I'm testifying today to support the EPA's proposal. This proposal is a step in the right direction to address the urgent climate emergency that we are living in right now.

Commenter: Villalpando Paer, Natalir

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 202-203.]

That is why I support this Administration's proposal to strengthen federal clean greenhouse gas emissions standards for passenger cars and light trucks for Model Years 2023 and 2026.

Commenter: Volkswagen Group of America, Inc. (Volkswagen)

Volkswagen Group Supports the Proposed Direction of EPA's NPRM Volkswagen supports the overall proposal from EPA for reductions in light-duty vehicle CO2 emissions for model years (MY) 2023-2026. EPA's proposed regulations are consequential both for the future transformation of the auto industry and for meeting the imperative of climate change. Volkswagen supports the Administration's ambitions to dramatically lower greenhouse gases (GHGs) from the transportation sector and accelerate the adoption of electric vehicles. [EPA-HQ-OAR-2021-0208-0237-A1, p.1]

Volkswagen supports the goals of the EPA proposal for reducing vehicle GHG emissions for 2023-2026MY. We are supportive of annual reductions in CO2 emissions from motor vehicles and in the flexibilities in the proposal that will continue to provide an important incentivizing effect on vehicle electrification. [EPA-HQ-OAR-2021-0208-0237-A1, p.7]

Commenter: Volvo Car Corporation

The automotive industry is currently undergoing significant changes driven both by technology shifts, digitalization and changing consumer behaviour. Volvo Cars is fully committed to promoting and advancing technology on electrification, connectivity, mobility services and autonomous driving (AD). But many uncertainties remain (tariffs, infrastructure, incentives) so government should pursue policies that encourage auto industry investment and jobs, development of the electric vehicle market and advancement of motor vehicle safety. With the right complementary government policies, this rulemaking presents an opportunity for government and industry to pursue these shared goals. [EPA-HQ-OAR-2021-0208-0253-A1, p.4]

Commenter: Whyte, Yolanda

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 142.]

I support this EPA Administration and this proposal to reduce pollution from passenger cars and light trucks for Model Years 2023 to 2026 with the goal of reducing our consistently-increasing greenhouse gas emissions. Urgent actions must be taken now.

Commenter: Wisconsin Department of Natural Resources

The 2020 Safer Affordable Fuel Efficient (SAFE) Vehicles Rule substantially weakened the standards that had been established in 2012. Due to the pressing need to reduce both GHG and criteria pollutant emissions from light duty vehicles, WDNR urges EPA to move expeditiously to promulgate a final rule that strengthens these standards and reduces emissions from these vehicles. [EPA-HQ-OAR-2021-0208-0223-A1, p.1]

Commenter: Wiste, Leah

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 87.]

The draft clean cars proposal can be a moral opportunity. We have in front of us a chance to respond to the cry of our communities and the cry of the earth, an opportunity to follow the science and to move rapidly to make the emissions reductions we know are necessary.

Commenter: World Resources Institute (WRI)

The World Resources Institute (WRI) appreciates the opportunity to comment on this important rulemaking. This rulemaking can be an important step toward achieving the pollution-free transportation system the United States needs to respond adequately to the climate crisis, to provide clean air for all Americans, and to realize billions of dollars in consumer fuel savings. To achieve these ends the final rule will have to incorporate key improvements as discussed in these comments. [EPA-HQ-OAR-2021-0208-0207-A1, p. 1]

EPA Response

EPA acknowledges the comments received expressing general support for EPA’s rulemaking. Some of these commenters had additional comments that disagreed with or suggested changes in specific aspects of the proposed program; we address these in other sections of this RTC or in the preamble.

1.2. General Opposition to the Proposal

Turlo, Andy
Valero Energy Corporation (Valero)
Zimmerman, Don and Linda

Commenter: Anonymous Public Comment 1

Whatever social ills automobiles and emissions may cause, there is no overriding ill so profound as to allow for an overreach of government authority. Moreover: there is no problem so profound as to justify a ban on anything! Customers are well-served from having multiple vehicle options and are perfectly capable of making intelligent adult decisions for themselves without the need for expansive mileage regulations from the EPA. If customers truly valued high-mileage vehicles (as is suggested in the EPA's logical overreach), then there would be a sizable profit opportunity for major automobile manufacturers in meeting that need. There is no need for the EPA to push unwanted products on customers under the mandate of an explicit mileage regulation.

As a consumer who values choice, I firmly reject the EPA's authority to set these rules and think that this mileage tightening exercise is a massive mistake. The country would be better off if OEMs were allowed to chart their own path and make cars truly desired by consumers without government intervention. [EPA-HQ-OAR-2021-0208-0357, p. 1]

Commenter: Attorney General of Missouri et al.

Building on the IWG's flawed analysis, the EPA's rush to carbon-zero vehicles compounds the risk to the American economy with ever more stringent mandates. Although promising, such technology also comes with substantial negative impacts to the environment, the economy, the poor, and to national security. For these reasons, we urge the EPA with withdraw this proposed rule and leave in place the rule promulgated by the previous administration. [EPA-HQ-OAR-2021-0208-0288-A1, p.17]

Commenter: Competitive Enterprise Institute et al.

The authors and undersigned organizations strongly oppose the EPA’s proposal to replace the Safer Affordable Fuel-Efficient (SAFE) Vehicle Rule’s GHG standards with more stringent regulatory requirements. [EPA-HQ-OAR-2021-0208-0292-A1, p. 1]

Commenter: Taxpayers Protection Alliance

On behalf of millions of taxpayers and consumers across the country, the Taxpayers Protection Alliance urges you to reconsider onerous proposed emissions standards on light-duty vehicles (i.e., passenger cars and light trucks). [EPA-HQ-OAR-2021-0208-0202-A1, p.1]

Commenter: Turlo, Andy

The EPA needs to extricate themselves from the automotive industry. They have repeatedly proven the do not understand the industry or the science behind it. They push a clear political agenda while bulling private companies in shakedown techniques that were previously employed by organized crime. If anyone at the EPA actually read or understood the science then they would see the glaring problems with the studies done. They are based more on guesses and thin air than science. The EPA at best is run by incompetent individuals or in my opinion run by individuals lacking integrity. It is a sad and depressing state the country has come to to rely on people doing their best to justify their existence while taking resources from private citizens to do so. [EPA-HQ-OAR-2021-0208-0367, p. 1]

Commenter: Valero Energy Corporation (Valero)

Valero urges EPA to revise the GHG emission standards to provide a level playing field in which different vehicle designs, fuel types, and technologies can compete fairly to meet an appropriate performance target where such targets act in harmony, not in conflict, with other statutory requirements aimed at reducing overall GHG emissions [EPA-HQ-OAR-2021-0208-0601-A2, pp.8-9]

Commenter: Zimmerman, Don and Linda

As an American I'm writing to express my firm opposition for EPA's proposed GHG emission standards for passenger cars and light trucks. I respectfully urge you to leave them as they currently exist. While the goal of zero emission vehicles is worth pursuing the process of achieving this standard has not been fully researched and a valid plan developed to achieve this standard. The current proposal has merit for highly urbanized areas but heavily penalizes rural areas.

The knee jerk reaction to achieve goals without fully researching, developing viable and effective plans and minimizing actual costs and impacts has got to stop. [EPA-HQ-OAR-2021-0208-0656-A1, p. 1]

EPA Response

EPA acknowledges these comments expressing general opposition to the proposed rule. For responses to specific issues raised by some of these commenters, please see the separate sections of this RTC and the preamble. Specifically, as context for the comment of the Attorney General of Missouri et al. in this section, see also EPA responses in Sections 12.3, 13, 14, 14.1, 16, 17.2, 19, and 23 of this RTC, and as context for the comment of the Competitive Enterprise Institute in this section, see also EPA responses in Sections 2.2, 15, and 21 of this RTC. We also summarize our general reasoning in support of our final standards and provisions in Section VI of the preamble.

2. CO2 Emissions Standards and Feasibility

<u>Commenters Included in this Section</u>

Commenter: California Air Resources Board (CARB)

U.S. EPA, by adopting this proposal along these lines, would be correcting serious errors in the current rule, the Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Years 2021-2026 Passenger Cars and Light Trucks (Final SAFE Rule),2 which improperly sets standards far below emissions levels that have clearly been feasible for many years. As U.S. EPA recognizes in its proposal, the extensive record supporting the National Program standards, the rigorous analyses that have been done since that record was developed, and the increasing pace and declining cost of the technology to reduce and eliminate motor vehicle emissions supports the proposed standards, including the most stringent alternatives. The draft Technical Assessment Report in 2016 and analyses by U.S. EPA in its Midterm Evaluation showed then that the National Program standards were technologically feasible (including with many extant technologies), appropriate, and would have benefits that far outweighed their costs. CARB reached similar conclusions about its greenhouse gas emission standards in its 2017 Midterm Review. [EPA-HQ-OAR-2021-0208-0643-A6, pp.6-7]

U.S. EPA properly recognizes this here and has weighed the factors relevant to setting emission standards in a manner consistent with Congressional direction. Because the National Program standards have been and continue to be appropriate and feasible, U.S. EPA has grounds to adopt its proposal and any combination of more stringent measures within its proposal.[EPA-HQ-OAR-2021-0208-0643-A6, p.7]

Stringent Federal Standards Will Reduce Pollution Nationwide and Lower Costs, Even in California. CARB supports more stringent federal greenhouse gas emission standards independent of and complimentary to its own standards adopted under as an exercise of authority preserved by the federal Clean Air Act. CARB has consistently and vigorously opposed the actions by U.S. EPA to improperly withdraw a waiver of federal preemption for its standards.10 CARB encourages U.S. EPA to quickly finalize its proposal to restore California's waiver of preemption for its standards.11 Nevertheless, more stringent federal standards would support greater emission reductions nationwide.

This is even more true where the Alternative 2 proposed standards would return to the National Program standards that are similar to CARB's standards for any model years for which they are adopted; the feasibility of the preferred alternative is also supported by CARB's voluntary agreements with many automakers and would yield significant reductions. Stringent California and federal emission standards can work together to facilitate compliance by manufacturers by creating a broader market to develop cleaner technologies. This is as true for greenhouse gas emission standards as it is for criteria pollutant standards, where U.S. EPA's Tier 3 standards for model years 2017-2025 and CARB's Low-Emission Vehicle III standards both reduce pollution from motor vehicles.12

Most importantly, stringent federal GHG emission standards are needed to address the worsening climate crisis. [EPA-HQ-OAR-2021-0208-0643-A6, p.9]

Commenter: California Attorney General Office, et al.

In sum, automakers are already producing a wide array of vehicles that would facilitate compliance with standards significantly more stringent than SAFE 2 as early as MY2023. That, combined with the additional fleet improvements that can be reasonably expected between MYs 2021 and 2023, establish automakers' ability to meet at least the preferred alternative standards in MY2023. [EPA-HQ-OAR-2021-0208-0245-A1, p.28]

Commenter: Center for Climate and Energy Solutions (C2ES)

Regarding feasibility of the standards for automakers, given the extended timeline over the initial 2012 final rule, automakers should be able to meet the annual performance targets with the proposed flexibilities, although some may need to rely more heavily on market credits than others. Additionally, the commitment of five major automakers to sign onto the California Clean Cars Framework Agreement with similarly ambitious targets to EPA's proposed rule demonstrates the willingness and ability of automakers to comply with the standards.

Many automakers have made voluntary commitments to electrifying 40 percent or more of their fleets by 2030 or 2035, including General Motors, Ford Motor Co., Stellantis N.V., Mercedes-Benz, and Volvo. Toyota projects 80 percent of its cars sold in 2030 to be battery, fuel cell, or hybrid electric. Adding to their ambitious targets, these companies have announced financial commitments of more than $150 billion in electric and autonomous vehicle development through 2030, even before the application of regulatory pressure of more stringent emissions standards.13 [EPA-HQ-OAR-2021-0208-0287-A1, p.5]

To date, fifteen states have adopted California's Clean Car standards, setting requirements for automakers to offer increasing shares of low- and zero-emission vehicles for sale. In setting emissions standards, EPA should take into account state-level ambition and align federal stringency to provide a more consistent level of ambition across the nation. [EPA-HQ-OAR-2021-0208-0287-A1, p. 5]

Commenter: Dream Corps Green for All et al.

We are heartened to see EPA state a target of reducing pollution by 60% by 2030, which will save lives and accelerate clean transportation choices, but changes are needed to ensure the final rule actually delivers on this goal. [EPA-HQ-OAR-2021-0208-0285-A1, p.1]

Commenter: Elders Climate Action (ECA)

EPA's proposed rule merely reduces carbon fuel combustion per mile driven. Zero emissions cannot be achieved if vehicles continue to burn carbon fuels. Internal combustion engines (ICEs) must be replaced as quickly as possible by zero emission vehicles (ZEVs). EPA's proposed rule does not chart a course toward implementing either the national policy declared by President Biden or reflect the urgent need to cut GHG emissions in half by 2030 to avoid much worse future climate catastrophes. The rulemaking fact sheet acknowledges that over the next 30 years the rule will only reduce emissions from light duty vehicles equal to one year's emissions. The rule does not achieve, or describe how it will contribute to achieving, zero emissions by 2050. [EPA-HQ-OAR-2021-0208-0521-A1, p. 2]

We petition the Administrator to make this finding as the predicate for re-opening this rulemaking for the purpose of promulgating a zero emission standard for LDVs, and a phase-in schedule that prescribes for each automaker a share of total LDV sales that must be ZEVs beginning with the 2026 MY. [EPA-HQ-OAR-2021-0208-0521-A1, p. 12]

Motor Vehicle Emission Control programs is Not Adequate to Protect Health. In most nonattainment counties, ozone emission inventories and a significant fraction of PM2.5 inventories are dominated by tailpipe emissions. Obviously the national emission control program for motor vehicles has not been, and is not now adequate to reduce mobile source emissions to the levels needed to attain the NAAQS in these regions. Only the conversion of vehicle fleets to zero emission technologies offers the possibility of attaining the NAAQS to resolve the public health crisis suffered by residents in these counties.

If EPA sets a zero emission standard for new motor vehicles, fossil fueled vehicles will be replaced with zero emission technologies. For ozone, reducing emissions of ozone precursors a few percent can make an observable difference in both ozone peak concentrations and the frequency of exceedance days. Precursor emissions increases in most metro nonattainment areas that exacerbate ozone violations are at the rate of VMT growth which typically is 2- 3% annually. So small changes in emissions, along with increasing heat that drives the atmospheric chemistry, can have a big impact on ozone formation.

As soon as a ZEV sales mandate takes effect, fleet-wide emissions will begin dropping at the rate of ICE replacement. Assuming a 20-year time horizon for full fleet replacement, each year 5% of the ICE fleet will be replaced. Under a zero emission standard for new vehicles, the portion of the replacement vehicles that will be zero emissions will be determined by the ZEV sales requirement for that MY.

That means total emissions of all reactive hydrocarbons emitted from tailpipes, aromatics included, will drop 5% after one year if 100% ZEV sales are required, or 1.5% if 30% ZEV sales. Under a 100% sales regime, ozone precursor emissions will drop quickly: 10% after two years. 15% after three years, etc. These reductions are HUGE compared to what can be accomplished with fuel additives, or EPA's proposed rule which aims to reduce emissions by 5% each year only from the new vehicles added to the fleet (i.e. in year one 5% of 5%, or 0.25% of total emissions); instead of reducing 5% from the entire fleet emission inventory. A ZEV sales mandate promises to completely resolve ozone nonattainment in nonattainment areas where a 20% reduction is enough in as few as four years. And clean air for our kids will be permanent because fleet replacement will continue to accelerate in future years to reduce emissions at a rate significantly faster than VMT growth.

When tailpipes no longer exist and coal is no longer burned to generate electricity, urban ozone exceedances and its devastating impacts on human health will become a footnote in history. Cities will have air quality safe for raising children. [EPA-HQ-OAR-2021-0208-0521-A1, pp. 14-16]

Commenter: Energy Strategy Coalition

As companies and utilities in the electric industry, we understand the importance of business and market certainty to our operations. Given the lead time necessary for investment in research and development and eventual deployment of new technologies, we need regulatory certainty that allows us to anticipate future challenges and opportunities and invest in solutions to meet them. In 2012, EPA, working with NHTSA and the California Air Resources Board, sought to do just that—by aligning standards and creating consistency across the three agencies and by creating standards that extend over the investment horizon. Returning to Proposed Standards that create a national program by harmonizing with California's standards will help repair the regulatory environment and help spur additional critical private and public investment. [EPA-HQ-OAR-2021-0208-0533-A1, p.3]

Commenter: Environmental Defense Fund (EDF)

Five manufacturers (BMW, Ford, Honda, Volvo, and Volkswagen) have signed voluntary agreements with the State of California committing themselves to reducing GHG emissions from their national fleets in MYs 2021-2026.24 Those agreements impact EDF's assumptions about the GHG performance of those manufacturers in those model years. In particular, we assume that the automakers that voluntarily committed themselves to reduce emissions in excess of requirements to which they would be subject under EPA's Proposed Standards through MY 2024 will, as a group, be able to comply with the Proposed Standards through MY 2024 without acquiring credits held by automakers that have not made such commitments. [EPA-HQ-OAR-2021-0208-0688-A1, p. 14]

The feasibility of EPA's Proposed Standards is supported by the California's ongoing Advanced Clean Cars II (ACCII) rulemaking. The California Air Resources Board ("CARB")'s ACCII standards will see automakers transition large percentages of their fleets to ZEVs between model years 2026 and 2035. Early rulemaking documents released in May 2021 indicate CARB will set a proposed Zero Emissions Vehicle (ZEV) standard that will achieve 26% ZEV and PHEV sales in 2026.56 The standards then increase to 76% ZEV sales by 2031 and ultimately eliminate tailpipe pollution by 2035, in line with the goal of 100% ZEV sales set out by Governor Newsom.57 CARB found that proposed 26% ZEV sales rule is feasible for manufacturers to comply, based on comparison with the redesign timeline for vehicles.58 The agency found that the trajectory of ZEV and PHEV sales doubled between MY 2016 and 2018 but decreased in MY 2019 (along with total vehicle sales). According to manufacturers' own projections, almost 25% of statewide sales will be ZEV and PHEV by MY 2025.59

California's Advanced Clean Car II standards will likely also be adopted by other Clean Air Act Section 177 states that have adopted the California standards. Currently 14 states and the District of Columbia have adopted California standards. Eleven of those states have adopted ZEV standards. 60 The ACCII rulemaking, supports the feasibility of the EPA emissions standards as manufacturers will have to comply with the ZEV regulations. As a result, EVs will likely make up a growing percentage of the vehicle fleet, due to market forces, consumer demand, and regulation, and improve manufacturers' corporate GHG performance. [EPA-HQ-OAR-2021-0208-0688-A1, p. 36]

Commenter: Holiday, Thomas

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 81.]

The reason I endorse that is it's already done by the top three hybrids, the top three, the most efficient, the most highest-achieving hybrids in production, the Toyota Prius, the Honda Insight, the Shindai Hyundai Ioniq, and so those three really already do that.

Commenter: Illinois et al. Corn Growers Associations (Corn Growers Associations)

The key defect with the proposal is that it does not provide a pathway for actually achieving the emissions goals it claims to seek. EPA acknowledges that "the vast majority of vehicles produced in the time frame of the proposed standards will be gasoline-fueled vehicles."3 But it does not seriously consider the current technological limitations that stand in the way of further emissions reductions from internal combustion engines. When coupled with EPA's extremely aggressive proposed timeline, this defect makes it virtually certain that automakers will not be able to comply with the proposed rule without what the proposal euphemistically calls regulatory "flexibility."4 That flexibility is promised in part in the form of extensions of "EV multipliers," which allow traditional automakers to buy their way out of compliance with EPA's standards by double counting electric-vehicle credits when calculating fleet-average greenhouse gas emissions. This is counterproductive because, as EPA admits, multipliers do not meaningfully encourage the adoption of electric vehicles, but instead serve only to enrich electric vehicle manufacturers at the expense of consumers, industry, and the environment. [EPA-HQ-OAR-2021-0208-0563-A2,p.3]

Commenter: Maine Department of Environmental Protection

Unfortunately, these standards were subsequently rescinded despite EPA's 2018 mid-term evaluation that confirmed the standards for model years 2022-2025 were both technically feasible and appropriate.1 [EPA-HQ-OAR-2021-0208-0225-A1, pp.1-2]

Commenter: Michalek, Jeremy and Whitefoot, Kate S.

Reexamining outdated artifacts of inter-agency coordination: The proposed regulation and cost-benefit analysis contains some legacy artifacts that were due to restrictions placed on NHTSA that are no longer relevant now that the agencies are not issuing joint regulations. Notably, EPA should account for all credit provisions in the regulations when examining their feasibility, costs and benefits. Additionally, we recommend that EPA examine a regulatory alternative that creates one standard across the full fleet of light-duty vehicles rather than two separate standards for passenger cars and light trucks. [EPA-HQ-OAR-2021-0208-0300-A1, p. 2]

Reexamine Outdated Artifacts of Inter-Agency Coordination. We recommend that EPA examine legacy elements of the regulation that were based on restrictions applied to NHTSA but not to EPA that are no longer relevant now that the two agencies are not issuing joint regulations. These include (1) separate standards for passenger cars and light trucks and (2) ignoring certain flexibilities of the regulations (such as averaging, banking, and trading of credits) in the cost-benefit analysis.

Separate standards for passenger cars and light trucks. A legacy element that appears outdated is setting two distinct regulations, one for passenger cars and one for light trucks. This provision was present in previous regulations because NHTSA was restricted by Congress to separately set regulations for passenger cars and light trucks, but EPA is not subject to such a restriction. We believe this separation is outdated for the following reasons:

1. The industry has seen an emergence and growth in SUVs and crossover vehicles, many of which are classified as light trucks.

2. Having less stringent standards for light trucks than passenger vehicles can create an incentive to sell more light trucks and design vehicles to be classified as light trucks than would have occurred with a single standard across the fleet of light-duty vehicles.

3. Multiple vehicle models, such as the Honda CRV and the Ford Escape, have a passenger car version and a light-truck version that are nearly identical, but the light-truck version is subject to a less stringent GHG emission standard.

4. Having a single standard would increase manufacturers' flexibilities to meet the standards across their full fleet, and reduce compliance costs.

EPA should study the alternative of issuing one set of average standards that would apply to the full fleet of light-duty vehicles. [EPA-HQ-OAR-2021-0208-0300-A1, p. 6]

Commenter: National Automobile Dealers Association (NADA)

NADA also objects to EPA decision to model its proposal, at least for MY 2023, on standards agreed to by five OEMs in conjunction with the State of California.40 Certainly, individual OEMs are entitled to go beyond what the law requires, and NADA does not object to them voluntarily electing to do so. However, the voluntary "framework" standards agreed to by California and five OEMs should not automatically serve as the basis for any revised federal GHG mandates that all OEMs must comply with. As EPA notes, the OEMs that entered the "framework" agreements represent only "about a third of U.S. vehicle sales."41 That OEMs representing the other 2/3 of U.S. vehicle sales did not enter similar agreements is telling and raises significant questions as to whether those standards are reasonable and appropriate. [EPA-HQ-OAR-2021-0208-0290-A1, p. 10]

Commenter: Platt, Keari

As such, I appreciate and approve of the EPA's decision to use the California Framework as the least stringent alternative. The EPA's decision to adopt a 10% stringency increase is reasonable considering how many automakers already made a voluntary commitment to improve fuel efficiency. Meeting the EPA's more stringent standards by 2026 would be feasible because automakers demonstrated a capability and willingness to do so. [EPA-HQ-OAR-2021-0208-0201-A1, p. 1]

EPA Response

CARB's request for EPA to finalize its proposal to restore California's waiver of preemption for its standards is addressed in Section 26.2 of this Response to Comments.

Elders Climate Action suggested that EPA establish a zero-emissions vehicles (ZEV) mandate. EPA did not propose or request comment on adopting a ZEV mandate; therefore this comment is outside the scope of this rulemaking. In addition, EPA disagrees with this approach for the time frame of this regulatory action (MY2023 – 2026). EPA believes the appropriate approach to structuring emissions standards through the MY2026 time frame is through performance-based standards with year-over-year increases in CO_2 emissions stringency. As shown in our analysis, this approach is projected to result in increasing EV penetrations (reference Table 4-29 and Chapter 4.1.4.1 of the RIA), as EVs are one of the technology options automakers can choose to use to comply with increasingly stringent standards. Most importantly, the final performance-based standards are projected to reduce air pollution emissions (both GHG and criteria pollutant emissions) with cumulative emission reductions growing as more of the light-duty fleet becomes subject to the more stringent standards through fleet turnover. Tables 34 and 37 of the Preamble detail the projected GHG and criteria pollutant emissions reductions, respectively, for the final standards.

In its comments, NADA objects to EPA basing its proposal on standards consistent with the California Framework Agreement. NADA also states that it "supports a harmonized set of federal light-duty vehicle GHG/fuel economy standards that are technologically feasible..." As described in Preamble VI.A and RIA 2.2, EPA considered many factors in assessing the feasibility of the standards and the California Framework Agreement nationwide targets were appropriately one of these many factors.

The Corn Growers Associations commented that EPA "does not seriously consider the current technological limitations that stand in the way of further emissions reductions from internal combustion engines." EPA disagrees with these comments, and on the contrary, EPA's projection of vehicle technology applications does consider the technological limitations for internal combustion engines[1] (including the potential improvements that come from multiple forms of powertrain hybridization which rely upon internal combustion engines), and we believe that the incremental improvements we project for gasoline-fueled vehicles are reasonable and the final standards are feasible. In response to increasingly stringent standards, manufacturers have shown a decade of continual innovation and technological progression. Furthermore, the technological achievements already developed and increasing in application to vehicles within the current new vehicle fleet (RIA Chapter 2.3) will enable the industry to achieve the final standards even without the development and implementation of additional technologies. EPA discusses the feasibility of the standards further in Preamble III and VI.A and RIA 2.2

Regarding the Corn Growers Associations' critique of EV multipliers, EPA responds to their comment in Section 6.1 of this RTC.

Drs. Michalek and Whitefoot requested EPA to examine an alternative of one standard for all light-duty vehicles rather than two separate standards for passenger cars and light trucks. EPA did not propose or seek comment on combining the footprint-based curves into one curve representing the entire light-duty vehicle fleet, and we believe that this would be a substantial change in the structure of the program which is not appropriate to undertake on the timeline of this rule, which is only intended to revise standards for MY 2023-2026. EPA may evaluate various approaches to setting light-duty vehicle CO2 standards as part of the planned future rulemaking.

Secondly, Drs. Michalek and Whitefoot requested that EPA consider certain flexibilities of the regulations (such as averaging, banking, and trading of credits) in the cost-benefit analysis. In the analyses for this final rule, we have updated the manufacturers' credit banks for the baseline MY 2020 fleet with best available data from the EPA certification and compliance program. For our primary analysis, we continue, as in past regulatory actions, to consider credit transfers between a manufacturer's car and truck fleets. We have also conducted a sensitivity analysis representing perfect credit trading between manufacturers. The results of that sensitivity are presented in Chapters 4 and 10 of the RIA.

---

[1] EPA did consider current technological limitations in its ICE modeling. As discussed in Preamble III.A and RIA 4.1.1.3, EPA did apply limitations to effectiveness of high compression ratio engine technology by restricting the CCEMS model to only HCR0 and HCR1.

2.1. Lead Time Issues

Commenter: Alliance For Automotive Innovation

Meeting the proposed MY 2023 targets will be challenging. EPA proposes to increase the stringency of MY 2023 targets by 10 percent relative to MY 2022.31 This unprecedented leap in stringency with virtually no lead-time will be a challenge for at least some manufacturers to meet. [EPA-HQ-OAR-2021-0208-0571-A1, p. 10]

In MY 2019, the last year for which EPA has published data, automakers on average trailed annual performance targets for both the passenger car and light truck fleets,32 meaning an even greater rate of improvement is necessary to close that gap and achieve performance requirements in future years. Based on estimated targets under the proposal for MY 2023,33 manufacturers on average will need to improve the passenger car fleet performance by 19%, the light truck performance by 31%, and the overall performance by 21%, relative to MY 2019, in only four years to meet such a target, or will need to continue to consume previously banked over-compliance credits. The future availability of such credits is limited for many manufacturers, and there are no guarantees that credits potentially offered for sale by some manufacturers will be available for all or purchased in advance by a limited few. [EPA-HQ-OAR-2021-0208-0571-A1, p. 10]

According to the most recent IHS Markit “Baseline Study,”34 fleet average performance improved in MY 2020 but continued to fall short of annual requirements (Figure 1). Comparing MY 2020 values from the Baseline Study to those estimated by EPA for the NPRM, manufacturers would have to improve U.S. fleet average performance, net of credits, by 18% overall between MY 2020 and MY 2023 to meet the proposed MY 2023 targets.35 [EPA-HQ-OAR-2021-0208-0571-A1, p. 10-11] [Figure 1 can be found on p. 11 of Docket number EPA-HQ-OAR-2021-0208-0571-A1]

These types of performance gains are usually only obtained through combined vehicle and powertrain redesigns or significant market shifts in powertrain choices. Given that four years is a short time for vehicle redesigns and extremely short for powertrain redesigns, it is unlikely that the entire fleet would be improved to this level. Thus, the burden would fall to a combination of changes to the smaller volume of vehicles actually redesigned and potential fleet mix changes where those actions fall short. [EPA-HQ-OAR-2021-0208-0571-A1, p. 11]

IHS Markit also assessed MY 2020 fleet performance against future targets including MY 2023 (Figure 2). Only 11.6 percent of vehicle production in MY 2020 meets MY 2023 targets. Assuming a normal distribution of vehicles above and below target, this would need to be improved to roughly 50 percent between MYs 2020 and 2023 for the fleet on average to meet its annual target (or higher to generate credit). Note that, despite the presence of some EVs in MY 2020, with only 41 percent of production meeting or exceeding annual targets (Figure 2), the fleet as a whole is still a net deficit generator (Figure 1). [EPA-HQ-OAR-2021-0208-0571-A1, p. 11-12] Figure 2 can be found on p. 12 of Docket number EPA-HQ-OAR-2021-0208-0571-A1]

EPA's statement that, "…in light of the design cycle timing for vehicles, EPA has basis to expect that the vehicles that automakers will be selling during the first years of the proposed MY 2023-26 program were already designed before the less stringent SAFE standards were recently adopted,"156 completely misconstrues the importance and significance of design cycles on real world response to changes proposed in today's policy. DOT and EPA jointly proposed the SAFE Vehicles Rule on August 24, 2018,157 signaling some probability of changes in federal regulations on GHG and CAFE. It is reasonable to expect that some manufacturers updated production plans for new vehicles accordingly, and consistent with the corporate strategies, for some of the affected model years in the SAFE proposal (MYs 2021-2024, for instance). The most reasonable way to characterize how each manufacturer responded to recent policies and market conditions is with an up-to-date fleet, and not conjecture about what manufacturers could have, or should have done in retrospect.158 A small portion of the fleet is redesigned every year, and often the burden of higher stringency weighs significantly on redesigned vehicles.159 In response to a rapid increase in standards like those in the proposed standards, manufacturers may use banked credits, produce many hybrid and electric vehicles, which the market will hopefully adopt, and continue to integrate fuel saving technologies, like tire rolling resistance technology, aerodynamic drag reducing technology, and mass reduction technology.

Tables 7 and 8 , below, show the portion of the fleet with at least one redesign after MYs 2023 and 2024, respectively. As can be observed, only a small portion of any manufacturer's fleet is likely to be redesigned in any particular model year. For most manufacturers, their entire fleet will not be redesigned until after MY 2026. [EPA-HQ-OAR-2021-0208-0571-A1, p. 52-53] [Tables 7 and 8 can be found on p. 54 of Docket number EPA-HQ-OAR-2021-0208-0571-A1]

Commenter: American Lung Association

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p.19]

EPA must finalize this rulemaking this year in order to set stronger tailpipe standards for Model Year 2023. Climate change is a health emergency and the Biden Administration must respond with dispatch.

Commenter: American Lung Association in the Mid-Atlantic

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 110-112.]

The need for the strongest possible clean car standards in the short term and on track for the clean electric vehicle market in the longer term implemented as soon as possible could not be clearer and lest there be any wonder about the need for these improvements, I can cite no more convenient example than the fact that today has been declared an air quality action day for ozone smog for much of the Mid-Atlantic, for Baltimore, Washington, and Northern Virginia, and the South, to Delaware and Philadelphia and the East, to Pittsburgh and the West, and quoting from the official forecast, "Ozone formation during the late morning, afternoon will be robust and eight-hour maximum concentrations are expected to reach into the Code Orange range," and the extended forecast continues, "The heat is expected to continue Thursday with sunshine for the most part and again Code Orange ozone concentrations are possible," and climate change is making these scenarios all the more likely. The need is clear.

Commenter: Bay Area Air Quality Management District (Bay Area AQMD)

The Bay Area Air District agrees that strengthened standards should start with MY 2023, without delay, and tighten over time. [EPA-HQ-OAR-2021-0208-0283-A1, p.2]

Additionally, credits are available from the current weakened standards to assist in meeting more stringent standards over the short term. [EPA-HQ-OAR-2021-0208-0283-A1,p. 2]

As outlined in this letter, the Bay Area Air District encourages EPA to adopt the strongest feasible standards. [EPA-HQ-OAR-2021-0208-0283-A1, p.3]

Commenter: California Attorney General Office, et al.

In addition, many automakers already have substantial credit banks and the opportunity to add to those credit balances under the unlawfully weak SAFE 2 standards through model year (MY) 2022. The crediting flexibilities already built into the program—including the ability to trade, carry-forward, and carry-back—place automakers in even better positions to craft strategies to comply with more stringent standards. [EPA-HQ-OAR-2021-0208-0245-A1, p.2]

For MY2023, automakers can comply with standards at least as stringent as EPA's preferred alternative without the use of the credit banks they will likely hold coming into that year. Those banks, including the windfall credits available under the SAFE 2 standards, support EPA's consideration of its Alternative 2 standards for MY2023 and underscore that EPA should not finalize standards less stringent than its preferred alternative for that model year. [EPA-HQ-OAR-2021-0208-0245-A1, p.2]

There Is Adequate Lead Time for Standards at Least as Stringent as EPA's Preferred Alternative for MY2023, and EPA Should Consider Finalizing Alternative 2's Standards for that Model Year

While the amount of lead time provided for MY2023 is not unprecedented for Section 202(a) standards,123 we recognize that lead time for that year is more limited than for other years covered by the proposal. Lead time is nonetheless sufficient for the industry to meet EPA's preferred alternative standards for MY2023 without substantial use of credits from prior model years.124 And because, inter alia, there will likely be significant prior-year credits available for use in MY2023, the industry has adequate lead time for standards more stringent than the preferred alternative, including Alternative 2.125 EPA should, thus, consider finalizing the Alternative 2 standards for MY 2023, based on the full record before it, including any new information EPA receives or develops concerning automaker plans and anticipated credit balances at the start of MY2023. If EPA concludes lead time is insufficient for the Alternative 2 standards for MY2023, EPA should finalize standards at least as stringent as the preferred alternative for that model year and should adopt the more stringent Alternative 2 standards for subsequent model years (see below). That latter option would produce most of the benefits of Alternative 2—returning to the more stringent standards promulgated in 2012 more quickly—but would obviate arguments some automakers may make that lead time for Alternative 2's MY2023 standards is inadequate. It is also entirely within the scope of EPA's Proposal. 86 Fed. Reg. at 43,739 ('EPA requests comments on … other alternatives roughly within the stringency range of the proposal and the Alternatives.'). [EPA-HQ-OAR-2021-0208-0245-A1, p.26]

In addition, as EPA found in the Proposal, a sizable number of vehicles being sold today (in MY2021) would support compliance with EPA's proposed MY2023 standards.138 For example, in the vehicle category with the highest sales in MY2021 (small SUVs, which make up 28% of the market), 23% of the models would generate credits under EPA's preferred alternative MY2023 standards.139 Similarly, 24% of the MY2021 standard-pick-up and large-car models (which, together, account for another 18% of the market) would generate credits under the preferred alternative MY2023 standards.140 In fact, there is no major vehicle category in MY2021 for which less than 12% of the models would generate credits under those standards. [EPA-HQ-OAR-2021-0208-0245-A1, p.28]

Anticipated Prior-Year Credit Balances Indicate Adequate Lead Time for Even More Stringent Standards. Automakers can also utilize the well-established flexibilities built into EPA's GHG regulatory regime since its beginning, including the credit carry-forward mechanism that allows automakers to bank credits from one model year and use them up to five model years later. The credit banks the industry will likely bring into MY2023 position automakers to comply with even more stringent standards, including Alternative 2, in MY2023, especially given the low-stringency SAFE 2 standards for MY2021-2022.141 EPA's 2020 Automotive Trends Report shows that, as of the end of MY2019, automakers, collectively, held more than 55 million credits that would not expire before MY2023. Moreover, credit modeling performed by several non-governmental organizations demonstrates that, even assuming only limited improvement in the fleets, automakers can be expected to have sizable credit banks available in MY2023 that could be used to comply with Alternative 2's standards (and, of course, with the preferred alternative's standards).142 That underscores that additional lead time for any of those standards is not required. Nat'l Petrochemical & Refiners Ass'n v. EPA, 630 F.3d 145, 165 (D.C. Cir. 2010) (affirming EPA's decision to provide limited lead time under similar circumstances where credit program was well-established and regulated parties would not need to invest in construction or technology development). Notably, if, as can reasonably be anticipated (see supra at 26-28), automakers make more improvements in fleetwide GHG emissions than the conservative assumptions underlying these analyses, automakers will not only earn more credits under the weak SAFE 2 standards in MYs 2021-2022 but will also require fewer credits for compliance in MY2023. Finally, we encourage EPA to adopt some form of multipliers (with a cap) for EVs, fuel cell vehicles (FCVs), and PHEVs in MYs 2023-2025.143 And, if EPA makes such multipliers available for MY2023 that will further reduce the need for additional lead time for that model year, especially given the anticipated expansion in sales of these vehicles (see supra at 27-28). [EPA-HQ-OAR-2021-0208-0245-A1, p.29]

Commenter: Consumer Reports (CR)

Consumer Reports strongly supports EPA's proposal to institute these new standards as soon as possible, which we agree is model year 2023. Consumer Reports agrees with EPA that this should not be a problem for automakers. The SAFE rule was only finalized in March of 2020. Prior to this, automakers were planning to meet much stronger standards. This has given them little time to make significant changes, given relatively long product cycles in the auto industry. Since automakers already had plans in place to meet the original standards, which are more strict, it should not be a significant challenge for them to reinstate them, if they ever abandoned them in the first place. [EPA-HQ-OAR-2021-0208-0602-A1, p.17]

Furthermore, the availability of large credit banks whose lifetimes have been extended in this proposal, the ability to carryforward and carryback, and the likelihood of credit generation in MY2021 and MY2022 under the much weaker SAFE rule, mean that meeting the higher standard in MY2023 should not be a problem for automakers. Furthermore, five automakers had already agreed to the California Framework, which already kept them on a trajectory more in line with the preferred alternative. In addition, nearly every automaker has committed to rapid electrification trajectories49 which should assist them in meeting strong standards. Given the immediacy of the climate crisis, and the significant consumer savings available, there is no room for delay, and EPA should stick to their plan to implement strong standards starting in MY2023. [EPA-HQ-OAR-2021-0208-0602-A4, pp.17-18]

Commenter: Environmental Defense Fund (EDF)

EDF stresses the importance of prompt finalization of this rule to ensure that these stronger and more protective emissions standards will apply to MY 2023 vehicles. Near-term emissions reductions are vital to the health of frontline communities and communities of color that are disproportionally impacted by transportation air pollution and are crucial to mitigating the effects of climate change. EPA has reasonably determined that the proposed MY 2023 standards are feasible and appropriate. [EPA-HQ-OAR-2021-0208-0688-A1, p.1]

EPA has reasonably determined the feasibility of the Proposed Standards for MY 2023 and 2024. First, automakers need no extended "period" of lead time to comply with the proposed MY 2023 standard as automakers hold a vast reserve of tradable compliance credits that will help facilitate compliance, and any emission-reduction technologies that would be used for compliance have already been developed and are in widespread use. EDF conducted analysis that confirms that the Proposed Standards can be adopted without extended lead time, assessing three scenarios for automaker compliance with the proposed MY 2023 and MY 2024 standards using the credits automakers held as of the end of MY 2019 and the credits they are projected to earn through MY 2024 under EPA's preferred alternative. The scenarios project outcomes based on different assumptions about automakers' use and generation of credits, use of off-cycle technologies, and GHG emissions performance, and range from extraordinarily conservative to mildly optimistic. All three scenarios support the feasibility of the standards as, even in the most conservative scenario, the analysis demonstrates that automakers will be able to comply with the proposed MY 2023 standard largely through the application of existing credits. Finally, the feasibility of early year standards, without extended lead time, is supported by market trends, as automakers' have made significant commitments to develop and sell more ZEVs in the near term and have already invested hundreds of billions of dollars to manufacture and sell ZEVs. [EPA-HQ-OAR-2021-0208-0688-A1, p. 7]

Second, automakers already hold a vast reserve of tradeable compliance "credits" available to facilitate compliance with standards for MY 2023-2026. Trading of credits, especially credits on the verge of expiring (and becoming worthless), is a well-established practice. U.S. EPA, The 2020 EPA Automotive Trends Report: Greenhouse Gas Emissions, Fuel Economy, and Technology since 1975, EPA-420-R-21-003, at 110 (Jan. 2021) (2020 Report). In fact, 8 automakers already have traded large quantities of credits that, under the Proposed Standards, could be utilized toward compliance in MY 2023 and MY 2024. Id. at 111 (reflecting more than 30 million megagrams of traded credits expiring in those model years). And automakers' reliance on their own banked credits to facilitate compliance is a longstanding and widespread practice. [EPA-HQ-OAR-2021-0208-0688-A1, p. 7-8]

Automakers' credit reserve is large enough that if EPA were to adopt the Proposed Standards, all automakers that have not already voluntarily committed via agreements with the California Air Resources Board ("CARB") to decrease their GHG emissions in a manner comparable to the Proposed Standards could comply with EPA's new standards through MY 2023 by doing no more than the following: trading credits among themselves, reducing tailpipe GHG emissions in parallel to the trend line the 2020 Rule imposes for MY 2021-2023, [EPA-HQ-OAR-2021-0208-0688-A1, p. 8]

EDF analysis confirms that the Proposed Standards for MY 2023-2026 can be adopted without further lead time.

EDF conducted analysis to assess the feasibility of automaker compliance with the proposed MY 2023 and 2024 standards using the credits automakers held as of the end of MY 2019 and the credits they are projected to earn through MY 2024 under EPA's preferred alternative. For our projections of credits earned through MY 2024, we have developed three scenarios that reflect different assumptions about deployment of existing emissions-reduction technologies that range from extraordinarily conservative (lesser assumed deployment of technologies) to mildly optimistic (more reasonable assumptions around technology deployment).

We offer a primary case, estimating credit availability and use in a conservative but plausible scenario, as well as two sensitivity cases. The first sensitivity shows credit availability and use in an extremely conservative scenario, and the second shows a more realistic scenario. All three scenarios support the feasibility of the standards as, even in the most conservative scenario, the analysis shows that automakers will be able to feasibly comply with the Proposed Standards beginning in MY 2023.

Each case focuses on compliance by automakers that have not entered into voluntary agreements with California ("Framework Agreements") because we assume that, for those five automakers who have ("Framework manufacturers"), compliance with the California Framework will facilitate compliance with EPA's Proposed Standards without using compliance credits held by manufacturers who have not entered into Agreements ("non-Framework manufacturers"). The primary case illustrates that non-Framework manufacturers could comply with EPA's Proposed Standards through MY 2024 by trading credits among themselves and acquiring existing credits already held through MY 2020 by Framework manufacturers; applying so-called "off-cycle" technologies that do not require significant lead time; and reducing tailpipe GHG emissions in parallel to the trend line that the 2020 Rule imposes for MY 2021-2024.23

The extremely conservative sensitivity case shows that even if non-Framework manufacturers (1) did not have access to credits held through MY 2020 by Framework manufacturers; (2) limited use of off-cycle and other credits; (3) and reduced tailpipe GHG emissions in parallel to the trend line that the 2020 Rule imposes for MY 2021-2023, they could still comply with EPA's Proposed Standards through MY 2023 using credits.

In comparison, the more realistic sensitivity case demonstrates that even a modest increase (2% annually) in ZEV sales, in line with recent public announcements by manufacturers of increased ZEV deployment, would allow manufacturers to easily comply with the Proposed Standards through at least MY 2024 using only credits. Table 1 captures these scenarios and key variables. [Table 1 can be found at docket EPA-HQ-OAR-2021-0208-0688-A1, pp. 10-11]

We describe our analysis in four parts. The first is an overview of the historic generation and use of GHG credits under EPA's regulations. Second, we present automakers' bank of credits as of 2019, the last year for which detailed data is available, and explain our basis for projecting the application of those credits to compliance in MYs 2020-2024. Third, we consider the effect of the agreements that five automakers have entered into with the State of California regarding voluntary GHG emissions reductions for MY 2021-2026 MY vehicles. These agreements commit Framework manufacturers to reduce emissions and include stipulations regarding the use of GHG credits earned during this timeframe under EPA's program, both of which affect their own compliance with the Proposal and their ability to sell credits to non-Framework manufacturers. Finally, we project manufacturers' future GHG performance through MY 2024 under three scenarios, which inherently leads to the generation or need for GHG credits.[EPA-HQ-OAR-2021-0208-0688-A1, pp. 9-11]

Future GHG Compliance with EPA's Proposed MY 2023 and 2024 Standards

The 2020 Trends Report includes details regarding the status of the EPA GHG credit bank through the end of MY 2019. Thus, GHG performance must be projected for MY 2020 and beyond. We perform this projection through MY 2024, as we assume manufacturers will have sufficient lead time to make major changes to their production plans by MY 2025. To be clear, this is not to say that manufacturers cannot make such changes for MY 2023 or MY 2024, or that production plans already in place will not enable compliance with the Proposed Standards.

To model future GHG compliance, we first adjusted EPA's baseline fleet. In the Proposal, EPA utilized a MY 2017 baseline vehicle fleet in its projection of the costs and benefits of the proposed GHG standards. This baseline fleet pre-dates the status of the MY 2019 GHG credit bank. NHTSA, in modeling its recent Proposal, utilized a MY 2020 baseline fleet ("MY 2020 baseline fleet"). This 2020 MY fleet is based on preliminary GHG and CAFE performance data and sales and may change in the next few months. Even so, it represents a reasonable estimate of MY 2020 GHG performance and so we use it as our starting point to project performance in future model years.

However, the one aspect of the MY 2020 data which is least representative of future model years is the level of vehicle sales. MY 2020 sales were significantly affected by the COVID-19 pandemic and are lower than sales in previous years. MY 2021 sales have also been affected by the pandemic, including the pandemic related shortage in the supply of computer chips. We assume that these sales impacts will dissipate by MY 2022. Thus, we use the vehicle sales in NHTSA's MY 2020 baseline fleet for MYs 2020 and 2021 and the vehicle sales in MY 2019 reported by EPA in their 2020 Fuel Economy Trends Report for MYs 2022, 2023 and 2024. Had we assumed that MY 2022 sales would still be affected by COVID, like MYs 2020 and 2021, sales would be lower and credit use would also be lower, extending the life of the credit bank. Thus, our assumption that vehicle sales in MY 2022 and beyond will recover to pre-pandemic levels is conservative as it relates to credit availability.

After establishing this baseline fleet, we considered several additional variables that influence the size of the credit bank available to support compliance with EPA's proposed MY2023–2024 standards. Those major variables are:

1. The rate at which automakers will improve their GHG emissions performance in MY 2021-2022. This includes both 2-cycle tailpipe reductions and the generation of air conditioning and off-cycle credits;

2. The availability of credits earned by Framework manufacturers prior to MY 2021 for purchase by non-Framework manufacturers; and

3. The rate of increase of ZEV deployment in MYs 2021 through 2024 and multiplier credits earned.

The three scenarios we developed take differing approaches to addressing each of these variables and describe the resulting effects on the credit bank and compliance with EPA's Proposed Standards. All three scenarios start with the bank of credits available at the end of MY 2019 and the GHG performance of the NHTSA MY 2020 baseline fleet. All three scenarios focus solely on non-Framework manufacturers' compliance with the proposed EPA standards in MY 2023-2024. All assume a reduction in GHG emissions consistent with the trendline of the 2020-2024 MY standards contained in the 2020 Rule. All three scenarios assume that manufacturers take full advantage of the additional 5 g/mi of off-cycle emissions and 2.5 g/mi advanced technology vehicle multipliers provided as part of EPA's Proposal.

The scenarios differ in whether they assume that the current credit banks of Framework manufacturers are available to non-Framework manufacturers, the degree to which manufacturers increase their use of air conditioning and off-cycle credits under the 2020 Rule and the degree to which manufacturers increase their sale of PEVs. [EPA-HQ-OAR-2021-0208-0688-A1, p. 14-16]

Primary (Conservative) Scenario:

For our primary case, we have conservatively assumed the following:

- Credits held at the end of MY2020 by automakers that entered into Framework agreements with California are available to trade to non-Framework manufacturers.

- Non-Framework manufacturers make modest improvement in GHG tailpipe emissions following the 2020 Rule's trend lines for MY2021-2024 passenger cars and light trucks.

- Non-Framework manufacturers increase their use of menu-based off-cycle credits in a trajectory to reach 10 g/mi in MY2023 under the 2020 Rule and increase these credits to 15 g/mi credits starting in MY 2023 as allowed under the Proposal

- Non-Framework manufacturers take full advantage of the reinstatement of the advanced technology vehicle multiplier credits at 2.5 g/mi per year starting with MY 2022.

- Non-Framework manufacturers take full advantage of direct and indirect air conditioning credits at 18.8 g/mi for cars and 24.4 g/mi for trucks by MY 2023.

This is a reasonable conservative scenario for the following reasons:

First, we assume credits held at the end of MY2020 by automakers that entered into Framework agreements with California are available to trade to non-Framework manufacturers. Framework manufacturers have voluntarily committed to the GHG emissions reductions specified in the Agreement, and it is therefore reasonable to assume that these manufacturers intend to make those reductions, have developed product plans to do so, and so will not need credits held at the end of MY 2020 to meet federal compliance obligations. Second, we assume that nonFramework manufacturers will decrease the 2-cycle tailpipe CO2 emissions from their MY 2020 levels in accordance with the progression of the 2020 Rule. The nominal progression of the 2020 Rule between 2020 and 2026 is 1.5% per year. However, when applied to NHTSA's MY 2020 baseline fleet, the year over year reductions of the 2020 Rule range from 1.4-2.6% per year for cars and trucks separately, as shown in Table 3. We assumed that non-Framework manufacturers would reduce their GHG emissions in accordance with the percentage reductions shown in Table 4. As shown, the reductions are generally somewhat greater than 1.5% per year. [Table 4 can be found on p. 16 of Docket number EPA-HQ-OAR-2021-0208-0688-A1].

Third, we increased the number of off-cycle and air conditioning credits earned by nonFramework manufacturer in addition to the overall GHG reductions shown in Table 4 to ensure compliance with the 2020 Rule. The first set of light-duty vehicle GHG standards in 2010 included an "early credits program" that created an initial bank of over 200 million metric tons of CO2 credits for automakers.25 Because of the large number of credits that was banked in the early years of the program, in recent model years, some automakers have chosen to exceed the GHG standards and comply by using credits that will otherwise expire. This trend is evidenced by the large number of credits that will ultimately be forfeited when they expire at the end of model year 2021.26 To account for the status quo of fleetwide exceedance of the MY 2020 standard and to maintain conservative projections for GHG improvement, in each scenario, we project that in MY2021 through 2024, automakers will decrease the 2-cycle tailpipe CO2 emissions from their MY 2020 levels at the same rate as the trajectory of the 2020 Rule and take advantage of offcycle credits to make up any the difference between their 2-cycle emissions and the emissions reductions required by the 2020 Rule.

EPA regulations cap direct and indirect air conditioning credits at 18.8 g/mi for cars and 24.4 g/mi for trucks. They also limit menu-based off-cycle credits to 10 g/mi for both vehicle groups. The technology required to achieve these credits does not require major redesign of the powertrain and can be implemented relatively quickly, as indicated by the historic growth in the earnings of these credits. Many manufacturers have already achieved the maximum air conditioning credits for their car or truck fleet. EPA's series of Trends Reports indicates that offcycle credit generation has been increasing over the past several model years. A number of truck manufacturers have already achieved 10 g/mi or more off-cycle credits.

Table 5-11 of EPA's 2020 Automotive Trends Report shows manufacturers' use of 10 distinct off-cycle technologies in MY 2019. Those which do not involve the operation of drivetrain (other than more rapid warm-up27) include: high efficiency lighting, active cabin ventilation, passive cabin ventilation, active aerodynamic improvements, active seat ventilation, glass or glazing, solar reflective coating and active engine and/or transmission warm-up. None of these technologies are new, nor involve intricate interaction with fundamental powertrain operation. Almost all of these specific technologies have been applied to at least one manufacturer's entire new vehicle fleet.

Thus, we believe that manufacturers can make, and possibly already have in place, plans to maximize their earnings of these credits and can do so by MY 2023 as part of their planned compliance with the 2020 Rule. In light of these factors, to ensure manufacturer compliance with the 2020 Rule, we increased manufacturer earnings of off-cycle and air conditioning credits to 10 and 18.8 or 24.4 g/mi, respectively. We included one-third of this increase in credits in MY 2021 and two-thirds of this increase in MY 2022. We also increased the use of off-cycle credits in MY 2023 and MY 2024 to 15 g/mi, as allowed in EPA's Proposal. [EPA-HQ-OAR-2021-0208-0688-A1, p. 16-17]

In the primary and more realistic scenarios evaluated below, we increased the number of offcycle and air conditioning credits earned by non-Framework manufacturers in addition to the overall GHG reductions shown in Table 4. EPA regulations cap direct and indirect air conditioning credits at 18.8 g/mi for cars and 24.4 g/mi for trucks. They also limit menu-based off-cycle credits to 10 g/mi for both vehicle groups. The technology required to achieve these credits does not require major redesign of the powertrain and can be implemented fairly quickly, as indicated by the historic growth in the earnings of these credits. Many manufacturers have already achieved the maximum air conditioning credits for their car or truck fleet. A number of truck manufacturers have already achieved 10 g/mi or more off-cycle credits. Thus, we believe that manufacturers can make, and possibly already have in place, plans to maximize their earnings of these credits and can do so by MY 2023. Thus, for those manufacturers projected to have a combined car-truck shortfall with the 2020 Rule in MY 2023, we increased their earnings of off-cycle and air conditioning credits to 10 and 18.8 or 24.4 g/mi, respectively. We included one-third of this increase in credits in MY 2021 and two-thirds of this increase in MY 2022. We maintained the increase occurring in MY 2023 into MY 2024.

EPA's Proposal also extends to MY 2025 the advanced technology vehicle multiplier credits. Plug-in electric vehicles (PEVs) are expected to dominate the vehicles qualifying for this credit. PEV sales decreased slightly in 2020 relative to 2019, but total vehicle sales decreased by more than 10%. Thus, PEV sales increased by 10% in terms of manufacturers' sales fractions. Here, we conservatively project modest growth of 10% per year in MYs 2021 and 2022 in non-Framework manufacturers' 2019 sales fractions of ZEVs.28 Beginning with MY 2023, we project that all non-Framework manufacturers will earn the maximum average multiplier credit of 2.5 g/mi. When projecting manufacturers' level of multiplier credits, we factor in that the level of the multiplier decreases in MYs 2020 and 2021, before increasing in MYs 2022 and 2023 and decreasing again in MY 2024, per EPA's Proposal. Also, while we project these increases in ZEV sales, resulting in ZEV multiplier credits, we did not adjust manufacturers' 2-cycle tailpipe GHG levels any further than the reductions shown in Table 4. In other words, we assumed that a portion of the reductions shown in Table 4 would occur through increased ZEV sales.

EPA also proposes to reinstate the credit for strong hybrid pickup sales. While we believe it is likely that some or all of the pickup manufacturers will qualify for this credit, we did not include any of this type of credit in our projections due to the absence of specific product plans from the pickup manufacturers. This a very conservative assumption and likely further understates credits available for compliance. 29

We combined each manufacturer's projected sales with their potential shortfalls to determine their generation or need for GHG credits by model year and vehicle class. Once determined at this level, the potential need for credits to enable compliance was summed up across the nonFramework manufacturers and compared to the 2019 credit bank. We assume that manufacturers will use their oldest credits first, to avoid their expiration. We also assume that credits are freely traded between manufacturers (118 million megagrams of GHG credits have been traded between manufacturers through MY 2019 per EPA's 2020 Automotive Trends Report). This means that credits generated in MY 2020 and beyond are assumed to be banked, while deficits are assumed to be eliminated through the use or purchase of credits of earlier vintage.

Table 5 shows the credit bank in this Primary Scenario. The column for MY 2019 describes the starting point of the analysis and is consistent with the 2020 Report. Framework manufacturers were included in the MY 2019 credit bank balance, as the Framework Agreements place no restriction on their sale. The performance of Framework manufacturers is also included in the need for and generation of credits in MY 2020. Starting with MY 2021, compliance by only nonFramework manufacturers is considered. [Table 5 can be found on p. 19-20 of Docket number EPA-HQ-OAR-2021-0208-0688-A1]

Table 5 indicates that non-Framework manufacturers, even under these very conservative assumptions, will be able to comply with EPA's proposed GHG standards through MY 2024 through the use of the numerous sources of GHG credits, modest improvement in 2-cycle tailpipe emissions consistent with the trend line of the 2020 Rule, and some additional off-cycle and air conditioning credits. All of the credits earned in MYs 2023 and 2024 are still available for future use, as well as most of those earned in MY 2022. The credit bank of 27 million megagrams at the end of MY 2024 is sizeable, being equivalent to a single model year's shortfall of 8 g/mi GHG across the entire fleet. [EPA-HQ-OAR-2021-0208-0688-A1, p. 18-20]

Extremely Conservative Scenario:

For the extremely conservative scenario we assumed the following:

• Non-Framework manufactures make modest improvement in GHG tailpipe emissions following the 2020 Rule's trend lines for MY 2021-2024 passenger cars and light trucks

• Non-Framework manufacturers cannot acquire any credits of any vintage held or earned by Framework manufacturers

• No additional off-cycle and air conditioning credits are applied to reduce shortfalls under the 2020 Rule other than an additional 5 g/mi of off-cycle credits in MY 2023, per EPA's Proposal.

• Non-Framework manufacturers take full advantage of advanced technology vehicle multiplier credits at 2.5 g/mi per year.

Table 6 shows the credit bank in this extremely conservative sensitivity. [Table 6 can be found on p. 20-21 of Docket number EPA-HQ-OAR-2021-0208-0688-A1]

As shown, even in this extraordinarily conservative scenario, again the level of credits available is sufficient to enable compliance for non-Framework manufacturers through MY 2023. [EPA-HQ-OAR-2021-0208-0688-A1, p. 20]

More Realistic Scenario:

For the more realistic scenario we made the following assumptions:

• Same assumptions as primary scenario and

• Non-Framework manufacturers will increase their sales of BEVs by an absolute 2% each year starting in MY 2022.

o This is assumed to occur over and above the 1.4-2.6% annual reductions in GHG emissions starting with MY 2021 under the 2020 Rule.

o These increased BEV sales would not affect advanced technology vehicle multiplier credits, as these were already assumed to be capped at 2.5 g/mi per year under the primary scenario. However, it would further improve automakers' GHG emission performance beyond MY 2020 levels and reflect the numerous announcements by non-Framework manufacturers that they plan to offer new ZEV models and increase ZEV sales.

Numerous manufacturers have stated publicly that they will be introducing new PEV models prior to MY 2025, as described below. The assumption that these and potentially other PEV models will account for 2-6% of new vehicle sales by MY 2024 appears quite reasonable. the California Air Resources Board recently found that manufacturers supplying vehicles to that State would achieve 23-25% sales of PEVs in MYs 2023-2024.30 PEV sales nationally have historically been about half of the levels in California. Given that current nationwide sales of PEVs represent 2% of national new vehicle sales, our projection only requires that national PEV sales be one-third of California sales on a percentage basis.

Table 7 shows the credit bank in this sensitivity. [Table 7 can be found on p. 22 of Docket number EPA-HQ-OAR-2021-0208-0688-A1]

The results in Table 7 show that increased ZEV sales would make it even easier for manufacturers to comply with EPA's Proposed Standards in MYs 2023 and 2024. As can be seen, banked credits would be far more than sufficient through MY 2024, with all of the credits earned in MYs 2019-2024 remaining at the end of MY 2024. The 107 million megagrams of credit remaining at the end of MY 2024 are equivalent to a single model year's GHG emissions of 32 g/mi. [EPA-HQ-OAR-2021-0208-0688-A1, p. 21-22]

In summary, through MY2024, the automakers that have not entered into agreements with California could comply with EPA's Proposed Standards by doing no more than the following:

• trading credits among themselves and acquiring credits held today by automakers that did execute agreements with California;

• applying air conditioning and off-cycle technologies that do not require significant lead time; and

• reducing 2-cycle tailpipe GHG emissions in parallel to the trend line that the 2020 Rule imposes for MY 2021-2024. See infra, at 16-23. 22 [EPA-HQ-OAR-2021-0208-0688-A1, p. 8]

It is eminently reasonable to assume automakers that voluntarily committed to GHG emissions reductions comparable to those required by EPA's Proposed Standards could collectively comply with those standards without utilizing their preexisting credits (leaving them available for trade to other automakers). See infra, at 16. [EPA-HQ-OAR-2021-0208-0688-A1, p. 8]

Last year, the trade association representing the automakers that did not execute agreements with California defended the 2020 Rule's trend line as "appropriate" on the ground that it "afford[s] the industry a return on its investment in emissions-reduction … technologies" and does not preclude industry from "meet[ing] consumer demand." Mot. of Alliance for Automotive Innovation to Intervene at 3-4, Competitive Enter. Inst. v. NHTSA, No. 20-1145, ECF No. 1844089 (D.C. Cir. May 22, 2020). Accordingly, those automakers would not require more lead time to comply with EPA's Proposed Standards for MY 2023. [EPA-HQ-OAR-2021-0208-0688-A1, p. 8]

Accordingly, EPA reasonably determined that automakers would not require additional lead time to comply with EPA's Proposed Standards for MY 2024. [EPA-HQ-OAR-2021-0208-0688-A1, p. 8]

Market trends support the feasibility of the Proposed Standards for MY2023-2026 without further lead time. The feasibility of early year standards is also supported by automakers' broad commitments to develop and sell more ZEVs and the billions of dollars they have invested to bring these commitments to fruition. A recent M.J. Bradley report on the status of the electric vehicle market found that automakers are investing $268 billion worldwide on electrification through 2030, with over $22 billion on domestic manufacturing.31 That number is even higher in light of more recent automaker announcements.

General Motors has set forth its aspiration to produce only EVs by 2035.32 In an effort to reach this goal, it plans to invest $35 billion into EV and AV development through 2025, with 30 new plug-in models arriving in that timeframe.33 GM is supporting this near-term commitment by accelerating plans to build two new battery cell manufacturing plants in the United States by mid-decade to complement the Ultium Cells LLC plants under construction in Tennessee and Ohio.34 General Motors is also creating a $25 million Climate Equity Fund that will focus on closing equity gaps as the auto industry transitions to ZEVs. 35

Ford has committed to spending more than $30 billion on electrification by 2025.36 It also announced thisweek that it will spend $11.4 billion to expand battery and electric vehicle assembly in the U.S. and creating 11,000 jobs. 37 CEO Jim Farley stated that Ford expects "to be well positioned to have fully electric vehicles account for 40 to 50% of our U.S. sales by 2030."38 The E-Transit cargo van will be available to customers later this year and the F-150 Lightning will be available by mid-2022. Ford has already taken more than 130,000 reservations for the Lightning, far surpassing projections.39

These commitments over the next few years by the nation's largest automakers signal that they recognize the feasibility and importance of transitioning to ZEVs. Many other automakers are also rolling out ZEVs over the next few years, indicating that the proposed MY2023 standards are feasible. Stellantis plans to launch 10 hybrid or electric models across its brands by the end of this year. Mercedes plans to introduce 10 new EVs through its EQ brand by the end of 2022.40 Nissan plans to have launched eight EVs by the end of 2023 and hopes to be on pace to sell 1 million hybrid or electric vehicles per year globally.41 Toyota plans to launch 60 new hybrid, electric, or fuel-cell vehicles by the end of 2025 and expects to have reached its goal of selling 5.5 million electrified offerings each year.42 Volkswagen plans to have built 1.5 million EVs across its brands by the end of 2025.43 And Volvo has pledged to put 1 million hybrid or electric vehicles on the road by the end of 2025, and expects 50 percent of its global sales to come from EVs.44 Honda announced it will sell only battery-electric and fuel-cell vehicles by 2040.45 [EPA-HQ-OAR-2021-0208-0688-A1, p. 23-24]

Commenter: Environmental Protection Network (EPN)

The proposal provides a clear and compelling discussion showing the lead time for the MY 2023 to 2026 standards is appropriate. EPA discusses the long lead time provided when standards were originally adopted in 2012; the widespread availability of vehicles already meeting the proposed MY 2023 standards; the approximate five-year cycle to design, develop, and produce vehicle models, indicating manufacturers are unlikely to have made significant changes to their product plans based on the rollback standards adopted just over a year ago; the agreement of several manufactures to meet standards similar to those proposed in the California Framework Agreement; and other factors such as credit banking, trading, and deficit carry-forward provisions. All these factors support the conclusion that the lead time for the proposed standards is appropriate.

Lead time must be evaluated considering all the relevant circumstances. It would be improper to consider just the period between when these standards are adopted and the beginning of the MYs at issue. That view would artificially truncate the actual lead time provided to manufacturers and would ignore several relevant factors. [EPA-HQ-OAR-2021-0208-0213-A1, p. 11-12]

Commenter: Institute for Policy Integrity

EPA Can Finalize Its Proposed Standards with Adequate Lead Time for the 2023 Model Year, Consistent with Prior Standards. Under Clean Air Act Section 202(a), emission standards may take affect ‘after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period.’17 Thus, when setting new standards, EPA must consider—among other factors—how much lead time is necessary for automakers to comply with new standards. [EPA-HQ-OAR-2021-0208-0299-A1; pp. 3-4.]

’Lead time’ is generally understood to be the time period between a new standard being finalized and the beginning of the relevant model year to which the standard applies. The model year varies by manufacturer production cycle and by vehicle model, since it starts on either January 2 of the preceding calendar year or ‘when any vehicle or engine within the engine family is first produced’ (whichever is later), and ends on either December 31 of the year for which the model year is designated or when ‘the last such vehicle or engine is produced’ (whichever is sooner).18 This provides automakers with significant flexibility in setting their production schedules to comply with upcoming standards.19 Thus, automakers could begin producing vehicles subject to the proposed MY 2023 standards as early as January 2, 2022, though they also have flexibility to delay the start of their production periods as needed in anticipation of regulatory standards and other factors.20 [EPA-HQ-OAR-2021-0208-0299-A1; p. 4]

The Clean Air Act does not require a specific number of days or months for lead time. Instead, EPA has the discretion to balance what is required of manufacturers by any particular regulatory standard versus the time to comply and determine in its judgment how much lead time is necessary. When previous standards have required significant investment in new technologies and could not be achieved with existing technology, EPA has provided somewhat longer lead times in the past. But if a new standard can already be met with existing technology, without extensive redesign of powertrains and engine lines, EPA has the discretion to provide much shorter lead times. Here, EPA has properly exercised its discretion to determine how much lead time is necessary given existing compliance options, and has acted consistently with its historical regulation of vehicle tailpipe emissions.

Congress Provided EPA With Significant Discretion to Determine Appropriate Lead Time. The statutory history and structure suggest that EPA should balance lead time against how technology forcing its standards are, so when compliance options are readily available, a shorter lead time is permissible. When drafting the Clean Air Act, Congress sought to confront the problems of an automotive industry that previously had no obligation or incentive to reduce its emissions. Congress understood that state-of-the-art pollution controls would not be developed ‘until some sort of regulation took it by the hand and gave it a good pull.’21 So Congress crafted a statutory scheme that would require EPA to regulate through the ‘drastic medicine’ of setting stringent standards that would ‘force the state of the art.’22 Through the technology-forcing structure in Title II of the Clean Air Act, Congress readily demonstrated its intent for EPA ‘to project future advances in pollution control capability . . . [and] ‘press for the development and application of improved technology rather than be limited by that which exists today.’’23 Congress instructed EPA in 1970 that it must set standards for MY 1975 that would reduce hydrocarbons and carbon monoxide emissions by more than 90% compared to MY 1970 levels,24 and set future standards to take effect ‘after such period as the Administrator finds necessary to permit the development and application of the requisite technology.’25 Congress directed EPA to consider lead time when setting standards because it expected EPA to set stringent standards that would require the development of new emissions controls. Over more than five decades of mobile source regulation since then, EPA has drastically reduced automotive emissions. And it has indeed done so by issuing standards that have sometimes asked automakers to ‘do what seems to be impossible.’26

But EPA’s proposed standards here do not ask the same of automakers. Instead, the current proposal seeks to remedy a misguided, arbitrary rollback27 by re-proposing standards for MY 2023 that are equivalent to, or even less stringent than, those that were set almost a decade ago28—standards with which many vehicle models already comply. This hardly presents a situation where automakers need significant lead time to rework their product lines. Given the discretion granted to EPA, the agency need not ‘provide detailed solutions to every engineering problem’ or ‘rebut all speculation that unspecified factors may hinder [meeting the standard]’ when evaluating adequate lead time.29 Rather, EPA ‘need only identify the major steps necessary for development . . . and give plausible reasons for its belief that the industry will be able to solve those problems in the time remaining.’30 Here, EPA has provided a more than sufficient explanation in the Proposed Rule for why the agency expects automakers to be able to meet its proposed MY 2023 standards.

Indeed, given that a significant percentage of the MY 2021 automotive fleet already meets the MY 2023 proposed fleet average standard,31 EPA's analysis is far from a ''crystal ball' inquiry,'32 but rather is based on a reasonable assessment of the domestic automotive fleet. In addition, EPA is providing multiple new flexible compliance options for automakers, including extending the availability of credits generated in MYs 2016–2020, extending multiplier credits, and expanding the off-cycle credits program. These extended flexibilities come on top of other existing flexibilities, like credit trading, the large bank of available credits,33 and the carryback period for compliance. Further, five automakers (and more than one-third of domestic automotive sales) since 2019 have been in compliance with a framework agreement with California to voluntarily meet emission targets for MY 2023 that are equivalent to EPA's new proposed standards. Indeed, EPA could easily increase the standards' stringency, especially for MYs 2024–2026, and, if it retains sufficient flexible compliance options, still determine that 'the development and application of the requisite technology'34 already exists. [EPA-HQ-OAR-2021-0208-0299-A1; pp. 4-6.]

EPA Has Historically Provided Lead Time in Proportion to Necessary Technology Development. The lead time that EPA can provide when it finalizes these proposed standards will hardly be an outlier in comparison to its previous rules. EPA will likely finalize standards for MY 2023 in late 2021 or early 2022, and EPA has issued new tailpipe standards mere months before a new model year begins on numerous occasions. For example, EPA finalized standards for MY 1975 light-duty trucks in August 1973, noting in its discussion of lead time that roughly fifty percent of models available in the MY 1973 truck fleet were already capable of meeting the new MY 1975 standards, that EPA believed automakers would be able to meet the MY 1975 standard in time, and that there was 'no evidence to suggest that any manufacturer would be required to utilize [new technology] to meet these standards.'35 Likewise, EPA finalized heavy-duty truck standards for MY 1979 in September 1977.36 EPA noted that automakers did not object to the short lead time provided to meet the MY 1979 emission standards because they 'could be met by all of the manufacturers with the use of currently available emission control technology.'37

When EPA has provided exemptions in consideration of short lead time, it has been because of limitations in compliance testing procedures, rather than technological feasibility. For example, EPA finalized high-altitude standards for MY 1982 in October 1980,38 explicitly rejecting calls for additional lead time from automakers because EPA did not believe major hardware or retooling was necessary to meet the standards.39 But, given the complexities in certifying engines for high altitude performance, EPA permitted a one-year exemption for thirty percent of an automaker's high altitude fleet based solely on the 'availability of testing facilities' and 'available personnel'—not on technological feasibility.40 And EPA's judgment regarding technological feasibility was correct, as the agency noted in a subsequent rulemaking that '[t]he adequacy of the 9-month leadtime is now apparent from the fact that manufacturers' scheduled introduction dates for 1982 model year vehicles were not adversely affected.'41

More recently, EPA issued the first-ever greenhouse gas standards for light duty vehicles for MYs 2012– 2016 in May 2010, noting that it believed seven months of lead time before MY 2012 began was appropriate because 'the vast majority of technology required by this final rule is commercially available' and the 'vast majority of the emission reductions which will result from this final rule will be produced from the increased use of these technologies.'42 And, again, EPA's judgment on lead time was confirmed when automakers easily met the MY 2012 standards and even outperformed the standards by 11 g/mile industrywide.43 Indeed, a trade group for automotive dealerships suggested during the next round of rulemaking that EPA was providing too much lead time when it issued standards for MY 2017 in 2012.44

Conversely, when EPA has finalized standards further in advance of the affected model year, those standards typically required a longer lead time in order to develop and implement new emission control technologies across the fleet. For example, in February 2000, EPA issued stringent hydrocarbon and oxides of nitrogen standards for MY 2004 and beyond, which were designed to significantly reduce vehicle emissions in order to attain and maintain the national ambient air quality standard for ozone.45 And EPA applied the same flat standard across all passenger cars, light trucks, and larger passenger vehicles.46 These standards included a lengthy lead time in light of the ultimate goal to reduce emissions by more than 90% by 2009, requiring 'widespread applications of upgraded and improved technology across the fleet.'47

As discussed above, a significant portion of existing models already meet the proposed MY 2023 standard, and EPA believes automakers will be able to meet the fleet average standards without significant development of new electric vehicles, but instead with increased application of conventional technologies already developed for internal combustion vehicles, in combination with multiple flexible compliance options.48 To the extent automakers choose to comply with the standards by selling more electric vehicles, many have already made voluntary pledges to do so independently of these standards.49

Further, a number of factors make it easier for manufacturers to comply with these proposed standards than various past standards that may have necessitated somewhat lengthier lead times.

First, these standards are in the form of a fleet average rather than requiring individual compliance for each vehicle model, a significant flexibility not provided for most of EPA's earlier light duty vehicle standards.50 When EPA enacted the first greenhouse gas emissions standards for passenger vehicles in 2010, it noted that it was using fleet averaging because it 'resolve[d] issues of lead-time or technical feasibility, allowing EPA to set a standard that is either numerically more stringent or goes into effect earlier than could have been justified otherwise[,] . . . increas[ing] flexibility and reduc[ing] costs for the regulated industry.'51 The fleetwide averaging and trading provisions built into the Proposed Rule offer critical flexibilities that justify EPA's approach to lead time. In addition, the Proposed Rule provides for size- and sales-based standards that are not the same across the entire vehicle fleet. Rather, automakers have targets unique to their fleet and sales mix depending on the size of the models produced by that manufacturer in that model year, with larger vehicles subject to less stringent standards than smaller vehicles.52 And since that target is not determined until the model year is over and final production numbers are available, each automaker can set its own path based on its own individual production plans—unlike earlier standards that required automakers to rework their production schedule ahead of time to ensure every engine family individually met its flat tailpipe emission standards.53 Yet even when EPA in the past required more stringent flat standards that applied to all individual vehicles, the agency still issued numerous standards with mere months of lead time—further supporting that the Proposed Rule here, with its flexible footprint-based fleet average standard, does not necessitate significant lead time. [EPA-HQ-OAR-2021-0208-0299-A1 , pp. 6-8]

Second, manufacturers have access to significantly more compliance flexibilities under the Proposed Rule than they did under EPA's past criteria pollutant standards, including credit trading, credit multipliers, a large bank of available credits, and credit carryback provisions that allow automakers to make up for any possible shortfalls in earlier model years by increasing their efforts in subsequent years. Thus, even if automakers do not quite meet the MY 2023 standards, they have several years of lead time to adjust their production in MYs 2024–2026 and apply any credits earned in those years backwards to MY 2023. In addition, automakers are sitting on a significant bank of credits earned in past model years that can be applied toward any shortfalls in MY 202354 (and indeed, EPA has proposed extending the lifetime of those credits to provide even more flexibility55). [EPA-HQ-OAR-2021-0208-0299-A1, p. 8.]

As demonstrated by the examples provided above, the anticipated finalization of these proposed standards in the near future will be consistent with the lead time provided for other MYs throughout EPA's regulatory history, and reflects a proper use of EPA's discretion to provide shorter lead times when compliance requires less technological development and investment. Indeed, the significantly more flexible form of these standards provides evidence that even less lead time is necessary here than EPA may have provided historically for standards that did not contain the multiple complex flexibilities offered now. [EPA-HQ-OAR-2021-0208-0299-A1, p. 8]

Commenter: Tesla

Manufacturers Have Had Ample Lead Time Necessary to Implement the Technology Needed to Meet a More Stringent Standard. As EPA suggests, 'although manufacturers have less lead time before these standards would be implemented than with previous rulemakings, the significant progress that has been made in implementing advanced gasoline technologies in the fleet (as well as advances in electric and hybrid vehicle technology) since 2012 means the proposed standards can be achieved at roughly the same cost as previous estimates, and additional lead time is unnecessary.'130 Tesla believes, and has demonstrated through our own experience, that the automobile industry is technologically ready to meet LDV standards in the near term that are far more stringent than the agency has proposed. To that end, the proposal's implementation and start date of MY 2023 is more than reasonable—and meets the legal obligations for lead time under the CAA—without need for the extension of the compliance flexibilities which otherwise undermine the EPA's proposed stringency goals.

As the agency knows well, the regulatory structure around averaging, banking, and trading of compliance already builds in flexibility that allows for product lead adjustments. Under the existing regulations, manufacturers unable to meet the fleet level standard can carry forward a credit deficit for three years before it must be offset by a credit surplus.131 Some manufacturers may also be eligible for the Temporary Lead Time Allowance Alternative Standards, delaying the relevant compliance year (and hence level of standard stringency) they are required to meet.132[EPA-HQ-OAR-2021-0208-0278-A1] [p.15]

For over a decade, manufacturers also have been on notice and aware that GHG standards more stringent than the agency proposes were set to be in place after MY 2021. Indeed, in July 2011, Ford, GM, Chrysler, BMW, Honda, Hyundai, Jaguar/Land Rover, Kia, Mazda, Mitsubishi, Nissan, Toyota and Volvo – which together account for over 90% of all vehicles sold in the United States – as well as the United Auto Workers (UAW), all joined President Obama to support new MY 2017-2025 vehicle GHG standards that are effectively more stringent than the EPA's current proposal.133 Indeed, the automakers signed commitment letters that outlined their support for the standards and the future process 'to help our country address the need to reduce dependence on oil, to save consumers money, and to ensure regulatory predictability.'134

As the chart below demonstrates at a minimum, since these OEMs signed commitments, Tesla's market and technological success has more than proven that the last decade has allowed and permitted 'the development and application of the requisite technology' to achieve zero tailpipe emissions.135 In 2012, the first year of EPA and NHTSA's Final Rule for Model Year 2012 - 2016 Light-Duty Vehicle GHG Standards and CAFE Standards,136 Tesla delivered 2,636 vehicles to customers137 and had just under 3,000 employees. By 2020, Tesla delivered almost 500,000 vehicles to customers, including over 180,000 vehicles in the fourth quarter of 2020 alone—during the ongoing COVID-19 pandemic, its highest sales quarter to date,138 and employed over 70,000 people worldwide. In sum, from 2012 to 2020, under the current EPA and NHTSA performance standards, Tesla's vehicle deliveries grew by nearly 19,000% and its American manufacturing footprint and workforce have expanded rapidly. In 2021, Tesla's production and delivery has continued to accelerate.139 At the same time, according to the latest Consumers Reports Owner Satisfaction Survey, Tesla has received the highest owner satisfaction rating of any car brand in 2020—recognition which we have achieved seven times since 2013.140[EPA-HQ-OAR-2021-0208-0278-A1][p.16] [Figure 2 can be found on p. 16 of EPA-HQ-OAR-2021-0208-0278-A1]

While EPA points to the voluntary California Framework Agreements as an acknowledgment of manufacturer capability to meet the proposed standard, such an assertion is fundamentally incomplete. The agency fails to acknowledge that some manufacturers may have entered into the framework agreements not because of technological capabilities, but as an opportunistic hedge and safe harbor from the more rigorous California GHG standards should the SAFE rule's rescinding of California's Advanced Clean Car (ACC) waiver been found to be illegal.141 EPA's new proposal does not recognize that manufacturers also have continued to be subject to the regulatory rigors of the California and CAA Section 177 state zero emission vehicle mandates142 and GHG standards consistently over many years.143 While EPA is now in the process of reinstating the ACC waiver that underpins these programs,144 even under SAFE Rule Part 1, the agency recognized that these state regulations remained enforceable.145 California and the Section 177 states have written their ZEV mandates and GHG standards into their EPA approved State Implementation Plans (SIPs). As a result, these more stringent standards have remained in place and enforceable while the waiver gets reinstated because EPA never compelled any of these SIPs to be amended or revised to remove the purportedly preempted standards. Accordingly, they have remained important guideposts for company technology development and new production efforts, and the new rules do not significantly alter these trajectories in a way that would raise any legitimate lead time concerns. EPA-HQ-OAR-2021-0208-0278-A1][p.17]

Moreover, manufacturers also now deliver and deploy technology to meet stricter GHG standards globally. Since 2020 manufacturers have had to prepare and deploy technology in the European Union that meets far more stringent GHG emissions standards. It is not a question of needing additional lead time to develop and commercialize the technology to meet a standard more stringent than the one proposed. Simply put, EPA needs to put stronger standards in place so that manufacturers choose to bring their already developed and deployed advanced technology into the U.S. market. The fact that manufacturers can already deploy this technology imposes a heightened burden on EPA to explain why 'technology that is currently available could not be applied' to obtain greater emissions reductions.146 EPA-HQ-OAR-2021-0208-0278-A1][p.17]

The standards may permissibly be made more stringent, particularly with respect to MY 2024-2026, without running afoul of any lead time requirement. The CAA requires that for any standard adopted or revised under Section 202, the Administrator must take into consideration factors such as the availability and costs of the technology, and noise, energy, and safety factors, and lead time.147 Lead time is thus only one of a set of factors the Act instructs EPA to consider, and the Act's 'language does not resolve how [EPA] should weigh all these factors in the process of finding the 'greatest emission reduction achievable.''148 As the D.C. Circuit has recognized, EPA need not always establish long lead times.149 Indeed, the D.C. Circuit has explained that a lead time of less than two years can be acceptable.150 Particularly where, as here, the more stringent Obama-era standards nearly a decade ago prompted adjustments in the industry, manufacturers have had sufficient lead time for more stringent standards.151 As the Proposed Rule recognizes, 'significant progress … has been made in implementing advanced gasoline technologies in the fleet (as well as advances in electric and hybrid vehicle technology) since 2012.'152 Further lead time is not necessary. EPA-HQ-OAR-2021-0208-0278-A1][pp.17-18]

Finally, any lead time concerns are particularly misplaced considering that it is only EPA's unlawful decision to depart from the 2017 mid-term evaluation's correct conclusion that the 2022-2025 standards were entirely feasible that gave rise to a change in the standards. Tesla and many other parties challenged EPA's decision on the mid-term review in the D.C. Circuit, and the merits of that decision were never reached.153 But the uncertainty over the legal authority for the Trump Administration's rollback of the standards certainly put the industry on notice that a more stringent compliance pathway was not completely off the table. And other automakers consistently have noted that their product planning cycles take years,154 so the timely correction of the standards from the SAFE rule departure off of consistently increasing levels of stringency would not be prejudicial to manufacturers' planning and investment cycles for the affected model years, which have long been locked in. Moreover, to the extent EPA relies on any lead time considerations, it should immediately 'schedule a future rulemaking' timetable for MY 2027 and beyond to address the need for enhanced stringency.155 [EPA-HQ-OAR-2021-0208-0278-A1] [p.18]

Commenter: Union of Concerned Scientists (UCS)

EPA can and must finalize strong standards for MY2023, and the industry is well positioned to comply with those standards thanks in large part to a significant bank of credits that the agency did not fully account for in the compliance pathways modeled for the proposal. [EPA-HQ-OAR-2021-0208-0277-A1, p.3]

Support for setting strong greenhouse gas emissions standards in 2023. It has been more than a decade since the first federal LDV greenhouse gas standards were finalized4—since then manufacturers have responded with significant advancements in technology while amassing a tremendous quantity of banked credits from overcompliance with the greenhouse gas regulations.5 At the same time, few of the internal combustion engine technologies identified to reduce fuel use in line with those standards have made their way into the majority of the new vehicle fleet, indicating substantial room for improvement with off-the-shelf technology.6 Even newer combustion technologies continue to be developed and deployed, including high-energy ignition systems, electrically assisted turbochargers, and more.7 And all this is happening as manufacturers continue to deploy an increasing number of electric vehicle models, indicating that the transition to electrification is fully underway now, and through the timeframe of the proposed rule.

All of these ongoing developments support finalizing a strong rule as quickly as possible, beginning no later than MY2023. Below we address the explicit support industry's progress provides for any concerns around lead-time in the early years of the Preferred Alternative or Alternative 2.[EPA-HQ-OAR-2021-0208-0277-A1, p.4]

Industry product cycles and current product plans

Market analysis shows that in the MY2022-2025 period, industry is expected to annually launch 50 percent more new vehicle models than the historical average and replace over 80 percent of the fleet.8 The annual replacement rate increases from 1 in 6 to 1 in 5 vehicles over this time period, and some manufacturers like Honda and Toyota will be replacing the entirety of their fleet in this four-year window, indicating a rapid, ongoing transition; even General Motors, which is expected to have a below average turnover in this timeframe, is doing so as the result of 'a concerted effort on powertrain investment and launch of niche, lower-volume electric vehicles over our forecast period."9 It is clear that the market is currently preparing for a significant period of product development in the timeframe of these rules, with more than 60 percent of these vehicles having an hybrid-electric or electric powertrain option, including more than 90 standalone electric models, 10 a level of technology deployment well above what is needed to comply with the current federal greenhouse gas program.11

These product plans indicate an industry that is well-prepared for stringent regulations. While 30 percent of the industry has committed to meeting national fleet greenhouse gas targets that well exceed what is federally required and generally match the stringency of the Preferred Alternative in MY2023, 12 the remainder of the industry has not likely altered their product plans to increase fleet emissions in response to the weakening provided by the SAFE rule, given that the rule being replaced by this proposal was finalized just 18 months ago (and quickly became the subject of litigation)—and the market analysis bears this out.

UCS concurs with EPA's analysis that manufacturer plans are not likely to have changed significantly in response to the SAFE regulation.13 But to the extent that manufacturers may have adjusted their product portfolio, such flexibility from manufacturers would only further demonstrate the feasibility of more stringent standards under the proposal—not only does that mean they have additional foregone technology strategies at the ready, but if a rule finalized in March 2020 was sufficient for them to adjust product plans for MY2021 or MY2022, then finalizing a change in standards by December 2021 allows adjustments are possible by MY2023 or MY2024. Or, alternatively, manufacturers continue to move forward with their own product plans that pre-date the SAFE rule, i.e. greenhouse gas standards finalized in 2012 which are actually more stringent than the agency's proposal.14 [EPA-HQ-OAR-2021-0208-0277-A1, pp.4-5]

EPA Response

The California Attorney General's comments on lead time and stringency are addressed in Preamble VI.A.

Many commenters (e.g., ALA, Bay Area AQMD, Consumer Reports, EDF, UCS) supported the MY 2023 start date for the revised standards, urging that revised standards must begin as soon as possible since further emission reductions are both needed and feasible in this time frame. Several commenters (Consumer Reports, EDF, EPN, the Institute for Policy Integrity, UCS, Tesla) were supportive of EPA's assessment that the MY 2023 standards are feasible with adequate consideration of lead time. UCS and EDF conducted independent analyses of MYs 2023 and 2024 using publicly available modeling tools. As described further in Preamble VI.A, both UCS and EDF concluded that manufacturers will be able to comply using existing credits by following product planning trajectories for the no-action case, even with conservative assumptions that restrict technology deployment beyond what is already projected under the no-action case. EPA agrees with these commenters that the lead time provided is reasonable, as discussed in Preamble VI.A and RIA 2.2 and 2.4. The Alliance for Automotive Innovation commented in support of the proposed standards (as discussed in this response to comments (RTC) document, section 2.2) but also commented that the stringency of the MY 2023 targets would be challenging for some automakers in consideration of lead time.

The Alliance commented about required fleet improvements from 2019 MY to meet 2023 standards, the importance of considering redesign cycles, and regarded that timeframe as a short window for redesign to occur. The commenter provided an example of the pace of redesign opportunities based on DOT CCEMS modeling inputs in its Tables 7 and 8 and suggested that these are appropriate. EPA agrees that redesign opportunities are only available to a portion of the fleet in any given year. In its compliance modeling EPA included consideration for vehicle refresh and redesign – in fact, EPA used the same redesign assumptions as DOT for its CCEMS modeling (referenced by the Alliance in Tables 7 and 8 of their comments). Shares of vehicle sales available for refresh and redesign are provided in Table 4-3 of the RIA. Based on comments from UCS providing market evidence of accelerating refresh and redesign rates within the industry, our modeling assumptions may even be conservative. Finally, it is important to note that some redesigns are already planned for every model year, including MY 2022 and 2023.

In referencing an IHS Markit study which claims that while only 11.6 percent of vehicle production (sales volume) in MY 2020 meets EPA's proposed MY 2023 targets, the Alliance asserts (assuming a normal distribution of vehicles above and below target) that roughly 50% of the sales volume should meet the target in a given model year to achieve overall compliance. EPA disagrees with the Alliance's claim. As we discuss in Preamble VI.A, even a small number of BEVs and PHEVs can have a large influence on a manufacturer's compliance credits in a given year and, while the program does not require any manufacture to produce specific technologies such as BEV/PHEVs, we note that this situation is true even where such credits are produced by one manufacturer and purchased by another. EPA also notes that manufacturers are already producing many vehicle products that would be credit-generating vehicles under the MY 2023 standards, and we consider the availability of models in production more relevant for assessing feasibility than a sales-weighted approach. As described in Preamble VI.A and RIA 2.4, a considerable portion of the current new LD fleet (16% of all MY 2021 vehicle models today, across a wide range of vehicle segments) would generate credits under the final MY 2023 standards. In addition, as several commenters including the Bay Area AQMD and California Attorney General point out, manufacturers will have additional opportunity to generate credits in MYs 2021 and 2022 against the weakened SAFE standards.

The Alliance also commented that on average manufacturers used credits to meet compliance requirements for MYs 2019-2020, the availability of credits is limited for some manufacturers, and there are no guarantees that they will be available for sale. As described in Preamble VI.A, our central case analysis was done without accounting for credit trading between manufacturers, and yet still projects feasible compliance pathways. However, EPA recognizes that credit trading does occur, and as a result we believe that our central case is conservative. EPA recognizes that manufacturers are using credit banking and trading provisions for compliance, but we believe that is neither surprising nor cause for concern as a large bank of GHG credits exists within the industry overall and we anticipate that for some automakers for some years or models using credits will be more efficient than applying emissions technologies. Moreover, the use of those credits is not restricted to the manufacturers who currently hold them. Indeed, publicly available information suggests that some manufacturers have designed business strategies around selling credits, while others have designed strategies around purchasing credits.[2] EPA considered how trading between manufacturers can contribute towards compliance in MY 2023 and 2024 in a perfect trading sensitivity described in Preamble VI.A and RIA 4.1.5.1. Finally, in its independent modeling, UCS applied conservative assumptions about the continued trajectory of Framework and non-Framework manufacturers under the No-Action case and concluded there is "sufficient credit availability for manufacturers to comply with the proposed MY2023 and 2024

[2] For example, according to EPA's 2021 Automotive Trends Report, Tesla outperforms its fleet standard by the largest margin of any automaker, yet has the fewest credits on hand. According to one calculation, the $518 million revenue Tesla reported from selling emission credits in the first quarter of 2021 represented nearly all of its profit for the quarter. See "Tesla Made More Money Selling Credits and Bitcoin Than Cars" Autoweek, April 27, 2021. By contrast, Stellantis has stated publicly that it historically has relied on credits for compliance where that is cost-effective, and it currently holds the largest number of credits. See Stellantis N.V. (2020). ''Annual Report and Form 20–F for the year ended December 31, 2020."

standards, even without resorting to additional technology deployment or credit carryback from improvements made post-MY2024."

EPA accounted for a number of important factors related to lead time in our modeling. However, the CCEMS model does not account for the ability of manufacturers to borrow credits from future model years. Furthermore, CCEMS projects manufacturer's decisions to apply technologies while holding vehicle model shares fixed within car and truck regulatory classes. CCEMS does not account for the opportunity for manufacturers to adjust the sales mix towards existing credit-generating vehicles as a compliance strategy. Although our modeling supports the conclusion that there is appropriate lead time for the final standards, we believe that by excluding these factors our modeling is somewhat conservative.

In its assessment of lead time for MY 2023, EPA considered in its analysis all of the aforementioned factors: vehicle refresh and redesign opportunities, the existing credit banks present within the industry, the ability of manufacturers to trade credits, and their ability to carry back credits earned in future years. EPA believes that its modeling results, along with the flexibilities provided by averaging, banking and trading and other aspects of the final program, as discussed in in Preamble VI.A, support the agency's conclusion that manufacturers have sufficient lead time to meet the final standards.

The Institute for Policy Integrity commented on EPA's discretion under the Clean Air Act in determining the appropriate amount of necessary lead time based on the standards it is considering, and that EPA has acted consistently with its historical consideration of lead time in regulating vehicle tailpipe emissions. EPA agrees with this comment. See Preamble I.A.2. for a discussion of how lead time and other factors were considered in determining the appropriateness of the final standards.

In its comments, Tesla provided similar arguments for why manufacturers have had ample lead time to implement the technology needed to meet not just the proposed standards, but also more stringent standards for MY 2024-2026. Tesla expressed that the proposal is more than reasonable and meets legal obligations for lead time under the CAA without need for the extension of the compliance flexibilities. While EPA agrees that the lead time provided is appropriate, we have chosen to finalize a more targeted set of flexibilities primarily limited to MYs 2023 and 2024, as discussed in Preamble II.B and RTC Sections 4, 5, 6, 7, and 8. Based on public comments and newer available data, EPA has also revised the standards to be more stringent than the original proposal for MY 2025 and MY 2026 as discussed in Preamble Section II and RTC Section 2.2.

Commenter: Advanced Engine Systems Institute (AESI)

Over the past 50 years, U.S. technology leadership has been based upon stringent and predictable standards allowing domestic suppliers to establish competitive advantage through the early adoption and optimization of technologies on vehicles. The 2012 GHG standards allowed suppliers to rapidly introduce new technologies to the market. Subsequently, when EPA conducted their mid-term review, the pace and breadth of technology options for compliance grew and cost reductions exceeded expectations. The decision to weaken GHG standards in 2018 have left many advanced technologies on the shelf and put the US behind other leading auto manufacturing regions like Europe and China where CO2 standards accelerated. [EPA-HQ-OAR-2021-0208-0267-A1, pp. 1-2]

We enthusiastically support the standards proposed in this MY 2023-2026 NPRM, contained in EPA's Preferred Alternative. [EPA-HQ-OAR-2021-0208-0267-A1, p. 3]

Commenter: Agortsas, George

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 188.]

I support the swift action on clean cars and urge the EPA to adopt the most stringent standards that would deliver greater environmental benefits and savings to consumers.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 190.]

Therefore, I urge the EPA to adopt these stringent guidelines for the automotive industry, transportation industry, so we can reduce emissions because I believe we can make a difference in the world not only for our children but also for others as we've done in the past.

I know we're capable. We just need the willpower.

Commenter: Allen, Martin

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 23.]

I strongly support this Administration's efforts to encourage production and use of clean cars and urge the EPA to adopt the second alternative which would deliver greater savings to consumers and eliminate industry loopholes.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 27.]

Improved fuel economy standards by the EPA is but one way to put industry on a path to reduce greenhouse gas emissions by encouraging development and sales of electric vehicles. EPA's strong car standards will drive down overall pollution, spur technological electrification innovation and drive down consumer costs.

The EPA should not accept a rule which with a weak proposal and loopholes for the automaker industry. There's no need to compromise. I therefore ask the EPA to take action to set the strongest clean car standards possible, reinstate the Obama/Biden federal standards, and Alternative 2, and even stronger standards thereafter

Commenter: Allergy & Asthma Network, et al.

The undersigned health and medical organizations write to urge the United States Environmental Protection Agency (US EPA) to set the strongest possible standards to curb climate-forcing greenhouse gas (GHG) emissions from the light-duty vehicle sector. We call on US EPA to act now to revise the existing standards set by the previous administration, and to finalize model year 2023-2026 rules that aggressively respond to the immediate and generational threat climate change poses to public health and health equity. [EPA-HQ-OAR-2021-0208-0296-A1, p. 1]

While US EPA has proposed increasing the stringency of the inadequate standards set by the previous administration, our organizations believe US EPA must establish a more stringent standard than has been proposed as the final rule. The final rule must require greater real-world GHG reductions and set a stronger pathway toward the full transition to zero-emission technologies. [EPA-HQ-OAR-2021-0208-0296-A1, p. 2]

The 2023-2026 standards are a critical steppingstone to climate and clean air benefits that are desperately needed in communities throughout the United States. We urge US EPA to finalize the rule this year so it will implemented in Model Year 2023. US EPA must take full advantage of the opportunity to revise these standards and must set the course to a healthier, more sustainable future for all Americans. [EPA-HQ-OAR-2021-0208-0296-A1, p. 3]

US EPA must select the more health-protective Alternative 2 as a starting point for the 2023-2026 standards. The US EPA proposal notes that an alternative proposal ('Alternative 2') would yield greater climate, health and societal benefits. US EPA estimates that Alternative 2 would reduce carbon dioxide emissions by 72 million metric tons, or nearly twice the EPA central proposal, during 2023-2026.3 As noted in the documentation, US EPA estimates that by 2050, Alternative 2 would result in approximately $170 billion in health and other societal benefits (excluding fuel savings, which are valued at an additional $290 billion), significantly higher than benefits outlined for US EPA’s central proposal.4 Further, the regulatory impact assessment notes that Alternative 2 would reduce consumption of by 486 million barrels of oil more than the central proposal.5 For communities living at the fenceline and downwind of refineries, every reduction counts. Alternative 2 must be the baseline for US EPA’s final rule revision to maximize climate and health benefits and reduce burdens in highly impacted communities. [EPA-HQ-OAR-2021-0208-0296-A1, p. 2]

However, US EPA should not rely solely on post-2026 rules to accelerate the transition to ZEVs when more stringent standards for 2023-2026 are needed to secure major health and climate benefits of non-combustion transportation.7 Adopting Alternative 2 with limits on excess credits and loopholes that diminish effectiveness of the rule will spur greater ZEV deployment across multiple platforms. We encourage US EPA to establish standards that position the nation for a smoother transition to zero-emission vehicles today. [EPA-HQ-OAR-2021-0208-0296-A1, p. 3]

Commenter: Alliance For Automotive Innovation

Auto Innovators opposes the adoption of the more stringent and less flexible alternatives discussed in the proposed rule. [EPA-HQ-OAR-2021-0208-0571-A1, p. 7]

Actions must start now to ensure the necessary conditions are in place for manufacturers to meet the proposed standards through MY 2026. Meeting the proposed standards will be a challenge, requiring significant increases in EV market share in only four model years. EPA projects a 7.8 percent market share for EVs by MY 202617 (a threefold increase from calendar year 2020 at 2.5 percent18). NHTSA projects an even higher 13 percent EV penetration by MY 202619 (a fivefold increase). According to recent estimates shared by IHS Markit in August 2021, auto manufacturers are planning sales of battery electric and plug-in hybrid electric vehicles to reach approximately 23 percent of new light vehicle sales in the U.S. market in 2026.20 While such levels are possible, a market and necessary supporting conditions and policies must be in place to achieve them.

Manufacturers are also already announcing plans to reduce or eliminate investments in ICEs.21,22,23,24,25,26 Some automotive executives are saying that they no longer intend to develop new ICEs, are no longer setting aside significant money for new ICEs, or that ICEs will only get incremental work.27

Others, such as policymakers, may suggest that little or no investment is needed in ICE technologies because they are "off-the-shelf" or present in the fleet today. This view ignores that technologies can't simply be "bolted on" to existing engines. Instead, they must be carefully integrated into existing designs, requiring engineering resources, and in many cases, new engine designs. A new engine design can cost as much as $1 billion.

The EPA analysis diverges in compliance pathways in 2018-2021 model years, both between alternatives considered today, and with what manufacturers achieved. Vehicles produced in these years are already produced and sold. MY 2022 vehicles are in production now. Manufacturers cannot go back in time and change past decisions about engines or transmissions offered in products, and it's not instructive at all for how changes in policy considered today may affect societal costs and benefits, or future stakeholder actions. The DOT analysis uses the SAFE rule stringency as the baseline, and ensures compliance pathways chosen by manufacturers are the same for 2021, and 2022, regardless of alternative, and this is a recommended approach. However, the DOT analysis also bakes a ZEV program into the baseline, and as a result, the technology costs associated with ZEV compliance do not appear to affect incremental technology cost, or future sales, and this is incorrect (a very large ZEV mandate could increase technology costs significantly, and consumers may be less likely to purchase as many vehicles at higher prices, but the current form of the DOT analysis would not consider this, and this is an error, and a failure to properly account for the technology cost of other vehicle standards affecting fuel economy and economic practicability). [EPA-HQ-OAR-2021-0208-0571-A1, p. 53]

Thus, it is critical that EPA, NHTSA, CARB, Auto Innovators, automobile manufacturers, suppliers, technology companies, and other stakeholders work together to make sure this rule sets the right balance – to provide greater GHG benefits in the near term, to encourage and enable a shift to EVs and other net-zero emission vehicles, and to continue to support U.S. auto jobs. The revised EPA GHG regulations must balance these policy goals with a market and ecosystem for EVs that are still developing and highly uncertain; in the context of major, increasing investments in EVs and declining or eliminated investments in ICEs; and while recognizing the limited opportunity to incorporate major changes through vehicle redesigns between MY 2023 (which starts in as little as three months) and MY 2026 (beginning less than four years from now). [EPA-HQ-OAR-2021-0208-0571-A1, 7-9]

The Proposed GHG Standards for MYs 2023-2026

Auto Innovators generally supports EPA's proposed GHG standards with appropriate and necessary flexibilities included in the program. Auto Innovators generally supports the proposed

GHG standards, but complementary policy measures to greatly expand the EV market are critical to manufacturers' ability to meet them. Fueling infrastructure, supply chains, recycling industry, purchase incentives and more will be necessary. Necessary complementary measures also include recognition of the zero tailpipe emissions of vehicles operating on electricity or hydrogen, and various flexibility mechanisms including EV production multipliers for at least model years 2022 through 2025.30 The proposed targets and flexibilities establish a strong foundation for additional standards in subsequent years. [EPA-HQ-OAR-2021-0208-0571-A1, p. 9-10]

The proposed MY 2026 targets will likely require significant electrification.

As shown in Figure 2 [Figure 2 can be found on p. 12 of Docket number EPA-HQ-OAR-2021-0208-0571-A1], MY 2020 vehicles (many of which already include ICE technologies modeled by EPA) were also assessed against the MY 2026 proposed targets. In the MY 2020 fleet, only EVs are capable of meeting the proposed MY 2026 targets. The same holds true for the proposed MY 2025 targets.

The projections of the Agencies also make it clear that significant increases in the EV market are anticipated. EPA projects a 7.8 percent market share for EVs by MY 202636, and NHTSA projects 13 percent.37 According to recent estimates shared by IHS Markit in August 2021, auto manufacturers are planning sales of battery electric and plug-in hybrid electric vehicles to reach approximately 23 percent of new light vehicle sales in the U.S. market in 2026.38

Regarding More Stringent Standards

Other stakeholders, such as environmental and health NGOs, have expressed their desire for EPA to adopt more stringent standards than proposed. These arguments fail to appreciate fundamental engineering timelines, namely that vehicles and powertrains are not redesigned every year, and that even redesigned vehicles have a limited engineering and design budget that must cover every need of a vehicle or powertrain program. Even more importantly, greater stringency will increase electrification needs even further, putting greater pressure on the development of the EV market while government legislators and others continue to debate the need for and quantity of complementary supporting measures.

Auto Innovators opposes adoption of Alternative 2.

EPA considered a more stringent "Alternative 2" that is broadly based on regulations finalized in 2012 (the "2012 Rule") 39 that include the removal of proposed EV incentives and other flexibilities.40

Auto Innovators and its predecessor organizations noted many times during the midterm evaluation process that changes were necessary from the 2012 Rule. We re-affirm that position here, and as such, believe that returning immediately to the stringency of the 2012 Rule would be bad policy.

We therefore cannot support EPA's Alternative 2. It is broadly the same as the 2012 Rule with an additional year of standards (MY 2026) defined. Moreover, based on the EV market and other challenges described above in our response to the proposed standard, Alternative 2 would be an unrealistic standard to meet in the near-term. [EPA-HQ-OAR-2021-0208-0571-A1, p. 12-13]

Comments on Alternative Standards for Small Volume Manufacturers

Auto Innovators appreciates and supports the inclusion and the maintenance of alternative fleet average standards for manufacturers with limited U.S. sales under the criteria set forth at 40 C.F.R. § 86.1818(g). To comply with provisions on fleet average GHG emissions, small volume manufacturers must intervene on substantial elements related to the primary characteristics of their vehicles. However, these actions must be consistent with their business models and investment sustainability. For these reasons, it is crucial that the option to apply for alternative GHG standards is maintained in this and future rulemakings so that the actions required under EPA's regulations are proportionate to the GHG emissions share for which each stakeholder is responsible.

Auto Innovators recommends that EPA consider process improvements to speed consideration and approval of petitions for alternative standards to provide more regulatory certainty and business stability. [EPA-HQ-OAR-2021-0208-0571-A1, p. 15-16]

Auto Innovators opposes adoption of more stringent standards specific to model year 2026.

EPA requests comment on increasing the proposed MY 2026 standards by 5-10 g/mile.41

Increasing the proposed standards by another 5-10 g/mile in MY 2026 presumes that the lead-time provided is sufficient to make an even larger leap forward in stringency in the next four years. The development of the EV market and complementary policy measures remains highly uncertain. If, over the next several years, such uncertainties are resolved and a robust market for EVs is developing, it may be appropriate at that time for EPA to consider whether a stronger standard in subsequent (MY 2027 and later) years is warranted. [EPA-HQ-OAR-2021-0208-0571-A1, p. 13-14]

Commenter: Alliance for Vehicle Efficiency (AVE)

EPA's Proposed Standards are Ambitious but Achievable with Flexibilities such as Multipliers and Credits

As EPA correctly states, OEMs have already, and will continue to, incorporate '…an increasing array of advanced gasoline vehicle GHG emission-reducing technologies at a rapid pace throughout their vehicle fleets.'3

OEMs and technology suppliers spend over $100 billion per year on research and development of technology to meet increasing fuel efficiency standards and to reduce vehicle emissions. Automotive suppliers provide over two-thirds of the value of a new vehicle and are the largest patent recipients in this sector. These supplier investments will provide OEMs with the advanced technologies necessary to comply with the standards proposed by EPA. By supporting multiple pathways for compliance today and in the future, EPA will allow technology suppliers to invest with confidence in even greater emission reduction technologies. [EPA-HQ-OAR-2021-0208-0256-A1, pp. 2-3]

Commenter: Alliance of Nurses for Health Environments

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 22-23.]

The preferred alternative identified by EPA is not as strong as the standard finalized during the Obama Administration. The EPA itself identified a much better rule, Alternative 2, which would put 400,000 extra electric vehicles on the road by 2026 and result in a 130 million metric tons fewer greenhouse gas emissions.

Commenter: American Council for an Energy-Efficient Economy (ACEEE)

The US needs strong vehicle standards

The United States will need to greatly reduce light-duty vehicle greenhouse gas emissions if it is to have any chance of meeting the Biden Administration’s emissions reduction goal of 50% by 2030 and to stave off the worst impacts of climate change. The central aim of Title II of the Clean Air Act, which establishes the authority and obligation for the Environmental Protection Agency (EPA) to set vehicle standards, is 'the protection of public health and welfare.' After a summer of severe forest fires and flooding, the EPA cannot miss an opportunity to make significant progress on emission reductions from the 2023 to 2026 vehicle model years (MY). These standards must also set the foundation for further efficiency gains and electrification beyond model year 2026 and ambitious targets will help to meet President Biden’s 2030 goal of 50% zero emission new vehicles sales (White House 2021). The stringency and structure of these standards will have lasting impacts and it is crucial that EPA gets them right. Electric vehicles (EVs) are widely recognized as the future of the automotive industry and post-2026 standards should be consistent with this future (NAS 2021a). [EPA-HQ-OAR-2021-0208-0251-A1, pp. 1-2]

EPA’s proposal is weak

The proposed targets for MY 2023-2026 fall far short of what is needed to make significant progress on addressing GHG emissions from light-duty vehicles. EPA has chosen to move forward with standards that do not maximize the social and environmental net present benefit (NPB) and fails to justify its reasoning for this decision. Of the various scenarios considered by EPA in the NPRM, Alternative 2 is shown to have the highest NPB. [EPA-HQ-OAR-2021-0208-0251-A1, p.2]

The weakness of the proposal is further supported by EPA’s own analysis that shows that the proposed rule will only lead to an EV market share of 8% by MY 2026, far short of what is needed by then to make progress towards the White House’s goal of a of 50% new EV sales by calendar year 2030 (White House 2021). ACEEE discusses key areas of concern in additional detail below. [EPA-HQ-OAR-2021-0208-0251-A1, p.2]

BANKED CREDITS

The existing pool of banked credits makes reaching standards substantially more stringent than the EPA proposal much easier than the nominal gram-per-mile targets would suggest. Even ignoring EPA's proposed extension of credit lifetimes, automakers earned over 56 million MMT of credits in MYs 2018 and 2019, which could be applied toward meeting the proposed 11% increase in stringency for MY 2023 under Alternative 2. This is a realistic scenario because none of these credits would need to be spent before MY 2021, given that the available early action credits earned in MY 2009-2011 greatly exceed the need for banked credits in those model years. Automakers would also have access to the earned credits of MYs 2016 and 2017 and could use them to meet targets for MYs 2021 and 2022 meaning that they would not need to use the later MY credits. MYs 2018 and 2019 credits alone would be worth over 17 g/mi for MY 2023.15 If all of MY 2018 and just 60% of MY 2019 credits are used toward MY 2023 compliance, the proposed 9.5% reduction in the average gram-per-mile target could actually be achieved with under a 3% reduction in that year. For Alternative 2 this would reduce the 11% target reduction in emissions to a 4.8% reduction in emissions. [EPA-HQ-OAR-2021-0208-0251-A1, p. 11]

Automakers are also more likely to save all their banked credits or even earn more credits before MY 2023 because of the SAFE rule's decrease in stringency for MYs 2021 and 2022. Should the automakers simply manage to preserve their 56 million MY 2018-2019 credits until MY 2023 and earn only an additional 22 million MMT of credits16 over MYs 2020, 2021, or 2023, then automakers would need to produce no actual improvement in MY 2023 to comply with the new standards. In all likelihood, automakers could exceed this and enter MY 2024 with banked credits as well. Even without extending credit lifetimes, as EPA proposes to do, the existing stock of banked credits make compliance with the Alternative 2 MY 2023 target achievable, contrary to what the 11% reduction in emissions headline would suggest. [EPA-HQ-OAR-2021-0208-0251-A1, p. 11]

To reach 2030 and 2035 climate and vehicle electrification goals, the MY 2023-2026 targets need to be considerably stronger than proposed and push faster growth in EV penetration. [EPA-HQ-OAR-2021-0208-0251-A1, p.13]

EPA's light-duty vehicle emission standards are a vital tool to protecting vehicle owners, the environment, and the public. Standards that push technology forward help consumers save on fuel costs, reduce environmental damage, and reduce dangerous pollution that increases the risk of breathing-related illness. ACEEE believes that EPA has built a good framework for the SAFE replacement rule, but believes it needs to be more ambitious to reflect the White House's new goals for emission reductions by 2030 and EV market development. ACEEE thanks EPA for the opportunity to contribute these comments and improve the final rule. [EPA-HQ-OAR-2021-0208-0251-A1, p. 15]

EPA has built a good framework for the MY 2023-2026 emissions regulations. However, the rule needs improvements. As discussed above the proposed rule is weakened by counterproductive and discretionary credit provisions. Even without these credits the proposed rule is not stringent enough to pave the path towards the White House's goal of 50% EV market share by 2030 (White House 2021). ACEEE proposes the following recommendations for the final rule. [EPA-HQ-OAR-2021-0208-0251-A1, p. 14]

Alternative 2 with an additional 10 g/mi in MY 2026 is the minimum starting point for the SAFE replacement standards

EPA requests comment on Alternative 2, which adds 10g/mi to the stringency of targets for model year 2026 (EPA 2021b). This scenario should be the absolute minimum stringency that EPA considers when setting emission limits. This is the most stringent option that EPA puts forward and yet it only achieves 84% of the emission reductions for MYs 2021-2026 as the 2012 rule (plus another year of growth in MY 2026) and achieves a fleetwide average compliance of 160 g/mi in our modelling. The proposed standard, on the other hand, even without any incentive provisions, only achieves about 73% of the emission reductions as the 2012 rule. Also, by EPA's own calculations, Alternative 2 has the highest net present benefits (NPB) of any option that EPA investigated. The NPB of Alternative 2 ranges from $110 to $180 billion compared to $86-140 billion for the rule as proposed. EPA has not shown, or even asserted, that the proposed rule is the strongest and most reasonable rule possible, and indeed their own analysis finds that Alternative 2 has greater net benefits. [EPA-HQ-OAR-2021-0208-0251-A1, p. 14]

One benchmark for the SAFE replacement rule should be achieving at least the net carbon savings of the 2012 rule. To recapture these savings, ACEEE estimates that the rule would need to increase in stringency linearly from the proposed MY 2023 target to 155 g/mi in MY 2026. Making these changes would not only ensure that we capture back the losses from the SAFE rule, but also better position the nation to set post-2026 standards in line with the White House's 2030 goals. [EPA-HQ-OAR-2021-0208-0251-A1, p. 14]

Commenter: American Honda Motor Company (Honda)

The agency's proposed standards move quickly to begin delivering emissions reductions promptly, calling for a significant g/mi drop (increase in stringency) in 2023 and bringing federal standards in line with the California Framework stringency. Honda supports this approach for the societal benefits it ensures. By contrast, standards set further into the future could be viewed as having less certainty associated with them.

Beginning in MY2024, the agency's proposed standards go beyond the California Framework topline stringency, with proposed MY2026 standards well below (more stringent than) MY2025 levels set during the Obama administration. Figure 1, at right, charts output from EPA's scenario modeling analyses. Clearly, the revised MY2023-2026 federal standards would deliver substantially more environmental benefits than the regulatory construct they are proposed to replace.12 These standards represent challenging and ambitious targets that will require significant levels of electrification, particularly in the outer years of the program. [EPA-HQ-OAR-2021-0208-0565-A1, p.5] [Figure 1 can be found at docket number EPA-HQ-OAR-2021-0208-0565-A2, p. 5]

Model Year 2026 Stringency

The agency requests comment on appropriate level of stringency for Model Year 2026, including whether an additional 5-10 g/mi reduction (increase in stringency) should be applied. Honda supports the proposed MY2026 targets, but for the reasons stated above opposes the agency's alternative proposals as well as an additional 5-10 g/mi reduction. We believe the proposed targets represent challenging near-term obligations, calling for fleet average levels in 2026 notably cleaner than those finalized under President Obama's Final Rule, as well as the California Framework agreement. Considering the fact that the proposed reconsideration significantly limits use of advanced technology vehicle multipliers, the base proposal's MY2026 stringency already represents a daunting near-term requirement. We believe that setting a requirement 5-10 g/mi more stringent than those targets could create a highly disruptive compliance landscape as industry heads into the next round of standards. [EPA-HQ-OAR-2021-0208-0565-A1, p. 8]

EPA's modeling analysis suggests MY2026 standards can be achieved with an industry average of 6.9% ZEVs. A further reduction (increased stringency) of 10 g/mi would likely have a non-trivial impact on the amount of electrification needed to comply. As shown in Table 1 [Table 1 can be found at docket number EPA-HQ-OAR-2021-0208-0565-A2, p. 9], by our calculations, doing so would drive the number of ZEVs from 6.9% to 12.3% of the national fleet, representing a 78% increase17 in the volume of electrified powertrains needed to comply. Given the near-term regulatory window, comparatively limited opportunity for product refresh/redesign, and current supply chain challenges with unknown resolution dates, this represents an exceedingly difficult compliance target. [EPA-HQ-OAR-2021-0208-0565-A1, p. 9]

Figure 3, similar to Figure 1 shared earlier in our comments, shows the additional emissions benefits of a further 10 g/mi reduction in MY2026. As can be seen, this would only slightly increase the cumulative CO2 emissions benefits though, as stated above, require a non-trivial increase in electrified volume. Using EPA's cost data for this NPRM, we estimate these additional reductions could have a marginal abatement cost of as much as $300/metric ton.18 Honda has long voiced support for steady and reasonable increases in stringency. Rapid escalation – or de-escalation – can create significant regulatory uncertainty that is anathema to automobile manufacturers' strategic planning efforts. In our view, a more reasonable approach is to maintain the proposed 2026 targets, and to seek additional reductions under the subsequent (MY2027 and later) regulatory construct. [EPA-HQ-OAR-2021-0208-0565-A1, p. 9] [Figure 3 can be found at docket number EPA-HQ-OAR-2021-0208-0565-A2, p. 9]

17 This percentage increase is a fleet average; while some OEMs would see more modest increases, others could be expected to face more severe obligations.

18 Analysis based on substitution of turbocharged ICE with BEV300 for the MedSUV tech class in 2026.

Commenter: American Lung Association

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p.19]

Third, EPA's own analysis points to more Protective Alternative Number 2, which would provide more pollution reduction and more electric vehicles on the road by 2026.

EPA estimates that Alternative 2 would result in significant present value net benefits of up to a 180 billion and analyzed net benefits of up to 9.1 billion. Quoting from the NPRM, "The total benefits far exceed the costs of the program." As noted above, this is a health emergency and maximizing pollution reductions is needed.

We encourage EPA to pursue at minimum the stringency laid out in Alternative 2 and remove excess crediting and loopholes that will reduce the real world benefits of a more health-protective alternative.

Commenter: American Lung Association (Sacramento, CA)

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 254-255.]

Given that the transportation sector is the leading source of greenhouse gas emissions, U.S. EPA must act this year to adopt and finalize standards through 2026 that go beyond previous standards and deliver real-world emission reductions. This is necessary in order to reflect the urgency of our climate crisis and to set a course for the rapid transition away from combustion technologies.

The American Lung Association urges the U.S. EPA to build off of and really to go beyond the foundation set by the 2012 standards to really at a minimum achieve the stringency outlined in Alternative 2.

Alternative 2 could provide the strongest foundation for more stringent rules to follow, would usher in greater reductions in harmful pollutants, yield health and societal benefits that EPA states will far exceed the costs, and really can accelerate the pathway to zero emission technologies that is urgently needed to protect our health and our climate.

We call on U.S. EPA to set the standards at least to the level outlined in Alternative 2 and to ensure that these stringency levels are achieved in the real world.

Commenter: Anderson, Laurie

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 103.]

The EPA must set the strongest possible federal clean car standards through 2026, avoiding loopholes, and putting automakers on track to meet ambitious pollution reduction goals.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 105.]

In order to set us on the path to 100 percent zero emissions new vehicle sales by 2035, the near-term standards for climate pollution must be as strong as possible. Therefore, please finalize the strongest possible national greenhouse gas emissions standards for passenger cars and light trucks for Model Year 2026.

Commenter: Baier, Mary Ann

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 62.]

I support this Administration's swift action on clean cars but urge the EPA to adopt their second alternative that would deliver greater savings to consumers and eliminate unnecessary loopholes for automakers.

Commenter: Bay Area Air Quality Management District

Thus, the Air District urges EPA to move forward with the strongest feasible requirements, presented in EPA's Alternative 2, rather than promulgate the less stringent Proposal. [EPA-HQ-OAR-2021-0208-0283-A1, p.2]

Regarding MY 2026, the Air District is supportive of the addition of a model year beyond the range of the 2012 Obama-era standards, continuing a trend that ramps down past MY 2025 and requires even lower greenhouse gas emissions for 2026. With respect to the request for comment on EPA considering a 5-10 g/mi stronger requirement for MY2026, the Air District reiterates that it supports the strongest standards feasible, in order to achieve maximum air pollution reductions and boost air quality benefits. A 10 g/mi more stringent MY 2026 requirement is feasible and should be adopted. [EPA-HQ-OAR-2021-0208-0283-A1, p.2]

Commenter: Begley, Amanda

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 246.]

I urge you to keep those standards as originally designed to ensure the greatest reduction in oil use and global warming emissions.[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 248-249.]

Not only will setting the strongest standards possible help with climate change, but they will also help clean the air.

Once again, I urge this Administration to set the strongest standards possible because they are working.

Commenter: Beitzel Snow, Stephanie

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 240-241.]

Thank you for the chance to testify before this panel on the Revised 2023 Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards and I plead with you to finalize the strongest possible national vehicle greenhouse gas emission standards for passenger cars and light trucks.

Commenter: Bjork, Deb

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 37-38.]

Moving quickly and decisively to zero pollution vehicles paves the way for people to take action. Please enact the strongest federal clean car standards through 2026 to meet ambitious pollution reduction goals. Please eliminate loopholes for automakers. Strong regulations puts them on track to sell millions of vehicles and sets us on the path to a hundred percent zero emissions new vehicles sales by 2035.

We have the technology. We have the science. We have the large automakers posed to comply, and we have the American public clamoring for change. Vehicle pollution not only causes climate change but it also degrades air quality and threatens our health. Strong regulations can give my grandchildren and all children clean air and a trajectory towards a healthier climate

Commenter: Blue Crab Strategies

This is the moment to go big. Choose Alternative #2, and really make a mark on our country's future. The climate crisis demands it, the health of millions of at-risk Americans demand it, moral imperative demands it. Please be bold in your work; these are times that call for boldness. [EPA-HQ-OAR-2021-0208-0639, p.1]

Commenter: Brandt, Dorothy

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 208-209.]

Please hear my urgent plea to create the strongest possible federal clean air standards to protect us as Americans who are hit hard by climate change and breathing polluted air. As a mom, grandmother, teacher, and principal, I highly recommend that the EPA work to strengthen these standards to ensure that our most precious national treasure, our children, are given the best air we can give them. This is our responsibility. Our country's future depends on it and as a Roman Catholic my sense of morality dictates it. I urge the EPA leadership to fight to protect life and health for each American child.

Commenter: Brandt, Elizabeth

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 197.]

Please finalize the strongest possible national greenhouse gas emission standards for passenger cars and light trucks through Model Year 2026.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 199.]

The EPA must set the strongest possible federal clean car standards through 2026, avoiding loopholes and putting automakers on track to meet ambitious pollution reduction goals.

Commenter: Buzzelli, Melanie

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 124.]

I ask that EPA finalize this rule as quickly as possible so that it can take effect as quickly as possible and in doing so, I ask that EPA maximize the emissions reductions and health benefits of this rule.

EPA must also hold automakers accountable in order to ensure that the standards actually result in real-world reductions in greenhouse gas emissions and then, perhaps more importantly, I ask that EPA set up stronger standards to follow. Stronger standards covering cars, SUVs, and light trucks through at least 2030 and stronger standards for heavy-duty vehicles are necessary to drive the transition to zero emission vehicles that the nation and the world desperately need.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 122.]

thank President Biden and his Administration for recognizing and seeking to address climate pollution from transportation.

I'm happy to see this proposal and the broader efforts on the part of the Administration regarding clean cars, but I'm here to say that it is not enough.

Commenter: California Air Resources Board (CARB)

However, if U.S. EPA believes additional lead time is appropriate in model year 2023, then the best option is to adopt a standard as least as stringent as its preferred alternative for model year 2023 and greater stringency thereafter consistent with Alternative 2, with additional reductions required in model year 2026 to remedy the lost emission reductions if the most stringent alternative is not adopted in model year 2023. CARB offers the following comments in further support of the proposal. [EPA-HQ-OAR-2021-0208-0643-A6, p.6]

The Alternatives and the Proposal Meet Lead Time Requirements.

Manufacturers have developed the requisite technology, have time to deploy it, and can do so at a reasonable cost within the time provided to meet the preferred alternative, Alternative 2, and the requirement for further emission reductions for model year 2026. Considering the urgency of the public health crisis created by these emissions, CARB believes adopting the Alternative 2 standards as quickly as possible (and no later than model year 2024) with the additional model year 2026 stringency best responds to the agency's mandate to reduce emissions in raw terms. As we have noted above, should lead-time considerations lead U.S. EPA to finalize less stringent standards for Model Year 2023, it should recoup emissions consistent with Alternative 2 for later model years, including strengthening Model Year 2026 as U.S. EPA proposes. [EPA-HQ-OAR-2021-0208-0643-A6, p.28]

Alternative 2, a return to the National Program standards with an improvement of those standards for model year 2026 by an additional 10 grams of carbon dioxide per mile, would maximize the reduction in emissions. However, CARB recognizes that U.S. EPA may determine additional lead time is appropriate; if so, the best option is to adopt a standard at least as stringent as its preferred alternative for model year 2023 and greater stringency thereafter, along the lines of Alternative 2 for later model years, with additional reductions required in model year 2026 to recoup further lost emission reductions. [EPA-HQ-OAR-2021-0208-0643-A6, p.1]

Alternative 2, to return to the 2017-2025 Model Year National Program1 standards and improve those standards for model year 2026 by an additional 10 grams of carbon dioxide (CO2) per mile, certainly maximizes emission reductions and should be adopted for all model years for which U.S. EPA determines it is feasible. [EPA-HQ-OAR-2021-0208-0643-A6, p.6]

CARB agrees that manufacturers have developed the technology to meet U.S. EPA's more stringent alternative, identified in the proposal as Alternative 2, to return to the National Program standards. The technology exists to extend and improve those standards for model year 2026 by an additional 10 grams of carbon dioxide per mile. [EPA-HQ-OAR-2021-0208-0643-A6, p.7]

Time is of the essence to stabilize our climate. The worsening climate catastrophes show the urgent need to recover the progress lost under the previous federal administration. CARB urges U.S. EPA to quickly finalize this proposal and adopt the most stringent standards feasible. Alternative 2, a return to the National Program standards with an improvement of those standards for model year 2026 by an additional 10 grams of carbon dioxide per mile, would achieve the greatest emission reductions amongst the proposal. However, should U.S. EPA determine additional lead time is appropriate, the best option is to adopt standards at least as stringent as its preferred alternative for model year 2023 and greater stringency thereafter, along the lines of Alternative 2 for later model years, with additional reductions required in model year 2026 to recoup further lost emission reductions. These would deliver tangible benefits to everyone who breathes and drives that they will be able to feel. [EPA-HQ-OAR-2021-0208-0643-A6, pp.40-41]

Commenter: California Attorney General Office, et al.

In the Proposal, EPA set forth three alternative sets of standards—a preferred alternative, a less stringent alternative (Alternative 1), and a more stringent alternative (Alternative 2). We urge EPA to adopt the most stringent standards for which the statutory requirement to provide adequate lead time is satisfied. [EPA-HQ-OAR-2021-0208-0245-A1, p.2]

As discussed in more detail below, the need for standards far more stringent than SAFE 2 is critically urgent. And the industry's ability to meet such standards and to cost-effectively reduce dangerous pollution is clear [EPA-HQ-OAR-2021-0208-0245-A1, p.2]

EPA SHOULD REPLACE ITS SAFE 2 STANDARDS WITH MORE STRINGENT ONES AS PROPOSED [EPA-HQ-OAR-2021-0208-0245-A1, p.18]

THE PROPOSED STANDARDS ADVANCE THE OBJECTIVES OF SECTION 202(A) OF THE CLEAN AIR ACT

As discussed in more detail below in Section II, we support EPA's adoption of standards for MY2023 that are at least as stringent as the preferred alternative and urge EPA to consider the more stringent Alternative 2 standards for that year, in the context of the full record (including these comments). We also support adoption of the most stringent standards in the proposal for MYs 2024-2026—in other words, the Alternative 2 standards for MYs 2024-2025 and the Alternative 2 standards strengthened by 10 grams/mile for MY2026. EPA must begin now to address the devastating risks of climate change and the on-going harms facing communities over-burdened by harmful pollution, and EPA must do so with the gravity these threats require. [EPA-HQ-OAR-2021-0208-0245-A1, p.18]

Automakers Are Well-Positioned to Sell Fleets that Comply at Least with the Preferred Alternative for MY2023

There are a number of reasons automakers are well-positioned to meet standards at least as stringent as the preferred alternative as early as MY2023. First, as EPA noted in the Proposal, automakers had long planned to meet the MY2023 standards promulgated in 2012. It would be reasonable, then, to reinstate those standards as proposed in Alternative 2. [EPA-HQ-OAR-2021-0208-0245-A1, p.26]

The evidence demonstrates that there is sufficient lead time for automakers to develop compliance strategies for MY2023 standards including both the preferred alternative and Alternative 2. We urge EPA to consider standards as stringent as Alternative 2 for this model year, and to adopt the most stringent standards—but at least the preferred alternative—for which it determines lead time is adequate, based on the full record before it. [EPA-HQ-OAR-2021-0208-0245-A1, pp. 29-30]

There Is Adequate Lead Time for the Alternative 2 Standards for MY2024

There is sufficient lead time for automakers to comply with the Alternative 2 standards for MY2024.144 Assuming EPA finalizes new standards relatively quickly, automakers will have more than a year to make adjustments for MY2024. That is more than sufficient lead time where, as here, compliance is a matter of designing a cost-effective strategy that combines decisions about which vehicles to manufacture and market (including by way of sales incentives) and decisions about credit acquisition, banking, and use. As noted above, automakers are already producing vehicles in all major vehicle categories that can satisfy more stringent standards and have been steadily increasing their use of GHG-reducing technologies across their fleets (in conventional vehicles, hybrids, and BEVs). Again, there is no reason to think these trends will stop; and many reasons—including global trends, technological availability, and consumer and shareholder demands—to believe they will continue. For example, the further expansion of mild hybrids—which have been broadly adopted in Europe and Japan and can achieve emission reductions of 10% or more—can be expected in the United States market beginning in MY2024, especially given their already demonstrated cost-effectiveness and performance advantages.145

The increasing production and sale of BEVs and PHEVs also supports the promulgation of Alternative 2’s MY2024 standards. EPA projects that automakers would comply with these standards if only 7.4% of their MY2024 fleets comprised BEVs and PHEVs.146 The industry is on track to meet, or even exceed, that figure.147 Neither those sales nor the fleetwide sales of internal combustion engine vehicles needed to meet the Alternative 2 MY2024 standards requires the development of new technology, and, as discussed above, automakers have continued to plan to expand applications of these technologies, even after the promulgation of the SAFE 2 standards. Compliance with the Alternative 2 MY2024 standards is, thus, mostly, if not entirely, a matter of automaker strategy—of which vehicles to incentivize and market heavily and of planning whether and how to utilize the flexibility provided by the credit provisions. It requires modest, if any, changes to production plans (e.g., automakers could choose to speed up technology transfers from other markets). None of that requires more than a year’s lead time.148 [EPA-HQ-OAR-2021-0208-0245-A1, p.30]

For MYs 2024 and later, there is adequate lead time for the Alternative 2 standards and for the proposed additional 10 grams/mile of stringency in MY2026. EPA should thus finalize those standards— the most stringent it proposed—for MYs 2024-2026. [EPA-HQ-OAR-2021-0208-0245-A1, p.2]

THE PROPOSED STANDARDS ADVANCE THE OBJECTIVES OF SECTION 202(A) OF THE CLEAN AIR ACT

As discussed in more detail below in Section II, we support EPA’s adoption of standards for MY2023 that are at least as stringent as the preferred alternative and urge EPA to consider the more stringent Alternative 2 standards for that year, in the context of the full record (including these comments). We also support adoption of the most stringent standards in the proposal for MYs 2024-2026—in other words, the Alternative 2 standards for MYs 2024-2025 and the Alternative 2 standards strengthened by 10 grams/mile for MY2026. EPA must begin now to address the devastating risks of climate change and the on-going harms facing communities over-burdened by harmful pollution, and EPA must do so with the gravity these threats require. [EPA-HQ-OAR-2021-0208-0245-A1, p.18]

There Is Also Adequate Lead Time for the Alternative 2 Standards for MY2025 and MY2026, As Well As for Additional Stringency in MY2026

We urge EPA to adopt the Alternative 2 standards for MY2025 and to adopt the Alternative 2 standards plus the proposed additional 10 grams/mile of stringency for MY2026. There is no question that lead time is sufficient for these standards. There is ample time for automakers to apply available and proven GHG-reducing technologies in a broader array of vehicles, including, for example, substantially expanding the availability of mild hybrids which reduce emissions and provide other features consumers demand.149 Of course, automakers would also have ample time to plan to manufacture and sell already-existing or already-planned vehicles that could support compliance of their fleets. Notably, by MY2025, the lead time automakers will have had to adjust to more stringent standards will equal, or exceed, the period during which the SAFE 2 standards were in effect. As shown above, reliance on SAFE 2 would never have been reasonable, but, in any event, by MY2025 any reliance on SAFE 2 should be irrelevant.

Moreover, EPA projects that the Alternative 2 standards would require 7.5 and 9.6% penetration of BEVs and PHEVs in MY2025 and MY2026, respectively. The market share for these vehicles is on track to exceed those figures, with market share of BEVs alone reaching 10% in MY2025 and growing from there.150 Compliance will, thus, be easier than EPA anticipates. As EPA noted in the Proposal, multiple major automakers have projected that their fleets will be between 40 and 100% BEV by 2030.151 Those automakers, at least, can be expected to have reached levels well above 10% by MY2025 and MY2026, meaning the industry as a whole should have sufficient credits for compliance even if one or more automakers' EV sales fall below the projected average. [EPA-HQ-OAR-2021-0208-0245-A1, p.31]

Moreover, Alternative 2, which would require larger emissions reductions, would produce even greater net benefits. See id. at 43,742 (Table 12). The range of standards from the preferred alternative to the more stringent Alternative 2 (and the 10 grams/mile of additional stringency for MY2026) would not only faithfully execute EPA's statutory mandate to reduce emissions and protect public health, but their benefits would also significantly outweigh their costs. [EPA-HQ-OAR-2021-0208-0245-A1, p.33]

Commenter: Campbell, Nancy

PLEASE! Let's quit dithering around. Let's get unstuck. Let's MOVE FORWARD and return to clean car standards. Let's ditch the 'dirty car standards' that are decades old and shamefully behind the rest of the world. LET'S BE A LEADER IN FUEL STANDARDS!

I can't believe that the EPA has proposed car fuel standards that – while better than the dirty fuel standards of the previous president – are weaker than the ones in 2012! So we're worse off than we were a full decade ago!

TECHNOLOGY KEEPS MOVING AT LIGHTENING SPEED BUT AMERICA'S FUEL STANDARDS STAGNATE, creating huge waste, massive pollution, and unbelievable cost.

The EPA proposal is also FULL of loopholes.

And giveaways to car makers.

All of which are just a way of trying to make things look good while maintaining the status quo. God forbid we should actually move forward, right??

The current proposal falls short of what we desperately need.

It doesn't meet the Intergovernmental Panel on Climate Change targets.

It doesn't mett American commitments under the Paris Agreement.

It doesn't require car makers to meet President Biden's goals.

It doesn't come anywhere close to what our scientists say is necessary.

PLEASE go with Alternative #2 instead – with one significant change: require car makers to start selling ZEV's by 2026 and all ZEV's by 2030. We can't afford to fool around any longer. We can't afford to stand still or slide backwards.

PLEASE TAKE THESE STEPS:

1. In this rulemaking, adopt Alternative #2 through model year 2025.

2. Supplement this proposal with another, to be finalized before the end of 2022, that sets a ZEV mandate for model year 2026 consistent with a pathway toward requiring 100 percent of new vehicles to be ZEVs by 2030.

3. Start another rulemaking for model years 2027 to 2030 that achieves 100 percent ZEVs by 2030.

The world's scientists have made it clear: we have a rapidly-closing window to prevent the most dire consequences of climate change.

Nothing short of the strongest possible clean car standards will deliver the carbon reductions that President Biden has promised the country and the world -- and, more importantly, that we deserve. [EPA-HQ-OAR-2021-0208-0418, p. 1]

Commenter: Cantley, Jennifer

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 274-275.]

This is why the EPA must make stronger possible federal air standards for 2026, avoiding the loopholes and putting automakers on track to meet ambitious pollution-reducing vehicles.

The Federal Government must hold these companies to the highest standards, especially for foreign companies coming to rural communities. Low-income families, especially Native communities, 13 percent of Indigenous children, have asthma attacks compared to 8.6 percent of the children of non-Indigenous descent.

A lithium site currently in Nevada could produce 5,800 tons of sulfuric acid a day towards the Piute Shoshone Territory in Nevada. This is why we need to make the strongest possible national greenhouse emission standards for passenger cars and light trucks through Model Years of 2026.

Commenter: Caudill, Gregory

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 311.]

Strong standards have been established before and I have seen them gutted every time.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 312-313.]

The EPA should tighten light-duty emissions and this Administration must once again make those rule changes by law.

Strong clean air standards will drive down pollution, provide communities savings, and spur innovation such as membrane nano-fiber hydrogen fuel cells, lithium alkaline long-term storage batteries, and wind and solar-powered rapid-charging stations.

So I say let's save money and move ever forward toward the Alternative 2 clean standards.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p.310.]

I fully support this Administration's swift action on clean cars and I strongly urge the EPA to adopt the second alternative for more stringent regulations.

Commenter: Center for Biological Diversity

According to the Rule's Draft Regulatory Impact Analysis, while the proposal projects a reduction in greenhouse gas emissions compared to Trump's SAFE Rule rollback, it would still allow millions of metric tons of greenhouse gases and other criteria pollutants to be emitted. This is especially stark when the proposal is compared to EPA's suggested Alternative 2, which would save 293 million metric tons CO_2 and 426,545 metric tons of methane compared with the proposal through 2050.27 Similarly, compared to the proposal, Alternative 2 would reduce emissions of NO_x by approximately 30,000 tons and SO_2 by over 100,000 tons through 2050.28 In other words, by making the decision to adopt the proposal instead of Alternative 2, EPA is, in its discretion, authorizing an addition 293 million metric tons of CO_2 and 426,545 metric tons of methane, in addition to other greenhouse gases and increased criteria pollution. Of course, EPA could have analyzed other alternatives stronger than Alternative 2, which would have made these emissions savings even higher.

These numbers are not insignificant, and they can be directly tied to harm to species or critical habitat, such as to precise losses of sea ice and sea ice days in the Arctic. For instance, the greenhouse gas emissions can be tied to precise losses of sea ice and sea ice days in the Arctic;29 the excess 293 million metric tons of CO_2 alone—not including the other greenhouse gases—that will be emitted if EPA decides to adopt the proposal instead of Alternative 2 will lead to a sustained loss of sea ice of 879 square kilometers,30 larger than the area of New York City. This loss will have devastating consequences for polar bears, as described below. [EPA-HQ-OAR-2021-0208-0726-A1, p. 5]

Commenter: Center for Biological Diversity, Earthjustice, and Sierra Club

EPA must adopt the most stringent standards feasible to reduce light duty vehicle emissions Instead of the current proposal, EPA should have chosen Alternative 2 as its preferred alternative. Alternative 2 mirrors the agency's 2012 standards in stringency for Model Years 2023 through 2025 and extends the same annual trajectory to MY 2026. Alternative 2 produces more benefits than the proposal under every category analyzed and offers adequate lead time for automakers to comply. [EPA-HQ-OAR-2021-0208-0270-A1, pp.1-2]

EPA's stated arguments for the feasibility of the Proposal provide virtually equal support for Alternative 2's feasibility. The agency acknowledges that most automakers likely have not significantly changed their product plans in reliance on SAFE II. As EPA states, '[T]he industry's product plans developed in response to EPA's 2012 GHG standards rulemaking for MYs 2017-2025 [have] largely continued' despite the less stringent 2020 SAFE rule because automakers 'generally require about five years to design, develop, and produce a new vehicle model.' As a result, 'in most cases the vehicles that automakers will be selling during the first years of the proposed MY 2023-26 program were already designed under the original, more stringent GHG standards finalized in 2012.' Moreover, 'the ability of the industry to commit to revised plans based on the SAFE rule's relaxed standards, especially for MYs 2023 and later, has been highly uncertain in light of pending litigation.' Several automakers have admitted as much.4

Therefore, any reliance on the SAFE rule would have been relatively recent, and as EPA notes, 'the automakers' earlier plans could be reinstated or adapted with little change.' Moreover, 'some automakers may have adopted product plans to overcomply with the prior, more stringent standards, with the intention of selling credits to other automakers,' which would help to insulate them from the tighter standards currently proposed. [EPA-HQ-OAR-2021-0208-0270-A1, p.2]

EPA also underestimates the rate of electric vehicle ('EV') market penetration in MY 2023-2026, which inaccurately makes Alternative 2 appear less feasible. A 'wide range of stakeholders, including but not limited to the automotive manufacturers and the automotive suppliers,' informed EPA 'that significant investments [are] being made now to develop and launch new EV [models] and in the expansion of EV charging infrastructure could enable higher levels of EV penetration . . . than EPA has projected . . . for both the proposed MY 2026 standards and the Alternative 2 MY standards.' Automakers are also increasing their EV commitments: GM, Volvo, Volkswagen, Honda, and Fiat have all promised that EVs will make up half or more of their US sales by 2035 or sooner.8 Consumer demand is also strong: during the first half of 2021, US EV sales have surged despite the impacts of the pandemic. 9 These facts support the likelihood that EV penetration will be higher than EPA has assumed in all of the Model Years this rulemaking covers.

Furthermore, automakers' EV production targets for the European Union suggest most automakers have the capacity to vastly scale up EV technology. For example, Ford, which did not sell any EVs in Europe in 2020, states that it will sell 100% EVs by 2030,10 as will Volvo and Jaguar. Volkswagen will sell 70% EVs by 2030.11 While there are differences between the European Union and the American context, this trend demonstrates that manufacturers have the capacity to produce additional EVs if lax regulations do not make internal combustion engine vehicles ('ICEVs') seem more profitable than they actually are.12

In sum, these trends and observations all underscore the feasibility of Alternative 2 and erode the agency's justification for preferring the less stringent proposal. [EPA-HQ-OAR-2021-0208-0270-A1, pp.2-3]

Alternative 2's Benefits Dwarf those of the Proposal

As EPA explains in detail, Alternative 2 produces superior benefits across every metric. Alternative 2 would result in at least $40 billion more in net benefits by 2050 than the Proposal.13 While the proposal will save $91 billion in climate benefits, Alternative 2 will save $100 billion, including an additional 110 MMT of saved upstream CO_2, as well as 183 MMT of tailpipe CO_2.14 Alternative 2 would also eliminate roughly 2,340 MT of $PM_{2.5}$, 29,896 MT of NO_x, 104,468 MT of SO_2 and 36,147 MT of VOCs over the Proposal, saving more than $7.2 billion in human and environmental health.15 EPA's analysis does not even capture the full benefit because the agency did not model $PM_{2.5}$ environmental impacts; health and environmental impacts from ozone, NO_2, and SO_2; visibility improvements; ecosystem benefits; and air toxics impacts.16 These impacts are severe, serious, and extensive, including lung and other cancers, cardiovascular and respiratory effects, respiratory and other forms of premature mortality, tree mortality, acid deposition, and coastal eutrophication.17 EPA should recognize that these uncounted benefits further tip the balance in favor of Alternative 2.

Under Alternative 2, consumers would directly save $360 billion on fuel (accounting for reductions in gasoline consumption and increased electricity use), $50 billion more than under the Proposal. 18 This would reduce domestic fuel consumption by 486 million barrels of gasoline and as well as domestic electricity use by 151,305 gigawatt hours by 2050.19 The resultant non-emissions benefits would be $18 billion over the Proposal from a rebound effect (the increase in driving resulting from reduced operating costs), reduced fueling time, energy security, and reduced dependence on foreign petroleum.20

Despite the benefit imbalance in favor of Alternative 2, EPA has not performed a direct cost and benefit comparison of the Proposal and Alternative 2, noting only that 'the total benefits [of both the Proposal and Alternative 2] far exceed the total costs' of both programs.21 EPA should provide that comparison and follow it to its logical conclusion: 'that it is appropriate, particularly in light of the accelerating transition to electrified vehicles, to require additional reductions in'

MY 2023-2026.22 Alternative 2 Plus would further increase those benefits. [EPA-HQ-OAR-2021-0208-0270-A1, pp.3-4]

In future years, EPA should return to its historical practice of considering more alternatives that span a broader range of emission reductions

EPA acknowledges that the current alternatives, which differ by only 8 grams per mile and would prescribe equivalent annual stringency increases of roughly 4.5%,52 represent a 'fairly narrow' range of potential regulations.53 This narrow range limits the ability of both EPA and the public to analyze the proposal's benefits through comparison to more stringent alternatives. In the past, EPA has considered not only a greater number of alternatives but a broader range of stringencies between the least and most restrictive alternatives. In future rulemakings, the agency should revert to this prior practice.

EPA's analysis of alternative options should achieve the same goals as the environmental review process under the National Environmental Policy Act. It is well-understood that Clean Air Act rulemakings are exempt from the National Environmental Policy Act's ('NEPA') formal environmental impact statement ('EIS') requirement precisely because EPA's analysis should be the functional equivalent of the EIS process. As the D.C. Circuit explained, there is 'little need in requiring a NEPA statement from an agency whose raison d'etre is the protection of the environment and whose decision . . . is necessarily infused with the environmental considerations so pertinent to Congress in designing [NEPA].'54 Other courts and legislators have confirmed that EPA was granted this exemption because NEPA requirements were viewed as 'redundant' of the CAA requirements.55

According to NEPA regulations, an agency must 'present the environmental impacts of the proposed action and the alternatives in comparative form' 'so that reviewers may evaluate their comparative merits.'56 The agency need not consider an infinite array of potential alternatives, merely those that are feasible or reasonable.57 In this context, the process is meant to ensure that the agency and the public can compare not only the costs and feasibility of different levels of stringency, but also whether the proposed standards are as environmentally protective as they could be. A thorough evaluation of more alternatives would more meaningfully achieve this purpose. For example, a broader scope might shed light on whether the proposal will put light duty vehicle emissions on track to meet President Biden's goal of reducing national emissions 50% by 2030, a goal which requires immediate reductions. 58

Of the several reasons EPA cites for limiting its discussion to two alternatives, the agency mentions lead time most prominently.60 Yet even here, the agency might have analyzed alternatives that would mitigate lead time concerns by ramping up stringency incrementally in the later MYs. For instance, while Alternative 2 increases in stringency by roughly 4.5% from MY 2023-2026, EPA could have considered an alternative that started with only a 4.5% increase in 2024, 5.5% in MY2025, and 6.5% in MY2026. Such an approach might have discussed other ways to address any lead time concerns in the earliest years while maximizing emissions reductions in later years when lead time is not a factor. [EPA-HQ-OAR-2021-0208-0270-A1, pp.9-10]

EPA should further strengthen its Alternative 2 plan by adding an additional 10 grams per mile of stringency in Model Year 2026 ('Alternative 2 Plus'), and by making the other improvements described below. This letter details why Alternative 2 Plus is a more effective response to climate change than the current proposal, and several ways in which the alternative should be strengthened prior to adoption. [EPA-HQ-OAR-2021-0208-0270-A1, p.1]

Alternative 2 Plus

In addition to adopting Alternative 2 for MY 2023 to 2025, EPA should add an additional 10 grams per mile of stringency to MY 2026. The additional stringency is feasible in MY 2026 because it does not raise the same lead time concerns that exist for earlier years, and it produces even more benefits than Alternative 2 across a range of metrics.

An independent analysis by Dan Meszler found that Alternative 2 Plus would confer an additional $20 billion of total net benefits by 2050 (with a 3% discount rate).23 In many areas, the difference in benefits between Alternative 2 Plus and Alternative 2 is greater than between Alternative 2 and the Proposal. For example, Alternative 2 Plus would produce $27 billion in additional climate benefits over Alternative 2, as compared to the $9 billion difference between Alternative 2 and the Proposal. Similarly, Alternative 2 Plus would save consumers an additional $82 billion over Alternative 2, whereas the difference between Alternative 2 and the Proposal was only $50 billion.

Because Alternative 2 Plus affects MY 2026, potential lead time issues do not present a real challenge to automakers. This standard would begin at least three years, and as many as four years, after the finalization of this rule. The longer time frame will give automakers more time to comply with what is otherwise a more significant annual increase in stringency. The potential lead time concern would be further lessened if the agency is underestimating future EV market penetration, as EPA admits is a possibility. 24 The additional 10 grams per mile stringency would help automakers reach President Biden’s goal of 50% of new vehicle sales being electric by 2030,25 and it would put the US light duty vehicle fleet on track to meet 100% EV sales by 2035, a crucial target to achieve compliance with the Paris Agreement. By contrast, weaker standards would necessitate steeper annual improvements in later years to meet the same targets.

Though Alternative 2 Plus outperforms Alternative 2 in many ways, it too should be further improved. EPA needs to begin to lay the groundwork to an all-electric future in order to further spur development of EV technology. To meet the demands of the climate emergency, the country needs 100% of vehicles sales to be electric by at least 2035, and even better, by 2030. EPA should begin to set the stage for this future now by analyzing paths of annual stringency increase that reach zero emissions by both 2030 and 2035.

In 2019, transportation emissions accounted for 37.5% of U.S. CO2 emissions, the largest share of any sector, of which 57.7% came from passenger cars and light duty trucks.26 These vehicles cannot simply be swapped for EVs in 2050, and new vehicle technologies are often slowly adopted. A 2019 study found that if new vehicle technology, such as electric vehicles, is immediately adopted and incorporated into 100% of all new vehicle sales, it will still only be present in 90% of the on-road vehicle fleet in 20 years.27 Another recent study further concluded that immediately phasing out all fossil fuel technology at the end of its design lifetime would preserve only a 64% chance of limiting global temperature rise below 1.5â„ƒ.28 Thus, even a future with 100% ZEV sales in 2030 might still not be enough to meet the Paris Agreement's 1.5â„ƒ goal due to long lived ICEVs that would continue to emit carbon pollution for decades.

We have laid out the case for a 100% ZEV future in a past comment letter.29 We urge EPA to begin modeling the pathways to this future now. [EPA-HQ-OAR-2021-0208-0270-A1, pp.4-5]

23 The alternative '10 g/mile in MY2026 beyond Alternative 2' run was modeled by revising the Scenarios input files for EPA runs 7 and 8 (the Agency's Alternative 2 runs). In the Scenarios input file, only the CAFE standard coefficients A, B, C, and D were changed for model years 2026 through 2032 (effectively replacing the Alternative 2 coefficients for those same model years). The revised inputs were developed to produce a precise 10g reduction in the effective car and truck standards (and thus the same reduction in the overall fleet) and were set as follows for cars: A=68.74545094, B=51.40090295, C=0.000327233, and D=0.001129867; and for trucks: A=55.1193845, B=33.07946016, C=0.000366297, and D=0.00312426. All other CAFE model inputs were left unchanged, and all model runs and post-processing steps were performed identically to those of EPA's Alternative 2 evaluation.

Commenter: Center for Biological Diversity, et al.

There is Sufficient Lead-time for Automakers to Comply with Either EPA's Proposed Standard or with Alternative 2.

EPA's vehicular emission standards "shall take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period." 42 U.S.C. § 7521(a)(2). The phrase cost of compliance "encompasses only the cost to the motor vehicle industry to come into compliance with the new emission standards." Coal. for Responsible Regulation v. EPA, 684 F.3d 102, 128 (D.C. Cir. 2012), rev'd in part on other grounds sub nom. Util. Air Regulatory Grp. v. EPA, 573 U.S. 302 (2014). Given the state of technology development and application and available compliance pathways, the agency would be compelled in this instance to find that automakers need no "period" of lead time to comply with Alternative 2. For the same reasons, it is also the case that no period is needed prior to implementation of EPA's proposed standards.

First, the emission-reduction technologies needed to comply with Alternative 2 for MY2023-2026 already have been developed and applied in each category of vehicles to which those standards would apply. The requisite technologies were "developed in response to EPA's 2012 GHG standards rulemaking for MYs 2017-2025." Proposal, 86 Fed. Reg. at 43,782. Indeed, even when EPA decided in the 2020 Final Rule to weaken the standards set in 2012, the agency acknowledged that "the technologies projected to be used to meet" the 2012 Final Rule were by then already "available and in production." 85 Fed. Reg. at 25,108. [EPA-HQ-OAR-2021-0208-0651-A1, p. 24]

Second, automakers already hold a vast reserve of tradeable compliance "credits" available to facilitate compliance with standards for MY2023-2026.68 Trading of credits, especially credits on the verge of expiring (and becoming worthless), is a well-established practice.69 In fact, automakers already have traded large quantities of credits that, under more stringent standards, could be utilized toward compliance in MY2023 and MY2024. And automakers' reliance on their own banked credits to facilitate compliance is a longstanding and widespread practice.70 Automakers' practice of complying with EPA's GHG standards by using earned or acquired compliance credits is thus an essential part of the agency's Section 202(a)(2) analysis.

Automakers' credit reserve is now so massive that if EPA were to adopt Alternative 2, all automakers could comply with MY2023 without changing their vehicle fleets at all in response to the finalization of Alternative 2. In fact, the credit reserve is large enough that this is true for both Alternative 2 and the proposal even without the proposed extension of credit lifetimes. The analysis conducted by Dr. David Cooke of the Union of Concerned Scientists demonstrates this by preventing the Volpe model from deploying new technology for MY2023 beyond levels consistent with the 2020 Final Rule and, in the case of automakers that joined the agreement with the California Air Resources Board, the trajectory contained in that agreement. See Comments of Dr. David Cooke, to be filed in docket EPA-HQ-OAR-2021-0208 on Sept. 27, 2021. In those model runs, Dr. Cooke found that all automakers not in the voluntary agreement could comply with EPA's new standards through MY2023 by doing no more than the following: trading credits among themselves and reducing tailpipe GHG emissions consistent with the trend line the 2020 Final Rule imposes for MY2021-2023. Dr. Cooke's analysis assumed that automakers not party to the voluntary agreement with California would utilize the optimal mix of new technologies and banked credits in order to comply with the 2020 Final Rule standards in 2021, 2022 and 2023 and further assumed, when modeling compliance in those years, that the 2020 Final Rule standards remained in effect through MY2026. Automakers that are party to the voluntary agreement complied with that agreement in Dr. Cooke's modeling.

Importantly, use of credit banks to comply with Alternative 2 for MY2023 would still leave additional banked credits available for automakers who decide to use them in later years. Indeed, in MY 2024, Dr. Cooke's analysis suggests that automakers would use a mix of banked credits remaining following MY 2023 and increased deployment of technology on the portion of each manufacturer's fleet that the Volpe model determined would get a major or minor redesign as part of the automakers' normal product development cycle. There is a sufficient period prior to MY 2024 that automakers can reasonably add additional technologies for that model year. But the banked credits that remain available means that automakers are not required to install sufficient technologies in MY2024 to achieve the standards for that year but can comply by using a mix of additional banked credits and technology. The same is true for model years 2025 and 2026.

Importantly, Dr. Cooke's analysis does not account for the fact that prior to 2020 automakers were planning to comply with the stronger standards adopted in 2012 and very likely retained most or some of their plans to improve their fleets in line with those standards even following adoption of the 2020 Final Rule. Nor does Dr. Cooke's analysis reflect automakers' current trends toward electrification that will only facilitate compliance with strong GHG standards. In fact, auto sector analysts at Bank of America published a report in June 2021, prior to EPA's proposal, indicating that automakers are expected to introduce 50% more new models starting in MY 2022 and continuing through MY2025 compared to the historic average number of new models, and that sixty percent of the new models are expected to be electric vehicles, hybrid vehicles or fuel cell vehicles.71 This increase in the number of new models and the percentage of advanced powertrains likely reflects automakers' plans to comply with the 2012 Rule standards in place prior to the 2020 Rule, and in any event shows automakers' existing plans to improve the performance of their fleets, especially in 2022 and beyond. This analysis indicates that the industry is on a better trajectory than that assumed in Dr. Cooke's modeling analysis.

Dr. Cooke's analysis also does not include several immediately available means by which automakers can improve the greenhouse gas performance of their fleet. These include adding features that do not require much if any lead time such as applying already approved off-cycle technologies to more of their vehicles and prioritizing sales of the least emitting vehicles within an automaker's fleet.

In light of the credit banks and other compliance options available, finalizing EPA's Proposed MY2023-2026 Standards even on the (theoretical) eve of MY2023 would comport with CAA Section 202(a)(2).72 In this case, there are multiple compliance options available to automakers, including not changing their plans at all through 2023 and utilizing available credits. No waiting "period" can be "necessary" if the pace of "application of the requisite technology" to comply, 42 U.S.C. § 7521(a)(2), will not require any additional technology beyond those that would be deployed under the pre-existing standards. That is especially so where the 1.5 percent annual improvement required by the existing 2020 Rule standards falls well short of the 5 percent annual improvement that automakers long expected the law would require of them in MY2023-2025.

Section 202(a)(2) notably differs from other provisions—including other provisions of the same statutory subsection—in that it does not prescribe a minimum period before new or revised standards can take effect. Cf. 42 U.S.C. § 7521(a)(3)(C) (four model years); 49 U.S.C. § 32902(a) & (g)(2) (18 months). And there is substantial precedent for EPA finding that no lead time, or very little lead time, is needed before new or stronger standards may take effect under Section 202(a)(2). E.g., 48 Fed. Reg. 1,148 (Jan. 12, 1983) (imposing new standards for model year 10 days after model year might have begun); 45 Fed. Reg. 66,984 (Oct. 8, 1980) (providing 2 months' lead time before model year could commence); 42 Fed. Reg. 45,132 (Sep. 8, 1977) (3 months); 38 Fed. Reg. 21,362 (Aug. 7, 1973) (4 months); 38 Fed. Reg. 21,348 (Aug. 7, 1973) (same); 35 Fed. Reg. 17,288 (Nov. 10, 1970) (1 month). In those instances, as here, EPA's prompt imposition of new or stronger standards was warranted by the absence, or relative modesty, of shifts in product development required of automakers in the near term. Cf. 69 Fed. Reg. 38,958, 38,996 (June 29, 2004) (explaining that credit averaging, banking, and trading "allows the manufacturer to adjust [its] compliance schedule … without special delays or exceptions having to be written into the rule" under CAA Section 213; such a rule "shall take effect at the earliest possible date considering the lead time necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period and energy and safety," 42 U.S.C. § 7547(b)).

As for the later model years of EPA's proposed standards (MY2025 and MY2026), given that the requisite emission-reduction technology is and has long been available and applied in a wide variety of vehicles, there is ample lead time for automakers to apply as much of that technology as is required to meet the standards for those model years, even taking into account the standard product-development cycles for light-duty vehicles. Cf. 49 U.S.C. § 32902(a) & (g)(2) (requiring 18 months' lead time for fuel-economy standards for light-duty vehicles). In any event, recent announcements by automakers comprising a supermajority of the market presage far broader and deeper deployment of zero-emission and hybrid vehicles by MY2025.73

Finally, it should be emphasized that the foregoing analysis does not account for the demonstrated compliance strategy of automakers "borrowing" against credits they expect to earn through overcompliance in future model years. Specifically, EPA's program allows automakers to run deficits that they can satisfy by carrying back overcompliance credits from the subsequent three model years. See, e.g., Proposal, 86 Fed. Reg. at 43,753. The credit borrowing provisions mean that any automaker that does not wish to comply in MY2023 by obtaining or using credits from existing credit banks or by raising its fleet average by applying technologies or promoting its lowest emitting vehicles, can also comply by borrowing credits from future model years. That strategy further lengthens the effective period before automakers need to come into compliance with the proposed standards and further underscores that Section 202(a)(2) does not require any delay in the effective date of EPA's rulemaking revising MY2023-2026 standards. [EPA-HQ-OAR-2021-0208-0651-A1, p. 24-27]

EPA should adopt mechanisms to maximize GHG reductions across the fleet to guard against the effects of underestimating EV penetrations.

Like in the case of an unanticipated vehicle mix shift described in the previous section, an unanticipated growth in EV adoption could lead to fewer GHG reductions than projected by the agency.

If EPA has significantly underestimated EV deployment when designing standards, then compliance with the standards could be achieved without improvements to internal combustion engine vehicles (ICEVs) and even backsliding in ICEV emissions performance. This could be the case in the MY 2023-2026 proposal and alternatives, as noted in Comments of the World Resources Institute. 187

For example, the proposal's MY 2027 standard of 171 g/mile is projected to be met with EV sales of 7.8%. This implies that ICEVs need to achieve 185 g/mile, assuming all EVs have a compliance value of 0 g/mile. If EV sales are instead 19.0% in MY 2026—as projected in a recent analysis by the Rhodium Group based on current policy188—then ICE vehicles could emit as much as 211 g/mile. This shift would also increase fuel costs for ICEV owners. Under the higher EV scenario, an owner of a MY 2026 ICEV rated at 211 g/mile can be expected to spend an additional $1,731 at the gas pump compared to owning an ICEV rated at 185 g/mile over 200,000 miles of driving with gasoline priced at $3.00 per gallon. [EPA-HQ-OAR-2021-0208-0651-A1, p. 77]

Commenters welcome and strongly support EPA's reconsideration of its 2020 rule concerning greenhouse gas emission standards for model years (MY) 2021-2026 passenger cars and light trucks (the 2020 Final Rule). We urge the agency to reverse that indefensible rule and instead finalize the most stringent standard it has considered in the Proposal. [EPA-HQ-OAR-2021-0208-0651-A1, p. 6]

I support the Administration's action on cleaner cars and urge the EPA to adopt the second alternative that would deliver savings to consumers, eliminate loopholes, and, most importantly, reduce pollution and greenhouse gases.

Each of the alternatives EPA presents in the Proposal is entirely feasible, and we urge EPA to finalize the most stringent one: Alternative 2, with the addition of 10 grams per mile in MY 2026. Automakers are well-positioned for compliance through MY 2026. Nearly a decade ago, EPA had already found, correctly, that the requisite technology was available and cost effective; it validated that finding in 2016, noting that the task had become easier as costs had declined. Today these technologies are in wide use in many types of vehicles. Also nearly a decade ago, automakers themselves agreed to reach the 2012 Final Rule’s annual stringency increases by 2025. They have been planning to do so ever since and have stated that they did not rely on the 2020 Final Rule to delay those plans and actions. Beyond that, since the 2020 Rule became final, many automakers have fully committed themselves to tens of billions in additional investments and aim to build only zero or near-zero emissions vehicles by 2035, plans that must necessarily include significant stringency increases now and that will very likely result in many more EVs than EPA projects. On top of that, automakers already have a glut of credits available to help smooth out any remaining lead time concerns, and can earn more by outperforming the minimal standards of the 2020 Final Rule through MY 2022.

There is no doubt that the most stringent proposed alternative is urgently needed in light of the climate crisis, that it is eminently feasible, and that its many benefits will exceed its costs both at the societal level and for consumers, who will save money at the pump. This alternative also produces benefits that far outstrip those of the others. EPA should finalize it as quickly as possible. [EPA-HQ-OAR-2021-0208-0651-A1, p. 6-7]

EPA must adopt stronger standards than its preferred alternative.

Given the urgency of the climate crisis detailed in Section 1 above, EPA should adopt its more stringent alternative, Alternative 2, which mirrors the 2012 standards in stringency for Model Years 2023 through 2025 and extends the same annual trajectory to MY 2026. Proposal, 86 Fed. Reg. at 43,738. In addition, EPA should add the additional 10 grams per mile of stringency to MY 2026 (hereinafter “Alternative 2 plus”). Even if EPA were to adopt its proposed alternative in lieu of Alternative 2, EPA should add the additional 10 grams per mile of stringency to MY 2026.

EPA concludes that Alternative 2 “may be feasible” and that “[s]everal arguments can be made in support of Alternative 2 that are similar to those that support the proposed standards.” Id. at 43,777. Indeed, most, if not all, of the agency’s justifications for its main proposal are equally, if not more, applicable to Alternative 2. EPA cites only “lead time” as a potential reason not to use Alternative 2 as its preferred alternative. Id. This concern is unfounded, for the reasons discussed below. See infra Section 5. Automakers have had nearly a decade of notice that they would have to comply with Alternative 2’s standards for MY 2023 - 2025. Lead time concerns should not deter EPA from quickly reverting to the 2012 standards in the current rule. [EPA-HQ-OAR-2021-0208-0651-A1, p. 19-20]

Costs and Benefits of Alternative 2 and the Proposal

EPA acknowledges that Alternative 2 surpasses the Proposal across virtually every metric, and that it will result in at least $40 billion additional net benefits. DRIA at xvii, Tbl. 4; xxv, Tbl. 12. As compared to the Proposal, by 2050 Alternative 2 will save 110 MMT of upstream CO2, as well as 183 MMT of tailpipe CO2, for a total of 293 MMT of CO2 savings. DRIA at 5-1, Tbl. 5-1; 5-3, Tbl. 5-3.62 In addition to these significant CO2 reductions, Alternative 2 is superior on overall climate benefits, calculations which take into account the social cost of CO2, CH4, and N2O. The Proposal would produce climate benefits of $91 billion by 2050, while Alternative 2 would generate $100 billion—a difference of $9 billion. DRIA at 3-39, Tbl. 3-14; 3-41, Tbl. 3-16.

Aside from greenhouse gases, EPA also notes the health and environmental benefits of Alternative 2 that result from reduced emissions of and exposure to criteria pollutants and airborne toxics. By 2050, Alternative 2 would save at least $7.2 billion across these categories, including fewer hospital admissions, fewer respiratory conditions, and fewer lost work days. DRIA at 7-26, Tbl. 7-5; 7-28, Tbl. 7-7. Notably, these benefits “do not include the full complement of health and environmental effects that, if quantified and monetized, would increase the total monetized benefits.” DRIA at xvii, Tbl. 4, note (e). EPA omitted PM2.5 environmental impacts, as well as health and environmental impacts from ozone, nitrogen dioxide (NO2), sulfur dioxide, visibility improvements, ecosystem benefits, and air toxics impacts. DRIA 7-4. These omitted impacts include, but are not limited to, PM2.5 induced cancer and emergency department visits for cardiovascular issues, ozone induced premature respiratory mortality, NO2 induced premature mortality, increased vegetation mortality, acid deposition, and coastal eutrophication. DRIA, Tables 7-1, 7-2 & 7-3. We encourage EPA to model these impacts further in future rulemakings, but in any event, the benefits of

Alternative 2 clearly exceed those EPA now assumes by a considerable margin. Alternative 2 also outshines the Proposal with regards to consumer benefits. Because both the Proposal and Alternative 2 will be more stringent than the 2020 Final Rule standards, EPA predicts that consumers will spend less on gasoline (and more on electricity) in the coming years. By 2050 consumer fuel savings would be $310 billion under the Proposal, compared with $360 billion under Alternative 2, a $50 billion difference. DRIA at 6-5, Tbl. 6-4; xxv, Tbl. 12. Alternative 2 would also result in consumption of 486 million fewer barrels of gasoline by 2050. DRIA at 5-7, Tbl. 5-7; 5-9, Tbl. 5-9. [EPA-HQ-OAR-2021-0208-0651-A1, p. 20]

EPA has also quantified the non-emission benefits from the rebound effect (the increase in driving resulting from reduced operating costs), changes in refueling time, and energy security benefits from reduced dependence on foreign petroleum. EPA projected non-emission benefits for the Proposal to be $35 billion through 2050, while Alternative 2 would generate $53 billion—a difference of $18 billion. DRIA, Tables 6-8, 6-10.

EPA's cost analysis of Alternative 2 is mixed. On one hand, compliance with the stronger rule would cost automakers less per vehicle. In 2026, the fleet average cost per vehicle is $1,044 under the Proposal and $1,030 for Alternative 2. DRIA, Tables 4-16, 4-20. On the other hand, EPA calculates the overall costs of Alternative 2 —from foregone consumer surplus, adoption of emissions technology, and increased congestion, noise, fatalities, and non-fatal crashes—as higher than the Proposal ($290 billion compared to the Proposal's $240 billion). DRIA at 6-2, Tbl. 6-1; 6-4, Tbl. 6-3. However, these additional costs are more than offset by Alternative 2's higher benefits. Net benefits reflect fuel savings plus benefits minus costs. EPA projects that through 2050, the Proposal has a net benefit of $140 billion, compared with Alternative 2's net benefit of $180 billion. The cumulative weight of costs and benefits is unambiguous: Alternative 2 outranks the Proposal across virtually every metric, and would result in at least $40 billion more in net benefits. DRIA at xvii, Tbl. 4; xxv, Tbl. 12. [EPA-HQ-OAR-2021-0208-0651-A1, p. 21]

For these reasons, EPA should adopt Alternative 2. By EPA's own calculations, Alternative 2 would produce greater benefits under each category analyzed and greater net benefits than the Proposal. Despite this, EPA has not performed a direct comparison of the costs and benefits of the Proposal and Alternative 2, noting only that "the total benefits [of both the Proposal and Alternative 2] far exceed the total costs" of both programs. Proposal, 86 Fed. Reg. at 43,741. EPA should provide that comparison and follow its work to its logical conclusion: that Alternative 2 produces superior benefits across every metric. Alternative 2 plus would further increase those benefits, as explained infra. [EPA-HQ-OAR-2021-0208-0651-A1, p. 21]

Feasibility of Alternative 2

While EPA notes that reaching Alternative 2's standards "may be feasible" for the same reasons it considers the Proposal to be feasible, the agency prefers the less beneficial Proposal because it provides a "more gradual transition to the 2012 [rule] trajectory," which "may be appropriate taking into consideration lead time." Proposal, 86 Fed. Reg. at 43,777. However, EPA's stated arguments in support of the Proposal's feasibility provide nearly equal support for Alternative 2.

To start, EPA notes that "the ability of the industry to commit to revised plans based on the 2020 Rule's relaxed standards, especially for MYs 2023 and later, has been highly uncertain in light of pending litigation." Id. at 43,782. Indeed, given the eight years between the finalization of the 2012 standards and the 2020 Final Rule, automakers' own statements indicate that they likely continued to follow pathways for compliance with the 2012 Final Rule,64 and, in light of the immediately pending litigation about the 2020 Final Rule, they are not likely to have changed much, if at all, since 2020.

EPA also notes that any change since 2020 would be easily reversible: "Although we do not believe that automakers have significantly changed their product plans in response to the 2020 Final Rule, any that did would have done so relatively recently and there is reason to expect that, for any automakers that changed their plans after the 2020 Final Rule, the automakers' earlier plans could be reinstated or adapted with little change." Proposal, 86 Fed. Reg. at 43,782. Moreover, "some automakers may have adopted product plans to overcomply with the prior, more stringent standards, with the intention of selling credits to other automakers." Id.

In sum, EPA's observations all underscore the feasibility of Alternative 2 and support the conclusion that it has a higher net benefit than the Proposal. EPA also acknowledges why lead time concerns should not be a barrier to implementing Alternative 2, which is only slightly more stringent than the Proposal itself. In light of the lack of distinction between the relative feasibilities of the Proposal and Alternative 2, EPA should conclude that the more stringent approach needs no additional lead time. Given that both the Proposal and Alternative 2 are feasible, and that EPA itself does not believe lead time is a concern, EPA should instead at a minimum adopt Alternative 2. [EPA-HQ-OAR-2021-0208-0651-A1, p. 21-22]

Alternative 2 Plus

Commenters strongly urge EPA to add 10 g/mile of stringency to MY 2026, as a stronger rule would increase all of the benefits described above and put the industry on a more secure path to full electrification over the coming years. According to an independent analysis by Dan Meszler, Alternative 2 Plus would confer an additional $20 billion of net benefits by 2050 (with a 3% discount rate), including an additional $82 billion in pre-tax fuel savings and an additional $27 billion in criteria and GHG emissions benefits.65

Importantly, EPA should add 10 g/mile to MY 2026 even if it were to decide not to adopt Alternative 2. There are no lead time concerns with this option, as MY 2026 would be at least three years from the finalization of the current rule. Also, based on many automakers' announced plans, there will likely be an even higher EV penetration in MY 2026 than EPA currently forecasts. For example, General Motors has pledged to be 100% electric by 2035, Ford has announced that 40% of its fleet will be electric by 2030, and Stellantis (formerly Fiat-Chrysler) promises to offer an electrified variant for every new model released from now until 2025.66 Those targets drive automakers by themselves to reach significantly increased EV market penetration by MY 2026. And indeed, these automakers echoed President Biden's commitment in August 2021 that 50% of all new vehicle sales be electric by 2030.67

These pronouncements have reached the agency: "EPA has also heard from a wide range of stakeholders over the past several months, including but not limited to the automotive manufacturers and the automotive suppliers, that the significant investments being made now to develop and launch new EV product offerings and in the expansion of EV charging infrastructure could enable higher levels of EV penetration to occur in the marketplace by the MY 2026 time frame than EPA has projected in this Proposal for both the proposed MY 2026 standards and the Alternative 2 MY 2026 standards." Proposal, 86 Fed. Reg. at 43,738. EPA should not set too low of a bar in the current rule, when the industry is poised to make a significant jump in the coming years in any event and the planet is in peril.

Adding 10 g/mile to Alternative 2 would also put the vehicle fleet on a steadier path to achieving 100% electrification by 2035, which climate science confirms is the latest acceptable date for reaching that benchmark. Manufacturers would face a gentler slope of improvement to reach 100% ZEV sales by 2035 than if the substantial improvements start with the next rule, which would require steeper annual improvements to reach the same target. Instead, a gradual rate of improvement, completed over more years, would ease the pathway to electrification, rather than requiring a very large jump in MY 2027. This approach requires that there be a significant step forward from the 2012 Final Rule standards in MY 2026. For these reasons, commenters urge EPA to solidify the path to full electrification by adding 10 g/mile of stringency to Alternative 2 in MY 2026. [EPA-HQ-OAR-2021-0208-0651-A1, p. 23-24]

62 This and the following calculations in this section assumes a 3% discount rate, as calculated by EPA.

65 The alternative “10 g/mile in MY2026 beyond Alternative 2” run was modeled by revising the Scenarios input files for EPA runs 7 and 8 (the Agency's Alternative 2 runs). In the Scenarios input file, only the CAFE standard coefficients A, B, C, and D were changed for model years 2026 through 2032 (effectively replacing the Alternative 2 coefficients for those same model years). The revised inputs were developed to produce a precise 10g reduction in the effective car and truck standards (and thus the same reduction in the overall fleet) and were set as follows for cars: A=68.74545094, B=51.40090295, C=0.000327233, and D=0.001129867; and for trucks: A=55.1193845, B=33.07946016, C=0.000366297, and D=0.00312426. All other CAFE model inputs were left unchanged, and all model runs and post-processing steps were performed identically to those of EPA's Alternative 2 evaluation.

Commenter: Center for Climate and Energy Solutions (C2ES)

C2ES welcomes the proposed greenhouse gas emissions standards for passenger cars and light trucks and supports the expedient reinstatement of standards that are significantly more stringent than the SAFE rule. That said, in order to keep the nation on track to meet mid-century decarbonization goals, the standards should be at least as stringent, if not more so, than proposed in Alternative 2, and Alternative 1 should be eliminated as a feasible option. The current rate of emissions reductions is not sufficient to negate light-duty vehicle emissions in the United States by 2050 without significant acceleration of this rate of year-over-year change in subsequent standards. If EPA determines that Alternative 2 is more stringent than appropriate for model year (MY) 2023, given the relatively short lead time between the implementation of the SAFE rule and the year this proposal would go into effect, C2ES suggests that EPA consider an intermediate approach that would start at the proposed standard in MY 2023 but lower the gram per mile (g/mile) standard (i.e., increase stringency) more rapidly than in the proposed approach, in order to reach the same level of stringency in MY 2026 as under Alternative 2. Regardless of whether EPA finalizes C2ES’s proposed approach, Alternative 2, or something in between, in subsequent EPA rulemakings, standards beginning in MY 2027 should follow a more accelerated rate of change to be consistent with a target of 100 percent reductions in tailpipe greenhouse gas emissions from new light-duty vehicles by 2035. [EPA-HQ-OAR-2021-0208-0287-A1, p.2]

C2ES believes that the proposed standards, along with Alternative 2, represent a return to the approximate level of ambition displayed by the 2012 Final Rule and will drive emissions reductions from the light-duty vehicle fleet; however, alone they are not sufficient to put the United States on a path to net-zero by 2050. C2ES recommends that EPA adopt the standards presented in Alternative 2, or if EPA determines these are more stringent than technologically feasible for automakers to meet in MY 2023 given the relatively short lead time, an intermediate approach that would start at the proposed standard in MY 2023 but reach the same stringency in MY 2026 as in Alternative 2. [EPA-HQ-OAR-2021-0208-0287-A1, p.4]

EPA should set the emissions standards at a stringent enough level to preserve ambition while still allowing this flexibility. Lowering the MY 2026 fleet average target levels five to 10 g/mile below the current level proposed would support increased ambition and prepare the auto industry for more ambitious targets beginning in MY 2027, while preparing the national fleet to meet the decarbonization challenge ahead. [EPA-HQ-OAR-2021-0208-0287-A1, p.4]

Commenter: CERES

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 82.]

I'm here today to testify in support of the Biden Administration's Alternative 2 Proposal for updating the SAFE 2 regulations.

The U.S.'s ability to meet climate goals and the future competitiveness of the U.S. auto industry are both contingent on strong vehicle standards and a rapid shift to low-emission vehicles and electrification, and Alternative 2 comes closest to realizing those goals.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 83.]

We strongly support EPA adopting the strongest possible emissions standards and see this as a first of many steps it should take to reduce transportation emissions.

As you know, commercial vehicles are a major driver of emissions and transportation emissions disproportionately impact low-income and communities of color.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 84.]

The stronger standards represented by Alternative 2 will accelerate the cost-effective deployment of fuel-efficient commercial vehicles, allow our members to meet financial and climate goals, and significantly reduce fuel costs for businesses and consumers.

We applaud EPA and the Biden Administration for these initial steps.

Commenter: Ceres BICEP (Business for Innovative Climate and Energy Policy) Network

I write to urge you to adopt the most stringent proposal - Alternative 2 - to replace the SAFE Part II regulations adopted by the Trump Administration. [EPA-HQ-OAR-2021-0208-0273-A1][p.1]

The recent IPCC report, which was characterized as a 'code red for humanity' by UN Secretary-General Guterres, underscores the urgency of drastically reducing greenhouse gas (GHG) emissions in the next decade. Given that the transportation sector is the largest source of U.S. GHG emissions, strong standards are critical to meeting U.S. climate goals. In order for our member companies to meet their own climate goals and commitments, strong policy is needed to ensure sectoral change, and ensure the availability of clean vehicles across the U.S., as well as drive the necessary shift to electrification. Adopting standards at least as stringent as Alternative 2 will be necessary to ensure this critical transition. [EPA-HQ-OAR-2021-0208-0273-A1][p.1]

Our members see climate change as a significant business risk, and reducing GHGs as a major economic opportunity. They recognize that strong standards will serve to mitigate the economic risks associated with our continuing dependence on oil. In light of the volatility of fuel prices, strong standards are needed in order to reduce transportation costs for businesses and consumers; and electric vehicles will reduce operating and maintenance costs in addition to providing important air quality benefits, especially in disadvantaged communities. In addition, given the important role of strong standards in driving innovation, strong standards will also help ensure the global competitiveness of the U.S. industry. [EPA-HQ-OAR-2021-0208-0273-A1][p.1]

A recent analysis [1] commissioned by Ceres and produced by independent automotive industry analysts finds that strong standards would benefit the U.S. auto industry. Specifically, strong standards would make automakers more globally competitive, and reduce risk in the event of future fuel price spikes. Strong standards would especially benefit auto suppliers, which account for about 78% of auto industry jobs. [EPA-HQ-OAR-2021-0208-0273-A1][p.1]

Finally, standards driving EV production will not only benefit U.S. suppliers in particular, but also provide incentives to build a robust domestic EV supply chain, which is critical to job growth. [EPA-HQ-OAR-2021-0208-0273-A1][p.2]

I urge EPA to adopt regulations at least as stringent as the Alternative 2 proposal. We also urge EPA to ensure that the next round of standards ensure at least 60% reduction in emissions, and at least 50% EV sales by 2030, in order to put the industry on a glide path to 100% EV sales by 2035 at the latest. [EPA-HQ-OAR-2021-0208-0273-A1][p.2]

Commenter: Chun, Mark

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 250-251.]

Today, I'm testifying to urge the EPA to adopt Alternative Number 2.

Alternative 2 drives customers to make decisions not only for lofty global warming aspirations but, more importantly, the basic pocketbook. Federal plus state incentives can level the playing field against nice cars plus provide gateways to the every-day low-to-middle-income families.

We need to enforce higher standards to address immediate global warming concerns as soon as possible.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 252.]

Next, we need to mandate the automakers to do the right thing for our environment by legislating a pathway to compliance and not leave it to their own means.

Finally, let's ensure USA takes the leading role amongst the global community by setting the bar to ensure success.

Commenter: City of Albuquerque, NM

Further, the City supports the benefits of more stringent emissions standards, as they will:Be cost effective as the total benefits of more stringent standards far exceed the total cost of the program; [EPA-HQ-OAR-2021-0208-0535-A1, p.2]

Recommending EPA adopt the standards in Alternative 2,[1] which will decrease the fleet average CO2 target level to 169 g/mile by model year 2026 ('MY2026'); 2. Recommending EPA increase the stringency of the fleet average compliance CO2 targets for MY2026 by 10 g/mile more than the proposed rules (Table 8 and Figure 2);[2].

Commenter: City of San Antonio, Texas

While the Model Year (MY) 2024-2026 standards are proposed at a level of 5 percent per year, the City of San Antonio recommends the MY 2024-2026 standards continue at 10 percent as proposed through MY 2023. In addition, the City of San Antonio also recommends the mix of Electric Vehicles/Plug-in Hybrid Electric Vehicle's (EV/PHEV) at a level of 10 percent compared to the 8 percent that is proposed in the base revision. These recommendations will have long-lasting health benefits. [EPA-HQ-OAR-2021-0208-0236-A1, p.1]

Commenter: Climate Group EV100

At a minimum, the US must implement Alternative #2. Compared to the current US EPA proposed standards, Alternative #2 is a safer, more beneficial option for both the climate and consumers.

Clean car standards must not be undermined by complex credit schemes that reward automakers for emission reductions on paper that are not reflected in real-world performance. Without stronger clean car standards, the US will not meet its Nationally Determined Contribution (NDC) of 50-52% emission reductions below 2005 levels by 2030 or achieve net-zero emissions by no later than 2050. [EPA-HQ-OAR-2021-0208-0200-A1, p. 1]

Alternative #2 would put 400,000 extra EVs on the road by 2026 and eliminate 130 million metric tons of greenhouse gas emissions. It would also save American drivers a total of $150-290 billion in fuel savings through 2050. [EPA-HQ-OAR-2021-0208-0200-A1, p. 1]

We urge the US Environmental Protection Agency (EPA) to set the strongest possible clean car standards for vehicle model years 2023-2026 to achieve 100% of all new passenger car and truck sales to be zero-emission ideally by 2030. We appreciate that the Biden-Harris Administration is following through on its promise to reverse clean car standard rollbacks from the previous administration. Additionally, we're pleased to see President Biden send the correct market signals that electric vehicles (EVs) are the future. However, we need stronger, more ambitious action. Stronger clean car standards ensure automakers produce more efficient vehicles and market them to all consumers. [EPA-HQ-OAR-2021-0208-0200-A1, p. 1]

Our members, which include leading US employers, directly support establishing strong vehicle standards designed to achieve 100% zero-emission vehicle sales for new passenger cars and trucks ideally by 2030. [EPA-HQ-OAR-2021-0208-0200-A1, p. 1]

Ultimately, the US EPA must act to make clean car standards as strong and comprehensive as possible, which would be a win for the American people and all those looking to spur job creation, economic growth, family cost savings, and public health protection at a time when we most need it. [EPA-HQ-OAR-2021-0208-0200-A1, pp. 1-2]

Commenter: Collins, Molly

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 231.]

I wanted to share my story with you today and ask you to commit to making the strongest possible clean car standards so that my two kids and my community can breathe easier.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 232.]

We have the tools to begin to address these issues. The EPA must finalize the rule this year and ensure that these standards result in real-world reductions in greenhouse gas emissions.

Commenter: Competitive Enterprise Institute (CEI)

In addition, EPA has ignored the more lenient regulatory alternatives that were proposed by CEI and others in the SAFE rulemaking. It has instead set an arbitrary limit to the range of alternatives that it will consider in this rulemaking. The illegality of this approach warrants that EPA initiate a new rulemaking. [EPA-HQ-OAR-2021-0208-0652-A1, p. 2]

EPA Has Arbitrarily Restricted the Range of Alternatives that It Is Considering

EPA states that it will not consider alternatives less stringent than the California Framework: 'EPA views the California Framework as a reasonable basis for the least stringent alternative that EPA would consider finalizing, since it represents a level of stringency that five manufacturers have already committed to achieving.' 86 FR 43737-38; see also 86 FR 43766. However, the fact that five carmakers have committed to meeting this standard says little about whether it satisfies all the appropriate criteria, which include health and safety.

Similarly, Walter Kreucher, an individual petitioner in CEI v. NHTSA, proposed in his SAFE comments that the agencies keep the standards at the 2016 level, and impose only modest stringency increases for the three model years after that. 85 FR 24257. And several other commenters in that proceeding, such as Borg Warner and the Alliance for Vehicle Efficiency, argued for lowering the CAFE baseline to what the auto industry had actually achieved in MY 2018. Id. EPA should examine these proposals rather than artificially limit the scope of the alternatives that it is considering.

EPA's use of the California Framework to limit the alternatives open to public comment has skewed this proceeding from the outset. It should abandon this limit and issue a new notice of proposed rulemaking, inviting public comment on a far broader range of regulatory alternatives. [EPA-HQ-OAR-2021-0208-0652-A1, p. 8]

Commenter: Connecticut Department of Energy and Environmental Protection

CTDEEP believes that at a minimum, EPA must restore sufficiently stringent GHG emission standards as the National Clean Car Standards EPA adopted in 2012. These federal GHG emissions standards for MYs 2017 and later LDVs were developed based on an extensive record of scientific data and comprehensive technical analyses, and received overwhelming support from a wide-range of stakeholders. The automotive industry has planned accordingly for nearly a decade, and these GHG standards are readily achievable as evidenced by industry announcements and EPA's 'Consideration of Technological Feasibility and Leadtime'. [EPA-HQ-OAR-2021-0208-0264-A1, p.1]

EPA should at a minimum, adopt Alternative 2, augmented with a MY 2026 standard that is 10 grams/mile more stringent.[3]This option comes the closest to returning to more aggressive light-duty vehicle standards that are more in line with the 2012 National Clean Car Standards, and would establish a trajectory designed to meet the deployment goals established in President Biden's August 5, 2021 Executive Order 14037, 'Strengthening American Leadership on Clean Cars and Trucks' [4]. Many state and local jurisdictions, including Connecticut, were counting on the benefits of the 2012 rule. Nine years later, these reductions are still urgently needed. EPA should do everything possible to recapture those benefits – including those related to climate change, ground-level ozone and particulate matter. [EPA-HQ-OAR-2021-0208-0264-A1, p.2]

Commenter: Consumer Federation of America

While the EPA's proposed rule has made strides in correcting the dozens of fundamental errors made by the Trump administration, CFA urges the current administration to vigorously support the transition to electric vehicles (EVs). Given the current trajectory of fuel economy standards, over 100 million gasoline vehicles will still be sold before the full transition to EV's. Stronger fuel economy standards are just one way to help spur the transition, as setting high standards on the gasoline part of the fleet will speed the adoption of electric vehicles. Additionally, with a significant amount of the gain in efficiency seen in traditional internal combustion (ICE) vehicles – both in vehicle design and operation – these may be applicable to the electric portion of the fleet as well.

Second, it is critical to close the remaining loopholes, especially those that could allow the automakers to 'use' the electric vehicle part of their fleet to 'relax' the efficiency of the gasoline-powered part. This trade-off must not be allowed.

Establishing a national goal of transitioning to an all-electric fleet while simultaneously accelerating the transition of the electrical grid to cleaner renewable sources is essential. It is clear the current administration has recognized this and is working hard to move the country in this direction.

As our economic analysis shows, and the agency seems to agree, that these additional changes can be made with a net positive benefit-cost ratio. The total cost of driving for consumers will go down, measured by the pocketbook savings. Public health and environmental benefits will further increase an already positive benefit-cost ratio. By fully embracing the transition to EVs, Americans of all income levels will be better off at the end of the changeover. [EPA-HQ-OAR-2021-0208-0297-A1, p. 2]

Commenter: Consumer Reports (CR)

CR's own analysis finds that EPA's preferred alternative will only recover ~75% of the consumer and climate benefits of the original Obama-Biden standards.2 [EPA-HQ-OAR-2021-0208-0602-A1, p.4]

CR strongly supports the administration's stated goal of reducing greenhouse gas emissions from new vehicles by 60%, while achieving 50% electrification by 2030.3 Achieving this goal would result in over $1 trillion in consumer savings while reducing emissions by 10 gigatons through 2050.4 Unfortunately, EPA's preferred alternative will leave the US fleet off the pace to achieve this important goal. [EPA-HQ-OAR-2021-0208-0602-A1, p.4]

Consumer Reports asks EPA to increase the stringency of their proposal such that it achieves similar consumer savings through model year 2026 as the original 2012 Obama-Biden standards would have achieved, while putting the US fleet on track to achieve President Biden's climate commitments.5 [EPA-HQ-OAR-2021-0208-0602-A1, p.4]

In order to achieve these goals CR provides the following recommendations for strengthening the standard:

1) Adopt Alternative 2 stringency from MY23-25

2) Increase the stringency of the standard in 2026 by 10 g/mi beyond Alternative 2 [EPA-HQ-OAR-2021-0208-0602-A1, pp.4-5]

EPA's own analysis shows that Alternative 2 will result in greater net benefits and CR's own analysis comes to the same conclusion. This alternative essentially matches the stringency of the original Obama-Biden standards for MY23-25, which automakers already agreed to almost a decade ago and were planning to comply with up until the SAFE rule was finalized last year. Furthermore, trends have shown that declining compliance costs, and growth in electrification will make meeting this level of stringency even easier. There is no strong justification for setting a standard weaker than Alternative 2. [EPA-HQ-OAR-2021-0208-0602-A1,p.5]

CR also strongly supports increasing the stringency of the 2026 standard by 10 g/mi. According to EPA's own analysis, the current proposal will result in less than 8% electrification by 2026, putting the US fleet well behind both automakers' and President Biden's stated goals of achieving 50% electrification in 2030. Increasing the stringency in 2026 will provide automakers with sufficient lead time for factoring these stronger standards into their production plans, while putting the US on a better trajectory to meet our climate commitments. [EPA-HQ-OAR-2021-0208-0602-A1, p.5]

3. Recommended Improvements to EPA's Preferred Alternative

Consumer Reports asks EPA to strengthen the standards they have proposed. We specifically ask that EPA set stringency at the same level as Alternative 2 for MY23-25, further increase the stringency of the MY2026 standard by 10g/mi, and that EPA reins in various credits and multipliers that weaken the effectiveness of the standard. [EPA-HQ-OAR-2021-0208-0602-A1, p.10]

a. Adopt Alternative 2 levels of stringency for MY23-25

EPA's own analysis shows that Alternative 2 would result in an additional $40B in net benefits through 2050.20 It also shows that Alternative 2 would result in $34B in benefits through MY2026 compared to only $24B in benefits for EPA's preferred alternative.21 Furthermore, Alternative 2 fully restores the top line stringency of the original 2012 Obama-Biden standards which automakers have already agreed to, and were planning to achieve prior to the finalization of the SAFE rule only last year. Throughout the NPRM and RIA, EPA provides very little justification for selecting the weaker proposal with lower benefits over their stronger Alternative 2 that has demonstrably greater net benefits across multiple analysis frames. Consumer Reports' own analysis comes to similar conclusions.22 [EPA-HQ-OAR-2021-0208-0602-A1, p.10]

b. Increase 2026 stringency by 10 g/mi

EPA asked for comment on increasing the stringency of the MY2026 standard by between 5-10 g/mi. Consumer Reports recommends that EPA strengthen the MY2026 standard by 10 g/mi. Consumer Reports estimates that making this change would result in an additional $8 billion in consumer savings through MY2026.23 Achieving our climate commitments will require strong action, and a more stringent 2026 target will set automakers up for success in achieving longer term emissions reductions targets.24 [EPA-HQ-OAR-2021-0208-0602-A1, p.11]

In increasing the stringency in MY2026, EPA provides automakers with more than enough lead time to adjust to these higher standards. Automakers are all in the process of developing, updating, and increasing their electrification plans, and touting them to their shareholders.25 Growing consumer interest (see section 2 of this comment) and improving economics of electrification (see section 3d of this comment) will also contribute to the feasibility of this higher standard. [EPA-HQ-OAR-2021-0208-0602-A1, p.11]

Conclusions

EPA’s proposal is a good start, but can and should go further to protect consumers and reduce emissions. Consumer Reports recommends that EPA adopt the stringency levels of Alternative 2 for MY23-25, increase the stringency in MY2026 by 10 g/mi beyond the stringency of Alternative 2, and tighten up the credits and flexibilities provided within the standards. Consumer Reports concludes that these improvements are justifiable based on cost-benefit analysis, and feasible for automakers to achieve. [EPA-HQ-OAR-2021-0208-0602-A1, p.22]

Commenter: Cooper, Almeta

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 77.]

In closing, on behalf of Georgia's moms, dads, and children, we ask that EPA finalize the strongest possible option to regulate how much and how quickly to limit climate pollution from cars and light trucks.

We support Alternative Number 2.

Commenter: Corporate Electric Vehicle Alliance (CEVA)

As companies that represent over $1 trillion in annual revenue1 and collectively own, lease, or operate more than one million fleet or networked vehicles in the United States, we are writing to express our support for strong light duty vehicle standards, and to urge you to adopt the most stringent proposal - Alternative 2 - in strengthening the SAFE Part II regulations adopted by the Trump Administration. [EPA-HQ-OAR-2021-0208-0276-A1. p.1]

Strong vehicle standards are critical to ensuring economic benefits as well as meeting climate goals. While we are working to do our part as individual companies, we need strong standards to ensure the widespread availability of clean vehicles in the U.S., as well as to drive the economies of scale that will accelerate the necessary transition to electrification. [EPA-HQ-OAR-2021-0208-0276-A1. p.1]

In sum, we urge EPA to adopt standards at least as stringent as Alternative 2, which are necessary to accelerate the cost-effective deployment of fuel-efficient and electric light-duty commercial vehicles, and allow our members to meet our climate goals. Further, we strongly urge that the next round of standards be aligned with climate goals by ensuring at least 50% ZEV sales, and a 60% reduction in emissions by 2030, and that put the U.S. on a glide path toward 100% passenger ZEV sales by 2035. [EPA-HQ-OAR-2021-0208-0276-A1. p.1]

Commenter: Cuny, Phillip

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 246.]

Once again, raising mileage standards and cleaning up vehicle emissions is one of the few things that we can do now. I urge you to raise these standards as high as feasibly possible to make our transportation system the most efficient in the world. Let's lead by example. We need to do this for our children and our grandchildren.

Commenter: Dang, Vinh

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 221.]

I urge this Administration and the EPA to set the strongest standards possible, one that is stronger than the original Obama clean car standards.

Commenter: Davidson, William

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 207.]

I urge the Administration to set the highest standards possible because it is the right thing to do. We should be making our vehicles cleaner and more efficient. I urge you to adopt the second alternative and set even higher standards through 2030 and beyond and ensure there are no loopholes.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 206.]

I fully support this Administration's swift action on clean cars and I strongly urge the EPA to adopt the second alternative for more stringent regulations.

Commenter: Davis, Darien

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 160.]

I urge the EPA to create the strongest possible limits on vehicle pollution. The EPA should seek to finalize Alternative 2, the strongest standards the EPA analyzed on the proposal.

In order to tackle the climate crisis at the speed and scale that science demands, we need standards that will reduce 60 percent of carbon emissions from new cars by 2030.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 161-162.]

Once again, I urge this Administration to set the strongest standards possible because they are practical and meet the moment that we're in. The EPA should finalize standards at least as strong as Alternative 2 presented in the proposed rule. These standards can put us on the path to upholding our NBC of 50 to 52 percent net economy-wide greenhouse gas emission reductions below 2005 levels in 2030.

Ultimately, these standards set for 2026 can lay the groundwork for eliminating pollution from new vehicles by 2035. It is clear that we have no time to waste.

Commenter: Dessart, Peter

As the UN IPCC Climate Change 2021 report makes clear, any chance we have of arresting further permanent damage to our environment requires immediate decisive action. When it comes to automobiles (including SUVs and light trucks), this means completely eliminating tailpipe emissions as quickly as possible. Despite any stated plans by auto manufacturers to transition to battery electric vehicles, there is a tremendous amount of vested interest in continuing to produce vehicles with internal combustion engines (including Hybrids and PHEVs). The free market alone cannot counteract this - looking after the health and well-being of citizens is the role of government. Therefore, it is important to recognize that the end goal of Greenhouse Gas Emissions Standards is not merely limiting tailpipe emissions, but disincentivizing them. At the very least, the EPA should look to the EU standards which are more stringent. But ideally, the Greenhouse Gas Emissions Standards enacted by the EPA should be so strict as to make continued production of internal combustion engines uneconomical when compared with the cost of producing vehicles with zero tailpipe emissions. [EPA-HQ-OAR-2021-0208-0506, p. 1]

Commenter: District of Columbia Department of Energy and Environment

In the Proposed Rule, EPA presented a baseline proposal and two alternatives. While all three alternatives move in the right direction, DOEE recommends choosing Alternative 2. On June 18, 2021, DOEE published a proposal to adopt California GHG standards for light duty-vehicles (68 DCR 6298). DOEE found this to be necessary in part because the District was not able to rely on the national program for GHG emission reductions from vehicle emissions standards and compliance requirements to meet the District's GHG reduction commitments due to EPA's rollback of federal light-duty vehicle GHG standards on April 30, 2020 (85 Fed. Reg. 24174).

Vehicle emissions constitute twenty-one percent (21%) of the District's GHG emissions. However, many of the vehicles that travel on District streets come from out of state, so strong federal GHG standards are necessary. EPA's light-duty vehicle GHG standards as adopted in 2012 were found to be the fourth most important program in terms of GHG reductions and second most important in terms of energy use reductions when the District analyzed how to achieve its commitment to reduce GHG emissions by fifty percent from 2006 levels by 2032.1 Alternative 2 is the only option presented by EPA that achieves the same GHG fleet targets in MY 2023 onward that were in place prior to the April 30, 2020, so Alternative 2 is the only option that aligns with the District's GHG reduction commitments. [EPA-HQ-OAR-2021-0208-0240-A1, p.2]

In particular, DOEE supports Alternative 2, which includes the additional 10 g/mile reduction in Model Year (MY) 2026. [EPA-HQ-OAR-2021-0208-0240-A1, p.1]

Additionally, since the level of GHG reduction was not as strong in MYs 2021 and 2022 as they were prior to the August 2020 rollback and carbon dioxide is a long-lived pollutant, implementing the additional 10 g/mile stringency in MY 2026 is necessary to make up for increased emissions that occurred due to the 2020 rollback. [EPA-HQ-OAR-2021-0208-0240-A1, p.2]

The District of Columbia calls on the EPA to finalize GHG standards for light-duty vehicles as expeditiously as practicable along the lines of Alternative 2, which includes the additional 10 g/mile reduction in MY 2026. [EPA-HQ-OAR-2021-0208-0240-A1, p.3]

Commenter: Donnelly, Russel

As an EV driver and concerned citizen, I urge that you select the more stringent "Alternative #2" option for GHG reductions as detailed in your proposed clean car standards and to go beyond it. Given that the market for EVs in the U.S. has already doubled from 2% in 2020 to nearly 4% in 2021, automakers in this country should have no problem meeting these requirements, and in fact, it's reasonable to assume that even more stringent reductions can easily be achieved by Model Year 2026. Please follow President Biden's lead and implement standards that more fully support an electrified transportation future [EPA-HQ-OAR-2021-0208-0458, p. 1]

Commenter: Dream Corp Green for All

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 305-306.]

We are heartened to see EPA state a target of reducing pollution by 60 percent by 2030 which will save lives and accelerate clean transportation choices, but changes are needed to ensure the rule actually delivers on this goal.

second, EPA's Alternative 2 reduces more pollution and has higher net benefits than EPA's proposal, and Alterative 2 should be the basis for the final rule.

According to EPA's own analysis, the fuel savings alone offset the costs of Alternative 2. Alternative 2 has almost 30 percent higher net benefits and even applying a seven percent discount rate, both EPA's proposal and Alternative 2 have the same delta between the costs and fuel savings. Therefore, there's no downside to adopting Alternative 2 compared to the proposal.

The higher net benefits under both three percent and seven percent discount rate make Alternative 2 the most rational option.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 307-308.]

When it comes to passenger vehicle emissions, there's room for dramatic improvement. In Model Year 2019, average emission rates for all new vehicles increased three grams per mile, even as all automakers were compliant with the standards.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 309.]

EPA's Alternative 2 is the clear superior choice to reach these goals.

Commenter: Dream Corps Green for All et al.

On behalf of [GreenLatinos, EVHybridNoire, National Parks Conservancy, and Dream Corps Green For All] we urge the Environmental Protection Agency to adopt Alternative 2 in its final rule setting light-duty GHG emission standards for passenger vehicles [EPA-HQ-OAR-2021-0208-0285-A1, p.1]

When it comes to passenger vehicle emissions, there's room for dramatic improvement. In model year 2019, the average estimated real-world CO2 emission rate for all new vehicles increased 3 g/mi even as all automakers were compliant.[8] There are too many loopholes and bonus credits even in the existing program, and stricter standards and less potential for gaming the system will be needed to reach a 60% reduction in emissions by 2030. Most automakers (but not all of them) are making real improvements indicating feasibility and affordability of meeting stronger standards. The standard should not be set by laggards, and bringing them up to speed is overdue. [EPA-HQ-OAR-2021-0208-0285-A1, p.3]

EPA's Alternative 2 is the clear superior choice to reach these goals. [EPA-HQ-OAR-2021-0208-0285-A1, p.5]

EPA's Alternative 2 reduces more pollution and has higher net benefits than EPA's proposal and should be the basis for the final rule. [EPA-HQ-OAR-2021-0208-0285-A1, p.2]

EPA's Alternative 2 reduces more pollution and has higher net benefits than EPA's proposal and should be the basis for the final rule. According to EPA's own analysis in Table 15, the fuel savings alone fully offset the costs of Alternative 2 (using a 3% discount rate). Alternative 2 has almost 30% higher net benefits, and even applying a 7% discount rate, both EPA's proposal and Alternative 2 have the same delta between the costs and fuel savings ($30B). Therefore, there's no downside of adopting Alternative 2 compared to the proposal. The higher net benefits under both a 3% and 7% discount rate make Alternative 2 the most rational option. Given the risks of abrupt changes from global temperature rise identified in the 2021 IPCC report,[6] the benefits of reducing emissions are very likely underestimated in the government's analysis.[EPA-HQ-OAR-2021-0208-0285-A1, p.2] [Table 15 can be located at Docket EPA-HQ-OAR-2021-0208-0285, p. 3]

Commenter: Dugan, Maureen

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 297.]

I'm here to implore you to institute the second alternative for clean car emissions. History has shown us that the auto industry will fight this with everything that they have.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 300.]

Enact the second alternative.

Commenter: E2 - Environmental Entrepreneurs

E2 strongly supports reconsideration by the Environmental Protection Agency (EPA) of the 2020 rule weakening greenhouse gas emission standards for model years (MY) 2021-2026 passenger cars and light trucks (the 2020 Final Rule). We urge the agency to reverse that rule and to finalize the strongest standard it has considered in the Proposal (Alternative 2). [EPA-HQ-OAR-2021-0208-0604-A1, p. 1]

In terms of cost savings: EVs save consumers an estimated $6,000- $10,000 over the lifetime of their vehicle. That includes as much as $1,000 per year in fuel costs and $4,600 in maintenance costs. Businesses with commercial fleets can expect to save $200,000 over the lifetime of one of their heavy-duty electric trucks. That's money that can be reinvested into our economy. [EPA-HQ-OAR-2021-0208-0604-A1, p. 1]

Consumer Benefits: Alternative 2 also outshines the Proposal with regards to consumer benefits. Because both the Proposal and Alternative 2 will be more stringent than the 2020 Final Rule standards, EPA predicts that consumers will spend less on gasoline (and more on electricity) in the coming years.

• By 2050 consumer fuel savings would be $310 billion under the Proposal, compared with $360 billion under Alternative 2, a $50 billion difference. DRIA at 6-5, Tbl. 6-4; xxv, Tbl. 12.

• Alternative 2 would also result in consumption of 486 million fewer barrels of gasoline by 2050. DRIA at 5-7, Tbl. 5-7; 5-9, Tbl. 5-9. [EPA-HQ-OAR-2021-0208-0604-A1, p. 3]

For all of these reasons we strongly urge EPA to finalize the strongest standard it has considered in the Proposal (Alternative 2). [EPA-HQ-OAR-2021-0208-0604-A1, p. 3]

In light of all that is at stake, EPA must strengthen the vehicle standards that were weakened in 2020 rulemaking. And we urge EPA to finalize the most protective and costeffective proposal: Alternative 2, with the addition of 10 grams per mile in MY 2026. Automakers are well-positioned for compliance through MY 2026. Nearly a decade ago, EPA had already found, correctly, that we had the technologies needed to reduce vehicle emissions and also save customers, including small businesses, money at the pump. EPA needs to put the standards in place to ensure that these technologies are broadly deployed and that they are deployed soon enough and widely enough to ensure the auto sector does its part to reduce emissions sufficiently to meet the President's climate goals of at least 50% reduction in US emissions by 2030.

EPA's cost benefit analysis of the proposals shows why it is in the public interest for the agency to support Alternative 2.

Benefits: While both the proposal and alternative 2 are better than the current standards, the evidence shows that Alternative 2 is far superior for the climate and consumers. [EPA-HQ-OAR-2021-0208-0604-A1, p. 2]

Other Non-emissions Benefits: EPA has also quantified the non-emission benefits from the rebound effect (the increase in driving resulting from reduced operating costs), changes in refueling time, and energy security benefits from reduced dependence on foreign petroleum. EPA projected non-emission benefits for the Proposal to be $35 billion through 2050, while Alternative 2 would generate $53 billion—a difference of $18 billion. DRIA, Tables 6-8, 6-10. [EPA-HQ-OAR-2021-0208-0604-A1, p. 3]

The cumulative weight of costs and benefits is unambiguous: Alternative 2 outranks the Proposal across virtually every metric, and would result in at least $40 billion more in net benefits. DRIA at xvii, Tbl. 4; xxv, Tbl. 12. [EPA-HQ-OAR-2021-0208-0604-A1, p. 3]

EPA's own analysis shows that Alternative 2 surpasses the Proposal across virtually every metric, and that it will result in at least $40 billion additional net benefits. DRIA at xvii, Tbl. 4; xxv, Tbl. 12.

As compared to the Proposal, by 2050 Alternative 2 will save 110 MMT of upstream CO2, as well as 183 MMT of tailpipe CO2, for a total of 293 MMT of CO2 savings. DRIA at 5-1, Tbl. 5-1; 5-3, Tbl. 5-3.1

In addition to these significant CO2 reductions, Alternative 2 is superior on overall climate benefits, calculations which take into account the social cost of CO2, CH4, and N2O. The Proposal would produce climate benefits of $91 billion by 2050, while Alternative 2 would generate $100 billion—a difference of $9 billion. DRIA at 3-39, Tbl. 3-14; 3-41, Tbl. 3-16. [EPA-HQ-OAR-2021-0208-0604-A1, p. 2]

Commenter: Egbert, Judi

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 176.]

I support and appreciate President Biden's steps toward renewing sensible standards for vehicle fuel efficiency but am concerned that automakers will do as they have repeatedly done before, that is, seek ways in which they conduct and avoid improving fuel efficiency.

Hence, I ask that the EPA choose Alternative Number 2 which will more effectively and rapidly close loopholes sought oftentimes by automakers and Alternative 2 will enable significant savings for consumers, perhaps as much as $2,100 average per vehicle.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 177-178.]

my expectation that the EPA will apply Alternative Number 2 for a more effective, sensible, and healthy standard and vehicles that are marketed in the U.S.

By having stronger standards, we not only save at the gas pump but we save by having better air, land, and water quality and healthier citizens. 90 percent of American consumers favor more efficient and safer vehicle standards that reduce greenhouse gas emissions and promote healthier communities.

We don't need additional decades of research and development. We have the ability and technology to implement better standards now and Alternative Number 2 will enable that.

Commenter: Elders Climate Action (ECA)

We ask EPA to supplement the current proposed rule for the 2026 MY to 1) set a zero emission standard for new motor vehicles, and 2) establish a phase-in schedule for the standard that includes a 30% ZEV sales target for MY 2026 to begin charting a regulatory path that will transition the auto industry toward achieving 100% production and sale of ZEVs in the U.S. by 2030. [EPA-HQ-OAR-2021-0208-0521-A1, p. 3]

Commenters understand that additional rulemaking will be required to establish a zero emission standard and phase-in schedule. We ask that the Administrator not delay completion of the current proposed rule so that it can apply to 2023-25 MY vehicles. We ask that the Administrator re-open the rulemaking for the 2026 MY to promulgate a zero emission standard and a phase-in schedule that begins with the 2026 MY. [EPA-HQ-OAR-2021-0208-0521-A1, p. 4]

EPA’s current proposed rule will not achieve anywhere near those reductions, and fails to identify any future strategy for achieving those reductions. To fulfill the Agency’s statutory mission to protect public health and welfare it must issue regulations that achieve these targets. [EPA-HQ-OAR-2021-0208-0521-A1, p. 11]

To achieve the zero emission economy needed to stop heating the climate, and to attain urban air quality safe for children to grow up healthy and adults to remain healthy as elders, we ask EPA to determine that a zero emission standard for motor vehicles is necessary to protect public health. To put the nation on the path to zero emissions as soon as possible, and to minimize the atmospheric loading of GHGs as we make the transition to zero emissions, we ask EPA to re-open the current rulemaking for 2026 MY vehicles to 1) promulgate a zero emission standard for LDVs, and 2) establish a schedule for phasing in that standard beginning with the 2026 MY. [EPA-HQ-OAR-2021-0208-0521-A1, pp. 16-17]

Commenter: Energy Innovation Policy and Technology LLC

Of the options analyzed in the proposed rule, we consider Alternative 22, combined with additional 10 g/mile stringency for MY 2026, (“Alternative 2+”) to be the strongest option, relative to the preferred option and Alternative 1. Based on the EPA’s analysis, Alternative 2+ will reduce transportation sector emissions more quickly and will support the deployment of clean, electrified transportation technologies more affordably and efficiently. Finally, while these rules represent an important step to align the U.S. transportation sector with a cleaner and more consumer-oriented future, our research shows that more must be done going forward. We need greater ambition and more stringent tailpipe standards for all vehicle classes to meaningfully reduce transportation sector pollution and GHGs, benefit consumers economically, stimulate our economy, and ensure global competitiveness. [EPA-HQ-OAR-2021-0208-0605-A1, pp. 1]

We concur with the EPA that 'we are at a pivotal moment in the history of the light-duty transportation sector—a shift to [ZEV] technologies is already underway, and it presents a strong potential for dramatic reductions in GHG and criteria pollutant emissions over the longer term.'iv While improved stringency in the proposed rules is a good start, it is not enough. [EPA-HQ-OAR-2021-0208-0605-A1, pp. 2]

Since the EPA recognizes more can and should be done to appropriately address the GHG emissions and other harmful pollutants (and associated environmental injustice) caused by continued overreliance of fossil fuels in the transportation sector, we recommend the following:

As part of this rulemaking, the EPA should adopt the most stringent standards for model years 2023-2026 in the proposed rules (Alternative 2), including adopting more stringent standards for MY 2026 that would result in fleet average target levels that are in the range of 5-10 g/mile lower than the levels proposed (Alternative 2+). [EPA-HQ-OAR-2021-0208-0605-A1, p. 4]

Alternative 2+, on the other hand, would put the U.S. back on track to reduce GHG and air pollution emissions and deploy more ZEVs and clean transportation technologies faster than the preferred option. In its updated analysis, the EPA appropriately integrates updated data and recent market developments, including the availability of advanced GHG and pollution reduction technologies, vehicle electrification trends, auto manufacturers' voluntary commitments, cost declines of battery technologies, and other factors.[xiii] As such, adopting the most stringent standards is appropriate and justified, based on the EPA's analysis and other compelling factors. Nonetheless, while adoption of Alternative 2+ would be an improvement over the status quo, more is needed to meaningfully address climate change, mitigate harmful pollution, and alleviate the burden of transportation pollution, especially for BIPOC and low-income/low-wealth populations. EPA's proposed 2023-2026 vehicle standards do not on their own adequately address the imperative transition to ZEVs made possible by rapid innovations in battery technology, manufacturer investment, and growing customer adoption. The standards also fall short of the imperative to push the U.S. auto industry to keep pace with ZEV sales in China and Europe, which are accelerating and yielding considerable economic benefits. At this juncture and moving forward, the U.S. needs to adopt the most stringent tailpipe standards possible and eliminate loopholes that further delay widespread deployment of clean vehicles. [EPA-HQ-OAR-2021-0208-0605-A1, p. 5]

The companion Policy Report finds that achieving the DRIVE Clean Scenario requires a combination of policy and regulatory changes at the federal, state, local, and utility level, including:

• Strengthened EPA tailpipe emission standards that support ZEV sales and reduce overall tailpipe emissions for all ground vehicle classes to 0 g/mile by 2035;

• Continued adoption of state ZEV standards and rules;

• Incentives for EVs and charging infrastructure to help more consumers access affordable new and used EVs and convenient charging;

• Workforce programs that help streamline the transition to EVs and create new jobs;

• Incentives for domestic manufacturing to encourage the production and sale of electric cars and trucks;

• EV-friendly rules, codes, permitting, interconnection, and rates. [EPA-HQ-OAR-2021-0208-0605-A1, pp. 9-10]

Commenter: Environment America

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 237.]

However, I urge you to make the proposed standards even stronger to ensure the greatest reduction in global warming emissions and air pollution and to accelerate the expansion of the electric vehicle market.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 238-239.]

The preferred alternative identified by EPA is not as strong as the Obama/Biden standard and is riddled with loopholes and give-aways to automakers that undermine otherwise strong emissions reduction targets.

It's been almost 10 years since the Obama/Biden vehicle fuel efficiency standards were set. We must start by reinstating at least those standards and ideally stronger ones as the climate crisis has progressed rapidly over the last decade.

The sense of these standards are essential in spurring innovation and clean car technology, but the U.S. can achieve 100 percent zero emission vehicle sales by 2035 which is in line with the Biden Administration's goal of net zero greenhouse gas emissions by 2050.

The EPA itself identifies a much better rule, Alternative 2, which would put 400,000 extra electric vehicles on the road by 2026 and result in a 130 million metric tons fewer greenhouse gas emissions.

Once again, I urge this Administration to set the strongest standards possible because they are working. We should maximize the benefits by making our cars and light-duty trucks more efficient and I urge you to go back to at least the Obama/Biden federal standards and ideally to even stronger ones.

Commenter: Environmental Defense Fund (EDF)

EPA should find that automakers need no extended "period" of lead time to comply with the proposed MY 2023-2026 standards. EPA should determine that automakers need no extended "period" of lead time to comply with the proposed MY 2023-2026 standards. 42 U.S.C. § 7521(a)(2). First, the emission-reduction technologies needed to comply with EPA's Proposed Standards for MY 2023-2026 already have been developed and applied in each category of vehicles to which those standards would apply. The requisite technologies were "developed in response to EPA's 2012 GHG standards rulemaking for MYs 2017-2025," 86 Fed. Reg. at 43,782, which were more protective in MY 2023-2025 than the standards EPA has now proposed. Indeed, even when EPA decided in the 2020 Rule to weaken the standards set in 2012, the agency acknowledged that "the technologies projected to be used to meet" the 2012 Final Rule were by then already "available and in production." EPA & National Highway Traffic Safety Administration ("NHTSA"), The Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Years 2021–2026 Passenger Cars and Light Trucks, 85 Fed. Reg. 24,2714, 25,108 (Apr. 30, 2020) (2020 Rule). [EPA-HQ-OAR-2021-0208-0688-A1, p. 7]

As for the later model years of EPA's Proposed Standards (MY 2025 and, especially, MY 2026), given that the requisite emission-reduction technology is and has long been available and applied in a wide variety of vehicles, lead time for those model years would be sufficient taking into account the standard product-development cycles for light-duty vehicles. Cf. 49 U.S.C. § 32902(a) & (g)(2) (requiring 18 months' lead time for fuel-economy standards for light-duty vehicles). In any event, recent announcements by automakers comprising a supermajority of the market presage far broader and deeper deployment of zero-emission vehicles by MY 2025. See infra, at 23-24. Even modest increases (2% annually) in deployment of zero-emission vehicles by those automakers that did not enter into agreements with California would allow those automakers to easily comply with EPA's Proposed Standards. See infra, at 21-23.[EPA-HQ-OAR-2021-0208-0688-A1, p. 9]

Accordingly, in addition to the feasibility of the Proposed Standards for the early model years of the program, we urge the administration to consider further strengthening the standards by 10 g/mi in MY 2026 in a way that ensures ZEV deployment is encouraged. EPA could adopt an alternative compliance pathway in the final rule to secure these reductions, including design features and incentives that would help to ensure these additional 10 g/mi were delivered by ZEVs. Doing so would allow automakers choosing this pathway greater certainty in complying with the next generation of standards, which must be based on substantial ZEV deployment, and will create an even stronger foundation for EPA action to adopt those standards. [EPA-HQ-OAR-2021-0208-0688-A1, pp. 1-2]

EPA should consider strengthening the standards by 10 g/mi in MY 2026 in a way that incentivizes greater ZEV deployment

EPA has separately requested comment on standards for MY 2026 that would result in fleet average target levels that are in the range of 5-10 g/mile lower (i.e., more stringent) than the levels proposed. EPA should consider further strengthening the standards by 10 g/mi in MY 2026 and do so by developing an alternative compliance pathway that would help ensure those additional reductions are delivered by ZEVs. EPA has a critical responsibility in this rulemaking to ensure the MY2026 standard increases deployment of ZEVs, creating the needed on-ramp for new standards for MYs 2027 and beyond that will eliminate tailpipe pollution from at least half of all new passenger cars and trucks. [EPA-HQ-OAR-2021-0208-0688-A1, p. 31]

EDF supports standards for MY 2026 that would result in fleet average target levels that are 10 g/mile lower than the MY 2026 levels proposed in a manner that would also achieve significant ZEV deployment beyond business-as-usual projections for MY 2026. Our analysis above shows that, under a range of assumptions, an additional 10 g/mi in 2026 is cost-effective, and that the most cost-effective manner to achieve those reductions is likely through deployment of additional ZEVs. Indeed, automakers have already committed to spending billions of dollars through 2025 on ZEV deployment. Additional ZEV deployment in the 2026 timeframe will help to create an even stronger foundation to achieve 50 percent ZEV deployment in the 2030 timeframe, consistent with the President’s goal. To that end, we encourage EPA to consider an alternative compliance framework that would encourage and incentivize automakers to meet an additional 10 g/mi of stringency through increased ZEV deployment as opposed to ICE control technologies. [EPA-HQ-OAR-2021-0208-0688-A1, p. 35-36]

Commenter: Environmental Law & Policy Center (ELPC), et al.

EPA must issue strong, technology-forcing standards for cars and light trucks to slash U.S. climate pollution. EPA itself notes that '[a] ddressing the climate crisis will require substantial reductions in GHG emissions from the transportation sector' and that we are in a 'pivotal moment.'[15] The climate crisis should leave no doubt that EPA should go beyond its proposed emissions standards. EPA must adopt its more stringent Alternative 2, which adopts the same stringency as 2012 standards in MY 2023–2025 and extends the same level of stringency to MY 2026.[16] [EPA-HQ-OAR-2021-0208-0567-A1, p. 3]

Because Alternative 2 is feasible, there is no reason for EPA not to adopt this alternative that achieves larger, urgently-needed climate benefits and greater consumer benefits. According to EPA’s analysis, Alternative 2 will result in greater net benefits than the proposed standards, including lower tail pipe carbon dioxide emissions, reduced upstream greenhouse gas emissions,[18] increased consumer savings, and other benefits.[19] [EPA-HQ-OAR-2021-0208-0567-A1, p. 3]

The technology 'requisite' to achieve the Alternative 2 standards already exists.[21] Adopting any weaker standards would run counter to EPA’s statutory mission to reduce pollution that endangers the public health and welfare. [EPA-HQ-OAR-2021-0208-0567-A1, p. 3]

EPA should also adopt the 10 g/mi greater stringency for MY 2026 on which the agency requested comments.[17] [EPA-HQ-OAR-2021-0208-0567-A1, p.3]

An increased 10 g/mi stringency in MY 2026 is also appropriate in light of both the greater 'lead time' available before MY 2026 and the accelerating transition to electric vehicles. [EPA-HQ-OAR-2021-0208-0567-A1, pp. 3-4]

Critically, gasoline-fueled light trucks dominate the new vehicle market.[23] These vehicles will be on the road, spewing climate-changing pollution well beyond 2030. Each year that automakers can exploit flexibilities to continue to sell polluting trucks with little to no change in greenhouse gas emissions undermines our ability to mitigate the climate crisis. In order to meet this moment in the climate crisis, EPA must adopt Alternative 2, adopt the additional 10 g/mi stringency in MY 2026, and eliminate flexibilities that are untethered to emissions reductions. [EPA-HQ-OAR-2021-0208-0567-A1, p. 4]

EPA makes clear that its proposed standards will be met with existing technology.[25] And loopholes will allow automakers to do more of the same with the climate paying the price. Adopting Alternative 2, along with the additional 10 g/mi stringency in MY 2026 and without the multipliers and other loopholes, will spur innovation, drive deployment of emissions-reducing technologies, and help sustain clean car manufacturing jobs across the Midwest and beyond. [EPA-HQ-OAR-2021-0208-0567-A1, p. 5]

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 291.]

In conclusion, EPA must strengthen and adopt Alternative 2 with at least the additional reduction in 10 gram per mile for Model Year 2026 while closing loopholes.

Commenter: Environmental Law and Policy Center (ELPC)

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 289.]

Second, EPA must issue strong technology-forcing standards for cars and light trucks. EPA itself notes that addressing the climate crisis will require substantial reductions in greenhouse gas emissions from the transportation sector and that we are in a pivotal moment.

We agree, and we appreciate that EPA is using its authority under the Clean Act to begin with Model Year 2023 and act separately from NHTSA, but the climate crisis can leave no doubt that EPA must adopt Alternative 2 with at least the 10 grams per mile increase in stringency for Model Year 2026.

EPA acknowledges that automakers were already planning for stronger standards and they should not be rewarded with anything less than Alternative 2.

Commenter: Environmental Protection Network (EPN)

The proposal should be seen as the minimum level of progress needed to lay a strong foundation for reaching the longer-term goals. EPA should seriously consider ways to strengthen the combination of standards and flexibilities so that greater progress is made in these four MYs [EPA-HQ-OAR-2021-0208-0213-A1, p.1]

While the standards proposed for these MYs would promote a real increase in zero-emissions vehicles from current levels, it is at best modest progress towards 50% electric power by MY 2030 and near 100% electric power by MY 2035. As we will discuss in Section II, there is no time to lose given the dire need to reduce GHGs from the transportation sector as part of addressing climate change and the compelling need for large reductions in nitrogen oxides (NOx) and particulate matter (PM).[EPA-HQ-OAR-2021-0208-0213-A1, p.1]

Proposed Standards and Flexibilities

The NPRM's analysis shows the combination of proposed standards and flexibilities are projected to result in about 8% EVs/PHEVs for MY 2026.22 While this is a real increase from current levels, it is at best modest progress towards 50% electric power by MY 2030 and near 100% electric power by MY 2035. The proposal should be seen as the minimum level of progress needed to lay a strong foundation for reaching the longer-term goals. EPA should seriously consider ways to strengthen the combination of standards and flexibilities so that greater progress is made in these four model years towards electric power for cars and light trucks. Any changes to the proposal should be in the direction of increased stringency and greater progress to electric power, not less stringency and less progress. [EPA-HQ-OAR-2021-0208-0213-A1, 9-10]

EPA adopted standards in 2012 for MYs 2023 to 2025 that are more stringent than those proposed in this rulemaking, and manufacturers have been on notice since 2012 of their obligation to prepare for the introduction of vehicles that meet those standards. In 2017 EPA confirmed the validity of those standards.

EPA withdrew this determination in 2018, however, EPA stipulates that this withdrawal was not final agency action and provided no more than a starting point for potential futurechanges. The 2018 withdrawal did not change any of the manufacturers' legal obligations. Manufacturers remained obligated to comply with the 2012 standards until EPA took final action in April of 2020, little more than a year ago. The revised standards adopted at that time were immediately litigated.

Given the manufacturers' expected five-year cycle of design and development and their continuous obligation to meet the 2012 standards until just over a year ago, it is quite reasonable for EPA to conclude that manufacturers will be producing and selling vehicles designed and developed to meet the 2012 standards for the first years of the proposed MY 2023 to 2026 program. Combined with the other evidence and analysis produced by EPA, it is clearly reasonable to conclude that the lead time provided for the proposed standards is reasonable and appropriate.

EPN recognizes the proposed 2023-2026 standards as an important building block to establishing the foundation for a strong 2035 rule. The proposal should be seen as the minimum level of progress needed to lay a strong foundation for reaching the longer-term goals. EPA should seriously consider ways to strengthen the combination of standards and flexibilities so that greater progress is made in these four model years towards zero-emissions cars and light trucks. As stated above, any changes to the proposal should be in the direction of increased stringency and greater progress to electric power, not less stringency and less progress. [EPA-HQ-OAR-2021-0208-0213-A1, p. 14]

Commenter: EOS at Federated Hermes (on behalf of its stewardship clients)

As long-term investors with over $2.723 trillion in assets under management, we are writing to express our support for strong light duty vehicle standards, and to urge you to adopt the most stringent proposed alternative - Alternative 2 - to strengthen the SAFE Part II regulations adopted in 2020. The U.S.' ability to meet climate goals, and the future competitiveness of the U.S. auto industry, are both contingent on strong vehicle standards as well as a rapid shift to low-emission and electric vehicles. Adopting standards at least as stringent as Alternative 2 will be necessary to effect this critical transition and to maximize economic benefits. [EPA-HQ-OAR-2021-0208-0568-A1, p. 1]

Commenter: Fleischer, Cara

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 47-48.]

All of this happened when the Obama/Biden vehicle emissions regulations were in effect. That is why I strongly feel that we need to not only return to those standards but to go further to cut vehicle emissions that are making us sick, causing thousands of deaths, and speeding up the climate crisis. The science is clear. The solutions are available, and the political will has risen to make climate action the top voting issue in the 2020 election.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 49.]

Creating strong vehicle emissions rules is a substantial step in showing the world that we are serious about doing our part to solve the climate crisis that our wealthy country played a large part in creating. There is no time to waste. The IPCC Report was as devastating as it was obvious.

Commenter: Fleming, Melinda

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 201.]

I'm terrified when I hear that even the strongest formal measures, like Alternative 2, are not really good enough. The reason this terrifies me the most is simple. Even if you build a bridge almost all the way, you might as well not have bothered because it simply won't do the job it was intended to do. We need to stop the atmosphere from heating up further. The EPA's rule for clean vehicle standards need to go all the way for us to cross the chasm of global warming.

Our margin for error has become so slim that we cannot afford half measures of any kind. This is why I urge the EPA to propose and implement the strongest rules possible to create the cleanest vehicles possible.

Commenter: Ford Motor Company

Ford supports EPA's proposal to increase the stringency of the SAFE standards. In the NPRM, along with the primary proposal, several alternatives are offered. We believe EPA's primary proposal - which would deliver similar overall GHG reductions as the California Framework Agreement - is the appropriate level of stringency. Similarly, the program flexibilities in the EPA proposal such as EV multipliers, off-cycle credits, and credits for full-size pickups provide essential regulatory support for the technologies that will be needed to enable future GHG reductions. [EPA-HQ-OAR-2021-0208-0294-A1, p.2]

EPA's proposal to revise the 2023-2026MY SAFE standards is an important step towards reducing lightduty GHG emissions, and more importantly, sets Industry on the right pathway to begin the transition to electrified vehicles. The transformation of the light-duty fleet toward zero-emissions will require unprecedented levels of ingenuity and investment to succeed. Over the last 10 years, rapid improvements in internal combustion engine (ICE) fuel efficiency and criteria emissions performance have been accomplished. Further improvements are possible, but will be marginal, and will come at high cost. Ford requests that the agencies carefully weigh these considerations in the current and future rulemakings to ensure that resources and investment are not diverted from our primary objective: fulfilling President Biden's goal of achieving 40-50% ZEV sales by 2030. [EPA-HQ-OAR-2021-0208-0294-A1, p.3]

Commenter: Gallagher, James A.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 263-264.]

Once again, I urge this Administration to set the strongest possible standards because they work. We should be making our cars and light-duty trucks even cleaner and more efficient.

I urge you to reinstate the earlier federal standards with your Alternative 2 and set even stronger ones for 2030, plus ensure there are no loopholes for automakers to get around these standards.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 260-261.]

I strongly support this Administration's swift action on clean cars but urge the EPA to adopt their second alternative which would deliver greater savings to consumers and eliminate unnecessary loopholes for automakers.

Commenter: Garcia Mann, Jackie

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 248.]

We need things even stricter than these proposed regulations. We need to move fast and people are ready to cooperate.

Commenter: General Motors LLC (GM)

GM acknowledges EPA's request for comment on a potential stringency increase of 5 to 10g/mi for the standards proposed for the 2026 model year. GM does not believe the current record includes sufficient technical analysis of this potential increase upon which to comment. GM believes that such analysis should include, among other things, (i) the likely impact of such an increase on BEV versus PHEV penetration in light of projected charging infrastructure expansion and consumer acceptance during the timeframe, and (ii) the impact of increased BEV versus PHEV penetration on United States' ability to meet its Nationally Determined Contribution under the Paris Agreement. GM would welcome the opportunity to provide additional comments if EPA chooses to supplement the proposal with sufficient technical analysis. [EPA-HQ-OAR-2021-0208-0234-A1][p.6]

Commenter: Gerber-Fligel, Gerri

As a parent, I support the strongest possible greenhouse gas emissions standards for cars and light trucks. The transportation sector is the largest source of climate pollution in the US. This could be done in the next two years; change has to start now , not in 2030. By then the climate will be totally destroyed as it is very damaged right now. Pass emergency legislation to clean up starting today.

EPA's proposal details several options. Withdraw the "preferred" alternative. It's not thorough and anyone who is allowed loopholes will find them. Enough is enough. [EPA-HQ-OAR-2021-0208-0698-A1, p. 1]

Commenter: Gersten, Dana

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 280.]

I'm here to urge the EPA to adopt the strongest possible clean air standards because my patients simply can't keep breathing dirty air and live healthy lives.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 282.]

The EPA needs to adopt its alternative standard and enact the strongest possible rule that has aggressive targets, no loopholes, and which puts us on the path to zero emission future.

Commenter: Gillet, Victoria

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 289.] So, if we -- strong solution protections for vehicles, like the one that's being proposed by the EPA right now, is a really important tool to facilitate this transition. Therefore, I strongly support strengthening the U.S. light-duty vehicle greenhouse gas emission standards because this change will make my patients and our country happier and healthier. That's what I have.

Commenter: Godwin, Nadine

New York's Governor Hochul on Sept. 9, 2021, signed a bill into law that requires all new passenger vehicles and light-duty trucks sold or leased in New York State to be in the zero-emissions category by 2035, and all medium and heavy-duty vehicles must achieve the zero emissions goal by 2045.

The EPA, in reconsidering car-emissions standards, should at least match the goals set by my home state.

In its current form, it falls short of that and falls short of what we need for this country, especially given the lost years under Donald Trump and given the wake-up call offered by the latest IPCC report. It is astonishing (to me) that the current proposal is not even as aggressive as a plan agreed to by carmakers in 2011 and approved in 2012.

Furthermore, the Alternative #2, while definitely preferable to the opening proposal here, doesn't work either because of the EPA envisions giving carmakers credits for making electric vehicles as some kind of offset to cutting emissions.

Forget such trade-offs. They undermine our chances to move as quickly as current technology allows to drastically cut and eventually eliminate greenhouse gas emissions from our cars and light-duty trucks. Why throw away our best opportunity when the technology is deliverable, something that carmakers themselves acknowledged when they agreed to the 2012 rules.

Please go after greenhouse gas emissions as aggressively as is feasible, based on known technology and other practicalities. And do not offer the envisioned EV credits to carmakers in the final rulemaking. Thank you [EPA-HQ-OAR-2021-0208-0381, p. 1]

Commenter: GreenLatinos

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 45-46.]

These new standards will continue to promote innovation throughout the automotive industry and will ensure that the U.S. remains an auto industry leader, but I urge you to keep these standards as originally designed to ensure the greatest reductions in oil use in global warming emissions and protect communities from pollution and emissions impacts.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 47.]

Strong standards can prevent this exposure and these completely unnecessary deaths. EPA must set the strongest possible federal clean car standards to ensure that we are protecting families from vehicle pollution, saving drivers' money at the pump and fighting climate change.

This means restoring standards to at least the levels set by the Obama/Biden Administration and even stronger than the Obama-era standards. By implementing the strongest possible fuel economy standards, the EPA would also be following through on its commitment to environmental justice because issuing stronger clean car standards will help address key transportation-related impacts of pollution.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 45.]

I thank this Administration for acting swiftly on clean cars but urge the EPA to create the strongest possible limits on vehicle pollution as it reconsiders the previous Administration's attacks on clean car standards.

Commenter: Haines, Meredith

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 113.]

I urge the EPA to adopt at a minimum the second alternative.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 114.]

The better news is there is at a minimum an Alternative 2.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 115.]

Just in conclusion, I urge you to reinstate the Obama/Biden standards with your Alternative 2 and set even stronger ones through 2030 and loopholes undermine the possibility of meeting our emissions reduction target and delay undermines the messages of urgency that should accompany all action.

Commenter: Hall, Marilyn

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 21.]

I urge the EPA to adopt the second alternative of this rule. That alternative would deliver greater savings to consumers and eliminate loopholes for automakers.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 22.]

This proposed rule, especially the EPA's second alternative, is an essential step towards slowing climate change. I urge you to move forward with the second alternative as the final rule.

Commenter: Hauptman, Elizabeth

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 242.]

I'm asking the EPA to implement the strongest vehicle pollution standards possible.

Commenter: Hewes, Celerah

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 108.]

The EPA must set the strongest possible federal clean car standards through 2026, avoiding loopholes, and putting automakers on track to meet ambitious pollution reduction goals.

Commenter: Holmgreen, Jack

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 42.]

Just to be clear, I support Proposal Number 2 in order to eliminate loopholes that the transportation industry will most certainly take advantage of, but with only the two proposals on the table, you're asking us do you want me to cut off both your hands or do you just want me to cut off one? Given those two choices, Number 2 is far superior. I'm asking you to consider a third choice. How about offering us the hand, one that doesn't do more harm than good?

Commenter: Holmgren, Doug

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 95.]

I, like many others, am speaking to urge the EPA to adopt Alternative 2.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 97.]

We cannot bow to the need to maximize profits in manufacturing industries. We know what is required to avoid more climate catastrophes. So let's just get on with it. Please adopt tighter standards now. I thank you for this opportunity to speak before you today.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 97.]

The EPA is requesting comment on whether or not to adopt a tighter five to 10 gram per mile greater stringency for Model Year '26 CO2 gram per mile target, the so-called Alternative 2. So here then is my comment. Given all that is happening around the world, why would we not adopt the most stringent CO2 requirement possible.

Commenter: Hyundai America Technical Center, Inc. (Hyundai)

Proposed GHG ramp

EPA has proposed an industry fleet-wide CO2 combined car and truck target of 171 grams per mile ('gpm') in the 2026 MY. EPA has additionally outlined two alternative standards: Alternative 1 is less stringent than the proposed standard (with a 2026 MY CO2 target of 177 gpm), and Alternative 2 is more stringent than the proposed standard (with a 2026 MY CO2 target of 169 gpm).

Hyundai supports the agency's middle-ground proposal for year-over-year improvements reaching 171 gpm CO2 in 2026 MY. The proposal will require an acceleration of electrification and, while very challenging, is reasonable in stringency. [EPA-HQ-OAR-2021-0208-0603-A1, p.7]

Commenter: Institute for Policy Integrity

EPA can rely on legislative and regulatory history to help justify its approach to lead time. Through history, Congress and EPA have balanced the availability of compliance options against the necessary lead time. When existing technologies and flexibilities readily enable compliance, EPA has discretion to determine that relatively shorter lead time is sufficient. [EPA-HQ-OAR-2021-0208-0299-A1, p. 1]

EPA argues that its proposed standards are preferable to Alternative 2 largely because 'EPA believes a lower level of stringency increase for 2023 may be appropriate taking into consideration lead time.'16 EPA has considerable discretion to balance multiple factors in assessing lead time, as the next section of these comments explores. But even if EPA believes that lead time considerations favor a less stringent standard for MY 2023, that logic does not necessarily extend beyond MY 2023. To the extent EPA believes it cannot adopt Alternative 2 due to lead time considerations, EPA should explore a new alternative that combines the proposed standards' target for MY 2023 with Alternative 2's emissions targets for MY 2024 and MY 2025, followed by the 5–10 g/mile increase for MY 2026. [EPA-HQ-OAR-2021-0208-0299-A1, p. 3]

EPA should select the alternative that will maximize net social welfare and promote distributional justice. EPA's analysis shows that Alternative 2 will generate $180 billion in net monetized benefits ($40 billion more than the proposed program), plus additional unmonetized benefits. Further analysis of the option to increase the stringency of MY 2026 standards will most likely reveal such increased stringency is cost-benefit justified as well. EPA also finds that increased standards will generally promote equity and so are appropriate. [EPA-HQ-OAR-2021-0208-0299-A1. p. 1]

Unlike the net costly SAFE 2 Rule, which would increase emissions and jeopardize public welfare, EPA's Proposed Rule will reduce emissions and increase net social welfare and so is justifiable. However, EPA's analysis shows that Alternative 2 would result in net monetized benefits nearly 30% higher than EPA's proposed standards,9 not to mention significant unmonetized climate, health, and environmental benefits that would likely further increase Alternative 2's advantages over the proposed program. (Note also that a variety of methodological changes, such as correcting the sales elasticity estimate as described below, could further strengthen the case in favor of Alternative 2.) Thus, following EPA's own interpretation of how best to balance the factors under Section 202, as well as principles for rational rulemaking under longstanding executive orders, EPA should select Alternative 2 to maximize net social welfare. [EPA-HQ-OAR-2021-0208-0299-A1. p. 2]

Notably, comparing technology costs to fuel savings also suggests that Alternative 2 may have greater net benefits for individual consumers.10 Given EPA's findings that lower-income families benefit more from net fuel savings,11 Alternative 2 should also advance equity goals. [EPA-HQ-OAR-2021-0208-0299-A1. p. 2]

While EPA has not analyzed the expected costs and benefits of making the MY 2026 standards more stringent by 5–10 grams/mile,12 this alternative would likely also result in even higher net benefits. EPA should conduct such an analysis, and if it finds that Alternative 2, with the additional 5–10 g/mile adjustment for MY 2026, would maximize net benefits and be most consistent with EPA's statutory directives to protect and enhance national air quality, and to promote public health and welfare,13 EPA should select that combination of policy options. EPA should similarly analyze the relative distributional effects of Alternative 2 plus the 5–10 g/mile increase for MY 2026 as compared to the Proposed Rule.14 [EPA-HQ-OAR-2021-0208-0299-A1. pp. 2-3]

10 Discounted at 3% over calendar years 2021–2050, the proposal has $210 billion in technology costs versus $250 in fuel savings (a difference of $40 billion), while Alternative 2 has $240 billion in technology costs versus $290 in fuel savings (a difference of $50 billion); at 7%, the proposal has $130 billion in technology costs versus $120 billion in fuel savings (-$10 billion), while Alternative 2 has $150 billion in technology costs versus $150 billion in fuel savings (even). EPA, Revised 2023 and Later Model Year Light-Duty Vehicle GHG Emissions Standards: Regulatory Impact Analysis at tbls.6-1, 6-3, 6-4, 6-6 (2021) [hereinafter "DRIA"]. Alternative 2 also has more consistently net-positive non-GHG emissions benefits. Compare id. at 7-26, tbl.7-5 (showing some years with net negative sums for the Proposed Rule), with id. at 7-28, tbl.7-7 (showing no such years for Alternative 2).

Commenter: Interfaith Power & Light (IPL)

I speak on behalf of our 40 state affiliates, more than 22,000 congregations, and more than 6.5 million people of faith who are a part of our national network, urging the Biden administration and the EPA to enact the strongest and boldest standards to reduce vehicle pollution, at least as stringent at those in Proposal 2. [EPA-HQ-OAR-2021-0208-0224-A1, p. 1]

Commenter: International Council on Clean Transportation

International Comparison

Figure 1 and 2 show the progression of global CO2 emission standards in major vehicle markets for passenger cars and light trucks respectively.32 The recent regulatory proposal in EU includes a new CO2 target value for new vehicles by 2035. From that year onward, manufacturers must ensure a 100% reduction in CO2 for their new passenger car and light commercial vehicle fleets compared to the 2021 standard. In plain language33, this corresponds to a phase out of new combustion engine light-duty vehicles in Europe by 2035. This proposal, once approved, will greatly drive global technology innovation and investment in zero emission transition. [Figures 1 and 2 can be found on pp. 19-20 of Docket number EPA-HQ-OAR-2021-0208-0522-A1]

As a result, the number of national and sub-national governments committed to fully end the sale or registration of new passenger cars equipped with an internal combustion engine (ICE) keeps growing. The national and sub-national governments listed in the map (Figure 3) made up 12% of the about 54 million global new passenger car sales in 2020.34 [Figure 3 can be found on p. 21 of Docket number EPA-HQ-OAR-2021-0208-0522-A1]

Figure 4 compares the passenger car EV market shares in the US, EU, and China. As of July 2021, the EV market share for passenger cars in the US is 3.5% compared with 16% in the EU and 12% in China. The sharp increase in EV sales in EU came about due to 2020-2021 vehicle CO2 standards, whereas the increase in EV sales in China is supported by a combination of vehicle fuel consumption standards and a new energy vehicle mandate.

Not only is the US lagging in terms of EV deployment, it is falling behind in terms of manufacturing of electric vehicles as well. From 2017 to 2020, the U.S. share of cumulative global electric vehicle production since 2010 decreased from 20% to 18%, while manufacturing increased in China and the EU, and the US share was supported largely by a single manufacturer36. If the US auto industry is to remain competitive globally then these trends reinforce the need for the United States to achieve the electric vehicle sales outlined by President Biden, providing a strong additional rationale for the feasibility of EPA increasing the stringency of 2026 GHG standards by 10gCO2/mile. [EPA-HQ-OAR-2021-0208-0522-A1, pp. 19-22; Figure 4 can be found on p. 22 of Docket number EPA-HQ-OAR-2021-0208-0522-A1]

As documented in the following sections, technology effectiveness and cost have continued to improve. Thus, if technology costs and benefits were updated with the latest information, it would show that the proposed standards and Alternative 2 are even more feasible and lower-cost than EPA's analysis indicates. [EPA-HQ-OAR-2021-0208-0522-A1, p. 4]

President Biden has outlined a target of 50% electric vehicle sales share by 2030. The proposed EPA standards may not ensure even 7.8% market share of electric vehicle sales by 2026, as conventional technology could be implemented at much higher rates than modeled for the proposed rule instead of increasing electric vehicle share to 7.8%. Increasing stringency of the 2026 standards by at least 10gCO2/mile will provide additional incentive for vehicle manufacturers to deploy electric drive vehicles beyond the agency's projection of 7.8%. [EPA-HQ-OAR-2021-0208-0522-A1, p. 4]

Since 2010 the U.S. share of global EV production has fallen, from 20% to 18%, and without intervention that trend will continue: a mere 15% of the $340 billion total investment global automakers have planned in EV manufacturing is presently destined for the United States. Strengthening the 2026 standards by 10gCO2/mile beyond the Alternative 2 would allow the United States to close some of this gap, and set stage for more ambitious post-2026 standards. Therefore, ICCT strongly supports adoption of final standards for MY 2026 that would reduce fleet average target levels by 10 gCO2/mile beyond Alternative 2. [EPA-HQ-OAR-2021-0208-0522-A1, p. 4]

ICCT agrees with both of EPA's observations, that MY 2026 stringency should be greater in keeping with the additional lead-time and the accelerating transition to electrified vehicles. However, the case for 5-10 gCO2/mile lower target levels goes far beyond these two issues.

Table 3 compares the technology penetration rates in the proposed rule (DRIA Table 4-24 on page 4-19) for 2026 versus 2023 and for proposed rule versus the no action scenario in 2026. There is little increase in conventional technology penetration, both for the proposal from 2023 to 2026 and from the no action scenario to the proposal. The 2026 proposed standard has significant increases in PHEV+BEV (4.2%) and HCR2 penetration (16%) over the 2023 proposed standards. However, other increases are modest (2% mild hybrids, 3% P2 hybrids, 3% HCR1, 1.2% weight reduction) and counteracting the improvements there is a 9% reduction in turbocharged engines plus modest reductions in GDI (-4%) and cylinder deactivation (-2%). Only 71% of 2026 vehicles under the proposed rule have plug-in, turbocharged, HCR, or hybrid technologies, meaning that over 30% of non-plugin vehicles use nothing beyond basic engine technology even by 2026.

The comparison of the 2026 proposed standard to the 2026 no action scenario is quite similar, as there are only modest differences between the 2023 proposed and 2026 no action technology penetration rates. [EPA-HQ-OAR-2021-0208-0522-A1; p. 17; The tables can be found on p. 17 of Docket number EPA-HQ-OAR-2021-0208-0522-A1]

Finally, President Biden has outlined a target of 50% electric vehicle sales share by 2030. The proposed EPA standards may not ensure even 7.8% market share of electric vehicle sales by 2026, as conventional technology could be implemented at much higher rates than modeled for the proposed rule instead of increasing electric vehicle share to 7.8%. Increasing stringency of the 2026 standards by at least 10gCO2/mile will provide additional incentive for vehicle manufacturers to deploy electric drive vehicles beyond the agency's projection of 7.8%. [EPA-HQ-OAR-2021-0208-0522-A1, p. 18]

Strengthening the 2026 standards by 10gCO2/mile beyond the Alternative 2 would allow the United States to close some of this gap, and set stage for more ambitious post-2026 standards. Therefore, ICCT strongly supports adoption of final standards for MY 2026 that would reduce fleet average target levels by 10 gCO2/mile. [EPA-HQ-OAR-2021-0208-0522-A1, pp. 18-19]

30 DRIA Table 4-24 did not include BEV+PHEV technology penetration for the No Action scenario. These were calculated from the 'technology_utilization_report.csv' file by adding together all the individual technology penetrations for the various reported PHEV and BEV configurations.

Without the additional 10gCO2/mile stringency in 2026, the standards for years 2027-2030 will have to be that much more ambitious in order to meet the target set by the President and achieve reductions of GHGs that are clearly feasible and consistent with EPA's statutory mandate. We note in the section below that the United States is already falling behind the European Union and China in terms stringency of greenhouse gas regulations as well as deployment of electric vehicles. [EPA-HQ-OAR-2021-0208-0522-A1, p. 18]

Commenter: International Union, United Automobile, Aerospace & Agricultural Implement Workers of America (UAW)

UAW does not support alternative proposals that increase stringency or reduce flexibilities, as raised in the request for comment, which would set standards that would have counter-productive impacts by setting unachievable targets. Automakers have been living under the current Safer Affordable Fuel Efficient (SAFE) Vehicles rules and need time to adapt to stronger standards. [EPA-HQ-OAR-2021-0208-0749-A1, p. 1]

The Environmental Protection Agency's Revised 2023-26 Model Year (MY) Light-Duty Vehicle Greenhouse Gas (GHG) Emissions Standards by and large strike the right balance of continuing to reduce automotive GHG emissions and encourage automakers to invest in new technologies that will benefit autoworkers and the economy. [EPA-HQ-OAR-2021-0208-0749-A1, p. 1]

UAW does not support alternative proposals that increase stringency or reduce flexibilities, as raised in the request for comment, which would set standards that would have counter-productive impacts by setting unachievable targets. Automakers have been living under the current Safer Affordable Fuel Efficient (SAFE) Vehicles rules and need time to adapt to stronger standards.

The auto industry is dynamic and complex, which requires flexible regulations and continual input from stakeholders. Over time, automakers have faced increasing challenges in adhering to emissions standards. And in recent years, we have seen how the auto industry can be impacted by a variety of factors, including consumer preference, fuel prices, global supply chains, and even public health. This is why the UAW has long held that emissions regulations must be responsive to conditions on the ground to ensure a robust domestic auto industry.

Commenter: Jaguar Land Rover North America, LLC (JLRNA)

As mentioned above, Jaguar Land Rover supports efforts to reduce GhG emissions and to transition to Zero Emission Vehicles. We agree that, to achieve this, the targets in the proposal must increase in stringency to accelerate this goal. We would, however, like to put forward some amendments to EPAs route map to achieve the proposed 26MY target as some of the assumptions made to model the future target stringency do not accurately reflect our business position.

Jaguar Land Rover understands the principal of the statement in the NPRM that the EPA 'do[es] not believe that automakers have significantly changed their product plans in response to the SAFE final rule issued in 2020'.

While automakers may not have changed plans solely in response to the SAFE2 final rule, the status of the SAFE2 rule, coupled with the impact of the global pandemic and accelerating electrification across the world, was a key consideration in Jaguar Land Rover’s decision to commit to a more ambitious long-term EV portfolio, as defined by Reimagine strategy. In order to launch a superior 'BEV first' architecture, Jaguar Land Rover relinquished a BEV 'capable' architecture (platform prioritizing ICE but could support BEV options) which has subsequent timing implications. While it was a difficult decision to make, the product strategy decisions related to our new Reimagine strategy will unquestionably accelerate Jaguar Land Rover’s electrified future and deliver against our science-based targets as outlined above.

Even with our commitment to electrification and a net zero carbon future, JLR believes that the targets proposed by the NPRM would require Jaguar Land Rover to make commercially unviable CO_2 reductions, which would require a 39 g/mi reduction in target from 20MY to 23MY. The transition period of 23MY to 26MY would be especially challenging considering the impact that Covid-19 and semiconductor shortage have inflicted on our product plan for the period. Given this situation, Jaguar Land Rover proposes that EPA consider an alternative compliance route aimed at creating a fairer standard for niche manufacturers. Similar approaches have had previous success through the Temporary Lead-Time Allowance Alternative Standard (TLAAS) and Alternative Compliance Schedule from 2012-2020 MY with minimal impact to overall fleet emissions but, importantly, delivering the same cumulate target reduction in GHG by 26MY.

Jaguar Land Rover proposes that Intermediate Volume Manufacturers (IVMs) who, individually, make up less than 1% of 2019 MY vehicle sales, can qualify for a new Alternative Compliance Schedule. This would allow smaller manufacturers, who, due to their smaller product portfolio, do not have the flexibility to respond to tougher GhG standards, a viable compliance route to 26MY targets. This would be a flexibility to comply with the federal GHG requirement with targets that decrease at the same annual percentage (around 6.5% decrease annually) as an alternative to the rates in the NPRM’s proposal. This would mean that the Alternative Compliance Schedule targets would rejoin the proposed federal targets in 26MY and be equivalent to projected average target levels set out below: [EPA-HQ-OAR-2021-0208-0269-A1, pp. 3-4] [The table can be found on p.4 of Docket number [EPA-HQ-OAR-2021-0208-0269-A1].

Although EPA did consider an alternative (Alternative 1) that is less stringent than the proposal, we believe that our proposal is preferential for our unique position as an alternative compliance path for IVMs for two key reasons:

1. It should result in fewer Tons of CO_2 emissions than Alternative 1 (without significantly impacting the overall US fleet)

2. It brings manufacturers in-line with the end point of the proposed targets in 26MY, to align with the administrations long term zero-emission goals

Below is a representation of our proposal against the NPRM proposal and Alternative 1: [EPA-HQ-OAR-2021-0208-0269-A1, p.4] [The tables can be found on p.4 of Docket number [EPA-HQ-OAR-2021-0208-0269-A1]

We believe this is a viable alternative proposal that will:

• Put Jaguar Land Rover, as a niche manufacturer, on a direct path to the proposed 26MY GHG level of stringency.

• Set targets that result in lower CO_2 Tons (area under the curve) for 23-26MY compared with EPA's Alternative 1

• Due to Jaguar Land Rover only making up 0.7% of the US fleet, will have a negligible impact on total US fleet emissions at a level much lower than previous similar programs (e.g. TLAAS).

• Enables more realistic CO_2 reduction targets for Jaguar Land Rover in order to focus on the required investments for our zero-emissions journey and our recently modified product portfolio. [EPA-HQ-OAR-2021-0208-0269-A1, p.5]

Summary & Conclusion

Jaguar Land Rover is in alignment with the objectives of the EPA and agrees that the standards must become more stringent to reduce greenhouse gas emissions. Despite the difficulties we have faced over the past year we are committed to investing in long-term CO_2 reductions and making a positive societal impact on our journey to net zero carbon emissions. The impact of the Covid-19 pandemic combined with the semiconductor shortage has and continues to have an adverse effect on the automotive industry and due to these events, Jaguar Land Rover has been forced to make difficult decisions to prioritize the near-term business results to secure funding for future investments in electrification strategies and emissions reduction technologies. [EPA-HQ-OAR-2021-0208-0269-A1, p.7]

Regarding the additional proposal to lower 26MY targets to be 5-10 g/mi lower than the current proposal, Jaguar Land Rover does not see this to be a viable proposal because:

• As acknowledged by the EPA, 23-26MY product plans have already been designed, reducing the options available to a manufacturer to be able to meet increased stringency targets in this time period.

• The previous targets issued by the EPA for 26MY have either been the 2012 Final Rule Makings (finalized under the Obama administration) 25MY target carried over or SAFE part 2 targets, both of which are significantly less stringent than the current 26MY level proposal.

• The loss of Advanced Technology Vehicle (ATV) credits at this point will make the transition to 26MY an even greater challenge, without additional stringency increases.

Based on the above points, Jaguar Land Rover considers it unrealistic for EPA to amend the 26MY targets to be any lower than is already proposed. [EPA-HQ-OAR-2021-0208-0269-A1, p.5]

JLR is inviting the EPA to consider our proposals on an alternative compliance route, to allow for our unique circumstances, starting in 23MY and aligning with national targets in 26MY. [EPA-HQ-OAR-2021-0208-0269-A1, p.7]

Commenter: Kansas Senator Marci Francisco

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 294.]

As an elected representative, I believe stronger federal safeguards on vehicle emissions would benefit my constituents. Addressing vehicle pollution by strengthening vehicle efficiency and encouraging hybrid electric vehicle technology falls squarely in the EPA's mission.

Strengthened standards and a path to 60 percent vehicle emission reduction and a 50 percent electric vehicle fleet by 2030 should spur economic growth and public health protections.

Commenter: Klein, Stephanie

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 281-282.]

EPA has an important job in setting pollution limits for cars, but we must also go further to address the climate crisis by moving decisively to zero pollution vehicles. In order to set us on the path to 100 percent zero emissions new vehicles by 2035, the near-term standards for climate pollution must be as strong as possible.

On behalf of Moms Clean Air Force's more than 3,000 members in Washington, D.C., I urge EPA to finalize the strongest option possible.

Commenter: Kuntz, Laurie

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 209.]

We must enact the strongest fuel economy standards possible and support incentives and infrastructure for electric vehicles in order to achieve this.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 210.]

I do support the EPA's Alternative 2 in the proposed rule since it would eliminate many loopholes and would impose stronger standards for automakers.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 208.]

I support this Administration's swift action on clean cars but urge the EPA to adopt the second alternative.

Commenter: Levison, Laura

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 234.]

I request that EPA and NHTSA make the clean air standards much stronger than you have proposed in the draft rule. As we know, the transportation sector is now the largest source of greenhouse gas emissions in the U.S.

Commenter: Lish, Christopher

I applaud your efforts to cut back on U.S. vehicle emissions and chart a course towards a future with net-zero emissions from transportation, but I'm afraid they don't go far enough. I strongly urge that you select the more stringent "Alternative #2" option for greenhouse gas reductions as detailed in your proposed clean car standards and to go beyond it. [EPA-HQ-OAR-2021-0208-0218-A1, p. 1]

While the standards recently proposed by the Environmental Protection Agency are an important step forward, they unfortunately stop short of the ambition we need. They're riddled with loopholes and giveaways to automakers that undermine Page 2 of 3 otherwise strong pollution reduction targets, rely on unenforceable and unreliable promises by automakers, and fail to require the emissions cuts needed to protect our communities and the climate. [EPA-HQ-OAR-2021-0208-0218-A1, p. 1-2]

While this proposal is certainly an improvement on the regressive policies of the previous administration, it falls far short of what scientists say is needed and the Administration's promises on climate. It fails to achieve the greenhouse gas reductions necessary to meet the Intergovernmental Panel on Climate Change's targets of 45 percent by 2030 and zero emissions by 2050, or for that matter to meet U.S. commitments under the Paris Agreement. And it fails to require automakers to meet President Biden's goal of 50 percent zero emission vehicle (ZEV) sales by 2030 (a target that, itself, is far too lax). [EPA-HQ-OAR-2021-0208-0218-A1, p. 2]

Among the options presented, I urge you to choose the much more effective Alternative #2, with one important caveat: We cannot wait any longer to begin requiring automakers to sell ZEVs—and to get them working toward 100 percent ZEVs by 2030, which is what's necessary to meet science-based climate targets. I urge you to strengthen this rule to put us on track to make all new cars and light-duty trucks zero-emission vehicles no later than 2030 and ensure all new trucks and buses are zero-emission no later than 2040. In the coming weeks, I urge you to strengthen the toughest option the Environmental Protection Agency has considered for short-term auto pollution rules and adopt it. [EPA-HQ-OAR-2021-0208-0218-A1, p. 2]

Automakers already have the technology to safely reduce emissions. Given that the market for EVs in the U.S. has already doubled from 2% in 2020 to nearly 4% in 2021, automakers in this country should have no problem meeting these requirements, and in fact, it's reasonable to assume that even more stringent reductions can easily be achieved by Model Year 2026.

And consumers will save more at the pump than these technologies cost. Strong vehicle standards are a win for our environment, public health, public lands such as parks, and the economy. They are one of America's greatest opportunities to cut deadly pollution, save consumers money at the pump, create good jobs, and ensure the global competitiveness of the U.S. auto industry.

When the Obama administration introduced the first clean car standards, they were the most significant climate rules in U.S. history. The climate crisis has only become more dire and to meet the moment—it's not enough to simply reverse the preceding administration's damage. The world's scientists tell us we have a rapidly closing window to prevent the most catastrophic impacts of climate change. As such, nothing short of the strongest possible clean car standards will deliver the carbon reductions that President Biden has promised the country and the world. We are counting on you to strengthen these common-sense standards and accelerate our transition to a zeroemissions transportation future.

Please adopt at least the Environmental Protection Agency's Alternative #2 and a stronger fuel economy standard to drive much-needed short-term cuts in emissions and put us on the road to the goal of reaching 100% net-zero vehicle sales by 2030. I implore you to heed the dire warnings of the U.N. Intergovernmental Panel on Climate Change's new report and to strengthen clean car and fuel economy standards to ensure that our country can reach its climate goals. Now's the time for strong rules—not halfmeasures. It is time to hold car manufacturers accountable. I urge you to create the best clean car standards in the world. [EPA-HQ-OAR-2021-0208-0218-A1, p. 3]

In this rulemaking, adopt Alternative #2 through model year 2025. [EPA-HQ-OAR-2021-0208-0218-A1, p. 2]

Commenter: Lucid USA, Inc. (Lucid)

Lucid supports EPA's proposal to issue GHG standards for model years 2023-2026 that are more stringent than the present standards that were issued by the Trump Administration. We believe that the coming production of EVs by all manufacturers will enable everyone to meet even greater stringency than has been proposed in the NPRM. Accordingly, we support recommendations to increase the stringency of the proposed standards. In particular, we support the adoption of the stringency proposed in Alternative 2 in the NPRM.[EPA-HQ-OAR-2021-0208-0528-A1, p. 5]

Furthermore, the stringency of the proposed standards in the NPRM is insufficient to achieve President Biden's goal of 50% EV sales by 2030, announced in the August 2021 Executive Order. It will be too late to begin that transition to EVs with the next round of rulemaking starting with MY2027. The proposed standards are based on the assumption of only 8% EV penetration by MY2026. We believe that more stringent standards can encourage a higher rate of EV penetration by MY 2026. [EPA-HQ-OAR-2021-0208-0528-A1, p. 5]

With regard to the request for comments on increasing stringency for MY 2026, Lucid supports standards with at least 10 g/mi greater stringency. Although increased stringency can be achieved through improvements in ICE technologies, greater production and sales of EVs provide manufacturers a straightforward path to compliance with greater stringency. [EPA-HQ-OAR-2021-0208-0528-A1, p.5]

Commenter: Lynch, Vanessa

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 192.]

I'm asking the Environmental Protection Agency to choose the strongest option for their Late Model Light-Duty Greenhouse Gas Emissions Standard which avoids all loopholes for automakers.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 193.]

In order to set us on the path to 100 percent zero emissions new vehicle sales by 2035, the near-term standards for climate pollution must be as strong as possible and in order to protect families like mine from the most dire impacts of climate change, the Environmental Protection Agency must take bold and ambitious action at every opportunity to protect our children's health and future.

Commenter: Maine Department of Environmental Protection

Given the technological advancements, widespread commitments to electrification, and programs such as the ACC standards, EPA should maximize the proposal's environmental benefits by adopting final standards consistent with those provided in its 2012 national program. In the 2023 LDV proposal, EPA modeled three alternative regulatory scenarios, with 'Alternative 2' providing the greatest net benefit. Alternative 2, along with a more stringent standard for 2026 would most closely approach the GHG and criteria pollutant emission reduction benefits provided by EPA's 2012 standards. [EPA-HQ-OAR-2021-0208-0225-A1, p.2]

In closing, the 2023 LDV Proposal is an important step towards providing the significant GHG motor vehicle emissions reductions necessary to mitigate the climate crisis. Since the proposed GHG standards can be easily achieved with existing technologies that are already in widespread use, the Department encourages EPA to adopt the most stringent feasible GHG emission standards for model year 2023-2026 LDVs, and consider aligning future programs with efforts already underway in California and the Section 177 states. [EPA-HQ-OAR-2021-0208-0225-A1, p.2]

Commenter: Manufacturers of Emission Controls Association (MECA)

MECA enthusiastically supports EPA's reconsideration of the 2023-2026 light-duty GHG standards and the agency's preferred alternative for standards through MY 2026. [EPA-HQ-OAR-2021-0208-0261-A1, p.1]

Commenter: Marcot, Nicole

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 158-159.]

Given that the transportation sector is the largest source of carbon pollution in the U.S., cleaning up vehicle pollution is one of the most important things we can do to fight climate change.

I'm urging EPA to set the strongest possible federal clean car standards through 2026, avoiding loopholes and putting automakers on track to meet ambitious pollution reduction goals.

Commenter: Maryland Department of Environment

MDE agrees with the National Association of Clean Air Agencies (NACAA) recommendation that 'EPA should return to a national program that maintains the authority preserved to California and other states under the Clean Air Act… and should adopt standards sufficiently stringent to, at a minimum, achieve the same level of emission benefits as under the standards adopted in the 2012 rule…EPA's Alternative 2, augmented with a MY 2026 standard that is 10 grams/mile more stringent, comes the closest to NACAA's recommendation of adopting standards sufficiently stringent to, at a minimum, achieve the same level of emission benefits as under the final standards adopted under the 2012 rule.' [EPA-HQ-OAR-2021-0208-0241-A1, p.1]

Commenter: Mass Comment Campaign sponsored by American Lung Association (121)

We urge the U.S. Environmental Protection Agency to set strong greenhouse gas standards for light-duty vehicles that drive the transition to a zero-emission future. [EPA-HQ-OAR-2021-0208-0559-A1, p.1]

Please finalize near-term greenhouse gas standards for light-duty vehicles that are at least as strong as the standards that the SAFE rule replaced. [EPA-HQ-OAR-2021-0208-0559-A1, p.1]

Commenter: Mass Comment Campaign sponsored by Center for Biological Diversity (77,692)

Your proposed clean car rules miss the mark. They're riddled with loopholes, rely on unenforceable and unreliable promises by automakers, and fail to require the emissions cuts needed to protect our communities and the climate. In the coming weeks, I urge you to strengthen the toughest option the Environmental Protection Agency has considered for short-term auto pollution rules and adopt it. Then, to drive real progress, [EPA-HQ-OAR-2021-0208-0560-A1, p.1]

Automakers already have the technology to safely reduce emissions. And consumers will save more at the pump than these technologies cost. Now's the time for strong rules — not half-measures. I urge you to create the best clean car standards in the world. [EPA-HQ-OAR-2021-0208-0560-A1, p.1]

Commenter: Mass Comment Campaign sponsored by Consumer Reports (19,038)

Automakers already agreed to standards stronger than the current proposal almost a decade ago. The Administration must shift to stronger standards to hold the auto industry accountable, and ensure automakers take responsibility for their role in reducing climate-damaging pollution. [EPA-HQ-OAR-2021-0208-0602-A2, p.1]

Commenter: Mass Comment Campaign sponsored by Environment America (11,080)

The proposed rule is not as strong as the original Obama-Biden standard and is riddled with loopholes and giveaways to automakers that undermine otherwise strong emissions reduction targets. [EPA-HQ-OAR-2021-0208-0557-A1, p.2]

Given the above, we urge the EPA to set the strongest standards possible. At a minimum the EPA should reinstate the Obama-Biden era standards, [EPA-HQ-OAR-2021-0208-0557-A1, p.2]

The EPA should implement the strongest clean cars rule possible to effectively solve the climate crisis and protect public health. At a minimum, the EPA should reinstate the Obama-Biden era standards and ideally make them even stronger. [EPA-HQ-OAR-2021-0208-0557-A2, p.1]

This proposed rule is not as strong as the Obama-Biden standards and is riddled with loopholes and giveaways to automakers that undermine otherwise strong emissions reduction targets. [EPA-HQ-OAR-2021-0208-0557-A2, p.1]

The EPA itself has identified a far more effective rule (Alternative #2), which would put 400,000 extra electric vehicles on the road by 2026 and result in 130 million metric tons fewer greenhouse gas emissions. [EPA-HQ-OAR-2021-0208-0557-A1, p.2]

Environment America has collected 11,080 signatures calling for the adoption of the stricter standards detailed in Alternative #2. We ask that these names be entered into the official record and considered as separate public comments. [EPA-HQ-OAR-2021-0208-0557-A1, p.2]

but in order to effectively combat climate change and to enhance public health, the EPA should adopt Alternative #2. [EPA-HQ-OAR-2021-0208-0557-A1, p.2]

The EPA itself has identified a far more effective rule (Alternative #2), which would put 400,000 extra electric vehicles on the road by 2026 and result in 130 million fewer metric tons of greenhouse gas emissions. I urge you to adopt Alternative #2 to help clean our air. [EPA-HQ-OAR-2021-0208-0557-A2, p.1]

Commenter: Mass Comment Campaign sponsored by Interfaith Power & Light (1,093)

The Biden administration made a promise for bold investments in climate, jobs and justice as well as to electrify the transportation sector for all. As a person of faith and conscience, I am writing to ask you to enact the boldest and strongest possible clean car standards. [EPA-HQ-OAR-2021-0208-0553-A1, p.2]

The recently released draft rule is not strong enough. I am asking you to revise the standards beyond levels set during the Obama-Biden administration and put the nation on a trajectory to 100% electric cars and light trucks no later than 2035. This requires at least 60% to be electric by 2030. The EPA must also maximize emissions reductions and not allow loopholes to undermine this progress. [EPA-HQ-OAR-2021-0208-0553-A1,p.2]

This is a moral opportunity to follow the science and rapidly make the emissions reductions we know are necessary. It is possible and it can be done in a way that is beneficial to our country and to the world. [EPA-HQ-OAR-2021-0208-0553-A1,p.2]

Commenter: Mass Comment Campaign sponsored by Interfaith Power and Light et al. (1,599)

As religious leaders, we urge you to enact the strongest possible standards to reduce vehicle pollution. We ask that you:

• Restore national standards and revise them beyond levels set during the Obama-Biden administration; [EPA-HQ-OAR-2021-0208-0192-A1, p.2]

Commenter: Mass Comment Campaign sponsored by National Religious Partnership for the Environment-GA (563)

The Environmental Protection Agency has an opportunity to help address the injustice of pollution and climate change by enacting the strongest possible federal clean car standards. Since transportation is the largest source of carbon emissions in the US, strong fuel economy standards will protect families from vehicle pollution, save drivers money at the pump, and fight climate change. The standards EPA sets should achieve 100 percent zero-emission vehicles in by 2035. [EPA-HQ-OAR-2021-0208-0554-A1, p.1]

This means restoring standards at least to levels set during the Obama-Biden administration and ideally even stronger than Obama era standards. [EPA-HQ-OAR-2021-0208-0554-A1, p.1]

Commenter: Mass Comment Campaign sponsored by National Religious Partnership for the Environment-MN (92)

The Environmental Protection Agency has an opportunity to help address the injustice of pollution and climate change by enacting the strongest possible federal clean car standards. Since transportation is the largest source of carbon emissions in the US, strong fuel economy standards will protect families from vehicle pollution, save drivers money at the pump, and fight climate change. The standards EPA sets should achieve 100 percent zero-emission vehicles in by 2035. [EPA-HQ-OAR-2021-0208-0556-A1, p.1]

This means restoring standards at least to levels set during the Obama-Biden administration and ideally even stronger than Obama era standards. [EPA-HQ-OAR-2021-0208-0556-A1,p.1]

The standards EPA sets should achieve 100 percent zero-emission vehicles in by 2035. [EPA-HQ-OAR-2021-0208-0555-A1, p.1]

This means restoring standards at least to levels set during the Obama-Biden administration and ideally even stronger than Obama era standards. [EPA-HQ-OAR-2021-0208-0555-A1, p.1]

Commenter: Mass Comment Campaign sponsored by Natural Resources Defense Council (NRDC) (26,929)

Furthermore, your proposed rules deliver fewer carbon pollution reductions and fuel savings than the Obama-era standards. [EPA-HQ-OAR-2021-0208-0558, p.1]

We applaud President Biden's executive order mandating that 50% of vehicle sales be zero-emission vehicles by 2030. [EPA-HQ-OAR-2021-0208-0558,p.1]

We implore you to heed the dire warnings of the U.N. Intergovernmental Panel on Climate Change's new report and strengthen clean car and fuel economy standards to ensure that our country can reach its climate goals. [EPA-HQ-OAR-2021-0208-0558,p.1]

Please accept these 26,929 public comments from members and online activists of the Natural Resources Defense Council (NRDC), calling on the Biden administration to heed our growing calls for major climate action by going bigger on clean car and fuel economy standards before it's too late. [EPA-HQ-OAR-2021-0208-0558, p.1]

We applaud your efforts to cut back on U.S. vehicle emissions and chart a course towards a future with net-zero emissions from transportation, but we are afraid they don't go far enough. [EPA-HQ-OAR-2021-0208-0558, p.1]

Please adopt at least EPA's Alternative #2 and a stronger fuel economy standard to drive much-needed short-term cuts in emissions and put us on the road to the goal of reaching 100% net-zero vehicle sales by 2035. [EPA-HQ-OAR-2021-0208-0558,p.1]

Commenter: Mass Comment Campaign sponsored by Sierra Club (13,699)

We need even stronger policies on vehicle emissions! To have any hope of a livable planet for our children and grandchildren, EPA must establish much stronger policies that set us on a rapid path to electrifying all cars and light-duty trucks. We appreciate President Biden making cleaner cars a day-one priority and EPA moving quickly to propose a new regulation. However, our communities and our planet require a bolder standard that will deliver real world emissions reductions that match the urgency of the climate crisis. [EPA-HQ-OAR-2021-0208-0196-A1, p.1]

Despite the enormous technological progress in the auto industry, including on electric and hybrid vehicle technology and the extensive plans for electrification announced by many of the major automakers, the proposed EPA standards would unfortunately move us backward from where we were nine years ago. As climate disasters affect huge portions of our country and the global community, we need to make up for lost time from the previous administration's rollback. EPA must set the light-duty vehicle fleet on a course to reach at least 60 percent annual zero emission vehicles sales by 2030 so that we can achieve 100 percent zero emission vehicle sales no later than 2035. [EPA-HQ-OAR-2021-0208-0196-A1,p.1]

EPA must strengthen the final rule by accelerating the trajectory towards pollution-free vehicles and eliminating the credit scheme. [EPA-HQ-OAR-2021-0208-0196-A1, p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-1 (7,010)

As a member of the League of Conservation Voters, I am writing to ask you to support strong clean car standards and to require that all new vehicles sold by 2035 be zero emission vehicles. [EPA-HQ-OAR-2021-0208-0545, p.1]

I also welcome the Presidents commitment to a 50 percent reduction in carbon pollution from new cars by 2030, coupled with urgently needed action by Congress to ensure adequate investments in electric vehicles and clean energy. [EPA-HQ-OAR-2021-0208-0545, p.1]

As the EPA works to finalize new vehicle emissions standards, I ask that these and future standards are even stronger than those announced by President Biden and are developed to ensure that all new cars sold are zero emission vehicles by 2035. Now is the time to set the strongest possible clean car standards to meet the climate ambition goals that science and justice require. [EPA-HQ-OAR-2021-0208-0545, p.1]

Due to these considerations, I am asking for your consideration of strong vehicle emissions standards that would require all new vehicles sold by 2035 be zero emission vehicles. [EPA-HQ-OAR-2021-0208-0545, p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-10 (2,832)

We need 100% of new car sales to be zero-emissions by 2035. To reach that goal, the near-term standards for climate pollution must be as strong as possible, as soon as possible. Please finalize the strongest possible climate pollution limits on cars and light trucks, to help protect our children's health and future from the climate crisis. [EPA-HQ-OAR-2021-0208-0641-A1, p.1]

EPA's proposal details several options. The "preferred" alternative includes loopholes for automakers that may undermine the pollution reduction targets. Alternative 2 is the stronger option that would reduce climate pollution faster, putting 400,000 extra electric vehicles on the road by 2026 and resulting in 130 million metric tons fewer greenhouse gas emissions, among other significant benefits, including billions in economic benefits. Alternative 2 is the better option. [EPA-HQ-OAR-2021-0208-0641-A1, p.1]

As a parent, I am writing in support of the strongest possible greenhouse gas emissions standards for cars and light trucks. The transportation sector is the largest source of climate pollution in the US, and cleaning up this pollution is one of the most important things we can do to fight climate change. [EPA-HQ-OAR-2021-0208-0641-A1, p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-11 (1,667)

Passenger vehicles are one of the largest sources of climate pollution in the U.S. To combat this threat, the Biden administration must move forward with the strongest possible federal clean car standards. The standards adopted should achieve at least the same total emission reductions as those undertaken by the Obama-Biden administration and should not contain needless credits or other loopholes that reward automakers for reductions that aren't matched in the real world. [EPA-HQ-OAR-2021-0208-0642-A1, p.1]

It is time to hold car manufacturers accountable and move forward with the strongest possible clean car standards. [EPA-HQ-OAR-2021-0208-0642-A1, p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-2 (2,214)

Hello, I am a member of Public Citizen and I am writing to urge the Biden administration to adopt the strongest possible clean car standards as part of its commitment to tackle the climate crisis, particularly in addressing transportation sector emissions, the biggest contributor to U.S. greenhouse gas (GHG) pollution. [EPA-HQ-OAR-2021-0208-0546, p.1] From its first day in office, the Biden administration promised to reinstate strong clean car standards and take bold steps to address transportation sector emissions. Unfortunately, the Biden EPA has put forth a preferred option that is not even as strong as the Obama-Biden standard from 2012, and is riddled with loopholes and giveaways to automakers that undermine otherwise strong pollution reduction targets. [EPA-HQ-OAR-2021-0208-0546, p.1]

While this proposal is certainly an improvement on the regressive policies of the previous administration, it falls far short of what scientists say is needed and the Administration's promises on climate. It fails to achieve the greenhouse gas reductions necessary to meet the Intergovernmental Panel on Climate Change's targets of 45 percent by 2030 and zero emissions by 2050, or for that matter to meet U.S. commitments under the Paris Agreement. And it fails to require automakers to meet President Biden's goal of 50 percent zero emission vehicle (ZEV) sales by 2030 (a target that, itself, is far too lax). [EPA-HQ-OAR-2021-0208-0546, p.1]

THE PLANET IS ON FIRE!!!! The recent IPCC report made clear that we really do not have time for half measures and lackluster commitment to reversing carbon emissions. President Biden needs to stop just talking the talk, hoping that everyone will approve of his work and yet doing little overall to protect the planet: he needs to start walking the walk. It is already too late to reverse some of the effects of this crisis, so we cannot wait, otherwise why bother doing anything? [EPA-HQ-OAR-2021-0208-0546, p.1]

The world's scientists tell us we have a rapidly closing window to prevent the most catastrophic impacts of climate change. As such, nothing short of the strongest possible clean car standards will deliver the carbon reductions that President Biden has promised the country and the world. [EPA-HQ-OAR-2021-0208-0546, p.1]

Among the options presented, I urge you to choose the much more effective Alternative #2, with one important caveat: We cannot wait any longer to begin requiring automakers to sell ZEVs—

and to get them working toward 100 percent ZEVs by 2030, which is what's necessary to meet science-based climate targets. I urge the following steps:

1) In this rulemaking, adopt Alternative #2 through model year 2025.

2) Supplement this proposal with another, to be finalized before the end of 2022, that sets a ZEV mandate for model year 2026 consistent with a pathway toward requiring 100 percent of new vehicles to be ZEVs by 2030. [EPA-HQ-OAR-2021-0208-0546, p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-3 (2,178)

I would also urge you to immediately start work on an even stronger set of clean car standards for cars manufactured starting in Model Year 2026 that can send a strong signal to industry that a transition is underway to achieve 100 percent zero-emission new vehicle sales by no later than 2035 and net-zero GHG pollution economy-wide by 2050. [EPA-HQ-OAR-2021-0208-0547, p.1]

America has always led the way in most things and we should be leading the way on green energy, not following behind China. Companies can make as much if not more with clean green energy. [EPA-HQ-OAR-2021-0208-0547, p.1]

I am urging you to choose the much more effective Alternative #2, which would put 400,000 extra electric vehicles on the road by 2026 and result in 130 million metric tons fewer greenhouse gas emissions. [EPA-HQ-OAR-2021-0208-0547,p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-4 (195)

Please adopt the strongest possible standards against greenhouse gases and all pollution for motor vehicles. If these are "expensive", all the better to switch our lifestyles to active and public transportation more quickly. Personal motor vehicles, even electric ones, will be responsible for the extinction of our species! [EPA-HQ-OAR-2021-0208-0548, p.1]

I am writing to ask the EPA to finalize and implement the strongest possible greenhouse gas emissions standards for model years2023-2026 cars and light trucks. [EPA-HQ-OAR-2021-0208-0548, p.1]

The EPA must take this opportunity to put the auto industry on the path to cleaner vehicles by adopting Alternative 2 in the proposed rule. This stronger standard will result in greater benefits, including lower tailpipe p greenhouse gas emissions, increased consumer savings, and other benefits [EPA-HQ-OAR-2021-0208-0548, p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-6 (39)

Passenger vehicles are one of the largest sources of climate pollution in the U.S. To combat this threat, the Biden administration must move forward with the strongest possible federal greenhouse gas and fuel-efficiency standards for cars and light trucks. [EPA-HQ-OAR-2021-0208-0550, p.1]

Any standards adopted should achieve at least the same total emission reductions as those undertaken by the Obama-Biden administration and should not contain needless credits or other loopholes that reward automakers for reductions that arent matched in the real world. [EPA-HQ-OAR-2021-0208-0550, p.1]

Enacting more stringent clean car standards will provide numerous co-benefits for people and parks from saving Americans billions at the pump, to preventing unhealthy vehicle air pollution that severely harms public health and the wellbeing of park ecosystems. [EPA-HQ-OAR-2021-0208-0550, p.1]

It is time to hold car manufacturers accountable and move forward with the strongest possible clean car standards. [EPA-HQ-OAR-2021-0208-0550, p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-7 (37)

I urge the U.S. Environmental Protection Agency to set strong greenhouse gas standards for light-duty vehicles that protect health and accelerate a transition to zero-emitting vehicles. [EPA-HQ-OAR-2021-0208-0551, p.1]

Please finalize near-term greenhouse gas standards that will achieve emissions reductions to at least equal to standards finalized during the Obama Administration. [EPA-HQ-OAR-2021-0208-0551, p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-8 (25)

EPA’s proposed rules do not require automakers to make sufficient progress toward replacing fossil fueled vehicles at the pace needed to achieve IPCC targets for 2030 and 2050. [EPA-HQ-OAR-2021-0208-0552, p.1]

The proposal is not even adequate to achieve the 50% zero emissions vehicle (ZEV) sales target by 2030 established by President Biden’s Executive Order of January 21, 2021. [EPA-HQ-OAR-2021-0208-0552, p.1]

Indeed, in order to achieve a zero emission economy by 2050, the stated goal of the Executive Order, the rule should mandate a regulatory framework to transition all automakers to 100% ZEVs by 2030. [EPA-HQ-OAR-2021-0208-0552, p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-9 (3,219)

EPA’s proposed rule to strengthen federal greenhouse gas (GHG) emissions standards for passenger cars and light trucks is a necessary step to address the climate crisis and protect our communities from harmful air pollution. But it is not enough. Please restore American leadership on climate by promulgating strong standards to eliminate pollution from all passenger vehicles. Together, we can protect Americans’ health, the climate, and our pocketbooks. [EPA-HQ-OAR-2021-0208-0640-A1, p.1]

Commenter: Mathews, Mary

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 257-258.]

The previous Administration's rollback of clean car rules curtailed progress in improving air quality and moderating climate change. To make up for lost time for Waukegan and for all of our communities, the League of Women Voters of Lake County calls for standards that are at a minimum as strong as those finalized in 2012 and without any loopholes and give-aways to automakers. Stricter fuel efficiency standards coupled with greenhouse gas reductions standards, and enforceable requirements are needed. Reducing carbon pollution and fighting climate change must be a top priority for the EPA. The League of Women Voters of Lake County requests the clean car standards be the strongest possible and effective as soon as possible to protect public health and combat the climate crisis. Let's move to zero emissions before it is too late.

Commenter: McQuire, Terry

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 222.]

I urge you to move as quickly as possible to finalize the strongest possible cleaner car standards.

Our communities can't take any more air pollution and we need EPA to act. Cleaner car standards that move us closer to zero emissions vehicles will have the added benefit of reducing other dangerous air pollutants.

Commenter: Melton, Karen

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 252-253.]

I do appreciate that this Administration is acting to re-implement clean car standards but ask the EPA to create the strongest possible limits on vehicle pollution. These limits had already gone through the technical review process. They will ensure the greatest reductions in oil use and global warming emissions.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 254.]

Alternative Number 2 is the better proposal in this regard.

Once again, I urge this Administration to set the strongest standards to make cars and light-duty trucks more efficient by going back to at least the Obama standards.

Commenter: Mercedes-Benz USA, LLC

Mercedes-Benz supports year-over-year stringency improvements in greenhouse gas (GHG) standards. The standards proposed in 2012 required dependency on credit accrual while transitioning fleets to zero-emission vehicles. Although the 2012 program offered incentives during its early phases, many incentive opportunities phase-out by later years of the program, MYs2022-2025. At the time of the 2012 proposal, the agencies slated electric vehicles for mass deployment by the end of MY2025. Instead, industry still sees stalled electric vehicle adoption, largely due to inadequate infrastructure and lack of consumer acceptance.

Mercedes-Benz intends to address two main points. First, the EPA’s proposed target for MY2023 tightens the stringency to ~10% less GHG emissions relative to MY2022. This jump will be challenging to meet, especially in light of EPA's previous proposal which proposed a significant relaxation of the standards. These types of stringency improvements require significant changeover within the US automotive fleet, and given Mercedes-Benz's existing widespread adoption of incremental technologies, the next step to meet these standards is full electrification. Full electric transition requires complementary programs to support EV adoption, including infrastructure demands, financial incentives, state and local investments, and policies which support the transition to a zero-emission future. [EPA-HQ-OAR-2021-0208-0523-A1, p.3]

Mercedes-Benz supports EPA's proposal to tighten greenhouse gas standards through MY 2026 and encourages EPA to adopt the preferred pathway. [EPA-HQ-OAR-2021-0208-0523-A1, p. 2]

Second, EPA requests comment on an alternative which by MY2026 is 5-10% more aggressive than the proposed target for MY2026. EPA's proposal already presumes that the lead-time is sufficient to make a great leap in compliance stringency in MY2023. In view of the clear evidence suggesting that full-electric changeover is required to comply with the proposed standards in later model years, we urge the agency to consider that for successful EV deployment, the EV market must have complementary policies in place for EV infrastructure and incentives. Mercedes-Benz supports EPA's direction as proposed, without the added 5-10% increase in stringency. [EPA-HQ-OAR-2021-0208-0523-A1, p.3]

Commenter: Metropolitan Mayors Caucus

We support the the most stringent GHG emission standards for light-duty vehicles feasible [EPA-HQ-OAR-2021-0208-0504, p.22]

I wish to express our appreciation for the Biden Administration's swift action to restore necessary emissions standards for light-duty vehicles. Precious time was lost in the rollback of emission standards of the previous administration, and we need more aggressive standards to catch up and meet ever more apparent emission reduction targets. [EPA-HQ-OAR-2021-0208-0504, p.1]

For these reasons, the Metropolitan Mayors Caucus urges EPA to swiftly adopt the most stringent GHG emission standards for light-duty vehicles feasible for model years 2023 through 2026 [EPA-HQ-OAR-2021-0208-0504, p.1]

Commenter: Metropolitan Washington Air Quality Committee (MWAQC)

Emissions from the transportation sector are one of the major contributors of GHGs in the region. As such, MWAQC, CEEPC, and the TPB believe that revising the GHG emissions standards for passenger cars and light duty vehicles through model year 2026 to be more stringent than the SAFE Vehicles Rule is appropriate, feasible, and needed in order for the region to achieve its greenhouse gas reduction goals. Additionally, the program's inclusion of flexibilities to incentivize the production and sale of vehicles with zero and near-zero emissions technology would support COG's policy priorities to meet the region's climate goals. [EPA-HQ-OAR-2021-0208-0208-A1][p.3]

Commenter: MI Air MI Health

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 195.]

However, we also feel that it's critical to push even further and we call on you today to set much stronger standards covering cars, SUVs, and light trucks through at least 2030.

Commenter: Michalek, Jeremy and Whitefoot, Kate S.

Choice of Regulatory Alternative with Highest Net Benefits

We recommend that EPA should choose the regulatory alternative with the best estimated net benefits. EPA found that the net benefits of the 'Alternative 2' regulations are larger than those of the proposed regulations but did not choose this regulatory alternative and is instead proposing regulations that have lower net benefits. In the case of agencies choosing a regulatory alternative that does not have the maximum net benefits, a strong rationale should be provided. Such a strong rationale is not evident in the proposed rule. In discussing the choice of the proposed regulations, the proposed rule states that 'EPA recognizes that the additional penetration of electrification by 2026 [in Alternative 2] could be challenging for any manufacturers that are not currently investing in advanced technologies, such as EVs, for this timeframe, although with additional investment and product development, or greater reliance on the emissions ABT program including credit trading, this level of stringency may be achievable.' (p. 43777)

We raise the following concerns with this rationale and the choice of the proposed regulations:

(1) In choosing the proposed regulations over 'Alternative 2', EPA is effectively saying that achieving an 8% market share of plug-in vehicles (including PHEVs and BEVs) across the U.S. new vehicle fleet by MY 2026 is a feasible path, but achieving a 10% market share of plug-in vehicles is not feasible. However, the proposed rule does not provide evidence supporting this distinction.

(2) EPA's analysis of feasible compliance pathways for Alternative 2 does not incorporate the flexibilities associated with credit trading across manufacturers that would be available under the regulations. This credit trading allows manufacturers further flexibility to achieve the more stringent regulations and should be accounted for in consideration of the feasibility and cost-benefits of the alternative regulations.

(3) When considering feasibility of the regulations, EPA should consider the context of the industry as a whole. In previous joint rulemakings with the Department of Transportation's CAFE program, feasibility of the regulations was determined for the industry as a whole, not restricted to individual manufacturers:

'The law permits CAFE standards exceeding the projected capability of any particular manufacturer as long as the standard is economically practicable for the industry as a whole. Thus, while a particular CAFE standard may pose difficulties for one manufacturer, it may also present opportunities for another. NHTSA has long held that the CAFE program is not necessarily intended to maintain the competitive positioning of each particular company. Rather, it is intended to enhance the fuel economy of the vehicle fleet on American roads, while protecting motor vehicle safety and being mindful of the risk to the overall United States economy' (49 CFR p. 62668).

(4) If EPA believes that some manufacturers will need further lead time to invest in GHG-emission reducing technologies, a third alternative could be considered that adjusts the year-by-year stringency to start at the stringency level in the currently proposed regulation in MY 2021 and increase to the stringency level of Alternative 2 in MY 2026. We recommend that EPA calculate the net benefits of such an alternative against the proposed regulation and the other two alternatives and choose the alternative that has the highest net benefits. [EPA-HQ-OAR-2021-0208-0300-A1, pp. 4-5]

Commenter: Mid-America Regional Council (MARC)

The Air Quality Forum encourages the EPA to appropriately increase the stringency of the proposed standard for MY 2026 to set the stage for an ongoing GHG reduction program that will incorporate accelerating zero-emissions technologies and bring the strong, rapid and sustained reductions in GHG emissions needed to meet 2030 GHG reduction targets. [EPA-HQ-OAR-2021-0208-0265-A1, p.1]

Commenter: Minault, Kent

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 240.]

I'm calling to urge EPA to adopt the second alternative and basically to treat the climate disruption as the crisis that it is.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 241-242.]

But I urge you to take the most stringent stance you can take in regulating greenhouse gas emissions from transportation because that's the hard nut. We're progressing in a lot of areas, but if we don't lick transportation, then we'll lose the climate fight.

Commenter: Minnesota Pollution Control Agency (MPCA) and Minnesota Department of Transportation (MnDOT)

Emissions standards should push industries to advance new, cleaner technologies. In this case, EPA should set stringent standards that require the automotive industry to transition to widespread electrification and use of biofuels, beyond what the industry would do on its own without regulation, especially by model year (MY) 2026. [EPA-HQ-OAR-2021-0208-0211-A1, p.3]

EPA should adopt stringent national standards

EPA should finalize GHG emissions standards that at minimum restore the benefits of the standards finalized in 2012. EPA’s 'Alternative 2' has the greatest net benefits of the three approaches EPA modeled. Alternative 2, supplemented with the MY 2026 standard that is 10 grams/mile more stringent than the proposal appears to come the closest to achieving the GHG, particulate matter, and groundlevel ozone reduction benefits that would have been achieved under the 2012 standards. MPCA and MnDOT therefore support adoption of final GHG emissions standards that restore these benefits. [EPA-HQ-OAR-2021-0208-0211-A1, p.3]

Commenter: Moore, Cinthia

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 117.]

The EPA must set the strongest possible federal clean car standards through 2026, avoiding loopholes and putting automakers on track to meet ambitious pollution reduction goals.

Commenter: Moore, Kenneth

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 322-323.]

That's why I believe that the EPA must set the strongest possible federal clean car standards. Choosing to continue producing less-efficient vehicles just isn't wasteful, it's a moral travesty. It is critical that the United States move without delay toward a clean energy economy.

The EPA's rules can have a profound impact upon the sector that currently generates the largest percentage of climate pollution, transportation.

By adopting the strongest possible clean car standards, you will not only drive down vehicle pollution but you'll also spur the economy as new sustainable automotive technologies are brought online.

Commenter: Mothers and Others for Clean Air

I am writing to urge EPA to make the strongest vehicle emissions standards possible. [EPA-HQ-OAR-2021-0208-0491-A, p. 1]

I urge the EPA to require significant reductions in vehicle emissions as soon as possible. [EPA-HQ-OAR-2021-0208-0491-A, p. 1]

I am writing to urge EPA to make the strongest vehicle emissions standards possible.

I urge the EPA to require significant reductions in vehicle emissions as soon as possible. [EPA-HQ-OAR-2021-0208-0491-A, p. 1]

Commenter: Motor & Equipment Manufacturers Association (MEMA)

The proposed standards that EPA outlines are stringent and meaningful and provide the needed regulatory certainty for the industry. Supplier technology investments and developments are carefully planned according to production cycles and emissions standards so as to avoid stranded investments. It is imperative that EPA provide a stable roadmap of rules, targets, test cycles, and credit programs that are consistent and provide the industry adequate direction and stability. These standards, as well as standards set in post-2026, need to strike an appropriate balance between strengthening the U.S. supplier sector, continuing American technological leadership, providing greater consumer choice, and keeping vehicles affordable. Standards that continue to make progress will be those most likely to secure vehicle supplier technological investments.

As we outline further in MEMA's post-2026 recommendations, we emphasize that the overall goals of the pre-2026 proposal and the goals discussed in President Biden's Executive Order (EO) 14037 for post-2026,14 will require action from government and industries outside the motor vehicle industry. To even achieve the nation's short-term goals, the following key considerations must be addressed: consumer incentives allowing adoption of ZEV and GHG-reducing technology to be more financially feasible; consumer uptake of ZEVs; and, infrastructure to utilize and support ZEVs effectively.

Importantly for suppliers, a strategic plan should also include supply-side polices that aim to accelerate the development, commercialization, manufacture, and deployment of new, advanced technologies in the U.S. It is critical for the supplier industry to have increased access to government-provided resources, including investments and incentives for the research and development, and increased manufacturing, including funding for facility retooling and programs that further develop and sustain our skilled workforce. [EPA-HQ-OAR-2021-0208-0249-A1, p. 5-6]

Over a decade ago, vehicle suppliers committed to vehicle emissions technology innovation, ensuring vehicle manufacturers were able to meet the emissions standards set in 2012 for MYs 2017–2025. Consequently, MEMA supports EPA's vehicle GHG standards through MY2026 that are stringent but achievable and provide the needed regulatory certainty and stability for the industry. [EPA-HQ-OAR-2021-0208-0249-A1, p. 16]

Commenter: Muller, Melinda

I am a biologist and biology instructor. I am also a resident of the Pacific Northwest, where we experienced a deadly "heat dome" this past summer. Revised Clean Car Standards must be based on the urgency of climate change and the best available research about needed and effective mitigations. Transportation is the largest source of climate pollution in the U.S., accounting for nearly 30% of greenhouse gas emissions that are causing extreme weather events and other harms of climate change.

This proposal for new Clean Car Standards, while necessary progress, is not sufficient progress as written. [EPA-HQ-OAR-2021-0208-0500, p. 1]

A May report from the International Energy Agency asserts that globally ALL new cars sales must be electric by 2035 in order to achieve net-zero emissions by 2050 and limit warming to 1.5 C. [EPA-HQ-OAR-2021-0208-0500, p. 1]

The EPA rules on clean car standards must include the following if the rule is to be as effective as the climate crisis calls for:

1. Establishing a 2030 standard that achieves fleet average greenhouse gas emissions 60% or more below today's average;

2. Putting the nation on a trajectory to make all new cars and light-duty trucks zero-emission vehicles no later than 2035; and

3. Ensuring all new trucks and buses are zero-emission no later than 2040. [EPA-HQ-OAR-2021-0208-0500, p. 1]

Transitioning to cleaner cars reduces our dependence on oil and saves drivers billions at the pump. It also drives innovation and creates jobs in the auto industry manufacturing technology that reduces pollution and improves fuel economy.

As President Biden has said, time is running out to avoid the most catastrophic effects of climate change. This is a moment of essential opportunity to enact Clean Car Standards that meet the urgency of climate change. [EPA-HQ-OAR-2021-0208-0500, p. 1]

Commenter: National Association of Clean Air Agencies (NACAA)

EPA should adopt standards sufficiently stringent to, at a minimum, achieve the same level of emission benefits as under the standards adopted in the 2012 rule. Since the emission standards in the 2012 rule were adopted, clean vehicle technology and performance have progressed significantly, far more than anticipated and at lower cost, making a strengthening of those standards in this rulemaking feasible. [EPA-HQ-OAR-2021-0208-0255-A1, p.1]

As NACAA noted in its January 2021 transition paper to the Biden Administration,2 increasingly stringent standards to reduce emissions from passenger cars and light trucks are urgently needed. Such standards are critical components in an overall strategy to further reduce GHG and criteria pollutant emissions from passenger cars and light trucks, which are significant contributors to climate change as well as NAAQS nonattainment and maintenance problems in many areas of the U.S. [EPA-HQ-OAR-2021-0208-0255-A1, p.2]

EPA's Alternative 2, augmented with a MY 2026 standard that is 10 grams/mile more stringent, comes the closest to NACAA's recommendation of adopting standards sufficiently stringent to, at a minimum, achieve the same level of emission benefits as under the final standards adopted under the 2012 rule and put the nation on a clear trajectory to 50 percent of all new passenger cars and light trucks sold in 2030, and 100 percent of those sold in 2035, being ZEVs. [EPA-HQ-OAR-2021-0208-0255-A1, p.4]

As many states and localities continue to make significant investments and put forth bold efforts to ready the market to deploy LDV clean technology, we look to and encourage the federal government to step up and increase such efforts as well, and to use this rulemaking to, at a minimum, adopt EPA's Alternative 2, augmented with a MY 2026 standard that is 10 grams/mile more stringent, so that, together, we can create a pathway that will not only reduce air pollution and protect public health and the environment, but also create high-paying jobs, spur economic development and contribute to fuel security in our nation. [EPA-HQ-OAR-2021-0208-0255-A1, p.7]

Revised CO2 Emission Standards

EPA has proposed grams-per-mile (grams/mile) GHG emission standards that would increase the stringency of the 'SAFE 2' standards by about 10 percent in MY 2023 and 5 percent per year in MYs 2024 through 2026. The agency is also seeking comment on two alternatives to the proposed standards. For Alternative 1, EPA used the coefficients in the California Framework for the 2.7-percent effective stringency level as the basis for the MY 2023 stringency level and the 2012 rule MY 2025 standards as the basis for the MY 2026 stringency level, with linear year-over-year reductions between the two points for MYs 2024 and 2025. This alternative results in less stringent standards than EPA's proposal. For Alternative 2, EPA used the 2012 rule standards as the basis for the MY 2023-2025 targets, with the standards continuing to increase in stringency in a linear fashion for MY 2026. Alternative 2 adopts the 2012 rule stringency levels in MY 2023 and follows the 2012 rule standard target levels through MY 2025. EPA extended the same linear average year-over-year trajectory for MYs 2023–2025 to MY 2026 for the final standards under Alternative 2, resulting in more stringent standards than EPA's proposal. EPA is further requesting comment on MY 2026 standards that would result in fleet average levels that are 5 to 10 grams/mile more stringent than the MY 2026 standards under the proposed levels or the Alternative 1 or Alternative 2 levels.

EPA should set standards sufficiently stringent to, at a minimum, achieve the same level of emission benefits as under the final standards adopted under the 2012 rule. Further, these standards should create a pathway to 50 percent of all new passenger cars and light trucks sold in 2030 being zero-emission vehicles (ZEVs), including battery electric, plug-in hybrid electric or fuel cell electric vehicles, consistent with President Biden's August 5, 2021, Executive Order 14037, 'Strengthening American Leadership on Clean Cars and Trucks,'4 as well as lay the foundation for achieving, nationwide, a goal of 100 percent zero-emission new car and light truck sales by 2035, as is being pursued by countries such as Canada, the United Kingdom, Norway and the Netherlands as well as several states, including California, Massachusetts, New Jersey and New York, and various automakers. [EPA-HQ-OAR-2021-0208-0255-A1, pp. 3-4]

In the nine years since EPA adopted the emission standards in the 2012 rule there has been a significant expansion of ZEV technology and improvement in emissions performance. This progress has far exceeded what was anticipated in 2012 and has occurred at a lower cost than projected, thus supporting the feasibility of strengthening of the 2012 standards in this rule. In addition to these technology and performance improvements, other noteworthy factors lend further support for more stringent standards, including multiple studies and reports highlighting increasingly dire consequences of climate change; the increasing occurrence of climate-driven disasters; commitments by numerous auto manufacturers to strong electrification and ZEV targets and reductions in carbon emissions; commitments by numerous countries and U.S. states to accelerate the transition to a zero-emission transportation future; and the Biden Administration's 'Build Back Better agenda' as well as its ZEV commitments and intention to increase the United States' Nationally Determined Contribution for the upcoming COP-26.

Many state and local air agencies were counting on the benefits of the 2012 rule and nine years later these reductions are still urgently needed. EPA should do everything possible to recapture those benefits – including those related to climate change, ground-level ozone and particulate matter. Importantly, the record on which this proposal is based supports the technological feasibility, within the MY 2023 through 2026 timeframe, of standards at least as stringent as those in the proposal. Automakers have been successfully planning to meet the standards adopted in 2012 for nearly 10 years, as illustrated by the progress and commitments they have made, thus ensuring that there is more than adequate lead time available to meet the stringency of standards we recommend. [EPA-HQ-OAR-2021-0208-0255-A1, pp. 4-5]

Commenter: National Automobile Dealers Association (NADA)

EPA does not premise its proposal on information forecasting that there will be feasible and economically practicable changes in technologies and other improvements in light-duty vehicles manufactured and delivered to market in MYs 2023-2026. Nor does it base its proposal on new forecasts regarding the rate of customer acceptance and uptake of GHG reduction strategies. Instead, EPA opted simply to "[reconsider] how costs, lead time and other factors were weighed in the SAFE rule and [reached] a different conclusion as to the appropriate stringency of GHG standards."8 [EPA-HQ-OAR-2021-0208-0290-A1, p. 2]

Commenter: National Coalition for Advanced Transportation (NCAT)

NCAT strongly supports EPA adopting standards that would regain the GHG emissions reductions lost by the 2020 Rule by increasing the stringency of the standards as soon as feasible. Overall stringency is affected by the year-over-year reductions requirements and various flexibilities that may be afforded in EPA's standards. The conservative assumptions regarding electric vehicle cost and market penetration used in EPA's technical analysis supporting the Proposed Rule show the proposed standards should be even more stringent. The feasibility of the overall stringency increase in EPA's Proposed Rule is fully supported by the data and the agency's robust technical record that shows these proposed standards are clearly appropriate under Clean Air Act Section 202(a), as the minimum stringency EPA could adopt. NCAT strongly supports EPA's proposal to strengthen the MY 2023 to 2026 GHG emissions standards for light-duty vehicles to at least the stringency levels EPA has proposed, and urges EPA to adopt more stringent standards. And the technical record demonstrates that EPA should not adopt the less-stringent standard (Alternative 1) that it evaluated in the Proposed Rule. [EPA-HQ-OAR-2021-0208-0239-A1, p. 1-2]

THE LEAD TIME FOR THE PROPOSED RULE IS REASONABLE AND APPROPRIATE

EPA has reasonably determined that the lead time for the Proposed Rule, which would establish GHG emissions standards for MY 2023 through 2026 vehicles, is appropriate and consistent with the relevant statutory factors. Clean Air Act Section 202(a) provides that standards "shall take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period."128 The Act affords EPA significant discretion to balance these factors and courts have been deferential to EPA in matters of lead time. 129 If Congress had wanted to impose more specific or longer lead time, it knew how to do so, as it did in other parts of the Clean Air Act. For example, elsewhere in the Clean Air Act Congress expressly imposed a two-year lead time requirement for state adoption of California vehicle standards and a four-year lead time requirement for heavy duty vehicle standards. 130 And Section 202(a) stands in stark contrast to the statutory provision that governs NHTSA's corporate average fuel economy standards, which specifies 18 months lead time.131

By the plain text of the statute, when determining adequate lead time the agency considers technological feasibility and economic practicability.132 With respect to technological feasibility, when EPA provides sufficient justification for the technological feasibility of the standards, the agency has provided adequate lead time.133 The robust technical record EPA has provided to support the Proposed Rule more than justifies the technical feasibility of the standards set forth in the proposal. See Section VI below for further detail on EPA's conservative assumptions with respect to electric vehicle technologies. In the Proposed Rule, EPA analyzed the technological feasibility of the standards, in light of the lead time, in great detail. 134 Based on its extensive technical analysis, EPA determined "the technologies needed to meet the proposed standards are already widely available and in use on vehicles—there is no need for development of new technologies for the time frame of these proposed standards."135 The existing technologies includes electric vehicles. As EPA explains, "compliance with the proposed standards will necessitate greater implementation and pace of technology penetration through MY2026 using existing GHG reduction technologies."136 These conclusions are entirely reasonable and supported by the record. Under the economic factor with respect to lead time, Section 202(a) requires that EPA give "appropriate consideration to the cost of compliance within such period."137 EPA has clearly met this statutory requirement as it thoroughly considered compliance cost in the robust technical record, as described in the Proposed Rule.138

Furthermore, as EPA explained in the Proposed Rule, the lead time afforded to manufacturers for these MY 2023 through 2026 standards is even more reasonable in light of the history of this rulemaking. 139 See Section II.B above. According to the Proposed Rule, the standards in EPA's Proposed Rule are slightly less stringent for MY 2023-2025 than those set in the 2012 Rule nearly a decade ago.140 Although those 2012 Rule standards were weakened in July 2020, that rule revision was immediately subject to litigation challenge and remained in place for only a few months before President Biden's Executive Order directing EPA to reconsider the 2020 Rule. Moreover, California vehicle standards, which have been adopted by 14 other states, are more stringent than EPA's Proposed Rule. California and the Section 177 States that have adopted these standards make up more than one-third of the U.S. auto market.141 California's zero emission vehicle standards are part of California's State Implementation Plan (SIP), approved by EPA. Although EPA later revoked California's Clean Air Act waiver (an unlawful action that EPA had never before taken with any waiver it had issued), the SIP remained in place and California and other Section 177 states challenged the revocation on, among other grounds, EPA's lack of authority to take that action. At that time, California made clear that it considered its regulations to remain in place and even threatened enforcement. Given this background, it was clear that there was a high probability of very quickly reverting to more stringent standards—either on the federal or state level.

The Clean Air Act gives EPA discretion to determine lead time when setting vehicle emission standards, and EPA has clearly exercised that discretion reasonably in the Proposed Rule.

EPA MUST ADOPT THE PROPOSED RULE AS A MINIMUM STRINGENCY LEVEL, AND EPA'S CONSERVATIVE ASSUMPTIONS REGARDING ELECTRIC VEHICLES SUGGEST THE RECORD COULD SUPPORT EVEN GREATER STRINGENCY

The Robust Technical Record Demonstrates that EPA Must Adopt Standards At Least as Stringent as the Proposed Rule

EPA is proposing to revise the MY 2023 through MY 2026 GHG standards to substantially increase the year-over-year stringency from the relaxed standards that were adopted in the 2020 Rule.142 Specifically, the MY 2023 fleet targets in EPA's Proposed Rule are intended to reflect an increase in stringency of approximately 10 percent over the 2020 Rule MY 2022 targets. This is followed by a 5 percent increase in stringency year-over-year in MY 2024 through MY 2026 fleet targets.143 This proposal is intended to be in sharp contrast to the average approximately 1.5 percent year-over-year stringency increase in MY 2023 through MY 2026 under the 2020 Rule.144

NCAT strongly supports EPA adopting standards that would regain the GHG emissions reductions lost by the 2020 Rule by increasing the stringency of the standards as soon as feasible. The feasibility of the overall stringency increase in EPA's Proposed Rule is fully supported by the data and the agency's robust technical record that shows these proposed standards are clearly appropriate under Clean Air Act Section 202(a), as the minimum stringency EPA could adopt. As EPA notes, EPA's determination of feasibility is supported by EPA technical analysis compiled over a decade, including the analyses for the 2010 and 2012 Rules, the mid-term evaluation, the supporting record for the 2020 Rule, and updated analysis for the Proposed Rule.145

EPA seeks comment on a less stringent standard than the Proposed Rule, which EPA refers to as Alternative 1.146 NCAT does not support the less-stringent Alternative 1, and it is not supported by the record. Rather, NCAT views EPA's main proposal for MY 2023 through MY 2026 GHG standards as the minimum stringency supported by the robust technical record. As EPA acknowledges, its proposal "does not rely on dramatically increased penetration of electric vehicles into the fleet during the 2023–2026 model years."147 Rather, EPA assumes a very modest increase in market share of electric vehicles and plug-in hybrid electric vehicles of up to 8 percent by MY 2026.148 Given the significant increase in electric vehicle market penetration over EPA's assumed MY 2017 baseline and the projected significant increase in the coming years, see Section IV, A above, EPA's proposal should be considered the minimum stringency level supported by the record. EPA should not adopt the less stringent standard that EPA evaluated in Alternative 1 or the Proposed standards.

Given EPA's Conservative Assumptions in Support of the Proposed Rule, the Record Supports Even Greater Stringency

The conservative assumptions regarding electric vehicle cost and market penetration used in EPA's technical analysis supporting the Proposed Rule demonstrate that EPA should adopt even more stringent standards. Overall stringency is affected by the year-over-year reductions requirements and various flexibilities that may be afforded in EPA's standards. As EPA itself has acknowledged, the inclusion of multipliers in any standard tends to diminish the overall stringency (and resulting emissions reductions) of the standard.149 Moreover, the conservatism of EPA's assumptions has a meaningful effect on the stringency of EPA's proposal. [EPA-HQ-OAR-2021-0208-0239-A1, p. 19-22]

Very conservative electric vehicle penetration assumptions suggest even greater stringency is warranted:

In the Proposed Rule, EPA projected that over the MY 2023 to 2026 period "the proposed standards could be met with gradually increasing sales of plug-in electric vehicles in the U.S., up to about 8 percent market share (including both electric vehicles (EVs) and plug-in hybrid electric vehicles (PHEVs)) by MY 2026."150 As shown in the data discussed in Section IV, A above, this assumption of electric vehicle market share is very conservative as electric vehicles are projected to grow as a share of the market at a much faster rate. In one year's time—between 2019 and 2020 the proportion of new car sales of electric vehicles grew by 1.9 percent, 151 and IHS Markit estimates that electric vehicles will make up 10% of new car sales nationwide by 2025.152 EPA even acknowledges that "there may be the potential for higher levels of electric vehicle penetration by MY 2026, which could enable EPA to consider a more stringent standard for MY 2026,"153 and EPA requests comment on this topic.154 As explained in NCAT's comments and the comments of many other stakeholders, the technical data indicates that there will be much higher electric vehicle penetration by MY 2026. EPA seeks comment on a proposed standard for MY 2026 that is 5 to 10 g/mile lower than the Proposed Rule.155 The conservatism in EPA's assumption regarding electric vehicle market penetration suggests that there is indeed room for EPA to adopt a more stringent standard. [EPA-HQ-OAR-2021-0208-0239-A1, pp.22-23]

In conclusion, NCAT strongly supports EPA's proposal to strengthen the MY 2023 to 2026 GHG emissions standards for light-duty vehicles to at least the stringency levels EPA has proposed, and urges EPA to adopt more stringent standards. NCAT believes that the record EPA developed absolutely supports, at a minimum, that proposed level of stringency and timing for implementing the MY 2023 to 2026 standards in the Proposed Rule. However, conservative assumptions about electric vehicle penetration and cost show that more stringent standards are warranted. [EPA-HQ-OAR-2021-0208-0239-A1, p. 24]

Commenter: National Parks Conservation Association (NPCA)

Because transportation now accounts for more GHG emissions than any other sector in the U.S.—with passenger vehicles making up the bulk of those emissions—we strongly urge EPA to move forward with the most stringent clean car standards feasible. [EPA-HQ-OAR-2021-0208-0291-A1, p. 1]

Only with bold action can the administration set America on a path towards achieving 60% reduction in passenger vehicle emissions by 2030 and 100% zero-emission vehicle sales by no later than 2035. The actions EPA takes now will have lasting impacts on our parks and communities for generations to come. We appreciate your consideration of our comments and ask that you please move forward with the most stringent standards feasible under Alternative 2. [EPA-HQ-OAR-2021-0208-0291-A1, p. 2]

Of the alternatives provided in the proposed rule, NPCA urges EPA to move forward with Alternative 2, which would reduce more pollution and has higher net benefits compared to EPA's preferred alternative. NPCA further supports requiring an additional 10 g/mile improvement for MY 2026. [EPA-HQ-OAR-2021-0208-0291-A1, p. 2]

Commenter: Natural Resources Defence Council (NRDC)

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 25.]

This unprecedented moment demands strong action which is why EPA should finalize a rule at least as stringent as Alternate 2 which would achieve more emission reductions than the proposal.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 27.]

So NRDC urges EPA to finalize light-duty vehicle standards that maximize climate pollution reductions, deliver cleaner air, and help to secure a safer and healthier future.

Commenter: New Mexico Environment Department

First, NMED recommends the EPA adopt the standards in Alternative 2,3 which decrease the fleet average CO_2 target level to 169 g/mile by Model Year 2026 (MY2026), as opposed to the proposed standard which provides a target level of 171 gCO_2/mile. [EPA-HQ-OAR-2021-0208-0205-A1][p.1]

Second, NMED recommends the EPA increase the stringency of the fleet average compliance CO_2 targets for MY2026 by 10 g/mile more than the proposed rules (Table 8 and Figure 2),4 which in combination with Alternative 2 would reach a proposed fleet average target CO_2 level of 159 g/mile for MY2026. [EPA-HQ-OAR-2021-0208-0205-A1][p.1]

The total benefits of the more stringent standards far exceed the total cost of the program. Using a 3 percent discount rate, Table 139 shows that Alternative 2 has an estimated $34 billion net benefit in 2018 dollars. As shown in Table 1710 with the 3% discount rate, Alternative 2 has a $9 billion greater lifetime benefit in fuel savings to consumers, and $8 billion greater monetized environmental benefits than the EPA standard proposal. [EPA-HQ-OAR-2021-0208-0205-A1][p.2]

EPA's proposed standards can go into effect three years earlier - with Model Year 2023 - than New Mexico will be able to require compliance with the California advanced clean car standards. The New Mexico timeline for adoption is dictated, in part, by the required two-year waiting period for Section 177 states, such as New Mexico, under the Clean Air Act. EPA's proposed credit programs and technology incentives provide flexible pathways for the LDV manufacturers to meet EPA's tighter timeline. [EPA-HQ-OAR-2021-0208-0205-A1][p.3]

Commenter: New York State Department of Environmental Conservation

In light of the available technology and the transition to electric vehicles well underway, we question to need to provide manufacturers with more flexibility than provided by the prior standards. New York recognizes that EPA is attempting to rectify the past administration's backsliding of light-duty GHG Standards while at the same time providing all manufacturers with sufficient lead time. While New York generally supports the continuation of traditional credit flexibilities, providing too much compliance flexibility would effectively reduce the stringency and effectiveness of the proposed regulations, especially in the short term. [EPA-HQ-OAR-2021-0208-0238-A1, p.2]

It will also provide the average consumer close to $2000 in fuel savings over the life of a vehicle [EPA-HQ-OAR-2021-0208-0238-A1, p.3]

The proposed revised standards are not only technologically feasible but would achieve greater emissions reductions, public health benefits, and fuel savings to consumers over the life of the vehicles than would be achieved under the standards promulgated in the misguided SAFE rule in 2020. [EPA-HQ-OAR-2021-0208-0238-A1, pp.3-4]

Commenter: Newhouse, Richard

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 76-77.]

In any case, I want the EPA to shift to their Alternative 2 which would save consumers more money, close loopholes which you've heard a lot about in the testimony, for automobiles that would undermine these standards.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 78.]

The weaker proposal with additional loopholes for automobiles means that proposed standards would deliver only 75 percent of the savings of the original Obama/Biden standards. This is an unnecessary compromise, given the EPA's own analysis which indicates that loopholes around

EVs would deliver only the stated purpose of increasing EV sales. EPA's own Alternative 2 in the proposed rule eliminates many loopholes for automakers and includes slightly stronger standards that match the Obama/Biden-era standards from 2023 onwards that would deliver greatest savings.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 78-79.]

I feel very strongly about Alternative 2 as I think we owe it to our grandchildren to leave them a better world than the one we have now.

Commenter: Nissan North America, Inc.

Further, Nissan believes the ambitious standards proposed by EPA and NHTSA would likely require more electrification than estimated by the agencies. While the level of EV market development and implementation of critical EV market policies remains uncertain, considering more stringent standards than proposed is premature during this rulemaking time period. Nissan therefore urges the agencies to refrain from adopting more stringent standards than proposed for the period covering through model year 2026. Instead, the agencies, industry, and other stakeholders must focus their efforts on fostering the EV market in order to build a strong foundation for longer-term success in transforming the market. [EPA-HQ-OAR-2021-0208-0529-A1, p. 7]

Commenter: Northeast States for Coordinated Air Use Management (NESCAUM)

The climate crisis represents an increasingly clear and present danger to public health, the environment, and the economy. At the same time, the technologies needed to substantially reduce greenhouse gas (GHG) emissions from light-duty vehicles (LDVs) are already widely available and in use today, and the pace of technological innovation continues to accelerate. Strong national GHG standards are a critical building block for state efforts to substantially reduce GHG and criteria pollutant emissions from the transportation sector and accelerate the transition to electric vehicles (EVs). [EPA-HQ-OAR-2021-0208-0259-A1, p. 1]

As discussed more fully below, there is ample justification for EPA to finalize strong national GHG standards for LDVs that recover and restore the benefits of the national program that EPA adopted in 2012 and confirmed to be technologically feasible and appropriate in 2018. NESCAUM urges EPA to promptly adopt the most stringent GHG emission standards feasible for MYs 2023-2026, and to move swiftly to propose ambitious post-MY 2026 standards, to put the nation on track to rapidly electrify the entire light-duty fleet. [EPA-HQ-OAR-2021-0208-0259-A1, p. 2]

As EPA notes in its proposal, the shift to ZEV technologies is already underway, and it presents a strong potential for dramatic reductions in GHG and criteria pollutant emissions. This pivotal rulemaking presents EPA with the opportunity to exercise global climate leadership and put the United States on track to rapidly decarbonize the entire light-duty fleet, while serving as a critical building block for a comprehensive, multipollutant regulatory program. Strong federal GHG emissions standards will help mitigate the climate crisis while ensuring the competitiveness of the American automotive industry in a rapidly changing global marketplace, saving consumers money, and creating new economic opportunities. [EPA-HQ-OAR-2021-0208-0259-A1, p. 5]

For the reasons stated above, NESCAUM urges EPA to promptly adopt the most stringent GHG emission standards feasible for MYs 2023-2026, and to move swiftly thereafter to propose ambitious post-MY 2026 GHG standards, to put the nation on track to rapidly electrify the entire light-duty fleet. [EPA-HQ-OAR-2021-0208-0259-A1, p. 5.]

To accelerate the transition to widespread electrification, EPA should require more stringent standards, especially for MY 2026 given the additional lead time available. [EPA-HQ-OAR-2021-0208-0259-A1, p. 4]

NESCAUM urges EPA to promulgate final standards that would, at a minimum, restore the emission benefits provided under the national program adopted in 2012. EPA's 'Alternative 2' has the greatest net benefits of the three approaches EPA modeled. Alternative 2, augmented with a MY 2026 standard that is 10 grams/mile more stringent than its proposal, appears to come the closest to achieving the GHG and particulate matter emissions and ground-level ozone reduction benefits that would have accrued under the 2012 standards. Thus, NESCAUM strongly supports final GHG standards that restore these benefits. [EPA-HQ-OAR-2021-0208-0259-A1, p. 4]

Commenter: Olmstead, Thomas

The standards that EPA is proposing do not go far enough in meeting clean air and climate goals laid out by the Biden Administration in numerous executive orders (Executive Order 14037, August 5, 2021 Strengthening American Leadership in Clean Cars and Trucks; Executive Order 14008, January 27, 2021 Tackling the Climate Crisis at Home and Abroad; and Executive Order 13990, January 20, 2021 Protecting Public Health and the Environment and Restoring Science To Tackle the Climate Crisis).

Along with the proposed standards, EPA analyzed both a more stringent (Alternative 2) and a less stringent (Alternative 1) alternative. EPA should consider a third alternative (Alternative 3) that is more stringent than Alternative 2 and model the alternative with the NHTSA's Corporate Average Fuel Economy (CAFE) Compliance and EffectsModeling System (CCEMS) model. Alternative 3 would be based on the following:

- Incorporating more technology adoptions in future years like turbocharged engines (Turbo), gasoline direct injection (GDI), cylinder deactivation (CD), seven or more speeds, continuously variable transmissions (CVTs), stop/start, and alternative fuel vehicles;

- Lower CO_2 g/mile than the standards adopted in the 2012 rule

- Phaseout of the credits; and

- Ending the multipliers. [EPA-HQ-OAR-2021-0208-0190-A1, p. 1]

Commenter: Our Children's Trust

[W]e write to advise EPA to strengthen the federal greenhouse gas emission standards for passenger cars and light trucks for Model Years 2023-2026 beyond the proposed alternative and Alternative 2 so that they meet the urgency of the crisis and align with the kind of deep emission reductions scientists say are needed to protect the climate system and the constitutional rights of youth. [EPA-HQ-OAR-2021-0208-0281-A1, p.1]

Commenter: Pate, Susan

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 187-188.]

So I would like to just urge you to actually make the standards more stringent for auto emissions and remove that -- well, add the Alternative 2 so that nobody has a way to get out of meeting your standards.

Commenter: Pennoyer, Marguerite

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 29.]

his proposal and the broader actions on clean cars from the Administration are helpful, but we need the most stringent possible clean car and truck standards to truly make good on President Biden's commitments to address climate action and environmental justice.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 30.]

Truck manufacturers have been bypassing so many of the air quality protections that have been engineered into their smaller cars. This is but one personal example among so many of why stronger standards are needed to drive innovation, ingenuity, and provide many more clean truck and car options that don't further jeopardize our clean air.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 31.]

I support all EPA efforts to reduce greenhouse gas emissions for all cars, trucks, and larger vehicles that will protect the health of my family and my patients.

The EPA must set much stronger standards covering cars, SUVs, and light trucks through at least 2030 to drive the transition to zero emission vehicles that the nation needs and that President Biden has called for in his Executive Order.

The EPA must finalize this rule to cover the Model Years 2023 through 2026 and set up more health protective standards beyond that.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 32-33.]

Please finalize this proposal quickly and move forward with even bolder greenhouse gas and fuel efficiency standards for cars, light trucks, and SUVs into the future that will speed up this truly vital transition to zero emission vehicles.

Commenter: Peterson, Doug

Summary of My Specific Comments

First and foremost, I argue that the EPA is failing to fulfill its obligations under the Clean Air Act, placing far too much weight on concerns about the U.S. economy, feasibility, and regulatory flexibility and far too little weight on its solemn duty to protect our shared environment. My main argument includes a stern critique of the EPA's invalid cost benefit analysis, which greatly underestimates the benefits of controlling tailpipe carbon dioxide. Second, a great number of compliance credits are due to expire in 2021 and 2022, and the EPA appears determined to extend their expiration dates. I unequivocally oppose this rule change, believing that it will seriously undermine the stringency increases. Third, the EPA is seeking comment on the proposal to restore 2 the credit multiplier that allows zero emission vehicles to count as two ZEVs in the calculation of fleet performance. I oppose this rule change regarding battery electric vehicles (BEVs) and do not believe that capping the benefit is adequate to counteract the negative impact of restoring the multiplier. I do believe that the credit multiplier should be restored for fuel cell electric vehicles (FCEVs). Fourth, I support the plan to redraw the footprint curves that were altered when the Trump Administration was directing the EPA, returning them to their former shape. I also suggest that the curves be altered further to incentivize modest downsizing of our national fleet. Fifth, I support the plan to increase the overall stringency of the footprint curves and recommend that the stringency level be increased to the greatest extent possible, adopting Alternative 2 along with 10 grams per mile of additional stringency.

All my comments are consistent with my informed judgement that the footprint model fails to adequately control tailpipe CO2 and that the inherent limitations of the current regulatory framework can only be partially corrected by increasing stringency and applying rules that support the transition to zero emission vehicles. Given that the current framework is failing, it ought to be toughened to the greatest extent possible. Starting in 2027, the framework should be replaced with a more effective scheme that guarantees an orderly transition to ZEVs, with the sale of internal combustion vehicles ending in 2040. In the 2027 to 2040 timeframe, large vehicles driven by internal combustion engines should be phased out more rapidly than small ones, and we should continue struggling to improve the fuel efficiency of new ICE vehicles as their numbers dwindle.

The EPA is Not Adequately Controlling Tailpipe Carbon Dioxide

As the federal agency responsible for enforcing the Clean Air Act, the EPA is legally obligated to curtail, and eliminate as soon as possible, carbon dioxide emissions produced by light duty vehicles. The Supreme Court has ruled that carbon dioxide is a pollutant as defined by the Clean

Air Act and expressed its authoritative view that the EPA must make a determination as to the dangers posed by the buildup of carbon dioxide in the troposphere. The EPA has studied the issue, in keeping with the direction of the Supreme Court, and has determined that the buildup of CO_2 is indeed dangerous and needs to be regulated effectively.

The EPA could hardly determine otherwise. Measuring CO_2 levels in the well-blended troposphere is a straightforward procedure, and the measurements taken atop Mauna Loa in the state of Hawaii confirm that the concentration level of CO_2 is rising steadily. It is now over 50% higher than it was at the onset of the Industrial Revolution, higher that it has been for millions of years. Scientists have a strong understanding of radiative forcing and other forces that impact climate, and there is strong agreement that the relentless buildup of greenhouse gases in the troposphere is causing the extraordinary climate volatility we are witnessing around the globe, and the acidification of our oceans. The scientific community has its own thoughtful processes for assessing its level of certainty regarding new scientific findings and is extremely confident about the reality of anthropogenic climate change. Their certitude regarding anthropogenesis is the rough equivalent of their firm view that the Earth is a sphere that revolves around the sun. There are still large numbers of people living in the United States who do not believe in the basic science of climate change, but the EPA is obligated to act based on the best science available. The EPA has clearly made the correct determination regarding the profound dangers associated with carbon dioxide.

Sadly, the EPA has not implemented an adequate regulatory framework for light duty vehicles that is consistent with its own endangerment finding. The EPA is not allowed to shirk its legal obligations because effective mitigation strategies might be unpopular, or slow economic growth.

Carbon dioxide is clearly a dangerous gas that is the primary driver of climate change, and the EPA 3 has a duty to control it as part of the desperate international effort to restore climate equilibrium. If the EPA accepts the view that carbon dioxide is dangerous, there is no reasonable mitigation strategy that can be proposed other than one which unites our efforts with those of the rest of the world. If CO_2 is a problem at all, it is a global one. The regulation of excessive U.S. tailpipe emissions is crucial to the international CO_2 abatement effort, and the ongoing emissions from enormous, overpowered U.S. vehicles sends a strong message to the rest of the world that the United States has no intention of restraining its excessive carbon dioxide emissions. As the lead agency charged with administering U.S. environmental efforts, the EPA is obligated to craft policies that conform to the urgent goals of the Paris Climate Agreement.

Light duty vehicles powered by internal combustion engines create copious quantities of carbon dioxide, and this is especially true of the largest vehicles. Unlike other harmful trace pollutants, CO_2 is the fundamental component of auto exhaust, created in abundance whenever gasoline is ignited. The primary evidence that the EPA is failing to control the carbon dioxide from light duty vehicles is the undeniable fact that gasoline consumption in the United States is not going down. [EPA-HQ-OAR-2021-0208-0692-A1, p. 1-3]

The EPA's endangerment finding regarding carbon dioxide also obligates the agency to make a reasonable judgement about the urgency of the climate crisis and the appropriate pace of CO_2

abatement. Determining the necessary stringency level of the framework requires a correct ascertainment regarding the timeframe of the emission reductions that the framework might provide. It is not enough that the EPA make a showing that its regulations provide reductions; it needs to make a convincing case that the pace and scope of those reductions is sufficient to meet the challenge of the escalating crisis, contributing our nation's fair share to the international effort. We have already delayed for far too long. If we accept the IPCC's informed view that climate change is real and is a result of human activity, we must also accept their emphatic warning that carbon dioxide emissions must be reduced quickly. The EPA characterizes the GHG reductions provided by the proposal as being "very significant", but this simply isn't true. Compared to the nominal stringency increases of the SAFE rule, the EPA's proposal only provides a 6% average 4 reduction through 2050. Given the gravity of the crisis and the level of urgency expressed by the IPCC, the proposed scope and pace of improvement is entirely inadequate. It may well be true that the new framework currently taking shape for 2027 will provide faster, more dramatic reductions, but that start date is far off. We desperately need greater reductions in the near term, and this round of rulemaking provides an opportunity to make more meaningful gains right now.

The EPA argues unconvincingly when it claims that it must balance its obligation to protect air quality with issues involving feasibility, flexibility for automakers, and the health of the U.S. economy. Yes, the EPA must take these considerations into account, and it must also harmonize its regulations with those of the National Traffic Highway Safety Administration, an agency operating under the authority of different legislation addressing other concerns. But no, the EPA is not allowed to dismiss its primary obligations entirely in favor of these tangential concerns. The agency can take these concerns into account, but it cannot establish policies that are strictly determined by them, and that is what the agency is doing with respect to tailpipe carbon dioxide. The EPA's priorities are thoroughly out of balance, geared more toward political concerns than moral ones. The agency was established to protect the environment, not the U.S. economy and consumer choice. Its policies should embrace its duty to fulfill its core mission. The EPA's indifference to its primary responsibilities is reflected in the lengthy cost benefit analysis that helps form the justification for its proposal. All the attention placed on the theoretical benefits that will flow to consumers is also entirely inappropriate. It is in keeping with the EPA's warped view of its own priorities that the detailing of the proposal's environmental impact is not discussed in detail until after the EPA has hyped its economic and consumer benefits at great length. [EPA-HQ-OAR-2021-0208-0692-A1, p. 3-4]

Obviously, downsizing ICE vehicles would improve their fuel efficiency; the same basic law of physics applies to ZEVs. Over the course of the next three decades, it will be a great challenge to transition the national grid to clean electricity. Every effort should be made to conserve electricity any way we can. I write a biweekly column promoting the merits of BEVs, and I can't help but notice that the 9 industry is favoring large models here in the United States. Under current rules, BEVs with large footprints generate more compliance credits than BEVs with small footprints, and there are very few small BEVs being introduced on our shores. Small, efficient BEVs would use less electricity and conserve lithium, advancing worthy goals that the EPA should be considering. BEV adoption would accelerate more rapidly if there were more variety in the models available to consumers. Large, powerful BEVs are now seen as luxury cars for good reasons, status symbols rather than symbols of environmental concern. The EPA appears oblivious to all of this. To align the compliance credits generated by BEVs with the EPA's core mission, it might be wise to not use a ZEV's actual footprint to determine its value in the fleet performance calculation. A standard footprint the size of a small crossover could be used for all BEVs regardless of their actual size, and the generated credits could then be adjusted to account for upstream emissions. As the EPA begins to prepare for a world without internal combustion engines, they should be crafting policies that maximize the MPGe of BEVs and the fuel economy of vehicles fueled with green hydrogen, incentivizing the energy efficiency of both powertrains. The best and safest outcome would be a national fleet composed of BEVs and FCEVs optimized for energy efficiency that are similar in size and weight, roughly the size of four-passenger crossovers.

Conclusion

My comments have been very unequivocal regarding the failure of the EPA to enforce adequate, timely emission reductions from light duty vehicles. Know that the stern tone of my comments stem from my great concern regarding the escalating climate crisis. Unlike many climate activists, I do not believe that bad things only happen because of bad people. The crisis is the result of a complex technical problem that needs to be solved by sensible people acting together in a spirit of goodwill. I trust that the folks who work for the EPA have their hearts in the right place regarding their core mission. The tendency to prioritize tangential concerns appears to have developed over a long period of time and has now become institutionalized, and the inappropriate assumptions of the invalid cost benefit analysis are an unfortunate result of ossified attitudes about the superiority of quantitative methodologies. An unspoken rule has also developed prohibiting any restriction of consumer choice, and this is unfortunate. The challenge we are facing requires that we break loose from a business-as-usual approaches and reimagine the EPA's view of the constraints under which it operates. The EPA has the legal and moral authority to move aggressively on all fronts to mandate rapid, significant GHG reductions from all sectors, and now is the time for thoughtful, decisive action. It would help greatly if the legislative branch would cooperate with the EPA's core mission in a bipartisan fashion, but that looks highly unlikely in the near term due to obstructive extremists on both sides of the aisle. We do, however, have a pragmatic President with a genuine, passionate concern about the climate crisis, and the EPA is one of his most valuable tools for advancing his lofty climate goals.

I will conclude with one final thought about the special significance of light duty vehicle emissions. In order to defeat the scourge of climate change, we need to start doing a lot of things right, and there are many promising pathways that will ultimately lead us to victory. While it may appear that transportation is an especially problematic sector that will be very difficult to decarbonize, I do not see it that way. BEVs and FCEVs are proven, feasible alternatives to ICE vehicles with the potential to deliver desperately needed emission reductions relatively quickly. They will deliver the bulk of their benefits after our grids have been fully decarbonized and the production of green hydrogen has been ramped up, but these promising new vehicles are also extremely valuable in the near term. More than any other U.S. institution, the EPA is in position to actualize their potential to deliver rapid, substantial CO2 reductions. Gasoline consumption could theoretically begin to fall very soon. Make it happen. Be bold. [EPA-HQ-OAR-2021-0208-0692-A1, p. 12]

Finalize Alternative Two and 10 Grams Per Mile of Additional Stringency

I strongly favor increasing stringency to the greatest extent possible, and I applaud the EPA for considering comments regarding an increase of up to 10 g/mile of additional stringency above its most aggressive alternative proposal. Automakers have a wide variety of options for achieving the highest level of stringency, which I still consider inadequate given the severity of the climate crisis. Many of the largest automakers have already made substantial investments to build and market BEVs, and their plans could be accelerated even further within the 2023-2026 timeframe, adding new models to their fleet mixes that will substantially improve their average fleet performance scores. The highest stringency levels will prepare these automakers for the 2027 framework, which will hopefully include inescapable zero emission vehicle mandates like those being adopted by other nations. Toyota, Honda, and Hyundai are well positioned to lead the way with FCEVs, which would benefit from the restoration of the FCEV multiplier. Tesla will continue to thrive, generating plenty of excess compliance credits that will be available to automakers that wish to continue deploying a pay-to-pollute compliance strategy. There are also many cost-effective ways to continue making small efficiency improvements to ICE vehicles. Automakers can improve their fleet mixes, reducing the sales volume of models that fail to meet their footprint targets. They can make greater use of off-cycle credits, taking advantage of the proposed higher cap. They can build up their credit banks in 2021 and 2022 while the Trump Administration's lenient rules are in effect. Those who argue that achieving a large stringency increase is unrealistic are being disingenuous. It can be achieved, and it must be achieved.

I write extensively about BEVs, and I am very optimistic that BEV adoption is poised to accelerate rapidly here in the United States. Vehicle range and charging times are improving and are about to surpass important thresholds that will greatly improve consumer acceptance. Solid state batteries are close to becoming a reality, with enormous potential to improve BEVs even further. Consumers are just beginning to recognize the benefit of home charging, and early adopters are spreading the word about the actual infrequency of remote public charging. The high cost of batteries is coming down as automakers benefit from innovation and economies of scale. Supply chains for the raw materials used to build batteries are quickly being improved and expanded. Charging infrastructure is being put into place and is moving toward a higher percentage of efficient Level 3 chargers. There is an increasing amount of variation in the types of electric vehicles coming to showrooms, and automakers are developing standardized platforms that can easily be adapted to accommodate numerous BEV model variations at lower costs. Tesla has singlehandedly demonstrated that it can 12 market desirable products and deploy its own highly capable, proprietary charging infrastructure. The aggressive ZEV mandates of environmentally responsible nations guarantee that BEVs will soon be built and sold on a massive scale. If BEV adoption accelerates even slightly beyond current conservative projections, all automakers should be able to achieve extraordinarily strict average fleet requirements while still selling their most inefficient ICE vehicles. The automakers have it within their power to accelerate BEV adoption at the required pace, and the EPA should require that they do just that. [EPA-HQ-OAR-2021-0208-0692-A1, p. 11-12]

Commenter: Pien, Natalie

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 43.]

A livable planet can be achieved through net zero carbon emissions by 2050. This goal requires Alternative 2 for 100 percent zero emissions from vehicles and power plants by 2035.

In addition, Biden rejoined the Paris Agreement and Alternative 2 is essential to meet the commitment to cut greenhouse gas emissions in half by 2030.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 45.]

Auto manufacturers are already phasing out ICE models in favor of EVs. Adopt Alternative 2 to reassure manufacturers that they are not taking a risk. Take the opportunity to transition our nation off fossil fuels. My husband and I have already embraced it. We purchased our first hybrid in 2010 and our first EV in 2019. With more charging stations, the need for a hybrid and its greenhouse gas emissions will be eliminated. Following the footsteps of our Canadian neighbors, by 2035 Canada will require 100 percent of all new light-duty cars and passenger truck sales to be zero emissions.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 45-46.]

In conclusion, I urge you to adopt the strongest possible standard as proposed in Alternative 2. It will close loopholes for automakers to avoid the standards all together.

Further, Alternative 2 is necessary to comply with Executive Order 12866 requiring agencies to choose the regulatory alternative that maximizes net benefits.

Commenter: Platt, Keari

As the proposed revision to the LDV GHG emissions standards are intended to meet President Biden's target to make 50% of all LDV sales zero-emissions by 2030, I support the proposed 10% increase in stringency. [EPA-HQ-OAR-2021-0208-0201-A1,p. 1]

Conclusion – Approval of 2023 Revised Emissions Standards For the above reasons, I support the EPA's proposed revision for the 2023 and newer LDV emissions standards. The proposed 10% stringency increase is not only reasonable and feasible, but it will ensure that all Americans from all income groups can purchase fuel efficient cars. This will in turn help the nation reduce is contribution to GHG emissions and global warming. [EPA-HQ-OAR-2021-0208-0201-A1,p. 2]

Commenter: Plug In America, the National Association of Electric Vehicle Drivers

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 78.]

We commend EPA for acting quickly on the clean car standards and given the choices, we would advocate for Alternative Number 2, although we're concerned that it is not nearly ambitious enough.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 79-80.]

We would urge to go beyond these alternatives and establish standards that aim for 25 percent electric vehicle market share for 2026 which would put us on track to achieve a hundred percent electric vehicle market share by 2035 as many countries and many states have already committed to do.

This change in the American automotive landscape needs to be more fully recognized. This is no longer 2012 when the Obama standards came out. Times have changed and this proposal needs to more closely reflect today's realities rather than just continuing a trend from 10 years ago.

As it stands, this proposal is going to seem dated and quaint by the time we reach Model Year '26. This is EPA's chance to step out of the business as usual trend line and really step into a more ambitious goal that we and many others will fully support with the agency and the Federal Government.

Commenter: Price, Heather

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 296.]

We really need a strong -- you know, when you're moving forward with these fuel standards, go as far as you can because we don't have much time. Make them really strong because we really need to get to zero, and that means electrify, electrify, electrify.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 297.]

So please, please, please, make the strongest standards that you can.

Commenter: Rambo-Jones, Lynn

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 108-109.]

The fact that the second timeline proposed is almost 30 years away frightens me. The fact that its goal is a policy reduction is even worse. Leaving federal service for a large industry paycheck is a common practice and could change the long-range plans and standards. We do not have the luxury of waiting for the timeline as proposed.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 110-111.]

Of course, I would advocate for the strictest possible standards with rewards going to auto companies that achieve results. The health benefits that would be reaped would result in reduced illness and deaths. It will improve some of the social injustice issues that have fallen on marginalized groups in the United States, but if more is not done now, America will not catch up with the progress made in a number of other countries, including China which is the beneficiary of all that Tar Sands we are endangering our standards to send to them.

There is not much glory in almost achieving standards from the Obama Administration tenure. We can't settle for half measures.

Commenter: Rauch, Molly

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p.36.]

Alternative 2 is the stronger option that would reduce climate pollution faster, putting 400,000 extra electric vehicles on the road by 2026 and resulting in a 130 million metric tons fewer greenhouse gas emissions among other significant benefits, including billions in economic benefits. This is the better option and Moms want you to go with Alternative 2.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 34.]

On behalf of the more than one million members of Moms Clean Air Force, I'm asking EPA to finalize the strongest possible greenhouse gas emissions standards for light-duty vehicles.

Commenter: Remilien, Sandra

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 120.]

Once again, I urge the EPA to set the strongest possible standards because they help with air pollution and lower greenhouse gas emissions. Alternative 2 saves $2,100 per vehicle. Please make our cars and light-duty trucks clean and efficient. Please make the clean car standards through 2030 stronger and for automakers to avoid these standards.

Commenter: Representative Padma Kuppa

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 145.]

I urge you to keep these standards as originally designed to ensure the greatest reductions in fossil fuel use and global warming emissions.

Commenter: Richards, Claire

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 267.]

I'm here to urge you to set the strictest possible clean car standards.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 269.]

We need to slow the progression of climate change without delay within our infrastructure and systems. This means that the EPA must finalize an ambitious rule this year in 2021 without any loopholes.

Commenter: Rivian Automotive, LLC

We applaud the proposal’s year-over-year increases in stringency and welcome the Biden Administration’s vision on EV deployment but believe that the topline goals can be reached without many of the so-called “flexibilities” embedded in the current proposal that diminish the rule’s environmental and economic benefits. Overall, the proposed rule moves in the right direction, but we urge the agency to adhere to its own cost-benefit analysis and select Alternative 2 when it finalizes the regulation—the option with the greatest environmental and economic benefits and the one that will drive the most rapid electrification of America’s light-duty vehicles. [EPA-HQ-OAR-2021-0208-0274-A1, p. 1]

Rivian Welcomes U.S. EPA’s Efforts to Strengthen National GHG Emissions Standards but the Proposed Rulemaking Could be Stronger

Rivian’s mission to keep the world adventurous forever is made manifest in its commitment to the environment and addressing climate change. We strongly support a program of ambitious GHG regulation in the transportation sector as core to our values and vision for the world. Given transportation’s role as the country’s number one source of GHG emissions at a time when the urgency of the climate crisis has never been clearer, such a program is also vitally necessary. Rivian applauded EPA’s decision in early 2021 to review the U.S. emissions standards for passenger cars and light trucks and welcomes the strides made in the proposal now subject to public comment. The agency’s recently announced reconsideration of the revocation of California’s waiver to set its own unique vehicle emissions standards was just as important. Course-correcting these regulatory actions after drastic rollbacks and reversals is no easy task.

EPA’s proposed rule for federal vehicle emissions standards represents a significant step in the right direction given the recent and announced gains in vehicle efficiency and electrification. Rivian welcomes the increased stringency of the proposal, and we recognize that the EPA and the Biden Administration more broadly view this rule as just a steppingstone to a second rulemaking for MY 2027 and later that will seek to firmly move the auto industry past the tipping point to an EV future. Certainly, Rivian agrees that aggressive regulatory action will be necessary to accelerate the pace of change given our view that the country should set a goal to achieve 100 percent EV sales by 2030.

However, we believe that this acceleration can begin now. Our analysis of the proposed rule identified several provisions that appear likely to soften the regulation's impact and result in delays to the stated goals of this administration to reduce emissions and electrify transportation. These proposed provisions are not necessary given the rapidly growing availability of superior EVs in every market segment. A simpler regulatory framework aligned with the auto industry's recent investments and commitments will make the proposed rule even stronger, reducing emissions from the transportation sector at a faster pace to better protect our climate and public health.

To Maximize Emissions Reductions and Accelerate Transportation Electrification, EPA Should Select and Finalize Alternative 2 and Take Additional Steps to Strengthen the Rule

Agency staff detailed the results of an extensive cost-benefit analysis performed as part of its deliberations in the documents introducing and accompanying the proposed rule. EPA's own calculations show that Alternative 2, of the proposed alternatives, will deliver the greatest net benefits to Americans, including monetized climate, environmental, and public health benefits.1 Despite these clear findings, a less beneficial alternative was proposed as the preferred alternative and the proposal fails to adequately justify its selection. This is inconsistent with both the Biden Administration's stated goals and priorities and, perhaps most significantly, with the directive of Executive Order 12866, later reaffirmed by Executive Order 13563, that "in choosing among alternative regulatory approaches, agencies should select those approaches that maximize net benefits…"2 Accordingly, Rivian believes EPA should, and in fact is obligated to, select Alternative 2 in its final determination. Finalizing any of the other proposed alternatives would not be justifiable on cost-benefit grounds.

One of the reasons Alternative 2 delivers superior benefits is its elimination of advanced technology multipliers.3 These multipliers are intended to encourage the use of advanced technologies such as electric drivetrains and EPA originally established them in 2012 as "temporary regulatory incentives" that "would help bring low emission technologies to market…"4 A rapidly proliferating lineup of EVs in all body styles and vehicle segments, however, suggests that these incentives have more than succeeded and are no longer necessary. The auto industry has amply demonstrated its ability to develop and commercialize advanced technology vehicles.

While Alternative 2 appropriately eliminates the multiplier incentive, it includes several other "flexibilities" that undermine the environmental integrity of the proposal and would likely slow the auto industry's transition to EVs.5 Rivian encourages EPA to take several additional steps to strengthen Alternative 2 in the final determination. [EPA-HQ-OAR-2021-0208-0274-A1, p. 2-3]

Finalize Alternative 2 without Flexibilities for the Strongest Possible Rule

While some stakeholders are advocating for additional flexibility and less stringent standards in the shortterm, the rollback of the standards under the previous administration mean that we can ill afford to adopt anything less than the most ambitious standards possible. Adopting Alternative 2 without the added reductions in stringency that come with new “credit flexibilities” is needed to realize the proposed regulation’s economic and environmental benefits and maintain U.S. leadership in developing advanced vehicles. EPA should continue driving transportation electrification and job creation in the U.S. by building on what the auto industry has already committed to do in the coming years.

Rivian urges EPA to adopt Alternative 2 without additional flexibilities to ensure American competitiveness, accelerate electrification, and maximize the environmental and economic benefits of the rule. In addition, and through separate action, we also encourage EPA to move quickly to reauthorize California’s waiver under the Clean Air Act as part of a comprehensive, pro-climate slate of actions. [EPA-HQ-OAR-2021-0208-0274-A1, p. 6-7]

Rivian Believes the MY 2026 Standard Should be More Stringent

In its notice of proposed rulemaking, EPA sought comment specifically on the appropriateness of a MY 2026 standard approximately 5-10 g/mi more stringent than proposed. The proposal correctly cites a growing list of bold commitments to vehicle electrification by traditional automakers, rapidly developing charging infrastructure, and the relatively greater lead time for the out-year as reasons why a more stringent standard might be warranted.18 Recent sales data only strengthen the case for increased stringency in MY 2026. The auto industry is on pace to achieve record EV sales in calendar year 2021. Through August, automakers sold more than 374,000 plug-in vehicles—already setting a new calendar year record with four months remaining in 2021 and positioning the industry be well on its way to the approximately 8 percent sales EPA projects in MY 2026 under the current proposal. This is a moment to recognize the expected EV adoption rate in the proposed vehicle emissions standards. Coupled with the other actions Rivian recommends above, we believe it is appropriate to finalize the rule with a more stringent requirement in MY 2026. [EPA-HQ-OAR-2021-0208-0274-A1, p. 6]

Commenter: Sabetta, Tracy

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 101-102.]

To reduce these harmful pollution levels and dire climate impacts and set us on the path to 100 percent zero emissions new vehicles by 2035, the near-term standards for climate pollution must be as strong as possible.

Please do not accept options that allow loopholes for automakers that may undermine otherwise strong pollution reduction targets.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 2.2.]

I urge you to adopt the strongest standards possible for passenger cars and light trucks through 2026.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 102.]

As you've heard, Alternative 2 would put 400,000 extra electric vehicles on the road by 2026 and result in 130 million metric tons fewer greenhouse gas emissions.

Commenter: Securing America's Future Energy

SAFE applauds EPA's decision to revisit the emission standards that the Trump administration relaxed just 18 months ago, and EPA's proposal certainly moves in the right direction by moving back towards the same trajectory that the Obama administration set in 2011. Yet, SAFE believes that EPA should not only choose the most stringent alternative (Alternative 2), which also generates the largest net economic benefits, but should explore adopting a more stringent standard designed to further accelerate the deployment of electric vehicles. EPA's analysis indicates that under this rule 8 percent of new vehicles in 2030 will be either electric or hybrid electric. Unfortunately, the reality of this proposed rule does not match the boldness of President Biden's vision, even as SAFE's analysis concludes that domestic automakers can shift a substantial share of the vehicle production to EVs without stranding past capital investment. Moreover, were EPA to properly account for the military costs we incur due to our dependence on oil, and were EPA to recognize the fuel savings and emissions reductions that can be generated by new safety technology, an even more stringent rule would be cost effective and likely generate even larger net economic benefits.

There is time for the automakers to move sharply towards the President's goal without stranding any current investment and in a manner that can protect auto workers' jobs. There is time for the federal government to more fully engage in the competition for global leadership in the automotive sector of the future. And most importantly, perhaps, there still is time to catch up to our economic competitors. But time is running short. SAFE encourages EPA to adopt alternatives whose stringency matches the President's vision, and build the foundation on which the United States can claim a position of global leadership in an electrified transpiration future. [EPA-HQ-OAR-2021-0208-0527-A1, pp. 2-3]

Stringency of the GHG Emissions Standard

In the proposed rule, EPA has identified three potential levels of stringency. EPA proposed standards for the Model Years (MY) 2023 – 2026 that are projected to achieve a fleet-wide average emission rate of 171 g/mile of CO_2 by 2026.[23] EPA set the stringency so that it would achieve, by 2023, the level of stringency of the California Framework and then decline linearly with stringency increasing 4.7 to 5 percent a year. For MY 2026, the standards would be about 3 percent more stringent than 2025, making it the most stringent standard ever.[24] Still, the standards would be slightly less stringent than the standard established in the 2012 Rule. EPA did not propose significant changes to the structure of the program, though it proposed limited changes to some of the flexibility mechanisms in the rule, including a limited extension of credit carry-forward for one or two years for credits generated between 2016 and 2020, incentives for hybrid pickup trucks, and an extension of the multiplier, though not in either of the alternative proposals.[25]

In Alternative 1, the less stringent alternative, EPA used the coefficients in the California Framework for the 2.7 percent effective stringency level for the MY 2023, and the 2012 rule's MY 2025 standards as the basis for the MY 2026 stringency level, with linear increases in stringency for the intermediate years. EPA selected this alternative as the least stringent standard it should consider because five automakers already agreed to this standard as part of the California Framework.[26] In Alternative 2, EPA adopts the 2012 rule stringency levels for MY 2023 through 2025, and then extends the rate of increased stringency through MY 2026.[27] EPA also sought comment on the adoption of an emissions rate for MY 2026 that was between 5 and 10 g/mile lower than the rate proposed and the rate in each alternative.[28]

In its analysis, EPA also identified the costs and benefits associated with each of the three alternatives. In each instance, the benefits of the alternative exceeded the costs. In EPA's proposed standard, EPA forecast net benefits between $86 and $140 billion. For Alternative 1, EPA forecast net benefits to be between $76 and $130 billion. For Alternative 2, EPA forecast net benefits to be between $110 and $180 billion. It appears that EPA did not estimate the net benefits of adopting an increased level of stringency in MY 2026.[29]

SAFE carefully examined the preamble to the rule and the supporting RIA. We could not find an explanation of why EPA selected the preferred alternative. There was no indication in the preamble to the proposal that automakers are not capable of meeting the more stringent standard. In fact, the standards established in 2012 were just recently relaxed, making it unlikely that automakers substantially changed their plans such that they could not meet the more stringent standards, which, as recently as 17 months ago, were already expecting to have to meet.

EPA also forecast that under its proposed standard the combined sales of EVs and PHEVs could grow to eight percent of the market by 2026.[30] Unfortunately, President Biden's vision of EVs constituting 50 percent of all new vehicle sales by 2030 [31] is not matched by the stringency of EPA's regulation. For there to be any possibility of EV sales approaching President Biden's goal, EPA must consider a more stringent standard.

SAFE, therefore, requests that EPA revisit its choice of alternatives and choose an alternative that generates the greatest net economic benefits. This approach is consistent with Executive Orders 12866 and 13563. EO 12866, which outlines the government's regulatory philosophy and principles directs agencies to 'assess all costs and benefits of available regulatory alternatives, including the alternative of not regulating,' and 'in choosing among alternative regulatory approaches, [ ] select those approaches that maximize net benefits.'[32] This approach was reaffirmed in EO 13563, which restated the federal government's general principles of regulation. It stated that 'agencies must, among other things: (1) propose or adopt a regulation only upon a reasoned determination that its benefits justify its costs . . . and (3) select, in choosing among alternative regulatory approaches, those approaches that maximize net benefits.'[33]

Some stakeholders may suggest that there is not time for the automakers to make a quicker transition without incurring substantial stranded costs. Analysis included pages 6 through 8 of Attachment 1 shows that each of the top 15 vehicle programs produced in the United States are expected to transition to a new program before 2030. In fact, as also reflected in that analysis, most of the conventional vehicles that will be produced in the United States in 2030 are part of programs that are early enough in their production cycle that the automakers can transition the program to electric platforms without stranding investment.

At an absolute minimum, EPA should select Alternative 2. It should, however, perform additional analysis of the opportunity to establish a standard of between 5 and 10 grams per mile more stringent in 2026, and select the more stringent standard if the analysis indicates that it will achieve greater emission reductions and there is no obvious obstacle to automakers meeting the more stringent standard. If EPA has sufficient flexibility under the Administrative Procedures Act, it suggests that EPA consider increased levels of stringency, perhaps combined with a reinstituted multiplier for electric vehicles, as explained below. [EPA-HQ-OAR-2021-0208-0527-A1, pp.9-10]

Commenter: Sainz, Columba

[The following comments were submitted as testimony at the virtual public hearing on August 26 2021. See Hearing Testimony – 26Aug2021, p. 226.]

President Biden has promised to address climate change and fight for environmental justice and EPA should finalize the strongest possible option and put America's families and health first.

Commenter: Scholar, Reverend

By setting standards that put the U.S. on a pathway to eliminate all passenger vehicle tailpipe pollution by 2035, Environmental Defense Fund estimates that the U.S. could:

1. Prevent as many as 98,000 premature deaths by 2050;

2. Reduce a total of more than 11.5 billion metric tons of carbon pollution by 2050; and

3. Provide more than $1.6 trillion in benefits to Americans, including pollution reductions and economic savings.

EPA’s proposed rule to strengthen?federal greenhouse gas (GHG)?emissions standards for passenger cars and light trucks is a necessary step to address the climate crisis and protect our communities from harmful air pollution. But it is not enough. Please restore American leadership on climate by promulgating strong standards to eliminate pollution from all passenger vehicles. Together, we can protect Americans’ health, the climate, and our pocketbooks. [EPA-HQ-OAR-2021-0208-0724-A1, p. 1]

Commenter: Seeman, Carolyn

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 185-186.]

Please adopt Alternative 2 which would lead to cleaner air.

For all of us with respiratory problems, stronger emission standards for cars are a matter of life and death.

We all need to do our part go make the world a healthier place to live.

Please reinstate the Obama/Biden federal standards with Alternative 2 and set even stronger ones through the next decade.

Commenter: Shevelew, Jonathan

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 117-118.]

If you accept 20-year targets that will eliminate any sense of urgency, then it will take the full 20 years for this transition to happen.

The EPA is noting already the need for a longer-term rule. So why once again are you going to kick that can down the road? Your current proposals don't even meet the goals of the Obama Administration. This is not earth-shattering news to vehicle manufacturers. They have known that this was coming for years but had no incentive to move towards EVs.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 118.]

By setting 2025 as the goal to eliminate GHG emissions from light-duty vehicles, it assures there will be no future diversions based on a changing political landscape.

Faced with severe penalties for noncompliance beginning in 2026, I have no doubt that the OEMs will find a way to make this happen.

Commenter: Shiffrin, Joyce

Hello, my name is Joyce Shiffrin, and I am sending you this e-message because I am urging and begging you to do whatever you can to have 400,000 new electric vehicles on the roads by 2026. Why is this particular issue pertinent to me? Because as many of us unfortunately know, climate change is imminent.

Therefore, we must ALL do whatever we can to change that. One way is for ALL of us to drastically cut down on (ideally, ELIMINATE) ALL fossil fuel production as well as consumption. [EPA-HQ-OAR-2021-0208-0405, p. 1]

Commenter: Singh, Varsha

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 298].

This proposal and the broader actions on clean cars from the Administration are a meaningful step in the right direction, but we really need the strongest possible clean air standards to truly make good on President Biden's commitment to address climate action and environmental justice.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 299-300.]

So, what I'm saying here in this public hearing is that we need stronger standards. There is a need for stronger standards. EPA's proposal is a necessary step towards addressing the previous Administration's rollback of cleaner car standards, but it's not only a start. You must finalize this rule by this year, 2021, because we really do not have time because the covered model year is 2023 to 2026, and set up more health protection standards beyond that. Please ensure that the standards result in the real-world reductions in greenhouse gas emissions, and please don't include any shortcuts for auto makers to cut corners. We know that car is necessary for every one of us, and we all are going to use cars, but what we require is an eco-friendly car.

Commenter: Smith, Arthur

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 316-317.]

The Biden Administration has pledged to put the U.S. on track to reduce greenhouse emissions by more than 60 percent by 2030. Alternative 2 is the better plan because it closes loopholes, saves consumers, and addresses the ongoing climate crisis.

Let's get on with it. By 2030, we should be able to convert to all renewable energy. Fewer electric cars versus hybrids are the best, most efficient transportation alternative and emit zero pollution. We must fix the source of electric power, however.

Commenter: Smith, Graham

We need a far faster reduction in CO2 emissions than proposed if we are to survive the current path of climate change. Please be far more aggressive in pushing the auto industry to do the right thing and cut tailpipe emissions. [EPA-HQ-OAR-2021-0208-0345, p. 1]

Commenter: Smith, Rita L.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 103.]

I urge the EPA to set the strongest possible federal clean car standards to ensure we are protecting families from vehicle pollution.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 104-105.]

By implementing the strongest possible fuel economy standards, the EPA would be following through on the stated commitment to environmental justice because issuing stronger clean car standards will help address transportation-related impacts.

Commenter: South Coast Air Quality Management District

Regarding the request for comment on 5 to 10 g/mi greater stringency for MY2026, the District supports the greatest stringency and greatest degree of emission reduction that can be borne out by valid record support, while noting and agreeing with EPA that it has 'clear authority to set standards under CAA section 202 to be technology-forcing.' 86 FR at 43752. The proposal indicates that a greater acceleration in the transition to electrified vehicles bolsters the case for added stringency. [EPA-HQ-OAR-2021-0208-0215-A1, p.3]

Accordingly, the 10 g/mi greater stringency is reasonable and defensible on the mere point that the U.S. market should aspire to attain, or even keep pace with, these already materialized trends in the global market. Considering the state of development of the technology, anything less risks a failure of imagination and foresight.1 If the question is whether the U.S. can outperform an 8 percent market for electric vehicles (including PHEVs) by MY2026, the EPA should decisively land on greater stringency. To assume otherwise would suggest the United States in five years would still be behind where European Union sales are today, and that striking assumption appears untenable and should call for greater record justification. Notably, in Q1 2021 in California--the state with nation's largest vehicle market by virtue of population--plug-ins were already 10.8% of total vehicle sales.2 This trend will only increase and accelerate. Meanwhile, aggressive standards are warranted and needed to slash GHGs and further promote these trends. [EPA-HQ-OAR-2021-0208-0215-A1, p.3]

1 By way of analogy, consider that 50% of mobile phone using Americans shifted and adopted smartphones in the span of just 10 years (2011-2021). See Pew Research Center, Mobile Fact Sheet, April 7, 2021, https://www.pewresearch.org/internet/fact-sheet/mobile/

Commenter: Southern Environmental Law Center

The benefits of more stringent standards add up. Beyond the year-over-year increases in stringency, it is important to assess the cumulative impact the standards will have of GHG emissions reductions. The adoption of even the most stringent standards evaluated—Alternative 2—will not make up for GHG emissions reductions forgone due to the relaxation of the standards under the SAFE Rule, and it is critical that EPA maximize cumulative GHG emissions reductions under these standards. The alternatives analyzed by EPA have seemingly small differences in stringency for individual model years (the CO2 targets for the various alternatives differ between 2 and 6 grams per mile in any given model year[27]), but these differences add up: Alternative 2 would result in almost 300 million metric tons (MMTs) fewer GHG emissions through 2050 than the current proposal.[28] [EPA-HQ-OAR-2021-0208-0244-A1, pp. 4-5]

Stronger standards also make sense when considering the net benefits of the proposed rule. Alternative 2 is projected to deliver between $24 billion and $40 billion more in net benefits through 2050 than the current proposal.[29] Part of that benefit comes from fuel savings. Drivers are estimated to save between $150 billion and $290 billion through 2050 under Alternative 2 (as compared to between $120 billion and $250 billion under the proposed standards over that same period).[30] These savings make a real difference for drivers, especially for low-income households and households of color that generally spend a greater proportion of their income on transportation costs.[31] [EPA-HQ-OAR-2021-0208-0244-A1, p. 5]

For these reasons, EPA should, at a minimum, adopt Alternative 2 and the more stringent standards proposed for model year 2026. [EPA-HQ-OAR-2021-0208-0244-A1, p. 6]

Strong tailpipe GHG emissions standards represent one of the most valuable ways to begin to address the role of transportation in driving climate change. EPA should, at a minimum, adopt the more stringent Alternative 2 standards, as well as the stronger standards proposed for model year 2026. This will maximize the benefits and cumulative GHG emissions reductions from the regulations, and help to protect the environment and public health and safety.[EPA-HQ-OAR-2021-0208-0244-A1, p. 8]

In order to protect the environment and public health and safety, EPA should, at a minimum, adopt the more stringent Alternative 2 standards, as well as the stronger standards proposed for model year 2026. EPA's analysis shows that Alternative 2 would provide much greater overall benefits than its current proposal, and that compliance with the standards should be feasible for vehicle manufacturers [EPA-HQ-OAR-2021-0208-0244-A1, p. 2]

Commenter: Spencer, Sam

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 152-153.]

It is far too weak to achieve the climate progress we need and contains loopholes that would allow auto manufacturers to continue to double down on gas-guzzling vehicles.

The proposal would also result in much less pollution reduction than the auto industry already agreed to in 2012, nearly a decade ago.

So for sprawling southern cities, like mine, that have to work with state legislatures that ignore climate science, it just isn't good enough. The EPA should finalize the strongest possible clean car standards to protect our communities from vehicle pollution, save drivers and sprawling cities like mine from spending more money at the pump and fight climate change.

You have a prime opportunity to strengthen these standards and protect our climate, public health, and the economy by ensuring clean car standards are as strong as possible and for my city, my family, and our neighborhoods, I sincerely hope you take it.

Commenter: St. Julien, Rene

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 211.]

I support this Administration's swift action on clean cars but also urge the EPA to adopt their second alternative which would deliver greater savings to consumers and eliminate unnecessary loopholes for automakers.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 213.]

In conclusion, I would like to urge this Administration to be aggressive and set the strongest possible standards. They also need to prioritize Alternative 2 in the proposed ruling eliminating unnecessary loopholes for automakers.

Commenter: Stein, Karen

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 277-278.]

With my words in Spanish, I wish to underscore that limiting pollution from dirty vehicles is essential in achieving environmental justice. The EPA must set the strongest possible federal clean car standards and put automakers on track to meet the pollution reduction goals that the Intergovernmental Panel on Climate Change tells us we must achieve.

Commenter: Steitz, Jim

I urge you to set the most aggressive feasible auto efficiency standards, with an expansive view of what is technologically possible, not merely what automakers claim is economically feasible or compatible with their business model. Unless and until the oil and automotive industries lose the colossal subsidy of the free use of our atmosphere as carbon dumping ground, EPA must crack down on this ecological catastrophe through its existing regulatory authority. In setting new auto efficiency standards, the controlling, central organizing concern of EPA must be mitigating the existential threat of climate change. The need of human civilization to reduce carbon emissions must override all immediate economic objections from automakers, the oil industry, dealerships, or any other parties that may have financial objections to strong standards, but whose lives are not literally in jeopardy, as are those of our children. The selection of Alternative 2 and reinstatement of standards set by the Obama Administration should be considered a perfunctory minimum policy. In fact, EPA should look to the analysis of the International Energy Agency from May, outlining the most economically and technically plausible way to keep climate change below catastrophic levels. IEA found that internal combustion vehicle sales must end by 2035. Any EPA policy that does not force automakers onto this path does not acknowledge reality. [EPA-HQ-OAR-2021-0208-0422, p. 1-2]

Moreover, there must be no opportunity for evading the mileage standards by shifting around sales volume among categories. Auto efficiency standards for three decades have been undermined by the farcical classification of SUV's as 'light trucks.' Manufacturers then promote these quasi-military vehicles to satisfy masculine vanity or illusions of personal safety, neither of which are related to the category's original purpose of actual work vehicles [EPA-HQ-OAR-2021-0208-0422, p. 2]

The standards must commence immediately, with mileage improvements in the next vehicle year, not be backloaded to let manufacturers stall for time and lobby to weaken the standards later. The past three decades of feckless haggling with industry over carbon emissions demonstrates that targets for a decade or more away are consistently ignored, either as someone else's concern, or a nuisance for the government relations office to fix. [EPA-HQ-OAR-2021-0208-0422, p. 2]

Commenter: Stellantis

A three to fivefold increase in demand for electric vehicles is required to achieve the proposed requirements. The following supplemental policies and initiatives are critical to remove the barriers to electric vehicle acceptance and accelerate market demand in order to protect jobs:

- Update Federal EV Incentives and Apply at Point of Purchase

- Expand and Scale Charging Network to EV Volumes Required by Proposed Rule

- Implement Fleet Purchase Requirements

- Develop Domestic Battery Supply Chain (raw materials, manufacturing, and recycling)

- Increase Research & Development

- Improve Fuels and Implement a Nationwide Low Carbon Fuel Standard

- Increase Consumer Awareness of EVs [EPA-HQ-OAR-2021-0208-0532-A1, p. 6]

The EPA Proposed Rule is More Stringent by MY2026 than the Original Standards Set in 2012 by the Obama Administration

In 2012, EPA and NHTSA issued final and augural rules respectively covering MY2022-2025; the '2017 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions and Corporate Average Fuel Economy Standards' ('2012 final rule').8 The agencies concluded at that time, and again after the midterm evaluation, that these standards were appropriate and that they could be achieved with very little strong electrification (high voltage electrification as in HEVs, PHEVs, and BEVs).

In 2020, the EPA and NHTSA finalized a joint rule, 'The Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Years 2021–2026 Passenger Cars and Light Trucks' ('SAFE rule'),9 which revised greenhouse gas and fuel economy standards stating that assumptions made in the 2012 final rule were inaccurate. The SAFE rule revised standards for MY2021-2026 based on updated assumptions for market conditions and acceptance of electrification.

Separately, California withdrew the provision that deemed OEMs compliant with California's GHG requirements if they met federal standards, and instead negotiated a unique, nation-wide settlement agreements (i.e., 'California Framework Agreement') with some OEMs. This

Framework includes standards that are more stringent than the SAFE rule, but provides some relief compared to California's standalone GHG regulation. The EPA proposal (as defined) provides greater overall emission reductions than the California Framework.

Below is a chart comparing a fleet average light-duty footprint standard under the EPA NPRM proposed rule to the SAFE rule, California Framework, and 2012 final rule. [Figure 1 can be found on p. 8 of Docket number EPA-HQ-OAR-2021-0208-0532-A1]

The EPA proposed rule gets industry to a more stringent MY2026 endpoint than the California Framework, and the 2012 Final Rule (Obama). The stringency ramp rates proposed with the EPA rule are unprecedented, achieving a 10% reduction in MY2023 followed by 5% per year in MY2024-2026. [EPA-HQ-OAR-2021-0208-0532-A1, pp. 8-9]

Time is Needed to Transition the Fleet and Close the Gap to Current Standards

Stellantis supports the proposed rule because it allows time for industry to catch up to the standards. There is a significant market and industry challenge to achieve the necessary electrification to meet the requirements proposed and establish a pathway to 40-50% market penetration by 2030. This challenge is demonstrated by the magnitude of growth required to achieve these levels from today's starting point of 2.5%, as well as the need for immediate increases in the EV market to meet even the current requirements. [EPA-HQ-OAR-2021-0208-0532-A1, p. 11]

Shown in Figure 2 below from the 2020 EPA Trends Report, 11 of 14 major manufacturers underperformed their MY2019 standard and relied on the use of banked or purchased credits.17 [EPA-HQ-OAR-2021-0208-0532-A1, p. 11] [Figure 2 can be found on p. 11 of Docket number EPA-HQ-OAR-2021-0208-0532-A1]

In addition, as shown in the figure below, Industry's overall deficit to standard increased from 1 g/mi in MY2018 to 7 g/mi in MY2019 and third party analysis project the deficit will continue in MY2020 for the fifth consecutive year.18 This is a clear indication that the additional time afforded In the proposed rule is needed to grow the market demand for more efficient electric vehicles, before even more stringent standards, requiring higher rates of electrification, can be implemented. [EPA-HQ-OAR-2021-0208-0532-A1, p. 12] [Figure 3 can be found on p. 12 of Docket number EPA-HQ-OAR-2021-0208-0532-A1]

Establishing a pathway that can close the gap to current requirements, meet the EPA proposed rule and achieve 40-50% electrification by 2030 requires an unprecedented transition of the new vehicle fleet

It takes the automotive industry (and Stellantis) 2 to 4 years to introduce a new product. 'Top Hats', or vehicle renewals that only involve changes to the visible surfaces on the interior and exterior of a vehicle can be developed in as little as 2 years. In contrast, a brand new vehicle that includes a new powertrain, chassis, body architecture and electronic architecture; can take more than 4 years from concept to volume production. [EPA-HQ-OAR-2021-0208-0532-A1, p. 12]

OEMs historically have justified powertrain business cases over at least a ten-year time horizon, straddling two or more vehicle programs. This time horizon is driven by the need to introduce new technology, but constrained by the large levels of capital needed for the design, engineering, testing and validation of engine and transmission programs as well as the capital investment required for the machining and assembly lines for drivetrain components and assemblies.19 [EPA-HQ-OAR-2021-0208-0532-A1, p. 12]

As mentioned above, Stellantis is committed to an electrified future, targeting over 40% of sales in the United States to be plug-in hybrid or full battery electric vehicles by 2030. To achieve this ambitious vision, focus must remain on transformational electrification investments, starting now in order to minimize the time and maximize the success of this transition. [EPA-HQ-OAR-2021-0208-0532-A1, pp. 12-13]

More Stringent Alternatives than the Proposed Rule Add Risk

The EPA should not adopt the more stringent alternatives discussed in the NPRM since the EPA proposed rule is more stringent than the current rule, as well as the California Framework and 2012 final rule by MY2026, and requires at least three to fivefold growth in EV sales.

As shown in the figure below, the more stringent alternative (Alternative 2) proposed by EPA includes a steeper ramp rate in MY2023 than the already unprecedented 10% jump in the proposed rule. Additionally, EPA also proposes an added 5-10g/mi stringency for MY2026 – introducing an extra 6% jump in stringency in the final year. [Figure 4 can be found on p. 13 of Docket number EPA-HQ-OAR-2021-0208-0532-A1]

These more stringent alternatives add unnecessary risk to an already ambitious proposed regulation. The current demand for electrified vehicles is 2.5% and most OEMs (and industry on average) are not meeting standards on the books today. Even EPA's own modeling conservatively estimates that demand for EV's will need to at least triple by MY2026 to meet the proposed rule, whereas NHTSA modeling predicts a fivefold increase. Stellantis believes even more EV growth will be needed.

More stringent options propose high ramp rates earlier in the program at a time when industry is investing in EV technology and challenged to meet current standards. These alternatives place more strain on the supporting infrastructure and incentive programs. Additionally, increasing stringency an additional 6% in the final year does not significantly impact net CO_2 savings for the entire MY2023-2026 rulemaking period, but does add significant risk by introducing a single year jump in stringency at the end of the program.

EPA should avoid this additional risk and not adopt the more stringent Alternative 2 and instead move forward with the already ambitious targets as proposed without an additional 5-10g/mi increase in MY2026. [EPA-HQ-OAR-2021-0208-0532-A1, pp. 13-14]

Stellantis Supports EPA's Proposed Rule with Improvements to Flexibilities Stellantis supports EPA's proposed approach that retains MY2021-2022 SAFE standards, with an additional 10% reduction in MY2023, followed by 5% annual reductions through MY2026. These ambitious and challenging standards surpass fleet g/mi targets of the SAFE rule, California Framework and the Obama 2012 final rule standards by MY2026, delivering significant CO2 savings and relying on unprecedented growth in electrification far beyond the 2.5% penetration level seen today. [EPA-HQ-OAR-2021-0208-0532-A1, p. 2]

Stellantis Supports the EPA Proposed Rule with Improvements

Stellantis supports the EPA proposed rule for GHG. It strikes the right balance of core program stringency to aggressively reduce GHG emissions and fuel use, while not going so far as to dramatically shrink the light-duty vehicle market which would reduce the environmental benefits of a compliant new vehicle fleet. [EPA-HQ-OAR-2021-0208-0532-A1, p. 8]

Stellantis does not support EPA's other, more stringent, alternative or the addition of 5-10g/mi of added stringency in the final year. The preferred alternative strikes a better balance of ambitious targets with time to transition product line-ups necessary to support the projected mix of electrified vehicles by MY2026. [EPA-HQ-OAR-2021-0208-0532-A1, p. 2]

Commenter: Sturza, Taisia

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 171.]

That EPA must act to make clean car standards as strong and far-reaching as possible. It would be a win for the American people and all those looking to spur job creation, economic growth, family cost savings, and public health protection at the time when we need it most.

I urge the EPA Administration to be leaders in achieving a zero emissions future with strategic and aggressive goals to help mitigate the impact of air pollution on our health and therefore our livelihoods and our future.

Commenter: Tafoya, Ian

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 189.]

I am here today to ask you to go as strong as you possibly can. We need downpayment since even beyond tax incentives for us to truly make this change.

I've been involved in transportation electrification planning processes here at my Public Utilities Commission and through our conversations with business owners and people that is what they want.

Commenter: Terwilliger, Phyllis

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 34.]

The EPA must, must set the strongest possible federal vehicle emission standards to ensure we are protecting families from pollution and reversing climate change.

Commenter: Tesla

As EPA notes, the agency seeks, inter alia, comments as to whether 'there may be the potential for higher levels of EV penetration by MY 2026, which could enable EPA to consider a more stringent standard for MY 2026.' As described below, EPA's proposal has vastly underestimated the rapid and growing deployment of electric vehicles (EVs). Consequently, the agency proposes standards low in ambition and easily accomplished, due to unneeded compliance flexibilities that erode the level of greenhouse gas (GHG) emissions reductions that would be achieved by this rulemaking. Such reductions are critical to sufficiently protect the public health and welfare in view of the progressing understanding of climate science around climate-induced impacts.

Based on internal modeling that Tesla has confirmed with government and non-governmental experts, the proposed changes will make the GHG standards weaker than the Trump SAFE Rule's outcomes in Model Year (MY) 2021 and MY 2022 by making available new flexibilities without any accompanying increases to the standards' stringency for these model years. Additionally, from MY 2023 to MY 2026 the equivalent of 30% of EPA's proposed stringency is lost to the new and expanded compliance flexibilities. In contrast to these proposed outcomes, there are compelling grounds for EPA to adopt a rule whereby, starting in MY 2023, the standards should be made much more stringent, all proposed compliance flexibilities should be removed, and the final standards should put the country on a trajectory to achieve 100% EV sales by 2030.

As President Biden recently stated in a speech in the wake of Hurricane Ida, 'They all tell us this is code red; the nation and the world are in peril.' Unfortunately, this EPA proposal needs to be strengthened to get to the level of ambition required to meet the President's clarion call for action, especially considering the proven technological capability of automakers to meet much more stringent standards.[EPA-HQ-OAR-2021-0208-0278-A1][p.1]

As proposed, the EPA's new light duty vehicle (LDV) standards take an initial step backwards even for the standards which are well underway. EPA's proposal is neither sufficiently stringent through MY 2026 to meet the agency's statutory burden of protecting the public health and welfare from the impacts caused by climate change, nor does it support the level of EV deployment necessary to meet the Administration's near-term 2030 decarbonization goals. If implemented as proposed, the rules will: (1) increase carbon emissions near term; (2) result in a low-ambition deployment of the best available light duty emission-reducing technology (electric vehicles); and (3) further erode U.S. leadership in the manufacturing of advanced vehicle technologies. Such an outcome would not be justified in view of the extensive record supporting far more ambitious targets.

While the topline of EPA's proposal is anchored to the need to meet an increase in stringency in MY 2023 of about 10 percent compared to the SAFE rule MY 2022 levels, due to extensive compliance flexibilities offered, the actual near-term stringency achieved by the proposed rule would be significantly reduced. In granting one and two-year retroactive extensions to the existing bank of MY 2016 and 2017 credits coupled with increased and new 'flexibilities,' EPA takes a step backwards in overall carbon reduction for the next several years. Given these flexibilities, Tesla internally models that the proposal will result in a significant step backwards in stringency for MY 2020-2022, with higher actual fleet wide g/mi emissions levels than even the SAFE rule stringency attempts to deliver for these years. See Figure 1. Such a result adds to carbon emissions in these early years. In the MY 2023, fleet average is slightly reduced from SAFE MY 2023 levels but at level that falls significantly short of EPA's advertised 10% stringency reduction. [EPA-HQ-OAR-2021-0208-0278-A1][pp.3-4] [Figure 1 can be found on p. 4 of EPA-HQ-OAR-2021-0208-0278-A1]

While the proposal on its surface appears to improve upon the overall stringency from MY 2024-2026, when factoring in a conservative use of the expanded compliance flexibilities the cumulative stringency falls short of past standards and does not catch up to the levels of compliance required by the LDV standards originally put in place starting in MY 2017.26 In that regard, EPA has released a proposal that – despite the significant advancement and deployment of electrification technology that has occurred in the last decade – is less ambitious than what the agency deemed appropriately protective in late-2011. Emblematic of this inadequate ambition is the EPA's proposal use of a MY 2017 baseline.27 This baseline simply ignores the accelerating deployment of EVs, including the Tesla Model 328 and Model Y29 both of which have become some of the top selling vehicles in U.S. after the MY 2017 baseline year used by EPA. In fact, in the first half of 2021, EV sales in the U.S. doubled and outpaced rising ICE vehicles sales.30 Similarly, in July 2021, EVs represented 5% of all light duty vehicle sales and 20% of all U.S. passenger car sales.31 In light of this rapid market expansion, the agency's proposal does not reflect real world experience in envisioning only 'minor increases' in ZEV penetration in MY 2026 at rates below what already exists in many non-U.S. markets.32 [EPA-HQ-OAR-2021-0208-0278-A1][pp.4-5]

Given the acceleration of public health and welfare impacts associated with climate change, it is incumbent upon the EPA to recognize the appropriate role EV technology plays today and how widespread commercial availability of EVs in the U.S. today should inform the implementation of a far more stringent standard. Accordingly, for the reasons described herein, the EPA should amend its proposal using Alternative 2 as a starting point, add 10 g/mi of stringency, and take the following additional steps to increase its overall stringency:

• Eliminate the one and two-year lifetime retroactive extensions of previously earned and expiring credits;

• Eliminate the Alternative Vehicle Technology multiplier which serves to diminish real life delivery of EVs (as is proposed in Alternative 2);

• Eliminate the proposed Advanced Technology Incentive for Full-Size Pick-ups; and

• Eliminate the Expansion of Off-Cycle Crediting volumes and eliminate all off-cycle crediting, at a minimum, after MY 2025.

These changes will significantly reduce emissions, result in increased deployment of the best available emissions reduction technology (ZEVs) consistent with the emissions reduction technology requirements of the Clean Air Act standard setting mandate under section 202, and ensure the Administration is meeting it statutory mandate to protect the public health and welfare.

As currently formulated, the EPA's proposal represents indifferent and diminished views of the status of electrification in the light duty sector, fails to recognize the pace and acceleration of EV deployment that will occur between now and MY 2026, and perpetuates, albeit perhaps unintentionally, a general disregard for the superior emissions and efficiency benefits delivered by EV technology. The result is a proposed rule that fails to meet a reasonable level of protection for addressing the public health and welfare impacts from air pollutant emissions and climate change. While Tesla also believes it is essential for EPA to establish longer-term rules of the road as well that actively embrace a more wholesale transition to EVs, and that the time for doing so is ripe, our comments here are focused on those elements of the proposal that impede what these rules purport to accomplish immediately and in the short term.

The EPA is in a position to create the benchmark for North American emission standards. For example, it is not uncommon for Canada to align its standards with the EPA. Addressing the weaknesses introduced by the compliance flexibilities could push other countries to further accelerate emissions reductions in the transport sector. On the other hand, Canada has already announced plans to require 100% ZEV sales by 2035.33 If EPA's final rules are seen to be insufficiently stringent to reach the 2035 goal, Canada could establish its own rules, which could perversely impact the ability for U.S.-based manufacturers to export compliant products to Canada. Finalizing a much more stringent rule is essential to put the country back into a position of international leadership and to deliver on the President's stated goal of 50% emission reductions by 2030 and reach mid-century decarbonization. [EPA-HQ-OAR-2021-0208-0278-A1] [p.5]

President Biden has himself established goals 'that 50 percent of all new passenger cars and light trucks sold in 2030 be zero-emission vehicles'44 and asserted that to respond to the climate crisis 'will require both significant short-term global reductions in greenhouse gas emissions and net-zero global emissions by mid-century or before.'45 Given the long fleet vehicle turnover time,46 the EPA's proposal that would result in a 7.8% fleet penetration for EVs (including PHEVs) is wholly inadequate given the state of EV technology and the urgency to reduce GHG emissions from the transportation sector.47 A recent analysis has shown that to achieve the Administration's emissions reduction goal the U.S. fleets needs to achieve, as Tesla urges, between 95- 100% light-duty EV sales by 2030.48 Others analyses point out that rapid electrification during the decade of 2025-2035 is essential to staying within the needed carbon budgets.49

Stringent performance standards are critical to accelerating the electric transformation of the light duty sector. As the EPA notes:

Title II emission standards have stimulated the development of a broad set of advanced automotive technologies, such as on-board computers and fuel injection systems, which have been the building blocks of automotive designs and have yielded not only lower pollutant emissions, but improved vehicle performance, reliability, and durability. In response to EPA's adoption of Title II emission standards for GHGs from light-duty vehicles in 2010 and later, manufacturers have continued to significantly ramp up their development and application of a wide range of new and improved technologies, including more fuel-efficient engine designs, transmissions, aerodynamics, and tires, air conditioning systems that contribute to lower GHG emissions, and various levels of electrified vehicle technologies.50

Despite recognizing how past stringency has ramped up electrification technologies, the EPA's proposal fails to reflect the need for rapid electrification, instead settling for stringency levels that will result in only 'relatively minor increases in penetration of plugin electric vehicles,'51 in contrast to the demonstrated availability and cost effectiveness of this emissions reduction technology.

As the only U.S.-based manufacturer of EVs that exports its vehicles abroad, Tesla believes maintaining the stringency of the current performance-based LDV standards is also essential to ensuring U.S. manufacturers' ability to compete abroad and build greater export markets. Ensuring stringent long-term standards will create stability and an investment environment that propels domestic manufacturers like Tesla to invest continually in technology and to expand manufacturing for both the U.S. and foreign EV markets. As the Department of Energy (DOE) has concluded, without specific support of EV deployment the U.S. will lag other countries and the country needs to 'move fast to catch up.'52 [EPA-HQ-OAR-2021-0208-0278-A1][pp.7]

Indeed, other regions and countries have implemented and/or proposed performance standards that establish decarbonization trajectories that are markedly more aggressive than the EPA's proposal. Despite being the world's second largest vehicle market, the U.S. lags dramatically behind other countries in both EV fleet penetration and the stringency of the performance standards that advance the deployment of advanced technology vehicles. In the first half of 2021, EVs accounted for 12% of all passenger cars sold in China53 because of a comprehensive national plan for EV deployment including more stringent efficiency standards.54 In the fast half of 2021, 1 million EVs were also sold in Europe, accounting for 15% of new cars.55 In 2020 the E.U. established emissions standards at 95 g CO2/km (152.9 g/mi56), with a 15% cut coming in 2025,57 and has adopted a proposal to accelerate GHG emissions reductions with a next generation of light duty standards that will achieve a 55% reduction in CO2 emissions from new passenger cars by 2030, relative to 2021, and a full phase-out of new combustion engine vehicles – including PHEVs - by 2035.58

While EPA's proposal requests comments as to whether the investments being made now for expanded EV products allow for more stringent MY 2026 standards,59 individual country markets – including in North America – have demonstrated that EV market sales rates can achieve high percentages of total vehicles sales now.60 According to the World Economic Forum, thirteen countries had over 10% of electric vehicles make up new light vehicle sales in 2020.61 In 2021, all regions and most countries have seen strong increases in EV sales, with growth rates 3 to 8 times higher than for total light duty vehicle markets.62 Indeed, this market share reached 14% in the first half of 2021 in Europe (EU+EFTA+UK).63 Importantly, these figures demonstrate that manufacturers, when operating in markets with more stringent performance standards, can and will deliver the vehicles and electrification technology now in volumes far greater than EPA has proposed to achieve five years into the future in MY 2026. Moreover, new and expanded charging and consumer incentives currently under Congressional consideration could drive new EV deployment in the U.S. up as high as 61% of total vehicle sales in 2030.64 Simply put, failure to amend the proposal to put in place more stringent standards risks the U.S. failing further behind other countries in its share of EV sales.65 [EPA-HQ-OAR-2021-0208-0278-A1][pp.8]

The Protective Nature of Clean Air Act Section 202(a)(1) Requires EPA to Implement Standards with Greater Stringency Than Proposed

The Clean Air Act (CAA), and Section 202(a) in particular, is directed at protecting public health and welfare. See 42 U.S.C. § 7401 (identifying the Act's purpose as to 'protect and enhance the quality of the Nation's air resources so as to promote the public health and welfare and the productive capacity of its population.'); 42 U.S.C. § 7521(a)(1) (providing that the Administrator shall prescribe and from time to time revise 'standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines, which in his judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare.'). The Proposed Rule recognizes that 'the purpose of adopting standards under CAA section 202 is to address air pollution that may reasonably be anticipated to endanger public health and welfare. Indeed, reducing air pollution has traditionally been the focus of such standards.'66 As courts have recognized, given the overriding goal of the statute to protect public health and welfare, EPA should 'plac[e] primary significance on the 'greatest degree of emission reduction achievable,'' and consider other factors such as 'cost . . .energy and safety factors as important but secondary factors.'67

However, even though the Proposed Rule asserts that, '[i]n light of the statutory purpose of section 202,' EPA is 'placing greater weight on the emission reductions and resulting public health and welfare benefits,'68 in actuality the proposal's level of stringency is not sufficient to align with the protective nature of the Act and Section 202.

In 2012, when MY 2012-2025 standards were first established 'mobile sources addressed in the endangerment and contribution findings under CAA section 202(a)—light-duty vehicles, heavy-duty trucks, buses, and motorcycles—accounted for 23 percent of all U.S. GHG emissions in 2010.'69 As EPA now acknowledges, this contribution has now grown to represent 29 percent of all U.S. GHG emissions.70 As one recent analysis has shown, to make up for the carbon pollution attributable to the SAFE Rule rollbacks new LDV standards need to be much stronger by MY 2026 than those proposed in 2012.71 Thus, it strains credulity that the agency is proposing MY 2023-2026 standards that are weaker and less protective than those proposed in 2012 when the transportation sector's contribution to U.S. GHG emissions has risen and superior mitigating automotive technology – electric vehicles – has become readily commercially available and provides the most effective means of emissions reductions. As such, the EPA's proposal fails to meet the agency's statutory burden of protecting the public health and welfare.

Courts have found that EPA's authority to regulate light duty vehicles via CAA Section 202 is not conditioned on evidence of a particular level of mitigation; only a showing of significant contribution is required – a showing the agency completed in 2009 with the Endangerment Finding.72 However, in exercising this authority by proposing new regulations, the agency must reasonably ensure its action meaningfully achieves a level of emissions reduction that contributes to mitigating the endangerment at hand.

Here, the agency's proposal falls short. The agency has proposed a standard with less emissions reductions and stringency than regulations completed in 2012 and reaffirmed in January 2017. As a result, despite nearly a decade of new, commercial deployment of EV technology and acceptance, the agency is not ameliorating the accelerating public health and welfare impacts from climate but sliding backwards.73 This is particularly troubling given the EPA, as it should, acknowledges in the proposal:

In light of the statutory purpose of section 202, the Administrator is placing greater weight on the emission reductions and resulting public health and welfare benefits, as well as the savings in vehicle operating costs for consumers, and proposing significantly more stringent standards for MYs 2023–2026 compared to the standards established by the SAFE rule.74 [EPA-HQ-OAR-2021-0208-0278-A1][pp.8-9]

Reducing the Stringency of the GHG Standards in the Face of Increased Pollution Impacts Would Be Arbitrary and Capricious

In light of EPA's recognition of the increasing impacts of GHG emissions, adopting standards less protective than the Obama-era standards would be arbitrary and capricious. Agencies are obligated to articulate a satisfactory explanation for their actions, including a rational connection between the facts found and the choice made.90 Therefore, '[i]llogic and internal inconsistency are characteristic of arbitrary and unreasonable agency action.'91 Here, the adoption of standards less stringent than the Obama-era runs counter to the recognized increase in evidence of and scientific consensus around the impacts of GHG emissions in the time since the Obama standards were adopted. EPA cannot reduce the stringency of the GHG standards while at the same time recognizing that the impacts necessitating those standards have increased, as has the imperative for decisive action. That internal inconsistency is 'illogical on its own terms.'92

Indeed, in the January 2017 mid-term evaluation EPA found that the Obama-era standards were readily achievable, even predicting only 2-4% electrification by MY 2025.93 Now, however, the proposal projects 4.6% electrification by MY 2023, and 6.4% by MY2025, yet proposes reduced stringency.94

In addition, EPA's failure to adequately consider how the Proposed Rule's flexibilities would impact the stringency of the standards also is arbitrary and capricious. When an agency decides to rely on a cost-benefit analysis as part of its rulemaking, as EPA is proposing to do here, a 'serious flaw undermining that analysis can render the rule unreasonable.'95 EPA claims that the GHG standards are stringent but ignores the ways in which the stringency will be significantly reduced by certain flexibilities when the rule is applied in the real world, as described below. EPA's failure to consider the impact of these added flexibilities on the stringency of the standards is a serious flaw that would render the rule unreasonable. [EPA-HQ-OAR-2021-0208-0278-A1] [p.11]

Conclusion

For the reasons set forth above, described herein, the EPA should amend its proposal using Alternative 2 as a starting point, add 10 g/mi of stringency, and take the following additional steps to increase its stringency:

- Eliminate the one and two-year lifetime extensions of previously earned and expiring credits;

- Eliminate the Alternative Vehicle Technology multiplier which serves to diminish real life delivery of EVs (as is proposed in Alternative 2);

- Eliminate the proposed Advanced Technology Incentive for Full-Size Pick-ups; and

- Eliminate the Expansion of Off-Cycle Crediting volumes and eliminate all off-cycle crediting, at a minimum, after MY 2025.

Tesla believes these changes will significantly reduce emissions, result in increased deployment of the best available emissions reduction technology (ZEVs), maintain U.S. manufacturing leadership in EV technology, and ensure the Administration is meeting it statutory mandate to protect the public health and welfare from the significant and accelerating impacts from air pollution and climate change. [EPA-HQ-OAR-2021-0208-0278-A1][p.23]

Commenter: Tomcik, Patrice

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 257.]

I'm asking the EPA to finalize the strongest possible greenhouse gas emissions standards for light-duty vehicles in order to protect children's health in the future.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 259.]

Please finalize the strongest possible climate pollution limits on cars and light trucks to help protect our children's health and futures.

Commenter: Toyota Motor North America, Inc. (Toyota)

To be clear, achieving the proposed standards and laying the foundation to reach the Administration's 2030 electrification objectives requires complementary market development and sustainment measures, including non-discriminatory consumer tax credits, infrastructure investments for electric vehicle charging and hydrogen refueling, critical mineral supply chain development, and a robust system to recycle end-of-life vehicle batteries. Toyota stands ready to work with lawmakers, federal and state regulators, and others to support and implement these complimentary measures provided they maintain a level, competitive playing field.

The attached comments focus on EPA's technology and market assessments, modeling approach, and potential adjustments to regulatory flexibilities. While EPA has a somewhat limited role in many of the complimentary measures needed to promote consumer acceptance of electrified vehicles, Toyota suggests minor revisions within EPA's regulatory authority that we believe better recognize the challenge of these standards, while providing regulatory tools to incentivize more rapid electrification of the fleet toward our 2030 objectives. [EPA-HQ-OAR-2021-0208-0531-A1, p. 1-2]

EPA has Underestimated the Level of Electrification Needed to Meet the Standards
The proposed GHG standards present a formidable challenge in attaining the levels of electrification being projected for compliance. EPA estimates the share of BEVs, FCEVs, and PHEVs will need to grow from an average of 2.4 percent[1] today to 8 percent (NHTSA is projecting 12 percent for its proposed CAFE regulation) by 2026. Efforts to build the market must start now to more than triple the share of these technologies in just four years. For perspective, it's taken conventional hybrids 20 years to eclipse 3 percent of the U.S. market, even though hybrids require no new infrastructure, have no range anxiety issues, can be refueled virtually anywhere, and require no behavioral changes.

As described below, Toyota believes the task is even greater than projected by EPA because more electrification will be needed to comply with the proposed standards, which overestimate the likely contribution of ICE vehicle improvements and thus underestimate the level of BEV, FCEV, PHEV, and conventional hybrid volumes likely needed for compliance.

EPA has Overestimated the GHG Performance from ICEs

Toyota has provided extensive information, in public comments and under CBI, on the effectiveness of CO2 reduction technologies including those for advanced gasoline engines.[2] The data has consistently documented that even advanced ICE-only powertrains will fall short of the proposed standards and that while future advancements are possible, a point of diminishing returns is in part driving the transition to electrified powertrains, including conventional hybrids. EPA notes manufacturer plans and announcements of "a rapidly growing shift in investment away from internal-combustion technologies and toward high levels of electrification".[3]

EPA projects roughly 87 percent of the 2026 model year fleet will continue to be conventional gasoline powertrains. We are confused by EPA's statement that "the standards can be met largely with the kinds of advanced gasoline vehicle technologies already in place in vehicles within today's new vehicle fleet …".[4]

This position is at odds with findings from the most recent evaluation of U.S. fleet performance conducted by IHS Markit using manufacturer-supplied data. This baseline study assessed the percentage of 2020 model year vehicles capable of meeting the proposed GHG standards. As Figure 1 illustrates, only electrified powertrains (HEV, PHEV, BEV and FCEV) can attain the proposed targets for the 2024 model year and later passenger cars and 2025 MY and later light trucks. Most gasoline engine technologies modeled by EPA are already being used in the 2020 model year fleet. A more widespread adoption of top-performing gasoline engine technologies through 2026 model year will not result in fleet compliance.

The Focus is on Successful Outcomes

Pointing out these ICE limitations in no way diminishes Toyota's general support for the proposed standards, but rather is intended to stress that compliance will require a more substantive shift to electrified powertrains, including conventional hybrids. We need to begin working together now to chart a path for near-term market readiness and growth of electrified powertrains.

Success Depends on Converting Growing Consumer Openness to Vehicle Purchases

Shifting Consumer Tastes

Electrified powertrains must become more accessible to mainstream consumers for a carbon neutral future to be realized. Toyota market research has found consumer attitudes are shifting to a greater openness about alternative powertrains as seen if Figure 2. That growth in consumer openness is also being observed in vehicle segments that have traditionally been less inclined toward alternative powertrains. The changing attitudes appear to stem from increasing consumer exposure to electrified powertrains via the growing availability of vehicle models, styles and types, and the media attention created through manufacturer and government announcements.

Figure 2 – Growing Consideration of Alternatively Fueled Vehicles

Challenges Coming into Sharper Focus

While the openness to electrification is growing, converting that openness to purchase intent and ultimately vehicle sales remains a challenge. As mentioned previously, the market share for BEVs, PHEVs, and FCEVs has averaged 2.4% percent over the 2018 – 2021 period. Potential buyers still see obstacles to ownership because of price, range anxiety, charging time, lost utility and host of other factors presenting a more expensive and less convenient proposition compared to their current vehicle as seen below (Figure 3). A general lack of knowledge and misunderstanding contribute to these purchase barriers. [EPA–HQ–OAR–2021–0208-0531-A1, pp 1-6]For the reasons outlined in Sections 2 and 3 above, any additional increase in stringency beyond the proposed standards would create significant risk that threatens the feasibility of the standards. Toyota does not support either Alternative 2 or the 5 to 10 g/mi stringency increase in the 2026 model year standards for which EPA has sought comment. [EPA-HQ-OAR-2021-0208-0531-A1, p. 8]

Commenter: Trombetta, Nick

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 219.]

We must take the recent IPCC Report seriously and enact the strongest possible regulation on car emissions.

Commenter: Uberuaga, Michelle

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 284.]

So for these reasons, I urge the EPA to set the strongest possible federal clean car standards. We need to keep U.S. automakers on track to meet ambitious pollution reduction goals as soon as possible.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 286.]

Strengthening car standards is a simple step and we can and must continue to do more to protect communities from air pollution and climate change.

Commenter: Union of Concerned Scientists (UCS)

Given the deeply flawed justification for the LDV standards currently on the books, President Biden's Executive Order (EO) 13990 directing EPA to reconsider these standards was a welcome action. We appreciate both the recognition of the inadequacy of these regulations and the speed with which the administration is moving forward to address these shortcomings—UCS strongly supports protecting public health and the environment and agrees that policy must be based on the best available science to adequately address the climate crisis. Unfortunately, EPA's proposed replacement for MY2023-2026 falls short of this goal.

Of the proposed alternatives, Alternative 2 comes closest to the level of stringency that would best support the agency's mandate under the CAA. However, even this proposal should be strengthened in MY2026 to support EO 14037 and better ensure that the industry is prepared for the requirements which will be needed beyond MY2026 to address climate change and achieve a net-zero economy by 2050.

In our comment, we support the need to take action immediately, as EPA proposes, while providing data in support of going even further in order to better address greenhouse gas emissions from LDVs, the largest single source of global warming emissions in the United States today. Not only does this information support moving forward with Alternative 2, but it also supports reducing the scope of incentives proposed by EPA—such incentives are not necessary to support a short-term strengthening of the greenhouse gas program and risk an erosion of the benefits of the program that could jeopardize the long-term ability to adequately deal with climate change and support the administration's critical goal for half of all new LDVs sold in 2030 to be zero-emission vehicles (ZEVs). [EPA-HQ-OAR-2021-0208-0277-A1, pp.2-3]

Commenter: Valentine, Lucia

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 265-266.]

The transportation sector is the largest source of carbon pollution in the U.S. and the EPA must set the strongest possible federal clean car standards throughout 2026, avoiding loopholes and putting automakers on track to meet ambitious pollution reduction goals.

The EPA proposal includes several options for how much and how quickly to limit climate pollution from cars and light trucks. Preferred alternative identified by EPA is not the strongest option and includes some loopholes to automakers that may undermine other pollution reduction targets.

Option Number 2 would put 400,000 extra vehicles on the road by 2026 and result in 130 million metric tons of greenhouse gas emissions. In order to set us on the path to 100 percent zero emissions by 2035, the near-term standards for climate pollution must be as strong as possible.

Commenter: Venner, Marie

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 17-18.]

However, it is important to finalize standards for Model Years 2023 to 2026 before working on pollution standards for later years. Also, please go with your Alternative Number 2 as that would put 400,000 extra EVs on the road by 2026 and result in a 130 million metric tons fewer GHG emissions. I was concerned to see and urge you not to go with your initial preferred alternative as it includes some loopholes to automakers that may otherwise undermine strong pollution reduction targets. EPA should finalize the strongest possible option.

Commenter: Verdin, Langston

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 266.]

This proposal and the broader action on clean cars from the Administration are a meaningful step in the right direction, but we need the strongest possible clean car standards to truly make good on President Biden's commitments to address climate action and environmental justice. As a parent of a 12-year-old with asthma, I urge the EPA and the Administration to finalize this proposal quickly and move forward with bold greenhouse gas and fuel efficiency standards for cars, light trucks, and SUVs that accelerate the critical transition to zero emission vehicles.

Commenter: Villalpando Paer, Natalir

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 203-204.]

The EPA has a responsibility to make sure we all live in healthy communities. The EPA must set the strongest possible federal clean car standards through 2026, avoiding loopholes and putting automakers on track to meet ambitious pollution reduction goals.

Making sure regulations for our cars are the best for all of us is recognized and manufacturers have a responsibility for the effects of the engines they produce and the air we all breathe.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 204.]

It is time to think of a future when children will give that first breath into worst quality air because we were not bold enough. We need to recognize that not moving forward to fight climate change is already creating inequalities, health problems, and a strain on the health system for all of us.

We need to do everything we can to ensure our children can continue to play outside all summer and we cannot address the climate crisis without moving decisively to zero pollution vehicles.

That is why I urge the EPA to set the strongest possible pollution standards for cars.

Commenter: Volkswagen Group of America, Inc. (Volkswagen)

Volkswagen committed to achieve CO2 reductions through 2026 in its Framework Agreement with California and the other Section 177 States. Volkswagen appreciates EPA's consideration of the programmatic goals and flexibilities that were included in the agreement with California. We are confident that this proposal from EPA will be capable of delivering comparable levels of overall CO2 reductions and that this will help continue the path into future standards with additional long-term CO2 reductions. [EPA-HQ-OAR-2021-0208-0237-A1, p.7]

Commenter: Whyte, Yolanda

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 144.]

Therefore, since traffic has now become the main source of air pollution, the strongest clean car standards are urgently needed, especially since many of the health impacts mentioned earlier are preventable.

Therefore, I urge EPA to set the strongest standards on the fastest timeline to protect our health, especially for the most vulnerable who cannot defend themselves or be able to speak today.

Commenter: Williams, Emerson

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 249-250.]

The proposed rule before us today is not only not new, it is wholly inadequate.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 250-251.]

Further, these standards are still decades behind the rest of the developed world. In 2009, the EU implemented standards to reduce their emissions to 153 grams CO_2 per mile by 2020. They have since updated these goals and far surpassed our efforts.

China likewise enacted the Euro 4 standards in 2010 which includes very strict standards for CO_2 as well as other pollutants. Both regions also have strict enforcement mechanisms which this proposed rule is decidedly lacking.

I understand my statement today may come across as accusatory and unsympathetic to the work done to bring us here. I assure you that is not my intent. Rather, I am very upset by the extraordinary lack of leadership and urgency I continue to see around environmental issues.

We simply do not have the luxury of slowly ramping up standards or relying on the supposed promises of the capitalist market that caused this impending global disaster.

In conclusion, I recommend EPA go back and write a new rule, a rule that sets zero emissions standards to be met no later than 2030, a rule with strong enforcement mechanisms.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 250.]

This refreshed rule originates from Executive Order 14037 which states in part America must lead the world on clean and efficient cars and trucks by setting a goal that 50 percent of all new passenger cars and light trucks sold in 2030 be zero emission vehicles. This proposed rule, even if the second alternative were implemented, falls terribly short of this order. In fact, with the second alternative implemented, the allowed combined cars and trucks grams CO_2 per mile by 2026 is 161. This means we are yet again passing the buck to the next EPA, next Administration, etcetera, and it is a huge burden to pass on.

To reach the goals expressed in the Executive Order, this future they will need to implement standards to remove 161 grams CO_2 per mile in only four years, nearly triple the reductions in this proposal.

Commenter: Wisconsin Department of Natural Resources

EPA should finalize its more stringent alternative (Alternative 2), to both maximize GHG reductions and minimize the need to mitigate any increases in criteria pollutant emissions.

In its rule, EPA proposes to increase the stringency of its emissions standards in MY 2023 by about 10 percent (from the existing SAFE rule standards in MY 2022), followed by stringency increases thereafter of nearly 5 percent per year from MY 2024 through MY 2026. In addition to this preferred alternative, EPA is also requesting comments on whether it should instead finalize a less stringent alternative (Alternative 1) or a more stringent alternative (Alternative 2).

EPA should finalize the more stringent Alternative 2. EPA's preferred alternative, although a vast improvement over the SAFE rule, does not restore the standards to the levels EPA deemed to be achievable back in 2012 – almost ten years ago. In contrast, Alternative 2 not only reinstates the 2012 standards for MYs 2023 through 2025, it increases the stringency of the standards further beginning in MY 2026. Of the options EPA is considering, Alternative 2 best recognizes the urgent need for GHG emission reductions and the significant changes that have occurred in the automotive manufacturing sector since 2012 that include a rapid shift in investment away from internal-cumbustion technologies. Specifically, Alternative 2 reflects what EPA has heard from key stakeholders, including automotive manufacturers and the automotive suppliers, that the significant investments being made now to develop and launch new electric vehicle (EV) product offerings and expanding EV charging infrastructure could lead to greater EV market penetration than otherwise assumed in EPA's proposal. The compliance flexibilities that EPA would retain in Alternative 2 (i.e., the extension of credit carry-forward for MY 2016-2020 credits, the increase of off-cycle menu cap from 10 to 15 g/mile, and the reinstatement of full-size pickup incentives for strong hybrids or equivalent technologies for MYs 2022-2025) help ensure the technical attainability of this alternative. EPA's analysis also shows that the increased costs associated with Alternative 2 would be more than offset by increased fuel savings and other benefits, resulting in larger net economic benefits than the preferred alternative.4 [EPA-HQ-OAR-2021-0208-0223-A1, p.2]

Note that WDNR recommends that EPA further increase the stringency of this alternative by 10 g/mile starting with MY 2026 (see comment #2). [EPA-HQ-OAR-2021-0208-0223-A1, p.2]

EPA should increase the stringency of MY 2026 standards by an additional 10 g/mile. EPA requests comment on standards for MY 2026 that would result in fleet average target levels that are in the range of 5-10 g/mile lower (i.e., more stringent) than the levels proposed. To maximize the benefits of this rule, in addition to proceeding with Alternative 2, EPA should finalize MY 2026 standards that are 10 g/mile lower than that standard. As noted by EPA in its proposal, rapid changes in the automotive sector, particularly the accelerated transition to electrified vehicles, makes this more stringent standard technologically feasible, particularly given the compliance flexibilities contained within the rule (see comment #1). Note that EPA should ensure any increases in the NOx, VOC and SO2 emissions associated with this change are fully mitigated (see comments #3 [p.3] and 4[p.4]). [EPA-HQ-OAR-2021-0208-0223-A1, p.2]

Commenter: Wiste, Leah

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 86.]

The current proposal falls dangerously short. The proposed standards are full of loopholes and rely on voluntary commitments from the automakers, the same automakers who got an $80 billion government bailout in 2009, agreed to stronger emissions reductions under President Obama and then reneged on that commitment when the political winds changed. Too much is at stake for us to rely on the voluntary commitments of this monster untrustworthy industry now.

Commenter: Witt, Anthony

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 167.]

The second alternative would deliver greater savings to consumers, an average of $2,100 per vehicle, and eliminate auto manufacturer loopholes.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 167-168.]

Auto manufacturers will not produce vehicles with drastically higher fuel efficiency unless they're required to do so. We need to set high standards and eliminate loopholes that would prevent us from achieving these goals. The Administration's ‘voluntary targets’ and the U.S. automakers ‘shared aspirations’ are not sufficient. To achieve the goal of reducing greenhouse gas emissions from new faster vehicles sales by more than 60 percent, we need to set the strongest possible standards for 2026.

I urge the Administration to set the strongest standards possible because they're necessary and they work.

I urge you to reinstate the federal standards with your Alternative 2 and set even stronger ones through 2030.

I ask you to ensure that there are no loopholes for automakers to get around these standards.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 167.]

I fully support the strengthening of the clean cars standards with the adoption of the EPA's second alternative.

Commenter: World Resources Institute (WRI)

Our comments focus on EPA’s estimates of the market share obtained by zero-emission vehicles (ZEVs) through model year (MY) 2026 and the implications of those projections for the emissions reductions that would result from the proposal compared with what could be achieved by fully accounting for ZEV market trends as well as available technology to reduce emissions from internal combustion engine vehicles (ICEVs). In summary, WRI concludes:

• EPA’s proposal is based on a substantial underestimate of the likely ZEV market share.

• Much greater emission reductions could be achieved with available technology than would result from the proposal or either of the alternatives considered by EPA.

• If ZEV sales follow the trajectory projected by independent analysts assuming current policies ICEVs would be able to emit 204-216 gCO_2/mile in MY2026, which represents no improvement compared to the emissions rate EPA assumed for ICEVs in MY23 under the proposal.

• If ZEV sales follow the trajectory projected by independent analysts assuming tax credit extensions and charging infrastructure investments consistent with proposals under active consideration in Congress, ICEVs would be able to emit 265 gCO_2/mile in MY2026, which is 35 g/mile more than ICEVs were allowed to emit in MY2020. [EPA-HQ-OAR-2021-0208-0207-A1, p. 1]

Based on these observations WRI recommends that:

• EPA should update its projections of ZEV market shares to reflect current trends in battery prices, automaker investment plans and EV market development. EPA should also consider higher penetration scenarios that would occur if Congress enacts additional incentives and infrastructure investments and should update the final rule to reflect any enacted legislation.

• EPA should set light duty vehicle standards at levels that reflect these updated ZEV market share projections and EPA's current projections of technology penetration rates for ICE vehicles. Such standards would be significantly more stringent than either the proposal or Alternative 2.

• Given the uncertainty regarding future ZEV market shares, EPA should set standards for ICE vehicles (in addition to fleet-average standards) that ensure continued year-over-year emissions reductions from ICE vehicles regardless of the ZEV market share. [EPA-HQ-OAR-2021-0208-0207-A1, p. 1-2]

EPA's proposed MY2023-MY2026 greenhouse gas emissions standards are fundamentally flawed because the agency failed to update its compliance model to reflect recent advances in ZEV technology. EPA should finalize revised standards that reflect the level of performance that would be achieved with ZEV market penetration rates consistent with the rapidly declining cost of batteries and expanding ZEV model offerings. EPA should also consider scenarios based on enhanced consumer incentives and charging infrastructure investments and be ready to reflect any such legislation enacted by Congress. EPA should also set standards for ICEVs that ensure year-over-year emissions rate reductions regardless of future ZEV market shares. [EPA-HQ-OAR-2021-0208-0207-A1, p. 5]

Under the proposed fleet-wide target of 171 g/mile in MY2026, and assuming that all ZEVs are credited with an emissions rate of -20 g/mile (as EPA assumes for Tesla in the RIA), ICEVs would have an effective emissions rate target of 187 g/mile under EPA's projection of a 7.8% ZEV market share in MY2026. 5 Based on the same algebra, under the proposal the effective emissions rate target for ICEVs would be 204 g/mile, 216 g/mile, or 265 g/mile if ZEV penetration follows the BNEF, RhG–C, or RhG–I scenario, respectively.

Conversely, assuming the ICEV fleet has an average emissions rate of 187 g/mile, the performance implied by the proposed standards and EPA's ZEV market share projection of 7.8% in MY2026, appropriate standards would result in fleetwide emissions targets of 156 g/mile, 148 g/mile, or 119 g/mile if ZEV penetration follows the BNEF, RhG–C, or RhG–I scenario, respectively.

The results of these calculations assuming more conservatively that ZEVs are credited with an emissions rate of 0 g/mile are similar: ICEVs effective emissions rate target in MY2026 would be 185 g/mile, 201 g/mile, 211 g/mile, or 255 g/mile if ZEV penetration follows the EPA, BNEF, RhG–C, or RhG–I scenario, respectively.

Conversely, assuming ZEVs are credited at 0 g/mile and the ICEV fleet has an average emissions rate of 185 g/mile, the performance implied in this case by the proposed standards and EPA's ZEV market share projection of 7.8% in MY2026, appropriate standards would result in fleetwide emissions targets of 158 g/mile, 150 g/mile, or 124 g/mile if ZEV penetration follows the BNEF, RhG–C, or RhG–I scenario, respectively.

The upshot of this analysis is that under more reasonable ZEV market penetration projections the appropriate standards would result in fleetwide emissions rates well below those projected for the proposal or either alternative considered by EPA. Conversely, if EPA finalizes standards at the proposed levels (or either alternative) ICEVs would most likely not have to reduce their emissions rates after MY2023. Indeed, if ZEV market shares follow a trajectory based on enhanced incentives and charging infrastructure investment, ICEVs would be allowed to increase their emissions rates above the MY2020 standard. [EPA-HQ-OAR-2021-0208-0207-A1, p.3]

Recommendations

In order to have a rational basis for setting emissions standards that allow averaging across ICEVs and ZEVs EPA needs to update its battery cost assumptions and likely additional assumptions related to ZEV adoption rates. For example, consumer preferences evolve as ZEVs become more prevalent and ZEV adoption has been shown to be influenced the prevalence of charging infrastructure as well as the availability of consumer rebates. 6

With updated ZEV assumptions EPA should set emissions standards that reflect the ICEV emissions reduction technology penetration rates used in the proposal as well as updated ZEV penetration rates more consistent with independent projections, such as the BNEF and RhG projections presented here. Such standards would likely be in the range of 119 g/mile to 158 g/mile in MY2026, significantly more stringent than either the proposal or Alternative 2. ZEV penetration rate scenarios consistent with enhanced purchase incentives and charging infrastructure investments would yield fleet-wide targets at the lower end of this range. (To the extent that EPA concludes that this update requires a reproposal we recommend finalizing the Alternative 2 MY2023 standards considered in the current proposal to provide adequate lead time, and reproposing standards for MY2024-MY2026.)

Due to the dynamic nature of ZEV technology and the ZEV market, future ZEV market penetration rates are far more uncertain than the cost and performance of available ICEV emissions reduction technologies, which EPA notes have not required significant updates since EPA's 2012 rulemaking. For example, 2026 ZEV market share in the three scenarios presented here range from 15% to 33%, and additional scenarios published by RhG that assume more robust policy support range up to 40%.7

Because the actual ZEV penetration rate can have such a dramatic impact on the implied emissions target for ICEVs and the achievable fleet-wide emissions rate, particularly given EPA's approach of not counting upstream emissions in electricity generation, EPA should set additional standards that apply to the ICEV fleet independent of future ZEV adoption. This is necessary to ensure that the final set of standards achieve all reasonably available emissions reductions and consumer fuel cost savings given that even in the most optimistic scenario 60% of passenger vehicles sold in MY2026 will be ICEVs.

The standards set for ICEVs should reflect available emissions reduction technologies, but could be somewhat less stringent than what would be reflective of the ICEV technology penetration rates projected for compliance with the proposal. For example, EPA could set the ICEV standards to reflect the ICEV technology penetration rates projected for Alternative 1. This would provide flexibility for OEMs while ensuring that the emissions rates of ICEV vehicles decline year-over-year. [EPA-HQ-OAR-2021-0208-0207-A1, p. 4]

5 Calculated as (171 – (-20)*(ZEV%))/(1-ZEV%)

Commenter: Wyman, Stephen

It is clear that without specific, defined and regulated direction, from the EPA, vehicle manufacturers are more inclined to respond to pressure from powerful voices in industries that want to maximize profit margins, from oil and gas products, for as long as is possible... Consequences be damned. The EPA must delineate a specific direction or significant progress in reducing GHG emissions from vehicles may not soon be forthcoming.

I implore the EPA to create a rigorous regulatory regimen, devoid of loopholes, to expedite reduced GHG emissions from vehicles. [EPA-HQ-OAR-2021-0208-0307, p. 1]

Commenter: Zero Emission Transportation Association (ZETA) and EVHybridNoire (EVHN)

ZETA and EVHN fully support ambitious standards to cut GHG emissions and expand stringency beyond the most ambitious option presented in the proposed rulemaking (Alternative 2) with the elimination of extended credits. ZETA's members and EVHN's partners are already demonstrating that EV innovation and job creation go hand-in-hand. We urge the EPA to accelerate this transition and expedite the economic and environmental benefits of light-duty vehicle electrification with stringent standards without exception.

It has been made abundantly clear that without the electrification of the transportation sector, there is no way the United States will meet its climate targets.1 To that end, the proposal does not recognize the rate at which electrification of the transport sector is accelerating, and it fails to put the country on track to achieve the President's stated objective of ensuring 50% EV and plug-in hybrid electric vehicle (PHEV) sales by 2030 without additional incentives from Congress, which is still less than half of ZETA's EV sales target for 2030.

The baseline proposed standards to achieve 171 g/mi in 2026 fall short of the necessary GHG targets to meet the EPA proposed reduction targets set in 2012. According to internal modeling from ZETA's members, the EPA proposal falls short of the 2012 CAFE standards when compliance flexibilities are extended by 6.2 g/mi in 2026. Extending credit multipliers, advanced technology vehicles (ATV) credits, hybrid pickup truck credits, and the off-cycle cap increase result in GHG reductions that are higher than the SAFE rule through 2022, and fall short of the proposed reduction by a cumulative 3.3 g/mi.

The proposal also fails to achieve the stringency necessary to meet the electrification goals set by states and experts. An analysis by Rhodium Group found that to achieve 100% zero-emission vehicle (ZEV) sales by 2035, consumer incentives combined with GHG standards of approximately 90 g/mi in 2031 are required, which is 48% higher than the EPA proposal in 2026. That translates to a 12% improvement each year from 2027 to 2031 to achieve the Biden Administration's goal.2

Alternative 2 will also result in greater public health savings by the Agency's own analysis. While the proposal will generate $86 billion in net savings, Alternative 2 will generate $110 billion by 2050. This is a direct result of the standards in Alternative 2 creating a market for an additional 400,000 EVs to be on the road by the end of the rule period in 2026. In terms of economic benefits, Alternative 2 will result in $29 billion less in social harms, and $57 billion less spent on gasoline by American drivers.3

While the standards set forth in Alternative 2 will achieve greater emissions reductions and save taxpayers money than the EPA proposal, it still falls short. While the proposed stringency of the Alternative 2 standards is a step in the right direction, ZETA and EVHN recommend that the Agency implement a rule that is more stringent and will result in greater emission reductions than any of the proposals analyzed. To achieve this outcome, the EPA should take further steps to close loopholes and eliminate many of the flexibilities — including the advanced technology vehicle multiplier which will not incentivize, but rather suppress, the actual deployment of EVs. Taking this action and working with congressional leaders to expand consumer incentives will help move federal EV sales further toward 100% by 2030. [EPA-HQ-OAR-2021-0208-0275-A1, pp. 2-4]

ZETA and EVHN encourage the EPA to ambitiously cut GHG emissions by implementing the proposed rulemaking in Alternative 2 along with eliminating extended credits and loopholes. ZETA's members are already demonstrating that EV innovation and job creation go hand-in-hand. We urge the Biden administration to accelerate this transition and expedite the economic, environmental, and public health benefits of light-duty vehicle electrification. [EPA-HQ-OAR-2021-0208-0275-A1, p. 4]

Commenter: Zewadski-Bricker, Edith

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 230.]

In your wisdom, from the depths of your soul, as the voice of conscience, that little Jiminy Cricket on your shoulder, decide in favor of the strictest emissions standards and the highest of vehicle efficiency that will exceed the Obama/Biden federal standards.

<u>EPA Response</u>

EPA received many comments supporting, opposing, or recommending changes to the proposed or alternative standards. As discussed in greater detail in Preamble III.D, in evaluating the proposal and alternatives, EPA considered differences in costs, cumulative CO2 emissions reductions and combined BEV+PHEV technology penetration projections.

The following responses address similar comments made by multiple commenters.

EPA received many comments in support of the proposed or more stringent standards. Numerous commenters either urged EPA to require greater stringency, or specifically requested EPA to finalize proposed Alternative 2, often with the additional 10 grams/mile of increased stringency for MY 2026 upon which EPA had sought public comment. Several commenters (such as the California Attorney General) argued that feasibility of more stringent Alternative 2 is not an issue in 2026 because increased stringency in the latter years of the program does not raise the same lead time concerns as the early years. However, some comments (including the Alliance For Automotive Innovation, Honda, JLR, Mercedes-Benz USA, Stellantis, Toyota, and UAW) supported the proposed standards, but opposed the more stringent alternatives (predominately due to concerns of increased EV penetration required, and complementary measures commenters feel are necessary – these topics are addressed in separate paragraphs below). EPA acknowledges Stellantis' concerns of increases in stringency (beyond that of the proposal) early in the program and EPA has chosen to retain the stringency level of the proposed standards for MY 2023 and MY 2024. Stellantis claims that more stringent MY 2026 standards would add risk by introducing a single year jump in stringency. EPA explains why more stringent standards for 2026 are feasible and appropriate in Preamble II, III, and VI.

After considering all of the comments and our updated technical analysis, EPA selected final standards that are a combination of the proposed standards for MYs 2023 and 2024, Alternative 2 standards for MY 2025, and Alternative 2 minus 10 g/mi standards for MY 2026 and later vehicles, based on our consideration of emission reductions, technological feasibility, costs, lead time (including manufacturer refresh and redesign opportunity) and other factors. See Preamble Sections II and VI for details on the final standards and their basis, including why we are finalizing the proposed standards for MYs 2023 and 2024 and more stringent standards than the proposed standards for MYs 2025 and 2026. A more detailed comparison of the per-vehicle costs (4.1.3), GHG emission reductions (5.1), and technology penetrations (4.1.4) for each alternative can be found in the RIA. For a more detailed discussion of how EPA considered refresh and redesign cycles in our analysis, refer to RIA 4.1.

While supportive of the proposed standards, the Alliance for Automotive Innovation, Mercedes-Benz USA, Stellantis, and Toyota commented that complementary policies are needed to encourage broader EV adoption to achieve the necessary levels of EV penetration. Many of the comments we received concerning the need for complementary policies, either in the context of complying with this rule or to facilitate a longer-term outlook beyond the time frame of the rule, are addressed in Section 12.1 of this RTC document. For example, Stellantis provided a list of policies that should be pursued to facilitate automaker ability to comply with the proposed standards. Most of the policy items are outside EPA's purview and instead require Congressional or State and Local action. The one item within EPA's purview is low carbon fuel standards, but EPA did not propose or solicit comment on any fuel standards, and this comment is outside the scope of this rulemaking. For additional response to commenters' suggestions of complementary policies please see RTC Section 12.1.

Many commenters expressed concerns that the proposal's projected BEV penetration rate of 8 percent by MY2026 was too low, while other commenters such as the Alliance for Automotive Innovation, Mercedes, Honda and Toyota expressed concerns over the level of electric vehicle penetration that will be required to meet the proposed standards. At the same time, the Alliance noted a projection for the industry from August 2021 that the industry will achieve new vehicle sales of 23 percent electric vehicles by 2026, which is higher than EPA's projection of 17 percent in that same time frame. Based on our updated analysis, EPA's final standards are projected to result in an increased EV/PHEV penetration rate in MY2026 of 17 percent. We believe this updated rate is appropriate and a reasonable projection which the industry can achieve especially given the public announcements about manufacturers' plans to transition to electrified vehicles.[3] As we also note in Preamble I.B, this rate of penetration is comparable or conservative when compared with recent independent market forecasts.[4,5,6] A recent survey of automobile executives found that they anticipate just over 50% of U.S. automobile sales will be all-electric by 2030.[7] These factors, as well as continuing advancements in EV technology, support our projections on the level of BEV+PHEV penetration during the time period of the rule (see Preamble VI). To the degree that commenters cite consumer acceptance as a potential barrier to EV adoption, in addition to our response to comments on this topic in Section 17 of this Response to Comment document, EPA notes that consumer acceptance of EVs has improved over time as more models have become available and consumers have become more familiar with the technology. For example, Toyota commented that "market research has found consumer attitudes are shifting to a greater openness about alternative powertrains," and "changing

[3] In their comments the Alliance for Automotive Innovation state that "According to recent estimates shared by IHS Markit in August 2021, auto manufacturers are planning sales of battery electric and plug-in hybrid electric vehicles to reach approximately 23 percent of new light vehicle sales in the U.S. market in 2026."

[5] IHS Markit, "US EPA Proposed Greenhouse Gas Emissions Standards for Model Years 2023-2026; What to Expect," August 9, 2021. Accessed on October 28, 2021 at https://ihsmarkit.com/research-analysis/us-epa-proposed-greenhouse-gas-emissions-standards-MY2023-26.html (Table indicates 12.2% in 2023, 16% in 2024, 20.1% in 2025 and 24.3% in 2026).

[6] Rhodium Group, "Pathways to Build Back Better: Investing in Transportation Decarbonization," May 13, 2021. Accessed on November 1, 2021 at https://rhg.com/research/build-back-better-transportation/ (Figure 3 indicates EV penetration of 11% to 19% in 2026 under a current policy scenario).

[7] KPMG 22nd Annual Global Automotive Executive Survey 2021. Accessed on the internet on 12/08/2021 at: https://assets.kpmg/content/dam/kpmg/xx/pdf/2021/11/global-automotive-executive-summary-2021.pdf

attitudes appear to stem from increasing consumer exposure to electrified powertrains via the growing availability of vehicle models, styles and types, and the media attention created through manufacturer and government announcements." Similar comments can be found in Section 17. For example, Consumer Reports cites evidence of growing consumer interest in electric vehicles, indicated by 71 percent of U.S. drivers saying they would consider buying one in the future, and almost a third considering it for their next purchase.[8] A recent survey of U.S. adults showed that 43 percent would be likely consider purchasing or leasing an EV over the next decade.[9] This suggests that consumer acceptance will continue to improve over time as OEMs continue to introduce this technology, and that OEMs have the ability to promote consumer acceptance by promoting these products just as they promote their other products. We also note that EPA's standards do not require manufacturers to produce EVs or any other type of technology; rather, our modeling estimates one possible technology pathway to meet the standards. For the final standards, projected technology penetration rates for EVs and PHEVs are presented in Preamble III.B and RIA 4.1.4. However, standards are performance-based, and do not mandate a specific penetration of EVs and PHEVs. As shown in more detail in Chapter 4 of the RIA, together with moderate levels of electrification, the final MY 2026 standards can be met by continued adoption of advanced ICE technologies already existing in the market. Additionally, other flexibilities are in place for those manufacturers that choose to comply without achieving these levels of electrification. In light of these considerations, EPA believes that the MY 2026 standards (as well as the MY 2023-2025 standards) are feasible and provide sufficient lead time for manufacturers.

A variety of commenters urged EPA to eliminate, retain or modify some or all of the proposed manufacturer compliance flexibilities. EPA is finalizing a more limited set of optional manufacturer flexibilities than proposed, as discussed in greater detail in Preamble II. Refer to RTC Chapter 4 for additional responses.

Several commenters were supportive of the additional stringency of Alternative 2 minus 10 g/mi in 2026, to better align with goals they identified such as those in EO 14037 (50% of new vehicle sales electric by 2030) and the Paris Agreement. EPA agrees that Alternative 2 minus 10 g/mi standards in MY 2026 are appropriate, as discussed in Preamble II.A.

Several stakeholders provided comment on alternatives identified in the NPRM (including the effects of multipliers), specific to their impact on EV penetration. For example, EDF commented that "EPA should consider strengthening the standards by 10 g/mi in MY 2026 in a way that incentivizes greater ZEV deployment". Likewise, the ICCT argued that strengthening the 2026 standards would increase required EV penetration. Other commenters were in favor of eliminating the advanced technology multiplier as a means of promoting higher EV penetration. As previously stated above, EPA projects an increase in the penetration of EVs commensurate

with the more stringent standards in its final rule. Preamble Sections II.B.1.ii.a and b provide a detailed discussion on the advanced technology multipliers.

Finally, some commenters (EDF and UCS) provided their own modeling analysis of the standards as part of their submission. As described in Preamble VI.A, the analyses are consistent with EPA's conclusions that first, the standards can be met for MYs 2023-2024 with a combination of technology adoption following the trajectory of existing regulations for those MYs, and the use of banked credits; and second, that it is appropriate to finalize standards in MY2026 that are more stringent than the proposed standards. For reference, EPA has updated its own analysis of benefits and costs of the final rule and the alternatives it considered (Preamble I.D, VI and VII, and chapters 6 and 10 of the RIA).

The following responses address comments of specific commenters.

The Alliance commented that the NPRM modeling showed changes to vehicles in the MY 2018 through 2021 timeframe, years clearly in the past. EPA has updated the analysis in the final rule to include a MY 2020 base fleet rather than a MY 2017 base fleet, to ensure that the modeling is based on actual fleets as of MY 2020, which is the latest available data; we believe this update addresses this concern. EPA recognizes that its modeling assumes some degree of redesign in MY 2021 and MY 2022, but EPA believes the level of refresh/redesign assumed in these MYs is consistent with industry practice (see RIA Table 4-3). EPA does not believe that it would be realistic to assume that manufacturers would make no progress in MYs 2021 and 2022 beyond meeting the no-action SAFE standards, particularly given the existence of the California Framework Agreements. Further, our modeling shows just 1.7 g/mi improvement in 2-cycle CO_2 in MY 2021 and a 4.2 g/mi improvement in MY 2022 relative to the no-action scenario along with less than one additional gram of CO_2 credit via the averaging and/or banking program in each of those years. As for MY 2022, we believe that although those vehicles are being sold, time exists for auto makers to achieve additional reductions beyond current plans via shifting more sales to credit-generating vehicles (most advantageous for auto makers would be additional existing BEV and PHEV sales) as this strategy is not constrained by refresh and redesign schedules. In any case, EPA recognizes that the modeled emissions improvement for these years may vary somewhat from what individual manufacturers achieved, but, taking into consideration the averaging, banking and trading flexibilities of the program, EPA continues to believe that on balance the modeling is reasonable and the standards are appropriate in light of the cost of compliance and the availability of technology.

In response to the Center for Biological Diversity, Earthjustice, and Sierra Club, and the Michalek and Whitefoot, concerns regarding EPA's benefit-cost analysis (that EPA's cost-benefit analysis did not support the choice of the proposed alternative), we note that EPA follows applicable guidance and best practices when conducting its benefit-cost analyses, including OMB Circular A-4, EPA's Guidelines for Preparing Economic Analyses. For more information on how EPA quantifies the benefits of reducing GHG emissions, see section 14.1 of this Response to Comments document, as well as Section 3.3 of the RIA. .We consider our analysis methodologically rigorous and a best estimate of the projected benefits and costs associated with the final rule. Further, we note that the Clean Air Act does not require EPA to establish standards based on maximized net benefits. The Administrator gives consideration to several factors including emission reductions, technological feasibility, lead time and costs. Michalek and Whitefoot claimed that EPA has decided, by rejecting proposed Alternative 2, that a 10 percent penetration of plug-in electric vehicles is not feasible. EPA in fact does believe that a greater than 10 percent level of EV penetration is feasible, and our final analysis projects a 17 percent plug-in vehicle penetration by MY 2026. We also acknowledge the Center for Biological Diversity's comment describing previous instances where EPA adopted standards with short lead times.

Center for Biological Diversity, et al. and World Resources Institute recommended that EPA adopt anti-backsliding measures (e.g., for ICE vehicles) in case EV penetrations exceed the projected levels: CBD commented: "EPA should adopt mechanisms to maximize GHG reductions across the fleet to guard against the effects of underestimating EV penetrations... an unanticipated growth in EV adoption could lead to fewer GHG reductions than projected by the agency." In response, EPA has set fuel neutral, performance-based standards and considers electrification to be one of many technologies available to manufacturers toward meeting those standards. The final rule continues the performance-based fleet averaging approach that we have used for prior GHG standards. EPA did not consider standards which would apply vehicle or technology specific emissions limits as the commenter suggests. An averaging approach provides the greatest flexibility to meet a given level of overall emissions. If limits are placed on individual vehicles, the standards would need to be set at a lower numeric value to achieve the same emissions reduction benefits as this rule, but potentially at higher cost due to the additional constraints placed on the manufacturers' design decisions. Furthermore, EPA did not propose or solicit comment on setting a separate set of standards unique to ICE vehicles as a backstop in the event that BEV penetrations are higher than projected. The nature of fleet-wide averaging banking and trading is that high BEV penetrations could allow for ICE vehicles overall to do less to reduce GHG emissions. However, provided the standards are met, the projected fleetwide emission reductions will be achieved. EPA may further consider this issue in the future rule for 2027 and later model years.

The Competitive Enterprise institute (CEI) asserted that the range of alternatives considered in the proposal was insufficient, that Alternative 1 with stringency similar to the California Framework was arbitrary, and that less stringent alternatives should have been considered. EPA disagrees that the choice of Alternative 1 was an arbitrary lower bound for the proposal. Consistent with OMB Circular A-4, EPA included in the NRPM alternatives that were more and less stringent than the proposed alternative. EPA concluded that the proposed alternative was preferable to Alternative 1 considering the balance of factors, mainly, the greater emissions reductions. Our conclusion regarding the balancing of factors of any alternative with lower stringency would be even less favorable than Alternative 1, which was already excluded as being less favorable than the preferred alternative.

Elders Climate Action (ECA) asked that EPA set a zero emission standard for new motor vehicles and establish a phase-in schedule for the standard that includes a 30% ZEV sales target for MY 2026 to begin charting a regulatory path that will transition the auto industry toward achieving 100% production and sale of ZEVs in the U.S. by 2030. EPA did not propose or seek comment on a zero emissions standard or a ZEV sales target and has adopted more stringent, performance-based emissions standards for MYs 2023-2026, as described in Preamble II and VI.

GM commented, in response to a solicitation of comment in the NPRM, that the technical record is insufficient to comment on a potential additional stringency increase of 5 to 10 g/mi for the 2026 MY standards. EPA disagrees that there was insufficient information available to comment on the proposed additional stringency. EPA provided numerical upper and lower bounds for the range of stringencies being considered, and clearly defined the basis from which the additional stringency would be measured (Alternative 2). EPA also understands, based on extensive and longstanding engagement with vehicle manufacturers, that manufacturers have in-house modeling capabilities and do not rely on EPA projections for evaluating technology adoption pathways and the impact of standards on their future vehicle fleets and product plans, including developing compliance pathways and costs and associated advanced technology penetration requirements. In fact, other commenters, such as two NGO organizations (UCS and EDF), submitted independent modeling analyses in response to EPA's request for comment on a 5 to 10 grams/mile additional stringency for MY 2026, using publicly available modeling tools. Secondly, modeling information was made available in the docket at proposal. As detailed in the RIA Chapter 4 (and in the proposed RIA), the CCEMS model projects technology pathways, including BEV and PHEV market penetrations, for the final standards as well as alternatives of differing stringencies. To the extent GM believes it could not reasonably extrapolate from the extensive modeling presented for Alternative 2 or use other modeling tools for purposes of commenting, it could have used the CCEMS model. The CCEMS model was available at proposal, and our input and output files and all post-processing analysis files were available in the docket for this rulemaking.

Regarding GM's comment that EPA's analysis should include the impact of BEV and PHEV penetration in the context of the Nationally Determined Contribution and the Paris Agreement, EPA disagrees, as that target (and associated analysis of that target) is outside the scope of this rulemaking.

EPA received comments regarding provisions for intermediate volume manufacturers and small volume manufacturers (SVMs). Jaguar Land Rover North America suggested that EPA consider an alternative compliance option for intermediate volume manufacturers allowing them to comply with less stringent standards since they comprise only a small portion of the US fleet. The Alliance suggested that EPA improve the process for considering and approving SVM petitions. EPA notes that it did not propose or solicit comment on any aspect of or changes to the SVM standards regulations, or on an intermediate volume manufacturer program, so these comments are outside the scope of this rulemaking. EPA will consider the Alliance comments regarding the process of approving SVM applications as part of implementing the existing SVM GHG standards program.

The National Association of Clean Air Agencies (NACAA) and others urged EPA to set standards that would achieve the same level of emission benefits (which is an ambiguous phrase but EPA understands to mean "emission reductions") as the 2012 final rule. As discussed in section VI of the preamble to the final rule, EPA sets emission standards based not only on emission reductions but also technological feasibility, costs, lead time and other factors. That said, the final standards are projected to achieve more GHG emission reductions through 2050 than would occur were the 2012 standards to remain in place (see RIA Figure 5-4).

Many individual commenters expressed concerns that EPA is not doing enough to protect the environment and to reduce GHG emissions. These commenters support finalizing the most stringent set of standards possible, and many of them further support applying these standards as early as possible. EPA believes that the final standards strike the right balance between environmental goals and other goals such as concern for the continued viability of auto makers, auto suppliers, and the US economy. EPA is required to set standards considering not only emission reductions but also technological feasibility, costs, lead time and other factors.

Stellantis also argued that manufacturer underperformance relative to the MY 2019 standards, and manufacturer reliance on credits to achieve compliance, suggests that more time is needed to achieve the levels of electrification needed to meet the proposed standards. EPA does not agree with this comment that more time is needed. Past underperformance relative to standards does not mean the standards were unachievable or inappropriate based on the timeframe for compliance. A manufacturer's noncompliance with standards in one or more model years may be the result of product planning decisions and risks taken by the manufacturers and consideration of that manufacturers CO2 credit bank and the availability of banked CO2 credits which could be purchased from other manufacturers. Manufacturers historically have made use of the full suite of current EPA program flexibilities to achieve compliance, including credit trading. These flexibilities are an important part of the program. Credits may have been earned early in the GHG program, i.e., voluntary overcompliance resulting in early emission reductions and banked credits. Some manufacturers, more than others, have chosen to rely on credit purchases to facilitate compliance. Other manufacturers have chosen to focus on adding technology and earning credits for later use or potential sale. Both paths are available under the GHG program. The commenter also argues that stringency beyond the timeframe of the proposed standards does not significantly impact net CO2 reductions during the MY 2023 to 2026 implementation period. EPA disagrees with this characterization of the impact of CO2 reductions attributed to our standards. EPA MY 2026 standards continue for all model years beyond 2026 until such time as EPA revises the standards in a subsequent rulemaking, so the increased stringency carries forward and results in considerable GHG reductions relative to the less stringent alternatives considered in the proposal, as the fleet turns over. The final standards' increased stringency compared to the proposal results in a 50 percent increase in the amount of CO2 reductions projected to be achieved through 2050. See Preamble Section IV.

Tesla commented about the flexibilities in the proposal and that the flexibilities made the SAFE standards even less stringent in MY 2021 and 2022. EPA responds to such issues and describes the final program's flexibilities in Preamble II.B and VI. Tesla takes issue with EPA's use of a MY 2017 base fleet, to which we have been responsive by updating the final rule analysis to use a MY 2020 base fleet which contains an updated representation of Tesla actual sales (nearly 300,000 Tesla vehicle sales). The commenter also urged EPA to strive for greater stringency than the proposed standards -- this EPA has done by adopting Alternative 2 standards for MY 2025 and Alternative 2 standards with additional 10 grams/miles CO2 stringency for MY 2026 and beyond.

Toyota questioned EPA's projection that roughly 87 percent of the 2026 model year fleet would be comprised of conventional gasoline powertrains. EPA's analysis shows that MY2026 standards can be met without the introduction of new ICE technologies that are not already existing in the market. The commenter was apparently confused regarding EPA's discussion of 'technologies already in place in vehicles within today's new vehicle fleet' and misinterpreted the statement to mean that the vehicles themselves will necessarily be the same. This is incorrect. EPA's analysis shows that gasoline technologies that exist in the fleet today, together with electric vehicle technologies that exist today, can be implemented by manufacturers to meet the standards. Further, the commenters reference an IHS-Markit study (summarized within Figure 1 within their comments) which they did not include as an attachment to their comments or include a citation to publicly available data or a publicly available study, thus EPA was not able to evaluate the veracity of the underlying cost and effectiveness data from the study that was used to create Figure 1 within the Toyota comments.

Mr. Williams expressed concern that the stringency of the proposal is not in line with the goal of 50% electric vehicle sales by 2030 as expressed in Executive Order 14037. Also, several commenters supported the rule; in the final rule, EPA is revising the MY 2025 and MY 2026 standards to be more stringent (as described in Preamble II) in consideration of many factors, including updated analyses, public comments received, and recent developments within the automotive industry. As described in the Preamble I.A.2, EPA plans to initiate a rulemaking to establish multi-pollutant emission standards for MY 2027 and beyond.

2.3. Footprint Curve Shapes and Cutpoints

The continued use of footprint-based standards in setting GHG gram/mile emission targets for separate car and light truck vehicle classes is wholly appropriate, as these standards have proven to be a valuable means of incentivizing automakers to focus on fuel efficiency/ emissions improvement across all vehicle classes through greater use of lighter, yet stronger materials. As larger vehicles comprise an ever-growing portion of US light duty vehicle sales, the footprint-based approach provides an incentive for reducing weight in such vehicles, where weight reduction is the most beneficial in terms of GHG emission reduction and fleetwide safety. [EPA-HQ-OAR-2021-0208-0233-A1, p.3]

Commenter: Anonymous Public Comment 2

Regarding the revised emissions standards for vehicles, I am encouraged by the shift towards more accurate real-world testing of emissions. Especially after the scandals of the past decade, these changes are welcome. However, I feel troubled by the emission targets for vehicles themselves.

As a citizen residing in New Hampshire (using a VPN right now though), I am able to observe a variety of different population densities and the resulting demographics' choices regarding vehicles. My family currently owns a 2018 Ford Explorer, a 2007 Ford Mustang, and a 2011 Subaru Outback. We are a pretty average family both in terms of monetary class and housing density - we live in suburbs next to Manchester, NH. Around the neighborhood such types of vehicles are quite average. Furthermore, in more spacious suburban neighborhoods, I have noticed an even higher average size of vehicles. There are many Chevy Traverse's and Ford Explorer's, etc. The issue is that these vehicles are not usually needed for the short journeys they are often utilized for. Due to a more lenient approach regarding civilian SUV's and Pickup Trucks compared to passenger Sedans in these revised regulations, I believe that such wasteful and large un-needed vehicles will become even cheaper compared to more tightly-restrained cars. These cars will cost civilians more to repair and fill versus an alternative sedan or electrified SUV (which would be more attractive options if the price difference was higher between the two classes).

Even in the city of Manchester itself, large SUV's and Pickups are quite high in ratio. In places like rural Plymouth, sensible hatchback owners must share the streets with drivers of large Pickup trucks, which are thought by the public to be almost a necessity when away from cities due to Americans' need to carry extra un-needed space. In every scenario, the ratio of large vehicles ought to be reduced.

Thus, I propose that the emissions targets for the Sedans and SUV's / Pickups should be the same. It may be said that larger vehicles can't achieve as good gas mileage as smaller vehicles. This is true to an extent but it has already been proven by hybrid F-150's, the F-150 Lightning, the Kia Niro, the Cybertruck, the Rivian, and other similar vehicles can, with today's technology, easily incorporate electric power which strongly reduces emissions while maintaining competitive prices. In 2023 and beyond, this point will become even more valid as the price of batteries decreases. In fact, the company BYD in China has already achieved an electric vehicle fleet (including SUV's) that is the same price as ICE counterparts. Furthermore, the cost for electric Sedans will go down as well. Not only will an equal emissions target encourage electric drivetrain adoption, it will encourage people to buy those cheap Sedans instead of moderateprice SUV's, leading to more efficient transport. And electric Sedans tend to have more space than ICE Sedans due to their frunks and floor batteries anyhow.

Also, by comparing the emissions targets between the USA and European nations it seems that even the Sedan targets lag behind. It would be foolish to assume everyone will buy a small electric British car, but perhaps the difference should be split. I propose a maximum of 160 CO2 grams/mile which would take into account the larger American car sizes and give a bit extra.

And finally, I believe that your estimates for an 8% BEV market share in 2026 is not accurate, as disruptive adoption rates curve exponentially in an S shape. As prominent car enthusiast Sandy Munroe has pointed out, the US car makers are far behind Asian competition. So even if American car companies slow down EV adoption due to lax emission standards, Chinese automakers are poised to invade the market and make the switch for us well before 2030 (Not to mention Tesla!). So having a stricter emissions target would encourage the US automakers to avoid the fate of the Japanese auto invasion of the 20'th Century (or at least lessen its impact)

To conclude, because of the un-needed large SUV and Pickup surge, I do not believe it necessary to be lax on the already overpopulated car segment by decreasing the strength of emissions targets for the segment. Furthermore, the small vehicle target itself should be stricter (about 160 CO2 grams/mile), because not only are electric powertrains affordable now, they will continue to get cheaper and be integrated into more vehicles either by the USA or China (and we would prefer to maintain our automaking industry!). If you have taken the time to read my long and somewhat poorly composed comment, I thank you very, very much. Please consider what I have to say as I believe the ramifications of these guidelines may directly benefit American cardriving families like mine, and indirectly benefit our American economy. [EPA-HQ-OAR-2021-0208-0575, p. 1]

Commenter: Center for Biological Diversity, et al.

EPA should consider adopting a mix-shift backstop.

In each of their vehicle standard rulemakings since 2009, and again in this Proposal, EPA and NHTSA have acknowledged that their standards are for individual vehicles and vary based on vehicle-type (i.e., car or truck) and vehicle size (or "footprint"), and that, as a result, the projected level of fuel savings and GHG reductions in the rules are estimates and likely will not actually be met, as the real-world fleet will likely differ from the agencies' projections. Average Fuel Economy Standards Passenger Cars and Light Trucks Model Year 2011, 74 Fed. Reg. 14,196, 14,409-12 (March 30, 2009); Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards, 75 Fed. Reg. 25,324, 25,363(May 7, 2010) (2010 Rule); 2012 Final Rule, 77 Fed. Reg. 62,624, 63,020-23. Proposal, 86 Fed. Reg. at 43,731 FN.36. For that reason, commenters have urged EPA to set a "backstop," or minimum standard below which actual performance may not fall.

Commenters have repeatedly pointed out that, because the targets in attribute-based standards assume a particular fleet mix between passenger vehicles and light trucks during the years of the rulemaking, changes to that fleet mix will alter the fuel efficiency actually achieved. Further, particular features in the compliance curves and different stringency levels for passenger vehicles and light duty trucks incentivize manufacturers to re-classify their passenger cars as light trucks, shifting the fleet mix to trucks and lowering the overall fleet performance. Manufacturers can also manipulate the standards by adding size to vehicle footprints to qualify for weaker standards. See 2010 Rule, 75 Fed. Reg. 25,362-70, 25,608-610; 2012 Final Rule, 75 Red. Reg. 63,029-23.

EPA and NHTSA have agreed that these concerns are well-founded. E.g., 2010 Rule, 75 Fed. Reg. 25,363. NHTSA agrees that it has the authority to set backstops, complementing the Congressionally-mandated backstop for domestic passenger cars, and EPA agrees it has the same authority to set backstops under section 202(a) of the Clean Air Act. E.g., 2012 Final Rule, 75 Fed. Reg. 25,368. See also Center for Biological Diversity v. NHTSA, 538 F.3d 1172, 1205-06 (9thCir. 2007). While acknowledging that implementing additional backstops is squarely within their discretion, the agencies did not do so because they remained confident their projections would be met and believed the attribute-based standards did not create sufficient grounds for manufacturers to shift their vehicle mix toward the light truck fleet segment. They stressed that "insufficient time" had passed "in which manufacturers have been subject to the attribute-based standards to assess whether or not backstops would in fact help ensure that fuel savings anticipated by the agency . . . are met." 2012 Final Rule, 77 Fed. Reg. 63,022. And they twice committed to revisit the issue in their next rulemaking to assess whether this analysis remained correct. 2010 Rule, 74 Fed. Reg. 25,610; 2012 Final Rule, 77 Fed. Reg. at 63,022.

It is now clear that the fleet mix has dramatically shifted towards higher-emitting light trucks, despite the attribute-based system. Since 2013, the fleet mix has shifted from 50 percent cars to only 33 percent cars in MY2019.186 In part because of that shift, the fleet average real-world results are lower than those the agencies have projected.

Given the agencies' recognition of this issue and their prior commitments to conduct ongoing assessments of the need for a backstop, we urge EPA to explain why it has not considered one for the instant rulemaking, and to provide assurances that it will also consider it for MY 2027 and later standards. [EPA-HQ-OAR-2021-0208-0651-A1, p. 76-77]

Commenter: Manly, Hugh

Cars over 15ft produce 3x the exhaust waste, and 4x the heat than smaller vehicles do. This is why the UK stopped making vehicles, longer than 14ft.8in and now mass produces, the Mini-Morris for local and export use,which, is 30x more energy efficient than a Cadillac. The GAG rules can be easily met by shorter vehicles,but not by larger ones,start there. [EPA-HQ-OAR-2021-0208-0660-A1, p. 1]

Commenter: National Automobile Dealers Association (NADA)

Despite its concerns regarding the substantive basis the proposed new mandates, NADA supports EPA's intent to retain the SAFE rule's footprint-based structure for both passenger cars and trucks, as mandated by the Energy Independence and Security Act (EISA),32 and to retain related passenger car and light truck fleet definitions. Retail and fleet consumers demand vehicles that meet a wide-variety of needs and duty-cycles, ranging from short daily commutes, to the commercial transport of persons and goods, to the weekend trailering of horses and snowmobiles. Consumers need and desire personal transportation choices from diesel pickups with off-road capabilities to two-seater sports cars with small turbo-charged engines. OEMs must be enabled to build more fuel-efficient vehicles across the broadest possible light-duty passenger car and truck spectrum. [EPA-HQ-OAR-2021-0208-0290-A1, p. 9]

Commenter: Peterson, Doug

You can talk from here to tomorrow about all that is being done to improve the efficiency of light duty vehicles, but in the end there is no denying that our best efforts are failing. The footprint model insulates automakers from any obligation to downsize their vehicles or manage the horsepower necessary for them to accelerate quickly, two vehicle attributes that are known by the EPA to increase the amount of CO_2 our jumbo vehicles emit. North American vehicles are, on average, much larger that vehicles in other countries, and more powerful. Our nation's per capita gasoline consumption is excessive. The Corporate Average Fuel Economy program that was refined under the Obama Administration in consultation with the automotive community has only resulted in slow incremental improvements to fuel economy that are entirely inadequate for fulfilling the EPA's legal and moral obligations. The EPA's 2020 Automotive Trends Report includes ample statistical evidence that fuel efficiency is improving slowly, and that these minor incremental gains are being offset by changes in the national fleet mix favoring larger and larger vehicles. This is the inevitable result of the impotent footprint model and the lenient system of compliance credits that form the basis of the EPA's ineffective regulatory framework. Increases in highway speeds and vehicle miles traveled are two other factors that increase gasoline consumption, but the EPA does little to reverse these destructive trends, seeing them as outside its administrative domain. If consumer desire for larger vehicles, faster highway speeds, and greater vehicle miles traveled can offset the slow, meager benefits provided by the EPA's regulatory framework, that framework is patently inadequate and needs to be strengthened. [EPA-HQ-OAR-2021-0208-0692-A1, p. 3]

The Footprint Curves Should Be Altered to Incentivize Modest Downsizing

I support the EPA's decision to restore the footprint curves to their original shapes, as this will increase the stringency of the framework. All my comments are consistent with my firm belief that the framework is far too lenient and needs to be strengthened. I need not elaborate on why the Trump Administration's alteration of the curves increased the leniency of the framework. We all understand the function of the footprint curves.

I am going to go out on a limb and suggest that the footprint curves be altered even further to incentivize modest downsizing of the largest light duty vehicles, particularly full-size pickup trucks and SUVs. This could be accomplished by altering the footprint curves, gradually decreasing the maximum amount of carbon dioxide the largest vehicles are allowed to produce. It could also be accomplished by gradually lowering the threshold footprint size at which a vehicle is no longer allowed to emit a greater amount of carbon dioxide. Either adjustment to the curves, or a combination of the two, would encourage downsizing by making it more difficult for the largest vehicles to meet their standards.

The current framework based on footprints was designed to discourage downsizing, and this has become the framework's fatal flaw. The desire to maintain the perceived safety benefits of large vehicles has more to do with politics than it does with logical arguments about road safety. In a two-car collision between vehicles of different sizes, the larger vehicle provides an added measure of safety to its occupants at the expense of the smaller vehicle's occupants. Research on the relationship between vehicle size and safety is extraordinarily complex, but it currently doesn't much matter what the truth is; the general public sees larger vehicles as being safer, and this is the reason why downsizing has been shunned. Many parents prefer a larger vehicle out of concern for the safety of their children, and this understandable consumer preference generates a powerful political force that disallows regulations that might encourage downsizing. The ongoing inflationary trend toward larger and larger vehicles appears to be closely related to public concerns about safety; individual car buyers, particularly parents, search out ever larger vehicles to keep up with the larger vehicles purchased by others. The automakers benefit from the upsizing trend, and their advertisements are clearly designed to capitalize on parental insecurity regarding the safety of their children.

If the EPA had its priorities in the right place and was insulated from purely political considerations, they would be working to reverse the environmentally destructive trend toward larger and larger vehicles. Other countries drive vehicles that are, on average, considerably smaller than ours, and there is little evidence that their roads are less safe because of their reasonably sized fleets. Larger vehicles inevitably produce greater quantities of carbon dioxide, so the EPA has a valid reason to encourage at least a small amount of downsizing as it strives to advance its core mission. There is some statistical evidence that our roads would be safer if there were less variation between the largest and smallest vehicles. It seems especially disingenuous that the automakers 11 argue against downsizing, feigning concerns about safety. Their advertisements often glorify excessive acceleration capabilities, depicting people operating vehicles with reckless abandon, and their advertised specifications highlight top speeds that far exceed legal limits. The automakers can't have it both ways. They either care about public safety or they don't. A nationwide effort to reduce highway speeds would save lives and substantially reduce emissions, but no such effort is even contemplated because it would be very unpopular. Given that climate change involves dangers of its own that will ultimately threaten public safety, it would seem reasonable to implement new footprint curves that encourage a moderate degree of downsizing, aiming to reduce the size and weight of the largest passenger vehicles. If zero emission vehicles are to be phased in systematically after 2027, a steady, coordinated effort to downsize the national fleet, including ZEVs, would reduce gasoline consumption and electricity consumption. The EPA would be wise to begin that downsizing effort immediately in order to maximize these valuable environmental benefits. [EPA-HQ-OAR-2021-0208-0692-A1, p. 10-11]

Commenter: Thomas, Gary

I've never understood how a pickup truck or SUV is any different from a car when it comes to pollution regulations. Most of the uses are the same as those for a passenger car with the occasional use for towing or hauling large objects. It seems to me that this agency's inability to understand that obvious fact has lead the pickup truck and SUV manufacturers to not adapt their hybrid and electric vehicle knowledge to the much bigger vehicle market that the EPA is currently ignoring. When the American public is buying more SUVS and pickups than conventional cars but have fewer regulations and pollute more, I think it's time to change the thinking and regulations for ALL vehicles to be the same [EPA-HQ-OAR-2021-0208-0349, p. 1]

Commenter: Wolf, Barry

Please, considering people now use large SUVs and pickup trucks as commuter vehicles, do not be lenient with those vehicles' carbon dioxide emissions. Please institute a fleet wide 100 grams CO_2/mile standard beginning with the 2025 model year and getting stricter by 20% every year after that. Please do not provide less strict rules for the most polluting and now most often purchased class of vehicles (big SUVs and pickups). [EPA-HQ-OAR-2021-0208-0339, p. 1]

EPA Response

Several commenters expressed views on the shape and structure of the footprint standards curves. Multiple commenters argued that the usage of most pickup trucks and SUVs is similar to that of passenger vehicles and they should be held to the same standards. The Center for Biological Diversity, et al. commented on the differences in the standard curves between passenger vehicles and light trucks, and the observations of the overall fleet mix shifting more towards light trucks in recent years. They also requested that EPA explain why it has not considered a backstop to prevent further fleet shift to light trucks, and that EPA consider this approach for future standards. Mr. Peterson commented that the footprint curves should be altered to incentivize modest downsizing.

As indicated in Preamble II.A, EPA retains the footprint-based structure for both passenger cars and light-trucks in this final rulemaking. EPA is restoring the upper cutpoint for light trucks (which was changed in the SAFE rule) to 74.0 sq ft, which is the original value from the 2012 rule. In response to Center for Biological Diversity, et al., EPA did not propose or solicit comment on establishing a backstop which CBD argues is needed to prevent additional fleet mix shift to light trucks. EPA believes that a significant restructuring of the footprint curves, such as eliminating the separate curve for light trucks or a "backstop" to prevent fleet shifting, would not be appropriate given that this rule is only revising standards for model years 2023-2026, and model year 2023 can begin as early as January 2, 2022. EPA is also planning to initiate a new rulemaking to establish multi-pollutant emission standards for MY 2027 and beyond, and looks forward to engaging with all stakeholders (including those that commented on these issues) on this issue and others to inform the development of these future standard.

3. Technological Feasibility of the Standards

Commenter: Advanced Engine Systems Institute (AESI)

Available Advanced Technologies

There are numerous, robust technologies whose costs have declined and which remain available for deployment such as were highlighted by EPA in the 2020 Trends Report. AESI believes that vehicle manufacturers are well positioned to comply with the Preferred Proposal (38.2 mpg real world average) proposed by 2023-2026 LD GHG standards. 2) The Potential of Advanced Hybridized Powertrains Hybridized powertrains are an obvious technology to be further exploited as they are presently only deployed on roughly 7% of vehicles. Current popular hybrid models reduce CO_2 broadly by an average of about 30% while employing batteries of only 1 to 2 kWh. The latest new generation hybrids continue to show further efficiency improvements as they incorporate the latest IC engine, battery, electric motor and powertrain developments. Specific new generation MY2021 hybrids have shown an ability to reduce CO2 by as much as 70% compared to the previous vehicle generation. As hybrids do not rely upon local grids, their benefits apply equally across all 50 U.S. states making hybridization an ideal technology to ensure the most efficient legacy fleet possible. [EPA-HQ-OAR-2021-0208-0267-A1, p. 2]

Commenter: Alliance For Automotive Innovation

Comments on Potential Future Technology Additions

Aside from the previous discussion of HCR2, which is a prominent issue in EPA's analysis with respect to technological feasibility, Auto Innovators provides the following comment and guidance for current and near-future analysis.

The Agencies should maintain a performance-neutral approach when estimating technology benefits.

Vehicle design parameters are never static. With each new generation of a vehicle, manufacturers seek to improve vehicle utility, performance, and other characteristics based on research of customer expectations and desires, and to add innovative features that improve the customer experience. The Agencies have historically sought to maintain the performance characteristics of vehicles modeled with fuel economy-improving technologies. Auto Innovators encourages the Agencies to maintain a performance-neutral approach to the analysis, to the extent possible. Auto Innovators appreciates that the Agencies continue to consider high-speed acceleration, gradeability, towing, range, traction, and interior room (including headroom) in the analysis when sizing powertrains and evaluating pathways for road-load reductions. All of these parameters should be considered separately, not just in combination. (For example, we do not support an approach where various acceleration times are added together to create a single "performance" statistic. Manufacturers must provide all types of performance, not just one or two to the detriment of others.)

Tire rolling resistance improvements

Auto Innovators discourages the addition of 30% tire rolling resistance reductions ("ROLL30") to the analysis at this time. Performance neutrality for cold weather traction, hot weather performance, wet weather traction, load handing (for addition weight of batteries, for instance), wear and durability, and noise, vibration, and harshness can be challenging to achieve for 20% tire rolling resistance reduction, and the technology pathway to ROLL30 for many vehicles remains unclear.

Aerodynamic improvements

A 20% aerodynamic improvement relative to 2015 baseline vehicles remains challenging to achieve for many body styles, given form drags, and other regulations, like side view mirror requirements. Auto Innovators does not recommend considering additional aerodynamic improvements (such as 25 percent aerodynamic improvements, etc.). Some additional reductions in aerodynamic forces may be possible if side view mirrors were no longer required by NHTSA and Federal Motor Vehicle Safety Standards. [EPA-HQ-OAR-2021-0208-0571-A1, p. 61-62]

Commenter: American Council for an Energy-Efficient Economy (ACEEE)

Stronger standards are achievable

Standards that go above and beyond the proposed standards are achievable, without resorting to any of the counterproductive incentives previously discussed. Fuel efficiency and electrification technology has advanced significantly since the MY 2017-2025 standards were finalized in 2012 and electric vehicles are now a mature technology. EPA itself also makes the claim in the NPRM that automakers are more than prepared to meet the proposed standards; noting that they have continued to invest in new technology and have been doing so since the 2012 Final Rule (2021b, p. 177-178). We believe that due to the availability of banked credits, existing electrification options, and declining costs of electrification stronger standards are achievable. We also believe stronger standards will set the United States up to meet 2030 goals and continue to advance fuel efficiency technology. [EPA-HQ-OAR-2021-0208-0251-A1, pp. 10-11]

Commenter: Bay Area Air Quality Management District

However, a relative improvement is not enough. The technology to meet all standards considered in the NPRM is available now. [EPA-HQ-OAR-2021-0208-0283-A1, p.2]

Commenter: Begley, Amanda

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 246.]

These standards will continue to promote innovation throughout the automotive industry and will ensure that the U.S. remains an industry leader. These standards have already gone through a rigorous technical review process which found that auto manufacturers have the technology to meet the standards.

Commenter: BorgWarner Inc.

In summary, regulatory standards should be technology neutral and performance based to encourage advanced technology development and drive innovation. There are multiple pathways to achieve compliance in the future. All technology pathways with practical 4 applications should be included as potential technology solutions to assist the U.S. in achieving its environmental goals. EPA should allow for a review of increased stringency should technology pathways demonstrate earlier readiness to maximize environmental benefits. With one of the broadest portfolios of propulsion products, BorgWarner understands the interrelation between vehicle electrification and emissions reduction. We have a long history of setting trends with our products to meet the needs of the industry and customers all over the world. Focusing on the rate of improvement that results in rapid adoption of high-volume technology solutions is good for consumers, the industry, government initiatives, and most importantly, the environment. [EPA-HQ-OAR-2021-0208-0260-A1, p. 3-4]

Commenter: California Air Resources Board (CARB)

All the proposed standards – the preferred alternative, the more stringent alternatives, and thus necessarily the less stringent alternative - are technologically feasible. [EPA-HQ-OAR-2021-0208-0643-A6, p.1] The solutions are at hand. The ingenuity of engineers and scientists has improved vehicle emission technology and significantly reduced emissions of greenhouse gases and other pollutants. In many instances these improvements pay for themselves in fuel savings, and in all ways their benefits to public health and welfare far outweigh their costs. Automobile manufacturers are already including in their vehicles the technologies to meet these proposed standards, including in other markets. The proposed standards will ensure they accelerate deployment here. [EPA-HQ-OAR-2021-0208-0643-A6, 2]

All the proposed standards – the preferred alternative, the more stringent alternatives, and necessarily the less stringent alternative - are technologically feasible considering the cost of compliance and the time provided to apply the requisite technology. [EPA-HQ-OAR-2021-0208-0643-A6, p.6]

CARB agrees that manufacturers have developed the technology to meet U.S. EPA’s more stringent alternative, identified in the proposal as Alternative 2, to return to the National Program standards. The technology exists to extend and improve those standards for model year 2026 by an additional 10 grams of carbon dioxide per mile. [EPA-HQ-OAR-2021-0208-0643-A6, p.7]

Manufacturers have Followed a Trajectory of More Stringent Standards.

In response to comments on the SAFE Rules and actions, including from CARB, U.S. EPA has revised its prior analysis of technologies for meeting the GHG emission standards.76 U.S. EPA correctly recognizes in the proposal that over the past decade, auto manufacturers have developed and deployed a variety of technologies to sufficiently reduce greenhouse gas emissions from vehicles to meet the National Program standards adopted in 2012. U.S. EPA improved its analysis for the proposal by recognizing numerous emission-reducing technologies have been incorporated into vehicles at lower costs than previously projected.

These technologies include high-compression ratio engines, cooled exhaust gas recirculation, and fixed-cylinder deactivation.77 In particular, U.S. EPA has allowed advanced high-compression ratio engines to be adopted on all engines with less than 8 cylinders. Unlike the analysis supporting the Final SAFE Rules, there are no 'skip flags' for such engines in the modeling supporting the proposed standards, where the modeling previously inappropriately precluded many 6- and 4-cylinder engines from adopting this technology. Consistent with U.S. EPA’s assessments through the Final Determination, the analysis supporting this proposal reflect the capability of more improvement from advanced high-compression ratio engines beyond what was originally derived from first-generation production engines like the early Mazda SkyActiv Atkinson-cycle engines deployed in model year 2014.

U.S. EPA also recognizes that about half the vehicles in model year 2020 already have direct injection in spark-ignition vehicles and planetary automatic 8-speed transmissions, a third have turbochargers, and a quarter have continuously variable transmissions.78

CARB agrees with U.S. EPA that the costs for meeting the proposed standards have remained in line with previous estimates, and if anything, are less than previously estimated. U.S. EPA's estimated average per-vehicle cost to meet the preferred alternative's standards in model year 2026 of $1,044 is a reasonable estimate and an eminently reasonable cost to achieve the benefits of more stringent standards.79 [EPA-HQ-OAR-2021-0208-0643-A6, p. 29]

As CARB explained in its comments to U.S. EPA on its proposal to restore its waiver for California's GHG emission and ZEV standards, manufacturers are well-positioned to meet those California standards.84 Entering the first model year of the Final SAFE Rules, 2021, manufacturers as an industry will be on a trajectory to comply with California's standards at or below previous cost projections. The same technologies similarly leave automakers well-positioned to meet more stringent federal GHG emission standards. [EPA-HQ-OAR-2021-0208-0643-A6, p.30]

Further, as Gary W. Rogers, Vice President of Advanced Technology at Roush Engineering explains in the accompanying expert report,86 manufacturers are already incorporating at a rapid and increasing rate advanced technologies that reduce emissions, improve performance, and provide additional features that consumers prefer.

These technologies have been developed to meet regulatory and consumer demand across the global market in which auto manufacturers compete. Globally, despite the Final SAFE Rules, emission standards and customer demand for cleaner transportation technology have remained strong. The Roush report illustrates the GHG emission standards in Asia, Europe, and Canada continue to require annual emission reductions more stringent than and on a similar trajectory as the National Program standards.87 Manufacturers have continued to reduce the pollution from their products offered domestically and regularly incorporate advanced technologies from foreign markets in offerings here.

Manufacturers are also able to adjust, within a given model year and within their normal product planning, the emissions performance of the vehicles they offer to meet fleetwide GHG emission standards. Automotive manufacturers routinely offer variations of the same model vehicles with different combinations of powertrain components. This allows them to offer a range of pricing and features. As shown in the Roush report, models from several manufacturers that sell well can meet standards that are more stringent, in many cases by more than 10 percent, with existing and imminent vehicles and components that are already schedule for production.88

Moreover, the expansion of mild hybrid technologies at declining costs enables even greater improvements, to say nothing of the growing sales of these technologies89 and zero-emission vehicles, which are discussed below. And the potential to reduce emissions while offering benefits to consumers of those technologies continue to expand, such as by offering the capability to power external devices.90

A confluence of factors shows that U.S. EPA can expect manufacturers to be well positioned to comply with its proposal. Technologies continue to advance, costs continue to decline, and global regulatory, consumer, and investor demands motivate manufacturers to plan their products to meet stringent GHG emission standards – including the preferred alternative and Alternative 2 standards being considered here. [EPA-HQ-OAR-2021-0208-0643-A6, pp. 30-31]

Commenter: California Attorney General Office, et al.

EPA must give due regard to the facts that the necessary technologies have already been developed and brought to market and that automakers have had to plan for substantially more stringent standards in large portions of the global market as well as in the United States. [EPA-HQ-OAR-2021-0208-0245-A1, p.2]

Second, as the records for the MTE, the SAFE standards, and this proceeding consistently show, none of the standards in EPA's current proposal requires the development of new technologies or raises questions about whether existing technologies can be applied to vehicles. The technologies necessary to meet even the most stringent standards included in this proposal have already been developed and are widely deployed in vehicles on the market today. E.g., 86 Fed. Reg. at 43,728 ('Auto manufacturers are currently implementing an increasing array of advanced gasoline vehicle GHG emission-reducing technologies at a rapid pace throughout their vehicle fleets.'); id. at 43,731 ('The technological achievements already developed and applied to vehicles within the current new vehicle fleet will enable the industry to achieve the proposed standards even without the development of new technologies beyond those already widely available.'). [EPA-HQ-OAR-2021-0208-0245-A1, p.25]

Second, with more stringent regulations covering large segments of the global market in which automakers operate, the industry has continued to expand the application of GHG-reducing technologies in those market segments.126 There is a long history of automakers transferring those applications across market segments, and those transfers (and plans for transfers) have continued even in the face of the SAFE 2 standards.127 Thus, automakers are well-positioned to quickly comply with increases in stringency due to the ability to continue and/or speed up the transfer of technologies deployed in other market segments to the vehicles they offer here. [EPA-HQ-OAR-2021-0208-0245-A1, p.27]

Commenter: Chicago Metropolitan Agency for Planning

The proposed rule also acknowledges and speeds the deployment of the technological advancements that have already been made since the EPA established these emissions standards [EPA-HQ-OAR-2021-0208-0219-A1, p.3]

Commenter: Climate Group EV100

Through the Climate Group's EV100 initiative, members have committed to convert over 5 million vehicles to electric and zero-emission and to deploy charging at over 7,000 locations. However, members routinely describe leading barriers to getting more EVs on the road include the lack of correct vehicle types and uncertain and undeveloped policy landscape among other challenges. [EPA-HQ-OAR-2021-0208-0200-A1, p. 1]

Commenter: Dream Corps Green for All et al.

Strong GHG emission standards for passenger vehicles help lower transportation costs for low-income drivers and advance long standing environmental justice goals. [EPA-HQ-OAR-2021-0208-0285-A1, p.1]

Commenter: Environmental Law and Policy Center (ELPC)

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 291.]

EPA makes clear in the NPRM that the proposed standards will be met with existing technology. Even Alternative 2, while stronger, will not spur innovation and fuel-saving technologies because loopholes will allow auto manufacturers to do more of the same with the climate paying the price.

Commenter: International Council on Clean Transportation

While ICCT supports the proposed rule, the cost of compliance is overstated due to the use of outdated technology data and information. Vehicle efficiency technology has been consistently improving for decades. This technology trend shows no signs of slowing down, as supported by a variety of recent comments and publications. For example:

• The EPA Fuel Economy Trends report1 documents rapid development and deployment of many technologies that are now commonplace in the market.2 [EPA-HQ-OAR-2021-0208-0522-A1, p. 2]

• Section 1.2.1 (pages 1-6 through 1-9) of EPA's draft RIA for its proposed rule summarizes updated technology analyses and data from EPA's TSD for EPA's 2018 MTE Analysis. [EPA-HQ-OAR-2021-0208-0522-A1, p. 3]

Further, two recent reports 78 demonstrate that further technology improvements are coming that can boost ICE efficiency well beyond even HCR2 efficiency levels, and a third shows the declining costs of a 48-volt mild hybrid and BEVs9.

The EPA draft RIA (DRIA) acknowledges that technologies have improved since the publication of the TSD in 2016 for the November 2016 Proposed Determination. For example, the DRIA states:

‘EPA has continued its independent evaluation of advanced engine and transmission technologies and update and improve our assessment of light-duty vehicle GHG emissions over the intervening 4 years since publication of the TSD. The results of these analyses have been published in over a dozen peer-reviewed technical and journal papers.’ (see DRIA 2021 page 2-10) [EPA-HQ-OAR-2021-0208-0522-A1, p. 3]

As documented in the following sections, technology effectiveness and cost have continued to improve. Thus, if technology costs and benefits were updated with the latest information, it would show that the proposed standards and Alternative 2 are even more feasible and lower-cost than EPA’s analysis indicates. [EPA-HQ-OAR-2021-0208-0522-A1, p. 4]

Even if EPA chooses to not incorporate the full extent of new data and information into the final rule for MY2023-2026, EPA should at least acknowledge that the technology assessments in the proposed rule are out of date, explain that this causes the costs of more stringent standards to be overstated, briefly summarize new technology developments, and commit to incorporating the latest data and information into future rulemaking. [EPA-HQ-OAR-2021-0208-0522-A1, p. 4]

2 Specific technologies reported in the 2020 EPA Trends Report are port fuel injection, gasoline direct injection, multivalve, variable valve timing, cylinder deactivation, turbocharging, stop/start, hybridization, and electric vehicles

Commenter: Manufacturers of Emission Controls Association (MECA)

The Proposed Standards are Attainable

MECA stresses that technology-neutral, performance-based regulations continue to be a proven strategy for meeting environmental goals through a diversity of competing, cost-effective technology solutions.

MECA agrees with staff’s conclusion that the original LD GHG standards set in 2012, provide a basis for the proposed 2023-2026 standards. MECA concurs with the agency’s conclusion that the broader deployment of commercially available technologies for combustion engines and electrified powertrains, in addition to those recently announced for market introduction can be used by manufacturers to attain compliance with the proposed standards.

Furthermore, MECA agrees with EPA that the costs of the technologies needed to comply with the proposed standards have remained approximately consistent or have declined since EPA first estimated them in 2012. Overall, MECA members have continued to commercialize engine and powertrain technologies to allow vehicle manufacturers to comply with the agencies Preferred Proposal (ca. 38.2 mpg real world average).[EPA-HQ-OAR-2021-0208-0261-A1, p.2]

Commenter: Motor & Equipment Manufacturers Association (MEMA)

MEMA agrees with the EPA that the improvements proposed through MY2026 are feasible and achievable through deployment of currently available technologies. MEMA supports the proposed standards and the program's performance-based approach. The framework for MYs 2023ï€¬2026 encourages a wide range of electrification technologies while also requiring further technology advances and innovation to ICE technologies thereby encouraging a broader spectrum of advanced technologies. These existing technologies, including advances in the ICE and electrification, are solutions that vehicle suppliers started investing in and developing after the 2012 final rule and will continue to develop and improve.

These innovations in the ICE and the advances made in battery electric vehicles (BEVs), plug-in hybrid electric vehicles (PHEVs), and fuel cell electric vehicles (FCEVs) indicates that EPA's proposed standards can be achieved. Moreover, these targets can be achieved at around the same cost as previous EPA estimates.9 This approach, along with the proposed credit programs, will sustain long-term supplier technological investments.

The EPA's rule and analyses account for the availability of innovative, advanced GHG emission reducing technologies for gasoline-fueled vehicles.10 MEMA agrees that vehicle manufacturers are "implementing an increasing array of advanced gasoline vehicle GHG emission-reducing technologies."11 The EPA explains that the feasibility of the proposed standards does not rely on dramatically increased penetration levels of PHEVs and BEVs in the fleet during MYs 2023–2026, rather only about 8 percent by MY2026.12 EPA also suggests that the majority of vehicles produced in MYs 2023–2026 time frame will be gasoline-fueled vehicles (i.e., ICE vehicles).13 MEMA supports continued innovation and increased efficiency of the ICE. [EPA-HQ-OAR-2021-0208-0249-A1, p. 4-5]

Commenter: National Association of Clean Air Agencies (NACAA)

However, EPA does not reflect the impacts of these commitments in the standards it proposes. Instead, the agency acknowledges in the proposal that the technologies needed to meet the proposed standards are already widely available and in use on vehicles, that very little electrification is necessary and that there is no need for development of new technologies for the timeframe of the proposed standards. Further, EPA states that rather than necessitating new technology, compliance with the proposed standards will necessitate greater implementation and pace of technology penetration through MY 2026 using existing GHG reduction technologies. Instead of this approach, which fails to take advantage of the already-planned availability of ZEVs, EPA should increase deployment of ZEVs and more ambitiously build on technology readiness rather than allow it to serve as the ceiling for the proposed standards. [EPA-HQ-OAR-2021-0208-0255-A1, p.4]

Technological Readiness of the Auto Industry in Meeting Revised GHG Standards

NACAA agrees with EPA's assessment, in Section VI(A)(1) of the proposal, of the technological readiness of automakers to meet revised GHG emission standards beginning in MY 2023 and ramping up through 2026: '…the technologies needed to meet the proposed standards are already widely available and in use on vehicles – there is no need for development of new technologies for the time frame of these proposed standards. Instead, compliance with the proposed standards will necessitate greater implementation and pace of technology penetration through MY2026 using existing GHG reduction technologies. In addition, as we discuss further below, our assessment shows that a large portion of the current fleet (MY2021 vehicles), across a wide range of vehicle segments, already meets their proposed MY2023 footprint-based CO2 targets' (see 86 Fed. Reg. 43,781). Given this level of readiness, EPA should enact more ambitious emission standards, as NACAA recommends above. [EPA-HQ-OAR-2021-0208-0255-A1, p.8]

Commenter: National Automobile Dealers Association (NADA)

EPA Has Not Demonstrated That Its Proposed Standards Are Technologically Feasible, Economically Practical, or Cost Beneficial.

NADA has long supported continuous motor vehicle emission improvements, but in the context of the constraints inherent in a "push" approach to achieving such improvements. Even assuming OEMs and their suppliers will be able to conduct the research, development, design, and manufacturing necessary to produce vehicles that meet specific GHG emissions mandates, it is critical that EPA remind itself that OEM regulatory obligations end when compliant vehicles are delivered to the 16,000 independent franchised businesses licensed to sell or lease them to the motoring public. And importantly, real life GHG emission reductions cannot be achieved (and related policy benefits cannot be realized) unless and until prospective purchasers buy (or lease) and use those new vehicles.

NADA does not have access to product plans and other proprietary OEM information available to EPA. Consequently, NADA does not purport to suggest what levels of GHG reduction are technologically feasible and economically practical for MYs 2023-2026. Rather, NADA generally defers to the OEMs on these issues and recognizes that they will endeavor to conduct the vehicle research, design, and manufacturing that can incorporate technologies necessary to meet appropriate MY 2023-26 standards. However, given that many OEMs have been unable to comply with EPA's GHG standards since at least MY 2016 (but for the application of credits),16 NADA believes serious questions exist regarding their ability to meet the proposed mandates in a cost effective, economically practicable manner that will bring vehicles to market which preserve consumer choice and feature preferences. The fact that a select few OEMs have entered into agreements with the State of California regarding GHG emissions moving forward or have announced aspirational targets to become carbon neutral or to aggressively market zero-emission vehicles, does not make EPA's proposed GHG mandates technologically feasible or economically practical.17 [EPA-HQ-OAR-2021-0208-0290-A1, p. 3]

Commenter: National Coalition for Advanced Transportation (NCAT)

Electric Vehicle Model Availability and Range Improvements

The electric vehicle industry is advancing in terms of the number of manufacturers producing electric vehicles and their commitments to an all-electric future, the diversity of models available, and the range now offered for models.

OEM Electric Vehicle Commitments: Automakers with existing electric vehicles offerings are planning to add new models. A few examples of these investments:

• Ford announced plans to invest $29 billion in electric vehicles through 2025.30

• BMW announced $30 billion in investments for "future-oriented technologies."31

• GM announced it would spend $20 billion on its next generation of all-electric and autonomous vehicles through 2025.32 And in 2021, GM increased this commitment to $35 billion.33 GM plans to be carbon neutral in its global products and operations by 2040, with a goal to eliminate tailpipe emissions from new light-duty vehicles by 2035.34

• Volvo has announced plans to be fully electric by 2030.35

• Honda set a goal to be fully electric by 2040.36

Several major automakers have recently announced commitments to releasing their first electric vehicle models. Land Rover plans to launch its first electric vehicle in 2024 and add five more models by 2026.37 Its parent company Jaguar set a 2025 target for going all-electric.38 Mazda's first electric vehicle will be released in California this fall,39 and by 2030, it plans to offer at least hybrid options for all of its models.40 And Subaru announced an electric vehicle to be released in 2022.41

Atlas Public Policy estimates that U.S. automakers and manufacturers have committed approximately $100 billion to electric vehicle programs, much of which supports U.S. factories and jobs.42 Globally, that number is $230 billion.43

Vastly Expanded Model Availability: This boom in the electric vehicle market has led to increases in consumer choice, including in larger model classes. For example, NCAT member Tesla introduced the Model Y compact SUV in 2020. The Model Y has already become one of the top selling vehicles in the U.S. In the first half of 2021, the Model Y was the 2nd best-selling SUV in California. 44 NCAT member Rivian recently produced the first electric pickup truck, the R1T, for customer delivery.45 Rivian also expects to begin deliveries of a full-size SUV, the R1S, and delivery vans by the end of 2021. Ford has received over 100,000 pre-orders for its electric F-150 pickup model.46 Other companies have also planned to release light-duty electric trucks: Tesla's Cybertruck, GMC's Hummer, and Chevrolet's Silverado.47

Significant Range Increases: Across manufacturers, battery technologies and vehicle design have improved the range of electric vehicles. Consumer Reports called range increases "[o]ne of the most significant changes" in the electric vehicle market.48 A 2018 Center for American Progress report noted that of the 14 MY 2018 battery electric vehicle models, just four listed a range of more than 200 miles.49 The contrast between 2018 and 2021 is stark: of the 41 MY 2021 battery electric vehicle models, 33 list a range of more than 200 miles, and 10 list a range of more than 300 miles.50 Vehicles currently on the road have batteries with "high levels of sustained health"—although all batteries deteriorate, "the loss is arguably minor" year-over-year. 51 This trend will only improve. As range increases, the relative amount of charging that can be done at home increases. For battery electric vehicles with 300 mile range, the Argonne National Laboratory estimates that 94% of charging can be done at home.52 [EPA-HQ-OAR-2021-0208-0239-A1, p. 7-10]

Commenter: New York State Department of Environmental Conservation

In California's Advanced Clean Cars Midterm Review, GARB noted that various truck, SUV, and passenger car configurations available in 2016 were able to meet 2020 or later greenhouse gas standards with a conventional gasoline powertrain. Based on the multi-year design and engineering process for automotive vehicles, manufacturers have already designed their vehicles to meet the greenhouse gas standards established in 2012 and should not have any issues meeting the proposed revised standards, which are generally less stringent than the 2012 standards until model year 2026. In August 2020, five auto manufacturers, collectively representing one-third of the U.S. light duty vehicle market, voluntarily signed on to the California Framework Agreement. Under the agreement, the five auto manufacturers committed to supporting annual reductions of vehicle greenhouse gas emissions through the 2026 model year at rates similar to those previously established in 2012, indicating that at minimum the standards set by the California Framework Agreement, slightly less stringent than the proposed, are feasible. New York agrees that the proposed standards are feasible. Further, many manufacturers have made recent announcements of their intentions to produce ZEVs exclusively, or at least most of their product offerings, by 2035. [EPA-HQ-OAR-2021-0208-0238-A1, p.2]

The proposed revised standards are not only technologically feasible but would achieve greater emissions reductions, public health benefits, and fuel savings to consumers over the life of the vehicles than would be achieved under the standards promulgated in the misguided SAFE rule in 2020. [EPA-HQ-OAR-2021-0208-0238-A1, pp.3-4]

Commenter: Northeast States for Coordinated Air Use Management (NESCAUM)

NESCAUM's agrees with EPA's finding that the proposed GHG standards are readily achievable with technologies that are currently in use. [EPA-HQ-OAR-2021-0208-0259-A1, p. 3]

The 2019 Framework Agreements offer additional support that the technologies needed to meet the proposed GHG standards are readily available. Under those agreements, several manufacturers voluntarily agreed to comply with California's GHG emission reduction targets through model year 2026 across their national vehicle fleets, notwithstanding the unjustified weakening of federal standards in the SAFE Vehicles Rule. [EPA-HQ-OAR-2021-0208-0259-A1, p. 3]

EPA's proposal highlights recent commitments by many automakers to aggressively pursue zero-emission technologies. However, the impact of these commitments is not apparent in the proposed standards. Instead, EPA's proposed standards can be met with very little electrification. EPA's proposed rule also acknowledges that the technologies needed to meet the proposed standards are already widely available and currently in use and that there is no need to develop new technologies to meet the proposed standards. Rather than forcing new technologies, EPA acknowledges that compliance with the proposed standards will only require greater implementation and pace of technology penetration through MY 2026 using existing GHG reduction technologies. In NESCAUM's opinion, industry's technological readiness should serve as the floor, and not the ceiling, for the proposed standards. [EPA-HQ-OAR-2021-0208-0259-A1, p. 3]

Commenter: Piper, Edward

I recommend not adopting this proposal.

Besides performance, fuel economy, and pollution control; other desirable vehicle characteristics are durability, serviceabilty, and repairability. High fuel economy standards and pollution controls lead to more complex or specialized propulsion systems. How long with these systems go between repairs? What will the replacement parts cost? How easy will it be to make repairs? What specialized equipment and training will be necessary to make these repairs? Can repairs be made by third party repair shops or by customers, or only by dealers? If repairs are available outside of dealers, will those making these repairs have to sign intellectual property agreements to get the information necessary to make these repairs (undesirable)? Will third party suppliers be allowed to manufacture replacement parts? The repair and replacement costs (frequency of repair, repair time, parts costs, labor costs, vehicle life, and replacement costs) need to be included in the cost of the proposed change. [EPA-HQ-OAR-2021-0208-0520, p. 1]

I recommend weaking CAFE and pollution requirements (although not prohibiting better fuel economy and pollution control) and accepting the climate consequences of the use of hydrocarbon fuels in vehicles and adapt to these consequences. I also recommend we maintain our existing hydroelectric energy sources (essentially solar energy with the battery built in) and research the production of hydrocarbon fuels through carbon capture. [EPA-HQ-OAR-2021-0208-0520, p. 1]

Commenter: Representative Padma Kuppa

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 145.]

Here in Michigan, we've invested in innovation throughout the automotive industry and work hard to ensure that the U.S. remains an auto industry leader. These standards have already gone through a rigorous technical review process which found that auto manufacturers have the technology to meet the standards.

Commenter: South Coast Air Quality Management District

EPA can readily find that the technological capabilities for meeting these standards, including by use of zero emissions technologies, far exceed what EPA anticipated in 2012 (or even what EPA ignored in 2017 as it began its illegal rollback); thus, the technological feasibility of the proposal is emphatically clear, and the proposed stringency is fully supportable. [EPA-HQ-OAR-2021-0208-0215-A1, pp.2-3]

Commenter: Southern Environmental Law Center (SELC)

While the proposed rule mentions that 'EPA is afforded considerable discretion under section 202(a) [of the Clean Air Act] when assessing issues of technical feasibility and availability of lead time to implement new technology,' [24] EPA further notes that no new technology is needed in this case; existing technology utilized in today’s fleet could be used to meet the proposed standards.[25] Moreover, EPA states that Alternative 2 may be feasible '[c]onsistent with . . . discussions regarding feasibility, compliance costs, and lead time' for the proposed standards.[26] These factors provide support for the adoption of Alternative 2, which utilizes the 2012 Rule stringency levels starting in model year 2023, as well as the adoption of the stronger standards proposed for model year 2026. [EPA-HQ-OAR-2021-0208-0244-A1, p. 4]

[24] Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards, 86 Fed. Reg. at 43752. Under section 202(a) of the federal Clean Air Act, the standards 'shall be applicable to such vehicles . . .for their useful life' and take effect 'after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period.' 42 U.S.C. § 7521(a). These determinations “are subject to the restraints of reasonableness.” NRDC v. EPA, 655 F.2d 218, 322 (D.C. Cir. 1981).

Commenter: Tesla

Electric Vehicle Technology Is Efficient, Reduces Oil Dependence, Saves Consumers Money, and Facilitates the Safest Vehicles on the Road.

In its proposal, EPA also indicates several additional elements the agency looks at when assessing the technical feasibility of the proposed standards, including the impacts on emissions reductions (GHG and non-GHG), oil conservation and energy security, consumer fuel savings, broader auto industry impacts, other energy impacts, and safety. In all these categories EVs reign as the superior technology.

First, as described above, EVs are recognized as the best tailpipe emissions reduction technology not only for mitigating GHGs, but also for reducing the criteria air pollutants that cause over ten million excess deaths annually.156 Numerous studies continue to show EVs can play a leading role in reducing U.S. air pollution, represent an opportunity to achieve large public health benefits in the U.S. in the short term, and have been estimated as providing public health-related benefits on average of over $10,000 per 150,000 miles driven.157 Replacing just 25% of the ICE vehicles on the road with EVs would save approximately $17 billion annually by avoiding damages from climate change and air pollution.158

Second, EV technology can support setting standards that result in positive impacts on U.S. oil conservation and energy security. Numerous assessments conclude that increasing deployment of EVs will hasten the onset of peak fossil fuel demand and lead to falling oil demand.159 Recently, the DOE has found that EVs displaced 500M gallons of gasoline in 2020, and over 1.9B gallons cumulatively since 2011.160 This displacement will only continue to grow. As the International Energy Agency recently noted, 'In addition to being two- to four-times more efficient than conventional internal combustion engine models, EVs can reduce reliance on oil-based fuels and, if running on low-carbon power, can deliver significant reductions in greenhouse gas emissions. Plus, with zero tailpipe emissions, EVs are well suited to help solve air pollution issues.'161

Third, stringent standards that result in accelerated deployment of EVs will save consumers substantial money from fuel savings.162 Indeed, DOE has found that EVs have the lowest annual fuel costs for MY 2021 of all available vehicles technologies.163

Fourth, the basic characteristics of EV design, including small or no motors in front, large crush space for energy absorption, lack of combustible fuel, and low centered batteries that result in extremely low center of gravity and nearly perfect weight distribution, mean EVs are the safest vehicles in the world. Tesla produces the safest vehicles on the road and has proven that manufacturing highly efficient, fully electric vehicles enhances, rather than sacrifices, safety. Recently, Tesla Model X, 3 and Y have all received five-star ratings in all categories as rated by NHTSA's New Car Assessment Program (NCAP).164 Moreover, via numerous Over the Air (OTA) software updates Tesla has and will continue to improve the safety of Tesla vehicles already on the road.

In short, EV technology meets and exceeds any and all criteria by which EPA should analyze vehicle technology and set standards stringency. EVs improve emissions reductions, are readily available, save consumers money over the lifetime of vehicle operations, provide superior vehicle safety, and manufacturers have been on notice on the need to deliver the technology for well over a decade. EPA must factor EVs into its standards in its final rule, and there should be no impediments to it doing so. [EPA-HQ-OAR-2021-0208-0278-A1][pp.18-19]

Commenter: Trevino, Erandi

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 194.]

The other thing that I wanted to say is that one of the reasons why this is so important is because again it's one easy solution that we have the technology for. It's already out there. It's something. It's sort of just low-hanging fruit at this point because carbon emissions from vehicles, we accept such a large portion of our air pollution, it's one of the most important things that we can tackle at the present moment.

Commenter: U.S. Chamber of Commerce ('the Chamber')

The President's Executive Order, 'Strengthening American Leadership in Clean Cars and Trucks,'1 not only set an ambitious goal that 50 percent of light duty sales be zero-emissions vehicles, but it also recognized the need to resolve other important variables needed to achieve this goal. The Executive Order references the need for expanding key charging infrastructure and spurring innovation. These efforts are all needed and more.

In the Chamber's view, effective development and implementation of light-duty vehicle standards requires a comprehensive approach that considers factors well beyond the standards themselves. Facilitating programs and policies are necessary in order to advance a cleaner, stronger transportation system—not just the roads and bridges that are the foundation of America's infrastructure, but the vehicles and enabling systems that are necessary to modernize transportation in America.

With respect to greenhouse gas emissions, the transportation sector is of growing interest and importance. While immense technological progress has been made—passenger vehicle fuel economy has improved almost every year since 2005—challenges remain, as the transportation sector now represents the largest source of greenhouse gas emissions since surpassing the power sector in 2016, according to the Energy Information Administration.

Tackling this challenge will not be easy. The tremendous success that the industry has had incorporating catalytic and other post-combustion emissions treatment technologies onto the existing internal combustion engine platform led to 98-99% reductions in tailpipe emissions compared to the 1960s. However, doing the same for greenhouse gas emissions from light-duty vehicles is complex due to the platform changes, but also the ancillary infrastructure, supply chains, and consumer preferences that must be navigated. In addition, fleet turnover is generally slow, and balancing unpredictable technological and market factors is difficult. Because of this, regulatory certainty is paramount, particularly in the light-duty passenger vehicle sector.

The Chamber's Global Energy Institute examined these challenges facing the light-duty passenger vehicle sector in a 2019 report, Divided Highway, the findings of which remain just as relevant today.2 The report highlights the importance of a workable path forward on vehicle fuel economy and greenhouse gas standards that provide regulatory certainty, continued progress on mileage and emissions reductions, and preserving the unified national program for vehicle sales.

At the time of this comment filing, Congress is considering bipartisan infrastructure legislation that would provide an important foundation for enabling achievement of these goals. Passage of the bill is important to overcoming challenges associated with adoption of higher efficiency vehicles. For example, while more than 40 models of zero emissions vehicles (ZEVs) are currently available in the U.S., sales represent less than two percent of the light-duty market, illustrating the necessity in understanding technological, market, and policy factors that could improve adoption.

The Chamber believes that our clean energy future is dependent on a vibrant, healthy auto sector that can plan for and invest in the technologies necessary to accelerate progress on emissions reductions and continue building safe and affordable vehicles for American consumers.

As manufacturers continue to address ongoing challenges related to supply chain disruptions and pandemic-driven market uncertainties, the need to advance a harmonized, flexible, and achievable rulemaking that preserves a unified national auto market is more important than ever. As the EPA considers finalization of this proposal and development of associated follow-on rulemakings, the Chamber urges careful consideration of the broad spectrum of factors likely to influence progress toward the aforementioned goals. Ultimately, this broader perspective is critical to settling on a balanced approach that considers market and technological realities, provides regulatory certainty for auto manufacturers and the supply chain, and accelerates both emissions reductions and vehicle electrification. [EPA-HQ-OAR-2021-0208-0524-A1, pp. 1-3]

Advance government research and development to support and accelerate vehicle technology innovation

Finally, over the longer term it is imperative that the federal government fully fund the Energy Act of 2020 and conduct the research and development needed to drive innovation in battery and vehicle technology. The development of processes that would reduce demand for strategic materials through efficiency improvements, recycling, or identification of substitutes holds great promise to contribute to supply chain security. Moreover, the development of new and improved vehicle technologies -- such as increased efficiency, improved component materials, and electric vehicle or hydrogen fuel cell powered drive trains -- is essential to long-term emissions reduction from light duty vehicles.

EPA should work closely with the Department of Energy in these research and development efforts. Specifically, section 7001 of the FY2021 Omnibus Appropriations Act (which included the Energy Act) authorizes $23 million for DOE research on recovery of rare earth elements and critical materials from coal and coal byproducts, while section 7002 calls for $125 million for research on critical materials recycling, innovation, efficiency, and alternatives, including establishment of an innovation hub to coordinate and integrate crosscutting activities. Additionally, the Better Energy Storage Technology (BEST) Act—included in the same legislation— authorizes $50 million for the Department's Advanced Manufacturing Office and Vehicle Technologies Office to address critical supply chain matters, including enhancement of recycling and reuse capabilities.

In addition, the bipartisan Infrastructure Investment and Jobs Act (IIJA) currently under consideration would provide more than $7 billion to address vehicle- and battery-related supply chain vulnerabilities. This includes $3 billion for battery manufacturing and recycling grants, $3 billion for battery material processing grants, $125 million for battery recycling R&D, and $10 million for the lithium-ion battery recycling prize. Passage of this bipartisan legislation is a top priority for the Chamber, and would provide a foundation upon which to ease supply chain security vulnerabilities that threaten implementation of ambitious vehicle electrification goals. [EPA-HQ-OAR-2021-0208-0524-A1, pp. 6-7]

It is clear that there are many challenges to developing and implementing ambitious climate policy, such as the EPA GHG and NHTSA CAFE standards, that extend beyond the automotive sector's simply designing more efficient light duty cars and trucks. Across the government, coordination is needed in many areas, such as securing the supply chains for strategic minerals and streamlining permitting processes for needed infrastructure and mining to support any ambitious standards.

Not only is coordination needed in areas such as federal permitting and supply chain security, but coordination between government agencies and states is essential to help support the planning and long-term investment needed to implement sound regulatory policy. Without sufficient collaboration among relevant federal agencies and stakeholders, discordant regulatory action will inject more uncertainty into markets and disrupt efforts to plan, invest, and deliver continued fuel economy and emissions gains. [EPA-HQ-OAR-2021-0208-0524-A1, pp. 7-8]

Commenter: Volkswagen Group of America, Inc. (Volkswagen)

Volkswagen projects that with the increased consumer adoption of EVs and with the successful execution of our US electrification strategy, the standards proposed by EPA through 2026 will be achievable. The enhanced flexibilities proposed by EPA to incentivize and support electrification will be critical to the success of this regulation and to the overall market transition to electrification in the United States. We appreciate that the proposal reflects many of the same elements incorporated within the Settlement Agreement between California Air Resources Board and Volkswagen Group of America, Inc.1 ('Framework Agreement'). We feel that this proposal, similar to the agreement with California, strikes a balance between meaningful CO2 reductions and pragmatic incentives that will help support our shared long-term vision for vehicle electrification [EPA-HQ-OAR-2021-0208-0237-A1,pp.1-2]

EPA Response

We received many supportive comments that the proposed standards are technically feasible (AESI, ACEEE, Bay Area Air Quality Management District, Begley, Amanda, California Attorney General Office, et al, Chicago Metropolitan Agency for Planning, MECA, MEMA, NCAT, New York State Department of Environmental Conservation, Representative Padma Kuppa, South Coast Air Quality Management District, Tesla, Erandi Trevino, Volkswagen).

We received one comment regarding vehicle types and uncertainty within the policy landscape (Climate Group EV100). We anticipate that the final standards will provide such regulatory certainty.

In response to the comments regarding aerodynamic improvements (Alliance), EPA continues to believe that manufacturers have a wide variety of technologies that are available and that have been increasingly added to additional vehicle models to reduce drag losses, as appropriate to the functional characteristics of the vehicle. We do not expect that cargo vans, large SUVs or light-duty pickup trucks will necessarily achieve the same aerodynamic performance as passenger cars, but within a given segment, there remain opportunities to achieve reductions in aerodynamic drag compared to less aerodynamically-optimized model generations that exist within the same segment. EPA did not include aerodynamic improvements beyond AERO20within the analyses for the proposed rule or this final rule , which is consistent with the

Agency's approach in previous analyses and the recommendations from 2015 and 2021 NAS reports.[10,11,12,13,14]

In response to the Alliance's comments on tire rolling resistance improvements, EPA did not include tire rolling resistance improvements beyond ROLL20 within the analysis for the proposed rule or this final rule, which is consistent with previous EPA analyses and 2015 NAS 2015 recommendations.[11,12,13] The 2021 NAS report describes the potential for introduction of ROLL30 technologies after 2025, and EPA will continue to monitor the development of tire technologies and update its analyses of tire rolling resistance in future rulemakings as new technologies become available.[14] Table 3-1 provides a summary of the technology penetrations of specific levels of aerodynamic improvements and tire rolling resistance improvements for MY2026 that are outputs of compliance modeling with CCEMS for the final rule. For more information regarding CCEMS, see Chapter 4 of the RIA.

Table 3-1: Model Year 2026 Aerodynamic (AERO) and tire rolling resistance (ROLL) technology penetration combined-fleet percentage results from the CCEMS analysis for this final rule.

Technology in CCEMS Analysis	MY2026 No-action Case	MY2026 Action Case (Final Standards)
AERO0	13%	5%
AERO5	16%	2%
AERO10	15%	6%
AERO15	42%	53%
AERO20	14%	34%
ROLL0	0%	0%
ROLL10	3%	3%
ROLL20	97%	97%
Notes: AERO*x* refers to to a percentage reduction in the coefficient of drag (C_d) relative to a baseline C_d by vehicle class for MY2015 (e.g., AERO20 represents a 20% reduction in C_d by specific vehicle class).[15,16] ROLL*x* refers to a percentage reduction in the coefficient of rolling resistance (C_{rr}) relative to a baseline C_{rr} of 0.009 (e.g.,ROLL20 represents a 20% reduction or a C_{rr} of approximately 0.0072).		

[10] AERO20 represents a 20% reduction in drag coefficient below the model year 2015 average drag coefficient for each vehicle class within CCEMS.

[14] National Academies of Sciences, Engineering, and Medicine 2021. "Assessment of Technologies for Improving Light-Duty Vehicle Fuel Economy 2025-2035". Washington, DC: The National Academies Press. https://doi.org/10.17226/26092
[15] For average MY2015 baseline C_d by vehicle class, see Table 7.1 in National Academies of Sciences, Engineering, and Medicine 2021. Assessment of Technologies for Improving Light-Duty Vehicle Fuel Economy 2025-2035. Washington, DC: The National Academies Press. https://doi.org/10.17226/26092.
[16] For examples of specific technologies corresponding to specific percentage aerodynamic improvements, see 85 FR 24552, Table VI-132.

In response to BorgWarner's comment supporting a future review of the standards and an increase in the stringency of the standards if a future analysis of technology pathways demonstrates earlier readiness, EPA is planning to initiate another rulemaking to establish multi-pollutant emission standards over the longer term, for MY 2027 and later (see the Preamble to this rule at section I.A.3), consistent with the direction of Executive Order 14037, "Strengthening American Leadership in Clean Cars and Trucks." EPA will again review GHG emission-reducing technologies as part of the regulatory impact analysis for the MY2027 and later light-duty GHG standards rulemaking. With respect to the near term, the Agency has confidence in our technical analysis of the final standards, including our estimates of potential technology pathways through the relatively near-term time frame of the MY2026 standards and does not believe further technical review of the MY2023-2026 standards is necessary. It is also important to maintain regulatory certainty for manufacturers during the relatively short time period covered by this rule.

In response to comments from several commenters regarding the feasibility of setting lower standards than the proposed standards, in particular "Alternative 2" standards or standards more stringent than "Alternative 2" (e.g., comments from CARB, ELPC, NACAA, NESCAUM and SELC), EPA's final standards are the proposed standards for MYs 2023 and 2024, Alternative 2 standards for MY 2025, and Alternative 2 minus 10 g/mi standards for MY 2026 and later (see the Preamble to this final rule, sections II.A, II.B, and VI.). In response to comments that the analysis in the NPRM showed levels of EV penetration that were generally too low (NESCAUM, NACAA, ELPC) or costs that were overstated (ICCT), EPA has reviewed the battery costs used within the proposal and revised the battery costs for this final rule to better reflect:

- Current and anticipated automotive Li-ion battery chemistries
- Modern battery pack, module, and cell topologies
- Economies of scale from higher production volumes that better reflect current and anticipated EV sales volumes.

When taken together, the changes in the analysis for the final rule result in battery cost reductions of approximately 25% relative to the battery costs used within the analysis for the proposed rule. For more information on EPA's updated automotive lithium-ion battery costs, please refer to RIA Chapter 2.3.4 and Chapter 4.1.1.2. The per-vehicle reduction in costs for BEVs within the analysis for the final rule resulted in increased combined PHEV and BEV technology penetration, approximately 14% in 2025 and 17% in 2026, which are consistent with publicly available EV market forecasts of 12%-20% in 2025 and 16-24% in 2026.[17,18] Other, non-battery costs are consistent with previous EPA analyses, as are per-vehicle technology costs

---

[17] IHS Markit Automotive Research and Analysis. US EPA Proposed Greenhouse Gas Emissions Standards for Model Years 2023-2026; What to Expect. August 9, 2021. Accessed on the Internet on 10/29/2021 at https://ihsmarkit.com/research-analysis/us-epa-proposed-greenhouse-gas-emissions-standards-MY2023-26.html
[18] Loren McDonald, EVAdoption, LLC. EV Sales Forecasts - US EVs (BEV & PHEV) Sales and Sales Share Forecast: 2021-2030. Accessed on the Internet on 10/29/2021 at https://evadoption.com/ev-sales/ev-sales-forecasts/

(see RIA Chapters 1.2.2 and 4.1.3). We disagree that the specific vehicle technologies analyzed are outdated (ICCT).

NADA commented that while it does not have access to vehicle manufacturer product plans and other proprietary OEM information available to EPA, does not purport to suggest what levels of GHG reduction are technologically feasible and economically practical for MYs 2023-2026, and generally defers to the OEMs on these issues, NADA nonetheless believes serious questions exist regarding OEMs' ability to meet the proposed mandates in a cost effective, economically practicable manner that will preserve consumer choice. In response to these NADA comments, we disagree and note that several OEMs and the Alliance submitted comments supporting the proposed standards. In addition, EPA has demonstrated that the proposed and, more importantly, final standards are technologically feasible at reasonable cost and preserve consumer choice (see sections VI.A., VI.B., and VI.C. of the Preamble to this final rule). We also note the NADA comments did not provide details or data supporting their claims, so no further response is necessary.

In response to comments on the repair and replacement costs of vehicle powertrain technologies that reduce GHG emissions (Edward Piper), we disagree that powertrains that reduce GHG emissions necessarily increase the costs of maintenance relative to a no action case. The commenter did not provide any data to support the supposition that GHG-reducing technologies necessarily increase maintenance costs or that any reduction in costs could potentially exceed the benefits of reducing GHG emissions. Reduced brake wear from regenerative braking in BEVs, PHEVs, and HEVs, reductions in scheduled lubricant and cooling system maintenance for BEVs, and the elimination of belt accessory drives in BEVs would suggest reduced maintenance costs for many GHG reducing technologies. This appears to be confirmed by a recent study from Argonne National Laboratories (ANL).[19] We will continue to study maintenance costs for vehicle electrification and other GHG-reducing technologies as additional vehicles with these technologies enter the fleet and we will consider updating future cost analyses using data on cost of ownership from ANL and other relevant sources.

Regarding comments that implementation of the light-duty vehicle GHG standards require an approach that goes beyond the standards themselves (the Chamber), the comments primarily address incentives and programs that are outside EPA's authority or the scope of this rulemaking, though EPA agrees that such programs may facilitate adoption of EVs. For a full response to comments regarding such complementary policies comments, please reference section 12.1 of this response to comments document. As discussed in Preamble Section I.A.2, EPA is planning to initiate a rulemaking to establish light-duty multi-pollutant emission standards for MY 2027 and later.

Commenter: Allergy & Asthma Network, et al.

US EPA must ensure real-world emissions benefits. We call on US EPA to avoid excess credit schemes and loopholes that impact the total tons of benefits achieved by the rule. While Alternative 2 represents a more stringent standard, it includes various crediting provisions that would ultimately diminish the real-world GHG benefits and associated health and societal benefits. Alternative 2 includes fewer credits than the central proposal, but it would still offer a range of loopholes and credits that diminish the stringency of the rule. We urge US EPA to reduce credit options in the final rule to ensure real-world benefits and emission reductions occur as projected. [EPA-HQ-OAR-2021-0208-0296-A1, p. 2]

Commenter: Alliance For Automotive Innovation

Comments on Technology Incentives, Credits, and Regulatory Flexibilities. Auto Innovators appreciates and supports the inclusion of technology incentives that encourage the production and adoption of certain higher cost / market-challenged GHG-reducing technologies, credits for technologies such as off-cycle and air conditioning system improvements which provide onroad benefits, and regulatory flexibilities such as the fleet averaging and credit banking and trading program that allow better alignment of product plans to compliance requirements. These collective flexibilities have reduced compliance costs while enabling greater environmental benefits and/or encouraging the development and marketing of technologies expected to play a much greater role in GHG reductions in the future.

Such flexibilities do not “squander” emissions benefits as some stakeholders assert. Rather, they help to ensure a well-balanced program that achieves its near-term goals and enables greater future emissions reductions. EPA has taken care in past rulemakings and in this proposal to evaluate the costs, benefits, and emissions impacts of various flexibilities to ensure policy decisions are well-informed. In such evaluations, it is important for EPA and other stakeholders to understand that it is unlikely that any given manufacturer will fully utilize all potential flexibilities. Each manufacturer creates its own product plan and compliance strategies, utilizing flexibilities as each sees fit. [EPA-HQ-OAR-2021-0208-0571-A1, p. 16]

Commenter: Alliance of Nurses for Health Environments

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 23.]

And lastly, while the top line numbers of the proposal look like they will lead to meaningful emissions reductions, the standards are undermined by unnecessary give-aways to automakers that reduce their benefits and delay progress towards cleaner technology.

Commenter: American Council for an Energy-Efficient Economy (ACEEE)

Incentives counterproductive to the primary goal of reducing emissions should not be included in EPA rule

EPA has included many provisions that would change the effective stringency of the proposed rule. While some of these changes are improvements over the SAFE rule, many of the proposed credit provisions would have the effect of weakening the standards for model years 2023-2026. [EPA-HQ-OAR-2021-0208-0251-A1, p.2]

Tables 2 and 3 highlight the estimated impacts of the above incentive proposals on the effective stringency of the rule. Year-by year-changes are presented in table 2. The individual impacts of the incentives and the change in the level of emissions savings compared to the proposed rule are presented in table 3. [EPA-HQ-OAR-2021-0208-0251-A1, p.9] [Tables 2 and 3 can be found at docket number EPA-HQ-OAR-2021-0208-0251, pp. 9-10]

Commenter: American Lung Association

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p.19]

Secondly, we must maximize the real-world emission reductions from this program. We are concerned about loopholes and credits that reduce the actual emission reductions from the vehicles on the road. EPA must not allow these credits to undermine the emission reductions.

Commenter: American Lung Association (Sacramento, CA)

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 254.]

We call on U.S. EPA to ensure that crediting and other loopholes are not allowed to reduce the emission reductions or real-world benefits of the final rules.

Commenter: BorgWarner Inc.

Industry needs flexibilities such as multipliers and off-cycle credits in order to achieve compliance, as well as the ability to leverage all available technologies to ensure a successful shift to electrification. This pace of annual improvement requires flexibilities to be included that both benefit the environment and the economy. It enables industry to respond with a variety of cost-effective solutions that could be rapidly adopted in high volumes, invest in R&D and workforce training, and avoid stranded capital. [EPA-HQ-OAR-2021-0208-0260-A1, p. 1-2]

Commenter: Cantley, Jennifer

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 274.]

When I say avoiding loopholes, this is another important issue for Nevadans as we hold 25 percent of the world's lithium for the EV vehicles that will be producing the batteries for these EV cars.

Commenter: Center for Biological Diversity, Earthjustice, and Sierra Club

EPA's Proposed Credit Flexibilities Undercut Real-World Compliance and Should be Limited or Ended. EPA should not create or extend regulatory loopholes that allow automakers to continue producing high emission fleets that avoid or delay significant emissions reductions. While the credit system is intended as a tool to help manufacturers smooth annual compliance levels in light of their multi-year production plans, manufacturers have routinely used them to delay technological improvements. Emissions reductions will continue to be eroded if EPA re-adopts or increases the credit programs described below. At a minimum, should EPA finalize any of them, it should make abundantly clear that they will apply only in this unusual circumstance where lead time is shorter and the MY 2023 nominal stringency appears steeper than usual; do not set any precedent for later rulemakings; and will not be adopted in its forthcoming rule for MY 2027 and beyond.

In recent years, the emissions reductions that generated the credits were achieved through the adoption of existing and economically feasible technologies. Instead of fostering the development of ever cleaner emissions technologies, the glut of credits that still exists today delays making these advances. For example, between 2012 and 2018, the industry generated 96 Teragrams worth of credits, and by 2016 the industry average tailpipe emissions exceeded federal standards by 8 g/mi due to the use of previously earned credits.30 Since 2016, the industry average emissions as measured from the tailpipe remained above federal standards as manufacturers continue to utilize the early year credits.31 As of MY 2019, the tailpipe emissions of 15 of the 20 largest manufacturers, including Ford, GM, and Fiat-Chrysler, exceeded the federal standards.32 [EPA-HQ-OAR-2021-0208-0270-A1, pp.5-6]

Commenter: Center for Biological Diversity, et al.

EPA Should Eliminate or Reduce the Proposed Additional Credits. Beginning with the 2010 Final Rule, EPA adopted several types of credits manufacturers may use to meet the light duty vehicle fleet greenhouse gas standards. Proposal, 86 Fed. Reg. at 43,753. Some credits (the "averaging, banking and trading" credits) are designed to assist automakers in adjusting their multi-year product development cycles to meet stringency increases that occur every year. For instance, during years when automakers first introduce new, less polluting vehicles, their average fleets exceed the standard, and credits awarded for that over-performance can be used to smooth compliance shortfalls for up to five future years, during some of which automakers may not be selling new vehicles meeting increased stringencies. See id. Automakers may also apply these over-performance credits to remedy up to three years of planned or unanticipated past underperformance. EPA does not propose to change the averaging, banking and trading credits, and Commenters support that decision in connection with this Proposal. Other types of credits, however, have proliferated over the years even though they dilute or erode the standards' real-world results, and would do so again if readopted or increased, as EPA proposes here.

Commenters believe that the proposed credits discussed below are not required to ease any lead time concerns. As discussed in Section 5 above, Dr. Cooke's modeling shows that automakers can comply with the most stringent proposal, Alternative 2, through 2024 by complying with the standards that already govern them now – either the 2020 Final Rule or the California Framework agreement – and by some increases in their performance in MY2024, primarily through increases in EV penetration at rates consistent with automakers' announcements. 138 This is so even when the model also excludes the proposed credit life extensions, and even though Alternative 2 itself excludes all EV multipliers. Dr. Cooke's model does include the proposed off-cycle credit extension and the extension of treating EV emissions as zero to reach these conclusions. The model, however, is constricted by features of the Volpe model that do not take account of or disallow modeling other compliance scenarios requiring no or little additional lead time.

For example, as discussed above, the model does not reflect an accelerating trend in the automotive industry: automakers are currently preparing to launch new vehicles in the MYs 2022-2025 time frame at rates 50 percent higher than their historical averages, replacing some 80 percent of the fleet.139 Sixty percent of the new vehicles feature a hybrid-electric or electric powertrain option, including more than 90 standalone electric models. Id. These launch plans are entirely in line with automakers' own assertion that they did not alter their 2012 production and compliance plans in response to the 2020 Final Rule because of continuing regulatory uncertainty.140 Dr. Cooke's model also excludes the effects of a combination of existing compliance strategies that are available for automakers to take through MY 2024 to improve their performance with little or no lead time. These include increasing the sales incentives for and marketing of existing vehicles that already significantly exceed the standards, and the shifting of currently in-use trims and packages for many models, which can result in greenhouse gas emissions reductions of up 25%-30% per vehicle.141

The Volpe model—and thus Dr. Cooke's work—also excludes automakers' ability to remedy any remaining deficits from MYs 2023 or 2024 by exceeding the standards in later years and utilizing the three-year credit carry-back feature. Yet, as discussed above, this is a well understood compliance strategy.

For these reasons, we believe automakers may be well-positioned to comply with Alternative II even without any of the additional credits EPA has proposed. We strongly urge EPA to evaluate whether any of the additional credits discussed below are necessary to address any lead time concerns; if not, EPA should not finalize any of them, as they would increase emissions and exacerbate the climate crisis. We note that historically, previous credit extensions have enabled automakers to delay compliance significantly. At a minimum, EPA should make clear that whatever additional credits it finalizes are solely intended to accommodate these specific, unusual circumstances, where lead time is more limited and the MY 2023 nominal stringency appears steeper than usual, and will not be adopted in its forthcoming rule for MY 2027 and beyond. [EPA-HQ-OAR-2021-0208-0651-A1, p. 59-60]

Commenter: Consumer Reports (CR)

In order to achieve these goals CR provides the following recommendations for strengthening the standard:

Reign in credits and loopholes that undermine the real-world benefits of the rule [EPA-HQ-OAR-2021-0208-0602-A1, p.5]

CR also recommends that EPA further limit credits and multipliers that reduce the effectiveness of the rule. [EPA-HQ-OAR-2021-0208-0602-A1,p.5]

Top line stringency levels are important, but equally important is ensuring that automakers actually deliver real world performance that comes close to matching those stringency levels. Various credits and multipliers can reduce the real world benefits delivered by the standards. [EPA-HQ-OAR-2021-0208-0602-A1, p.11]

Commenter: Cooper, Almeta

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 77.]

Please reject any alternative that contains big loopholes for automakers and that may undermine otherwise strong pollution reduction targets by 2026.

Commenter: DENSO International America, Inc. (DENSO)

Support for Credits, Incentives, and Flexibilities. DENSO is committed to supporting our customers in their application of technology to improve the fuel economy performance and reduce the greenhouse gas emissions of their products to match consumer preferences, while meeting regulatory requirements. While there are challenges and sometimes tradeoffs to allowing multiple pathways to compliance, we believe a balance can be found to achieve successful regulatory programs that include credits, incentives, and other flexibilities. Around the world, successful fuel economy and emissions programs offer credit and incentive programs to support the deployment of technologies, which would otherwise take multiple years to penetrate the market. DENSO encourages the agencies to continue to offer flexible options supporting emerging technologies. [EPA-HQ-OAR-2021-0208-0282-A1, p. 3]

Commenter: Dream Corp Green for All

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 308.]

There are too many loopholes and bonus credits even in the existing program and stricter standards and less potential for gaining the system will be needed to reach a 60 percent reduction in emissions by 2030.

Commenter: Dugan, Maureen

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 300.]

Close the loopholes and don't give credence to the industry's specious claims that this cannot be done.

Commenter: Edison Electric Institute (EEI)

Regulatory Flexibilities Are Impactful and Necessary. Regulatory flexibilities are a practical and longstanding method of helping affected sources, both mobile and stationary, comply with environmental regulations in efficient, cost-effective, and commonsense ways. The broad and continued success of the CAA and the other environmental statutes is largely due to these flexibilities: namely, EPA has set standards and then provided compliance pathways that enhanced options available to industry instead of limiting the methods and manners that sources have used to meet those standards. EPA's own most recent report acknowledges this reality: since the 1990 amendments, the many flexible compliance regimes promulgated by the Agency have resulted in significant emissions reductions and a marked reduction in unhealthy air quality days, all at lower than predicted costs to industry.13 Many of the regulatory programs enacted by EPA to attain and maintain the NAAQS in the past three decades have contained significant regulatory flexibilities—from market-based trading,14 to wide ranging averaging provisions,15 to creative permit terms,16 to innovative methods of estimating reductions from new industry activities.17 In sum, EPA sets targets, and American industry engineers the least cost and most effective way to get there.

The SAFE Vehicle Rule reversed this trend by eliminating many existing and long-relied-upon compliance flexibilities utilized by the automakers. These flexibilities allow industry to find least cost, innovative solutions to environmental problems. With this rule, the Agency returns to utilizing compliance flexibilities that will allow automakers to comply with both EPA's GHG tailpipe standards that lowers costs and provides more consumer choice. 86 Fed. Reg. at 43,731.

Commenter: Environmental Law and Policy Center (ELPC)

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 289-290.]

It is, however, hard to decipher how the veritable smorgasbord of so-called flexibilities undermines the top line targets EPA sets out and therefore the benefits. Flexibilities allow automakers to stall gasoline vehicle improvements and fail to significantly boost the electric vehicle market given automakers already announced plans.

Light truck vehicles with dismal fuel economy dominate the market today. The market is now 50/50 as EPA assumes. These vehicles will be on the road guzzling gas and spewing climate pollution well beyond 2030. Each year that automakers can exploit flexibilities and ship out gas-guzzling trucks with little or no change undermines our ability to mitigate the climate crisis. EPA must shut down this smorgasbord and strengthen Alternative 2 to meet the climate moment.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 291.]

EPA makes clear in the NPRM that the proposed standards will be met with existing technology. Even Alternative 2, while stronger, will not spur innovation and fuel-saving technologies because loopholes will allow auto manufacturers to do more of the same with the climate paying the price.

Commenter: Environmental Law & Policy Center (ELPC), et al.

While we support EPA's proposal to strengthen vehicle emissions standards, we note there are flaws in the proposal which potentially undermine its climate goals and which should not be finalized: EPA's proposed rule goes beyond allowing automakers to use credits —which reallocate the burden of emission reductions, while achieving the same overall reductions—to allow for 'flexibilities' that as a practical matter will increase emissions.

EPA's proposed rule, unfortunately, also contains 'flexibilities,' such as 'multipliers' that allow automakers to generate credits without reducing emissions, and other loopholes. As EPA acknowledges, inclusion of such flexibilities undermines the proposed rule's topline targets and therefore its emissions-reduction benefits.[22] EPA should not include in its final rule any flexibilities that allow for credits to be generated without emissions reductions. These excessive technology credits and loopholes will allow automakers to stall gasoline vehicle improvements and will fail to significantly boost the electric vehicle market given automakers' announced plans. [EPA-HQ-OAR-2021-0208-0567-A1p, 4]

EPA makes clear that its proposed standards will be met with existing technology.[25] And loopholes will allow automakers to do more of the same with the climate paying the price. Adopting Alternative 2, along with the additional 10 g/mi stringency in MY 2026 and without the multipliers and other loopholes, will spur innovation, drive deployment of emissions-reducing technologies, and help sustain clean car manufacturing jobs across the Midwest and beyond. [EPA-HQ-OAR-2021-0208-0567-A1, p. 5]

Commenter: Environmental Protection Network (EPN)

EPA also proposes a variety of other provisions to the flexibilities provided to manufacturers, ranging from changes to the off-cycle credit provision to extensions of credit life for certain credits. As with all issues for the proposal, the way to analyze these proposed changes is to ask whether they are needed and important for achieving the MY 2030 and 2035 electrification goal, or whether they hinder or delay reaching that goal. EPA should explicitly evaluate these proposed changes in that light and explain any decisions in those terms. As with the standards and other flexibilities, any changes from the proposal should be to increase the overall stringency of the program, not to relax it. The proposal is already the bare minimum level needed considering the longer-term goals. [EPA-HQ-OAR-2021-0208-0213-A1, pp. 10-11]

Manufacturers may raise concerns that some limited or unique situations exist where the lead time is not adequate for specific vehicle models. Even if there are such situations, the discussion above shows that the lead time is appropriate for broad segments of the industry, covering all kinds of manufacturers and all kinds of vehicle models. Limited and unique situations for certain specific models are not a basis for delaying the standards beyond MY 2023 or changing the level of the standards.

If EPA believes these situations call for some sort of relief, then the proper approach is not to delay the standards or change their level. At most EPA should consider providing a narrow administrative avenue for limited, temporary relief for individual vehicle models, where a manufacturer demonstrates there are severe technical or other problems that make compliance with their fleet average standard highly unlikely, notwithstanding reasonable preparation by the manufacturer since 2012 and considering all the flexibilities and other circumstances discussed above. EPA could consider providing limited and temporary relief on a case-by-case basis. [EPA-HQ-OAR-2021-0208-0213-A1, p. 11-12]

If EPA decides to consider a temporary relief program, the agency should consider a case-by-case application process where a manufacturer demonstrates, for specific models and volumes of production, that it is highly impractical for them to comply with the otherwise applicable fleet-average standard, based on changes that the manufacturer made in its design and production plans for those models after March 30, 2020. That is the date the final rule relaxing the stringency of the MY 2021 to 2025 standards was signed and released to the public. Prior to that date, a manufacturer had no legally-recognized basis to change its design and production plans. While a manufacturer may have envisioned and expected changes in the stringency of the MY 2021 to 2025 standards, any change in design or production plans taken considering a manufacturer's projections of what EPA's 2020 final rule might contain was, at best, a business decision to take a risk on what the future action of EPA might be. Until March 30, 2020, the GHG standards for these model years remained unchanged from those adopted in 2012. It would not be appropriate for EPA to provide additional lead time to a manufacturer prior to March 2020 based on a business decision to prematurely change plans without knowing what, if any, changes EPA might make. In determining whether temporary relief should be allowed, EPA should consider all the compliance flexibilities provided in the GHG program. EPA should require a manufacturer to demonstrate that notwithstanding these flexibilities, it is highly impractical for a manufacturer to comply with the otherwise applicable fleet-average standard given the specific circumstances involving the models at issue. EPA should only provide temporary relief if there is a clear and convincing demonstration of the need for such relief. In addition, EPA should impose appropriate conditions on the temporary relief, such as production volume limits and limits on emissions levels, so the relief is narrowly tailored to the need and to limit the amount of adverse environmental impact. For example, assuming a manufacturer makes a clear and convincing demonstration of need, EPA could consider a temporary and limited adjustment of the footprint attribute curve as it applies to a specified volume of the specific model or models at issue. This adjustment would become part of how the manufacturer shows compliance with their overall fleet-average standard. [EPA-HQ-OAR-2021-0208-0213-A1, p. 13]

Commenter: Gentherm, Inc.

We support continued improvement in fuel efficiency and CO_2 emissions reductions along with flexibilities in technology credits. This will encourage innovation and provide OEMs with greater options for improving vehicle performance and efficiency. [EPA-HQ-OAR-2021-0208-0216-A1, p. 7]

Commenter: ITB Group, Ltd. (ITB)

The ITB Group supports continuous improvement in vehicle fuel efficiency and CO_2 emissions. Performance-based standards encourage technology-agnostic development of high-value solutions. Such solutions are expected to benefit the environment as well as the health and welfare of the United States citizens and reduce potential dependency on petroleum. Technology credit flexibilities are an important and cost-effective pathway to reducing vehicle fuel consumption and CO_2 emissions. Furthermore, technology credits provide additional flexibilities for auto manufacturers to meet their specific fleet requirements in the most cost-effective way while reducing national fuel usage and CO_2 emissions. [EPA-HQ-OAR-2021-0208-0222-A1, p. 1]

Commenter: Lish, Christopher

The new standard allows too many giveaways, or “credits,” to the automobile industry, which could cut short our carbon pollution reductions by a large margin. Excessive loopholes allow automakers to keep selling gas guzzlers that erase much of the benefits from electric vehicles, while failing to boost the electric vehicle market as quickly as needed. The standards adopted should not contain needless credits or other loopholes that reward automakers for reductions that aren’t matched in the real world. Furthermore, your proposed rules deliver less carbon pollution reductions and fuel savings than the Obama-era standards. [EPA-HQ-OAR-2021-0208-0218-A1, p. 2]

Commenter: Mass Comment Campaign sponsored by Center for Biological Diversity (77,692)

I urge you to write new long-term rules that: Close loopholes that allow manufacturers to avoid making real improvements; [EPA-HQ-OAR-2021-0208-0560-A1, p.1]

Commenter: Mass Comment Campaign sponsored by Consumer Reports (19,038)

We are calling on the Administration to eliminate loopholes for automakers that would undermine our nation's Clean Car Standards. [EPA-HQ-OAR-2021-0208-0602-A2, p.1]

Commenter: Mass Comment Campaign sponsored by Natural Resources Defense Council (NRDC) (26,929)

The new standard allows too many giveaways, or "credits," to the automobile industry, which could cut short our carbon pollution reductions by a large margin. [EPA-HQ-OAR-2021-0208-0558, p.1]

Commenter: Mass Comment Campaign sponsored by Sierra Club (13,699)

Moreover, the standards must not be undermined by complex credit schemes that reward automakers for reductions on paper that aren't matched in real world emission benefits. Excessive loopholes allow automakers to keep selling gas guzzlers that erase much of the benefits from electric vehicles, while failing to boost the electric vehicle market as quickly as needed. [EPA-HQ-OAR-2021-0208-0196-A1, p.1]

EPA must strengthen the final rule by accelerating the trajectory towards pollution-free vehicles and eliminating the credit scheme. [EPA-HQ-OAR-2021-0208-0196-A1, p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-3 (2,178)

We need strong standards that are not riddled with loopholes so we can drastically reduce carbon pollution driving the climate crisis. [EPA-HQ-OAR-2021-0208-0547, p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-4 (195)

EPAs proposed rule, unfortunately, contains flexibilities that allow automakers to generate credits without reducing emissions, and other loopholes. As EPA acknowledges, inclusion of such flexibilities undermines the standards benefits. The EPA should eliminate these loopholes in the final rule to ensure automakers put pollution-cutting technology to work especially on high-emitting SUVs and other trucks that will be on the road for a decade or more. [EPA-HQ-OAR-2021-0208-0548, p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-6 (39)

Any standards adopted should achieve at least the same total emission reductions as those undertaken by the Obama-Biden administration and should not contain needless credits or other loopholes that reward automakers for reductions that arent matched in the real world. [EPA-HQ-OAR-2021-0208-0550, p.1]

Commenter: Melton, Karen

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 254.]

The impacts of climate change we see all around the world today should tell you that we are way past the point where we can be creating loopholes and credit schemes to benefit automakers who are looking for ways to stall on efficiency improvements.

Commenter: Muller, Melinda

The new standard allows too many giveaways, or "credits", to the automobile industry, which could cut short our carbon pollution reductions by a large margin. [EPA-HQ-OAR-2021-0208-0500, p. 1]

Commenter: National Parks Conservation Association (NPCA)

Finally, NPCA requests that the final rule should not include unnecessary loopholes or credits, such as multipliers, that allow manufacturers to avoid real world reductions. [EPA-HQ-OAR-2021-0208-0291-A1, p. 2.]

Commenter: New York State Department of Environmental Conservation

DEC strongly supports ambitious standards but questions the need for some of the proposed compliance flexibilities that could potentially diminish the stringency of the program in the near term. [EPA-HQ-OAR-2021-0208-0238-A1, p.1]

In light of the available technology and the transition to electric vehicles well underway, we question to need to provide manufacturers with more flexibility than provided by the prior standards. New York recognizes that EPA is attempting to rectify the past administration's backsliding of light-duty GHG Standards while at the same time providing all manufacturers with sufficient lead time. While New York generally supports the continuation of traditional credit flexibilities, providing too much compliance flexibility would effectively reduce the stringency and effectiveness of the proposed regulations, especially in the short term. [EPA-HQ-OAR-2021-0208-0238-A1, p.2]

Commenter: Nissan North America, Inc.

Short-Term Flexibilities Necessary for Near-Term Challenges. Nissan supports the maintenance and expansion of compliance flexibilities for manufacturers under both the GHG and CAFE programs. The automotive industry development cycle is planned several years in advance, and manufacturers have already accounted for these credits in their fleet planning. Given the myriad supply chain issues and uncertainties affecting the automotive industry, and indeed the world, as a result of the COVID-19 pandemic and the semiconductor shortage, compliance flexibilities are critical for withstanding the current challenges facing the industry and for ensuring that manufacturers can continue to invest in developing EV and other clean technologies, particularly in the near term as the market for zero emission technologies continues to become established. Some of the key flexibilities that Nissan encourages EPA and NHTSA to consider are discussed below. [EPA-HQ-OAR-2021-0208-0529-A1, p. 8]

Commenter: Pennoyer, Marguerite

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 30-31.]

Please ensure that these standards don't include any shortcuts or loopholes for automakers to cut corners so that we see significant and genuine reductions in greenhouse gas emissions. Please do not allow unnecessary give-aways or complex credit scheme for automakers that look good on paper but that negate real-world benefits and delay progress toward newer and cleaner technologies.

Commenter: Rauch, Molly

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p.36.]

EPA's proposal details several options. The preferred alternative, the quote unquote preferred alternate, includes loopholes for automakers that may undermine the pollution reduction targets.

Commenter: Sierra Club

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 29.]

While I'm pleased to see the EPA has taken steps to strengthen the current standards, I'm disappointed to see that the agency is still offering loopholes which would allow automakers to double down on gas guzzlers.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 32.]

We're also deeply concerned about the loopholes that the proposal contains that would allow auto manufactures to double down on gas-guzzling vehicles.

Commenter: Stellantis

Establishing a pathway to 40-50% electrification by 2030 means that consumer willingness to adopt plug-in vehicles is even more critical. Recognizing this challenge, adjustments to the program flexibilities are needed to help us bridge the gap between the current market acceptance of EVs and this regulatory proposal. Motivating manufacturers to deploy the lowest emitting technologies in the near term will accelerate low and zero-emissions vehicles as a mainstream solution for light-duty transportation needs. [EPA-HQ-OAR-2021-0208-0532-A1, p. 8]

Commenter: Tesla

Each of the EPA's Proposed Compliance Flexibilities Are Unnecessary, Reduce Stringency, and Should Be Eliminated. In 2020, Tesla generated almost $1.6 billion in revenue selling zero-emission regulatory credits to other manufacturers.165 Proceeds from such sales will go towards building new factories to produce EVs that will continue to displace ICE vehicles. While it is common practice today for ICE vehicle manufacturers to purchase regulatory credits from other companies (such as Tesla) to offset their total CO2 emissions, it is not a sustainable strategy. For the U.S. to meet its decarbonization goals and to mitigate the public health and welfare impacts from climate change, EPA's proposal should be amended to meet increasingly more stringent regulatory requirements that has all auto manufacturers rapidly scaling up delivery of high-quality EVs. Unfortunately, the flexibilities built into the EPA's proposal do the opposite. The various flexibilities expand the crediting systems in ways that penalize past investment in electrification and will dampen actual near-term delivery of EVs, without a sufficient basis for doing so. Accordingly, the flexibilities provided in the proposal should be eliminated.

Commenter: Toyota Motor North America, Inc. (Toyota)

Toyota Supports Flexibilities that Can Accelerate the Shift to Electrification. Most of the necessary investments discussed above in infrastructure, R&D, and consumer incentives essential to building a viable electrification market fall outside of EPA‘s (and NHTSA's) authority and control. This makes it important for EPA (and NHTSA) to leverage the flexibility provisions under existing authority. We appreciate EPA's holistic approach and support regulatory flexibilities that help manufacturers manage compliance and push desired technologies into a growing but uncertain market.

As EPA noted, technology incentives available in the GHG program can help manufacturers get advanced technologies into the market more quickly than without those incentives. 13 While concerns have been raised about lost environmental benefits associated with regulatory flexibilities, we share EPA's policy position that any near-term loss needs to be balanced with the potential for significant longer-term, sustainable payoffs from electrified powertrains successfully transitioning from the current early adopter stage to one of self-sustained growth.

Further, EPA fully accounts for the potential environmental impacts in the benefit-cost analysis. EPA "recognized that they would reduce the effective stringency of the standards, but believed that it was worthwhile to have a limited near-term loss of emissions reduction benefits to increase the potential for far greater emissions reduction and technology diffusion benefits in the longer term."14 Such a pragmatic approach should also apply to the incentive expiration dates and benefit caps intended to limit potential near-term environmental losses. The temporary nature of the proposed provisions helps limit any losses. [EPA-HQ-OAR-2021-0208-0531-A1, p. 8-9]

Commenter: Union of Concerned Scientists (UCS)

Not only does this information [in the UCS comment submission] support moving forward with Alternative 2, but it also supports reducing the scope of incentives proposed by EPA—such incentives are not necessary to support a short-term strengthening of the greenhouse gas program and risk an erosion of the benefits of the program that could jeopardize the long-term ability to adequately deal with climate change and support the administration's critical goal for half of all new LDVs sold in 2030 to be zero-emission vehicles (ZEVs). [EPA-HQ-OAR-2021-0208-0277-A1, pp.2-3]

Proposed flexibilities undermine the greenhouse gas emissions program. EPA has proposed a number of changes to so-called 'flexibilities' in the greenhouse gas emissions program. Each of these changes results in increases in emissions, most frequently from windfall credits that over credit manufacturers for emissions reductions strategies they are already deploying. Such actions result in a direct erosion of the consumer and climate benefits of the rule. Many of these flexibilities were deployed under the original 2012 standards and set to expire, so we have historical evidence of their impacts.

Given the relatively weak stringency of the proposal, EPA should not move forward finalizing any of the proposed changes in flexibilities under the Preferred Alternative. By pre-charging the credit banks, the agency risks a repeat of the error with the early credit program that allowed the industry to strategically choose not to meet the standards over the past four years, and yet the credit bank has still not yet significantly dissipated.43 Should the agency move forward with some of these proposed credits, it should do so only in a specific, limited way in support of stronger alternatives that require them.

As we deal with the climate crisis, we need certainty from EPA's regulations. These proposed flexibilities amount to loopholes, which undermine the regulation and could significantly erode the projected benefits of the rule at a time when every metric ton of greenhouse gas reduction is needed. [EPA-HQ-OAR-2021-0208-0277-A1, p.23]

Commenter: Zero Emission Transportation Association (ZETA) and EVHybridNoire (EVHN)

ZETA and EVHN discourage the inclusion and extension of overly generous crediting, which creates potential loopholes for meeting the proposed standards, particularly for technologies that are no longer contributing to reductions in emissions from the transportation sector. Any system that indirectly encourages the production of combustion engine vehicles will delay the drawdown of carbon emissions and lock us into more global warming and deadly criteria emissions. This is determined in the Agency's own Environmental Impact Statement, which shows the emissions and public health benefits of Alternative 2 compared to the proposal.5

Extending many of these loophole credits will encourage traditional automakers to not comply with the stringent standards. Analysis from the Union of Concerned Scientists shows that these extensions could result in an additional 130 million metric tons of GHG emissions compared to Alternative 26 and be a lost opportunity compared with more stringent standards. Rather than artificially expanding the lifetime of older technologies, the standards should be pushing the entire auto industry toward electrification. [EPA-HQ-OAR-2021-0208-0275-A1, p. 3]

Commenter: Zewadski-Bricker, Edith

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 228.]

Now is not the time to pander to the automakers with complex credit schemes and tax loopholes that can be manipulated in the name of profits.

EPA Response

EPA acknowledges that many commenters commented generally in opposition of EPA's proposed credit and incentive provisions, many characterizing them as "loopholes." Other commenters, mostly auto manufacturers and automotive suppliers, generally supported these proposed compliance flexibilities as necessary to meet the proposed standards, especially in the near-term. For the Final Rule, EPA has narrowed these provisions as discussed in detail in sections II.A.4 and II.B of the preamble to focus them on MYs 2023-2024. More detailed comments regarding the proposed flexibility provisions and EPA responses to those comments are provided below (where not otherwise covered in the preamble).

The Environmental Protection Network (EPN) had several suggestions for types of flexibilities that EPA should consider in place of those proposed, along with a suggestion that EPA set more stringent standards than those proposed. EPA did not propose or seek comment on the concept suggested by the commenter of providing flexibility to individual vehicle models in limited circumstances, and thus the comment is outside the scope of the proposal. Such a program would be resource intensive to implement as it would involve responding to potentially many industry requests for vehicle model-specific flexibility.

5. Credit Averaging, Banking, and Trading (ABT)

Commenter: Alliance For Automotive Innovation

Credit Averaging, Banking, and Trading ("ABT") Flexibilities. Auto Innovators supports the proposal to expand carry-forward of credits generated in MYs 2016-2020.

Auto Innovators supports EPA's proposal to expand credit carry-forward provisions for MYs 2016-2020. Credit carry-forward allows manufacturers who over-comply in earlier years to carry those carbon reductions into future model years to account for product cadence or technology schedules. A limited expansion of credit carry-forward provisions may provide some additional flexibility for a limited number of manufacturers, and in theory could provide some additional credit market liquidity during the rapidly tightening standards in MYs 2023-2026. Credit carry-forward flexibility has been a key component of compliance since MY 2016 when the industry (on average) first moved from general over-compliance to consuming credits on an annual basis.

Carry-forward credits do not reduce the environmental benefits of the standards. These credits represent tons of emissions avoided in advance of requirements. As such, it is appropriate to allow their use as a flexibility for meeting later requirements.

EPA should consider additional deficit carry-forward (i.e., credit carry-back) provisions. Credit carry-back is an additional ABT mechanism that has proven useful for manufacturers to cover previous year deficits with future year credits. EPA is not directly proposing to adjust the existing credit carry-back mechanism within the GHG NPRM, but Auto Innovators recommends that EPA consider a modification under the broad scope of the GHG NPRM. Our proposal is to supplement the extended carry-forward with a limited allowance for a one-time extended credit carry-back provision. This proposal could provide manufacturers with an additional compliance flexibility through MY 2026 to address the proposed rapid increases in regulatory stringency and an uncertain EV market in the near-term. With regards to future rulemakings covering MY 2027 and later, Auto Innovators also recommends that EPA consider a broader extension of the credit carry-back to five years matching the longer carry-forward allowance.

Credit carry-back is an important mechanism for manufacturers, who may be facing near-term challenges with compliance, but have plans for later introduction of fuel-saving technologies (e.g., vehicle electrification) that can offset the deficits in later years. Like credit carry-forward, credit carry-back flexibility creates no loss in GHG benefits over the duration of the regulated time period. As illustrated in the 2020 Trends Report, an increasing number of manufacturers are not meeting MY 2016- 2020 targets and the overall volume of credits available to cover shortcomings is diminishing.107 With continuing compliance shortfalls and reduced availability of credits, more manufacturers may have to start carrying forward deficits into future model years. These manufacturers will need to plan additional technology for the future, to not only cover future standards, but to also create sufficient carry-back credits to cover historic deficits.

As noted throughout these comments and within EPA's technology projections, an increasing number of manufacturers are expected to rely on higher levels of electrification as investment portfolios shift into this long-term technology trend. Electrification plans will need to be executed within the three-year carry-back time window and at sufficient volume to generate credits to cover earlier deficits. There is an element of timing risk associated with electrification because much of the supply base and industrial capacity, while planned, is yet to be physically constructed or running at scale. Readiness delays with critical supply infrastructure could arise from many different angles including material capacity readiness, factory permitting, construction delays or workforce readiness. Any one of many potential delays could affect launch dates or volumes, which would put credit carry-back plans at risk. Timing delays would not necessarily impact overall GHG benefits associated with the future vehicles, but delays could result in manufacturers facing a "4th" year of deficits, potentially triggering enforcement proceedings.

Auto Innovators recommends that EPA consider adding an allowance for a limited extension of the credit carry-back allowance. A provision could be added to the regulation to provide a pathway for manufacturers, who may be at risk of exceeding the three-year window to cover a model year deficit to petition the Administrator for one additional model year of credit carry-back. The petition could be required to demonstrate circumstances that may delay or otherwise impact future credit generation. If approved, EPA could grant a conditional allowance for one additional year of credit carry-back. The restriction to a narrow window of extension would limit any negative effects of deferring GHG improvements for longer. Further limits could include mechanisms such as limiting a manufacturer to only one such application through MY 2026 and a limitation of the allowance to credits from a single future model year. Auto Innovators believes this additional flexibility would provide a pragmatic level of additional flexibility for manufacturers, who may face future delays in the yet to be built electrification supply chain, while not impacting overall GHG reductions. [EPA-HQ-OAR-2021-0208-0571-A1, p. 32-34]

Commenter: American Council for an Energy-Efficient Economy (ACEEE)

Currently any credits that automakers earn for overcompliance with a given model year's emission standards may be banked for up to 5 years. This limited lifetime is essential to ensure that any early miscalibration in emission standards does not propagate too far into the future. Credits that don't expire would effectively tie EPA's hands in setting future standards, as the agency would have to design standards that are both feasible for new entrants but also strong enough to force those automakers with extensive banked credits to make real improvements in emissions.

EPA proposes to retroactively extend the lifetime of MY 2016 credits to 7 years and MY 17-20 credits to 6 years (EPA 2021b)4. ACEEE strongly opposes this retroactive extension of credit lifetimes. Not only have automakers have already designed and sold these vehicles under the expectation of a 5-year credit lifetime, they additionally lobbied for a decrease in the 2012-rule stringency under the prior administration.

Automakers should not be further rewarded with additional credit extensions. Automakers generated credits worth 20.5 million metric tons (MMT) of CO_2in MY 2016. The extension of MY 2016 credits is particularly significant as those credits are set to expire in MY 2021, along with over 100 million earned early action credits from MYs 2009-2011 (EPA 2020a; 2021a). The existing pool of early action credits is more than sufficient to cover compliance for MY 2021 and this extension, therefore, allows all the MY 2016 credits to be carried forward to MY 2023, rather than expiring unused. The adjustment to the MY 2022 standards as part of the SAFE rule adopted in 2020, after MY 2022 vehicles had already been designed, also makes it unlikely that any of these credits will be needed for compliance before MY 2023. The reduction in stringency for MY 2021, under the same conditions, will also provide a large number of credits to use for MY 2022. If all these credits were applied to MY 2023, these credits would reduce the stringency of the proposed 2023 standard by over 6 g/mi per vehicle5.

The proposed lifetime extensions for MY 2017-2020 credits would also substantially weaken the proposed standards. Extending the lifetime of the 21.8 MMT of credits generated in MY 2017 would allow up to a 7 g/mi increase in average emissions rate in MY 2023, beyond the increase due to the 2016 credit extension. Together, the 2016 and 2017 credits would allow a reduction in improvement in MY 2023 from 10% to just 4%6.

The MY 2018-2020 credit extensions would allow up to a 10 g/mi increase in emissions in MYs 2024 and 7 g/mi in MYs 2025-2026.7 This is summarized in Table 1 [Table 1 can be found at docket number EPA-HQ-OAR-2021-0208-0251, p. 8].

This scenario is made even more likely by the increase in MYs 2021 and 2022 credits earned due to the SAFE rule. The weak standards for MYs 2021 and 2022 should lead to an increased credit balance in those years, given that vehicles for those model years were designed prior to the adoption of the SAFE rule. These additional credits could be used for MYs 2023-2026/2027 or saved until MYs 2026 and 2027. As a result, EPA is enabling automakers to save the credits earned during the SAFE rule, instead of spending them in the early years of compliance with the proposed rule, furthering the damage associated with the SAFE rule. Overall, ACEEE found that the credit extensions would reduce the emissions savings from the proposed rule by 22%.[EPA-HQ-OAR-2021-0208-0251-A1, pp.7-9]

Retain the 5-year lifetime for MY 2016-2020 credits [EPA-HQ-OAR-2021-0208-0251-A1, p. 15]

8 MY 2022 emission target is unchanged from SAFE rule. All credits extended into MY 2022 are also extended to MY 2023 and credit usage and changes in achieved fleet emissions are assumed to take place then.

Commenter: American Honda Motor Company (Honda)

Extended Credit Carry Forward. In order to help support compliance flexibility, the agency proposes extending the current 5-year credit carry forward provision by two additional years for Model Year 2016 credits, and by one additional year for Model Year 2017-2020 credits.

Honda has previously13 supported the concept of extended credit carry forward for Model Year 2016- 2020 credits, and does so here as well. Considering industry-wide fleet average performance over the past few years, as noted in the EPA Trends Report, it is not unreasonable to expect that the pace of environmental progress called for in the proposed regulations may present compliance challenges for some if not many automakers. A robust credit market is one way to ensure that manufacturers continue to have a path to compliance, and that environmental gains continue to be realized, even in the face of challenging standards. [EPA-HQ-OAR-2021-0208-0565-A1, p.5]

Honda respectfully requests that the agency consider additional regulatory flexibility in this space, for the following reasons:

• Credits generated under the ABT program reflect actual emissions reductions. Because GHG emissions persist in the earth’s atmosphere for roughly a century, the benefits of avoided emissions are equally lasting. Extending credit lifetimes beyond a 6-7 year period would not undermine the scientific integrity of the ABT program.

• As widely reported in the media over the past 18 months, the automobile industry is facing severe global supply chain issues that continue to disrupt vehicle production volumes, launch dates and compliance strategies. Slight modifications to the proposed credit carry forward provisions could provide much needed compliance flexibility during an exceedingly challenging compliance planning time.

• The agency's proposed targets include significant g/mi reductions (increases in stringency) in Model Years 2023 and 2026. While companies that signed up to the California Framework agreement can reasonably be expected to meet MY2023 stringencies, Model Year 2026 is likely to prove difficult for most, if not all, manufacturers.

In summary, while we strongly support the broad concept of extended credit carry forward of MY2016- 2020 credits, industry's navigation of the MY2023-2026 window will present very real cost, timing, and logistical challenges. As such, we see rationale for extending the credit carry forward provisions beyond those specified in the proposed rule. For example, a more flexible program could be (a) one in which two-year extensions are granted to model years 2016 through 2020 or, (b) under a slightly more conservative approach, two-year extensions to MYs2016-2019, while limiting MY2020's extension to just one year. The latter design would help telegraph to regulated parties the temporary nature of this approach to ABT, and that standard ABT rules would likely resume under future regulatory programs. We believe each of these alternatives remain aligned with the spirit and intent of the agency's proposed credit carry forward modification, while providing an important additional degree of compliance flexibility. [EPA-HQ-OAR-2021-0208-0565-A1, p.6]

Commenter: California Air Resources Board (CARB)

As we elaborate below, the credit-based structure of the rule, the availability of those credits, and the averaging times involved all readily support multiple paths for compliance. The proposal includes several options for credits and flexibilities for meeting these standards. Indeed, some of these flexibilities may be undue: Some should be adopted, but some should not, as we explore in detail in these comments. [EPA-HQ-OAR-2021-0208-0643-A6, p.7]

[S[hould not extend the life of credits [EPA-HQ-OAR-2021-0208-0643-A6, p.7]

In this section we discuss evidence supporting this point. We also discuss why U.S. EPA should not unduly protect credit banks earned as windfalls against the weak SAFE standards and make recommendations on how ZEV-only manufacturers' credits can further support U.S. EPA's proposal. [EPA-HQ-OAR-2021-0208-0643-A6, pp. 28-29]

And under the federal standards, the credit banks that automakers have amassed provide a trajectory and assurance they will remain in compliance with the standards.85 The flexibility offered by these provisions is discussed further in the next section. [EPA-HQ-OAR-2021-0208-0643-A6, p.30]

The Credit Provisions Support Meeting the Standards in the Given Lead-Time. Beyond the question of whether manufacturers have developed the technology to meet the proposed standards and its cost, the structure and design of the standards provide manufacturers with options for meeting them in any given year. While recognizing that more stringent standards than those currently in place are feasible, CARB recognizes the value of providing a variety of means to comply. CARB supports credit averaging, banking, and trading options that enable compliance to be determined over multiple periods and credits for innovation. CARB supports the continued use of such provisions so long as they maintain the effective stringency of the standards to reduce real-world emissions.

U.S. EPA also requested comment on whether the proposal would disrupt manufacturer plans to over-comply with current standards and produce credits to sell to other manufacturers, by raising the regulatory baseline. Fundamentally, this issue should not be a primary consideration, as the core need is to reduce emissions, not to protect potential windfall credit revenues created by the unduly weak current standards. The statute does not require that U.S. EPA protect windfall profits at the expense of public health.

Moreover, there is not a credible argument that such credit windfalls are needed for compliance nor that some manufacturers may have already developed plans that were reliant on such credit windfalls. Manufacturers must plan first to ensure they comply with their own obligations and have done so.91 Primarily, these obligations were defined by the National Program standards before the Final SAFE Rule emission standards. By necessity, each manufacturer had developed a path to compliance with those standards. The uncertainty and turmoil brought about from 2018 through 2020 from the SAFE standards proposals, litigation, and final standards that were not released until the 2020 calendar year happened much too late in the product planning cycle to allow manufacturers to make wholesale changes to their original plans. If anything, the SAFE standards inequitably disrupted manufacturer plans by providing an unexpected benefit only to manufacturers that had delayed technology deployment as long as possible, thereby taking the riskiest path to compliance and the worst for public health. No manufacturers will credibly be able to claim that they have dramatically changed their plans since the Final SAFE rule was finalized in 2020 such that U.S. EPA must now act to protect windfall credits.

But such a reliance scenario could only happen in two very unlikely instances – first, if a manufacturer had carried massive deficits into those years and needed overcompliance to avoid penalties, or second, if it planned to generate credits to offset even greater shortfalls in future years.

The first scenario requires assuming a manufacturer dramatically fell short of the weak Final SAFE Rule emission standards. But because those standards were, as conceded in the SAFE proceedings, below the expected level of manufacturer compliance, this is not at all likely. The second scenario is equally implausible. Under the Final SAFE emission standards, the standard remains constant from 2026 model year on so overcompliance in 2025 and 2026 model year would also mean continued overcompliance in subsequent years. Technology continues to improve, and manufacturers have publicly committed to deeper decarbonization of their fleets, so there is not a need to protect credits against the lax Final SAFE standards. To the extent this was intended to ease compliance for anticipated future GHG standards, such action would be highly speculative, not only to the stringency of such standards, but also to the timing of their adoption and to whether credits earned under the current standards would even be allowed towards compliance with the future standards.

This issue of manufacturer compliance planning presents itself in yet another way in the proposal, where U.S. EPA proposes to extend the years for which credits under the 2016 through 2020 model years may be used.92 U.S. EPA proposes these extensions to ease the transition to the more stringent standards and contends that existing provisions that provide a finite life for credits provides precedent for this proposal to reset those lifetimes. CARB disagrees with both premises.

When manufacturers planned their products to generate the credits, they were aware of the constraints on their use and available terms. Because these credits were earned before the Final SAFE Rules went into effect, they reflect manufacturer planning to meet the more stringent standards then in effect with improved technology after those credits had expired.

Furthermore, extending the credit life is not necessary to facilitate compliance. In the time available, manufacturers can incentivize sales of vehicles with more of the necessary technologies if they are needed to meet the proposed standards, including additional zero-emission technologies. As discussed above and in the Roush Engineering report, many manufacturers offer high-sales volume vehicles in a variety of configurations, many of which have emission rates that are more than 10 percent lower than other configurations. Manufacturers can adjust the technical content, additional features attractive to consumers, pricing, and incentives to use these attributes of their existing products to meet more stringent standards without significant additional research or development investment or changes to vehicle design. [EPA-HQ-OAR-2021-0208-0643-A6, pp. 31-33]

Commenter: Center for Biological Diversity, et al.

EPA should not extend the carry-forward life for MY2016-2020 credits. EPA has proposed to extend the number of years that banked MY 2016-2020 vintage credits may be carried forward by up to two years, making expired MY 2016 credits usable through MY 2023, and soon-to expire MY 2017-2020 credits usable through MY 2023-2026. Proposal, 86 Fed. Reg. at 43,764. The agency states that it is doing so to address the unusual current circumstances, where lead time is shorter than in some previous rulemakings and the nominal stringency increase for MY 2023 is nominally steeper.

Automakers factor banked credits into their production and compliance planning for the following five-year period. But automakers’ production planning does not, and cannot, rely on expired credits; retroactively granted credit life extensions thus do nothing to spur the development or application of more advanced technologies or vehicle electrification: they constitute windfalls. Moreover, some banked credits have been earned even though they were already untethered from any real-world emissions reductions, such as is the case for multiplier credits, and thus would constitute double-windfalls. Retroactive credit life extensions are also not required due to lead time concerns, as Dr. Cooke's modeling establishes for both the Proposal and Alternative 2.

We therefore urge EPA not to extend the lifetime of MY 2016-2020 credits as proposed—or, at a minimum, not to extend them beyond MY 2024. [EPA-HQ-OAR-2021-0208-0651-A1, p. 64-65]

Commenter: Center for Climate and Energy Solutions (C2ES)

The extensions of credit carry-forward included in this proposal provide significant flexibility for automakers and reduce the effective stringency of the standards. While C2ES supports compliance flexibilities for the private sector and incentives to accelerate the deployment of zero-emissions technologies, these should not come at the cost of necessary reductions in emissions. [EPA-HQ-OAR-2021-0208-0287-A1, p.4]

Commenter: Chemours Company (Chemours)

EPA should increase the transparency of data concerning the generation, holding and sale of GHG emission credits, making additional information on such activities available to the public. While EPA's supporting technical documents provide a good overview of the current credit market for LDVs, additional, more granular detail (consistent with claims of Confidential Business Information) is needed to fully understand how credits are being generated and utilized. Such transparency would benefit the efficiency of the credit market as well allow for further assessment of the relative performance of various credits.[EPA-HQ-OAR-2021-0208-0232-A1, p. 3]

EPA Should Increase Transparency of Vehicle GHG Credit Market. EPA's 2020 Automotive Trends Report58 provides helpful information concerning how vehicle manufacturers comply with EPA vehicle standards. Among the information provided is a breakdown, by manufacturer, of the footprint and standards for each vehicle in a manufacturer's fleet, trends in compliance, the relative production of EVs and PHEVs, advanced technology credits earned per manufacturer and adoption of alternative refrigerants.59

While the data in Tables 5.1 – 5.19 in the Trends Report is valuable in understanding the overall credit position of different manufacturers, EPA should also provide public access to the underlying data upon which the tables were generated. Nearly all the data in the Trends Report is based on vehicle manufacturer's direct submissions to EPA and from testing either performed by EPA or the vehicle manufacturers themselves.60 And while EPA has provided additional ability to download data from supplemental data tables, EPA notes that "[t]he full database used for the analysis is not publicly available."61 This lack of availability is apparently based on a claim of Confidential Business Information ("CBI") by manufacturers.

EPA should further review what data may be made available to the public concerning vehicle emission credits, consistent with its obligations and regulations regarding the treatment of CBI.62 To the extent that additional underlying data on credits can be released by EPA, it should be to increase the transparency of EPA's proposed rule and help to inform both the commercial marketplace and consumers of relevant information concerning vehicle performance, approaches to controlling GHGs and the compliance strategy for different vehicles.

A more fulsome release of emission data which identified specific regulated parties is not unprecedented. For example, EPA's Clean Market Division allows access to Air Markets Program Data, including customized data inquiries.63 Public inquiries can be made down to the level of allowance transaction totals, transaction types, the facility involved in the transfer, transaction date, and the vintage of allowances including serial numbers.64 While Chemours recognizes that CBI considerations may limit access to all data on which the Trends Report is based, EPA should during the remaining course of this rulemaking seek to expand the level of information available to the public regarding credits generated, held and transacted in compliance with LDV GHG standards. [EPA-HQ-OAR-2021-0208-0232-A1, p. 13-14]

EPA should also strive to implement greater transparency with regard to the generation, use and trading of vehicle GHG credits. While care must be taken to protect confidential business information, the current amount of information available is insufficient to allow the broader market and the public to understand how the generation and use of credits is occurring. Because credits are interwoven with the overall compliance of vehicle OEMs with GHG emission targets, clearly understanding how the credit market is functioning is vital information for all market segments and the general public to understand. [EPA-HQ-OAR-2021-0208-0232-A1, p. 18]

Commenter: Edison Electric Institute (EEI)

Of the many compliance flexibilities historically available to automakers, fleet averaging has allowed for emissions reductions in a cost-effective way that also serves to expand the vehicle options available to customers. These flexibilities can allow for greater environmental benefits, more cost-effective compliance and expanded customer options. [EPA-HQ-OAR-2021-0208-0284-A1, p. 9-10]

Similarly, the inclusion of averaging, banking, and trading is well-supported for all the reasons discussed, supra. EPA proposes to retain these provisions with certain carry-forward limitations. See 86 Fed. Reg. at 43,733. Averaging, banking, and trading provisions are important tools that allow automakers to average ZEV across their fleet in a way designed to produce lowest-cost regulatory compliance. The inclusion of these provisions is, therefore, appropriate and essential to programmatic success. [EPA-HQ-OAR-2021-0208-0284-A1, p. 12]

Commenter: Environmental Defense Fund (EDF)

Background on GHG Credits. Each model year, manufacturers are required to calculate both their individual corporate average GHG standard and their corporate average GHG performance. This is done separately for passenger cars and light trucks. The corporate average GHG standard is essentially the sales weighted average of each vehicle model's GHG target taken from the footprint curves. Corporate average GHG performance is, similarly, the sales-weighted average of each vehicle model's emissions over the 2-cycle test, adjusted for off-cycle emission controls, advanced technology vehicle multipliers (e.g., PHEVs and BEVs), air-conditioning efficiency and refrigerant credits less any debits accrued for exceeding the methane and nitrous oxide emission standards. If GHG performance exceeds (is numerically lower than) the standard, credits are earned. If GHG performance fails to meet the standard, deficits (or negative credits) are accrued. The basic formula for determining the number of credits in a given model year is:

Credit= sales * (corp. avg. GHG standard - corp. avg. GHG level) * lifetime VMT / 1,000,000

The credit is calculated in terms of megagrams of GHG. The lifetime VMTs for passenger cars and light trucks are specified in the GHG regulations. If "Credit" in the above equation is positive, it is termed a credit. If "Credit" is negative, then it is termed either a negative credit, a debit or a deficit. Credits are earned, traded and used by individual manufacturers, all of which must be reported to EPA. The current and proposed expiration dates for banked credits are as follows: [Table 2 can be found at docket EPA-HQ-OAR-2021-0208-0688-A1, p. 12]

For example, under current law, GHG credits earned during MY 2018 can be used through the end of MY 2023. Under EPA's Proposal, these credits could be used through the end of MY 2024. Deficits can be carried forward for a maximum of three years.

Credits are earned and deficits are accrued for passenger cars and light trucks separately. Credits earned for one vehicle class can be used to address a deficit in the other vehicle class on a megagram basis. Because credits for passenger cars and light trucks are treated separately, a manufacturer could earn credits for their car compliance in a given model year and sell these credits to another manufacturer even though they accrued a deficit for their truck performance in the same model year, and vice versa. In practice, this allows manufacturers to extend the life of their credits, assuming that credits from previous model years are available for use or purchase (which has historically been the case).

Since credits and deficits are earned by individual manufacturers, it is possible and very likely that even if the vehicle fleet as a whole barely meets the GHG standards, some manufacturers will be earning credits and others accruing deficits. As described above, it is even possible that individual manufacturers will earn credits for their cars and accrue a deficit for their trucks. As the deficits can be made up with banked credits from previous model years, the credits just earned can be used to compensate for future deficits. This requires that GHG compliance be tracked by manufacturer and vehicle class and model year.

MY 2010-2019 Bank of Credits. The EPA 2020 Fuel Economy Trends Report (2020 Report) provides a detailed description of each manufacturer's credit bank levels at the end of MY 2019, as well as the year in which they expire. The current level of banked credits for all manufacturers (less deficits) is 229 million megagrams. This is equivalent to 73 g/mi GHG for an industry-wide fleet of 15,000,000 vehicles using an average of the lifetime mileages of cars and trucks. In other words, the current, industry-wide reserve of credits is very large.

Roughly two-thirds of this reserve (151 million megagrams) is due to expire after MY 2021. These credits were earned in MYs 2010-2016. EPA is proposing to extend the life of credits earned in MY 2016 from the end of MY 2021 to the end of MY 2023. The 2020 Report does not distinguish between the number of credits earned prior to MY 2016 and those earned in MY 2016, which would have differing expiration dates under the Proposal. For the purpose of this analysis, the number of banked credits earned industry-wide in MY 2016 was conservatively estimated by assuming that they equal the lesser of:

1) the credits earned in MY 2016 (i.e., the maximum possible level), and

2) the total level of banked credits at the end of MY 2019 less those expiring in later model years (which were presented in the 2020 Report).

Another way to put this assumption is that, for each manufacturer and vehicle-class combination, we assume that manufacturers act to maximize the life of their credits. This assumption is reasonable. EPA allows manufacturers to carry a net deficit credit balance for 3 years. Credits do not earn interest or carry interest charges. Thus, there is no risk for a manufacturer to carry a deficit balance for their car or truck performance while carrying a positive credit balance for the performance of the other vehicle class. If the manufacturer is able to use or purchase credits of an earlier vintage to cover its credit deficit at a reasonable price, it is reasonable to assume that a manufacturer would do so, enabling the manufacturer to carry its newly earned credits for up to five years when the value of credits is likely to be higher for both itself and other manufacturers due to more stringent GHG standards.

Table 3 shows each manufacturer's credit balance at the end of MY 2019. Manufacturers not producing MY 2020 vehicles (i.e., not contained in NHTSA's MY 2020 baseline fleet) were omitted, but the total GHG credit balance held by those omitted manufacturers was only 182,000 megagrams, less than 0.1% of the industry-wide balance. [EPA-HQ-OAR-2021-0208-0688-A1, p. 11-13] [Table 3 can be found at docket EPA-HQ-OAR-2021-0208-0688-A1, p. 13]

Framework manufacturers do not need these pre-MY 2021 credits for compliance with EPA's Proposal for two reasons. First, they should earn substantial credits under the 2020 Rule in MY 2021 and 2022, which requires fewer emissions reductions than those specified in the Framework Agreements; and those specified reductions are comparable to those required to meet EPA's Proposed Standards for MYs 2023 and 2024. Second, we compared the credits that some of the Framework manufacturers might need to comply with the 2020 Rule and the Proposed Standards, respectively, over MYs 2021-2024 to those being generated by other Framework manufacturers over this timeframe. These manufacturers together have ample credits to facilitate compliance through MY 2024.

In order to achieve the emissions reductions contemplated by the Framework Agreements through MY 2024, Framework manufacturers may use up to 4 million megagrams of credits from their current credit banks – only a small fraction of the 34 million megagrams of pre-MY 2021 credits held by these manufacturers. Thus, we conclude that Framework manufacturers can make the vast majority of their pre-MY 2021 credits available to non-Framework manufacturers without implicating their own ability to apply credits to meet their voluntary commitments under the Framework Agreements. This means that credits earned by Framework manufacturers could be sold to non-Framework manufacturers for use toward compliance with the Proposed Standards.

In light of Agreement provisions limiting use of credits generated under the federal standards, we assume here that the Framework manufacturers will not sell any federal credits accrued under the Framework (i.e., credits earned in MYs 2021 and beyond) to non-Framework manufacturers. This is a conservative assumption regarding the ability of non-Framework manufacturers to acquire credits to comply with the proposed EPA standards. [EPA-HQ-OAR-2021-0208-0688-A1, p. 14]

22 Some automakers may only need to do a subset of these actions. See EDF analysis infra, at 9.

Commenter: Environmental Law & Policy Center (ELPC), et al.

EPA allows an automaker that over complies with the standards in a given year to earn credits, which it can then either use to offset its own undercompliance in a different year or trade to another manufacturer to offset that manufacturers' undercompliance. Such a system ensures that the entire U.S. automobile fleet's emissions meet the overall standards and emissions reductions goals. [EPA-HQ-OAR-2021-0208-0567-A1, p. 4]

Commenter: Gentherm, Inc.

Support the limited credit carry-forward proposal. Gentherm supports the limited credit carry-forward proposal that provides additional flexibility for credits earned during MY2016 to MY2020. This provision simply preserves credits which might be lost for future compliance. There is limited lead-time before 2023 for automakers to make technology changes to ensure compliance with the tighter requirements proposed by the EPA. The proposed extension of credit life may help bridge the 10 percent decrease in top line stringency for MY2023 and generally provide flexibility for industry to meet proposed targets. [EPA-HQ-OAR-2021-0208-0216-A1, p. 7]

Commenter: Hyundai America Technical Center, Inc. (Hyundai)

Credit bank carry-forward extension and carry-back provision. Hyundai supports the credit bank carry-forward and carry-back provisions to provide flexibilities to account for unexpected variations in vehicle sales. [EPA-HQ-OAR-2021-0208-0603-A1, p.8]

Commenter: Institute for Policy Integrity

EPA should carefully assess whether a more tailored application of any of its credit extensions would further increase net benefits and equity while still preserving sufficient flexibility for manufacturers. [EPA-HQ-OAR-2021-0208-0299-A1, p. 1]

Similarly, EPA should also more critically evaluate the trade-offs resulting from its proposed extension of multiplier credits and the credit carry-forward period and consider the forgone benefits to public health and consumer fuel savings associated with these compliance flexibilities. To the extent that these extended compliance flexibilities are intended to provide additional lead time for manufacturers to comply with the MY 2023 standards, EPA should evaluate whether such flexibility is needed beyond the first model year of its proposed standards. As detailed below, we do not believe EPA is required to provide significant lead time for standards (such as the proposed standards) that do not require significant technology investment and development. EPA should consider whether scaling back even some of the multiplier credits or carry-forward period, or limiting their application to MY 2023, would increase net social benefits while still preserving more than enough compliance flexibility to satisfy the requirement for lead time. [EPA-HQ-OAR-2021-0208-0299-A1, p. 3.]

Second, manufacturers have access to significantly more compliance flexibilities under the Proposed Rule than they did under EPA's past criteria pollutant standards, including credit trading, credit multipliers, a large bank of available credits, and credit carryback provisions that allow automakers to make up for any possible shortfalls in earlier model years by increasing their efforts in subsequent years. Thus, even if automakers do not quite meet the MY 2023 standards, they have several years of lead time to adjust their production in MYs 2024–2026 and apply any credits earned in those years backwards to MY 2023. In addition, automakers are sitting on a significant bank of credits earned in past model years that can be applied toward any shortfalls in MY 202354 (and indeed, EPA has proposed extending the lifetime of those credits to provide even more flexibility55). [EPA-HQ-OAR-2021-0208-0299-A1, p. 8.]

Commenter: ITB Group, Ltd. (ITB)

ITB also supports the limited credit carry-forward proposal that provides additional flexibility for credits earned during MY2016 to MY2020. This provision simply preserves credits that might be lost for future compliance. There is limited lead time before 2023 for automakers to make technical changes to ensure compliance with the tighter requirements proposed by the EPA. The proposed extension of credit life may help bridge the 10 percent decrease in top-line stringency for MY2023 and generally provide flexibility for the industry to meet proposed targets. [EPA-HQ-OAR-2021-0208-0222-A1, p. 1]

Commenter: Lucid USA, Inc. (Lucid)

To promote a faster path towards the full electrification and net zero goals that President Biden has announced, as well as the interim goal of 50% electrification in the Executive Order that the President issued last month, EPA should limit and/or phase out certain flexibilities under the GHG regulatory program. EPA has over-expanded credit carry-forward for model years 2023-2026. While Lucid understands that some degree of flexibility in the use of credits is important to facilitate the transition to more stringent standards, the proposed increase in flexibility (particularly to meet the requirements for model year 2023) weakens the stringency jump in the standards. Although the proposed standards are more stringent than the Trump standards, the increased flexibilities proposed in the NPRM would effectively make the standards less stringent than the standards issued under the Obama Administration until Model Year 2026. [EPA-HQ-OAR-2021-0208-0528-A1, pp. 4-5]

Commenter: Mercedes-Benz USA, LLC

Mercedes-Benz supports EPA's proposal to adopt a one-time credit carry-forward provision from MYs2016-2020 credits and MYs2017-2020 from five to seven years and five to six years, respectively. [EPA-HQ-OAR-2021-0208-0523-A1, p.2]

Proposed Extension of Credit Carry-forward. EPA is proposing a one-time extension of credit carry-forward for credits generated in MYs2016 through 2020 from five to seven years and credits generated in MYs2017-2020 from five to six years. Mercedes-Benz supports EPA's credit extension proposal as another opportunity for EPA to provide flexibilities to manufacturers in their compliance strategies, particularly within later years of the GHG program, where we believe credits will be critical for fleet compliance to bridge the gap between internal combustion engine vehicles and the all-electric transition. [EPA-HQ-OAR-2021-0208-0523-A1, p.4]

Commenter: Motor & Equipment Manufacturers Association (MEMA)

Extended Credit Carry-Forward Proposal. EPA's current program limits credit carry-forward to five years (and carry back three years). EPA is proposing a limited extension of credit carry forward for credits generated in MYs 2016–2020. Credits received in MY2016 extend from five years to seven years, and from MYs 2017–2020 from five years to six years. EPA explains that, because of the transition to more stringent standards from MYs 2023–2026 and the stringency increase between MYs 2022–2023, an extremely steep step with a relatively limited lead time, it is appropriate to provide a limited amount of additional flexibility for carry-forward credits.31

MEMA supports the carry-forward proposal that provides additional flexibility for credits earned during MYs 2016–2020. This extension will help bridge the 10 percent decrease in MY2023 and generally help the industry in meeting the proposed targets. MEMA also supports the credit carryforward returning to the normal five years in the existing averaging, banking, and trading (ABT) regulations in the post-2026 program. [EPA-HQ-OAR-2021-0208-0249-A1, p. 10]

Commenter: New York State Department of Environmental Conservation

More specifically, New York recommends against extending the credit carry forward beyond 5 years for 2016-2020 credits. The current 5-year credit carry forward is adequate and provides a buffer for unanticipated compliance shortfalls. Extending credit carry forward to 6 or 7 years is unnecessary considering most manufacturers did not revise their product plans to comply with the misguided SAFE Rule and have numerous technology options available today. Extending credit carry forward will limit adoption of these technologies, thereby reducing the program's effectiveness. [EPA-HQ-OAR-2021-0208-0238-A1, p.2]

Commenter: Nissan North America, Inc.

GHG Credit Life. In general, Nissan supports EPA's proposal to extend the life of GHG credits generated between model years 2016 and 2020 under the averaging, banking, and trading ("ABT") provisions; however, Nissan encourages EPA to go further. EPA's current proposal offers only a one-year extension for credits generated between model years 2017 through 2020, and no extension for credits generated after model year 2020. The ABT mechanism has been a key compliance flexibility under the GHG regulations and would become more necessary under the increasingly stringent standards in the future. Extending credit life would enable automobile manufacturers to invest appropriate resources at the appropriate time without eroding overall industry GHG benefits. EPA should therefore extend the life of all model year 2015 and later GHG credits through at least model year 2026 to provide manufacturers with necessary compliance flexibility. Extending the applicable life of GHG credits attained by overachieving the standards with the early introduction and ever-growing use of ZEVs would be consistent with the Administration's environmental policy. Early production of EVs has played an important role in laying the ground for the initial EV market. Such early action was instrumental for the long-term future of the EV market, and allowing the use of credits generated by such early environmental action is appropriate. [EPA-HQ-OAR-2021-0208-0529-A1, p. 9]

Commenter: Peterson, Doug

The Expiration Dates of Existing Compliance Credits Should Not Be Delayed. It is unclear to me whether the EPA intends to consider objections to the proposal to delay the expiration of compliance credits. As you can see, I intend to object. It seems to me that it would make a mockery of the rulemaking process if this very destructive alteration to the agreed upon regulatory framework were allowed to become part of the finalized 2023-2026 rule without input from all stakeholders. The issue of the credit expirations should be vetted publicly, as the proposed change has great significance that is closely related to the stringency increases and the effort to accelerate the adoption of zero emission vehicles. This is not a trivial matter about how the EPA chooses to administer the CAFE standards, subject to its administrative discretion alone. The enormous glut of credits expiring at the end of the 2021 model year has undermined the stringency of the CAFE standards for far too long already, coddling the most irresponsible automakers with its pay-to-pollute "flexibility".

According to the EPA's 2020 Automotive Trends Report, a whopping 151,139,573 megagrams of compliance credit are scheduled to expire at the end of the 2021 model year. 21,747,811 megagrams of credit are scheduled to expire at the end of 2022. It was originally agreed that earned and purchased credits would expire after five years. The enormous number of credits expiring in 2021 was created because additional leniency was extended to automakers that allowed them to delay all credit expirations through 2021, a questionable extension in its own right. The five-year lifespan of credits was a sensible way to balance the need for flexibility with the need to enforce the 6 increasing stringency of the footprint targets, and it should never have been tampered with. Some argued that the credits should never expire, and this was wisely rejected, but delaying expiration through 2021 has provided the same outrageous flexibility benefit. An enormous glut of compliance credits quickly became available at the beginning of the CAFE program, far more than enough to keep all automakers in compliance whether they met their standards or not. No automaker has ever come close to falling out of compliance. When fourteen out of twenty automakers failed to meet their standards in 2019, it generated an industry-wide credit deficit of 23,821,639 megagrams. The enormous portion of the credit glut expiring in 2021 is over six times as great as the discouraging 2019 shortfall. If a glut of this magnitude is allowed to persist, the stringency increases that the EPA is proposing will be severely undermined in the near term. Any automaker wishing to exceed its footprint targets can do so by using banked credits or paying more responsible automakers for their excess credits, and history shows that they will. The CAFE program is now only generating small incremental improvements in fuel economy, and between 2018 and 2019 it apparently generated no improvement whatsoever, with industry performance holding steady at 253 grams per mile. Delaying these expirations any further is indefensible. Plenty of credits will still be available to provide a reasonable amount of flexibility if we allow these credits to expire, as originally planned, after five years.

Over half of the industry credit deficit in 2019 was due to one irresponsible automaker, Chrysler, know then as Fiat Chrysler Automobiles (FCA), now embedded in the Stellantis conglomerate. FCA's 2019 fleet was assigned a very lenient target of 275 due to the large footprints of its popular models, and it fell far short, performing at an abysmal 303. Their poor performance generated a deficit of 13,345,869 megagrams, which was roughly 56% of the entire industry shortfall that year. The failure of FCA's fleet of over 2 million vehicles was almost completely offset by one small automaker that only sold 125,538 vehicles, Tesla, which earned 11,070,481 credits exploiting the overly generous rules governing electric vehicles. Since the onset of the supposedly rigorous 2012 CAFE standards, FCA has openly ignored its responsibility to improve the fuel efficiency of its fleet, maintaining compliance year after year with purchased credits. They ended 2019 with an enormous bank of 47,069,423 credits, more than any other automaker, having purchased 82,128,881 credits over the years. General Motors has purchased 10,677,251 credits during the same timeframe. The EPA is not authorized by the Clean Air Act to collect civil penalties from automakers as an alternative to meeting their emission standards, but the ability to purchase compliance credits from other automakers provides the same destructive pay-to-pollute benefit. Delaying the expiration of the credits that expire in 2021 extends inappropriate leniency to the brands of Chrysler, by far the most irresponsible large automaker, which has 19,348,175 purchased credits set to expire that year.

The EPA's justification for maintaining the glut of compliance credits is highly questionable. The proposal states that the expirations are being delayed in order to compensate for the large stringency increase that will occur in 2023 and then be followed by more increases the following three years. The argument includes the silly notion that automakers only had two years to plan for the large 2023 stringency increase, and that extra flexibility is in order to compensate for the lack of notice, two years being seen as a short period of lead time for automakers to make adequate plans. None of this makes any kind of sense. Automakers do indeed make their plans well in advance, and Trump's rollbacks weren't even finalized until 2020, and they were subject to the uncertainties of legal challenges. It is not as if automakers adjust their fleet mixes and model designs at the drop of a hat to please the EPA. Most automakers sell as many gigantic gas-guzzlers as they possibly can 7 no matter what the EPA decides, counting their ample banks of compliance credits after the EPA does its yearly calculations. Their ongoing advertisement campaigns are more than enough proof that they hope to maximize the sales of their largest, most profitable models, just as they always have. If it looks like they might be running low on credits, they can purchase more from Tesla, which is sure to have plenty for sale, or from Honda, the most responsible large, conventional automaker. The automakers don't have to change their plans one bit. If these credit expirations are delayed, the credit glut will be maintained at a very high level. While they are using up credits that would otherwise expire, automakers will be building up their credit banks quickly in 2021 and 2022 as the Trump Administration's nominal stringency increases go into effect. By the time 2023 rolls around, the credit glut will have exploded. The only reasonable argument for delaying the expirations is that the glut is already so enormous that it doesn't really matter if it gets even bigger. I emphatically reject that idea. The glut needs to be brought under control.

The leniency of the Trump standards will be accompanied by increasing EV adoption, inflating the glut of credits even further as more and more automakers begin to enjoy the excessive windfall credits generated by their own electric vehicles. Ford already has orders for over 120,000 F-150 Lightning EVs. General Motors might be selling electric Hummers along with its popular Mustang Mach-E. If the current rules regarding EVs remain in place, these vehicles will generate an extraordinary number of compliance credits, removing any restraint the stringency increases might place on the conventional models in their fleets that fail to meet their footprint targets. There simply is no rational justification for delaying the scheduled expiration of these credits. The glut of credits is going to be larger than it has ever been, severely undermining the stringency increases. The CAFE framework was designed to act like a cap-and-trade system. It wouldn't really matter which automakers improved efficiency and which did not, nor did it matter which models in an automaker's fleet provided emission reductions as long as some did. Compliance credits could be earned, purchased, and banked to provide flexibility. As long as the stringency of the footprint curves continued to increase, collective carbon dioxide reductions would be insured. A company could evade improving its fleet by purchasing compliance, but not forever. Eventually, the tightening of the footprint targets would leave its fleet further and further behind and its pay-to-pollute strategy would become unsustainable. Sounds reasonable.

But the EPA cannot deny that the framework is not functioning according to its theoretical design. Electric vehicles are generating far more compliance credits than they deserve because they are not held accountable for their upstream emissions, earning an automatic zero on their two-cycle tests. The generous credit windfall has then been doubled because of the credit multiplier. The theoretical cap-and-trade system leaks carbon dioxide, failing to deliver an actual cap on CO2 emissions. While it may be true that all automakers have been forced to take the standards seriously to some degree, real-world fuel economy improvements have fallen far short of the CAFE program's promises. Fuel economy was supposed to double from 27 mpg to 54 mpg by 2025, preventing huge quantities of CO2 from entering the troposphere. But by the EPA's own admission, real-world fuel economy only improved 7% from 2012 to 2019. These meager gains averaging roughly 1% a year occurred while the Obama Administration's supposedly stringent rules were in place, and during this same period annual gasoline consumption increased from 3.2 to 3.4 billion barrels. The failure of the program is due to the inherent leniency of the footprint model, the overly generous credits generated by BEVs, and the excessive flexibility of credit trading. Automakers appear to keep up with the standards, but when all is said and done the program fails to deliver. Delaying the 8 expiration of credits compounds that failure when the EPA should be looking to correct it. The Earth needs these emission reductions right now, and U.S. gasoline consumption is not going down. [EPA-HQ-OAR-2021-0208-0692-A1, p. 5-8]

Commenter: Rivian Automotive, LLC

Do Not Extend Credit Carry-Forward. Credit averaging, banking, and trading provisions have historically been a reasonable and important compliance flexibility, particularly when the vehicle emissions standards finalized in 2012 were promulgated. At the time, industry was required to achieve unprecedented emissions reductions and various flexibilities were appropriate to aid in the transition to a newly ambitious regulatory paradigm.

In a much different context, EPA now proposes to extend the conventional five-year "carry-forward" window for credits earned in MY 2016-2020. The proposal argues that an extension of the carry-forward provision is warranted as part of the rulemaking in part to help "address any potential lead time issues" manufacturers could face in meeting the newly revised standards and that "there is precedent for extending credit carry-forward."6 These arguments are unpersuasive. Simply because there is precedent does not mean that an action continues to make sense. Additionally, the existing program of less stringent vehicle emissions standards—the "SAFE Rule"—was only finalized in March 2020. Automakers adhered to the previous 2012 standards, more stringent even than the current EPA proposal, until that time. Given the brief period that has elapsed since finalization of the SAFE Rule, it seems unlikely that automakers would experience any lead time issues developing and tooling compliant product portfolios. They likely would not have had sufficient opportunity to unwind business plans previously developed to meet the standards of the 2012 rules, which in turn should be adequate to the task of complying with EPA's current proposal. Extending credit carry-forward is therefore unnecessary. [EPA-HQ-OAR-2021-0208-0274-A1, p. 3]

Commenter: Southern Environmental Law Center

EPA must also ensure that the credit structure adopted is carefully designed so that the stringency of standards is not unnecessarily diluted. To this end, EPA should strongly consider discounting credits generated during model years 2021 and 2022 and should not extend the five year carry-forward period for such credits, due to the substantial weakening of the GHG emissions standard under the Trump administration's SAFE Rule. [EPA-HQ-OAR-2021-0208-0244-A1, p. 2]

When utilizing compliance flexibilities, EPA must ensure the credit structure does not unnecessarily dilute the stringency of the standards. The credit system is a long-standing component of the federal tailpipe emissions standards. It allows vehicle manufacturers to average, bank, and trade credits generated for overcompliance with the standards in order to design compliance strategies that best suit their unique fleet composition. These existing compliance flexibilities mean that even manufacturers that have not invested in EVs and other advanced technologies to-date have ample ways to comply with the more stringent standards being considered.

It is critical that EPA carefully construct the credit system in a way that balances compliance flexibility and innovation incentivization with the inevitable loss of stringency of the standards resulting from the use of credits. This is especially important during the transition from the substantially weaker SAFE Rule standards for model years 2021 and 2022. As noted in EPA's analysis and discussed above, it is unlikely that many vehicle manufacturers have altered their design and engineering plans developed to comply with the 2012 Rule. This means manufacturers may generate a substantial amount of overcompliance credit while the SAFE Rule is in effect during model years 2021 and 2022. Not discounting credits generated during these model years would be problematic and is likely to effectively weaken the GHG emissions standards for many years in the future. For these same reasons, EPA should not extend the five-year carry-forward for credits generated in these model years.[EPA-HQ-OAR-2021-0208-0244-A1, p. 6]

In order to ensure the stringency of the standards, EPA should also adopt several changes to the standards' compliance flexibilities. The substantial relaxation of GHG emissions standards under the Trump administration's SAFE Rule means EPA should discount credits generated during model years 2021 and 2022, and should not extend the five-year carry-forward period for such credits. [EPA-HQ-OAR-2021-0208-0244-A1, p. 8]

Commenter: Tesla

EPA Should Not Extend the Lifetime of Previously Earned Credits. In its proposal, EPA extends the lifetime of existing credits generated in MY 2016 by two years and MY 2017 and beyond by one year. Such a proposal rewards manufacturers that have not adequately moved to deploy technologies in the U.S. to meet the past performance standards. This is highlighted by the fact that in 2011 auto manufacturers received 'a one-time carry-forward of unused MY 2010-2016 credits through MY 2021.'166 Allowing MY 2016 and MY 2017 credits to extend out for use in compliance years MY 2022 and 2023 undercuts the near-term stringency of the agency's proposal. Tesla's modeling estimates the extension of the MY 2016 and 2017 credit bank will result in a reduction in stringency of 4.3 g/mi in MY 2023. See Figure 1. Tesla notes that the one-year extension of the credit lifetime for model years beyond MY 2017 will further reduce stringency by another ~5 g/mi.

Additionally, the credit lifetime extension will also lessen the immediate value of earned credits in the trading market as underperforming manufacturers now may have greater opportunity on when to deploy credits. Operating under a consistent set of credit lifetime regulations, manufacturers over complying have been able to enter a robust credit marketing, basing credit value and need, in part, on a five-year lifetime. Under the proposal, the immediacy of the market will diminish, meaning less revenue and opportunity for overperforming manufacturer that seeks to utilize credit revenue sales to invest in increased manufacturing of advanced technology vehicles.

Like the other proposed flexibilities, this proposed change in credit lifetime reduces the standard's stringency, diminishes the level of investment going back into advanced manufacturing, and only serves to reward those manufacturers that delay deploying advanced technologies. Moreover, it retroactively undermines the value of Tesla's existing credits and penalizes Tesla's settled expectations as to the value of those credits.167 As courts have repeatedly reaffirmed, agencies generally may not promulgate retroactive rules,168 and when a regulation interferes with a party's reasonable investment-backed expectations, as the proposed rule would here, such action could rise to the level of a taking in violation of the Fifth Amendment.169 [EPA-HQ-OAR-2021-0208-0278-A1][pp.19-20]

167 In doing so, EPA's proposal upends Tesla's reliance interests related to the expected value of those credits. EPA's failure to consider those reliance interests would be arbitrary and capricious. See Dep't of Homeland Sec. v. Regents of the Univ. of California, 140 S. Ct. 1891, 1913 (2020) ('When an agency changes course … it must be cognizant that longstanding policies may have engendered serious reliance interests that must be taken into account. It would be arbitrary and capricious to ignore such matters.').

169 Whether a taking has occurred is determined by consideration of the extent to which the government action interferes with reasonable investment-backed expectations, along with the economic impact of the action and the action's character. See Ruckelshaus v. Monsanto Co., 467 U.S. 986, 1005 (1984) (quoting PruneYard Shopping Center v. Robins, 447 U.S. 74, 83 (1980)).

Commenter: Toyota Motor North America, Inc. (Toyota)

Averaging Banking Trading – Extended Credit Life Needed to Manage Stringency Jump. The proposal notes Averaging Banking and Trading allows more stringent standards than otherwise could be considered by providing manufacturers an important tool to resolve lead time and feasibility issues, and that the targeted extension of credit carry-forward is appropriate considering the stringency and implementation timeframe of the proposed standards. 20 Toyota agrees extending the life of credits manufacturers have earned from 2016 to 2020 model year can help manage the short lead time provided to comply with the proposed 10% stringency jump between 2022 and 2023 MY and the required annual improvements that follow. Well established design cycles dictate product cadence and limit the opportunities for new technology to be introduced between now and 2026 model year. About one-fifth of the fleet is redesigned each year, and therefore the compliance burden of rapidly increasing standards will fall significantly on a few models, many which are already well into product development. We agree with EPA that "it is again appropriate in the current context to provide a targeted, limited amount of additional flexibility to carry-forward credits into the 2023-2026 MYs, to ease the manufacturers' transition to these more stringent standards". 21 [EPA-HQ-OAR-2021-0208-0531-A1, p. 11-12]

Commenter: Union of Concerned Scientists (UCS)

Industry's ability to bank and use credits for compliance. A significant strategy for industry compliance with the greenhouse gas emissions standards to date has been to rely upon the use of overcompliance credits, either from a manufacturer's own credit bank (via credit transfers) or a competitor's (via credit trading). Credits generated through overcompliance are generally expected to have a lifetime of five years,15 and manufacturers have up to three years to address any deficits (including through credits carried back from model years following the deficit).

There are a number of flexibilities around the banking and trading provisions that enable liberal usage of credits. For example, credits and deficits are generated at the passenger car or light truck fleet level—this allows a manufacturer to use credits banked in prior years to offset deficits from a fleet in a given year, even if the other fleet generates credits. The net result of this is to effectively extend the lifetime of banked credits.16 Additionally, unlike the Corporate Average Fuel Economy (CAFE) program, credits are freely transferrable between fleets with no limit, which allows more flexibility if one fleet is at a significant deficit for an extended period of time. And finally because Tesla is an all-electric manufacturer, one now building and selling a significant share of credits as a result of the MY2017-2021 EV multipliers and a manufacturer which will continue to earn credits under any near-term standard, there will be a non-trivial trove of credits for some manufacturer(s) to purchase during this rule, should compliance be found challenging.17 [EPA-HQ-OAR-2021-0208-0277-A1, p.6]

Credit lifetime extension. EPA is once again proposing to extend the lifetime of credits beyond the five-year timeframe. It is worth considering both the impact of previous extensions and the necessity of this one. Both topics are discussed below.

The impact of the ‘one-time’ credit extension for MY2010-2015. While finalizing the MY2017-2025 greenhouse gas standards, EPA finalized a ‘one-time CO2 carryforward beyond 5 years, such that any credits generated from MYs 2010 through 2016 will be able to be used to comply with light duty vehicle GHG standards at any time through MY 2021.’65 The agency claimed extending the credit lifetime in this way ‘allows additional flexibility, encourages earlier penetration of emission reduction technologies sooner than might otherwise occur, and does so without reducing the overall effectiveness of the program.’66 However, this turned out to be incorrect.

The impact of the MY2010-2015 credit lifetime extension was compounded by the awarding of early credits for MY2009-2011, for which vehicles already planned (and even sold!) by manufacturers received retroactive credits. All told, this gave industry an absolutely massive cache of free credits at the start of the program, totaling 209 million Mg, of which 119 million Mg are eligible for the credit lifetime extension.67

The majority of early credits should have expired, limiting the damage of the credit bonanza EPA gave away at the start of the program. Unfortunately, the agency’s decision to grant a one-time extension has allowed at least 60 million credits to stick around beyond their expiration according to UCS analysis—because these credits were earned for status quo performance, the impact of this extended life only further diminished the stringency of the program.

The data speaks quite clearly to the impact of this credit extension: right when the program was meant to be more binding and spur technology advancement, manufacturers actually did less because they had amassed a tremendous credit bank from which they could simply draw upon in lieu of additional technology deployment. Even without the early credit program and one-time credit lifetime extension, manufacturers would have remained in compliance with the greenhouse gas program (Figure 14) [Figure 14 can be located at docket number EPA-HQ-OAR-2021-0208-0277-A1, p. 35].

The fall-out of artificially allowing manufacturers to kick the can down the road rather than comply is perhaps most clear when looking at a company like Toyota—Toyota amassed the largest number of early credits, and its light truck fleet has been running a deficit since 2012, largely because they neglected to make major improvements to an engine platform used throughout its light truck fleet.68 Toyota has used its large credit bank to offset these deficits, and yet the company has so many credits left over that they have recently been selling them to companies like Stellantis and Mercedes, who have relied on such credits for compliance for nearly the entire time this program has been in place rather than take the step of selling efficient vehicles as required.69

Modeling of the proposed credit lifetime extension. As at the start of the greenhouse gas program, EPA is once again proposing a credit lifetime extension, claiming that the provision 'provides greater flexibility for manufacturers in using the credits they have generated through overcompliance.'70 However, the manufacturer with the largest credit balance for MY2016-2019 is FCA, whose credits come not from overcompliance but from purchasing credits from Tesla explicitly to avoid significant technology improvements to its vehicle fleet. Moreover, while no doubt any given industry loophole would 'provide greater flexibility for manufacturers,' EPA did not actually establish whether or not such an extension is necessary for compliance with its proposed rule, since the agency did not model the extension.71

UCS modeling indicates that the credit lifetime extension is needed neither to comply with the Preferred Alternative nor Alternative 2 (Figure 15). Even under suboptimal credit utilization (not shown), the Volpe model was able to comply with the Preferred Alternative with the same level of technology adoption as outlined in § I.c. Under optimal credit utilization, the industry is able to comply without the credit lifetime extension and still enter MY2027 with a credit bank of 44 million Mg, plenty of sufficient headroom to handle additional increases in stringency. For Alternative 2 that bank is reduced to just under 12 million Mg. [Figure 15 can be located at docket number EPA-HQ-OAR-2021-0208-0277-A1, p. 37]

Because our modeling indicates that the credit lifetime extension is neither necessary for compliance with the Preferred Alternative nor the more stringent Alternative 2, the extension serves primarily as a loophole and risks repeating the type of harm caused by the first credit lifetime extension, which has delayed technology deployment. [EPA-HQ-OAR-2021-0208-0277-A1, pp. 34-37]

15 The 2012 regulations allowed credits earned for MY2010-2015 not to expire until after MY2021, in a 'one-time CO_2 carryforward beyond five years' (77 FR 62648).

16 For example, say Manufacturer A has a bank of 10,000,000 credits earned in MY2016. In MY2021 A's passenger car fleet generates a deficit of 10,000,000 credits, while their light truck fleet generates 8,000,000 overcompliance credits, yielding a net deficit of 2,000,000 credits. If credits were applied to the manufacturer's fleet in total, just 2,000,000 credits would be applied from MY2016, the remaining 8,000,000 credits in MY2016 would expire (after five years), and no credits would be earned for Manufacturer A in MY2021. Instead, the transfer is applied at the passenger car fleet level—all 10,000,000 MY2015-vintage credits are applied, so none expire.

And that leaves 8,000,000 credits earned by the light truck fleet to be banked for use up through MY2026, even though the manufacturer actually was at a net deficit in MY2021.

17 In 2019, Tesla earned over 11 million Mg of greenhouse gas credits, and in total has sold nearly 40 million Mg (EPA-420-R-21-003). Tesla has previously sold credits to Fiat-Chrysler (now Stellantis), General Motors, and Volkswagen—other large manufacturers could certainly avail themselves of this strategy as well in the future.

EPA Response

EPA is adopting a one-year credit carry-forward extension from five to six years for MY 2017-2018 credits, to allow their use through MYs 2023-2024, respectively. Comments regarding EPA's proposed credit carry-forward extension as well as EPA's response to those comments are provided in section II.A.4 of the preamble.

EPA received comments from the Alliance that EPA should allow manufacturers to petition EPA for an additional fourth year of credit carry-back to provide a pathway for manufacturers who may be at risk of exceeding the three-year window to cover a model year deficit to petition the Administrator for one additional model year of credit carry-back. The Alliance is concerned that there may be issues with supply base and industrial capacity that could negatively impact EV launch dates or volumes, which could put credit carry-back plans at risk. In response, EPA did not propose or seek comment on changing the current 3-year carry-back provision. Therefore, EPA is not making any changes in the Final Rule to this provision. Further, EPA believes that three years is a sufficient period of time to plan for and make up any deficit. The three-year credit carry-back provision is a way for manufacturers that planned to meet their fleet average standards but fell short for unforeseen reasons in a model year to avoid being found out of compliance for that model year. Manufacturers are allowed to cover the deficit with future credits earned over the next three years. EPA believes that a manufacturer that enters a carry-back situation should make up the deficit in the three years provided and that providing the possibility of a fourth year may encourage manufacturers to plan not to make up the deficit until the third or even a possible fourth year.

Chemours commented that EPA should make available additional information regarding credits. EPA disagrees with Chemours comment that the "current amount of information available is insufficient to allow the broader market and the public to understand how the generation and use of credits is occurring." At its discretion, EPA releases an annual report that details the generation and use of credits in the GHG program including the type of credit and amount of credits generated by each manufacturer. It also provides the number of credits used by the manufacturer or traded to another manufacturer.[20] It is unclear to EPA what additional information Chemours is seeking. Chemours states "Because credits are interwoven with the overall compliance of vehicle OEMs with GHG emission targets, clearly understanding how the

---

[20] See "The 2020 EPA Automotive Trends Report, Greenhouse Gas Emissions, Fuel Economy, and Technology since 1975," EPA-420-R-21-003 January 2021.

credit market is functioning is vital information for all market segments and the general public to understand." EPA has occasionally been asked for more details on specific credit trades, especially on the price of credits. EPA, however, does not require manufacturers to provide that information to EPA, only the volume of credits traded in a given model year. The price paid by one manufacturer to another as part of credit trading is not relevant for determining compliance.

Doug Peterson commented that extended credit carry-forward "should be vetted publicly, as the proposed change has great significance that is closely related to the stringency increases and the effort to accelerate the adoption of zero emission vehicles and that it should not be subject to EPA's administrative discretion alone." In response, the credit carry-forward provisions are specified in EPA's regulations and EPA sought to change those regulations through this notice and comment rulemaking, providing interested stakeholders an opportunity to comment. The credit carry-forward period is clearly specified in the regulations and not subject to EPA administrative discretion. In fact, EPA has modified extended carry-forward from the proposal, making the extension narrower, after considering comments as part of the rulemaking process.

Mr. Peterson commented also that "since the onset of the supposedly rigorous 2012 CAFE standards, FCA has openly ignored its responsibility to improve the fuel efficiency of its fleet, maintaining compliance year after year with purchased credits." Mr. Peterson also commented that "EPA is not authorized by the Clean Air Act to collect civil penalties from automakers as an alternative to meeting their emission standards, but the ability to purchase compliance credits from other automakers provides the same destructive pay-to-pollute benefit." The commenter is correct that EPA does not have authority under the CAA to collect civil penalties in lieu of compliance, However, EPA disagrees with the characterizations that purchasing GHG credits is not legitimate way to meet the GHG standards. Under the credit trading provisions of the GHG program, the environment is on net "whole" in that in order for one manufacturer to purchase credits (in lieu of adding GHG-reducing technologies), another manufacturer must over-comply (by adding more GHG-reducing technologies). Contrary to the commenter's point, FCA has not ignored its responsibility under the GHG program since it has complied with the GHG program through mechanisms provided in the regulations. Purchasing credits is a legitimate way to meet the standards. Also, purchasing credits generated by another manufacturer though overcompliance differs fundamentally from paying fines in CAFE since CAFE fines are not based on overcompliance by another manufacturer.

In response to Southern Environmental Law Center comment that credits generated in MYs 2021-2022 should be discounted, EPA does not believe that discounting is necessary in light of the more stringent standards EPA is adopting for MYs 2025-2026. EPA is finalizing standards for MYs 2025-2026 that are significantly more stringent than proposed. As part of the modeling and analysis of the more stringent final standards, EPA has taken into consideration the opportunity for manufacturers to generate credits in MYs 2021-2022 and believes that standards are appropriate without such discounting (see section III of the preamble).

EPA's response to Tesla's comments regarding the potential impact of a credit life extension on the value of credits is provided in preamble section II.A.4. Regarding Tesla's comments on reliance interests, EPA has narrowed the multiplier credits from proposal to final rule to focus those credits on MYs 2023-2024, where lead time is shortest, which directionally responsive to Tesla's concerns. To the extent that regulatory changes affecting the price of credits in an open market can be considered cognizable reliance interests, EPA has generally considered those interests and determined that the standards are reasonable given the circumstances, as discussed in sections III and VI of the preamble. EPA's action is not retroactive, as it only affects when credits are available in future model years.

Commenter: Advanced Engine Systems Institute (AESI)

Advanced Technology Multiplier Credits. EPA has recognized that advanced ZEV technologies have been around for many years and are no longer new. As a result, the 2012 midterm review and subsequent SAFE LD GHG rules phased out advanced technology multiplier credits for PHEVs, BEVs and FCEVs in MY 2022. The current multipliers provided for advanced technologies do not reflect actual in-use CO2 reduction benefits and therefore ultimately result in fewer advanced technology vehicles offered in the market. The numerous EV production commitments by OEMs suggest that the continued extended use of multipliers could reduce technology introduction for ICE, electrified and electric powertrain, while having minimal cost or environmental impact before they are fully phased out in MY 2025. [EPA-HQ-OAR-2021-0208-0267-A1, p. 2]

Commenter: Alliance For Automotive Innovation

Advanced Technology Vehicle Production Multipliers. Auto Innovators supports EPA’s proposal to extend the advanced technology vehicle production multipliers, particularly those for EVs (“EV Multipliers”). This existing policy flexibility has proven effective in incentivizing increased production and sales of EVs. Auto Innovators is aligned with EPA in recognizing that EV Multipliers have provided, and can continue to provide, a meaningful incentive for manufacturers to help drive additional EVs into the marketplace and to help overcome ongoing market headwinds. Auto Innovators agrees with EPA that electrification will play an increasingly important role, not only for the duration of this rule, but also for 2027 and later. Helping to bring technology to market that will be critical in delivering long-term, sustainable GHG reductions, even at the potential cost of near-term reductions, is a prudent policy choice for the current period during which EVs face higher incremental costs and ongoing challenges with public fueling infrastructure.

EV Multipliers have proven to be a successful incentive. EV Multipliers were originally limited to MYs 2017-2021. Through MY 2021, EVs were expected to be an emerging technology with limited customer acceptance due to higher upfront costs and a lack of sufficient public charging infrastructure. To help overcome these market barriers, the EV Multiplier provided a compliance incentive attractive to manufacturers, which in turn helped drive investment and deployment of volume beyond what might otherwise have been achieved. As EVs were expected to be low-volume through MY 2021, EPA did not cap or otherwise limit the potential effect of the EV Multiplier as there was not a concern for excessive program degradation. Through MY 2019, the 2020 Trends Report demonstrates that the EV Multiplier is being broadly used by many Comments from Alliance for Automotive Innovation Docket ID Nos. EPA-HQ-OAR-2021-0208 and NHTSA-2021-0053 September 27, 2021 17 manufacturers, and that the overall levels of credits, while meaningful, are not excessively detracting from GHG reductions.46 This illustrates that EPA met the two goals of creating a flexibility that is useful and not excessive in impact.

EV Multipliers remain a valuable tool to incentivize deployment of electric vehicles. Some stakeholders oppose the adoption of EV Multipliers on the principle that excessive crediting of electric vehicles will allow manufacturers to cease improvements in conventional technology or to even “backslide” on emissions.

A recent unpublished paper by Dr. Kenneth Gillingham47 provides an analysis of the potential impacts of EV Multipliers and potential problems with excessive crediting. Auto Innovators has not fully assessed the modeling presented within the paper, but the paper appears to provide an intuitive assessment that as EV costs (and manufacturer profitability) begin to converge with conventional ICE vehicles, the policy value of an EV Multiplier diminishes and could lead to increased overall fleet emissions. It is important to note, however, that the author appears to focus on cost parity and does not account for challenges with “utility” parity, meaning effects associated with market friction such as consumer concern over lack of public charging or concern with limited EV range or capability are not considered. Environmental advocates have cited this paper in opposition to EV Multipliers. In response, we draw EPA’s attention to a key takeaway: when EVs are less profitable in the near-term and market share is low, there is “substantial induced innovation” and EV market share is likely to increase with higher EV Multipliers.48 We posit that this is the very condition which EV technology and markets have experienced through MY 2021 (i.e. much higher costs and low market share) and that EVs may continue to experience, albeit at a potentially reduced level of disparity, through MY 2026.

Auto Innovators acknowledges that EPA must balance the incentivizing effect of an EV Multiplier in helping to overcome market barriers such as higher costs and limited refueling infrastructure against lower GHG and other benefits. EPA has accounted for these impacts in its benefit-cost analysis. EPA has also outlined the need to examine technology and market conditions anticipated for MYs 2022-2026 relative to today’s conditions.49

Furthermore, EPA will need to consider the impact of a continued EV Multiplier on broad market success for the time period following this rule. Auto Innovators believes that while many of the underlying conditions of higher costs and consumer concerns will improve through MY

2026, some will linger in the marketplace and therefore, the multiplier will still play an important role in helping to drive additional EV volume into the market.

Recent market data reveals that across the U.S., the overall adoption rate of electric vehicles remains relatively low at 2.5 percent new vehicle market in 2020.[50] One of the root causes of low adoption has been the higher costs associated with electric drive technology. For example, the National Academies of Sciences, Engineering, and Medicine ("NASEM") reported that in 2018 "[t]he incremental cost for BEVs are at least $8,500 for the medium car (i.e., $36,800 BEV150 versus $28,300 conventional) to about $26,000 for the long-range SUV (i.e., $57,000 BEV300 versus $31,000 conventional)."[51] These values from NASEM indicate cost disparities on an order of one third to over two thirds of the cost of conventional vehicles. This is far from price parity. Even with rapid reductions in annual costs over the past few years, manufacturers and consumers have faced significantly higher costs for EVs.

In the GHG NPRM, EPA describes that due to projected growth and expansion of the EV marketplace, electric vehicles should, through MY 2026, begin moving from an emerging technology into a transitional growth phase.[52] Manufacturer investment and increasing industry scale is expected to deliver cost reductions through the time period covered by the GHG NPRM. The NASEM Report projects that anticipated prices for EVs for segments such as small and medium cars could approach parity by 2024-2026,[53,54] but this would be for shorter range models, which are less attractive in the marketplace. For more popular segments such as crossover, SUV, and pick-up trucks, with ranges of 200+ miles, NASEM projects that these segments may not achieve price parity until 2026-2030,[55] beyond the time period covered by this NPRM. The U.S. new vehicle market has shifted heavily into these segments[56] and further capability associated with increased towing, cold weather performance, and off-road capability may delay these projected price parity timelines even further than what is reported by NASEM. As such, for the duration of this rule, it can be broadly summarized that while improving, there is projected to remain a lingering price disparity between EVs and conventional models. This disparity continues to support the basis of the EV multiplier to deliver "substantial induced innovation."

Separate from the issue of cost, there are several points of friction that EVs have and may continue to struggle to overcome. NASEM includes a summary of EV purchase avoidance reasons in its report.[57] At the top of the list is location and availability of public charging infrastructure. Auto Innovators recognizes the efforts of many stakeholders, including many of our members, who have committed to expanding and improving the public charging experience. We are confident that efforts to broaden the availability of public charging will eventually help overcome this consumer concern. National recharging plans such as those envisioned within recently proposed Congressional funding bills will help to address this concern from consumers. Nevertheless, these remain significant and demonstrated barriers to adoption, and new charging networks will take many years of planning and construction to come online in the volumes needed to support ubiquitous availability. These are issues that, even with improving EV price parity, may continue to dampen consumer interest and further delay broad market adoption of EVs. Again, EV Multipliers have and will continue to prove to be a valuable compliance incentive that will help drive volume into the market even in the face of these headwinds.

The California Framework Agreements provide a model for EV Multipliers. The California Framework Agreements,58 which EPA cites as helping to demonstrate the feasibility of the proposed standards,59 provide a potential model for EV Multipliers. Those agreements provide enhanced EV Multipliers in MYs 2020-2021 relative to the current EPA GHG rules, and EV Multipliers in general for MYs 2022-2026.60 The agreements also incorporate a cumulative cap on credits equivalent to approximately 23 g/mile over MYs 2022-2025 (about 5.8 g/mile/year) or 32 g/mile over MYs 2022-2026 (about 6.4 g/mile/year).61

In contrast, EPA proposes new EV Multipliers for MYs 2022-2025 (one year less) and a much lower credit cap of 10 g/mile over four years (less than half that included in the California Framework Agreements).62 We believe the inclusion of EV Multipliers for MY 2026 and a higher cap would better recognize the current state of EV technology and markets, and incentivize additional EV production.

Auto Innovators recommends that EV Multipliers be included through at least MY 2026. We suggest that EPA include an EV Multiplier in MY 2026, and reconsider the need for such incentives beyond MY 2026 based on technology and market development in a subsequent rulemaking. This approach would better recognize the uncertain state of the EV market and complementary policies. It would also recognize the heterogeneity of manufacturer EV product plan development, where some manufacturers have already begun introductions and others are still developing EVs and would be most influenced by later incentives. Including EV Multipliers through MY 2026 would also be consistent with the California Framework Agreements, which EPA cites in support of its assessment of the feasibility of the proposed standards.63

Auto Innovators agrees that an EV Multiplier credit cap should be calculated on a cumulative basis. Presuming adoption of an EV Multiplier credit cap, Auto Innovators agrees with EPA's proposed approach to apply the cap on a cumulative basis. The proposed approach provides some flexibility for manufacturers that may not be as prepared as others to immediately introduce additional EVs.

If EPA accepts our recommendation to include an EV Multiplier in MY 2026, the cumulative cap should be increased. As previously described, Auto Innovators believes that an EV Multiplier will remain an appropriate policy tool to increase EV production in MY 2026. If EPA accepts our recommendation to include an EV Multiplier for MY 2026, we believe a higher cap should also be adopted to account for that additional model year to maintain the incentive value of the EV Multiplier.

The EV Multiplier credit cap should be increased in general. A cumulative credit cap of 10 g/mile provides little incentive to increase EV production unless the entire incentive is taken in a single or very limited years. Auto Innovators believes additional EV production can be incentivized by a higher credit cap while still balancing with the policy goal to maximize near-term GHG benefits. More specific concepts to balance the incentive aspects of an EV Multiplier with current technology and market conditions, and with the environmental impacts of such an incentive, may be provided by individual manufacturers in their own comments.

EV Multiplier credits should not be considered a means of increasing standard stringency. Auto Innovators is recommending that the EV Multiplier cap be increased in general, and potentially increased as a conforming change to the recommended inclusion of an EV Multiplier in MY 2026. However, we believe EV Multiplier credits should not be considered as a means of increasing or reason to increase the stringency of the standard.

Including EV Multiplier credits in an evaluation of the potential feasible levels of a GHG standard would effectively remove their value as an incentive, replacing it with a de facto requirement. In addition, not every manufacturer may make use of such incentives at the same time or to the same degree, depending on their product plans and how quickly they can be shifted based on the presence of such an incentive. EPA should keep EV Multipliers as an incentive to achieve the desired policy goal of increasing EV production and market share beyond that which would otherwise occur under the proposed standards. Therefore, Auto Innovators recommends that an increase in the cap should not result in more stringent standards. [EPA-HQ-OAR-2021-0208-0571-A1, p. 16-21]

Commenter: Alliance for Vehicle Efficiency (AVE)

AVE supports EPA's goal of offering advanced multiplier credits up until 2026 and recommends EPA offer additional performance-based credits to automotive manufacturers (OEMs) for any vehicle that exceeds the standards ahead of EPA's compliance timeline.

AVE supports performance-based credits to incentivize rapid adoption of emission-reducing technology in ICE vehicles. [EPA-HQ-OAR-2021-0208-0256-A1, p. 2]

Advanced Technology Multiplier Credits. AVE supports EPA's goal of offering advanced multiplier credits up until 2026 and recommends EPA offer additional performance-based credits to OEMs for any vehicle that exceeds the standards ahead of EPA's compliance timeline.

AVE continues to support performance-based standards that incentivize the development, and accelerate the adoption of, multiple emission reducing technologies to market. Performance-based credits would provide OEMs with greater flexibility and incentive to invest in cost-effective pathways to meet, or exceed, future standards.

The credits EPA is proposing will impact a small percentage of the U.S. fleet. By steering OEMs towards specific technologies that may only affect about 8% of the fleet by 2026 with extensive credits, EPA risks losing immediate and more extensive environmental improvements in exchange for estimated environmental gains years from now. EPA instead has an opportunity to accelerate the adoption of advanced vehicle technologies and reduce emissions from the vast majority of vehicles that will be sold between model years 2023 to 2026 with performance-based credits. [EPA-HQ-OAR-2021-0208-0256-A1, p. 3]

Commenter: Aluminum Association

The Association supports the continued incentivization of advanced vehicle technologies including the performance incentive on pickup trucks that allows for manufacturers to exceed their targets by faster adoption of new technologies and fuel efficiency solutions, including the wider use of mass reducing materials across their portfolio to extend vehicle range and/or support battery downsizing to reduce battery costs [EPA-HQ-OAR-2021-0208-0233-A1 p.4]

Commenter: American Council for an Energy-Efficient Economy (ACEEE)

The current regulations allow for a multiplier2 to be applied for BEVs and PHEVs through MY 2021. EPA proposes to extend these multipliers through MY 2025, albeit with a cap of 2.5 g/mi per fleet year. Automakers can additionally take advantage of up to 10g/mi per fleet year, so long as the sum of the credit for MYs 2023-2026 is not greater than 10 g/mi. This incentive awards credits for EVs in excess of actual emission reductions, with the result that each EV sold serves to reduce the emissions benefit of the standards. Keeping these provisions in the final rule would reduce the actual stringency of the rule by almost 3 g/mi annually for the four years it would be extended if manufactures take full advantage of the multipliers.

EPA initially adopted multipliers to encourage the development and deployment of EV technology. Circumstances have changed since then; almost every major automaker has announced plans to have a full range of EV options, produced at scale, in the next decade. Many of these automakers have committed to moving to a fully electric vehicle line-up and phasing out conventional vehicles. EV technology is clearly no longer in its infancy and extending the life of the EV multiplier will only serve to increase total emissions. EPA, in this NPRM, even admits that this incentive has only improved EV sales by approximately 0.5% a small benefit that is clearly not worth the increase in emissions (EPA 2021b)3.

Research has even shown that providing generous EVs credits can actually depress the market for EVs (Gillingham 2021). This is because the increased pool of accumulated credits, earned from the production of a small number of vehicles, lessens the need to produce more efficient vehicles to meet assigned targets. This can be seen in a simple mathematical example where an automaker plans to produce four vehicles and needs to meet a goal of 125 g/mi. If their EVs are treated as having zero emissions and the automaker's conventional vehicles have emissions of 200 g/mi, then they need to make two EVs to be in compliance without the presence multipliers. If EVs are given a multiplier of two, as is currently proposed, then the automaker only needs to make one EV to sell three conventional vehicles. While the real automotive market is more complex, the reality remains that treating advanced efficiency technologies, like EVs, as more than one vehicle artificially reduces the manufacturer's average emissions rate and allows the manufacturer to comply with the standard with fewer efficient vehicles. For these reasons, ACEEE strongly opposes the extension of the EV and PHEV multiplier credits. [EPA-HQ-OAR-2021-0208-0251-A1, pp. 5-6]

Eliminate the advanced technology multipliers for plug-in vehicles and full-sized pick-up trucks. [EPA-HQ-OAR-2021-0208-0251-A1, p.14]

2 This multiplier allows an electric vehicle to be counted as multiple vehicles for fleetwide average emission calculations and credit purposes. A multiplier of 2 allows one ZEV to be counted as 2 vehicles.

3 Page 110 of the NPRM 'We have also analyzed the impact of the advanced technology multipliers on BEV and PHEV penetration rates and have found that the impact on the fleet is less than 0.5 percent in any MY 2023 through 2026 (see RIA Chapter 4.1.3)'

Commenter: American Honda Motor Company (Honda)

Policy Incentives Supporting Further Electrification. Honda understands and supports the administration's desire to encourage a transition to electrified vehicles. These technologies can offer revolutionary, rather than evolutionary, levels of emissions reduction, and are widely regarded as necessary to drive transportation sector emissions to levels in line with mid-century climate goals.

Honda has ambitious plans to electrify its fleet. In April, our global CEO Toshihiro Mibe outlined Honda's vision to realize corporate carbon neutrality by 2050, driven in part by the electrification of our entire auto lineup in major markets around the world, including North America. Our company has set a vehicle sales target of 100% ZEVs in all major markets by 2040, with intermediate targets of 40% by 2030 and 80% by 2035. [EPA-HQ-OAR-2021-0208-0565-A1, p.6]

While these commitments are serious, sincere, and very much underway, it is important that the agencies not approach such announcements as foregone conclusions. Market adoption of electrified technologies currently average about 2 percent in the U.S.,14 placing a profoundly challenging and still uncertain industry transition in front of us in order to meet future climate goals. Industry's commitment to these technologies requires significant sustained investment, a challenge exacerbated by other capital-intensive headwinds such as connected, automated and shared mobility. Indeed, the number of strategic alliances being formed amidst such a competitive industry is informative of the immense costs and challenges associated with this transition. Policy incentives, such as sales multipliers, remain critical in spurring ongoing investment in the face of these challenges.

The agency has, for many years, recognized advanced technology multipliers as a viable tradeoff between near-term and long-term goals: 'The agency recognizes that the temporary regulatory incentives will reduce the short-term benefits of the program, but…believes that it is worth a limited short-term loss of benefits to increase the potential for far-greater game-changing benefits in the longer run.'15 We concur with this position.

At the same time, Honda shares concern about emissions benefits erosion resulting from excessive use of multipliers, and supports a thoughtfully designed program including an appropriate usage cap. Honda supports capping the benefit of advanced technology multipliers to avoid excessive programmatic erosion, but believes it is appropriate to increase their magnitude beyond proposed levels. The agency proposes a cap of 10 g/mi over a four-year (MY22-25) window, averaging 2.5 g/mi per year. By contrast, the California Framework agreement provides twice that level of incentive, at 30 g/mi over a six-year window (MY21-26), an average of 5 g/mi per year. We believe a sales multiplier incentive closer to that of the Framework agreement will drive further electrification in the face of market uncertainty, such that hopefully there will not be need for sales multipliers in subsequent (MY2027+) regulatory constructs. One alternative the agency may also wish to consider is pairing an increased cap with a lower multiplier value (e.g., 2.0x, 1.75x, etc.) for each technology. Doing so would limit programmatic erosion while continuing to incentivize higher volumes of electrified product in the market. [EPA-HQ-OAR-2021-0208-0565-A1, p. 7]

Some parties have cautioned that multipliers can amount to 'giveaways' if applied to vehicles that are already planned, pointing to industry electrification announcements as evidence for the lack of need of multipliers. Honda disagrees with this position. Planning cycles in the auto industry dictate that strategic decisions and investments be made well in advance of having a complete picture of future market landscapes. This presents strategic challenges for any vehicle technology, let alone a transition seeking to overcome the inertia of a century of petroleum use. While Honda is planning a suite of activities to help build a market for these products, again, the market is not guaranteed. Policy levers such as advanced technology multipliers can play an important role in driving continued investment in the face of market uncertainty. As shown in Figure 2 [Figure 2 can be found at docket number EPA-HQ-OAR-2021-0208-0565-A2, p. 8], multipliers have the potential to bring the cost-effectiveness of long-term technologies more in line with those of shorter-term technologies.16 This can help facilitate a virtuous cycle in which reduced technology costs, passed along to consumers, can further assist market uptake. [EPA-HQ-OAR-2021-0208-0565-A1, p. 8]

Commenter: BorgWarner Inc.

EV and PHEV Incentives. In principle, we support technology-neutral standards that focus on end objectives without picking winning and losing technologies. BEVs, PHEVs, HEVs and FCEVs are vehicles that offer environmental benefits at some cost to the consumer. Consumer acceptance has improved and continues to improve, but still needs significant encouragement due to factors such as BEV range and charging time, FCEV fuel availability, and infrastructure. Incentives to manufacturers and consumers are consistent with public policy objectives of encouraging these new technologies. These incentives can take the form of direct subsidies to the consumer, EV multipliers, and disregarding any upstream CO2 of electric vehicles for the manufacturers. While these incentives are by nature market distorting, BorgWarner recognizes that these incentives have been necessary to encourage the development of new technologies. However, consistent with our belief that technology-neutral regulations promote the most effective solutions to achieve societal goals, we strongly support the phase-out over time of any incentives for a particular technology. Therefore, we support the proposal to extend the advanced technology multiplier incentives for MYs 2022– 2025 with lowered credits and a sunset in MY2025. [EPA-HQ-OAR-2021-0208-0260-A1, p. 3]

Commenter: California Air Resources Board (CARB)

Specifically, U.S. EPA:

• should retain its proposed cap on the available advanced technology vehicle production multiplier credits for battery-electric vehicles (BEV), plug-in hybrid electric vehicles (PHEV), and fuel-cell electric vehicles (FCEV);

• but should decrease the per vehicle multipliers for model years 2023 through 2025;

• should not provide any multipliers for model year 2022 because of the relaxed emission standards; [EPA-HQ-OAR-2021-0208-0643-A6, p.7]

The Proposed ZEV Multipliers Should be Reduced. Although ZEV sales are projected to increase, they currently remain a minority portion and could benefit from continued incentives. U.S. EPA's emission standards incentivize various advanced technologies for reducing emissions through credit from production multipliers. The proposed standards would revive these kinds of incentives for advanced technologies to promote market penetration that were a feature of the National Program standards through model year 2021.109 These incentives took the form of production multipliers for electric vehicles, plug-in hybrid electric vehicles, fuel cell vehicles, and natural gas vehicles. The SAFE Final Rule allowed these multipliers to lapse, with the exception of natural gas vehicles for which it increased and extended the multiplier. The proposal would revive and extend the multipliers for model year 2022 through model year 2025 for BEVs, FCEVs, and PHEVs, and end the multiplier for NGVs after model year 2022.

CARB supports the appropriate use of multipliers to incentivize clean technology. But incentives for BEVs, PHEVs, and FCVs are not appropriate under the relaxed SAFE Final Rule standards for model year 2022 that will remain in place. This would effectively weaken the program for model year 2022 even more than was already done under the SAFE Final Rule, setting the nation even further behind in much needed GHG reductions. The multipliers should not be reinstated for that year, contrary to the proposal.

For model years 2023-2025, the proposed per car advanced technology vehicle multipliers are too generous to sufficiently incentivize zero-emission technology. Based on simple calculations, the proposed cap will be met with BEV sales of far less than 2% per year of manufacturers' fleets. Nationwide, many manufacturers already are selling ZEVs at or near these levels and as discussed above, manufacturers are poised to produce ZEVs in greater percentages. The multipliers should be set to require manufacturers to increase their production of ZEVs to receive the maximum credit allowance. For example, a BEV multiplier at 1.3 for model years 2023 and 2024 and 1.15 for model year 2025 would require a manufacturer to average BEV sales of approximately 8% per year to reach the full credits under the cap. Similarly, multipliers of 1.1 and 1.05, respectively, would require a manufacturer to average BEV sales of approximately 25% per year to meet the cap.110 U.S. EPA should revise the per car multipliers for BEVs, PHEVs, and FCEVs downward to effectively require a sales level that is above what typical manufacturers are expected to produce in order to properly incentive and reward those that achieve higher sales rates. The proposed cap should stay the same. This will adequately incentivize and reward increased ZEV sales in these key transitional years. [EPA-HQ-OAR-2021-0208-0643-A6, pp. 36-37]

Commenter: Center for Biological Diversity, Earthjustice, and Sierra Club

First, EPA should eliminate credit multipliers for EVs, PHEVs, and FCVs. Every EV, PHEV, and FCV automakers produce earns them large compliance benefits, since those vehicles reduce their overall fleet's GHG emissions. Multiplier credits, however, produce 'phantom emissions reductions,' by crediting automakers up to a factor of two vehicles for each vehicle produced, which necessarily decreases automakers' reductions from other vehicles in the fleet. In 2012, EPA granted multiplier credits to support the then-novel EV market, acknowledging that even while near-term emissions would increase, they would decrease in the long-term as the industry developed.33 From the beginning, EPA intended multiplier credits to be temporary, and they were set to expire in MY 2021. Yet in this proposal, EPA proposes to extend them for four additional years, through MY 2025.34

EPA should not adopt its proposed extension of multiplier credits, given the size of emissions reductions that would otherwise be captured by the rule. According to EPA, the new multipliers would reduce the stringency of its Proposal through MY 2021-MY2026 by about 6%--an amount exceeding one full year of emissions reductions.35 This represents 46 MMT of emissions over the lifetimes of MY 2021-2026 vehicles. 36 Moreover, multipliers are no longer serving their original purpose of incentivizing the production of more EVs. EV sales have surged despite the impacts of the pandemic and despite the minimal stringency increases set by the 2020 Final Rule.37 And manufacturers have already committed to producing vast numbers of additional zero- or near-zero vehicles. Nearly every automaker has announced multi-billion dollar investments; in total, their plans amount to as many as one hundred new and diverse electric vehicle types coming to market by 2025.38 Given these developments, recent analysis indicates that electric vehicles may account for as much as 19 percent of new vehicle sales as early as 2026.39

The EV future is here, and it will only continue to grow stronger. Additional nudges from EPA in the form of phantom credits are unnecessary, and will be counterproductive, since the huge numbers of multiplier credits generated allow automakers to comply with standards without producing more EVs.40 Because automakers have already committed many billions of dollars to make and sell EVs at levels exceeding any need for multipliers, multiplier credits worsen emissions without any benefit in return. Should EPA nonetheless finalize new multipliers, we urge EPA, at a minimum, to sunset them after MY 2024, not MY 2025, and also to end their carry-forward provisions at MY 2024. [EPA-HQ-OAR-2021-0208-0270-A1, pp.6-7]

Commenter: Center for Biological Diversity, et al.

As proposed in Alternative 2, EPA should eliminate credit multipliers for EVs, PHEVs, and FCVs. Every EV, HEV and FCV automakers produce earns them very large compliance benefits, as they reduce the greenhouse gas emissions of their average fleets. "Multiplier" credits, however, double up by counting each of these vehicles as more than one vehicle, and award phantom emission reductions (by up to a factor of two vehicles for each vehicle produced) for the non-existent vehicles. In 2012, EPA granted multiplier credits to incentivize manufacturers to develop and market these then-novel technologies and vehicles more rapidly. While acknowledging that multiplier credits lead to near-term emission increases, EPA anticipated greater emissions reductions in the longer run. Proposal, 86 Fed. Reg. at 43,756; 2012 Final Rule, 77 Fed. Reg. 62,812. EPA's Proposal stipulates that from the beginning, multiplier credits were designed to be "temporary" only. Proposal, 86 Fed. Reg. at 43,756. Anticipating matured technologies and rising electric vehicle sales long before the end of the 2012 rulemaking in 2025, EPA gradually phased them out, with the last, pared-back multipliers available for MY 2021 (.5 for EVs and FCVs and .3 for PHEVs and NGVs), and with none available thereafter. Id. at 43,755, 43,757. In the 2020 Final Rule, EPA did not change this result (except for natural gas vehicle credits, addressed below), and thus, all multipliers currently terminate at the end of MY 2021, just as EPA directed in 2012.

EPA now proposes to reinstate multiplier credits for EVs, PHEVs and FCVs for four more years, from MY 2022 through MY 2025, at the full 2012 rates through MY 2024 (at 2.0 for EVs and FCVs; and 1.6 for PHEVs), and at slightly lower rates for MY 2025 (at 1.75 for EVS and FCVs, and 1.45 for PHEVs). Proposal, 86 Fed. Reg. at 43,758. EPA proposes to cap them at 2.5 g/mile per manufacturer and model year for MYs 2022-2025, on average, not to exceed a cumulative total of 10.0 g/mile per manufacturer through MY 2025. EPA also proposes to permit manufacturers to allocate how much of the total 10.0 g/mile to use in any given year. Id. The new multipliers are to sunset at the end of MY 2025; once again, EPA states that multipliers are and always were intended to be "temporary." Id. at 43,757. According to EPA, even with the proposed cap, the new multipliers would reduce the stringency of its Proposal through MY 2021-MY2026 by about 6%. Id. at 43,759-60 & Fig. 7.142 Under EPA's Proposal, then, the new multipliers, whether taken at one time or over a number of model years, would create additional greenhouse gas pollution in an amount exceeding one full year of emissions reductions otherwise achieved under the proposed annual stringency levels.

Commenters urge EPA to remove the newly proposed multipliers. As EPA itself observes, multiplier credits increase pollution and were justified solely to incentivize the development of novel, advanced technology; indeed, EPA declares them to be inappropriate if they "provide a windfall" for building vehicles that would have been produced without them. Proposal, 86 Fed. Reg. at 43,747. Under this test, multipliers are inappropriate now. Electric vehicle technology has fully matured in the years since 2012. During the first half of 2021, EV sales have surged despite the impacts of the pandemic and despite the minimal stringency increases set by the 2020 Final Rule.143 And, as discussed above, manufacturers have already committed to producing vast numbers of additional zero- or near-zero vehicles. Nearly every automaker has announced multi-billion dollar investments; in total, their plans amount to as many as one hundred new and diverse electric vehicle types coming to market by 2025.144 Recent analysis indicates that electric vehicles may account for as much as 19 percent of new vehicle sales as early as 2026.145 Notably, automakers made their investment decisions and announcements before the publication of this NPRM and while the 2020 Final Rule—which provides no multipliers beyond MY 2021—has been in force. Thus, the prior justification for awarding phantom credits—the need to speed automaker investments and the maturation of EV technology—no longer exists.

Yet, the extra pollution internal combustion vehicle multipliers enable would continue to aggravate the climate crisis for the lifetime of those vehicles.

Indeed, as EV penetration increases, providing multiplier credits usable by the remaining internal combustion engine vehicles may impede the uptake of electric vehicles as well as slow the pace of emission reductions from ICE vehicles. Research indicates that multiplier credits, once EVs are "even remotely close to competitive" with conventional vehicles, are "more likely to actually reduce the incentive for automakers to sell electric vehicles" because their large multipliers enable automakers to comply with emission standards while selling fewer EVs.146 Bloomberg projects large EVs to achieve price parity with their fossil-fuel counterparts as early as next year, and in other segments by the end of the decade.147 With price parity fast approaching, multipliers may well have the opposite effect than what EPA intends.

We also note that, even though EPA's proposed multiplier credits would sunset at the end of MY 2025, EPA has not proposed to terminate or shorten their carry-forward lifetimes. Though the cap would prevent the total impact of the additional pollution from exceeding the total allowed, any multiplier credits not yet utilized for compliance through MY 2025 would continue to be available to erode real-world emissions reductions through MY 2030, despite an extremely robust electric vehicle forecast by then.148 A continuing carry-forward provision would run counter to EPA's own statement that multiplier credits should not act as industry windfalls. We urge EPA, at a minimum, to end the lifetimes of any multipliers it promulgates in the final year for which they are granted.

As part of its justification for new multiplier credits, EPA observed that in MY 2019, almost all companies used credits to comply with emission standards. Proposal, 86 Fed. Reg. at 43,757. But that is a non sequitur. The use of available credits is to be expected; it is a well-recognized and continually used business strategy and compliance pathway; indeed, EPA implemented them in 2012 with the express intent that automakers be incentivized to earn and use them. Id. at 43,756. Moreover, many if not most of the credits automakers have used would have expired otherwise, a result contrary to automakers' interests. In this situation, rational automakers can be expected to defer some investments in new emission reductions until after drawing down their banks of otherwise expiring credits. Thus, use of credits by "almost all" companies in MY 2019 does not show that they cannot meet the Proposal.

EPA estimates that the proposed multipliers, even when capped at 10 g/mile, will create an additional 46 MMT of emissions over the lifetimes of MY 2021-2026 vehicles. Proposal, 86 Fed. Reg. at 43,760. As discussed, these extra tons of emissions do not serve the purpose of leading to larger long-term emissions reductions as automakers have already committed many billions of dollars to make and sell zero- and low-emission vehicles at levels exceeding any need for multipliers.

As noted, Alternative 2 excludes all multiplier credits, and implementation of that alternative is feasible without additional lead time. Even if EPA were to finalize some other form of additional credits, it should not renew multiplier credits. But if EPA does so, commenters urge EPA, at a minimum, to sunset them after MY 2024, not MY 2025, and also to end their carry-forward provisions at MY 2024. After that model year, lead time cannot possibly function as a constraint on feasibility. [EPA-HQ-OAR-2021-0208-0651-A1, p. 61-63]

142 EPA notes that this emissions reduction is less than that built into the voluntary California Framework, which EPA estimates as producing a loss of 27% of the total emissions reductions under that agreement for MY 2021-MY 2026. Proposal, 86 Fed. Reg. at 43,759-60 & Fig. 7.

143 See Skidmore, Z., Electric Vehicle Sales Surge in 2021, Power Technology (updated Sept. 23, 2021), https://www.power-technology.com/news/electric-vehicle-sales-surge-in-2021/ (EV sales in the first half of 2021 have surged in all three top auto markets—China, the US, and Europe—representing 26% of new sales globally and 3% in the U.S), attached as Exhibit 93; Smith, C., March Sets All-Time US Monthly EV Sales Record, Atlas EV Hub Weekly Digest (May 24, 2021), https://www.atlasevhub.com/weekly_digest/march-sets-all-time-monthly-u-s-evsales-record/ ("If the first three months of the year are any indication, 2021 is shaping up to be a banner year for the U.S. passenger EV market. EV sales shot up by 95 percent in the first quarter compared to 2020 with March sales 2.5 times higher than the same month last year. The 41,627 all-electric and 13,626 plug-in hybrid vehicles sold in March make it the all-time highest month for U.S. passenger EV sales..."), attached as Exhibit 94; Adler, K., Global electric vehicle sales grew 41% in 2020, more growth coming through decade: IEA, IHS Markit (May 3, 2021), https://ihsmarkit.com/research-analysis/global-electric-vehicle-sales-grew-41-in-2020-more-growthcomi.html, attached as Exhibit 95.

Commenter: Center for Climate and Energy Solutions (C2ES)

The multipliers, credit carry-forward extensions, and incentives included in the proposal allow for significant flexibility in the means of meeting the standards. C2ES believes the advanced technology multipliers should be reinstated as proposed and supports the elimination of the multiplier for natural gas vehicles. However, given that (as EPA acknowledges in the proposed rule) the multipliers have the effect of allowing for slightly higher emissions in the near term, it is vital that they be implemented in a way that maximizes the acceleration of new zero-emission technology while minimizing the potential short-term increase in emissions. Multipliers should also be based on demonstrated data that they serve as incentives to spur the production of zeroemission vehicles without relaxing the overall emissions reductions produced by the standards. [EPA-HQ-OAR-2021-0208-0287-A1, p.2]

Advanced Technology Multipliers. C2ES supports the proposed reintroduction of advanced technology multipliers and the proposed multiplier cap and recommends extending the multiplier through MY 2026 to continue incentivizing automakers to scale up their share of zero emission vehicles. Prior to EPA’s proposal of the new standards, electric vehicles were projected to reach 10 percent of new sales by 2025 due to broader product offerings.19 Given major automakers’ electrification commitments and goals, and in conjunction with the proposed standards, this share is likely to be much higher. At this higher level of market penetration, the multiplier could then be phased out after MY 2026.

The proposed reinstatement of the advanced technology multiplier for battery electric, fuel-cell electric, and plug-in hybrid electric vehicles represents a market signal and strong incentive to support the continued development and scaling up of zero emission vehicle technologies. It encourages automakers to meet the fleet average performance standards through expanded offerings of zero emission vehicles, rather than through incremental adjustments to gasoline engine technology performance. While electric vehicle technologies have existed for decades, modern electric vehicles are a still-emerging industry. [EPA-HQ-OAR-2021-0208-0287-A1, p.6]

While plug-in hybrid electric vehicles are still responsible for tailpipe emissions when using the gasoline propulsion system, a recent study from the International Council on Clean Transportation found that, on average, plug-in hybrids are driven on battery alone for approximately 54 percent of their total miles traveled.20 This corresponds to the proposed initial multiplier of 1.6 for plug-in hybrid technologies, in comparison to the proposed multiplier of 2.0 for battery and fuel-cell electric vehicles. [EPA-HQ-OAR-2021-0208-0287-A1, p.6]

Additionally, ensuring that automakers are incentivized to bring more zero emission vehicles to market is essential to meeting mid-century goals. [EPA-HQ-OAR-2021-0208-0287-A1, p.6]

Commenter: Chemours Company (Chemours)

EPA should better “weight” projected GHG emission reductions from its proposed credit programs and reconsider how the proposed rule addresses credits that can be earned for the production of plug-in hybrid electric vehicles (“PHEVs”) and electric vehicles (“EVs”). Current information indicates that EPA may have underestimated the production and sale of such vehicles, resulting in excessive crediting of such actions. As a result, incentives for manufacturers to transition away from the use of HFC-134a are diminished and could conceivably result in a “switch back” to this high-global warming potential (“GWP”) refrigerant. [EPA-HQ-OAR-2021-0208-0232-A1, p. 3]

EPA Should Consider Other Actions Addressing GHGs as Part of Proposed Rule. EPA Should Limit and Better Weight Emission Credits to Reflect Actual GHG Reductions. EPA has proposed to retain multiplier incentives for advanced technology vehicles, including fuel cell vehicles (“FCVs”), plug-in hybrids (“PHEVs”) and electric vehicles (“EVs” or “BEVs”), subject to declining percentages a cumulative cap.47 Specifically, EPA is proposing to extend the 2.0 credit multiplier for EVs and FCVs from 2017-2019 MYs under the 2012 rule to MY 2022-2024 vehicles.48 EPA would also extend a reduced credit of 1.75 (available in MY 2020 in the 2012 Rule) to MY 2025, while reducing the multiplier to 1.0 in MY 2026.49 Concurrently, EPA is proposing to sunset the multipliers in MY 2026 so as to signal that it does not intend to include multipliers within any follow-on rules for MY 2027 or later MYs.

The rationale given for the extension of these multipliers is that “limited additional multiplier incentives are appropriate for the purposes of encouraging manufacturers to accelerate the introduction of zero and near-zero emission vehicles and maintaining momentum for that market transition.”50 But at the same time, EPA indicates that these multipliers are essentially the product of negotiation between automakers and the State of California and that they reduce the effective stringency of fleet average target levels for CO_2 emissions, albeit at a lesser rate than the California Agreement.51 EPA estimates that the total loss in stringency is equivalent to 46 million metric tons of CO_2.

EPA's projected rates of adoption of EVs and PHEVs within the LDV fleet vary according to manufacturer and vehicle type, but for passenger cars, EPA analysis indicates an overall 8.4% penetration rate for PHEVs and EVs combined in MY 2026. For some manufacturers in MY 2026, EPA is projecting zero or minimal penetration rates, while for other manufacturers (outside of Tesla at 100% EV production) adoption of PHEVs and EVs could constitute up to 19.5% their total fleet production for that MY.

There is considerable information, however, that indicates the transition to electric vehicle technology may occur at a much faster rate than EPA is projecting. IHS Markit's June 2021 forecast indicated that BEVs will make up 18.9% of total vehicle sales and PHEVs 4.3% of total vehicle sales by 2026, in part in order for manufacturers to be able to reach the higher electric vehicle that the Administration has articulated for 2030.52 This estimate is almost triple the amount of PHEV/EV sales that EPA is projecting as part of the proposed rule.

Otherwise, there is much private commentary that points in the direction of increased PHEV and EV production and sales. Consumer Reports indicates that "[a] record number of almost 100 pure electric vehicles (BEVs) are set to debut by the end of 2024 if all goes according to plan . . . 'These more affordable models have the potential to sway a significant percentage of the car-buying public toward buying an EV with their efficiency, performance, and lower ownership costs."'53 Taking a longer view, from 2011 to 2019, annual PHEV and EV sales "grew from fewer than 18,000 to more than 325,000, equivalent to an average year-over-year growth rate of 44%."54 Thus, given the number of incentives and state programs aimed at electrifying transportation, as well as the current market conditions noted above, it is possible to question why EPA's projected growth rate for PHEVs and EVs is not higher.

The other important aspect of EPA's proposed treatment of PHEVs and EVs is that the proposed rule would maintain a 0 g/mi imputed EV and PHEV tailpipe-only value.55 This valuation does not account for any upstream GHGs produced when electricity used to fuel EVs and PHEVs is produced (even while such upstream emissions contribute to the overall level of GHGs associated with the use of PHEVs and EVs). And while EPA is proposing to phase-down EV and PHEV credits, the proposed rule is silent with respect to the utilization of this imputed value in 2026 or thereafter. There is no consideration or proposal to phase down this imputed 0 g/mi value despite the value being obviously inaccurate in terms of assessing the CO_2 emissions associated with operation of any PHEV or EV. Thus, in this respect, EPA's proposed treatment of EVs and PHEVs would effectively maintain a "double-benefit" through at least MY 2025 and maintain an additional advantage in MY 2026 and perhaps thereafter which is untethered from a realistic assessment of the actual environmental impact of PHEVs and EVs.

Chemours recognizes that EPA is proposing to cap multipliers at a fleet equivalent of 2.5 g/mile per MY, or an overall cap of 10.0 g/mile on a cumulative basis over MYs 2022-2025.56 And this would directionally curb the benefit of the multiplier at least with respect to OEMs that produce higher numbers of PHEVs and EVs as a percentage of their overall fleet. But at the same time, the imputed 0 g/mi value allows for the accretion of a considerable amount of credits which do not accurately equate into direct environmental benefit due to actual emissions associated with the fueling of such vehicles. Within the proposed rule, EPA should therefore address the overall impact of the multiplier and the imputed 0 g/mi value to bring the available credits into line with actual environmental results. As EPA notes with respect to the California Agreement, unrestrained crediting can have a significant impact on the overall stringency of the program, with losses in the Framework Agreement estimated at 27 percent of the total stringency.57 Chemours concerns in this area do not center on any aversion to the electrification of our nation's transportation system. But as noted above, A/C credits are calculated and directly considered in setting the stringency levels of future year GHG standards. The same treatment is not afforded to PHEV and EV credits and, as a result, imbalances in the incentives sought to be promoted by LDV GHG requirements are created. As one possible consequence of this imbalance, multiplier incentives and unrestrained 0 g/mi values could work against or even create a temporary halt on the introduction of further emission reduction technologies between 2024 and 2026. It is also conceivable that this imbalance in incentives could stall or even cause a temporary change-back to the use of HFC-134a in MVAC systems if leakage and equipment credits are not needed for compliance or valued less by the marketplace.

While Chemours appreciates that EPA is intending to provide incentives for the market purchase and adoption of EV and PHEV technology, EPA should reconsider the credits available for such vehicles relative to other credits allowed under the proposed rule to account for overall environmental benefit. This would help to ensure incentives remain in place to introduce further emission reduction technologies apart from PHEV and EV technology between 2024 and 2026 and weigh against unintended results such as a change-back to the use of HFC-134a. [EPA-HQ-OAR-2021-0208-0232-A1, p. 11-13]

Commenter: City of Albuquerque, NM

Recommending EPA set the advanced technology vehicle multiplier and the credit caps [3] at levels appropriate to protect the rigor of the standard and increase the number of zero emission vehicles available for purchase. [EPA-HQ-OAR-2021-0208-0535-A1, pp. 1-2]

Commenter: Consumer Federation of America

Second, it is important to close the loopholes, especially those that might allow the automakers to 'use' the electric vehicle part of the fleet to 'relax' the efficiency of the gasoline-powered part. That trade-off must not be allowed. [EPA-HQ-OAR-2021-0208-0297-A1, p. 24]

Commenter: Consumer Reports (CR)

While CR applauds EPA's efforts to greatly limit the harm done by electric vehicle multipliers, these multipliers, by EPA's own analysis, do not significantly increase electrification and should be eliminated. [EPA-HQ-OAR-2021-0208-0602-A1, p.5]

EV Multipliers. Consumer Reports does not support the inclusion of electric vehicle multipliers. EPA's own analysis in table 4-25 of the RIA finds that they only increase EV penetrations under the preferred alternative from 7.4% to 7.8%. EPA concludes that "The results presented in this table suggest that the advanced technology multipliers are not expected to have a large impact on BEV and PHEV technology penetration."26 EPA also cites and discusses Gillingham's recent work that shows that electric vehicle multipliers can have a negative impact on EV penetration rates and emissions reductions.27 Consumer Reports strongly agrees with this research, and concludes that the inclusion of electric vehicle multipliers is unwarranted, even with caps as included in the proposal. [EPA-HQ-OAR-2021-0208-0602-A1, pp.11-12]

Even capped, EPA estimates that these multipliers decrease the emissions reductions by about 8% compared to standards without multipliers between MY21-26.28 EPA also states that: "As zero-emissions technologies become more mainstream, EPA believes it is appropriate to transition away from multiplier incentives."29 While Consumer Reports agrees with this statement, we also assert that EVs are already becoming more mainstream (see section 3d), and do not find the continued inclusion of these multipliers justifiable, especially given the reduction in emissions savings, and limited influence on the market demonstrated by EPA's modeling. [EPA-HQ-OAR-2021-0208-0602-A1,p.12]

Commenter: DENSO International America, Inc. (DENSO)

Support for Advanced Technology Multiplier Credits. DENSO supports the advanced technology credit multiplier program which incentivize battery electric vehicles (BEVs), fuel cell vehicles (FCVs) and plug-in hybrid vehicles (PHEVs) by counting each vehicle more than one vehicle as proposed by EPA this time through 2025MY. We also recommend EPA consider the necessity to include this incentive after MY2025 to continue to promote advanced vehicle adoption. As EPA works towards development of 27MY and beyond GHG regulations, it should fully evaluate jurisdiction's current and planning electricity sources, capacity, and infrastructure distribution capabilities before implementing vehicle emission programs. [EPA-HQ-OAR-2021-0208-0282-A1, p. 7-8]

Commenter: Edison Electric Institute (EEI)

Regulatory Flexibilities Are Appropriate as Long as They Further Program Goals. EPA is well supported in moving forward with new rules addressing vehicles out to MY 2026, leveraging the progress of the electric sector to reduce emissions in the transportation sector is important. As the Agency regulates the transportation sector, those rules should include compliance flexibilities to help incentivize automakers to deploy more electric vehicles—an approach that is both necessary and well supported. And—as highlighted by the Agency—those incentives and flexibilities should be "limited" and "focused" on "support[ing] automakers' acceleration of their introduction and sales of advanced technologies, including zero and near-zero-emission technologies," and the Agency should continue to monitor those flexibilities to ensure they facilitate the transition to increasingly stringent standards required for the zero-emissions future—not impede that transition. 86 Fed. Reg. at 43,731. [EPA-HQ-OAR-2021-0208-0284-A1, p. 8-9]

EPA Should Look to Tailor Flexibilities Here and in the Future. The Agency also tailors certain flexibilities and eliminates others, appropriately. EPA proposes to allow for ZEV multiplier incentives from MY 2022 though MY 2025 with a cap on multiplier credits in order to provide a limited ZEV incentive to automakers with the intent of inducing increased ZEV deployment in the near term. Further, EPA also proposes—understandably and correctly—to eliminate incentive multipliers for natural gas vehicles because they are not a ZEV or near-ZEV technology. Id. at 43,734.

Limiting ZEV multipliers and eliminating natural gas vehicle multipliers is entirely reasonable and well supported by the Agency. As EPA looks to future rulemakings—as discussed supra—tailoring or eliminating flexibilities may be appropriate for the Agency to consider given the facts and circumstances of EV deployment going forward. As more automakers offer greater ZEV opportunities, multipliers might not be as impactful in future years, and EPA should look to modify them as needed—possibly on a geographically specific basis in an effort to push adoption across the country in states that may lag in terms of overall electrification. [EPA-HQ-OAR-2021-0208-0284-A1, p. 12-13]

Commenter: Electric Drive Transportation Association (EDTA)

EDTA Supports the Advanced Technology Multiplier Credits – As EPA and NHTSA have previously determined, electric drive offers 'game changing' benefits in clean transportation. To achieve those benefits, we need to rapidly scale adoption of electric drive vehicles. To expedite the investment that will help secure those game changing benefits, EDTA supports incentive multipliers for BEVs, PHEVs and FCEVs. Electric drive is still an emerging market and industry is pushing to deliver enhanced performance at reduced cost, while building to full scale. The multipliers promote investment in innovation, which builds out the supply chain, puts downward pressure on costs and accelerates achievement of full market scale.

Electric drive technologies and the industries commercializing them are making great strides. Innovations in electric drive transportation that enhance performance and reduce costs are providing expanded choice to consumers, businesses and municipalities, while nationally reducing emissions and diversifying the transportation sector’s dependence on oil.

Nevertheless, there is significant uncertainty in multi-year market predictions, particularly regarding emerging technology and markets. The rationale for the multiplier, as provided in the current rule, is that it is needed as an incentive to accelerate the commercialization and widespread adoption of BEVs, PHEVs, and FCVs.

EDTA concurs that this incentive is needed, and we recommend that it be maintained at its current level. Further, expanding electric drive vehicle capacity will require substantial investments and long-term planning by manufacturers and other industry participants. The incentive to encourage those investments should be similarly long-term and not subject to an arbitrary time limit. [EPA-HQ-OAR-2021-0208-0569-A1, pp. 2-3]

The voluntary emissions reductions are generally comparable to those that would be required of all manufacturers under EPA’s Proposed Standards for MYs 2023-2026. A few notable differences are that EPA proposes new credits for pickups equipped with strong hybrid technology; EPA proposes to cap advanced technology vehicle multiplier credits at an average of 2.5 g/mi per model year (as opposed to 1% of GHG emissions reductions). [EPA-HQ-OAR-2021-0208-0688-A1, p. 14]

Commenter: Environmental Protection Network (EPN)

Flexibilities. EPA proposes to extend the use of multipliers for electric powered vehicles beyond that currently allowed, along with a cap on the amount of benefit that can be derived from this extension. EPA also recognizes that this extension reduces the overall GHG reductions that otherwise would be achieved by these standards, possibly reducing the percentage of electric vehicles that otherwise would be produced.

EPN recognizes that, conceptually, multipliers for electric power vehicles are important incentives for early progress in transitioning to electric power. EPN also recognizes that for automakers who are already committed to significant EV production, multipliers will reduce the number of EVs that they must sell, while for automakers who are not committed to significant EV sales, multipliers could increase EV sales. The net effect is not clear from EPA’s discussion.

But it is also clear that EV multipliers are not a long-term solution. They need to terminate as the technology becomes more mainstream. EPA’s proposal does not present a compelling justification for this extension.

Given the short time frame between now and MYs 2030 and 2035, the progress to date on electrification, and the stated public plans of many manufacturers to significantly expand their offerings and ramp up production of electric powered vehicles, EPA should seriously reconsider its proposed extension of EV multipliers. EPA has not shown that this extension is the optimum approach to lay a strong foundation and make strong progress to the longer-term electrification goals for MYs 2030 and 2035. EPA should reconsider this proposal given its impact on the long-term goals for the light-duty sector and the lack of a compelling justification for its inclusion. EPA should consider revising this proposal to make more progress to electrification and should not consider extending the multipliers even further than proposed.

EPN recommends that EPA base its decision on EV multipliers on whether it believes that the multipliers will increase EV sales in the MY 2023 to 2035 timeframe, and if the agency does believe this, that it provide an analysis to support that projection. [EPA-HQ-OAR-2021-0208-0213-A1, p. 10]

Commenter: Ford Motor Company

Multiplier Incentives for Advanced Technology Vehicles (ATV). Ford supports EPA’s proposal to extend the ATV multipliers first promulgated in the 2017-2025MY 'One National Program' GHG standards. The SAFE rule did not extend this provision, which phased out after 2021MY.

The California Framework Agreement includes these multipliers, recognizing the importance of continuing to provide regulatory support for electric vehicles in order to ensure continued progress toward electrifying the fleet.

EPA has proposed to 'cap' the ATV multiplier benefit to a cumulative 10 g/mi at the fleet level for 22- 25MY. The California Framework Agreement also includes a multiplier cap but utilizes a percentage-based mechanism that scales with an OEM’s fleet obligation, appropriately providing the same proportional benefit to all OEMs. Ford prefers the percentage-based approach but recognizes that it does add complexity to compliance and reporting. In light of the need to balance simplicity with a level competitive playing field, Ford recommends that EPA add additional cap space to the light-duty truck portion of the fleet, thus allowing an overall fleet level cap somewhat higher than the proposed 10 g/mi, depending on truck mix. This would help alleviate the proportionally lower benefit provided to OEM’s with higher truck mixes (trucks tend to have higher a GHG obligations). This approach also recognizes the additional utility provided by trucks and the pressing need to support accelerated electrification in this segment. [EPA-HQ-OAR-2021-0208-0294-A1, p.3]

Commenter: Gentherm, Inc.

EPA Proposed Advanced Technology Multiplier Credits. Gentherm supports the EPA’s proposal to extend advanced technology multiplier incentives for battery electric vehicles (BEV), Plug-in Hybrid Vehicles (PHEV) and Fuel Cell Electric Vehicles (FCEV) that sunset in 2025 or 2026 and include a cap. Working with automakers, Gentherm has made considerable investments in these technologies. Gentherm believes that harmonizing the advanced vehicle technology multiplier credit cap with California’s Framework Agreements is the appropriate path to allow flexibility in meeting the top line emissions stringency given the short time automakers have to respond to a sharp stringency change by 2023. [EPA-HQ-OAR-2021-0208-0216-A1, pp.6-7]

Commenter: Hyundai America Technical Center, Inc. (Hyundai)

EV multipliers and multiplier cap. EPA has proposed reinstating the advanced technology vehicle multipliers through 2025 MY. These multipliers encourage automakers to accelerate EV production while EVs continue to move toward cost parity with gasoline vehicles. EPA has also proposed adding a multiplier cap of 2.5 gpm/year.

Hyundai supports EPA’s proposal to reinstate the advanced technology vehicle multipliers, however to further encourage early electric vehicle sales Hyundai recommends raising the cap from 2.5 gpm/year to 5.0 gpm/year thus increasing the cumulative total from 10 to 20 gpm over four years (2023 – 2026 MY). If EPA raises the multiplier cap, the agency could consider lowering the advanced technology multipliers for BEVs and PHEVs in order to moderate the number of credits earned as shown in Table 1 below. This would also generate greater EV production volumes than proposed in the GHG NPRM. Hyundai recommends that the FCEV multiplier remain at 2.0 to spur sales and infrastructure investment in fuel cell vehicles. Hyundai also requests that the agencies maintain the EV multipliers through the 2026 MY. It is appropriate to continue to encourage EV production and sales using EV multipliers while EVs are moving towards cost parity with gasoline vehicles. [EPA-HQ-OAR-2021-0208-0603-A1, p.8] [Table 1 can be found at docket number EPA-HQ-OAR-2021-0208-0603-A1, pp. 7-8].

Commenter: Illinois et al. Corn Growers Associations

When coupled with EPA's extremely aggressive proposed timeline, this defect makes it virtually certain that automakers will not be able to comply with the proposed rule without what the proposal euphemistically calls regulatory "flexibility."4 That flexibility is promised in part in the form of extensions of "EV multipliers," which allow traditional automakers to buy their way out of compliance with EPA's standards by double counting electric-vehicle credits when calculating fleet-average greenhouse gas emissions. This is counterproductive because, as EPA admits, multipliers do not meaningfully encourage the adoption of electric vehicles, but instead serve only to enrich electric vehicle manufacturers at the expense of consumers, industry, and the environment. [EPA-HQ-OAR-2021-0208-0563-A2,p.3]

The costs of this approach are significant. According to the proposal, the multipliers will license an increase of nearly 46 million metric tons (MMT) of carbon pollution over the lifetime of the relevant cars and trucks.5 According to EPA's Greenhouse Gas Equivalencies Calculator, the 46 MMT EPA says will be added by the production multiplier for EVs is the equivalent of adding more than ten million cars to the road for one year, or burning over five billion gallons of additional gasoline, or operating 12 additional coal-fired power plants for one year.6 [EPA-HQ-OAR-2021-0208-0563-A2,pp.3-4]

These environmental and social costs would be one thing if EPA thought they would be offset by future improvements from electrification. But as EPA all but admits, multipliers will not meaningfully increase electric vehicle sales; rather, EPA anticipates that the increased penetration as a result of these subsidies will be "less than 0.5 percent" in any year.7 In other words, EPA plans on getting nothing for something. [EPA-HQ-OAR-2021-0208-0563-A2, p.4]

The sole reason for this approach appears to be the optics: EPA will be able to claim to have radically slashed emissions, while in reality creating less-stringent standards that automakers can actually comply with.8 In response to criticism, moreover, EPA will be able to point to the benefit to the electric vehicle industry, allowing it to "greenwash" the social, environmental, and economic costs of this wasteful approach. This is arbitrary and capricious and lacks any sound basis in evidence to support EPA's claim that its standards will benefit "public health and welfare." [EPA-HQ-OAR-2021-0208-0563-A2, p.4]

The approach is also out of step with the Clean Air Act. Section 202(a) requires EPA to "prescribe . . . standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines, which in [its] judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare."9 This does not allow the agency to set standards and then provide ways that regulated entities can avoid those standards by giving money to electric vehicle manufacturers. By definition, this is inconsistent with the EPA's duty to protect "public health and welfare" since it is deliberately designed to relax the standards that EPA concluded are reasonably anticipated to protect those interests. [EPA-HQ-OAR-2021-0208-0563-A2, pp.4-5]

Commenter: Institute for Policy Integrity

Similarly, EPA should also more critically evaluate the trade-offs resulting from its proposed extension of multiplier credits and the credit carry-forward period and consider the forgone benefits to public health and consumer fuel savings associated with these compliance flexibilities. To the extent that these extended compliance flexibilities are intended to provide additional lead time for manufacturers to comply with the MY 2023 standards, EPA should evaluate whether such flexibility is needed beyond the first model year of its proposed standards. As detailed below, we do not believe EPA is required to provide significant lead time for standards (such as the proposed standards) that do not require significant technology investment and development. EPA should consider whether scaling back even some of the multiplier credits or carry-forward period, or limiting their application to MY 2023, would increase net social benefits while still preserving more than enough compliance flexibility to satisfy the requirement for lead time. [EPA-HQ-OAR-2021-0208-0299-A1, p. 5.]

Commenter: ITB Group, Ltd. (ITB)

EPA Proposed Advanced Technology Multiplier Credits. ITB conditionally supports the EPA's proposal to extend advanced technology multiplier incentives for battery electric vehicles (BEV), Plug-in Hybrid Vehicles (PHEV), and Fuel Cell Electric Vehicles (FCEV) that sunset in 2025 or 2026 and include a cap. While there have been considerable supplier and OEM investments in these technologies, many of these technologies are still immature and incentives for a certain period of time can provide a catalyst to get more zero-emissions vehicles to the market sooner while reducing investment risk for the automotive industry.

ITB believes that harmonizing the advanced vehicle technology multiplier credit cap with California's Framework Agreements is the appropriate path to allow flexibility in meeting the top line emissions stringency given the short time automakers have to respond to a sharp stringency change by 2023. [EPA-HQ-OAR-2021-0208-0222-A1, p. 7]

Commenter: Jaguar Land Rover North America, LLC (JLRNA)

Incentive Multipliers. Jaguar Land Rover welcomes the proposed extension of ATV multipliers. In 19MY Jaguar Land Rover was the second highest claimant of ATV multiplier credits, behind only Tesla. Jaguar Land Rover considers the ATV multipliers a powerful driver in improving EV adoption.

However, the cap of 2.5 g/mi per year, combined with the proposed 2x BEV multiplier, means that (for a hypothetical company with a status without multipliers of ~200 g/mi) effectively only the first 1.25% of the manufacturers sales mix which are BEV could earn multiplier credits. Any BEVs beyond this would not be eligible for credits.

Jaguar Land Rover proposes that the cap is increased from 2.5 g/mi up to 5 g/mi while multipliers are maintained at the lower, 2021MY level (1.5x for BEV, 1.3x for PHEV). This would increase the BEV share at which OEMs would be additionally incentivized by ATV multiplier credits, which will help accelerate EV adoption. This would lead to incentivizing a BEV mix up to 4 times higher than the current proposal. We would propose that the cumulative cap is also raised respectively from 10 g/mi to 20 g/mi. [EPA-HQ-OAR-2021-0208-0269-A1, p.7] [The tables can be found on p.7 of Docket number [EPA-HQ-OAR-2021-0208-0269-A1]

We believe this proposal will help improve the administration's goal of incentivizing EVs to a percentage mix that aligns more closely with the expectation for the time period. [EPA-HQ-OAR-2021-0208-0269-A1, p.7]

In addition to this we propose an alternative to the new ATV incentive multipliers by increasing the cap and lowering the multiplier to further motivate the introduction of new electric vehicle models to the market. [EPA-HQ-OAR-2021-0208-0269-A1, p.8]

Commenter: Kreucher, Walter

The Agencies further propose in the rulemaking to modify these generous credits to add a vehicle multiplier for EVs and FCVs. Under the proposal, each vehicle counts as 2.0 for MYs 2022-2024, and 1.75 for MY 2025, subject to a cap on all vehicle multipliers. A clear indication that even they do not think the standards are achievable. [EPA-HQ-OAR-2021-0208-0199-A1, pp. 6-7]

Commenter: Lucid USA, Inc. (Lucid)

Lucid also supports the continued use of EV incentives as proposed in the NPRM, including the extension of multipliers for EVs into MY2025 and the continued assumption that EVs produce 0 g/mi of CO_2. Lucid encourages the Agency to consider adopting additional incentives for manufacturers that develop and manufacture electric vehicles and related technology and components in the United States. Incentivizing domestic innovation, development and manufacturing of EVs, across the entire supply chain, is consistent with the Biden Administration's Buy American efforts, which aim to encourage U.S. manufacturing and the purchase of U.S.-made goods. [EPA-HQ-OAR-2021-0208-0528-A1, pp. 3-4]

However, ZEV-only manufacturers like Lucid are accelerating the transition to a zero-emission future and should not be subject to an advanced technology multiplier cap. This cap was intended to target manufacturers that produce vehicles with internal combustion engines and prevents them from counterbalancing high-emitting vehicles with ZEV sales. ZEV-only manufacturers should not be subject to this cap because they are not offsetting sales of ICE vehicles in their own fleets. [EPA-HQ-OAR-2021-0208-0528-A1, p.5]

Commenter: Manufacturers of Emission Controls Association (MECA)

Advanced Technology Multiplier Credits. MECA has supported the early introductory use of incentives to promote innovative technologies that can be disadvantaged by lack of customer exposure and experience. However, in order for a technology to be a sustainable and successful solution, it must be competitive in cost and performance with other technologies to gain consumer acceptance. Indeed, this was recognized by the original EPA 2012 LD GHG rule, the Midterm Review and subsequent SAFE 2 LD GHG rules which all phased out advanced technology multiplier credits for PHEVs, BEVs and FCEVs in MY2022.

The phase-out of multiplier credits is justified as electrified vehicles have now been around for about 30 years and have matured to the point where almost every manufacturer is offering multiple hybridized and fully electric models, allowing consumers to make informed choices with respect report1 to advanced powertrain vehicles. A recent ICCT points out that similar to the latest EPA proposal, the California ZEV program forecasts only 8% EV penetration in 2025 due to credit multipliers. In their report, ICCT cautions that long term reliance on credit multipliers for ZEV technology may result in the unintended consequence of increasing real world emissions from the remaining non-ZEV portion of the fleet that is allowed to continue to emit at higher levels.

The revisions to the LD GHG standards for MY 2020 to MY 2026 created uncertainty for the supplier industry as well as our OEM customers. Furthermore, the proposed standards are scheduled to be implemented in a short time frame. Based on the agencies impact analysis and inclusion of the annual 2.5 g/mile cap on the use of the EV multiplier credits, we agree with the inclusion of the advanced technology multipliers for the limited number of years proposed because it offers some near-term compliance flexibility during this critical transition period for suppliers. However, for the reasons listed earlier in this section, we urge EPA to follow through with sunsetting these credit multipliers by MY 2025 and not grant further extensions in future LDV rulemakings. [EPA-HQ-OAR-2021-0208-0261-A1, pp.2-3]

Commenter: Mercedes-Benz USA, LLC

Mercedes-Benz supports the extension of the advanced technology vehicle multiplier incentive through MY2025, and encourages the agency to extend through MY2026 to conclude the regulatory period.

In addition to extending the sunset for the advanced technology vehicle multiplier, Mercedes-Benz requests that EPA increase the cap to 6.4 g/mi per year. [EPA-HQ-OAR-2021-0208-0523-A1, p.2]

Advanced Technology Vehicle Multiplier. The existing GHG program includes temporary incentives through MY2021 that encourage the use of advanced technologies such as electric, hybrid, and fuel cell vehicles. In EPA’s proposal, the agency proposed extending these incentives from MY2022-2025 with a cap on multiplier credits. Mercedes-Benz supports the extension of the advanced technology vehicle multiplier, in particular, because adoption rates for EVs and PHEVs remains lower than anticipated for the time frame under discussion.

First, EPA requests feedback on the extension of the cap from MY2021 (the original sunset date) through MY2025 under the revised proposal. Mercedes-Benz supports the extension of the multiplier incentives through MY2025, and requests that EPA reconsider its decision to exclude multipliers from MY2026. While we recognize that EPA's intention is to signal that multipliers will be excluded from future regulatory programs, we do see a need for multipliers as one complementary policy within the proposal timeframe to encourage the adoption of EVs during this critical time frame. We believe the extension to MY2026 nicely concludes the proposal's programmatic period and complements the opportunity to utilize one-time carry-back provisions included within EPA's proposal. In the event that EPA chooses to extend the advanced technology vehicle multiplier cap through MY2026, we recommend that the agency include the multiplier without adjustment to the proposed stringency of the MY2026 standard.

Second, in in addition to the extension of the advanced technology vehicle multiplier flexibility, EPA is asking for feedback on the application of a credit cap of 2.5 g/mi per vehicle or 10 g/mi cumulatively. Mercedes-Benz requests that EPA extend the cap to 6.4 g/mi per year in alignment with the model presented by the California Framework Agreement. These credits are a stimulus opportunity for the agency to incentivize all-electric powertrains and for manufacturers to reinvest their R&D expenditures through credit accrual. Credits are a low cost, low risk, win-win opportunity for EPA to support the all-electric transition.

In lieu of the 6.4 g/mi per year cap we previously mention, an alternative option would be including the advanced technology vehicle multiplier credits as part of the off-cycle credit menu. In this case, EPA would use the existing advanced technology vehicle multiplier credit values available through this proposal, and a manufacturer could choose whether to utilize the advanced technology vehicle multiplier as a type of off-cycle credit in their annual reporting rather than a separate incentive with its own cap. If EPA chooses to add the advanced technology as an option for the off-cycle credit menu, we recommend that EPA continue with its proposal to increase the off-cycle credit cap from 10 to 15 g/mi.

For the aforementioned reasons, Mercedes-Benz recommends extending the multiplier through MY2026, and increasing the fleet-wide cap for MYs 2023-2026 to 6.4 g/mi per year. [EPA-HQ-OAR-2021-0208-0523-A1, pp.3-4]

Commenter: Michalek, Jeremy and Whitefoot, Kate S.

Treatment of alternative-fuel vehicles: EPA is proposing to expand the favorable treatment of alternative fuel vehicles (AFVs) by treating AFVs as lower emitting than they really are and treating each AFV sale as though more than one AFV had been sold in compliance calculations. EPA recognizes that this approach to encouraging AFV technology advancement will increase fleet emissions but believes that long term benefits of advancing future technologies will outweigh near term losses. We recommend that EPA (1) test this belief with evidence, (2) consider the effect of this policy design on the ability of all other U.S. actors to encourage AFV adoption without triggering increased fleet emissions, and (3) measure and predict actual GHG emissions as closely as possible in the regulation, eschewing distorted measurement as a mechanism for encouraging AFV advancement in favor of other policies that can achieve AFV advancement without increasing fleet emissions. [EPA-HQ-OAR-2021-0208-0300-A1, p. 2]

Alternative Fuel Vehicles. In the proposed rule, EPA requests comment on proposed policies for handling of alternative fuel vehicles (AFVs) in the standard:

'EPA requests comment on all aspects of the proposed extension of multipliers, including the proposed multiplier levels, model years when multipliers are available, and the size and structure of the multiplier credit cap.' (p43757)

EPA's LDV GHG rule has incentives for alternative fuel vehicles (AFVs) that treat them in compliance calculations as though they are lower emitting than they actually are. This is done in two ways: (1) by ignoring emissions from locations other than the vehicle tailpipe, such as emissions from electric vehicle charging, and (2) by treating each AFV sold as though multiple AFVs were sold for compliance calculations. Both of these have the effect of reporting lower emissions for these vehicles than they actually produce and therefore permitting higher overall actual fleet emissions. EPA recognizes that this approach to incentivizing AFV technologies produces an effective loss of stringency for the standard and increases fleet emissions relative to what they would be if all vehicle emissions were counted equally. EPA's stated intent is to incentivize manufacturers to invest in technologies that can realize an ultra-low emission future.

'When EPA established these incentives in the 2012 rule, EPA recognized that they would reduce the effective stringency of the standards, but believed that it was worthwhile to have a limited near-term loss of emissions reduction benefits to increase the potential for far greater emissions reduction and technology diffusion benefits in the longer term. EPA believed that the temporary regulatory incentives would help bring low emission technologies to market more quickly than in the absence of incentives.'

Justifying Assumptions and Considering Effects on Other Actors. EPA states that they believe these incentives are worthwhile - that the loss of stringency in the near term is outweighed by the potential for far greater emissions reductions and technology diffusion benefits in the long term.

We recommend that EPA should (1) demonstrate this belief with evidence and (2) consider the interactions of this policy design with other federal and state policies when determining whether it is worthwhile. We discuss each in turn:

1. Evidence: EPA should state what evidence it has that (1) the LDV GHG incentives for AFVs have an effect on technology development and (2) that this effect is greater than the stringency loss. In the absence of other policies, it is plausible that EPA's favorable treatment of AFVs in compliance calculations could be a driver of innovation and technology development, though it is not clear whether or not the magnitude of this effect in accelerating penetration of AFVs and achieving future GHG reductions is larger than the stringency loss. Further, in the presence of other policies that also drive alternative fuel vehicle adoption, such as California's zero-emission vehicle mandate and other policies, it is also possible that AFV technology development would be unchanged by removal of AFV incentives in EPA's LDV standards because these other

policies may be the binding constraint for automaker decisions about AFVs. EPA should state what work it has done to test its belief that long term GHG benefits of these AFV incentives outweigh near term costs.

2. Policy Interactions: We recommend that EPA also consider that the design of AFV incentives in the LDV standards prevents all other federal, state and local efforts from encouraging AFV adoption without triggering unintended consequences of increased permitted fleet emissions. Peer reviewed studies have shown that efforts to increase alternative fuel vehicle adoption trigger an increase in permitted GHG emissions by up to 60 tons of CO2 equivalent per vehicle (depending on the vehicle and year of sale) (Jenn et al., 2016), and these federal incentives interact with state zero-emission vehicle policies to produce higher fleet GHG emissions than either policy alone (Jenn et al., 2019). EPA should consider the effect its policy choice has on constraining other entities from encouraging AFV adoption without triggering an increase in fleet emissions.

Measuring GHG Emissions Without Distortion. It is our view that in order to avoid unintended consequences, the federal LDV fleet standards should measure actual GHG emissions as closely as possible and not conflate the goal of reduced GHG emissions with the goal of technology advancement via distorted measurements. A better approach, in our view, would be to target actual GHG emission reductions with the LDV standards and use other policies to encourage AFV adoption. In this way, other policies can encourage AFV adoption without triggering an increase in permitted fleet emissions. The proposed cumulative cap and explicit sunset date on the AFV incentives is a step in this direction, but we are concerned that amplifying the distortion between now and 2025 will amplify the unintended consequences. [EPA-HQ-OAR-2021-0208-0300-A1, pp. 7-8]

Commenter: Minnesota Pollution Control Agency (MPCA) and Minnesota Department of Transportation (MnDOT)

The MPCA and MnDOT also encourage EPA to revisit its proposed multiplier and set it at a level that protects the rigor of the standards while still driving ever-increasing levels of EVs into the market to support the Biden Administration’s stated goal of 50% of new vehicle sales being electric by 2030. [EPA-HQ-OAR-2021-0208-0211-A1, p.3]

Commenter: Motor & Equipment Manufacturers Association (MEMA)

MEMA Supports the Advanced Technology Multiplier Credits - MEMA conditionally supports extending these advanced technology multiplier incentives. The proposed sunset and stringent credit cap encourage further improvements to ICE technologies. The program parameters are critical to suppliers as MEMA supports a structure that encourages a broad spectrum of innovative technologies. [EPA-HQ-OAR-2021-0208-0249-A1, p. 3]MEMA Supports the Proposed Advanced Technology Multiplier Credits

The 2012 EPA rule provided vehicle manufacturers with multiplier incentives that allow advanced technology vehicles – BEVs, FCEVs, PHEVs, and compressed natural gas vehicles

(CNGs) – to count as more than one vehicle toward compliance beginning in 2017 and expiring in 2021.36 EPA proposes extending the advanced technology multiplier incentives only for BEVs, FCEVs, and PHEVs for MYs 2022–2025 with lowered credits and a sunset in MY2025. EPA would impose a cap of 2.5 g/mi for car and light truck fleets per MY for MYs 2022–2025 or 10 g/mi on a cumulative basis. EPA requests comments on all aspects of the proposed multipliers.37

The advanced technology multiplier credit offers credits that help “incentivize technology in the near term.”39 Incentive credits are important to suppliers because these are the technologies in which suppliers have invested significant resources to develop. While there has been supplier and vehicle manufacturer investments in these technologies, many of these technologies are still new enough that incentives are needed to provide the initial catalyst to get more ZEVs to the market in the nearer term.

However, MEMA also strongly supports an EPA program that requires significant advances in a wide range of innovative technologies including improvements to ICE technologies. EPA justifies the proposed credit cap to prevent “backsliding for internal combustion engine” technologies and to “limit the potential effect of the multipliers on reducing the effective stringency of the standards.”40

These limits on the credits, the sunset and cap, are critical to suppliers as MEMA supports stringent standards that encourage a broad spectrum of innovative technologies. Suppliers have made significant investments in all these technologies, and all have a place in helping to meet the nation’s goals. Without a cap and sunset, the advanced technology multiplier credits could drive technologies down too narrow of a regulatory path, too quickly.

Consequently, MEMA conditionally supports extending these advanced technology multiplier incentives that sunset in 2025 and include a stringent cap. While MEMA can support these advanced technology multiplier incentives, these multiplier incentives should not be extended indefinitely, credits should not be set higher than the proposed levels, and the proposed cap should not be increased. If the incentives were set any higher or extended, these credits could cause a distortion in the market. MEMA agrees with EPA that these credits should be a temporary part of the program.41

In EPA’s post-2026 program, MEMA strongly supports a GHG emissions program that relies on performance-based standards and phases out incentives limited to specific technologies. MEMA, however, could support performance-based incentives for technologies that meet certain performance criteria. Such a program that focuses on performance rather than specific technology incentives would encourage more innovation and support the competitive marketplace paving the road to meeting the nation’s goals. MEMA is committed to a shift towards significantly higher levels of electrification while continuing to allow innovation to drive us toward a broad spectrum of advanced innovative technologies. [EPA-HQ-OAR-2021-0208-0249-A1, p. 11-12]

Commenter: National Association of Clean Air Agencies (NACAA)

ZEV Multipliers. EPA includes in the proposal an extension of the advanced technology vehicle multiplier incentives for MYs 2022 through 2025 with a cumulative credit cap. The level of this cap will depend on each automaker's actual fleet, specifically, what vehicles will become EVs and the footprint(s) of those vehicles compared to the fleet target, with a multiplier added.

Consistent with NACAA's recommendation above, to, at a minimum, restore the emissions benefits of the 2012 rule, EPA should reduce the multiplier to set it at a level that protects the rigor of the standards while still driving increased levels of EVs into the market beyond what manufacturers are likely to deliver without additional incentives. [EPA-HQ-OAR-2021-0208-0255-A1, p.7]

Commenter: National Automobile Dealers Association (NADA)

NADA generally supports the multiplier incentives EPA has proposed but opposes elimination of the multiplier for natural gas fueled vehicles. Moreover, NADA supports such additional compliance flexibilities as will afford OEMs a greater ability to deliver compliant vehicles in a more cost-efficient manner, and to help incentivize the acceptance of new technology and alternative fueled vehicles in the marketplace.38 [EPA-HQ-OAR-2021-0208-0290-A1, p. 10]

38 NADA supports the comments of the Alliance of Automotive Innovation in this regard.

Commenter: National Parks Conservation Association (NPCA)

Finally, NPCA requests that the final rule should not include unnecessary loopholes or credits, such as multipliers, that allow manufacturers to avoid real world reductions. [EPA-HQ-OAR-2021-0208-0291-A1, p. 2]

Commenter: New Mexico Environment Department

Third, NMED recommends the EPA set the advanced technology vehicle multiplier and the credit caps5 at levels appropriate to protect the rigor of the standard and drive increased levels of electric and other zero-emission vehicles into the market. [EPA-HQ-OAR-2021-0208-0205-A1] [p.1]

Commenter: New York State Department of Environmental Conservation

New York supports the proposed extension of multipliers for advanced technology vehicles for model, years 2022-2025 but questions the need for the proposed increases in multiplier values. The current incentives established by the 2012 SAFE Rule established an orderly decline in multiplier values from MYs 2017 to 2021. Instead of increasing the multiplier values for electric and plug-in hybrid vehicles, New York recommends maintaining the multiplier values for advanced technology vehicles at MY2021 values, or 1.5 for EVs and FCEVs and 1.3 for PHEVs for model years 2022-2025 (see Table 24). qEC supports EPA's plan to sunset the multipliers after MY 2025 and the incorporation of a cap. [EPA-HQ-OAR-2021-0208-0238-A1, p.3]

Commenter: Nissan North America, Inc.

The continuation of credit multipliers also is essential to encouraging manufacturer investment in and widespread deployment of these advanced powertrain technologies. Under the current rules, the multipliers for EVs, fuel cell vehicles ("FCVs"), and plug-in hybrids ("PHEVs") are scheduled to phase out after model year 2021. Nissan supports EPA's proposal to extend the credit multipliers available for EVs through model year 2025. EPA's proposal is a valuable step towards incentivizing investment in these technologies; however, Nissan encourages EPA to consider extending the multipliers even further, through at least model year 2026. In its reasoning for sunsetting the multiplier incentives in model year 2025, EPA focuses exclusively on the development and availability of zero-emission technology and does not consider the full context necessary for achieving such a market shift, including availability of infrastructure and consumer demand, which have lagged behind technological advancements. EPA is also proposing an average of 2.5 g/mile per year cap on such multiplier-based credits for model years 2022 through 2025, which is more restrictive than the cap adopted under the California Framework Agreements. Extending the credit multipliers beyond model year 2025 with a cap more equivalent to that under the California Framework Agreements would incentivize manufacturers to continue investing in these technologies despite these challenges. Encouraging manufacturers to continue improving and selling zero-emission technologies will facilitate infrastructure development and consumer education that will ultimately lead to a broader market shift.

The overall adoption of EVs remains relatively low today in spite of the billions invested by the automobile industry on technology and product development and other market actions. Many market barriers to mass EV adoption, such as cost parity and lack of consumer acceptance, continue to exist. These barriers must be overcome in an expedited manner in order to reach the longer term goal of a carbon neutral future. EV-related regulatory incentives, such as production multipliers and tailpipe-only calculations, are effective tools to ease such barriers and would encourage accelerated production of EVs. Without these incentives, transforming the current EV market would become more challenging and could place the Administration's long-term carbon neutral goals in jeopardy. [EPA-HQ-OAR-2021-0208-0529-A1, p. 6-7]

Commenter: Olmstead, Thomas

As seen in the following table, more credits are being used from prior years to meet the more stringent standards from 2016 onwards and the number of credits used by manufacturer varies greatly: [Figures and Table at docket number EPA-HQ-OAR-2021-0208-0190-A1, pp. 2 and 3]

The above tables shows that an active credit market exists, and numerous manufacturers have used credits to meet the standards. For this reason, the credits should be phased out. However, the multipliers should be ended because as EPA has noted in the proposed rule, the multipliers make the standard less stringent. Multiplier incentives for advanced technology vehicles including electric vehicles, fuel cell vehicles, plug-in hybrids were set to end after model year 2021. According to the American Council for an Energy-Efficient Economy (ACEEE), 'EV multipliers allow automakers to give extra weight to EVs (often 1.5 or 2x weight) when calculating their fleetwide average, which means that they can use EVs to offset the sales of larger, higher-emitting vehicles. Automakers need to meet an annual sales-weighted average efficiency level and the EV multipliers give disproportionate weight to EVs, which are generally more efficient. This means that each electric model sold actually increases overall fleetwide emissions despite EVs themselves emitting less. Also, while the multipliers may have been introduced to spur EV sales, there is evidence to suggest they are not having that effect and may actually hinder EV sales. The Obama standards included a phase-out of these multipliers by MY 2021.' With a 229,216,449 Mg credit balance for all manufacturers available in 2019, these credits provide more than enough to cover the more stringent standards for manufacturers that struggle to meet the standards in future years and additional lead time to meet increasing standards.

For these reasons, EPA should adopt more stringent standards, phaseout credits, and eliminate the multiplier incentives for advanced technology vehicles. [EPA-HQ-OAR-2021-0208-0190-A1, pp. 2-3]

Commenter: Peterson, Doug

The Credit Multiplier for Battery Electric Vehicles Should Not Be Restored. The credit multiplier under consideration was designed to accelerate electrification when zero emission vehicles were just getting started. It was a fairly sensible plan, seems to have served its purpose for BEVs, was sensibly phased out, and should remain phased out as far as BEVs are concerned. The excessive number of compliance credits generated by the multiplier has undermined the overall effectiveness of the regulatory framework. Reasonable people might disagree about whether or not it was worth it. Tesla has never had to be concerned about compliance but has benefited from the flow of pay-to-pollute dollars into its coffers and is now thriving. If there is any bright spot in the U.S. regarding auto emissions, it is the rapid ascent of Tesla, proving beyond a shadow of a doubt that BEVs are feasible and marketable. But the original justification for the multiplier is no longer valid. BEV adoption is accelerating around the globe, and most automakers are getting on board, making substantial investments in electrification. Environmentally responsible countries are implementing zero emission vehicle mandates and plan to phase out the sale of internal combustion vehicles in the 2030-2040 timeframe. The writing is on the wall; automakers will have to electrify or die.

I firmly believe that restoring the multiplier will slow BEV adoption within the United States. The automakers crave earned compliance credits more than purchased ones, and the multiplier allows them to earn the same number of credits by selling half as many BEVs. The EPA should go even further and align the credits generated by BEVs with the emission reductions they provide in the real world. The average carbon intensity of the national grid could be used to estimate upstream emissions, and BEVs would generate an appropriate number of credits that take those emissions into account. As local grids are steadily decarbonized, BEVs would steadily generate more credits that are aligned with their real world benefits. Such a system would not be perfectly accurate, but it would be better than the current rules that allow BEVs to generate unjustified windfall credits. This would restore integrity to the existing regulatory framework, which is essentially a cap-and-trade system without a sealed cap.

Under the current rules, BEVs generate windfall credits when they are averaged into fleet performance calculations, offsetting the shortcomings of overpowered gas-guzzlers that fail to meet their standards. I drive a Hyundai Ioniq because it gets extraordinarily high MPGe, but I am fully aware that this allows Hyundai to sell a much larger number of vehicles that do not meet their footprint targets, if they so choose, or they can sell my BEV's credits to an irresponsible automaker. The credit trading system and the use of averaging to determine fleet performance results in a system in which the altruism of an individual like myself ends up enabling the moral indifference of folks who drive gas-guzzlers, and this is especially troubling to me. I can feel satisfied that my vehicle does indeed reduce light duty CO2 emissions, but those gains are used to offset the shortcomings of inefficient vehicles that fail to achieve their footprint targets. It is worth mentioning at this juncture that the current framework also incentivizes the upsizing of ZEVs. If the EPA were bolder about protecting the environment, they would be establishing policies that aim to downsize our national fleet to some degree, including ZEVs.

I do support restoring the multiplier for fuel cell electric vehicles. Our regulations should guarantee a steady transition to a zero emissions fleet that includes roughly equal numbers of both ZEV powertrains. BEVs and FCEVs each have their own unique benefits, and there are important synergistic advantages to developing both. While it seems like this would require the development of two expensive fueling infrastructures, that is not completely the case. Green hydrogen fueling stations would reduce the need for so many public charging stations. It is going to be extremely difficult to bring the crucial benefit of home charging to people who live in apartment complexes, but there is nothing to prevent renters from filling up their tanks with green hydrogen. The two zero emission powertrains complement one another nicely. The development of green hydrogen as a means of storing intermittent solar and wind energy will also decrease the need for large banks of batteries that might serve the same purpose, reducing demand for lithium and scaling up the production of hydrogen fuel for a wide variety of environmentally helpful uses that ought to include FCEVs.

I favor restoring the credit multiplier for FCEVs for the same reason it was implemented to begin with, to incentivize this promising technology while it is struggling to get on its feet and creating a bigger market for green hydrogen. The fact that BEVs are currently seen as more feasible than FCEVs should not lead us to discard nascent fuel cell technology in favor of BEVs. Both are extremely valuable for defeating climate change, and our environmental policies should embrace them both. FCEVs are currently being sold in very small numbers, so I do not believe that restoring the multiplier for these vehicles will contribute greatly to the glut of compliance credits in the near term. Depending on how fast FCEVs catch on, it might be possible to phase out the restored multiplier after 2027. The flow of pay-to-pollute dollars to manufacturers that sell FCEVs would likely benefit them in the same way the flow has benefitted Tesla, accelerating FCEV adoption and the buildout of green hydrogen fueling stations.

I will not comment much on the cap that the EPA envisions which would limit the extent to which automakers might benefit from the restored multiplier. If the EPA follows my thoughtful recommendation to restore the multiplier to FCEVs but not BEVs, I advise against the cap. I would argue further that future rules should disallow the sale of ZEV credits to other automakers. Altruistic individuals who choose to drive BEVs or FCEVs should not be enabling irresponsible

10 automakers and consumers under the pay-to-pollute provisions of the outdated framework. A more robust framework would disallow the trading of credits generated by ZEVs, isolating all zero emission credits from the pay-to-pollute travesty as a mandatory electrification transition accelerates. If automakers are to advance the most promising technologies while improving their fleet performance, they should be forced to build their own ZEVs. If they refuse, they should not be allowed to achieve compliance by exploiting the current pay-to-pollute flexibility provision. If the new regulatory framework were to drive them into bankruptcy, so be it. Internal combustion vehicles are causing severe harm to the environment and need to be phased out. [EPA-HQ-OAR-2021-0208-0692-A1, p. 8-10]

Commenter: Rivian Automotive, LLC

Do Not Extend the Advanced Technology Vehicle Multiplier. EPA originally devised advanced technology multipliers to encourage the use of advanced technologies such as electric drivetrains. According to the agency, when first implemented in 2012 they were "temporary regulatory incentives" that came at the cost of program stringency but "would help bring low emission technologies to market…"10 However, at least one study of policy design issues in fuel economy and GHG emissions standards calls the efficacy of multipliers into question. By artificially enhancing the compliance value of EVs, the multiplier can enable manufacturers to sell additional conventional vehicles if those units deliver a greater financial return.11 It is also debatable whether the multiplier is even necessary at this stage to help commercialize EV technology. With a rapidly proliferating lineup of EVs in all body styles and vehicle segments, the auto industry has amply demonstrated its ability to bring compelling and competitive advanced technology vehicles to market

Additionally, Rivian is concerned about the impact of these incentives on the environment. In general, EPA's calculations indicate that even with a cap on the maximum benefit of the multiplier for any given manufacturer, including multipliers in the proposed rule erodes its GHG emissions reductions by effectively easing stringency. Over the lifetime of MY2021-2026 vehicles, EPA estimates that the multipliers in the proposed rule result in 46 million fewer metric tons of GHG reductions. And continuing to award multipliers for plug-in hybrid electric vehicles (PHEVs) specifically rewards a "pass-through" technology with significant variability in its environmental performance. Research from Europe suggests that PHEVs deliver significantly poorer environmental benefits in real-world usage than certified under test procedures, with troubling implications for the projected benefits of regulatory programs that encourage the development and sale of these vehicles.12 For all these reasons, we believe it would be imprudent for EPA to sustain the advanced technology vehicle multiplier incentive under any alternative. [EPA-HQ-OAR-2021-0208-0274-A1, p. 5]

Commenter: Securing America's Future Energy

Multiplier for Advanced Technology Vehicles. In the 2012 rule, EPA established a multiplier for alternative fuel vehicles to accelerate their market penetration. EPA used a multiplier for electric vehicles, plug-in hybrid electric vehicles (PHEVs), fuel cell vehicles (FCVs), and compressed natural gas (CNG) vehicles sold in MYs 2017 through 2021. This multiplier approach meant that each qualifying alternative fuel vehicle would count as more than one vehicle in the manufacturer's compliance calculations. This operated as an incentive for automakers to manufacture and sell alternative fuel vehicles. EVs and FCVs started with a multiplier value of 2.0, meaning that the sale of each car was treated as the sale of 2 cars for compliance purposes, phasing down to a value of 1.5 in MY 2021. PHEVs and CNG vehicles started with a multiplier value of 1.6, phasing down to a value of 1.3 in MY 2021. There we no multipliers for MY 2022 or later years.[40]

In the SAFE Rule in 2020, EPA established a multiplier of 2.0 for natural gas vehicles through MY 2026. It did not extend multipliers for any other types of vehicles.[41]

SAFE supports EPA's decision to reinstitute multipliers for electric vehicles, and believes that it should do so in selecting Alternative 2 or a more stringent alternative as well. SAFE is well aware of the criticisms of the multipliers. It is correct that the multiplier may allow for the sale of dirtier vehicles. In an averaging program, however, the sale of every cleaner car allows for the sale of some dirtier cars; that is a basic feature of averaging. SAFE recognizes that the availability of the multiplier further relaxes the overall standard by effectively increasing the number of cleaner vehicles that an automaker is credited with selling in the calculation of fleet emissions, thus allowing the sale of more vehicles with higher emissions. We view this, however, as a worthwhile tradeoff because of the importance of accelerating sales of electric vehicles, as explained above. Overall, electric vehicles not only operate more efficiently and have lower emissions,[42] but they will continue to get cleaner over time as the emission standards for power generation become more stringent. Stated otherwise, electric cars are the only cars that get cleaner as they get older.

A recent commentary concerning the GHG emission standards and their use of multipliers for electric vehicles expressed some concern about the overall effectiveness of a multiplier, including its effect on total emissions and on EV adoption rates.[43] The analysis observed that a multiplier that does not account for upstream emissions reduces the stringency of the standard, and that the multiplier enables the sale of more inefficient vehicles with higher emissions.[44] SAFE believes, for reasons explained below, that it is appropriate to exclude upstream powerplant emissions from the emissions calculation. And as noted above, it is a basic design feature of fleet averaging programs that the sale of an efficient vehicle allows the sale of a less efficient vehicle.

The analysis also observed that EV incentives can increase EV adoption rates when sales are small and/or technology costs are high, but that once EVs are priced competitively with conventional vehicles, extra credits may decrease EV market share because fewer EVs are needed to comply with the less stringent standard.[45] SAFE believes that at the current modest adoption rates and elevated costs, a higher multiplier will not decrease EV adoption rates. First, as described above, EV sales remain a small share of the overall new vehicle sales market. Further, EVs are not yet competitively priced with conventional vehicles. The average cost of a new vehicle in March, 2021, was $40,472, while the average cost of a new EV was $53,297. [46] It also is more expensive to insure an EV than a conventional vehicle,[47] and though EVs may need fewer repairs, the repairs they need may be more costly due to the complexity of the vehicles, the expense of the equipment needed to repair them, and the need to retrain mechanics.48 Finally, one cannot assume that non-commercial purchasers of new vehicles make vehicle purchase decisions on the basis of total cost of ownership. If a consumer was looking to minimize total cost of ownership, they would nearly always choose to buy a used car. In fact, recent research concludes that very few consumers examine the total cost of ownership as part of their decision to purchase a new vehicle.[49] It seems that a total cost of ownership analysis is more likely to affect commercial purchases than personal purchases, but without individuals transitioning to electric vehicles, they will be consigned to a limited corner of the marketplace. SAFE's recommendation that EPA reinstate an EV multiplier is supported by recent research that concludes that a multiplier will not begin to erode the total GHG emissions meaningfully until EV sales approach 7 to 8 percent of the market, and they are unlikely to reduce the overall EV sales until EV sales also approach 13 to 15 percent of new vehicle sales.[50] U.S. EV penetration rates do not yet approach the level at which they will reduce EV sales, and EPA does not forecast that sales rates would approach that level during the model years covered by this proposed rule.

If EPA remains concerned that the multiplier will result in fewer EV sales because the availability of the multiplier relaxes the stringency of the standard, EPA could modify the operation of the multiplier to mitigate those concerns while still incentivizing the sale of electric vehicles. First, EPA could take into account the possibility that the multiplier might relax the stringency of the standards, and then further tighten the standards to maintain its initial level of stringency. In the alternative, EPA could modify the multiplier so that it would only apply to the incremental percentage of EVs that an automaker sold over the percentage in the previous year. By limiting the availability of the multiplier to the incremental sales of EVs year over year, EPA could reduce the extent to which it decreases the overall stringency of the standard. Yet, by maintaining the multiplier for electric vehicles that represent growth of the EV segment of an automakers' sales, the multiplier would provide an ongoing and robust incentive for automakers to continually increase their EV sales. [EPA-HQ-OAR-2021-0208-0527-A1, pp. 11-14]

Commenter: Sierra Club

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 29-30.]

The current proposal would reinstate a prior loophole by treating each zero emission vehicle as multiple zero emission vehicles when measuring compliance. Not only does this loophole erode the effectiveness of the rule, but recent research shows that it is actually counterproductive to accelerating the deployment of electric vehicles.

We should be past the point of multipliers by now. Instead, the final rule should say loud and clear one zero emission vehicle counts for one zero emission vehicle.

Commenter: South Coast Air Quality Management District

The South Coast AQMD supports the prudent extension of incentives for production and sale of vehicles with zero and near-zero emissions technology. The District supports the proposed multiplier incentives from MY2022 through MY2025 to accelerate the introduction of zero and near-zero emissions vehicles.3 The District agrees that special watchfulness is warranted on how the incentives impact overall program stringency. A multiplier credit cap or other mechanism to protect against any stalling in the momentum of improved fleet average calculations seems especially appropriate. The District further agrees that it is sensible to sunset multipliers in MY2025 to signal their discontinuation and simplify the transition to a more stringent program for MY2027. Regarding whether to allow multiplier credits to be generated in 2026 without an increase in the cap, the District generally supports a rule design that may incentivize a manufacturer, even in MY2026, to bring to market its first models of advanced technology vehicles. If the rule design could recognize narrower eligibility for generating credits in 2026, e.g., extending the incentive only to those manufacturers that have used less than some fraction of the cap, it could promote this beneficial result without further ossifying multipliers. Moreover, if MY2026 had its own year-specific, lesser cap, such that a manufacturer would not rely too heavily on any new-gained multiplier incentive, that may partly address the stated concern that any MY2026 credits could 'potentially complicate transitioning to MY2027 standards for some manufacturers.' 86 FR at 43757. [EPA-HQ-OAR-2021-0208-0215-A1, p.4]

3 Going further, EPA should look at rule designs that would accelerate zero and near-zero emissions technology in the exercise of all its Title II mobile source responsibilities.

Commenter: Southern Environmental Law Center

EPA should also not utilize multipliers for natural gas vehicles (NGVs), electric vehicles (EVs), fuel cell vehicles (FCVs), or plug-in hybrid electric vehicles (PHEVs) under any standards adopted. [EPA-HQ-OAR-2021-0208-0244-A1, p. 2]

EPA should also not use multiplier incentives for EVs, FCVs, and PHEVs, and we support EPA’s proposal to eliminate the multiplier incentive for NGVs.[40] The use of these incentives—which EPA believes vehicle manufacturers will continue to utilize ‘to their fullest extent’[41]—will ‘result in roughly 46 MMT (596 minus 550 MMT) fewer tons of CO2 reduced over the lifetimes of [model year] 2021-2026 vehicles.’[42] This amounts to an approximately 7.7 percent reduction in the stringency of the proposed standards. EPA notes that it intends to transition away from multiplier incentives ‘as zero-emissions technologies become more mainstream,’ but, as discussed above, the time for such a transition is now.[43] Two of the three advanced technologies provided favorable treatment through the application of credit multipliers—EVs and PHEVs—are common technologies in today’s vehicle marketplace. One recent study suggests that application of multiplier incentives for EV and PHEV technology under these circumstances could create a compliance loophole that allows manufacturers to continue making and selling dirtier (but currently more profitable) vehicles and could result in reductions in EV market share—which would be contrary to the intent of the multiplier.[44] As a result, EPA’s proposed use of multiplier incentives could decrease the stringency of the overall emissions standards for little gain in technological advances or EV penetration.[45]

If EPA decides to move forward with the use of multiplier incentives for EVs, FCVs, and PHEVs—which, again, we urge that it not do—several changes should be adopted. One of EPA's rationales for proposing new multipliers is 'to provide continuity for the incentives,' but the proposed multiplier incentives are in fact more generous than the multiplier incentives utilized in the 2012 Rule.[46] The proposed multiplier values effectively restart the incentive program, applying the multiplier values that the 2012 Rule used for vehicles from model years 2017 through 2019 to vehicles from model years 2022 through 2024. As discussed above, EV and PHEV technology has advanced and costs have decreased since the 2012 Rule was promulgated, and these generous incentive values are no longer needed. At a minimum, EPA should revise the proposal so the model year 2022 through 2024 multiplier incentives values start at 1.5 for EVs and FCVs, and 1.3 for PHEVs—the values provided for the last year of advanced technology credits (model year 2021) in the 2012 Rule—and then decrease to a value of 1.0 (no multiplier credits) by model year 2026.

EPA should also reconsider the incentive for PHEV technology. While the current multiplier structure provides a lower multiplier incentive value for PHEVs, the multiplier value could be better calibrated to reflect the fact that PHEV technology, which utilizes both battery and internal combustion engines, is not true zero tailpipe emissions technology. Under California's Advanced Clean Cars program, for example, 'transitional zero emission vehicles,' which are most commonly PHEVs, earn credits based on their all-electric range (AER), with a minimum amount of AER required for the vehicles to qualify for credits in the first place.[47] If it adopts a multiplier incentive structure, EPA should provide more generous multiplier values for PHEVs with greater AERs and set an AER floor below which vehicles will not qualify for the multiplier, and it should cap the amount of credits generated by PHEVs that may be used to satisfy the overall multiplier incentive credit cap—similar to the cap established by California to transitional zero emissions vehicles.[48] [EPA-HQ-OAR-2021-0208-0244-A1, pp.7-8]

Additionally, EPA should not utilize multipliers for NGVs, EVs, FCVs, or PHEVs under any standards adopted [EPA-HQ-OAR-2021-0208-0244-A1, p. 8]

[40] NGVs vehicles are not zero-tailpipe-emissions technology and should not be incentivized.

Commenter: Stellantis

Stellantis supports EPA's ambitious and challenging GHG standards and its desire to extend and expand flexibilities to further incentivize GHG reductions aligned to our common goal of an electrified future. However, certain modifications proposed by EPA are overly constraining. Specifically,

• EPA proposes to extend EV multipliers through MY2025, but with a highly constrained cap making multipliers one third as effective as the multipliers in the California Framework; and

• EPA should increase the EV multiplier cap to the same level proposed in the California Framework to incentivize EV growth from the current 2.5% rate to an 8-13% rate, which is the range modeled by EPA and NHTSA for MY2026.

• EPA should extend appropriate EV multipliers through MY2026.

Conclusion. Stellantis is committed to executing an electrified future pledging over $35 billion through 2025 to electrify all 14 Stellantis brands offering best-in-class fully electrified solutions. Stellantis supports EPA's proposed GHG standards with revised flexibilities included in the program, Increased EV multiplier caps set at levels in the California Framework through MY2026, and postpone off cycle credit redefinition until the next rulemaking cycle (MY2027+). Stellantis does not support the more stringent alternatives evaluated by EPA or the addition of 5-10g/mi in the final year for proposed GHG standard. [EPA-HQ-OAR-2021-0208-0532-A1, p. 5]

EV Multipliers and Caps Should Follow California Framework. A number of changes are needed in the proposed rule to align flexibilities with the market challenges of higher electrification rates that are needed to achieve requirements. While electric vehicle adoption has increased in recent years, it is still considerably less than what will be required to meet the proposed standards and meet the goals of industry and the Biden Administration. The inclusion of sales multipliers for EVs, PHEVs, and fuel cell vehicles ('EV Multipliers') should work alongside complementary consumer-facing policies, such as financial incentives, to take a whole-market approach to growing electrification. We believe that minor changes to the structure of the EV multipliers will help to grow EV market.

The advanced technology vehicle multipliers and caps proposed unnecessarily limit the incentive for EV technology and should be expanded to the same levels proposed in the California Framework. Regulatory incentives are needed to foster additional growth in these markets, as acknowledged by the 2012 final rule:

'EPA believes that it is both reasonable and appropriate to accept some short-term loss of emissions benefits in the short run to increase the potential for far-greater game-changing benefits in the longer run. The agency believes that these multipliers may help bring some technologies to market more quickly than in the absence of incentives.'20

As shown in the table below, EPA's proposed EV multipliers are capped at a maximum 10 g/mi cumulative impact over four model years (MY2022-2025) with no multiplier for MY2026. Stellantis estimates that this reduces the EV multiplier benefit to one third of that proposed in the California Framework which has a cap structure defined as 1% difference in stringency and extends through MY2026. [Table 1 can be found on p. 15 of Docket number EPA-HQ-OAR-2021-0208-0532-A1]

While we understand the concerns of 'lost' GHG reduction from incentives, we believe the EV multiplier structure adopted in the Framework agreement better balances this against the need to grow the EV market.

Stellantis recommends adoption the California Framework's cap and multiplier structure. While still maintaining an overall cap on the maximum benefit, the California Framework's cap provides greater regulatory certainty as major manufacturers invest heavily in electrifying their portfolios. Additionally, in response to EPA's request for comment on the appropriateness of extending multipliers to MY2026, EPA should also adopt multiplier applicability time frames as described in the California Framework through MY2026. This harmonization would place the phase-out year for the multipliers in 2026, easing any potential transition into a new rulemaking without multipliers in 2027, which was another concern EPA had expressed. [EPA-HQ-OAR-2021-0208-0532-A1, p. 14-15]

Commenter: Tesla

EPA Should Not Reintroduce the Alternative Vehicle Multiplier. In its proposal, EPA renews alternative technology multiplier credits that were previously scheduled to be phased out in 2021 and raises the value of the multiplier from 2021 levels to 2.0 in MY 2022-2024 and 1.75 in MY 2025.170 This proposal will have the opposite of its intended effect of enhancing the deployment of this technology and is not based upon a sound record basis concerning the need for this concession to manufacturers. The renewal and increased value are unnecessary and, rather than serve as an incentive, will further delay manufacturers from deploying large amounts of electric vehicles in the U.S. Under the proposed architecture, manufacturers will likely deploy EVs to maximize generation of multiplier credits up to the 10 g/mi cap limit but move no further. In the E.U, a similar 'Super Credit' multiplier exists for vehicles which emit <50g CO_2/km, which can be earned from 2020- 2022 inclusive. In the first year of the Super Credit eligibility, eight out of ten manufacturers reached the cap.171 This was achieved by aggressive sales practices (pricing and pre-registrations) to capture the maximum value of the credits up to the cap, and then halting further sales once the cap was reached. Moreover, manufacturers with discretion on when to use the credits will likely deploy at least half of these credits in MY 2023, further delaying near term delivery of EVs and eroding the stringency of MY 2023 to the point that the proposed standards are, in effect, only slightly more stringent than the SAFE rule in that model year. See Figure 1.

Additionally, the enhanced multiplier unnecessarily rewards late-acting manufacturers with excessive credits and richer credits after over a decade of notice from the EPA that such incentives were temporary and destined to decline in reward. In 2010, EPA proposed and finalized rules that provided a temporary incentive to encourage the commercialization of, inter alia, electric vehicles but did not include a multiplier out of concern of creating excess credits.172 At the heart of EPA’s justification for these incentives was the finding that for MY 2012-2016, there is a tradeoff benefit from 'temporarily rewarding advanced emissions control technologies by foregoing modest emissions reductions in the short term in order to lay the foundation for the potential for much larger emission reductions in the longer term.'173

Similarly, in 2012, the EPA continued to create incentives by including an EV multiplier 'to promote increased application of these advanced technologies in the program’s early model years, which could achieve economies of scale that will support the wider application of these technologies to help achieve the more stringent standards in MYs 2022–2025.'174 Simply put, EPA’s multiplier has pined for EV technology in the future but continually deferred requiring actual deployment of the technology in the now. Such incentives are no longer necessary, as Tesla’s experience has demonstrated, because this technology is well established, widely available as a compliance strategy, and now highly cost effective. Continued deferral of the obligation to create real compliance through these means serves to place the U.S. as a laggard rather than a leader in global emissions reductions and again cuts against the EPA overall mission to protect the public health and welfare.

As noted at length, electrification technology has become widely available and represents the best-in- class emission reduction technology. In short, the technology is available to achieve an increase in stringency in the standards for MY 2023-2026—and simply does not justify eroding that stringency. Continuing and increasing the multiplier incentive is unnecessary and after a decade of being an element in standards proposals now threatens to further institutionalize a compliance crutch for manufacturers to deliver a limited number of compliance vehicles to maximize credit accumulation with no incentive to deliver more actual deployment and the accompanying emission benefits.175

As proposed, the ATV credit even rewards manufacturers that have delayed EV deployment over the last several years by creating a perversely richer multiplier for MY 2022-2024. As the technology has been now commercialized at scale, each EV manufactured already contributes to achieving the CO2 target by making each manufacturers' fleet more efficient. All the enhanced multiplier does is weaken the stringency of the standard with no further delivery of an actual zero emission vehicle and little further technology development benefit from this new incentive.

While EPA may believe that the increase of 46 MMT176 caused by the multiplier is not significant, as the IPCC report recently highlighted, 'every tonne of CO2 emissions adds to global warming.'177 Further, the multiplier credit even makes full decarbonization harder by allowing for more polluting, inefficient vehicles to populate the fleet for approximately 17 years, when meeting the Administration's decarbonization goal requires the entire fleet be turned over to electrification by mid-century. Perverse incentives that reward delay and make the full electrification of the light duty fleet more difficult should be eliminated.

Further, programs with EV multipliers have determined that fears of excess crediting, like those expressed by the EPA in 2010, have come to fruition and widespread availability and cost-effectiveness of EV technology warrant eliminating credit multipliers.178 Indeed, that EPA is now asserting that a multiplier is still needed is in many ways an indictment of the policy that after a decade of utilization - by EPA standards - has not compelled legacy auto manufacturers to deliver ZEVs. Moreover, these flexibilities are even less justified given the moderated ambition the current proposal reflects.

Tesla, even though being the largest EV manufacturer, supports eliminating the ATV multiplier to ensure overall program integrity and supports firmly establishing a one-for-one credit ratio that is a more rational and transparent compliance mechanism and creates actual ZEV vehicle deployment, thereby enabling deeper emission reduction targets. [EPA-HQ-OAR-2021-0208-0278-A1] [pp.20-22]

Commenter: Toyota Motor North America, Inc. (Toyota)

Advanced Technology Vehicle Multipliers – Striking an Appropriate Balance. Toyota requests the PHEV multiplier be increased closer to that provided for BEVs. As explained further in

Appendix 1, PHEVs have similar lifecycle CO2 emissions under many operating conditions, can be more financially accessible to a larger consumer base, and fill utility and range gaps currently associated with BEVs. Toyota requests the proposed 1.6X multiplier be increased to 1.8X, or alternatively the 1.6X multiplier not decline over the duration of the provision.

We also request the proposed 2.5 g/mi cumulative cap be increased to 5.8 g/mi consistent with the benefit provided under the CA Framework. 15 Alternatively, Toyota could support a 4.0 g/mi cap representing the approximate mid-point between the proposed 2.5 g/mi cap and the effective 5.8 g/mi cap from the CA Framework. Either approach can increase technology deployment while limiting concerns about potential loss of environmental benefits.

Finally, we request the multipliers and cap be extended to 2026 model year, or at least both be available any four years between and including 2022 and 2026 model years. The any four-year availability option is consistent with EPA's thought of allowing multiplier credits to be generated in model year 2026 without an increase in the cap. Allowing for the incentive in the 2026 model year via a slightly broader or more flexible period of coverage can motivate later product entries as EPA recognizes and ensure an equitable benefit for all manufacturers independent when products enter the market. 16 We understand part of EPA's intention is to signal that multipliers will not be a part of 2027 model year and later standards as technologies become mainstream and core to compliance. Given the current uncertainty of reaching such a desired outcome by 2026 model year, we request EPA defer the decision to eliminate the ATV multiplier until the 2027 and later rulemaking.

Manufacturers are at different stages in the transition to electrification. Any revision to the proposed flexibility needs to maintain a level competitive playing field recognizing electrification strategies and deployment plans are substantially fixed over the period of the regulation. For this reason, we could not support any lowering of the multipliers even if associated with raising the benefit cap. [EPA-HQ-OAR-2021-0208-0531-A1, p. 9-10]

Emissions Performance. The GHG performance of a PHEV can rival that of a BEV over many real-world operating conditions. Lifecycle CO2 emissions are an important consideration to achieving climate goals as we move towards electrified powertrains. A lifecycle analysis is an important tool for comparing the CO2 reduction capability of various technology pathways. Toyota has developed an open source tool that analyzes the lifecycle CO2 of different powertrains where parameters can be adjusted to determine the impact on emissions and costs. The tool, publicly available data sources, and reference and source code are available on the website https://www.carghg.org.

As seen on the left side of Figure 1, PHEVs can have as good or better lifecycle CO2 emissions performance than BEVs when electricity is generated from the national grid on average because of the lower manufacturing emissions for smaller batteries and lower well-to-tank emissions with PHEVs still covering a significant fraction of daily trips in electric drive. And PHEV CO2 performance comes at much less cost compared to a BEV and without need for access to fast charging. [Figure 1 can be found on p. 16 of Docket number EPA-HQ-OAR-2021-0208-0531-A1]

As we shift to the cleaner CA grid (right side of Figure 1), BEVs show a higher incremental CO2 improvement. However, the less expensive PHEVs also benefit from the cleaner electric driving and manufacturing, so their CO2 performance remains in line with BEVs.

The conclusion is that PHEVs at significantly lower cost and with greater convenience have similar or better lifecycle CO2 emissions performance compared to BEVs, even as the electricity grid becomes cleaner. [EPA-HQ-OAR-2021-0208-0531-A1, p. 16]

Efficient use of batteries. As the transition to electrification gains momentum, demand for batteries will increase placing greater importance on material supplies, mining requirements, and other considerations involving increasingly sought natural resources for battery production.

PHEVs can make the most efficient use of a limited global battery supply as illustrated in Fig. 2 below using an example of allocating 170 KWhr of battery capacity to displace ICE powertrains from a 10-vehicle fleet of SUVs. [Figure 2 can be found on p. 17 of Docket number EPA-HQ-OAR-2021-0208-0531-A1]

The first option is to split that 170 KWhr capacity into two 85 KWhr BEVs that leaves eight ICE powertrains on the road. The second option is to allocate the battery capacity among nine 19 KWhr PHEVs with only one of the ten-vehicle fleet remaining an ICE powertrain which results in lower estimated total lifetime emissions. The lower relative cost of a PHEV enhances the chance for this larger volume of PHEVs to be accepted by consumers.

PHEVs are not always the superior CO2 performer or the best choice for every consumer. Toyota believes they can play a significant role in reaching our climate change objectives and making the most cost-efficient use of battery production for electric vehicles. We intend to expand our efforts to increase customer acceptability of all electrified powertrains. [EPA-HQ-OAR-2021-0208-0531-A1, p. 17]

15 5.8 g/mi is the effective annual result of the CA Framework 1% (of the 3.7% annual stringency increase) limit on Advanced Technology Multipliers.

Commenter: Union of Concerned Scientists (UCS)

EV Multipliers. The original theory behind inclusion of EV multipliers was that such multipliers provided a needed boost to a new technology. This is no longer the case, and multipliers no longer provide such a boost. In fact, the opposite is true. Recent economic analysis by Ken Gillingham shows that EV multipliers at moderate levels of penetration generally act as a disincentive for EV adoption.44 While the agency acknowledged Gillingham's study in their Draft Regulatory Impact Analysis (RIA), the accompanying analysis did not agree with its conclusions.45 Our own analysis disagrees with EPA's conclusion and remains consistent with the conclusions of our previous analysis46 and that of Ken Gillingham. The model indicates that significantly more EVs are introduced under Alternative 2, which lacks multipliers, as compared to the Preferred Alternative, which includes them.

We support EPA's cap on the EV multipliers and smaller window of time by which those multipliers are used if multipliers are to remain in the rule. The best approach, however, is to eliminate the multipliers as the evidence shows that a strong standard is the most efficient regulatory tool to drive EV adoption at the federal level—and that means a rule that is not undermined by credits awarded beyond the effectiveness of a technology.

There are two significant points that were not well considered by the agency in assessing the impact that its EV multiplier would have: 1) federal regulatory incentives already exist in the current greenhouse gas program, and 2) the impact of state ZEV requirements. Moreover, historic evidence raises doubts about the value of even the current, uncapped multiplier in driving additional ZEV sales. This calls into question the entire premise of EPA's use of the multiplier moving forward.[EPA-HQ-OAR-2021-0208-0277-A1, pp. 23-24]

To the first point, EPA already substantially incentivizes EV adoption by excluding upstream emissions from the compliance calculation, thus overstating the net greenhouse gas benefits of EVs.47 The impact of this is significant—in the 2012 regulation, EPA calculated that this cut the advantage to a manufacturer deploying a Nissan Leaf in 2025 from 136 g/mi (under 0 g/mi accounting) to just 41 g/mi, equivalent to more than a 3X multiplier.48 Obviously a multiplier on top of this results in multiplicatively worse emissions outcomes—for example, the industry leader in EV sales, Tesla, generated 8.6 million Mg of credits from the use of the multiplier in 2018, despite representing only slightly more than 1 percent of industry sales. Even without the multiplier, 0 g/mi accounting alone represented an overestimate of about 6 million Mg of emissions impacts. In EPA's modeling, EV sales increase to around 8 percent of the market, which means that upstream accounting accounts for on the order of 40 million Mg of undue credit annually, even without multipliers—that's equivalent to a reduction of about 12 g/mi in stringency.49

Given an incentive this strong, it is no surprise that EPA's modeling shows only very low levels of additional internal combustion engine technology deployment.

A complicating factor about federal regulatory incentives to spur EV adoption is that states are already leading the way. California set the first ZEV sales requirements in the country, and eleven states have since adopted those ZEV requirements.50

Unsurprisingly, the states with ZEV requirements see more EV models and greater EV adoption.51 While complementary policies and differences in local demography may play a role, the data is clear: manufacturers preferentially distribute and sell EVs in states with ZEV policies. As a result, while so-called ZEV states make up less than 30 percent of the new car buying market, consumers in those states purchase nearly two-thirds of all EVs (Figure 10) [Figure 10 can be found at docket number EPA-HQ-OAR-2021-0208-0277-A1, p. 25]

However, while ZEV sales requirements are driving sales upwards in those states, EV sales around the country are on the rise. So, a natural question arises: Are EV credit multipliers helping to drive that boost? The data raises doubts.

Apart from Tesla's sales, which skyrocketed beginning in 2017 with the releases of the Model 3 and Model Y (which together now make up more than half of all EV sales annually), EV sales have grown steadily, consistent with the pace of growth required by state ZEV policies (Figure 11). [Figure 11 can be found at docket number EPA-HQ-OAR-2021-0208-0277-A1, p. 26]

While there may be some additionality from federal regulatory incentives (after all, EVs are not sold exclusively in ZEV states), there has been no proportional jump in sales in response to EV multipliers. For automakers other than Tesla, sales have remained proportional to the number of vehicle offerings, a number which is also related to increasing state ZEV requirements (since many of those models can only be found in ZEV states). [EPA-HQ-OAR-2021-0208-0277-A1, pp.23-26]

For Tesla, it is likely that federal EV incentives have helped support growth, since the sale of overcompliance credits to EV laggards like Stellantis and Mercedes helps improve profit margins on their EV offerings. However, such credits are reducing the incentive for those companies themselves to invest in electrification, so it is not clear how much of a win even Tesla's bonus credits are, on net.

Growth in EV sales predominantly coming from Tesla and from sales in ZEV states indicates that federal emissions regulations to date (applicable to all states) have not been a primary driver of EV sales. While this does not preclude federal regulations driving adoption in the future, particularly if EPA sets standards much stronger than those proposed, it appears that EPA's current incentives are not driving additional sales. This means that overcrediting EVs acts simply as a windfall for manufacturers responding to other policies and incentives.

As a windfall credit serving primarily to weaken the federal program, EV incentives are doing so at a significant environmental cost. Since 2011, manufacturers have reduced lifetime fleet emissions by nearly 1 billion metric tons by responding to strong standards set under the Obama administration for MY2012-2020—however, our analysis indicates that an additional 66 million Mg of extra EV credits were used for compliance, resulting in relative increases in emissions and fuel use of nearly 7 percent over where we'd be without those incentives.52

Impact of stringency on EV adoption, compared to EV multipliers. Given the directive in EO 14037 to target new EV market share of 50 percent in 2030, it makes sense to focus particularly on how well EPA's proposed MY2023-2026 standards align with that goal. As depicted in Figure 7, we see a clear and obvious trend—the best way to increase the levels of EV adoption is to increase stringency of the standard. Even EPA's relatively constraining cap on the adverse impacts of EV multipliers has a notable reduction in the incentive to adopt further technologies overall, including electrification—this directly results in a weaker rule and lower level of EV penetration in the fleet. [Figure 7 can be located at docket number EPA-HQ-OAR-2021-0208-0277-A1, p. 17]

Our previous analysis showed the same trend.53 In that analysis, the incentive was significantly more expansive, leading to an even more dramatic disparity in EV adoption. This makes clear just how critical it is to limit this type of incentive.

General support for capping multiplier effects. To best support the deployment of EVs, UCS strongly supports eliminating EV multipliers, which our modeling shows are ineffective in encouraging greater sales, and instead increasing overall stringency of the greenhouse gas program. However, should EPA continue to move forward with a new phase of EV multipliers, we are strongly supportive of the agency's proposed approach with the cap. The current cap is appropriately low—with a typical fleet compliance of 200-250 g/mi in this timeframe, even using all of the cap in a single year would affect no more than a few percent of a manufacturer's fleet in that year. Because the total impact is relatively low, allowing manufacturers to distribute the total cap utilization according to their own optimal usage does not pose a drastic risk—however, generally such flexibility is maximized by manufacturers at a cost to the goals of the program, and any increase in the total g/mi value of the cap or additional years in which the multipliers are made available significantly enhances such risk.

We urge EPA to reconsider its support for the EV multipliers, but the mechanism put in place is far superior to that linked to the California framework, and any future changes other than complete elimination should be modeled on the proposed cap. [EPA-HQ-OAR-2021-0208-0277-A1, pp.27-28]

49 This is a rough estimate based on 16 million vehicles and a 50/50 passenger car/light truck split and is solely meant to be illustrative of the magnitude of the incentive, which is worth roughly one year of stringency at the levels of EV adoption forecast in this rule.

50 In addition to California, the states that have formally adopted ZEV standards are: Colorado, Connecticut, Maine, Maryland, Massachusetts, Minnesota, New Jersey, New York, Oregon, Rhode Island, and Vermont. Moreover, Nevada is 'on track' to adopt the California standard (Bright, Z. 2021. 'Nevada on track to adopt version of California's low- and zero-emission vehicle-programs.' The Nevada Independent, July 29, 2021), and Virginia has signed legislation establishing a ZEV program in Virginia under HB 1965.

51 For a comprehensive look at local policy, see https://theicct.org/publications/ev-update-us-cities-aug2020. For an example of how this affects model availability, see this announcement from Hyundai of its brand new PHEV SUV: 'Currently, 2022, Santa Fe Plug-in Hybrid is only sold in CA, CO, CT, ME, MA, MD, NJ, NY, OR, RI, and VT.' https://www.hyundaiusa.com/us/en/vehicles/2022-santa-fe-plug-in-hybrid

52 Note that we are not considering a 1:1 relationship between credited emissions reductions and real-world impacts because of the difference between lab certification procedures and real-world performance. Also, because some of this loss is the result of not accounting for upstream emissions from the electrical grid, to the extent that the grid continues to get cleaner with time the long-term impact will be reduced somewhat.

Commenter: Valero Energy Corporation (Valero)

EPA seeks comment on its proposal to extend multiplier incentives to manufacturers of electric vehicles through 2025, and specifically, on whether to adopt a less aggressive standard

("Alternative 1") or a more aggressive target ("Alternative 2"), in either case without the use of multipliers. Among this limited range of options, Alternative 1 appears preferable as compared to the proposed standards. The current proposal inflates the light-duty vehicle emissions reduction goal so that it can be met only by using multipliers. [EPA-HQ-OAR-2021-0208-0601-A2, p.4]

Finally, the only rationale EPA provides for setting the multipliers at the high values in the proposed rule is to make the values match those in the California Framework Agreements for MY 2022-2025.[10] In doing so, EPA is unconstitutionally delegating its rulemaking authority to California and the automakers party to those agreements, in conflict with the non-delegation doctrine and the doctrine of equal sovereignty. While there is value to having consistent rules across the country, incentives appropriate to the California program may not be appropriate for a nationwide standard and certainly allocates preferential treatment to California. EPA must make the determination of the proper efficiency level and the necessary multiplier values for itself rather than delegate such rulemaking to California. [EPA-HQ-OAR-2021-0208-0601-A2,p.5]

Commenter: Volkswagen Group of America, Inc. (Volkswagen)

Support for Extending Advanced Technology Vehicle Multipliers. Volkswagen supports the comments provided by AFAI regarding the extension and enhancement of the advanced technology vehicle multipliers (EV multipliers). As described throughout Chapter 2 of these comments, Volkswagen's future market plans and compliance pathways are focused on delivering high levels of electrification to the US market through 2026 and beyond. The EV multiplier provides a valuable compliance mechanism that helps to incentivize early electrification programs that would otherwise be challenged with high costs and low levels of public charging infrastructure. Volkswagen agrees that while the multiplier may reduce the overall programmatic reductions in CO_2 in the near-term, the flexibility will drive additional volumes of electrification beyond which otherwise may achieved. This additional volume will help to further commercialize EV technology and will lay the groundwork for longer-term CO_2 benefits. Volkswagen has actively used the multiplier flexibility in the current GHG regulation and projects to continue to do so, both under this proposal and under our parallel California Framework Agreement.

Volkswagen believes the multiplier remains a prudent policy choice during this early and transitional phase of electric vehicle deployment. Volkswagen acknowledges that as the costs for EVs approach parity with conventional vehicles, and as the public recharging infrastructure improves, the need for this incentive will diminish. However, Volkswagen projects that for the duration of this NPRM (i.e. 2026MY), electric vehicles with market demanded ranges and functionality will not achieve price parity with comparable conventional vehicles. Furthermore, public policy efforts to build nationwide charging stations will still be in the midst of development and deployment, meaning consumers will still be facing challenges with finding adequate recharging infrastructure. Therefore, Volkswagen supports that EPA retain the multiplier and consider options to expand the overall level of support.

As a signatory to the California Framework Agreement, Volkswagen supported the inclusion of an extended EV multiplier which included a phase down of the multiplier and an overall programmatic cap. Volkswagen believes this was a pragmatic approach which balances the market incentivizing effect with overall CO2 reduction goals. A cap helps estimate the potential impacts on CO2 emissions and to weigh this against the incentivizing effect of the flexibility. EPA's proposal models their extension on the Framework by also including a phased reduction of the multiplier with a similar, but more restrictive, credit cap.

Volkswagen supports the extension of the multiplier, but recommends a higher overall credit cap. A higher cap will help the flexibility be applicable to an even greater number of EVs which will be helpful in further expanding the EV market. Volkswagen believes that one alternative approach EPA may consider is to reduce the per year multiplier value, but increase the annual average cap. This approach would motivate even further EV deployment in order for a manufacturer to fully utilize the flexibility. [EPA-HQ-OAR-2021-0208-0237-A1, p.12]

Commenter: Volvo Car Corporation

Compliance Incentives, Flexibilities, Credits. Volvo Car supports the agency’s proposed modifications to the Compliance Incentives and Flexibilities (86 FR 43733). Specifically, extending the advanced technology vehicle multiplier and increasing the cap for off-cycle technologies supports electrification and the introduction of new energy efficient technologies. [EPA-HQ-OAR-2021-0208-0253-A1, p. 3]

With respect to ATV credits, Volvo Cars is concerned the proposed cap of 2.5 g/mile per model year for these credits is too low and not reflective of the market value. Volvo Cars believes EPA should raise the cap so that it is consistent with the value of the other technology caps. Please refer to the Auto Innovators comments on EV Multipliers for more information. [EPA-HQ-OAR-2021-0208-0253-A1, pp. 3-4]

Commenter: Zero Emission Transportation Association (ZETA) and EVHybridNoire (EVHN)

ZETA and EVHN recommend the elimination of multiplier credits for EVs. Extending the lifetime of credits, including multipliers that double the credits earned for every EV sold, weakens the standards and indirectly incentivizes traditional automakers to continue manufacturing their least efficient vehicles that generate the highest profit margins, especially as EVs reach price parity. As the current standards are written, internal combustion engine vehicles (ICEVs) are sales-weighted for their average fuel economy. The current EPA standards were also set to phase out the advanced technology multiplier that had allowed EVs up to a 200% credit multiplier. This strategy allowed conventional automakers to meet the minimum standard while under-complying on their ICEVs, essentially acting as an offset of emissions reductions from EVs.7

Research has shown that as EVs become less expensive, as they have in the last decade, and there is still demand for ICEVs, using the multiplier credits will allow traditional automakers to continue making and selling their most inefficient vehicles. Credits made sense initially to incentivize automakers to develop new electric technologies, but now that EVs are more widespread, Advanced Technology Vehicle (ATV) multipliers should be phased out as initially intended.8 EPA should not extend the advanced technology multiplier. [EPA-HQ-OAR-2021-0208-0275-A1, pp. 3-4]

EPA Response

EPA is finalizing ATV multipliers for MYs 2023-2024 only rather than the proposed MYs 2021-2025 and at lower numeric multiplier values than proposed. Also, EPA is retaining the proposed cumulative cap of 10 g/mile for multiplier credits. These provisions as well as EPA's response to comments regarding the magnitude and timing of multipliers are provided in preamble section II.B.1. Comments regarding upstream emissions are addressed in section 6.2 below.

Chemours raises concerns that the incentives for manufacturers to transition away from the use of air conditioning refrigerant HFC-134a are diminished by the proposed multipliers and could conceivably result in a "switch back" to this high-global warming potential ("GWP") refrigerant. EPA understands the concern raised by Chemours that, since EPA's air conditioning refrigerant credits are voluntary, if too many other types of credits are available to manufacturers, they could opt not to claim the optional A/C credits. EPA believes these concerns are significantly diminished both due to the narrower scope of the multiplier incentives included in the final rule compared to the proposal and the more stringent standards EPA is finalizing in MYs 2025-2026, as compared to the proposal. While the A/C credits remain an optional avenue to help with compliance, EPA believes the refrigerant credits will remain attractive to manufacturers who have made the investment to switch over to the new refrigerants and it is unlikely that they would switch back and forego the credits in the time frame of this rule, given the stringency of the standards being adopted. These A/C credits have proven to be a cost-effective GHG control strategy as evidenced by most manufacturers claiming the credits by switching refrigerants and will likely remain so in the future.

The Environmental Protection Network commented that the impact of the multipliers on sales of EVs is not clear from the proposal. Other commenters too raised concerns that the multipliers could actually lead to reduced EV production in these MYs. For the Final Rule, EPA conducted model runs with and without the final multipliers and found the model predicted little difference in market penetration of EVs due to the multipliers alone (see RIA Chapter 4.1.4). EPA does not expect the final multipliers to adversely impact EV production.

Ford recommended that EPA add additional cap space to the light-duty truck portion of the fleet. Ford commented that "this would allow an overall fleet level cap somewhat higher than the proposed 10 g/mi, depending on truck mix and that this approach would help alleviate the proportionally lower benefit provided to OEM's with higher truck mixes (trucks tend to have higher GHG obligations)." EPA does not believe such an approach is warranted and is not differentiating between light-duty trucks and passenger cars for purposes of applying the multiplier cap. All manufacturers regardless of product mix will have the same magnitude of multiplier credits. The standards EPA is adopting for light trucks are feasible without additional multiplier credits for the vehicle class. Retaining the 10 g/mile cap as proposed preserves the most emissions reductions feasible. EPA also notes that in addition to multipliers it is providing another flexibility targeted specifically to full-size pickups (see section X).

Walter Kreucher commented that the proposed multipliers were a clear indication that EPA does not think the proposed standards are achievable. In response, EPA disagrees with the commenter's characterization. EPA is in fact adopting more stringent standards than proposed with less generous multipliers than proposed. While multipliers are one of the flexibilities EPA is including for the near-term MY 2023-2024 standards, EPA does not believe the feasibility of the standards hinge on manufacturers making full use of them. These are optional incentives that EPA is including to help manufacturer manage the transition to more stringent standards in the longer term by providing some additional flexibility.

Lucid commented that the cap was intended to target manufacturers that produce vehicles with internal combustion engines and prevents them from counterbalancing high-emitting vehicles with ZEV sales and that ZEV-only manufacturers should not be subject to this cap because they are not offsetting sales of ICE vehicles in their own fleets. EPA disagrees with this comment since ZEV-only manufacturers would likely sell those credits to manufacturers that would use them to offset ICE vehicle emissions, since the ZEV-only manufacturer would have no use for the credits within their own fleet. For example, it has been Tesla's practice to date to sell their credits to other manufacturers. This has the same practical impact as a manufacturer with a mix of vehicle types using the credits generated by ZEVs in their own fleet.

The Illinois Corn Growers Association commented that "multipliers do not meaningfully encourage the adoption of electric vehicles, but instead serve only to enrich electric vehicle manufacturers at the expense of consumers, industry, and the environment." It commented that "EPA will be able to point to the benefit to the electric vehicle industry, allowing it to 'greenwash' the social, environmental, and economic costs of this wasteful approach. This is arbitrary and capricious and lacks any sound basis in evidence to support EPA's claim that its standards will benefit 'public health and welfare.'" It also commented that "the approach is also out of step with the Clean Air Act. Section 202(a) requires EPA to 'prescribe . . . standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines, which in [its] judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare.' This does not allow the agency to set standards and then provide ways that regulated entities can avoid those standards by giving money to electric vehicle manufacturers." EPA disagrees with this characterization. EPA has fully incorporated the multipliers into its cost and emissions reductions estimates for final rule and has established a cap on the emissions impact of the multipliers. The final rule standards will provide significant emissions reductions even after taking the small impact of the multipliers into consideration. Furthermore, EPA continues to believe that zero-emissions EV technology is key to long-term GHG reductions and the multipliers signal EPA's continued support for this important technology while providing additional flexibility to manufacturers in the near-term.

Valero commented that the proposal inflated the light-duty vehicle emissions reduction goal so that it can be met only by using multipliers. Valero also commented that "the only rationale EPA provided for setting the multipliers at the high values in the proposed rule is to make the values match those in the California Framework Agreements for MY 2022-2025" and that "in doing so, EPA is unconstitutionally delegating its rulemaking authority to California and the automakers party to those agreements, in conflict with the non-delegation doctrine and the doctrine of equal sovereignty." EPA disagrees with both of these comments. The multipliers provide a very limited voluntary flexibility and as such are not required to be part of the compliance pathway for any manufacturer. The final standards are feasible without the use of the multipliers. In response to comments regarding EPA choosing to propose multiplier values in line with those of the California Framework, EPA disagrees that this choice represented some relinquishment of authority. EPA requested comment on the level and scope of the multipliers, making it clear that EPA could finalize different multiplier values than it proposed, and we are in fact doing so. Also, EPA proposed a cap that was much lower than that contained in the California Framework. Finally, EPA has decided, after fully considering comments, to finalize multipliers that are in line with its multipliers for MY 2021 and lower numeric multipliers than proposed. Please see section 16 for EPA's response to additional comments regarding delegation of rulemaking authority.

Regarding comments submitted by the Southern Environmental Law Center, regarding incorporating some differentiation in the multiplier for PHEVs based on their all-electric range, EPA has already limited multipliers significantly in both the level of the multiplier and the MYs when they are available. Given that they will be in place for only two model years, EPA does not believe this additional limitation is necessary.

Toyota comments that the multiplier for PHEVs should be the same as those for EVs, because PHEVs are capable of operating with zero tailpipe emissions depending on how they are used. In response, EPA is continuing to differentiate between the two technologies, with PHEVs receiving a lower multiplier compared to EVs or fuel cells, because PHEVs include an internal combustion engine and zero emissions operation depends on driver charging habits and how the vehicle is used. While PHEVs may be capable of operating with zero tailpipe emissions, zero tailpipe emissions are not assured in the same way it is for full EVs.

UCS commented that EPA's proposal did not consider that EVs are already incentivized in EPA's GHG program through the use of zero g/mile compliance emissions level (i.e., the EPA program does not require manufacturers to account for upstream emissions through MY2026) and are also incentivized in state programs. UCS is concerned that the multipliers represent a windfall for manufacturers that only act to weaken the program. Due to these and similar concerns expressed by other comments regarding the impact of multipliers, EPA has reduced the scope of multipliers, including them only for MYs 2023-2024, primarily to help address any potential lead time concerns for those model years as discussed in section II.B.1 of the preamble.

Upstream Fuel Production and Transport Emissions. Upstream emissions associated with electricity production should not be assigned to EVs for compliance purposes; limitations to this approach should be removed.

Under current regulations, EPA assigns a value of zero grams per mile of carbon-related exhaust emissions to vehicles for the electric portion of their operation.109 This approach is generally limited to certain model years and, for some model years, to a limited quantity of EVs.

Assigning a compliance value of zero grams per mile is technically correct—an EV operating on electricity has no tailpipe emissions, GHG or otherwise.

The recognition of zero tailpipe emissions from operation on electricity is also consistent with the treatment of vehicle operation on all other fuels—emissions are measured at the tailpipe no matter what fuel the vehicle is operating on, and upstream emissions are addressed at their upstream sources. Electricity should be treated no differently than gasoline, ethanol, natural gas, and every other fuel used in motor vehicles.

Nor does a compliance value of zero grams per mile negatively affect the emissions benefits of the GHG standards. The upstream emissions impacts of fuel production and transportation for all fuels projected to be used under the proposed standards are addressed in the benefit-cost analysis. If upstream emissions are assigned to vehicles, the benefit-cost analysis does not change. The only effect is to add additional technology and market pressures to manufacturers which would need to be considered by EPA in its analysis of what level of standard is appropriate.

We recommend that EPA remove all limitations (model year, production volume, or others) to the use of zero grams per mile for the tailpipe emissions of EVs operating on electricity and to move this compliance provision to a section more appropriate than that dealing with incentives for EVs (e.g., 40 C.F.R. Part 600).

If EPA does not eliminate all model year and production limits for the use of zero grams per mile for the GHG emissions of a vehicle operating on electricity, it should issue a rule to clarify that 40 C.F.R. 86.1866-12(a) applies to model years 2012 through 2026.

In the current regulation, there is a potential conflict between 40 C.F.R. § 86.1866-12(a), which allows the use of zero grams per mile in MYs 2012-2025, and 40 C.F.R. § 86.1866-12(a)(2), which specifies that the provision is unrestricted in MYs 2017-2026. EPA clearly intended to extend the zero gram per mile provision through MY 2026 in prior rulemaking.110 Notwithstanding our comment that upstream emissions should never be included for the purpose of compliance with EPA light-duty vehicle GHG regulations, we recommend that EPA correct the regulatory text at paragraph (a) to include an endpoint of MY 2026 for consistency with the subsequent subparagraph (a)(2). [EPA-HQ-OAR-2021-0208-0571-A1, p. 35-36]

Commenter: Alliance for Vehicle Efficiency (AVE)

AVE urges EPA to account for lifecycle and upstream emissions for all vehicle technologies, and the fuels that power them in future emission standards. AVE also requests EPA work with the Department of Energy and NHTSA to create a unified accounting approach for lifecycle emissions. [EPA-HQ-OAR-2021-0208-0256-A1, p. 2]

Lifecycle (Upstream) Emissions. AVE urges EPA to work with the Department of Energy and NHTSA to create a unified approach for including lifecycle emissions into the Proposed Rule and future standards.

It is essential that EPA incorporate a lifecycle analysis (LCA), and account for all upstream emissions, for all vehicle technologies and the fuels that power them in future emission standards. LCA is a necessary element of the U.S.'s efforts to transform the transportation system into one that is significantly less carbon intensive.

This transformation is already in process with significant investments in renewable sources of energy, renewable and lower carbon fuels, more sustainable forms of generation to power the electrical grid, and expanded supply chains to provide the resources necessary to support production of a greener light-duty fleet. Adoption of LCA would better prepare industry for the impact of expiring multiplier credits and the accounting of upstream, embedded, and end-of-life carbon emissions which influence the technology investments being made today by OEMs and suppliers. Yet, 'EPA is continuing to use tailpipe-only values to determine vehicle GHG emissions, without accounting for upstream emissions (EVs and PHEVs will continue to use 0 g/mile through MY 2026).'13

EPA's focus solely on tailpipe emissions appears in contrast to President Biden's January 25, Executive Order, in which he stressed the need for standards to account for all GHG emissions.

Accounting for the Benefits of Reducing Climate Pollution. (a) It is essential that agencies capture the full costs of greenhouse gas emissions as accurately as possible, including by taking global damages into account. Doing so facilitates sound decision making, recognizes the breadth of climate impacts, and supports the international leadership of the United States on climate issues.14

All transportation-related industries have a role to play in helping the U.S. meet our carbon reduction goals. LCA provides a holistic approach to truly impact the environment and has been recognized in environmental assessments in other jurisdictions. AVE agrees with the aspirations and direction of President Biden's Executive Order to address the 'full-costs of greenhouse gas emissions as accurately as possible.'15

LCA is challenging, and different LCA models exist, but LCA is not new:

• Low carbon fuel standards, such as the Federal Renewable Fuel Standard and the California Low Carbon Fuel Standard, have led to significant reductions in GHG emissions from transportation fuels. These standards rely on LCA as a tool to estimate the GHG emissions of fuels.16

• DOE's Argonne National Laboratory also engages in substantial research on the LCA of vehicle and fuel technologies to improve energy efficiency and reduce GHG emissions in the transportation sector. EPA should work with DOE to measure the true impact of all technologies and develop performance-based standards that incorporate the LCA of emissions from all vehicle technologies to create a more accurate assessment of their overall GHG impact.

• DOE has been conducting LCA data modeling for many years and EPA should be encouraged to use DOE's GREET model as a starting point. The chart below is one example of GREET modeling comparing the footprint of various vehicle technologies [EPA-HQ-OAR-2021-0208-0256-A1, pp.6-7] [Figure ES-1 can be found at docket number EPA-HQ-OAR-2021-0208-0256-A1, p. 7.]

Commenter: American Council for an Energy-Efficient Economy (ACEEE)

EPA proposes to continue treating electric vehicles as entirely zero emission vehicles (ZEVs). While it is true that EVs generate no emissions at the tailpipe, charging these vehicles does create emissions upstream. Treating electric, and other similar zero-tailpipe emission vehicles, as true ZEVs leads to a situation where the creation and sale of these vehicles actually increases fleetwide emissions (Jenn, Azevedo, and Michalek 2016; A. C. Mersky and Samaras 2020). This is because ZEVs are credited with emissions reductions in excess of their real reductions, which allows for a higher number of high-emitting vehicle sales. Additionally, as noted above, over-awarding emissions credits to EVs can depress EV sales (Gillingham 2021).

Another major flaw with ignoring refueling emissions is that EPA loses the opportunity to influence the efficiency of a growing component of the vehicle market. EPA is both empowered and required to regulate the emissions from on-road light duty vehicles. If 50% of all new vehicle sales are EVs by 2030, EPA cannot fulfill its obligations while ignoring the upstream emissions of these vehicles, which are directly tied to how effectively EVs convert kilowatt hours into miles traveled. While the White House also plans to significantly reduce emissions from the power sector in the long-run, emissions from electricity generation are expected to still exist into the next decade. This makes the emissions of EVs sold under the current rules significant, even in the face of other regulations in the power sector.

Additionally, ignoring upstream emissions may have the counterproductive effect of encouraging sales of larger vehicles. If all EVs are treated as having zero emissions then automakers are encouraged to focus efforts on those vehicles with the highest emission limits, in order to generate the most credits and reduce compliance costs for the rest of the fleet. This leads to an increase in total energy consumption and emissions, as well as increased wear and tear on our roads and congestion, compared to a scenario where upstream emissions are accounted for, and automakers have no incentive to increase EV footprint.

ACEEE research shows that accounting for upstream emissions for ZEVs, based on an average national grid over the life of the vehicle, would increase the annual effective stringency of the proposed standards by 1-3 g/mi and lead to an additional emissions savings of 9% for the MY 2023-2026 standards. Given the significant reduction in rule stringency that this zero-upstream emissions accounting causes ACEEE believes that it is necessary to revert to counting those emissions, as provided for in the MY 2017-2025 standards. [EPA-HQ-OAR-2021-0208-0251-A1, pp. 6-7]

Restore upstream accounting for zero tailpipe emission vehicles [EPA-HQ-OAR-2021-0208-0251-A1, p.14]

Commenter: American Fuel & Petrochemical Manufacturers (AFPM) et al

Moreover, the disparate tests EPA uses for assessing fuel economy and GHG emissions of ICEVs and EVs, and on which the Agency relies for this proposal, should not be used to award de facto ‘bonus’ credits to EVs for fuel economy or GHG reductions.31 EPA notes in the Regulatory Impact Analysis accompanying the proposal that the Agency ‘extended the ‘0 g/mi upstream’ incentive for electric vehicles through 2026 beyond its original sunset of MY 2021.’32 This is arbitrary and capricious. This ‘incentive’ arbitrarily fails to account for real-world fuel economy, and any emissions and other real-world environmental impacts.33 There is no such thing as a zero-emission vehicle.34 Policymakers must compare the environmental, economic, and performance attributes of current conventional vehicle technology with alternatives such as EVs. [EPA-HQ-OAR-2021-0208-0286-A1, pp. 5-6]

31 EPA’s test procedures for demonstrating compliance with these standards are arbitrary and the differences between procedures for EVs and ICEVs cannot be reconciled. EPA’s proposal states ‘EPA is continuing to use tailpipe-only values to determine vehicle GHG emissions, without accounting for upstream emissions (EVs and PHEVs will continue to use 0 g/mile through MY 2026).’ The omission of significant lifecycle emissions renders EPA’s analysis arbitrary and capricious. Moreover, EPA should not finalize this proposal based on this 0 g/mile EV assumption until it eliminates irreconcilable differences between its testing procedures of EVs and ICEVs for GHG emissions and fuel economy. For example, for fuel economy, ICEVs must be tested on a robust 5-cycle test method that factors in all types of real-world driving conditions (see, https://www.fueleconomy.gov/feg/fe_test_schedules.shtml). Conversely, EPA does not subject EVs to the same robust fuel economy tests as internal combustion engines. Instead, EPA has adopted a procedure that requires only the first two tests, in a laboratory setting, at ideal temperatures for batteries, ultimately divorced from real-world driving conditions (see, https://www.fueleconomy.gov/feg/pdfs/EPA%20test%20procedure%20for%20EVs-PHEVs-11-14-2017.pdf).

33 EPA has arbitrarily created an EV subsidy program that is beyond the authority granted to EPA by Congress. EPA attempts to justify its creation of this program by stating that the effect of the multipliers on electric vehicle penetration will be ‘less than 0.5 percent’ in any year. In making this statement, EPA concedes it has created an on-paper subsidy program that will increase EV sales.

Commenter: American Honda Motor Company (Honda)

Upstream Emissions Accounting. In the proposed rule, the agency states its intent to continue using 'tailpipe-only values to determine vehicle GHG emissions, without accounting for upstream emissions (EVs and PHEVs will continue to use 0 g/mile through MY 2026).'23 Honda supports this position. While full lifecycle accounting is necessary to quantify emissions inventories, it is inappropriate to hold the auto industry accountable for emissions that are beyond its control. As such, we support a clear division of regulatory responsibility between the auto and utility industries. Applying 0 g/mi upstream emissions accounting for BEVs, PHEVs and FCEVs is not only logically appropriate, but will encourage the transition toward greater levels of vehicle electrification. [EPA-HQ-OAR-2021-0208-0565-A1, p.12]

Commenter: BorgWarner Inc.

Lifecycle. We support the transition from a tailpipe-based standard (tank-to-wheel) to a more holistic assessment (well-to-wheel emissions, or more completely, full life-cycle emissions) as the proper metric for determining the environmental impact of the vehicle as a product. This approach is consistent with technology neutrality and global carbon neutrality goals. Regulations based on the end goals of a clean environment, minimizing CO2 emissions and preserving resources should not give preferential treatment to a specific technology. Public policies should let innovation and market dynamics determine the most effective solutions to achieve the end goals. [EPA-HQ-OAR-2021-0208-0260-A1, p. 2]

Commenter: Center for Biological Diversity, et al.

EPA should continue to count the upstream emissions of EVs, PHEVs and FCVs. The 2012 Final Rule treated the upstream (from electricity production) emissions of EVs, PHEVs and FCVs as zero through MY 2021, but, beginning with MY 2022, required automakers to account for them in their standard compliance calculations. 2012 Final Rule, 77 Fed. Reg. 62,651. EPA now proposes to again allow automakers to ignore upstream emissions for compliance purposes through MY 2026, Proposal, 86 Fed. Reg. at 43,746; EPA would include upstream emissions only in its analysis of the Proposal's costs and benefits, e.g., id. at 43,735.

We urge EPA to again require automakers to count these vehicles' upstream emissions in their compliance calculations for the same reasons discussed in connection with multiplier credits. In 2012, EPA stressed that the exclusion of upstream emissions was temporary only, and intended for the sole purpose of incentivizing the production and of then-novel zero- and near-zero technology that would produce far greater emissions reductions later. EPA provides no different justification in the Proposal. But as explained above, the conditions that earlier might have provided reasonable grounds for ignoring this pollution in the standard-setting process no longer pertain.

Moreover, as is the case with multipliers, ignoring upstream emissions ascribes more climate benefits to zero or near-zero vehicles than they achieve in the real world; and, also as is the case with multipliers, when those vehicles begin to reach price parity, not counting their upstream emissions is likely to impede their sale as automakers can use the extra but phantom emissions reduction to sell fewer of them while still reaching the stringency targets, or to sell more higher-polluting internal combustion vehicles. 149 A full accounting of the light duty vehicle fleet's actual greenhouse gas emissions is also necessary to correctly assess its contribution to the climate crisis and to set the stringency of emission standards accordingly.

At a minimum, EPA should not allow automakers to count them as zero g/mile after MY 2024, when any lead time concerns play no role. [EPA-HQ-OAR-2021-0208-0651-A1, p. 63-64]

Furthermore, should EPA finalize its proposal to reinstate crediting EVs with a compliance value of 0 g/mile or less while real-world EV emissions are positive due to emissions associated with electricity production, then a larger EV penetration will undercut the expected GHG reductions from the program.

EPA could address these concerns by adopting one or both of the following designs: (1) account for EV upstream emissions as it did for MY 2021 and later in the 2020 Final Rule – and as we already urge EPA to do in our credit discussion – and /or (2) set a minimum rate of improvement for ICE vehicles to ensure steady, meaningful progress in emissions reductions. [EPA-HQ-OAR-2021-0208-0651-A1, p. 77-78]

Commenter: Consumer Reports (CR)

EV Upstream Emissions. Consumer reports does not support continuing to expand the "0 g/mi" assumption for EV emissions through 2026. While EVs have much lower fuel cycle emissions than all gasoline vehicles, their emissions are not zero. The core purpose of these standards are to reduce emissions, and not counting the emissions from EVs unfairly benefits electric vehicles under a standard that is supposed to be technology-neutral. While electric vehicles are an important technology for meeting our long term climate goal, they should not be given unfair advantages under this standard. Transportation electrification is expected to rapidly increase, and as it does the lost consumer savings and emissions benefits due to the "0 g/mi" will also grow rapidly. See section 3d for further data to support the likelihood of higher EV penetration rates. [EPA-HQ-OAR-2021-0208-0602-A1, p.12]

Commenter: Edison Electric Institute (EEI)

Included in the proposed suite of compliance flexibilities is the continued recognition of EVs as 0 g/mi without any phase-out, consistent with the current regulations. See 77 Fed. Reg. 62,810-26 (Oct. 15, 2012). This determination is appropriate because these vehicles have no tailpipe emissions when operating on electric power.18 Accordingly, the Agencies should continue to credit EVs with a 0 g/mi emission factor for all future MYs as EVs do not emit pollutants from the tailpipe of the vehicle—without a combustion engine, there are no vehicle emissions, and treatment of each EV as 0 g/mi is an accurate and practical method of counting their impact on transportation sector emissions.

This recognition and EPA's decision not to specifically account for any upstream emissions impacts is consistent with CAA section 202(a)(1), which directs EPA to regulate "the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines…such standards shall be applicable to such vehicles and engines for their useful life." 42 U.S.C. 7521(a)(1). The statute clearly directs EPA to regulate emissions from vehicles and engines, and as EVs do not emit any pollutants, the continued recognition of their 0 g/mi tailpipe emissions is both technically and legally appropriate.19 [EPA-HQ-OAR-2021-0208-0284-A1, p. 10-11]

The continued reductions in GHG and criteria pollutant emissions from electricity generation will allow increased EV deployment to create additional environmental benefits, as the increased deployment of electric vehicles will use more of the increasingly clean power generated by the electric sector.20 Accordingly, EPA should continue to treat EVs as 0 g/mi sources and include averaging, banking, and trading provision. The continuation of these provisions is both appropriate and necessary in any final rule. [EPA-HQ-OAR-2021-0208-0284-A1, p. 12]

18 Recognizing that EVs are 0 g/mi sources, rather than having to account for the GHG emissions associated with upstream electricity generation up to a per-manufacturer cumulative production cap for MY 2022-2025, is well reasoned analysis—any upstream analysis of emissions is extremely difficult given that any upstream emissions will be a function of where and when a car is charged. Moreover, it is more appropriate and more direct to regulate upstream emissions at the point of generation, not at the point of consumption.

19 Should, however, EPA instead choose to take estimated upstream emissions into account when developing emissions factors for EVs, the Agency must note that the increased deployment of EVs will increase fuel economy and reduce dependence on imported petroleum, as well as reduce emissions of GHGs and criteria pollutants from the transportation sector. As power sector emissions have been reduced and are on a long-term trajectory toward further reductions, increased EV deployment, therefore, will not result in increased overall GHG and criteria pollutant emissions. Should EPA choose to analyze estimated upstream emissions, that analysis should be full and fair—it should consider all vehicle and battery and engine types and not single out EVs. As noted, however, the EPA should not engage in endless estimated upstream emissions analyses, and instead focus on emissions at the vehicle level, consistent with CAA's plain text. The Agency also should use the most recent available data in any emissions analysis to ensure accuracy in estimates.

Commenter: Michalek, Jeremy and Whitefoot, Kate S.

If the EPA's goal is to set standards for actual GHG emissions, it is important that all emissions associated with owning and operating a vehicle are accounted for. The largest of these missing from current EPA policy is the emissions from electric vehicle charging and from hydrogen production for fuel cell electric vehicles. As electric and fuel cell vehicles gain market share, these 'upstream' emissions will become a larger fraction of the emissions associated with the light duty fleet. Our view is that EPA should account for these emissions, because regulating only a particular subset of GHG emissions associated with operating a fleet distorts the incentives to reduce GHG emissions.

In accounting for EV charging emissions and other non-tailpipe emissions, we recommend that EPA use a consequential life cycle assessment framework, estimating the difference in emissions between a world with policy or AFV adoption and a world without that policy or AFV adoption. Such an assessment addresses the key question: identifying how a policy or technology action will change net GHG emissions. These assessments cannot be completed without uncertainty, since the counterfactual cannot be observed in the present, and all future projections are uncertain. However, the literature includes a range of regression-based and simulation-based methods for estimating consequential emissions from EV charging. EPA has used related methods in regulatory impact assessment to assess GHG implications of EV adoption, and we recommend that EPA seriously consider using such estimates in LDV GHG rule compliance.

Further, within the consequential framework, we recommend that EPA account for the projected emissions of electric vehicle charging and hydrogen production over the lifetime of the vehicles. Expected changes in marginal grid emissions associated with the electricity grid over the lifetime of the vehicles should be accounted for when determining the expected upstream emissions of these vehicles. [EPA-HQ-OAR-2021-0208-0300-A1, pp. 8-9]

Commenter: Minnesota Corn Growers Association (MCGA)

EPA's proposal continues to treat EVs as carbon neutral, without regard to the source of electricity powering the vehicles. Depending on the sources of electricity – whether coal, natural gas, wind or nuclear and the mix of those sources - full lifecycle emissions of EVs vary widely, masking the true GHG emissions from these vehicles. Without accounting for upstream emissions from these vehicles, full lifecycle emissions are not considered. Furthermore, EPA notes in the proposal that increases in electricity demand will result in increased non-GHG emissions for some upstream pollutants. EPA does a disservice to emissions reduction goals by accounting for upstream emissions from some fuels and vehicle technologies but not others, providing an advantage to the sources for which “wells to wheels” upstream emissions are excluded and concealing emissions from coal power generation, mineral extraction, and other high-carbon sources.

In a 2020 analysis of the impacts of preferential treatment for electric vehicles, such as credit multipliers and omitting electricity generation emissions in regulations in China, the European Union and the United States, researchers at Argonne National Laboratory found that GHG emissions in those three countries would reach 1 billion tons higher through 2050 than emissions would be without those preferences.31 They recommend that as the EV markets continues to grow and electricity generation remains GHG intensive in some markets, WTW GHG emissions need to be considered for all technologies to achieve GHG reductions, stating, “The WTW consideration will also level the playing field so that all technologies will compete on their GHG reduction merits.”32 We strongly agree with the need for a level playing field so that all low carbon fuels and technologies are compared on full and accurate lifecycle emissions on a technology and feedstock neutral basis. [EPA-HQ-OAR-2021-0208-0530-A1, p. 13-14]

Commenter: Motor & Equipment Manufacturers Association (MEMA)

MEMA Supports a Holistic Approach to a Climate Plan and Transportation Emissions. MEMA supports the administration’s goal of economy-wide net-zero carbon emissions by 2050. Accordingly, MEMA encourages EPA and the administration to provide a climate plan that is holistic, equitable, and economy-wide in scope, covering all industries and continuing to encourage innovation.

For the post-2026 program, a holistic or an ecosystem approach for the transportation sector includes looking beyond vehicle tail-pipe emissions. MEMA encourages upstream emission accounting for GHG emissions and criteria pollutant emissions associated with electricity generation used to power electric vehicles. Any transition to a new accounting method should provide sufficient time for industry to adapt. Agencies should fully evaluate current and planned electricity sources, capacity and infrastructure distribution capabilities before implementing future vehicle emission programs.

In MY2027 and beyond, the agency should consider a lifecycle analysis that evaluates the manufacture, materials, disposal, and transport for components needed for each vehicle technology. A lifecycle analysis is needed to evaluate the benefits of vehicle technologies and alternative and renewable fuels (potentially including efuels) to determine their impact on GHG emissions. This type of analysis will help policymakers understand the true GHG emissions cost for every vehicle technology and will be a necessary analysis to ensure the nation meets its economy wide goal of net-zero carbon emissions. Alternative or renewable fuels could be particularly useful as the electric utility sector is transitioning to a cleaner grid and as charging and refueling infrastructure continues to be developed. [EPA-HQ-OAR-2021-0208-0249-A1, p. 15]

Commenter: National Corn Growers Association (NCGA)

EPA's proposal continues to treat EVs as carbon neutral, without regard to the source of electricity powering the vehicles. Depending on the sources of electricity – whether coal, natural gas, wind or nuclear and the mix of those sources - full lifecycle emissions of EVs vary widely, masking the true GHG emissions from these vehicles. Without accounting for upstream emissions from these vehicles, full lifecycle emissions are not considered. Furthermore, EPA notes in the proposal that increases in electricity demand will result in increased non-GHG emissions for some upstream pollutants. EPA does a disservice to emissions reduction goals by accounting for upstream emissions from some fuels and vehicle technologies but not others, providing an advantage to the sources for which 'wells to wheels' upstream emissions are excluded and concealing emissions from coal power generation, mineral extraction, and other high-carbon sources.

In a 2020 analysis of the impacts of preferential treatment for electric vehicles, such as credit multipliers and omitting electricity generation emissions in regulations in China, the European Union and the United States, researchers at Argonne National Laboratory found that GHG emissions in those three countries would reach 1 billion tons higher through 2050 than emissions would be without those preferences.[31] They recommend that as the EV markets continues to grow and electricity generation remains GHG intensive in some markets, WTW GHG emissions need to be considered for all technologies to achieve GHG reductions, stating, 'The WTW consideration will also level the playing field so that all technologies will compete on their GHG reduction merits.'[32] We strongly agree with the need for a level playing field so that all low carbon fuels and technologies are compared on full and accurate lifecycle emissions on a technology and feedstock neutral basis. [EPA-HQ-OAR-2021-0208-0246-A1, p. 10]

Commenter: Nissan North America, Inc.

Continued Need for EV-Related Incentives. As noted above, EV market share has not grown as rapidly as many had expected over the last 10 years. In order to encourage auto manufacturers to further invest their time and resources in EV development (and to incentivize a more rapid transition to EV fleet offerings), Nissan urges EPA to maintain the EV-related incentives available under the current GHG program.

In particular, Nissan has consistently endorsed a policy of measuring GHG emissions for all vehicles, including EVs, based on tailpipe emissions, and not including upstream emissions associated with the electricity that powers these vehicles. Nissan supports EPA in continuing to allow manufacturers to use a 0 g/mi CO2 measure for all EVs without any quantity cap; however, as currently written in the regulations, this incentive would be phased out after model year 2026. Nissan encourages EPA to extend the applicability of the 0 g/mi incentive without limitation beyond model year 2026 in order to encourage manufacturer investment and widespread adoption of these alternative technologies. This is consistent with EPA's long-term goal of increasing the EV market share and with the fact that automobile manufacturers only control tailpipe emissions and have no control over the fuel source for electric power. An EV operating on electricity emits no tailpipe emissions, and automobile manufacturers should only be responsible for the emissions from the vehicles they produce. Including upstream emissions with EVs under the vehicle regulations would dis-incentivize EV production and could negatively impact automobile manufacturers' electrification efforts. [EPA-HQ-OAR-2021-0208-0529-A1, p. 6]

Commenter: Securing America's Future Energy

Treatment of Upstream GHG Emissions. In the final 2012 rule, EPA decided not to attribute upstream powerplant emissions to electric cars in calculating an automaker's average fleet emissions. EPA noted that even though '[t]he 0 gram per mile value accurately reflects the tailpipe CO2 gram per mile achieved by these vehicles,' the 'fuel use from these vehicles will impact the overall GHG reductions associated with the standards due to fuel production and distribution-related upstream GHG emissions which are projected to be greater than the upstream GHG emissions associated with gasoline from oil.'[51] EPA further acknowledged that combined tailpipe and upstream emissions for EVs are substantially lower than from gasoline vehicles using the average mix of fuel sources, and even lower where the electrical grid is cleaner than average.[52]

EPA then observed that because an EV's upstream emissions exceed those of gasoline vehicle, and 'there is currently no national program in place to reduce GHG emissions from electric power plants,' it was appropriate to consider upstream GHG emissions.[53] EPA ultimately declined, however, to consider upstream emissions in order to promote the commercialization of EVs and in recognition of the 'potential for game-changing GHG emissions and oil savings in the long-term.'[54]

SAFE believes that given the still nascent stage of EV deployment, that it remains appropriate to maintain this treatment of upstream emissions from EVs. In fact, in originally noting the rationale for regulating upstream emissions, EPA cited the fact that there was no national program to regulate powerplant GHG emissions. That, however, has changed. President Biden has stated his intentions to regulate emissions, and to do so to a more stringent standard than the Obama Administration's Clean Power Plan.[55] Moreover, Congress is actively considering doing so as well. Draft legislation recently released by the House Energy and Commerce Committee outlined the Clean Energy Performance Plan, a fee and subsidy program for load serving entities intended to subsidize the sale of renewable power and impose fees on the sale of GHG emitting power.[56]

In the preamble to the 2012 rule, EPA acknowledged that to the extent that upstream GHG emissions are already regulated effectively, attributing the emissions to the vehicle would constitute double counting. The primary justification for regulating emissions from a product or vehicle is to internalize the cost of emissions. If those costs are effectively internalized at the point of generation, to further regulate them at the point where the electricity is consumed constitutes double counting.[57] SAFE believes that the best way to regulate emissions of any emitting source is to regulate them at the point of emission, and that EPA should continue to exclude upstream emissions from electricity that powers EVs from the GHG calculation. If EPA is concerned that doing so relaxes the GHG emission standard too much, it should instead consider tightening the standard. [EPA-HQ-OAR-2021-0208-0527-A1, pp.14-15]

Commenter: Valero Energy Corporation (Valero)

Neither the structure of the rule nor EPA's assessment of benefits and impacts should arbitrarily favor a single technology or fuel source.

While the preamble to the proposed rule acknowledges that internal combustion engine ("ICE") vehicles powered by liquid fuels do and must play a critical role in reducing GHG emissions in the transportation sector, the structure of the proposed rule is expressly designed to incentivize increased production of electric vehicles. A key example is EPA's attribution of 0 g/mi upstream GHG emissions for electric vehicles: characterized as an "incentive," this measure skews the compliance demonstration by erasing the actual GHG emissions impacts for these vehicles. [EPA-HQ-OAR-2021-0208-0601-A2, p.2]

In so doing, EPA glosses over the GHG and criteria pollutant emissions associated with electrical vehicle and battery production and understates the emissions, reliability, cost, and safety considerations associated with increased demand for electrical generation. The very use of the term "zero-emission vehicle" throughout the preamble to describe electric vehicles highlights EPA's unsupported bias. As noted by the National Bureau of Economic Research, "...despite being treated by regulators as 'zero emission vehicles', electric vehicles are not necessarily emissions free."1 Battery production, transport, and disposal or recycling present emissions and waste impacts2 as well as national security concerns—including resource access, supply chain vulnerability, and cybersecurity risks for charging stations.3

Commenter: Volkswagen Group of America, Inc. (Volkswagen)

Support Maintaining Zero Upstream Emissions for Electrified Vehicles. Volkswagen supports EPA's proposal to maintain 0 g/mile upstream emissions accounting for fully electrified vehicles and electric operation for hybrid drive vehicles. Upstream emissions are not emitted by electrified motor vehicles, but are rather emitted by power generation facilities when consuming feedstock used to produce electricity. Volkswagen supports the premise that upstream emissions of electricity should not be accounted for in a motor vehicle regulation whose scope is to regulate the performance of motor vehicles. Volkswagen does not control or influence emissions from another sector and is opposed to being held accountable for those emissions in a motor vehicle regulation.

Volkswagen acknowledges that consuming feedstock to generate electricity used to propel electric vehicles results in emissions of greenhouse gases. Volkswagen recognizes that the rate of emissions is based in turn on the feedstock and efficiency of the generating facility and the transmission grid. Electricity generation is the US varies considerably by region, however data illustrates that overall the efficiency of generation and the transition to lower GHG intensive feedstocks is contributing to a decline in the greenhouse gas intensity. Shifting to sources such as natural gas has helped achieved significant reductions in GHG emissions from the power sector. In addition, the improving economics for renewable generation is further accelerating reductions in emissions as more zero emissions sources are being integrated within production grids.

One of the key policies to assure that a future electrified transportation system is enabled to deliver reductions in national emissions is to establish policies and regulations pushing the wide spread deployment of 'green' electricity, or electricity generated with net-zero emissions. Looking beyond the timeframe of this NPRM, future discussions regarding EV deployment pathways should be aligned with pathways that ensure matching levels of 'green' electricity generation are planned. This will ensure that the investment in electrified technologies are providing the fullest return on reduced GHG emissions. [EPA-HQ-OAR-2021-0208-0237-A1, pp.11-12]

EPA Response

In response to comments both supporting and not supporting accounting for upstream emissions associated with electricity use in determining the emissions levels for electrified vehicles, EPA did not propose or seek comment on making any changes to current upstream accounting regulations. In the SAFE rule, EPA extended the use of 0 g/mile value without limits through MY2026.[21] EPA did not revisit its previous decision for reconsideration in this rulemaking for MYs 2023-2026 by proposing changes or otherwise seeking comment on the issue. Comments, either for or against upstream accounting, suggesting that EPA proposed to revise or otherwise sought comment on the use of 0 g/mile are incorrect. Therefore, EPA is not including any changes to these provisions through MY2026 in this rulemaking. Starting in MY 2027, upstream accounting of emissions associated with electricity generation will be part of manufacturer compliance determinations unless EPA changes the regulations through a future notice and comment rulemaking.[22] EPA continues to believe that maintaining the current treatment of upstream emissions in this rule is appropriate given the timeline of this rule and the goal of encouraging further transition to electric vehicles. EPA notes that upstream emissions are included in EPA's analysis of emissions impacts and the use of 0 g/mile through MY 2026 is also included in its cost, technology, and feasibility analyses. The effect of manufacturers having to account for upstream emissions from electricity use starting in MY2027 is also incorporated in EPA's analyses for the rule as discussed in the Chapter 4 of the RIA.

The Alliance noted what they viewed as a discrepancy in the regulations, commenting that if EPA does not eliminate all model year and production limits for the use of zero grams per mile for the GHG emissions of a vehicle operating on electricity, it should issue a rule to clarify that 40 C.F.R. 86.1866-12(a) applies to model years 2012 through 2026. EPA acknowledges that the introductory paragraph 40 CFR 86.1866-12(a) provides for the use of the 0 g/mile value for MYs

[21] See 85 FR 25207 for further discussion including EPA's rationale for its previous decision.
[22] See 40 CFR 600.113-12 and 40 CFR 86.1866-12(a)(2).

2012-2025 whereas the more specific subparagraph 40 CFR 86.1866-12(a)(2) specifies the unrestricted use of the 0 g/mile factor for MYs 2017-2026. We recognize that the regulations could be clarified and will plan to do so in a future rulemaking. EPA notes that the current regulatory text does not prevent the use of the 0 g/mile factor in MY2026.

7. Full-size Pickup Strong Hybrid (or Equivalent Technology) Incentives

Commenter: Alliance For Automotive Innovation

Full-Size Pickup Hybrid and Over-Performance Incentive Credits. Auto Innovators supports the proposed full-size pickup hybrid and over-performance incentive credits through MY 2026.

Auto Innovators supports inclusion of the proposed full-size pickup hybrid and overperformance credits through MY 2026. Although many full-size pickup trucks are quite efficient for their size, weight, and utility, they remain among the highest emitting non-niche vehicles in the fleet. Incentivizing strong hybridization or other technology solutions that yield GHG emission rates 20% or better than their regulatory targets can help encourage manufacturer production and marketing to foster greater long-term consumer market adoption in the transition to EVs.

If minimum production requirements are adopted, Auto Innovators recommends that EPA allow them to be met in combination. EPA is proposing to require a minimum 10% penetration rate of strong hybrid or over-performance-qualified full-size pickup trucks out of a manufacturer's total full-size pickup truck production to qualify for credits. Given the current niche nature of such technologies in full-size pickup trucks, Auto Innovators recommends that EPA allow manufacturers to combine the production of strong hybrid and 20% over-performance full-size pickup trucks to determine if a single combined minimum production of 10% is reached. Both types of incentivized technology are provided the same proposed credit (20 g/mile) and would likely achieve similar emissions reductions. Such an approach could provide manufacturers with flexibility to develop multiple technical solutions to address different market needs.

EPA should consider expanding hybrid and over-performance credits to other light trucks with similar characteristics to full-size pickup trucks. EPA notes that full-size pickup trucks face "unique challenges in the costs of applying advanced technologies due to the need to maintain vehicle utility and meet consumer expectations."108 In recognition that certain other vehicles may face similar challenges, we suggest EPA consider slightly broadening this provision to vehicles with similar customer requirements as full-size pickup trucks. To ensure environmental objectives continue to be met while still providing some additional flexibility with this provision, a utility- and/or weight-based criteria could be developed to determine vehicle eligibility. Individual member companies may choose to comment on more specific concepts to slightly broaden the proposed provision to other vehicles with challenges similar to those of full-size pickup trucks. [EPA-HQ-OAR-2021-0208-0571-A1, p. 34-35]

Commenter: Aluminum Association

The Association supports the continued incentivization of advanced vehicle technologies including the performance incentive on pickup trucks that allows for manufacturers to exceed their targets by faster adoption of new technologies and fuel efficiency solutions, including the wider use of mass reducing materials across their portfolio to extend vehicle range and/or support battery downsizing to reduce battery costs [EPA-HQ-OAR-2021-0208-0233-A1 p.4]

Commenter: American Council for an Energy-Efficient Economy (ACEEE)

EPA proposes to extend the Advanced Technology Incentives for Full-size Pickups introduced in the 2012 standards. This is another instance of awarding credits in excess of actual emission reductions, which reduces the stringency of the standards. This specific incentive is also problematic because it could encourage production of full-sized pickup trucks at the expense of smaller vehicles. It also provides a loophole to the 2.5g/mi EV multiplier credit limit, by creating an alternative pathway for EV pickup trucks to earn unwarranted credits after the fleetwide EV multiplier limit has been reached. ACEEE estimates that this provision alone could reduce stringency by up to 2 g/mi by MY 2025 and reduce emissions savings by up to 1% for the entire period of the proposed rule. [EPA-HQ-OAR-2021-0208-0251-A1, p.7]

Eliminate the advanced technology multipliers for plug-in vehicles and full-sized pick-up trucks. [EPA-HQ-OAR-2021-0208-0251-A1, p.14]

Commenter: BorgWarner Inc.

Strong Hybrid Trucks Incentive. We support incentives for full-sized strong hybrid trucks / 20 percent better performance incentive and the carry-forward credits earned during MY 2016 to 2020. Hybrid trucks offer a significant opportunity for lower CO2 and fuel consumption due to their high sales volume and relative fuel consumption. The existing credits have not achieved their goal of significantly increasing hybridization of trucks. The conditions necessary to earn these credits are stringent. Eliminating the volume requirement and awarding credits based on a sliding scale which relates the fuel economy/CO2 of a hybrid vehicle to the same non-hybrid vehicle would provide a better incentive for hybridization in proportion to the value of the technology. [EPA-HQ-OAR-2021-0208-0260-A1, p. 2]

Commenter: California Air Resources Board (CARB)

[S]hould restore the advanced technology full size pick-up truck credits for model years 2023-2025, but not for model year 2022. [EPA-HQ-OAR-2021-0208-0643-A6, p.7]

The proposed standards would also reinstate a credit from the National Program for full-size pick-ups. The National Program standards provided two options for these credits. One option provided credits for hybrid technology, and the other provided performance-based credits if emissions were reduced by at least 20% less than the applicable footprint-based standard for a given vehicle. The SAFE Final Rules eliminated these options. EPA proposes to restore the credits with a modification to prevent any one vehicle from earning both kinds of credits.111 CARB supports restoring the full-size pickup credits in conjunction with revised standards for model years 2023 through 2026. But CARB disagrees the credits should be restored for model year 2022. As noted earlier, vehicles produced for model year 2022 will remain subject to the overly lax SAFE Final Rule standards and no action should be taken to effectively further weaken the 2021 or 2022 standards. There is no valid basis for providing additional credits. [EPA-HQ-OAR-2021-0208-0643-A6, p.37]

Commenter: Center for Biological Diversity, Earthjustice, and Sierra Club

Full-size pickup truck incentives are a second category that should be removed from the final rule. EPA must reduce emissions from light duty trucks, which have come to dominate the domestic market. Due to weaker emission standards and higher profitability, manufacturers have increasingly shifted from producing passenger cars to SUVs, pickups, and vans. Whereas passenger cars represented roughly 80% of the passenger car-light duty truck market in 1975 and 50% as recently as 2013, they now represent a mere 33%.41 The increasing share of light duty trucks subject to looser emissions standards means that while emissions are at near record lows for most vehicle types, cumulative emissions reductions have been offset by the higher portion of light trucks sold to consumers.42 The imbalance is particularly severe for the U.S. Big Three manufacturers, whose fleets also have the highest average emissions among the 14 largest auto manufacturers. Ford and GM’s fleets actually increased their emissions in 2020.43 Due to the long average lifespan of these vehicles, the imbalance of light trucks to passenger cars will persist for decades and continue to impede national emission targets. [EPA-HQ-OAR-2021-0208-0270-A1, p.7]

Against this backdrop, EPA proposes to offer more phantom credits to automakers for producing electric trucks, despite the fact that these credits were set to expire in MY 2021 and no manufacturer has applied for them since 2012.44 Yet as is true for multiplier credits, EPA does not need to incentivize production in this market segment because it is already happening. Automakers are making new electric trucks, and consumers are buying them. For example, as of early June 2021, Ford had reached 100,000 reservations for its 2022 Ford F-150 electrified full-size truck.45 Rivian's electric R1T will be released this year,46 and General Motors is planning an electric version of its popular Chevrolet Silverado for 2023.47 As these developments are happening on their own, there is no evidence that EPA's incentives would further spur production. [EPA-HQ-OAR-2021-0208-0270-A1, p.8]

Commenter: Center for Biological Diversity, et al.

EPA should not reinstate full-size pickup truck incentives. Since 2012, EPA has devised credits intended to incentivize the application of mild (10 g/mile) or strong (20 g/mile) hybrid technologies to full-sized pickup trucks if manufacturers meet minimum production thresholds or if the vehicles achieved 15 or 20 percent better performance than similar internal combustion pickup trucks. Proposal, 86 Fed. Reg. at 43,761. The incentives constitute another form of "phantom" credits because they come in addition to the emissions reductions these trucks already achieve when the technology is installed. Nonetheless, the incentives were intended to spur the advancement of hybrid technology and its application to these vehicles, which feature higher towing and hauling capabilities, in the early years of the program. But in the ensuing nine years, no manufacturer has applied for them, and the 2020 Final Rule terminated them at the end of MY 2021. Id.

EPA now proposes to reinstate them to further incentivize advanced technology penetration into this market segment. It does not, however, show that manufacturers are not likely to install the technology absent the extra incentives, particularly since they (and the public) will already reap the benefits that come from the resulting emissions reductions – for automakers, by decreasing their fleets' average emissions, and for the public, in the form of pollution harm reduction. Notably, full electrification has already penetrated the light duty truck segment, with extremely positive consumer uptake. As of early June 2021, Ford had reached 100,000 reservations for its 2022 Ford F-150 electrified full-size truck.150 Rivian's electric R1T will be released this year.151 General Motors is planning an electric version of its popular Chevrolet Silverado for 2023.152 Tesla's electric Cybertruck production is slated for 2022.153 And Bollinger's electric B2's production is also slated for 2022.154 Plainly, full pickup truck electrification is about to arrive without the proposed incentives in place.

In light of these developments, there is no evidence additional incentives are needed to spur the development of less-polluting trucks. And indeed. And indeed, EPA has not included their use in its evaluation of the standards' projected GHG emissions, costs, benefits, or other program effects. Proposal, 86 Fed. Reg. at 43761. We urge EPA not to reinstate them. [EPA-HQ-OAR-2021-0208-0651-A1, p. 65]

Commenter: Center for Climate and Energy Solutions (C2ES)

Along the same lines, C2ES supports the reinstatement of the pickup strong hybrid/20 percent better performance credit on the condition that EPA demonstrates they are likely to appreciably accelerate the development of zero-emission vehicles.[EPA-HQ-OAR-2021-0208-0287-A1, p. 2]

Full-size Pickup Performance Incentives. C2ES supports the reinstatement of the previously existing full-size pickup strong hybrid/20 percent better performance incentives on the condition that EPA demonstrates significant emissions reductions facilitated by this incentive. However, EPA should ensure that automakers are not allowed to apply both incentives, as this double counting would significantly loosen the effective stringency of the proposed standards. With pickups representing a large—and growing—segment of the national light-duty market, but emitting much higher amounts of greenhouse gases on a per-mile basis than other light-duty vehicles, it is necessary for EPA's incentives to support the rapid reduction in greenhouse gas emissions from pickups, both through improved efficiency among conventional models and increased deployment of zero-emission models.22

Currently, while some zero-emission pickup options are entering the market, many more electric SUV and sedan models are available, providing consumers interested in those models with more choice. In the near future, high-emitting pickups will likely represent a continuously increasing share of combustion engine vehicles as drivers of sedans and SUVs increasingly switch to zero-emission vehicles while fewer offerings of zero-emission pickups remain.

Preliminary data do not suggest that the pickup incentives under the 2012 Final Rule were highly successful in reducing emissions from pickups. Where we would expect to see an accelerated rate of improvement in the emissions of pickups from MY 2017–19, when the 2012 Final Rule was in effect with the incentive, realworld fleet average emissions from pickups only decreased 3 g/mile (from 470 to 467 g/mile) in this timeframe, according to EPA data.23 If strong hybrid incentives will not produce demonstrable emissions reductions among these remaining pickups, they should be eliminated in favor of advanced technology multipliers that directly incentivize the development battery electric, fuel-cell electric, and plug-in hybrid electric pickup models. [EPA-HQ-OAR-2021-0208-0287-A1, pp.6-7]

Commenter: Consumer Reports (CR)

Advanced Technology Incentives for Full-Size Pickups. This credit, although limited to a relatively small portion of the market, may have some unintended consequences. Hybridization is increasingly being used by automakers to boost performance rather than efficiency. Ford's full sized pickup hybrid is marketed as "Power Boost" and happens to be the most powerful truck in their lineup at 430 HP. However, it achieves only a 3 mpg improvement over their 2.7L EcoBoost powertrain but increases horsepower by 105. Compared to the 3.5L EcoBoost, it increases efficiency by 4mpg (in 4x4 configuration) and horsepower by 30.30 In addition to

Ford, Toyota just announced a new Tundra Pickup that will be available with a hybrid option that will add 48 HP compared to the non-hybrid version.31 EPA efficiency ratings for these powertrains are not yet available. While increasing the efficiency of full sized pickups is important, and can have an outsized impact on reducing emissions due to their low efficiency, any credits given for installing specific technologies should be designed to ensure that the technologies are actually used to increase efficiency rather than just used to boost power and performance. [EPA-HQ-OAR-2021-0208-0602-A1, p.13]

In Consumer Reports' 2019 Automotive Fuel Economy Survey, drivers of large SUVs and pickups told us they wanted to see their vehicle's fuel economy improved more than 6 times as often as they wanted to see their vehicle's horsepower increased (55% vs. 8%) as shown in Figure 3.1.32 This credit, as designed, allows automakers to comply by two pathways. The first is by installing a strong hybrid powertrain. The second is by achieving 20% lower emissions than the footprint based standard. If EPA decides to keep this credit in their final standard, Consumer Reports recommends that EPA simplify the credit by eliminating the "strong hybrid" credit, and only provide the credit to vehicles that meet the 20% improvement above the standard threshold, regardless of technology used. This would avoid potentially giving credits to strong hybrids designed to deliver increased performance, but minimal efficiency improvements. [EPA-HQ-OAR-2021-0208-0602-A1,p.13] [[See EPA-HQ-OAR-2021-0208-0602-A1, p.14 for Figure 3.1]]

Another concern with this credit is that it is also applicable to electric pickups. While EPA put a cap on the EV multiplier credits, this credit would provide a means to exceed that cap with additional credits for electric vehicles. [EPA-HQ-OAR-2021-0208-0602-A1,p.14]

Commenter: DENSO International America, Inc. (DENSO)

Support Incentives for Strong Hybridization for Light Trucks. DENSO supports the reinstatement of incentives that will further electrification of pick-up trucks to allow for increased fuel economy and reduced greenhouse gas emissions. We also ask the agencies to revise the strong hybrid pick-up truck incentives (20g/mi through 2025) by removing the production threshold requirement and expanding the eligibility to all light-duty trucks. [EPA-HQ-OAR-2021-0208-0282-A1, p. 7]

Commenter: Electric Drive Transportation Association (EDTA)

EDTA Supports the Extended Credit and Pickup Truck Credit Programs - EDTA supports the reinstatement of the incentives for full-size pickup strong hybrid/20 percent better performance incentive. We agree with EPA's rationale that advanced technologies are "particularly challenging due to the need to preserve towing and hauling capabilities" and will help to address initial market challenges. (Source: Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards, 86 Fed. Reg. 43726.)

EDTA recommends that minimum sales thresholds in the full-size pickup truck provision be eliminated. The prior regulation required that a minimum sales percentage of a manufacturer's full-size pick-ups be equipped with hybrid technology before credits could be generated. While the efficiency benefits of hybridizing this segment are large, the current market penetration is small. The minimum sales threshold undermines the effectiveness of the incentive, as low rates of adoption persist in this segment. Reducing or eliminating the sales threshold will grow the hybrid pickup truck segment by increasing investment, accelerating innovation, and reducing system and component costs. [EPA-HQ-OAR-2021-0208-0569-A1, p. 3]

Commenter: Environmental Defense Fund (EDF)

The voluntary emissions reductions are generally comparable to those that would be required of all manufacturers under EPA's Proposed Standards for MYs 2023-2026. A few notable differences are that EPA proposes new credits for pickups equipped with strong hybrid technology; EPA proposes to cap advanced technology vehicle multiplier credits at an average of 2.5 g/mi per model year (as opposed to 1% of GHG emissions reductions). [EPA-HQ-OAR-2021-0208-0688-A1, p. 14]

Commenter: Ford Motor Company

Reinstatement of Full-Size Pickup Incentives for Strong Hybrids or Equivalent Technologies. In the original 2017-2025MY GHG standards, EPA provided a 20 g/mi incentive for full-size pickups that achieved either a CO2 performance 20% better than the obligation or that applied 'strong' hybridization. The provision was subsequently removed in the SAFE rule but was included in the California Framework Agreement. This provision will help to build the customer base for advanced, but costly, fuel-efficient technologies in the full-size pickup segment, while also recognizing the unique challenges of improving the fuel efficiency of these vehicles while preserving important utility functions like payload carrying capacity, towing, and off-road capability.

Ford believes that this provision continues to be essential in enabling continued adoption of advanced technology in the full-size pickup segment and supports EPA's proposed reinstatement. One concern with this credit mechanism is the legacy requirement that 10% volume penetration of the relevant technologies must be reached within a given model before any credit is granted. This 'all-or-nothing' approach poses risks and uncertainty to OEM compliance planning since it is difficult to predict future volumes with precision, particularly for new or advanced technologies such as hybridization. The threshold is also unnecessary since an OEM is already motivated to maximize volumes to the greatest extent possible – within market and material constraints – in order to recoup the sizeable investments needed to implement such technologies.

For these reasons, Ford believes it is appropriate to lower or remove the volume threshold requirement. In the alternative, Ford asks that EPA clarify that an OEM may include multiple technologies toward the 10% threshold, for example, by combining BEV and HEV volumes to satisfy a given model's 10% threshold requirement for the performance-based credit pathway. [EPA-HQ-OAR-2021-0208-0294-A1, pp.3-4]

Commenter: Gentherm, Inc.

Advanced Technology Incentives for Full-Size Pick-up Trucks. Gentherm supports reinstatement of the incentives for full-sized pickup strong hybrid/20 percent better performance incentive. One improvement in the rule would be to provide a combined penetration requirement rather than independent 10 percent requirements for multiple types of technologies. This would mean that any combination of strong hybrid and other 20 percent better performance technologies would fall under one cap. This is an important technology agnostic requirement, since it is not clear the receptiveness that the market will have for a specific technology. As far as possible, the standards should be flexible and technology agnostic to incentivize fuel consumption and CO2 emissions reductions. Gentherm agrees with the EPA justification for reinstating the full-size pickup truck credits since full-size pick-up truck technologies are "particularly challenging due to the need to preserve the towing and hauling capabilities of the vehicles." [EPA-HQ-OAR-2021-0208-0216-A1, p. 6]

Commenter: Growth Energy

The proposal appropriately allows performance based GHG incentives for full-size pickups, which should be adjusted slightly to incentivize FFV pickups.

The NPRM gives "performance-based credits" for full-size pickups with 15 to 20% better CO2 performance than their footprint-based targets. (NPRM at 43,761). EPA offers this incentive because "introduction of low-emissions technologies in this market segment creates more opportunities for achieving the more stringent later year standards." (Id.). This approach is reasonable for full-sized pickups.

This technology neutral approach is appropriate whereby "These performance-based credits have no specific technology or design requirements; automakers can use any technology or set of technologies as long as the vehicle's CO2 performance is at least 15 or 20 percent below the vehicle's footprint-based target." (NPRM at 43,761). Performance-based, technology-neutral approaches for EPA vehicle incentives are generally preferred, as stated above, and this approach should allow FFVs and other alternative fuel vehicles to compete on a level playing field.

While this performance-based approach is appropriate, full-size pickups should qualify based on 10% CO2 reduction measured at the tailpipe. Thus, under 40 CFR §86.1870-12 ("CO2 credits for qualifying full-size light pickup trucks"), the figure 0.8 should be changed to 0.9 to allow incentives for full size pickup trucks that achieve carbon-related exhaust emissions less than or equal to 10% below the applicable target value. (See NPRM at 43,810 citing proposed regulatory text at 40 CFR §86.1870-12(b)(2)).

In the alternative, a 15-20% CO2 reduction below the vehicle's footprint-based target is appropriate to trigger incentives if the VCF is applied to full-size FFV pickups for purposes of calculating this CO2 reduction threshold. Under this approach, text would be added to 40 CFR §86.1870-12 so that, for purposes of qualifying for the credit under §86.1870-12(b)(2), the CREE for the ethanol portion of FFV fuel use would be multiplied by the VCF. If the CREE incorporating the VCF would be less than 15-20% of the applicable target value, FFV full-sized pickups should qualify for the incentive.

EPA notes that “full-size pickup truck credits are appropriate to further incentivize advanced technologies penetrating this particularly challenging segment of the market.” (NPRM at 43,761). FFV technology has been readily deployed for pickups, which provides yet another reason to align these pickup incentives for use with FFVs. Finally, these performance-based credits for full sized pickups, for which FFVs may qualify, should extend through the last year covered by this rulemaking (model year 2026), to allow for manufacturers to recoup the costs of upgrading these pickups as FFVs. The regulatory text states, “A pickup truck that qualifies for this credit in a model year may claim this credit for a maximum of four subsequent model years (a total of five consecutive model years).” (NPRM at 43,810). Given this timing, the credit should extend through model year 2026. [EPA-HQ-OAR-2021-0208-0279-A1, p. 12-13]

Commenter: ITB Group, Ltd. (ITB)

Advanced Technology Incentives for Full-Size Pick-up Trucks. The ITB Group supports reinstatement of the incentives for full-sized pickup strong hybrid/20% better performance incentive. One improvement in the rule would be to provide a combined penetration requirement rather than independent 10% requirements for multiple types of technologies. This would mean that any combination of strong hybrid and other 20% better performance technologies would fall under one cap. This is an important technology-agnostic requirement, since it is not clear the receptiveness that the market will have for a specific technology. As far as possible, the standards should be flexible and technology-agnostic to incentivize fuel consumption and CO2 emissions reductions. ITB agrees with the EPA’s justification for reinstating the full-size pickup truck credits since full-size pick-up truck technologies are “particularly challenging due to the need to preserve the towing and hauling capabilities of the vehicles.” [EPA-HQ-OAR-2021-0208-0222-A1, p. 6-7]

Commenter: Lucid USA, Inc. (Lucid)

Additionally, the NPRM proposes incentives for ICE vehicles that will effectively delay the transition to the net-zero emission future promised by President Biden. Reviving the full-size pickup truck incentives allows the highest-emitting vehicles to receive only modestly effective technology updates rather than a true conversion to zero emissions. The all-electric full-size pickups soon coming on the market from multiple manufacturers demonstrate that EV pickups are feasible and EPA does not need to reward partial reductions of GHG emissions to make progress in the pickup segment of the market. [EPA-HQ-OAR-2021-0208-0528-A1, p. 5]

Commenter: Manufacturers of Emission Controls Association (MECA)

Advanced Technology Credits for Pick-up Trucks. MECA supports EPA’s proposal to reinstate the original 2012 rule’s full-size pick-up truck incentive credits for strong (full) hybrids or similar performance technologies. Pick-up trucks, which are the second most popular light-duty vehicle segment in the North American market, are often identified as a greater technical and consumer acceptance challenge to higher efficiency standards. The presence of both electric, full hybrid and other advanced technology vehicle options in this segment is clearly beneficial to both consumers and the environment.

Unlike multiplier credits, the Advanced Technology Credits for pick-up trucks do require the use of additional full hybrid or other advanced technologies that deliver at least 20% better CO2 reduction performance than the footprint-based target value in a minimum 10% of total model production volume. In particular, MECA feels the additional 20 g/mile CO2 credit incentive is reasonable given that on average, pick-up trucks emit considerably more CO2 per year and are almost twice as likely to reach 200,000 miles compared to vehicles in other LDV segments. Given that large SUVs also commonly utilize the same chassis and powertrains as pick-up trucks, we believe that EPA should consider extending these advanced technology truck credits to similarly powered SUVs as well.[EPA-HQ-OAR-2021-0208-0261-A1, p.3]

Commenter: Motor & Equipment Manufacturers Association (MEMA)

MEMA Supports the Extended Credit and Pickup Truck Credit Programs - MEMA supports the reinstatement of the incentives for full-sized pickup strong hybrid/20 percent better performance incentive. Additionally, MEMA supports the carry-forward proposal that provides additional flexibility for credits earned during MYs 2016–2020. [EPA-HQ-OAR-2021-0208-0249-A1, p. 3]

MEMA Supports the Extended Credit and Pickup Truck Credit Programs. Advanced Technology Incentives for Full-Size Light Pickup Trucks. Under the 2012 rule, the full-size pickup strong hybrid/20 percent better performance incentive credit extended through MY2025 and required a 10 percent production threshold. The SAFE rule ended this incentive, but EPA is proposing to reinstate the credits for MYs 2022–2025. EPA justifies proposing to reinstate the full-size pickup truck credits as these advanced technologies in full-sized pickups are “particularly challenging due to the need to preserve the towing and hauling capabilities of the vehicles.”32 Further, reinstatement of this program incentivizes advanced technologies into the full-sized pickup segment to help address cost, utility, and consumer acceptance challenges.33 EPA requests comment on whether to reinstate the credit program and a proposed approach for doing so.34

MEMA supports the reinstatement of the incentives for full-sized pickup strong hybrid/20 percent better performance incentive. Now, even more than a few years ago, there are sufficient technologies and more consumer acceptance that can be used to help pickups meet the performance criteria and market penetration rates for strong hybrids. MEMA continues to urge EPA to consider extending these credits to all pickup trucks, not just full-size pickup trucks.35

In the post-2026 program, MEMA urges EPA to consider continuing the full-sized pickup incentive but structure the program for providing credits for full-sized pickup trucks that just achieve 20 percent or better performance. This structure will continue to encourage innovative, creative solutions without being partnered with credits awarded for targeted technology. [EPA-HQ-OAR-2021-0208-0249-A1, p. 10-11]

35 Program requires a minimum of 15 percent in MY2017 increasing to 40 percent in MY2021.

Commenter: New York State Department of Environmental Conservation

New York also supports EPA's proposal to restore full-size pick-up credits as they existed before SAFE rule (for MYs 2022- 2025). Should EPA proceed with this revision; the final rulemaking should estimate the resulting loss of stringency. New York agrees with EPA's outlined credit approach that would avoid double-counting of credits by restricting the use of credit types for the same vehicle. [EPA-HQ-OAR-2021-0208-0238-A1, p.3]

Commenter: Rivian Automotive, LLC

Do Not Revive Incentives for "Strong Hybrid" Trucks. EPA previously offered an incentive for "strong" and "mild hybrid" pick-up trucks in the form of a grams per-mile, per-vehicle credit. Rivian's own groundbreaking product offerings prove that hybridization of pick-up trucks is a technological dead end—while incrementally better than a conventional ICE, hybrids fail to excite the driving public and are insufficient to the task of decarbonizing the transportation sector. Only fully electric models will rise to the challenge of deep emissions reductions while providing customers with a superior ownership experience.

Rivian believes the agency made the right decision sunsetting this credit in the SAFE Rule and the proposed rule fails to adequately support a decision to reverse course. The EPA is quite explicit that such credits present trade-offs: effectively reduced regulation stringency in favor of catalyzing development and market entry for new technologies that promise greater environmental benefits in the long run.9 This trade-off might be worthwhile for true "end game" solutions such as BEVs but is harder to accept when the technology in question can never be more than a half-measure and is subject to real-world emissions increases driven by operation and age. The truck hybrid credit should be allowed to expire as originally intended. [EPA-HQ-OAR-2021-0208-0274-A1, p. 4]

Commenter: Securing America's Future Energy

Incentives for 'Strong Hybrid' Trucks. In the 2012 rule, EPA offered an incentive for 'strong' and 'mild hybrid' pick-up trucks, trucks with a 'start/stop capability and regenerative braking capability, where the recovered energy over the Federal Test Procedure is at least 15 percent.'[60] The incentive took the form of a grams-per-mile, per-vehicle credit available to vehicles with this 'game-changing technology,' but was sunset in recognition that the technology was intended primarily to 'help provide a bridge for industry to future more stringent light truck standards.'[61]

Today, hybridization of pick-up trucks is no longer an innovative technology. It has been replaced by full electric pickup trucks, with towing and hauling capacity similar to conventional pickups, that are entering the market shortly. Yet, in its proposal, EPA announced its intention to reestablish incentives for strong and mild hybrid trucks. In the proposal, EPA acknowledged the incremental emissions this decision would enable and failed to adequately support its decision to do so. [62] Given the current state of pickup truck technology, EPA should focus on incentivizing transformative electric pickup trucks and decline to extend incentives to hybrids. [EPA-HQ-OAR-2021-0208-0527-A1, pp. 16-17]

Commenter: Stellantis

Stellantis supports EPA's focus on crediting hybrid technology on trucks and believes crediting all hybrid technology on trucks has opportunity to maximize near term GHG reductions.

Incentivize All Hybrid Technology in Trucks. We applaud EPA for restoring the full-size pickup truck incentive for strong hybrids. Similarly, EPA should restore the credit for mild hybrid technology which offers considerable real world benefits by recovering up to 65%24 of total braking energy at a relatively low cost. This represents an important step on the path to stronger electrification. Rather than sunsetting this credit, we believe EPA should extend the mild hybrid pickup truck credits through MY2026 with corresponding shifts to the minimum percent of pickup sales thresholds. EPA recognized this benefit, and the need to incentivize further development of the technology, in its original MY2017-2025 rulemaking.

The mild hybrid credit also came with minimum volume requirements that, after rapidly increasing yearover- year, have proven to be impractical. From the detailed data supplied in the 2020 EPA trends report25, no OEM met the minimum sales volume requirement. Pickup trucks have a wider variety of powertrain options than most vehicles, and to meet minimum volume requirements of the credit, manufacturers would need to introduce mild hybrid technology across multiple models in the span of just a few years. This implementation pace did not align with product design cycles for any full size pickup truck and therefore minimum volume requirements were unachievable by any OEM. With mild hybrid market share currently sitting at 1.2% per the 2020 IHS baseline study, further incentives are needed to promote more widespread deployment of mild hybrid technology. [EPA-HQ-OAR-2021-0208-0532-A1, pp. 18-19]

24 40 CFR §86.1803-01 Mild hybrid electric vehicle means a hybrid electric vehicle that has start/stop capability and regenerative braking capability, where the recovered energy over the Federal Test Procedure is at least 15% but less than 65% of the total braking energy, as measured and calculated according to 40 CFR 600.116-12(d).

Commenter: Tesla

EPA Should Not Renew the Advanced Technology Incentives for Full-Size Pick-ups. EPA proposes to reestablish an additional credit incentive for full size pickups and underestimates the potential use of the credit. As noted above, EPA's analysis underestimates the deployment of newly manufactured full EV pick-up trucks. For example, EPA projects no delivery of the Tesla Cybertruck as is scheduled in MY 2022, ignores any deployment of pickups by Rivian, and appears to underestimate Toyota's deployment despite pronouncement of seven models by MY 2025.179 Just as EPA acknowledges recent manufacturer announcements on electrification in its preamble,180 the agency should recognize the increasing announcements around full electric pick-up trucks.181 Regardless, under a conservative estimate, Tesla's modeling anticipates that starting in MY 2023 this annual credit would further erode the proposed standard's stringency starting at .3 g/mi and grows in usage MY 24 and 25. See Figure 1.

For the reasons cited in Tesla's opposition to the ATV multiplier, Tesla also asserts this incentive is not needed to incentivize deployment of actual EV pickups and should be removed to increase the proposal's stringency. [EPA-HQ-OAR-2021-0208-0278-A1][pp.22]

Commenter: Toyota Motor North America, Inc. (Toyota)

Full-Size Pickup Truck Credits – A Challenge for Heaver, More Capable Light Trucks. Toyota supports reinstituting the advanced technology incentives for full size pick-up trucks, but requests the incentives apply through 2026 model year, or at least any four years between and including 2022 and 2026 for the same reasons provided for ATV multipliers. EPA has appropriately acknowledged the segment's "unique challenges in the costs of applying advanced technologies due to the need to maintain vehicle utility and meet consumer expectations". EPA's determination that "these full-size pickup truck credits are appropriate to further incentivize advanced technologies penetrating this particularly challenging segment of the market" remains sound policy to promote significant future GHG reductions.17

Unfortunately, the market challenge is not unique to full-size pick-up trucks. All pickup trucks and body-on-frame SUVs contend with similar difficulty in providing low CO2 performance while preserving towing and hauling capabilities. We request the strong hybrid incentive be extended to all light trucks having a gross vehicle weight rating (GVWR) greater than 6,500 lbs. As seen in Figure 5, the share of hybrids remains low in this segment of light trucks relative to the gains made in most every other segment. [EPA-HQ-OAR-2021-0208-0531-A1, p. 10] [Figure 5 can be found on p. 10 of Docket number EPA-HQ-OAR-2021-0208-0531-A1]

Incentivizing this slightly broader segment will help manufactures "address cost, utility, and consumer acceptance challenges" as noted by EPA. 18 The additional trucks with a GVWR greater than 6,500 lbs. represent about half the sales volume of full-size pickup trucks. Any environmental impact of expanding this flexibility should remain minimal given that EPA's past analyses have demonstrated a low relative impact of the full-size pickup truck provision. 19 [EPA-HQ-OAR-2021-0208-0531-A1, p. 11]

Commenter: Union of Concerned Scientists (UCS)

Strong pick-up credits. The final flexibility being considered by EPA is reinstating so-called 'advanced technology' incentives for full-size pick-ups, which awards 20 g/mi additional credit per full-size pick-up that is either a strong hybrid or has a performance at least 20 percent better than the applicable standard, provided it represents at least 10 percent of production.

EPA claims that 'the rationale for establishing them in the 2012 rule remains valid.'72 However, this seems to completely ignore the developments in the industry over the past decade. The Ford PowerBoost hybrid went on sale earlier this year and is already selling at a take-rate of 8.4 percent over the past three months, despite a chip shortage that is currently limiting production, making it quite likely that this vehicle will qualify for the credit.73 Additionally, Ford is slated to start producing the Lightning full-size EV pick-up in MY2022, 74 which shows that a strong hybrid pick-up isn't so 'advanced.' With a new production target of 80,000 units, the Lightning will also likely qualify for the credit under the performance provision. And it isn't just Ford who's rolling out these vehicles: Toyota's next Tundra full-size pick-up will only have two engine offerings, one of which is a hybrid.75

All of this is to say that even in the absence of the full-size pick-up strong hybrid/performance credit, manufacturers have moved forward with plans for full-size pick-ups that meet the criteria. The simple reason is that these vehicles are sold by only a small number of manufacturers, and as such represent a critical piece of the portfolio of those manufacturers—a company like Ford cannot afford for its best-selling vehicle to be a deficit-generator under the standards. Since these vehicles are already planned, the agency's reinstatement of the credit cannot be considered an incentive—instead, it is a windfall credit.

Because full-size pick-ups are a very concentrated part of the market, while the total credits generated under this flexibility may not be as large as some of the other proposed flexibilities, they will be available to only a small number of companies and thus have an outsized impact on those manufacturers. If 20 percent of F-150s sold qualify for this credit, this provision would generate over 700,000 Mg in credits for the company—this equates to a 2.5 g/mi credited improvement in Ford's light truck fleet thanks to this potential windfall credit.

In addition to the concentration of this credit in the hands of just a few manufacturers, there is an additional concern around the efficiency of the strong hybrid pick-ups. These vehicles are not being designed for efficiency, as acknowledged by the Tundra's Executive Program Manager.76 Given that, it makes sense to eliminate the strong hybrid credit entirely, and if EPA wishes to implement a full-size pick-up credit, it should only be for the 20 percent performance credit. This ensures that at least the credit windfall will be limited to efficient vehicles, not just a high-performance trim level.

UCS opposes the reinstatement of the full-size pick-up 'advanced technology' credit. However, if EPA includes such a provision in its final rule, it should only be under the performance mechanism. [EPA-HQ-OAR-2021-0208-0277-A1, pp.37-38]

Commenter: Zero Emission Transportation Association (ZETA) and EVHybridNoire (EVHN)

Extension of credits like those for hybrid trucks are outdated. While it made sense to provide these incentives when electric drivetrains were still being innovated, we currently have fully electric pickup trucks slated to be on the road by 2023 including from Rivian, Tesla, and Ford. There is no reason to give a generous credit to hybrid trucks when the bridge technology is well-established. The same is true for advanced gasoline vehicle technologies included for off-cycle credits, like start-stop technology. Off-cycle and hybrid credits should not be extended and should not be expanded. [EPA-HQ-OAR-2021-0208-0275-A1, p. 3]

<u>EPA Response</u>

EPA is finalizing the full-size pickup incentives only for MYs 2023-2024. EPA's response to comments regarding whether or not to include the incentives in the program are provided in section II.B.2 of the preamble, which also provides EPA's response to comments from Consumer Reports and UCS that EPA should not include an incentive for strong hybrid technology.

Several commenters recommended that EPA remove the 10 percent production threshold requirement from the program. In addition, the Alliance commented that if EPA continues to require manufacturers to meet the production threshold to qualify for the incentives that production for pickups meeting either the strong hybrid or 20 percent performance criteria should be combined to determine that they meet the threshold. The Alliance commented that both types of incentivized technology are provided the same proposed credit (20 g/mile) and would likely achieve similar emissions reductions and that such an approach could provide manufacturers with flexibility to develop multiple technical solutions to address different market needs. Ford, ITB Group, and Gentherm provided similar comments.

In response, EPA included the minimum percentage for each type of incentive to encourage significant penetration of these technologies, leading to long-term market acceptance.[23] In the 2012 rule preamble establishing the thresholds, EPA explained its decision in part stating "our goal is to create an incentive for manufacturers to commit to the large-scale application of hybrids and other advanced technologies in the challenging large truck sector and specifically that at least mild hybrid or comparable technology become a standard technology feature for large pickup trucks. Eliminating or greatly tempering the minimum penetration requirements might retain the incentive for niche applications but would lose any assurance of widespread 'game-changing' technology introduction and substantial penetration." EPA believes this remains an important aspect of the incentive. As several commenters recommending EPA not adopt the incentives noted, there are some advanced technology full-size pickups being introduced by auto manufacturers that may qualify for the incentives. EPA believes its rationale for including the thresholds remains important, that retaining the production thresholds will provide incentive for manufacturers to sell qualifying pickups in substantial numbers now that such vehicles appear to be entering the market. Therefore, EPA is not revisiting or changing the thresholds. For these reasons also, EPA did not propose or seek comment on reducing or removing the thresholds.

Some automakers commented on expanding the pickup truck incentive beyond what EPA had proposed. Stellantis commented that EPA should reinstate the mild hybrid incentives, believing that further incentives are needed to promote more widespread deployment of mild hybrid technology. Toyota requested that the strong hybrid incentive be extended to all light trucks having a gross vehicle weight rating (GVWR) greater than 6,500 lbs. Toyota commented that the share of hybrids remains low in this segment of light trucks relative to the gains made in most every other segment. Incentivizing this slightly broader segment, Toyota argues, will help manufactures address cost, utility, and consumer acceptance challenges. MEMA supported EPA's proposal to reinstate the full-sized pickup strong hybrid/20 percent better performance

[23] 77 FR 62826.

incentive, while also urging EPA to consider extending these credits to all pickup trucks, not just full-size pickup trucks.

In response, EPA does not believe expanding the full-size pickup incentive to other vehicle categories is reasonable. EPA must balance the need for flexibility with the environmental impacts of the incentives and long-term goals of the program. Expanding the incentives to smaller vehicle types would reduce the emissions reductions of the program to the extent it was used by manufacturers. Many commenters were very concerned about the impact of the incentives, commenting that they could weaken the program. EPA shares their concerns regarding the potential impact of the incentives and is only including a narrow set of flexibilities as needed to address lead time issues associated with MYs 2023-2024. Also, full-size pickups represent the highest degree of challenge due to vehicle utility needs of consumers that purchase such vehicles, which is why EPA established the full-size pickup incentives as part of the 2012 rule. In the proposal for the current rulemaking, EPA did not propose or seek comment on significantly expanding the previously existing full-size pickup incentives by extending it to other vehicle categories.

Rivian commented that it believes the agency made the right decision sunsetting this credit in the SAFE Rule and the proposed rule fails to adequately support a decision to reverse course. It commented “the EPA is quite explicit that such credits present trade-offs: effectively reduced regulation stringency in favor of catalyzing development and market entry for new technologies that promise greater environmental benefits in the long run. This trade-off might be worthwhile for true “end game” solutions such as BEVs but is harder to accept when the technology in question can never be more than a half-measure and is subject to real-world emissions increases driven by operation and age. The truck hybrid credit should be allowed to expire as originally intended.” In response, EPA believes that for full-size pickups, strong hybrids (or technologies providing similar emissions reductions under the performance-based option) have the potential to provide significant emissions reductions in the interim between the timing of this rulemaking and when full size pickups are converted to EVs on a widespread basis in the future. EPA also notes that EPA originally provided these incentives through MY 2025, so EPA “originally intended” them to be available through MY 2025. After considering comments, EPA is reinstating them only for MYs 2023-2024.

Growth Energy commented that EPA should reduce the performance incentive threshold from 20 percent to 10 percent so FFVs could potentially qualify. Growth Energy commented that alternatively a 15-20% CO_2 reduction below the vehicle’s footprint-based target is appropriate to trigger incentives if the “volumetric conversion factor” (VCF) of 0.15 is applied to full-size FFV pickups for purposes of calculating this CO2 reduction threshold.

In response, EPA is not making changes to the full-size pickup incentives to accommodate FFVs. FFVs have been available for many years, including for full-size pickups. While operating on E85, FFV CO_2 emissions are typically about 5 percent lower than when operating on gasoline. EPA already factors in this lower emissions level in determining the GHG emissions performance level of FFVs under the current regulations.[24] Often, FFVs are not refueled with E85 which negates any benefit for the vehicle technology.[25] Because FFVs have been available to consumers for many years and because there is no assurance FFVs will be refueled with E85, EPA is not including any new incentives for these vehicles. EPA is not reducing the percent reduction threshold form 20 percent to 10 percent also because such an approach would potentially allow many other less impactful technologies to qualify for the credit. EPA is also not including a "volumetric conversion factor" (VCF) of 0.15 for FFVs. Comments regarding applying a VCF are addressed in section 26.2 below.

Commenter: Advanced Engine Systems Institute (AESI)

Off-Cycle Technologies. EPA has proposed to increase the off-cycle credit cap from 10 g/mile to 15 g/mile. Off-cycle technologies are EPA evaluated technologies which are found to represent real-world CO2 reductions for vehicles under real world operation. Therefore, they should be further recognized to drive down CO2 emissions by all technological means. A pathway should be expanded to allow vehicle manufacturers as well as technology suppliers to document CO2 reduction performance and obtain off-cycle technology menu listings and credit values. These additional technologies are likely to be increasingly needed between 2023 and 2035 to achieve CO2 reduction goals. AESI fully supports the retention of off-cycle technology credits and the increase in the effective cap from 10 g/mile to 15 g/mile. Unlike credit multipliers, which do not represent additional technology deployment, off-cycle credits are awarded only when a technology's real-world benefits are validated and the technology is deployed. AESI strongly urges EPA to implement a pathway for technology suppliers to apply for conditional off-cycle technology credits that are verified in the real world. This supplier program could be modeled on that included in the California framework with 5 OEMs. [EPA-HQ-OAR-2021-0208-0267-A1, p. 3]

Commenter: Alliance For Automotive Innovation

Off-Cycle Technology Credits. The off-cycle technology program provides credit for the on-road benefits of GHG technologies that are not observed in standard compliance tests. EPA has taken great care to ensure that credits granted under the program are reflective of on-road emissions reductions. In the case of the pre-defined "menu" of off-cycle technologies,64 EPA chose conservative credit values and capped the amount of credit that can be claimed regardless of the absolute number of menu technologies incorporated in a manufacturer's fleet. In the case of credits made under an alternative method,65 credits have only been granted after a lengthy review process. We concur with EPA's assessment that off-cycle credits do not result in deterioration of program benefits.66

In response to the off-cycle credit program, manufacturers and suppliers continue to develop innovative technologies that reduce on-road GHG emissions. Auto Innovators supports the continuation of the off-cycle credit program in general, revisions to reflect new technology innovations, and other modifications to allow the program to work more efficiently.

Auto Innovators supports raising the credit cap for on the off-cycle technology menu, effective MY 2020. Auto Innovators supports raising the credit cap for the off-cycle technology menu. The current 10 g/mile cap was originally promulgated in the 2012 Rule and has become constraining to technology additions, particularly with the addition of new technologies. In the Safer Affordable Fuel-Efficient ("SAFE") Vehicles Rule ("SAFE Rule"), EPA added high efficiency alternator technology but did not raise the menu credit cap.67 Adding additional technology without increasing the credit cap fails to recognize that additional benefits beyond the original conservative cap may be realized with added technologies.

The addition of high-efficiency alternators to the credit menu without increasing the cap is particularly problematic for manufacturers who have already been granted credit for them outside of the cap using the alternative method process. EPA discusses not allowing manufacturers to generate credit for on-menu technologies through the alternative process unless additional benefits through other innovations can be demonstrated.68 If EPA takes this approach, the original credit cap becomes even more constraining.

We recommend that the cap be raised to 15 g/mile, effective MY 2020, aligning with the timeline in the California Framework Agreements.69

An increased off-cycle menu cap should not be tied to modified technology definitions. EPA is proposing to tie the proposed increase in the off-cycle menu cap to modified definitions for certain technologies.70 We believe that these issues should be considered separately. The cap should be raised regardless of the decision whether to modify technology definitions or not and, if modified technology definitions are adopted, regardless of when a manufacturer applies the modified definitions. As described in our support for raising the cap in general, additional technology has been added to the menu, but the cap was not modified to reflect this addition. In the balance, it is unnecessary to tie an increase in the predefined technology credit cap to proposed modifications to certain technology definitions.

Auto Innovators supports timely additions of technology to the menu, but the cap must be increased as technologies are added. Auto Innovators fully supports adding technologies to the predefined menu of off-cycle credits, but only if commensurate changes to the credit cap are made. Some technologies have found broad adoption across the industry following approvals under alternative methods. It makes sense to include these technologies in the menu. However, the credit cap should be raised commensurate with the potential benefits of the technologies under such a cap lest manufacturers forego technologies because they would not receive credit. As EPA notes, adding technology to the predefined list reduces the burden on manufacturers and EPA to evaluate off-cycle technologies through either the five-cycle or alternative methods, but potentially exacerbates the credit cap issue for some manufacturers.71

The lead-time for the adoption of new technology definitions for passive cabin ventilation, active transmission warm-up and active engine warm-up is insufficient; changes should take effect in MY 2027 or later. EPA proposes to modify certain technology definitions effective MY 2023 (or sooner if a manufacturer wishes to receive a higher credit cap for predefined off-cycle technologies).72 Model year 2023 vehicles can be built as soon as January 2022, leaving manufacturers only three to at most nine months to design, validate, and certify vehicles with systems that meet the new definitions. This lead-time is simply insufficient to make the necessary level of changes. In MY 2019, the fleetwide average use of active engine warmup, active transmission warmup, and passive cabin ventilation technologies resulted in a credit of approximately 3.6 g/mile.73 Modifying definitions without sufficient lead-time would likely result in an immediate loss of most, if not all of this credit, further escalating the challenge of managing the large increase in standard stringency proposed for MY 2023.

The new definitions will require innovative solutions and significant changes to vehicle design to meet them. EPA should consider comments made on modified definitions, but it would be more appropriate to forego making any changes until a subsequent rule with a more typical amount of lead-time than that minimally provided under this rulemaking.

If EPA adopts new definitions for passive cabin ventilation, active engine warm-up, and/or active transmission warm-up technologies, EPA should also continue to recognize existing designs. EPA justifies its proposal to modify technology definitions on the basis that current system designs are not meeting EPA's original expectations.74 However, current system designs are providing off-cycle emissions benefits. Given the benefits of such systems, EPA should continue to provide credit for systems that meet existing definitions through the menu, in addition to newly defined systems. If EPA were to instead eliminate credit for existing systems entirely, especially with no lead-time, manufacturers may remove those existing technologies from their vehicles.

Thermal control off-cycle technologies should be combined with credits for improving the efficiency of air conditioning systems. EPA includes “thermal control technologies” as a set of predefined technologies subject to a separate per-vehicle cap.75 These thermal control technologies should ideally have been analyzed and administered in combination with the mobile air conditioning (“MAC”) efficiency technologies from the earliest stages of the light-duty greenhouse gas regulation since they both address energy usage to power the air conditioning system.

We recommend that EPA move these technologies to the section on improving the efficiency of air conditioning systems (40 C.F.R. § 86.1868-12) and to combine and increase the caps on thermal control and air conditioning efficiency technologies as described below in comments on air conditioning efficiency technology credits.

Timely review, publication, and approval of alternative method off-cycle credit applications is needed. Time is of the essence when a manufacturer submits an off-cycle credit application for review. Lengthy delays in processing applications and in reviews subsequent to the public notice and comment process introduce uncertainty into compliance planning and reporting for manufacturers. Delays also affect timely determinations of compliance and valuation of credit trades and transfers. They also discourage further investments in off-cycle technologies due to the uncertainty of when (or if) credit will ever be granted.

EPA is required to review an application for completeness and to notify the submitting manufacturer if additional information is required within 30 days.78 Subsequent to determining an application is complete, EPA is required to make the application available to the public for comment within 60 days.79 These two processes should collectively take a maximum of 90 days. Thus far in 2021, the three applications that reached publication in the Federal Register took 111,80 290,81 and 34282 days. Other applications are still pending review or publication for public comment.83 We urge EPA to follow its regulations by providing an initial response on the completeness of credit applications within 30 days and to make complete applications available for public comment within 60 days.

Once the public comment period closes, the EPA decision process is also frequently lengthy. For example, EPA published off-cycle credit applications for public comment from Toyota in April 202084 and in October 2020,85 from Nissan in February 2021,86 and from Stellantis in April 2021.87 As of September 2021, all are still pending a decision. We recommend that EPA establish a reasonable deadline (e.g., a maximum of 60 days following the close of the public comment period and any manufacturer rebuttal of public comments) to make a decision on alternative method credit applications. [EPA-HQ-OAR-2021-0208-0571-A1, p. 21-26]

Commenter: Alliance for Vehicle Efficiency (AVE)

AVE supports EPA's proposal to increase of the off-cycle credits menu cap from 10 g/mile to 15 g/mile. [EPA-HQ-OAR-2021-0208-0256-A1, p. 2]

Expanding Off-Cycle Credits Menu from 10% to 15%. AVE supports EPA's proposal to increase of the off-cycle credits menu cap from 10 g/mile to 15 g/mile4 and the eventual phase-out of these credits.

EPA's off-cycle credit program incentivizes investments into technologies that provide real-world emission reductions, but that are not otherwise captured in the agency's two-cycle test. For decades, EPA has recognized that the two-cycle test is inadequate. Without off-cycle credits, OEM compliance with GHG emission standards could be jeopardized. Expanding the credits menu cap sends a strong message to industry that investments in new advanced technologies are needed for future compliance.

Although AVE recognizes the need to incentivize consumer acceptance in the short term, credits distort the marketplace and AVE supports efforts to move away from incentives such as these. [EPA-HQ-OAR-2021-0208-0256-A1, p. 3]

Commenter: American Council for an Energy-Efficient Economy (ACEEE)

EPA proposes to increase the credit cap for uses of off-cycle menu credits from 10 g/mi to 15 g/mi. They justify this increase with, among other reasons, proposed definition changes to two menu credit technologies to emphasize that certain implementations that have previously been awarded menu credits will no longer be considered eligible (EPA 2021b). EPA claims the current definitions are too vague and allow for underperforming technologies to earn full menu credits. We support EPA in this decision. EPA should continue to scrutinize menu credits to ensure that definitions only allow for technologies that have been researched and tested and not others that may be superficially similar.

That said, EPA has also proposed that the 5 g/mi increase in credit cap be applied retroactively to MY 2020-2022 vehicles, if all claimed credits fall under the new technology definitions. This proposal fails to account for the fact that these vehicles have already been designed, with the current rules in mind, and no new menu technologies are going to be added to such vehicles. This proposal would not lead to any reductions in actual emissions. Instead, it would effectively reduce the stringency of the proposed rule by giving automakers credits for decisions that they have already made and implemented. ACEEE opposes this retroactive increase in the credit cap. ACEEE estimates that if automakers were to take advantage of the entire 5 g/mi retroactive cap increase, emission savings from the proposed standards would be reduced by 19%.

The credit cap increase is also concerning as applied to future model years, as the off-cycle credit system already over awards credits. Any increase in the cap would exacerbate this element of the off-cycle program and further weaken the rule stringency. Research has shown that some technologies area awarded up to 100% more credits than appropriate, equaling up to 3 g/mi of credits per technology (Gonder et al. 2016; Kreutzer et al. 2017). Another concern is that technologies that qualify for menu credits have not been evaluated for redundancies or overlaps in benefits (Lutsey and Isenstadt 2018). A vehicle that has more than one of these technologies addressing the same inefficiencies may not achieve the sum of the benefits of the individual technologies. A vehicle that adopts both solar panels and ventilation improvements may see no additional improvement over solar panels alone, if the extra power from the solar panels was already sufficient to cover and used for the ventilation system. However, because the credits in the off-cycle program are simply additive, this could lead to the awarding of up to 2 g/mi1 in additional credits that do not correspond to reductions in actual emissions. EPA should not increase the cap on menu credits until after it has reviewed the literature on the effects of the current menu credits and has tested these technologies for synergistic effects and ensured that any overlaps are sufficiently accounted for. ACEEE estimates that, if only half of the additional off-cycle credits, or 2.5 g/mi per year, for model years 2023-2026 led to real emissions reductions, the proposed rule's emissions savings would be reduced by 14%. [EPA-HQ-OAR-2021-0208-0251-A1, 3-4]

The NPRM does not propose any changes in the off-cycle credit program in anticipation of emerging technologies. These emerging technologies including automated vehicle (AV) technologies, have the potential to substantially affect vehicle emissions but are not detectable under current emissions testing protocols. The current off-cycle credit program is unable to adequately account for the changes in emissions that this technology causes. The growth of the AV market has been rapid. In 2021 Level 1 automated vehicles reached a market share of 26% of all new vehicles, while Level 2 AVs grew from just 2%, in 2018, of the market to over 10%, in 2019 (Xie et al. 2020; NAS 2021; Low et al. 2019). The effect of these technologies is both highly uncertain and dependent on design decisions that are being made now. These design decisions are directly influenced by emission regulations and the current off-cycle program provides no incentive for automakers to design their AVs for fuel efficiency. Mersky 2021 has shown that near term AV technologies could increase fuel economy by up to 46% but could also decrease it by up to 14%, depending on automaker design decisions. ACEEE suggests that EPA investigate the how the off-cycle program can account for AV emission changes and to encourage efficient AV design. [EPA-HQ-OAR-2021-0208-0251-A1, p. 4]

ACEEE recommends that EPA:

• Keep the total off-cycle menu credit cap at the current 10 grams/mile and ensure that no retroactive changes in the credit cap are built into the final rule [EPA-HQ-OAR-2021-0208-0251-A1, p. 14]

• Clarify what a 'significant' reduction in emissions is in order to determine eligibility for off-cycle menu technologies for other credit pathways. ACEEE proposes a definition of at least 1g/mi greater than those currently assigned by the menu. Additionally, EPA should ensure that menu technologies that are granted credits through another pathway still count towards the menu cap.

• Begin considering how the GHG standards encourage efficient AV design by accounting of the emissions impacts of automated vehicles [EPA-HQ-OAR-2021-0208-0251-A1, p. 15]

Add new or clarify proposed provisions

ACEEE recommends the following clarification and additions that do not strictly change rule stringency. EPA should:

• Place a firm time limit on automaker applications to the non-menu off-cycle credit program, in line with the National Highway Transportation Safety Administration (NHTSA) proposal. This program has long been plagued by automaker applications for technologies implemented on old vehicle models. These retroactive requests have no bearing on OEM technology decisions and also cost a significant amount of time to process. Lastly, they make setting future standards difficult, as actual contemporary compliance is not set in stone. Requiring automakers to submit their requests for off-cycle credits in a timely manner would improve the effectiveness of the off-cycle program. [EPA-HQ-OAR-2021-0208-0251-A1, p. 15]

1 A solar system that charges batteries and provides power to active ventilation provides 0.8 g/mi credits less than battery charging alone, to attempt to account for this, but this change is non-variable. The ventilation credits are still worth up to 2.8 g/mi, which would be unearned if the solar system was sufficient to cover all ventilation and climate control needs.

Commenter: American Honda Motor Company (Honda)

Off-Cycle Technology Credits. Despite challenges to its implementation, Honda remains supportive of the off-cycle technology program for the real emissions reductions these technologies deliver. The off-cycle program provides a regulatory rationale for applying GHG reduction measures to new and/or existing technologies and systems that might not otherwise occur, given that the benefits are (by definition) not captured through standard test procedures. [EPA-HQ-OAR-2021-0208-0565-A1, p.12]

Uncertainty associated with agency approvals, as well as the magnitudes of compliance benefit, remain core impediments to the pursuit of these technologies. As such, Honda supports efforts to streamline the program, and to provide greater clarity and certainty to manufacturers regarding the menu credit value when pursuing credits for new technologies. An expanded credit menu could, for example, reduce the amount of time necessary for agency review of multiple applications that largely mirror one another, as well as provide greater certainty regarding technology credit values.

Honda supports periodic updating of the off-cycle menu, as technologies become better understood and as vehicle electrification becomes a more prominent portion of the new vehicle fleet. Changes should be data driven, include opportunity for stakeholder input, and provide sufficient lead time to ensure continuity of compliance plans. The agencies may also wish to consider creating a multiagency/ OEM/supplier consortium for off-cycle technology sensing. Such an effort could provide regulators insight into potential future technologies, helping facilitate important technical conversations among stakeholders well before any consideration of technology application. [EPA-HQ-OAR-2021-0208-0565-A1, p. 13]

Commenter: BorgWarner Inc.

Off-cycle Credits and Credit Caps. We support the continuation and expansion of credits for technologies that provide verifiable real-world improvements in fuel economy. The 10 g/mile off-cycle credit cap should be removed to allow and promote the true potential of these technologies to achieve the new standards. We do not see the value of a cap that excludes technologies that are shown to provide additional real-world fuel economy benefits. Credit programs should be continued and expanded to provide important flexibilities and broader pathways for greater innovation and lower compliance costs. [EPA-HQ-OAR-2021-0208-0260-A1, p. 3]

Commenter: Center for Biological Diversity, Earthjustice, and Sierra Club

Third, if it proceeds with its current proposal, EPA should end, reduce, or significantly reform the off-cycle credit program. Off-cycle credits reward manufacturers for adopting technologies that reduce GHG emissions that are not otherwise captured by the standard two-cycle testing system. In this rulemaking, EPA proposes to retain the program and to increase the cap for 'menu' technologies with pre-set credit values that manufacturers can adopt.48

Yet EPA itself has expressed considerable doubts about the off-cycle program, namely, whether it actually delivers the real-world emissions reductions it promises.49 These uncertainties arise both from a number of individual factors, and from their combination: the lack of data submission; the lack of testing; and the practice of 'one-size-fits-all installation' by which automakers who install the same technology not just on the specific vehicle type and model they tested, but also on many or all of the other cars and trucks in their fleets, without submitting any test data on the level of emissions reductions, if any, they generate on these different and diverse vehicles.50 Furthermore, there are enormous logistical and administrative concerns that hinder the agency's ability to manage these credits and inform the public about the state of the program. For example, manufacturers routinely miss deadlines and submit applications late, which, according to NHTSA, has caused 'significant challenges in finalizing end-of-the year compliance processes for the agencies….These late reports amount to more than just a mere accounting nuisance for the agencies; they are actively chilling the credit market.' 51 In short, the off-cycle credit program has delayed agencies' calculation of, and public formation about manufacturer compliance results since MY 2017, the last year for which NHTSA has issued compliance results. In addition to hindering the agencies, these delays make it difficult for the public to accurately inspect overall manufacturer compliance, which is critical to providing feedback for future rulemakings.

For these reasons, if EPA proceeds with its current proposal, off-cycle credits should, at a minimum, be limited and reformed so real-world results are assured and verified, as stated in the Joint Comments. If the agency adopts Alternative 2 plus, off-cycle credits should still not be expanded, and their cap maintained. [EPA-HQ-OAR-2021-0208-0270-A1, pp.8-9]

Commenter: Center for Biological Diversity, et al.

EPA should not increase the cap for off-cycle credits and should instead reduce and reform the off-cycle program. Off-cycle credits find their genesis in the proposition that some technologies can produce real-world greenhouse gas emissions reductions even though those reductions are not captured or measured for compliance by the so-called two-cycle testing system. Although any real-world reductions could be measured for the vast majority of these technologies by employing a five-cycle test (which, for example, captures results at high vehicle speeds, acceleration or cold temperatures), that test procedure is more expensive and time-intensive. Either way, testing is done by manufacturers, and EPA itself does no testing when reviewing and approving off-cycle credit applications. Proposal, 86 Fed. Reg. at 43,762.

Manufacturers currently use three ways to obtain off-cycle credits. (1) They install technology on or fitting within a category list, or "menu", of technologies and receive pre-set credit values, with minimal or no data submittal or testing requirements. EPA approves the application if the technology meets regulatory definitions. Id. (2) Manufacturers test the technology and its emission reductions using the five-cycle testing procedure and submit the results for approval. (3) If five-cycle testing is inadequate to show whether emissions are being reduced, manufacturers use a notice and comment process to obtain EPA approval based on other demonstration methods they have chosen.

EPA now proposes not only to retain the program, but to increase the cap for the first pathway for credit approval (it proposes no cap for credits approved under the latter two pathways). Id. However, the agency itself expresses considerable reservations about the program. Specifically, EPA previously capped menu credits to 10 g/mile per model year, and then declined to increase the cap, citing inherent uncertainty about whether new technologies manufacturers claim fall within the menu categories actually deliver the real-world results for which they receive credit. As EPA explains, these uncertainties arise both from a number of individual factors, and from their combination: the lack of data submission; the lack of testing; and the practice of "one-size-fits-all installation" by which carmakers install the same technology not just on the specific vehicle type and model they tested, but also on many or all of the other cars and trucks in their fleets, without submitting any test data on the level of emissions reductions, if any, they generate on these different and diverse vehicles.155 EPA does not mention yet another uncertainty: automakers sum the fixed credit amounts allocated to each new menu credit they receive together with already existing menu credits, without any verification that those technologies, installed in the same vehicles, are in fact additive, in the summed amount or any other, under real-world conditions.

NHTSA's recent proposed rulemaking describes serious and fundamental additional concerns. In its September 2021 proposed rulemaking for MY 2024-2026 fuel efficiency standards, NHTSA explains that since 2017 the off-cycle application process has caused "significant challenges in finalizing end-of-the year compliance processes for the agencies." Corporate Average Fuel Economy Standards for Model Years 2024-2026 Passenger Cars and Light Trucks, 86 Fed. Reg. 49,602, 49,836 (Sept. 3, 2021) (NHTSA 2021 NPRM). In particular, NHTSA explains that some manufacturers do not seek early reviews to determine technology eligibility, a review process NHTSA describes as of "critical importance," NHTSA 2021 NPRM, 86 Fed. Reg. at 49,835, even though automakers may begin their technical development and testing as much as six years before applying for credits. NHTSA reports that some manufacturers miss deadlines and submit applications late – or even retroactively, and explains that as a result, EPA “has had to identify and correct multiple testing and analytical errors after the fact.” Id. NHTSA describes the current situation as follows:

The backlog of retro-active and pending late off-cycle requests have delayed EPA from recalculating NHTSA’s MY 2017 finals and from completing those for MYs 2018 and 2019. Fifty-four off-cycle non-menu requests have been submitted to EPA to date. Nineteen of the requests were submitted late and another seven apply retroactively to previous model years starting as early as model year 2015. Since these requests represent potential credits or adjustments that will influence compliance figures, CAFE final results cannot be finalized until all offcycle requests have been disposed. . . . [¶] These late reports amount to more than just a mere accounting nuisance for the agencies; they are actively chilling the credit market.

NHTSA 2021 NPRM, 86 Fed. Reg. at 49,836. In short, the off-cycle credit program has prevented the agencies from being able to calculate, or inform the public about, manufacturer compliance results since MY 2017, the last year for which NHTSA has issued compliance results. The program is so bogged down that they impede vital functions.

Despite its own recitation of the interacting uncertainties concerning whether off-cycle credits properly reflect actual emissions reductions, and despite NHTSA’s account of a vast, time-consuming and expensive backlog impeding accurate compliance calculations, EPA now proposes to increase the menu credit cap to 15 g/mile, beginning (retroactively) as early as MY 2020. Proposal, 86 Fed. Reg. at 43,762. EPA previously declined to increase the 10 g/mile cap “because of the uncertainty inherent in using limited data and modeling as the basis of a single credit value for either cars or trucks,” id.; remaining headroom below the cap; and the time and cost involved to determine whether manufacturer applications meet regulatory definitions. In support of the Proposal to increase the cap another 10 g/mile, EPA states that the 2020 Final Rule added even more menu credits and that the program has been growing. It also observes that menu technology is often more cost-effective than other available technology; that the menu process reduces costs to EPA and manufacturers; that some companies were at or approaching the cap in MY 2019; and that it proposes to “tighten” regulatory definitions describing technology eligible for menu credits. Id. at 43,762-63. EPA further proposes to limit the “tightened” regulatory definitions to retroactive credit requests between 10 g/mile and 15 g/mile for MY 2020-2022, reasoning that otherwise the “transition” for those model years might affect credits already awarded. The new definitions would, however, apply to all credit requests for MY 2023 and later.

EPA should reject the proposed cap increase and should further restructure off-cycle credits as soon as possible to provide more comprehensive data and necessary guardrails to avoid the problems described above. NHTSA’s description of the current state of the application process demonstrates it is not performing as intended, despite efforts since the 2020 Final Rule to improve it. NHTSA 2021 NRPM, 86 Fed. Reg. at 49,836. Disregarding pleas from the agencies for more and early information, manufacturers are not keeping them apprised of the technologies for which they plan to request credit. They routinely fail to heed the application process’ various deadlines, submitting applications late – and even retroactively. Id. The number of unresolved credit applications, their timing, uncertainty about whether technology fits within a menu category, and the existing backlog has impeded vital functions at least at NHTSA – the accurate measurement of standard compliance levels and the timely conveyance of this information to the public. Indeed, as of August 2021, NHTSA still had not made public manufacturers' performance for MY 2017 – and for none of the model years thereafter.

At a minimum, EPA should not add to the problem by expanding the menu program cap – particularly since the process is already overwhelming the agencies, even though many manufacturers have not yet reached the existing cap. EPA should not expand a program that EPA and NHTSA both acknowledge is rife with substantive and procedural problems. The time and money spent, which is already extraordinary and deeply disruptive, would only increase, as would the uncertainty about actual results. And yet, EPA would still not be in possession of comprehensive testing data across the fleet.

Commenters urge EPA in any event not to finalize any additional MY 2020-2021 menu credits. They would be granted retroactively, as MY 2020 is complete and MY 2021 will be complete by the time the Proposal is finalized. These credits would add to the existing backlog and their analysis and approval would continue to impede a final accounting of manufacturers' emissions reductions. EPA itself cites the retroactivity of this Proposal when discussing why it does not intend to apply tighter regulatory definitions to menu items already granted. But, as discussed above, manufacturers do not base their product plans on credits they do not possess (or plan to purchase), and retroactive application therefore does not create real-world emissions reductions. Moreover, even assuming the new definitions will be effective in providing certainty that the claimed emissions reductions are real, applying them only to some but not all retroactive credits (those between 10 and 15 g/mile) would add even more complexity, confusion, time and agency expense to the process.

In addition to rejecting the proposed cap increase, we strongly urge EPA to codify provisions that prohibit, without exception, the submission of any application that has missed any of the applicable deadlines, a change clearly needed to avoid otherwise inevitable additional processing time, expense and delay in determining and reporting compliance results. As NHTSA has explained, manufacturers plan for off-cycle submissions years before the submission deadlines, and there is no reason to introduce additional delay, expense, and uncertainty about compliance and the status of approved credits. EPA should also require the submission of much more comprehensive testing results to assure accuracy, particularly for menu credit applications to vehicles in which the technology has not been tested, and in instances requesting automatic, and untested, "summing" of menu credits. To be viable, the program must be able to demonstrate that the credits it awards actually reduce greenhouse gases in the real world, and not only on paper. [EPA-HQ-OAR-2021-0208-0651-A1, p. 66-69]

155 Off-cycle technologies receive a one-size-fits-all credit amount even though their application in any particular vehicle may result in wholly different emissions reductions. For example, credits are fixed for active or passive cabin ventilation and active engine or transmission warm-ups, regardless of the characteristics of the vehicle.

Commenter: Center for Climate and Energy Solutions (C2ES)

Off-Cycle Menu Credits. C2ES supports the proposed off-cycle menu credits and the proposed 15 g/mile cap and believes the increased cap should begin in MY 2023 when the new standards would be implemented, in order to reflect the significant increase in stringency of the MY 2023 emissions standards over the MY 2022 standards. The off-cycle menu credits in the proposal support development of technologies to reduce emissions that may not be measured in the regular two-cycle emissions testing process, such as high-efficiency alternators, waste heat recovery, solar roof panels, and others. The flexibility to generate credits through these technology improvements provides an additional incentive for automakers to increase the efficiency of their vehicles. [EPA-HQ-OAR-2021-0208-0287-A1, p.7]

Commenter: Consumer Reports (CR)

CR also questions the expansion of the off-cycle credit cap without putting into place stronger requirements to ensure that these technologies actually deliver real world benefits. Without sufficient verification of emissions savings, these credits have the potential to be a massive giveaway to automakers for technologies that don't deliver real world benefits. [EPA-HQ-OAR-2021-0208-0602-A1, p.5]

Off-Cycle Credits. Consumer Reports generally disagrees with EPA's plan to expand the off-cycle credit limit by 5 g/mi. While other commenters will go into more detail on this program, CR's high level concern is with the lack of sufficient verification of real world emissions savings delivered by these technologies. We disagree with further expansion of this program without simultaneously increasing the requirements to verify real world emissions savings. [EPA-HQ-OAR-2021-0208-0602-A1, p.12]

As a separate point, Consumer Reports questions the idea of awarding off-cycle credits to battery electric vehicles. These vehicles emit zero tailpipe emissions, so no technology applied to these vehicles can further reduce real-world tailpipe emissions. As electric vehicles become a larger and larger portion of the fleet, the off-credit program may inadvertently hand out a significant number of "free" credits to electric vehicles that provide no real world emissions benefits. [EPA-HQ-OAR-2021-0208-0602-A1, p.13]

Commenter: DENSO International America, Inc. (DENSO)

Off-Cycle Technology Credits. We support the continuation and expansion of the program, and strongly encourage both EPA and NHTSA to also recognize the important contribution the off-cycle program makes to the overall goals of the regulations. DENSO, along with others in the supplier community working independently and in collaboration with OEMs, develop and engineer innovative technologies that contribute to vehicle manufacturers' strategies for real-world GHG and fuel consumption reductions often beyond those measured with standard test procedures. The off-cycle credit program helps support industry investment in innovative and forward-looking technologies that provide environmental benefits. These technologies offer measurable, demonstrable, and verifiable real-world benefits that improve efficiencies and reduce GHG emissions. They also provide an important cost-effective option for OEMs to achieve fuel economy and GHG targets. Therefore, DENSO has a vested interest in making sure innovative technologies are easily deployed and utilized by OEMS to ensure these benefits are realized.

Off-Cycle Credit Application Process. DENSO would also like to take this opportunity to recommend EPA streamline and standardize its process for evaluating applications for off-cycle credit. Timely processing of applications by EPA can encourage manufacturers to invest in new off-cycle technologies that do not offer a significant 2-cycle benefit. When processing of applications is delayed, it provides a disincentive to both the manufacturers and the suppliers to expand research, development, and eventual vehicle applications of technologies providing CO2 and fuel consumption reductions. The delay can also limit the positive benefits these technologies bring to society and the environment.

We appreciate EPA's commitment to the integrity of the off-cycle technology credit program, and we also encourage EPA to continue to examine options for improving the off-cycle application process so that it can continue to be a viable option for vehicle manufacturers. DENSO strongly supports changes to the off-cycle process that would streamline the program, which are proposed by the agencies in the NPRM. These improvements could include, but are not limited to:

- Revising the regulations to allow EPA to add technologies to the preapproved credit menu without going through a subsequent rulemaking;

- Revising the regulations to define a time period for which application will be finalized; and

- Creating a pathway for provisional off-cycle credits through a supplier application process.

DENSO also requests EPA consider new evaluation methods for off-cycle (and A/C efficiency) technologies. For example, EPA could consider approving credit evaluation methods that not only require implementing physical tests, but also methods such as calculation/simulation. We would welcome the opportunity to have a deeper discussion on this matter with EPA in the future and discuss DENSO ideas and calculation methods.

Revisions like these can lead to a reduction in redundancy of applications and subsequent approval processes for both manufacturers and the agency. There is wide support for having a more efficient offcycle technology program to allow for more certainty and faster deployment of emissions-reducing technologies that cannot be measured on-cycle.

Supplier Process for Off-Cycle Credits. A supplier process, allowing a menu of provisional credits, could also contribute to the streamlining of the process. As a member of the Motor & Equipment Manufacturers Association (MEMA), we have spoken with EPA regarding a proposed Supplier Process for Off-Cycle Credits that could provide one pathway to streamlining the process for all parties. We have appreciated the conversations with EPA on this topic and look forward to continuing dialogue. There is a considerable upside to establishing a supplier application process enabling innovative technologies to enter the market faster and with greater penetration. An independent supplier process would lower investment risks for both OEMs and suppliers and decrease the workload for EPA and OEMs.

Support Increasing Off-Cycle Credit Caps. We appreciate the proposal's request for information regarding increasing the credit caps. DENSO supports the increase to the credit cap. There are often situations where a technology provides additive and incremental improvements to the GHG performance of a vehicle outside of the two-cycle test. We have supported comments from MEMA in the past that have asked the agency to consider eliminating the cap on the accrual of off-cycle credits for MYs 22-25. Available data on OEM off-cycle technology credit utilization within the past few years demonstrates that the use of off-cycle technologies is expected to grow—particularly technologies on the credit menus.

Solar/Thermal Control Cap. As mentioned, DENSO supports the increase in the off-cycle credit cap; however, we request EPA to consider eliminating the solar/thermal credit cap (3.0 g/mi for cars, and 4.3 g/mi for trucks). Solar/thermal technologies (e.g., glass or glazing, active seat ventilation, passive cabin ventilation, etc.) are used for different purposes, which are activated in various situations, and therefore do not overlap.

For example, passive cabin ventilation and active seat ventilation are designed to prevent cabin temperature increasing when the vehicle is parked, while S-Flow reduces the cabin thermal load on the air conditioning system and improves the fuel economy when the vehicle is in operation. Therefore, we think these technologies should not be considered in the same group, and we recommend eliminating the solar/thermal control technologies' credit cap.

Credit applications for the S-Flow technology have been applied to the solar/thermal control credit cap, even if the approval path was the off-cycle credit alternative method. Furthermore, when the agencies determined the thermal control/solar cap, the credit amount for S-Flow, which is not included in the list, was not considered in the first place. Inclusion of such technologies towards solar/thermal control cap leads to an artificial expansion of the thermal control/solar menu, which when combined with the limitation of the cap, may inhibit the adoption of efficiency items by car manufactures.

We ask EPA to consider a credit cap increase to reflect newly adopted technologies –for example, allowing the proposed addition of 5g/mile credit to be used for any item without considering solar/thermal control cap. EPA mentions in the NPRM that off-cycle predefined menu cap is proposed to be increased due to the recent technology inclusion and the limited headroom. The thermal /solar credit would face the same situation if the S-Flow technology continues to be subjected to a cap. We would welcome the opportunity to further discuss this issue together if necessary. [EPA-HQ-OAR-2021-0208-0282-A1, p. 3-5]

Commenter: Ford Motor Company

Off-Cycle Menu Credit Cap. Ford commends EPA's continued support for the off-cycle credit program. This program serves a critical role by incentivizing technologies that provide real CO2 reductions and improved fuel economy for consumers. The ability to earn regulatory credit for CO2 reductions not captured during laboratory testing enables adoption of many technologies that would otherwise not be cost-effective.

Ford also supports raising the credit cap for off-cycle menu technologies to 15 g/mi, including for past model years. Additionally, the Notice and Comment process is the appropriate mechanism for making major policy or technology definition clarifications to the off-cycle program. However, such clarifications should not be retroactively applied, or be required in order to qualify for the 15 g/mi cap for previous model years. It should also be noted that Ford has relied on these credits to comply with current and past regulatory structures, such as 'One National Program' and the California Framework Agreement.[EPA-HQ-OAR-2021-0208-0294-A1, p.4]

Passive Cabin Ventilation Credits. Ford understand EPA's rationale for revising the definition for Passive Cabin Ventilation. However, Ford has concerns with the requirement to have windows or a sunroof open automatically, since the customer must retain control over window and sunroof open/closed status in order to accommodate inclement weather, security concerns or other unanticipated conditions. Additionally, Ford requests this definition only be applied in '23 model year and beyond, not retroactively. [EPA-HQ-OAR-2021-0208-0294-A1, p.4]

Off-cycle Demonstration Credits for Alternative Fuel and Electrified Vehicles. Ford has submitted off-cycle demonstration credit applications for BEV and PHEV technologies that provide real electrical load savings. These savings translate to reduced energy consumption and improved vehicle range for BEVs and PHEVs. Ford is also considering additional technologies to be applied to future programs, assuming that such technologies will be eligible for credit consideration. Ford requests that EPA give consideration to the relative benefit provided by off-cycle demonstration technologies on BEVs and PHEVs, similar to the granting of menu credits for these types' vehicles. This action would support further technological innovation and energy savings. [EPA-HQ-OAR-2021-0208-0294-A1, p.5]

Active Engine and Transmission Warm-up Definition. Ford understands EPA's rationale for clarifying the definitions for Active Engine and Transmission Warmup technology credits. Ford is confident that our systems meet the intent of the proposed definition for Active Engine and Transmission Warm-up. However, to provide further clarity within the proposed definition, we suggest the following changes (edits shown via strikeout/ bold blue text):

Ford Proposed Definitions for Active Engine and Transmission Warm-up:

§86.1869-12 CO2 credits for off-cycle CO2 reducing technologies (b)(4)(vi)(B) Starting in model year 2023, and optionally for model years 2020–2022, active engine warm-up means a system that uses waste heat from the vehicle's exhaust to warm up targeted parts of the engine so that it reduces engine friction losses and enables **faster** closed-loop fuel control ~~more quickly~~. Active engine warm-up may also include coolant systems that capture heat from a liquid-cooled exhaust manifold~~. if the system is segregated from the coolant loop in the engine block~~.

§86.1869-12 CO_2 credits for off-cycle CO_2 reducing technologies (b)(4)(v)(B) Starting in model year 2023, and optionally for model years 2020-2022, active transmission warm-up means a system that uses waste heat from the vehicle's exhaust to warm the transmission fluid to an operating temperature range using a dedicated heat exchanger. Active transmission warm-up may also include coolant systems that capture heat from a liquid-cooled exhaust manifold~~. if the system is segregated from the coolant loop in the engine block~~. [EPA-HQ-OAR-2021-0208-0294-A1, p.5]

Commenter: General Motors LLC (GM)

General Motors believes regulatory incentives for real world off-cycle emissions reductions will continue to play an important role in reducing CO_2 emissions and increasing fuel economy. As such, GM supports EPA's proposal to raise the cap on off-cycle technologies. As discussed in previous comments by GM and industry, there are technologies and innovations that are important for EPA to acknowledge in its program to ensure continued progress toward meeting the agency's standards.4 [EPA-HQ-OAR-2021-0208-0234-A1] [p.6]

Commenter: Gentherm, Inc.

Real-World Benefits of Off-Cycle and A/C Credits. Studies by the National Renewable Energy Laboratory (NREL) and others have confirmed that off-cycle and A/C efficiency credit technologies provide real-world benefits that are not currently captured by two-cycle testing. The analysis is based on energy consumption for vehicles across the United States. We believe that off - cycle and A/C efficiency technologies are more cost effective than other currently available or proposed on-cycle technologies. It is important to note that these credits do not distort the market and do not artificially create financial benefits.

Latest EPA trends report (2020) shows a 74 gCO_2/mile national fleet difference between average light vehicle two-cycle emissions (282 gCO_2/mile) and adjusted real-world estimate (356 gCO_2/mile) for MY2019. Per the ITB Group analysis, if we assume that 9.5 percent (27 gCO_2/mile) of the average two-cycle emissions is attributed to exogenous variables like load, grade, wind, rain/snow, tire pressure, etc. that leaves on average 47g of real-world CO_2 emissions due to off-cycle (A/C, thermal, electrical, powertrain and other) variables. This gap is due to off-cycle effects resulting from variation in acceleration, thermal, aerodynamic, and electrical losses. Current and future off-cycle technologies, including autonomous and predictive driving, are expected to provide benefits not contemplated in the current 10 gCO_2/mile cap. Therefore, the current 10 g/mile fleet level cap is low and should be raised. Gentherm believes that the EPA proposal of a 15 g/mile off-cycle credit cap is reasonable today, but is conservative compared to the 47g real-world vs. 2- cycle gap and may need future adjustment as new technologies are developed. [EPA-HQ-OAR-2021-0208-0216-A1, p. 2]

Conditional support for changing Technology Menu Definitions. The EPA has proposed changing selected off-cycle menu technology definitions. In principle, Gentherm agrees that menu definitions should be supported by representative data. It is important that the off-cycle menu credits represent accurate estimates of real-world fuel consumption and GHG emissions benefits which cannot be measured in 2-cycle testing. The menu definitions should correspond to the technology(s) tested and emissions reductions associated with verifiable testing and modeling.

The difficulty is that if menu definition changes take effect in 2023, automakers are given little to no time to respond. Automakers have developed their compliance plans based on previous definitions. Furthermore, there is no time to start a complete reevaluation of existing technologies which currently meet the definitions, particularly engine and transmission warm-up technologies. In a worst-case scenario, automakers may even remove fuel savings technologies which no longer receive credits.

The EPA proposes changing the definitions of certain technologies which may have real world benefits. For example, passive cabin ventilation has been shown to provide value, but less than the current menu credit (refer to NREL Presentation 17TMSS-0056). Likewise, active engine and transmission warm-up need not use exhaust waste heat to be effective as the EPA concluded in 2012. Active warm-up can involve controlling coolant flow to change component cooling and warming timing. This may include not overcooling with zero coolant flow for rapid engine and transmission warm-up. Revised definitions for effective technologies must be based on evidence of their effectiveness, not prescriptive definitions of exhaust waste heat or secondary coolant loop configurations. In conjunction with the proposed definition changes, the EPA should consider the real-world benefit of the technologies being “stranded”, or no longer applicable, and should add new menu credit(s) at a level based on the verifiable real-world benefit of the developed and commercialized technologies. Technologies which have been developed and applied based on the original definitions should have a place on the menu commensurate with the verifiable real-world benefit the technology provides.

Gentherm is aware of a number of commercialized technology developments with real-world benefits that are not yet credited by the EPA and NHTSA. New technologies under development utilize otherwise wasted thermal energy, moderate vehicle acceleration, and allow longer engine-off periods in real-world driving, among other potential benefits.

The EPA should take action on outstanding applications of technologies with verifiable real-world benefit and accelerate their approval, or rejection, and possibly adding them to the off-cycle technology menu. The EPA should also take this opportunity to add new off-cycle menu technology definitions for items with multiple substantially similar off-cycle credit approvals. [EPA-HQ-OAR-2021-0208-0216-A1, p. 2-3]

Expand the Menu List to Add Active Climate Control Seats. Gentherm supports expanding the list of the off-cycle and A/C efficiency menu options, including adding active climate control seats. Our passenger comfort technologies have been independently proven and validated by NREL to reduce fuel consumption and vehicle CO_2 emissions. Our engineers working in the United States developed these technologies with the intention of reducing fuel consumption while improving in-vehicle comfort. For example, we invested approximately $500,000 with NREL to validate the emissions benefits of our technologies. After this validation was completed by NREL, General Motors made an additional investment to prepare a submission based on our research and was awarded off-cycle credits. In addition, Hyundai and Kia have received similar approvals from the EPA, and Stellantis (FCA) has a substantially similar pending request for approval of active climate control seats. An important factor to consider in determining if a menu credit is warranted is its commercialization status. Active Climate Control Seat technology is in production for a number of auto manufacturers and other manufacturers should receive the same credit benefits to level the playing field.

Gentherm also recommends extending off-cycle and A/C efficiency technologies to medium- and heavy-duty classes 2b and 3, which utilize such technologies. Expanding the current credit program encourages commercialization of innovative and cost-efficient technologies, while also providing consumers with more choices. [EPA-HQ-OAR-2021-0208-0216-A1, p. 3-4]

Support credit approval process streamlining. Gentherm is in agreement with NHTSA as outlined in its 2024-2026 NPRM (docket: NHTSA-2021-0053) that the Off-cycle credit approval process can be improved. NHTSA proposes setting deadlines for OEM submissions, and we suggest that there should also be deadlines for the agencies (EPA/NHTSA) to respond to off - cycle credit request submissions for the off-menu approval pathways. [EPA-HQ-OAR-2021-0208-0216-A1, p. 4]

Develop a Process for Adding Technologies to the Menu List. We encourage the agencies to create a process to add technologies to the credit menus. An off-cycle or A/C efficiency credit menu approval process would allow for technologies to be added to the menu list once sufficient data is available to the agencies. Although two technologies were added to the menu in the previous "SAFE" rule, more technologies could be added to the menu more rapidly.

We must encourage the development of new technologies, and we believe that the regulations should encourage new technology developments with sufficient data is available to create a menu credit. When technologies are added to the menu lists, industry compliance costs are decreased, and national fuel consumption and exhaust emissions are reduced. A difficult to change menu deters companies from innovating by making the approval more burdensome than if a credit approval menu process was available. We recommend that the agencies develop a process which allows automakers to apply for adding technologies to the menu lists and which should include public review of such submissions.

Gentherm is currently developing several energy conservation technologies. In the future emissions reductions from off-cycle technologies and A/C efficiency technologies could be credited when used on BEVs, PHEVs and FCEVs. Such a pathway will become highly relevant when EV emissions account for upstream CO2 emissions, not only the 0 grams/mile tailpipe emissions. Certain off-cycle and A/C efficiency technologies, particularly cabin heating technologies help reduce the amount of energy used to power a vehicle. Consequently, technologies that reduce EV energy consumption should be recognized when the 0 g/mi electric drive incentive is potentially eliminated after 2026. Gentherm recommends that a program be developed by the agencies to consider developing a set of EV and autonomous technology off-cycle menu credits in preparation for future rule making. [EPA-HQ-OAR-2021-0208-0216-A1, p. 4-5]

Establish an off-cycle credit adjustment process. Gentherm believes that the agencies should consider adjusting menu credit values either up or down if new vehicle or component testing becomes available. For example, an NREL study raises questions about the efficacy level of current technology used for active and passive cabin ventilation credits. Establishing a credit adjustment process would allow benefit levels or formulas to be adjusted when new studies are performed or when technology interaction effects are identified. [EPA-HQ-OAR-2021-0208-0216-A1, p. 5]

Increase Off-Cycle Thermal Control and A/C Efficiency Technology Credit Levels. The latest estimate of average national CO2 emissions attributed to light duty vehicle air conditioning, per NREL, is 20.8 gCO2/mile for cars and 26.0 gCO2/mile for trucks1 . If the agencies deem that a A/C load reduction cap is necessary, Gentherm supports an increase and combination of the off-cycle thermal control technology and A/C efficiency caps to 14.3 gCO2/mile for cars and 18.5 gCO2/mile for trucks. This cap increase is based on new NREL A/C load estimates and preserves the original cap rationale. These calculations were made by The ITB Group using NREL data and are included in their comment submission to this docket.

The latest NREL A/C load estimates should be used to increase credit levels of certain Off-Cycle Thermal Control and A/C efficiency technologies. For example, General Motors'2 credit approval for active climate control seat was based on a study by NREL that estimated a 17 percent reduction in A/C energy consumption on average across the United States. General Motors scaled their actively cooled seat credit submission to the A/C fuel usage estimates using recognized A/C energy consumption equivalent to 13.8 and 17.2 gCO2/mile for cars and trucks from the augural standards. If one uses the latest NREL A/C national load estimates of 20.8 and 26 gCO2/mile for cars and trucks, then active seat ventilation and active climate control seat credit benefit levels would increase by approximately 51 percent as shown below. [EPA-HQ-OAR-2021-0208-0216-A1, p. 5]

For ventilated seats we propose increasing the credit levels as shown in the table below and in the NREL benefit calculations3. [Table can be found on p. 6 of Docket number EPA-HQ-OAR-2021-0208-0216-A1]

It may be appropriate for other A/C efficiency or off-cycle thermal control technologies to be scaled-up following the same methodology using the latest NREL A/C load estimates, if their credit levels are a function of vehicle A/C fuel usage.

The agencies currently place a VIN specific cap on A/C efficiency technologies and a sub-cap on off-cycle thermal control technologies which affect A/C load. Gentherm recommends that they be converted to fleet level caps for more flexibility and ease of implementation. Improved flexibility across a fleet average would reduce discounting of real-world benefits. [EPA-HQ-OAR-2021-0208-0216-A1, p. 6]

Commenter: Hyundai America Technical Center, Inc. (Hyundai)

Off-Cycle Credits. Hyundai appreciates EPA's continued inclusion of off-cycle credits which incentivize the application of technologies that have been proven to reduce greenhouse gas emissions during real-world driving but not captured by the prescribed certification test cycles. Following are our comments on the specific changes to the program proposed by EPA.

1. 15 gpm menu cap. EPA has proposed raising the off-cycle credit cap from 10 to 15 gpm for pre-defined off-cycle technologies. The credit cap was originally added by the agency 'because of the uncertainty inherent in using limited data and modeling as the basis of a single credit value for either cars or trucks'9. EPA acknowledges that new technologies have been added to the menu list (e.g. high efficiency alternator) without raising the cap, and some manufacturers are nearing or are already generating credits beyond the current credit cap. To properly adjust for additional technologies, EPA suggests raising the cap.

As new technologies are added to the menu, the cap will be further strained. Therefore, Hyundai supports the agency's proposal to raise the cap as technologies are added to the menu. Additional credit headroom will encourage continued off-cycle GHG improvements which will be realized as real-world emissions reductions. [EPA-HQ-OAR-2021-0208-0603-A1, pp. 8-9]

2. Approval timing for the alternative method. Speedy reviews are critical to automakers to ensure that investments in technologies are implemented in a timely manner. Decisions should be made prior to vehicle launch. Hyundai is one of several auto manufactures who have long-pending applications, some from 2020.

Both auto manufacturers and the agency should be held to timing requirements. Automakers should submit off-cycle applications in a timely manner. Similarly, the EPA should make applications available for public comment within 90 days of the manufacturers' submission and then establish a reasonable timeline to issue a decision on the applications (perhaps 60 days after the public comment period closes). This would result in a maximum review period of 150 days which would be more timely than the approval length for some current applications.

Finally, long application review and approval timelines for technologies using the alternative process result in multiple submissions to update GHG and Corporate Average Fuel Economy reports which is inefficient. Reducing these review times should resolve the need for multiple submissions. [EPA-HQ-OAR-2021-0208-0603-A1, p. 9]

3. Definition changes. EPA's GHG NPRM proposes modifying technology definitions for active transmission and active engine warm-up effective in the 2023 MY which is just a month after EPA is expected to publish their new rule. The definition changes would go into effect retroactively for auto manufacturers opting in to the higher credit cap for the off-cycle menu. The EPA proposed definition change states that 'systems that capture heat from the coolant circulating in the engine block [will no longer] qualify for the Active Engine and Active Transmission warm-up menu credits.'10

Both of these technologies are used in Hyundai vehicles to reduce real-world emissions. Hyundai does not agree with the agency's proposal to restrict credits for manufacturers choosing the higher credit cap. The menu credit cap should not be tied to whether a technology meets the proposed new definition or not. Use of the higher 15 g/mi cap should be permitted without prejudice in order to encourage the inclusion of more fuel saving technologies. Hyundai will separately provide the agency with data that supports this request.

Additionally, while the agency allows manufacturers to choose the alternative method of providing data to prove emissions reductions higher than the menu values, there is insufficient lead time to meet product timing. If the agency decides to proceed with this definition change, Hyundai requests that it not be implemented until 2027 MY to provide automakers lead time to make necessary design changes to meet the new definitions. [EPA-HQ-OAR-2021-0208-0603-A1, pp. 9-10]

4. Technologies on the menu must use menu pathway. The EPA GHG NPRM 'proposes to clarify that manufacturers claiming credits for a menu technology must use the menu pathway rather than claim credits through the public process or 5-cycle testing pathways'11. However, as automakers improve upon existing technologies they have been able to show that the actual benefits exceed those granted under the menu option. Therefore, Hyundai requests that EPA allow manufacturers to pursue approval of menu items using the alternative (public) method when those automakers have data which proves the benefits of their technology exceeds the amount provided by the menu.

We also request, for transparency, that EPA clarify and preferably quantify the statement 'new technology that represents an advancement compared to the technology represented by menu credits – that is, by providing significantly more emissions reductions than the menu credit technology – would be eligible for the other two pathways'. If EPA quantifies the word 'significant' this would serve as a guide for manufacturers to the appropriate approval path. [EPA-HQ-OAR-2021-0208-0603-A1, p.10]

5. Hyundai proposal to combine thermal control technologies under a single cap. EPA currently provides an individual cap for thermal control technologies. However, since these technologies impact the energy usage that powers the air conditioning system, it is logical to move these technologies under the same cap as those that control air conditioner efficiency. The subsequent combined cap should be raised in order to accommodate both sets of technologies. This combined cap would also provide more flexibility to maximize use of the menu cap by application of air conditioning, thermal, and / or both technologies under the larger cap. [EPA-HQ-OAR-2021-0208-0603-A1, p.10]

Commenter: ITB Group, Ltd. (ITB)

Off-Cycle Technologies Provide Real-World Benefit but are Limited by Credit Caps. The basis for EPA GHG and NHTSA CAFE measurements are repeatable vehicle two-cycle testing. Such testing does not include several "off-cycle" driving variables like thermal effects, electrical efficiency, aerodynamics, and acceleration rates. These variables have a significant effect on real-world fuel consumption and GHG emissions. Off-cycle and A/C efficiency technologies provide important reductions in energy consumption which are not measured through two-cycle testing. Automotive suppliers, vehicle manufacturers, and third parties perform testing to quantify real-world off-cycle benefits. For example, the US Department of Energy's National Renewable Energy Laboratory (NREL) has developed models to calculate real-world impact for different vehicle designs which take into account real-world trip time, duration, and ambient temperature across the United States.

ITB supports increasing technology credit cap(s). If the caps are set at a restrictive level, as they are today, then it may be quite costly to demonstrate that they should be raised in the course of individual technology credit approval submissions. The ITB Group has made an estimate of the credit level possible for a holistic off-cycle and A/C efficiency cap. The latest EPA trends report (2020) shows a 74 gCO2/mile national fleet difference between average light vehicle two-cycle emissions (282 gCO2/mile) and adjusted real-world estimate (356 gCO2/mile) for MY2019. If we assume that 9.5% (27 gCO2/mile) of the average two-cycle emissions is attributed to exogenous variables like load, grade, wind, rain/snow, tire pressure, etc., that leaves on average 47g of real-world CO2 emissions due to off-cycle (A/C, thermal, electrical, powertrain and other) variables. This gap is due to off-cycle effects resulting from variation in acceleration, thermal, aerodynamic, and electrical losses. Current and future off-cycle technologies, including autonomous and predictive driving, are expected to provide benefits not contemplated in the current 10 gCO2/mile cap. Therefore, the current 10 g/mile fleet level cap is low and should be raised. The EPA proposal of a 15 g/mile off-cycle credit cap is reasonable today, but is conservative compared to the 47g real-world vs. 2-cycle gap and may need future adjustment as new technologies are developed.

It is important to encourage new technology development and to do so properly, the technology credit programs should anticipate such new credits. One way to encourage new developments is to set caps in anticipation that technologies will address additional sources of energy losses, like autonomous and predictive driving technologies. Preserving credits will incentivize further development of rapid warm-up, heat retention, passenger comfort, and automated driving technologies.

One concern of the agencies and some third parties is potential technology interaction effects. Rather than set restrictive caps due to this concern, ITB recommends incorporating technology interaction effects into approved credit levels. For example, Section 6.5 of the EU Eco-innovation guidelines require the assessment of potential interaction effects and incorporating this into the technology credit level formula to avoid double counting of benefits where technologies may address the same losses. We recommend flexibility in using vehicle, component, and simulation technologies to calculate technology credit levels, including interaction effects. An alternative ITB recommends is to set a holistic cap reflecting the potential that technologies have to improve real-world fuel consumption and emissions. [EPA-HQ-OAR-2021-0208-0222-A1, p. 2]

Conditional Support for Changing Technology Menu Definitions. The EPA has proposed changing selected off-cycle menu technology definitions. In principle, ITB agrees that menu definitions should be supported by representative data. It is important that the off-cycle menu credits represent accurate estimates of real-world fuel consumption and GHG emissions benefits which cannot be measured in 2-cycle testing. The menu definitions should correspond to the technology(s) tested and emissions reductions associated with verifiable testing and modeling.

The difficulty is that if menu definition changes take effect in 2023, automakers have little to no time to respond. Automakers have developed their compliance plans based on previous definitions. Furthermore, there is no time to start a complete reevaluation of existing technologies which currently meet the definitions, particularly engine and transmission warm-up technologies. In a worst-case scenario, automakers may even remove fuel savings technologies that no longer receive credits.

The EPA proposes changing the definitions which may result in commercialized technologies which may have real-world benefits no longer receiving off-cycle credits. For example, passive cabin ventilation has been shown to provide value, but less than the current menu credit (refer to NREL Presentation 17TMSS-0056). Likewise, active engine and transmission warm-up need not use exhaust waste heat to be effective as the EPA concluded in 2012. Active warm-up can involve controlling coolant flow to change component cooling and warming timing This may include not overcooling with zero coolant flow for rapid engine and transmission warm-up. Revised definitions for effective technologies must be based on evidence of their effectiveness, not prescriptive definitions of exhaust waste heat or secondary coolant loop configurations.

In conjunction with the proposed definition changes, the EPA should consider the real-world benefit of the technologies being “stranded”, or no longer applicable, and should add new menu credit(s) at a level based on the verifiable real-world benefit of the developed and commercialized technologies. Technologies that have been developed and applied based on the original definitions should have a place on the menu commensurate with the verifiable real-world benefit the technology provides.

ITB is aware of several commercialized technology developments with real-world benefits that are not yet credited by the EPA and NHTSA. New technologies under development utilize otherwise wasted thermal energy, moderate vehicle acceleration, and allow longer engine-off periods in real-world driving, among other potential benefits. The EPA should take action on outstanding applications of technologies with verifiable real-world benefits and accelerate their approval, or rejection, and possibly adding them to the off-cycle technology menu.

The EPA should also take this opportunity to add new off-cycle menu technology definitions for items with multiple substantially similar off-cycle credit approvals. For example, active climate control seats have been approved by the EPA for two manufacturers with pending approval for a third manufacturer. Another example is high-efficiency alternators which have been received off-cycle credit approvals. [EPA-HQ-OAR-2021-0208-0222-A1, p. 3-4]

Improvements to the Off-cycle and A/C Efficiency Credit Programs. The current off-cycle and A/C efficiency program has some limitations which form the basis for making improvements. In general, there are two types of opportunities. First, reducing compliance and approval costs will reduce unnecessary burdens without affecting program effectiveness. Second, streamlining the credit approval processes will make approval faster and timing more certain, therefore increasing the rate of development and implementation of cost-effective fuel-saving and emissions-reducing technologies. [EPA-HQ-OAR-2021-0208-0222-A1, p. 4]

ITB Supports Adding Technologies to the Off-cycle Credit Menus. The A/C and off-cycle menu programs are widely used due to the ease and certainty of applying for prevalidated technology credit levels. Menu credits must be based upon quantification of a technology's benefits which can be based on formulas to adjust the benefits for different vehicle applications depending on the relevant variables. Ultimately, menu credits and benefit formulas may be just as effective as multiple individual vehicle tests by manufacturers, but at a much lower cost. Numerous examples of existing technology credit approvals in both the United States and Europe demonstrate that formulas can be developed to consider the main effects of a technology and its potential interactions with other technologies. As technologies are developed and proven, and sufficient evidence is available, they should be added to credit menus.

EPA should consider adding technologies to the off-cycle menu that NHTSA has deemed fuel saving. The NHTSA NPRM lists electric power steering (EPS), improved accessory devices (IACC), and secondary axle disconnect (SAX). NHTSA points out that there is a large opportunity to incorporate IACC for GHG reduction benefits in future model years. As shown in the NHTSA table below, the fuel savings, and emissions reduction impact for these three technologies are high. [EPA-HQ-OAR-2021-0208-0222-A1, p. 4-5] [Table can be found on p. 5 of Docket number EPA-HQ-OAR-2021-0208-0222-A1]

Additionally, Certain technologies are approved for the European Eco-innovation program and have been extensively evaluated by suppliers, automakers and regulators with confirmation of the technology benefit by the EU Joint Research Commission (JRC). The approved Eco-innovation technologies include the following items, which could be added to the agencies' off-cycle technology menu list. We note that adjustments in the benefit level formulas may be necessary to reflect different vehicle size and driving patterns in the USA. There may be other proven eco-innovation technologies not listed below.

Approved European Eco-Innovations Which Could be Added to US Off-Cycle Menu

- Coasting (Porsche / BMW)
- Encapsulation (Daimler)
- Enthalpy Storage (Mahle Behr)
- Adaptive SOC (Bosch)

Another example of an off-cycle technology that should be added to the menu list is active climate control seats which are approved by the EPA for General Motors, Hyundai, and Kia. Stellantis (FCA) also has a substantially similar pending request for approval of active climate control seats. An important factor to consider in determining if a menu credit is warranted is its commercialization status. Active climate-controlled seat technology is in production for several auto manufacturers and other manufacturers should receive the same credit benefits to level the playing field.

ITB Supports Credit Approval Process Streamlining. The ITB Group agrees with NHTSA as outlined in its 2024-2026 NPRM (docket: NHTSA-2021-0053) that the Off-cycle credit approval process can be improved. NHTSA proposes setting deadlines for OEM submissions, and ITB suggests that there should also be deadlines for the agencies (EPA/NHTSA) to respond to off-cycle credit request submissions for the off-menu approval pathways. ITB also recommends the development of a formal process for adding technologies to the menus and adjusting menu credits when necessary.

Develop a process for adding technologies to the menu lists. ITB supports the creation of a more formalized process to add technologies to the off-cycle credit menu. An off-cycle or A/C credit menu approval process would allow items to be added to the menu when sufficient data is available. Although two technologies were added to the menu in the previous “SAFE” rule, more technologies could be added to the menu more rapidly. When technologies are added to the menu lists, industry compliance costs are decreased and national fuel consumption and exhaust emissions are reduced.

In the current state, where it is not easy to add technologies to the menu, new developments are handicapped and require significantly higher costs for initial and subsequent approvals. We believe the regulations should encourage new technology developments when sufficient data is available to create a menu credit. It should not be strictly necessary to have multiple lengthy OEM off-cycle credit approval cycles to add a menu credit. Therefore, the agencies should develop a process that allows automakers to apply for adding technologies to the menu lists and which should include public review of such submissions. Creating a process for obtaining menu credit approval will reinforce and create incentives for the development of new energy-saving technologies.

We are certain new autonomous and energy conservation technologies will be developed and existing technologies refined. In the future emissions reductions from off-cycle technologies and A/C efficiency technologies could be credited when used on BEVs, PHEVs, and FCEVs. Such a pathway will become highly relevant when EV emissions account for upstream CO2 emissions, not just the 0 grams/mile tailpipe emissions. Certain off-cycle and A/C efficiency, technologies, particularly cabin heating technologies help reduce the amount of electric energy used to power a vehicle. Consequently, technologies that reduce EV energy consumption should be recognized when the 0 g/mi electric drive incentive is potentially eliminated after 2026. ITB recommends that a program be developed by the agencies to consider developing a set of EV and autonomous technology off-cycle menu credits in preparation for future rule-making.

Establish an off-cycle menu credit adjustment process. Additionally, the agencies should consider adjusting menu credit values either up or down if new vehicle or component testing becomes available. For example, an NREL study2 raises questions about the efficacy level of current technology used for active and passive cabin ventilation credits. Establishing a credit adjustment process would allow benefit levels or formulas to be adjusted when new studies are performed or when technology interaction effects are identified. [EPA-HQ-OAR-2021-0208-0222-A1, p. 5-6]

Summary of Recommendations and Conclusions. ITB expresses strong support for continuous improvement in vehicle fuel efficiency and CO2 emissions. One way of reducing real-world fuel consumption and CO2 emissions are off-cycle technologies. Technology credit flexibilities give automakers credits for applying off-cycle efficiency measures. These technologies provide real-world benefits in an economical way, therefore allowing the automakers to reduce fuel consumption and emissions at the lowest cost. The bottom line is our support for maximum United States environmental protection and fuel security at the lowest industry cost. [EPA-HQ-OAR-2021-0208-0222-A1, p. 7]

Commenter: Jaguar Land Rover North America, LLC (JLRNA)

Off-Cycle Credits. JLR appreciates the EPA's recognition of the importance of off-cycle technologies and that increasing the off-cycle cap will lead to reduced GhG emissions. To increase innovation across all off-cycle technology areas the EPA should also increase the Thermal Controls cap by the same proportion (from 3.0 g/mi for Passenger Cars and 4.3 g/mi for Light Trucks to 4.5 g/mi for Passengers Cars and 6.5 g/mi for Light Trucks).

As previously stated, JLR was one of the biggest claimants of off-cycle technology credits in EPA's 2020MY final report. The adoption of these technologies is based on their reduction of real-world emissions and was a significant investment for a niche manufacturer such as JLR. The retroactive action of discounting of MY2021 and MY2022 credits, despite the relaxed stringency of the SAFE standards in those model years will only unnecessarily burden manufacturers who have already made engineering and supply-chain investments to maximize their use. JLR have been fitting and claiming for these technologies based on the definition provided by the government agencies and so any retroactive changes would be unfair.

JLR understands the EPA's proposal to change the requirements around Passive Cabin Ventilation and Active Transmission/Engine Warm up but would like to request that the menu is expanded to include technologies which do not meet the new definition, but do meet the old definition, with appropriate credit values assigned. This will help to reduce the complexity of needing to showcase the impact via 5-cycle testing and other methods and reduce our cost burden on fitting technologies that will continue to benefit the real-world CO2 of our vehicles.

In the case of Passive Cabin Ventilation (PCV) Jaguar Land Rover proposes the following, based on the NREL study referenced by the EPA in coming up with the original and new definition:

- For vehicles which meet the new definition of passive cabin ventilation (with windows/sunroof open) can claim the 1.7 g/mi or 2.3 g/mi for Passengers Cars or Light Trucks based off the shown 5.7 °C.

- For vehicles which just have vents open, assume the benefit of this is the difference between sunroof only (2 °C) and the combination of sunroof and vents (5.7 °C) to give a benefit of 3.7 °C.

• Therefore, for vehicles that have just vents open, allow manufacturers to claim a proportion of the 1.7 g/mi or 2.3 g/mi, based off the reduction in temperature being 3.7 °C instead of 5.7 °C, resulting in a reduction of either 1.1 g/mi for Passenger Cars or 1.5 g/mi for Light Trucks. [EPA-HQ-OAR-2021-0208-0269-A1, pp 5-6] The tables can be found on p.6 of Docket number [EPA-HQ-OAR-2021-0208-0269-A1].

For other off-cycle technology definition changes, where there is not a clear alternative value to achieve partial accreditation such as our proposal above for Passive Cabin Ventilation, Jaguar Land Rover proposes that the option for manufacturers to remain at the 10 g/mile (lower) cap with the original technology definitions up to and including 25MY. This is required as, for technologies which involve significant changes to the vehicle to meet the new definition such as active transmission warm up, there must be a longer lead time for manufacturers to adapt to this change in the regulation.

We also propose that, when the new definition of these technologies does take effect, that a menu item is added which will attribute fair, partial, credit values for technologies which meet the old but not the new definition. This would result in manufacturers being able to continue claiming for these established technologies via the menu based approach (reducing the need for costly and time consuming 5-cycle testing or other methods) but at a fair value. We welcome comments and discussion on what partial credit values should be set at for these technologies and will look to make recommendations in the future on this. [EPA-HQ-OAR-2021-0208-0269-A1, p.7]

We also suggest that the off-cycle credits proposal is amended to continue to allow manufacturers to claim for technologies which meet current regulation definitions, but at a more appropriate value. This allows manufacturers to continue claiming for technologies which we have previously invested in due to their real-world benefits, without the need for expensive and complex additional testing. [EPA-HQ-OAR-2021-0208-0269-A1, p.8]

Commenter: Lucid USA, Inc. (Lucid)

The increase in the cap on off-cycle credits allows extra flexibility for ICE vehicle manufacturers in return for measures that offer only questionable reductions in GHG emissions. Extra credits and multipliers for hybrid vehicles also reward the continued use of ICE technology and slow progress towards a zero-emission future. Each of these proposed flexibilities should be revisited and reduced in the final rule. [EPA-HQ-OAR-2021-0208-0528-A1, p. 5]

Commenter: Manufacturers of Emission Controls Association (MECA)

Off-Cycle Technologies. MECA supports EPA’s continuation and improvement of the off-cycle credit program with the higher credit cap in order to provide the benefit of verifiable, GHG emission reductions through all technological means to accelerate CO2 reduction from all new vehicles. MECA recognizes the benefit to real-world CO2 reductions via the off-cycle credit program as a policy to expand the available technologies that vehicle manufacturers can deploy to reduce the GHG contribution from transportation. A key factor in MECA’s support is that off-cycle credits, unlike other flexibilities, such as technology multipliers, are only awarded for the inclusion of additional technologies that have been evaluated and found to represent additional CO_2 reductions for vehicles under real world operation.

Expanding the off-cycle credit process to include EPA, NHTSA and the California Air Resources Board may be one consideration in the post-2026 rulemaking to allow for resource sharing among the agencies for reviewing data and evaluating innovative technology pathways for CO_2 reduction. MECA looks forward to working with EPA to investigate the potential of verifying the climate benefit of advanced technologies through more rigorous technology definitions and testing in future rule development. We support the EPA's thinking, for a future rulemaking, of bringing as much technology evaluation "on-cycle" and therefore, increasing the transparency of the program and ensuring verification and compliance of real-world emission reductions. [EPA-HQ-OAR-2021-0208-0261-A1, pp.3-4]

Commenter: Motor & Equipment Manufacturers Association (MEMA)

MEMA Supports the Off-Cycle Technologies Credit Program p MEMA continues to strongly support EPA expanding the off-cycle technology credit program by increasing the credit cap on credits received through the off-cycle menu. This cap increase is critical for encouraging greater technology innovation. MEMA supports EPA's proposed technology definition revisions but provides recommendations on the resulting "stranded" off-cycle technologies. MEMA looks forward to working with EPA on improving the air-conditioning (A/C) efficiency program in the post-2026 program. [EPA-HQ-OAR-2021-0208-0249-A1, p. 3]

MEMA Supports the Off-Cycle Technologies Credit Program. EPA's current program includes credits for technologies that reduce GHG emissions that are not captured on the EPA test cycle, including improvements to A/C systems that increase efficiency and reduce refrigerant leakage. EPA is proposing that these credit programs do not sunset and will remain part of the program through MY2026. EPA requests comment on the proposal to increase the pre-defined menu credit cap from 10 to 15 grams per mile (g/mi) beginning as early as MY2020. EPA is also proposing to modify some of the regulatory definitions that are used to determine whether a technology is eligible for the off-cycle menu credits. EPA is not proposing changes to the A/C credit program.15

MEMA appreciates that EPA includes the off-cycle technologies credit program and the A/C efficiency technology credit program in the proposal, alternative 1 and alternative 2 for MYs 2023 and beyond. The off-cycle technology credit program along with the A/C efficiency credit program are important as they provide credits for technologies that achieve "real-world reductions and do not represent a loss of overall emission benefits."16 These credit programs are not loopholes and do not distort the market but recognize technologies that are not measured accurately on the existing test-cycles. MEMA agrees with EPA that these technologies are "often more cost effective than other available technologies that reduce vehicle GHG emissions"17 and that without these credits, manufacturers would "have to apply costlier technologies to meet the standards."18 It is important that the program from MYs 2023-2026 allow a variety of regulatory tools to broaden compliance pathways for vehicle manufactures to manage their product mix.

MEMA Strongly Supports an Increase of the Off-Cycle Menu Credit Cap. MEMA strongly supports EPA expanding the off-cycle technology credit program by increasing the credit cap on credits received through the off-cycle menu from 10 g/mi to 15 g/mi. More than 95 percent of off-cycle technology credits are generated via the menu pathway, and, for many vehicle manufacturers, it is the sole pathway used to generate off-cycle credits. Accordingly, multiple vehicle manufacturers are approaching the 10 g/mile menu credit cap.19 Furthermore, in recent years, off-cycle technology credits have been rapidly growing due to the cost-effectiveness of these technologies. The increase in the cap is critical as once vehicle manufacturers meet the cap, there is no compliance benefit or incentive for vehicle manufactures to continue to invest in these GHG reducing technologies.

An expansion and continuation of the off-cycle credit program is critical in encouraging technologies that allow greater innovation which can include a cost-efficient range of technology options that ultimately lower compliance costs and increase consumer choice. These technologies will continue to promote “consumer choice, spur technology development, and minimize compliance costs, while achieving significant GHG and oil reductions.”20 Importantly, expansion of the off-cycle technology credit program will help maintain market certainty for these technologies that would otherwise not be used.

MEMA was disappointed that EPA did not propose adjustments to the thermal control sub-cap for off-cycle thermal control technologies. From compliance data, the sub-cap for off-cycle thermal control technologies is being exceeded by some vehicle manufacturers.21 We look forward to working with EPA on potential adjustments to this sub-cap as appropriate in the post-2026 program.

MEMA Conditionally Supports the Revised Technology Definitions. EPA is proposing that all vehicle manufacturers that want to accrue menu credits between 10 and 15 g/mi from MYs 2020–2022 will need to meet the new revised definitions for passive cabin ventilation, active transmission warm-up, and active engine warm-up.22 For MYs 2023 and later, the proposed revisions of the technology definitions would apply exclusively if earning credits. However, EPA is not requiring the revised definitions prior to MY2023 for vehicle manufacturers not opting into the 15 g/mi credit cap. EPA proposes this as a transition to the new definitions. EPA explains that raising the menu cap is only appropriate if the technology definitions are tightened.23

MEMA supports this transition to the new credit cap and the use of the new proposed technology definitions for active transmission warm-up, active engine warm-up and passive cabin ventilation. Furthermore, MEMA conditionally supports EPA’s proposed technology definitions. MEMA continues to strongly support that off-cycle menu credit values represent accurate estimates of real-world fuel consumption and GHG emissions reduction benefits. The menu definitions and credit values should correspond to the technologies tested and emissions reductions associated with verifiable testing and modeling.

However, MEMA does have concerns with the resulting “stranded” off-cycle technologies. The EPA proposes refining the definitions of certain technologies to provide credits only for the more specified technologies. However, the original and less specific technology definitions and the associated technologies still provide real-world GHG reductions. For example, passive cabin ventilation has been shown to provide value, but is less than the current menu credit.24 Similarly, active engine and transmission warm-up does not need to use exhaust waste heat to be effective as the EPA concluded in 2012. Active warm-up can involve controlling coolant flow to change component cooling and warming timing. This may include not overcooling with zero or minimal flow for rapid engine and transmission warm-up. Consequently, in conjunction with the proposed wording changes, we urge EPA to consider the real-world benefit of the technologies being "stranded" or no longer applicable.

MEMA Supports Adding Technologies to the Menu Including the New "Stranded" Technologies. MEMA supports EPA adding the original off-cycle technologies to the menu with a new credit(s) level based on the verifiable real-world benefit. These off-cycle technologies that meet the original definitions should continue to have a place in the off-cycle technology menu just at the more accurate benefit levels. Revised definitions for effective off-cycle technologies must be based on evidence of their effectiveness, not prescriptive definitions of exhaust waste heat or secondary coolant loop configurations. Eliminating credits completely for technologies that meet the original definitions eliminates significant flexibilities. MEMA conditionally supports the proposed technology revised definitions, but urges EPA to create new menu credits based on the original and now "stranded" off-cycle technologies.

MEMA supports EPA's decision to add high efficiency alternators to the off-cycle technology menu in the 2020 rulemaking to streamline the program.25 Along these same lines, MEMA urges EPA to add additional new off-cycle technologies to the menu, particularly the technologies with several off-cycle credit approvals via the petition process. For example, EPA approved active climate control seats for two separate vehicle manufacturers with pending approval for a third vehicle manufacturer.26 Furthermore, MEMA urges EPA to consider technologies that NHTSA has deemed fuel saving. The NHTSA NPRM lists electric power steering (EPS), improved accessory devices (IACC), and secondary axle disconnect (SAX). NHTSA points out that there is a large opportunity to incorporate IACC for GHG reduction benefits in future model years.27 In 14 out of the 15 technology categories, the improvements in fuel economy are one or two percentage points. (See NHTSA tables in the Appendix) As industry progresses toward stricter emissions standards, vehicle manufactures need more proven, less expensive, reliable off-cycle technology menu options and tools.

MEMA Supports Streamlining the Off-Cycle Program. MEMA continues to support a supplier-initiated application process for supplier off-cycle technologies to be eligible for a provisional off-cycle credits, as MEMA provided in our mid-term evaluation comments, as this expansion of the program is included in the California framework.28 Having an established supplier application process would enable new supplier technologies to enter the market faster and gain penetration more efficiently. A supplier process would lower investment risks for both the vehicle manufacturer and supplier while reducing the workload for the agency and vehicle manufacturers.29 MEMA looks forward to working with EPA to find ways to make the supplier-initiated process work.

MEMA has consistently supported and advocated for EPA to evaluate ways to improve the offcycle program allowing vehicle manufacturers to more effectively use the off-cycle technologies to meet the goals of the program. Accordingly, MEMA encourages EPA to continue to improve and streamline the off-cycle and A/C efficiency program and its process by collaborating with NHTSA and CARB.

MEMA Supports Off-Cycle Credit Program Evolution in the Post-2026 Program. EPA explains that it “may make changes to the test procedures for the GHG program in the future that could change the need for an off-cycle credits program.”30 MEMA supports EPA’s goal of increasing the range of testing, such as the 5-cycle test, to pull as much of the technology into the formal testing assessment as possible. Revising the testing procedures that would capture more emissions reductions could help reduce the onerous process of industry applying for these credits and EPA reviewing the data for the credits. However, it is important that EPA continue to keep methods in place that would allow recognition of certain technologies, such as solar panels and several other technologies, the emissions reductions of which would still not be captured on a 5-cycle (or a similar alternative testing).

Similarly, MEMA encourages EPA to explore how emissions reductions from off-cycle technologies and A/C efficiency technologies could be rewarded when used on BEVs, PHEVs, FCEVs, and other ZEVs. Many of these off-cycle and A/C efficiency technologies could help in reducing battery use and therefore lower the amount of electricity used to power the vehicle. Consequently, technologies that reduce the amount of battery charging needed (and, therefore, the electricity used to power the vehicle) should be recognized in MY2027 and beyond. [EPA-HQ-OAR-2021-0208-0249-A1, p. 6-9]

Commenter: New York State Department of Environmental Conservation

Likewise, increasing off-cycle credits from 10 grams/mile to 15 grams/mile will reduce the stringency and effectiveness of the proposed regulations. New York believes the current cap of 10 grams/mile is sufficient to reward manufacturer's technological innovation while maintaining stringency. [EPA-HQ-OAR-2021-0208-0238-A1, p.3]

Commenter: Nissan North America, Inc.

Air Conditioning (A/C) Leakage and Efficiency and Off-Cycle Credits. Nissan supports EPA’s proposal to increase the cap on menu-based credits from 10 g/mile to 15 g/mile. Nissan also supports NHTSA’s proposal to maintain the A/C efficiency credit program and to increase the cap on off-cycle menu credits in a manner equivalent to the changes proposed by EPA. Additionally, Nissan supports EPA’s stated position that the off-cycle credits and A/C credits do not sunset under the current program and are intended to remain a part of the program through model year 2026 and beyond. Nissan urges EPA to maintain this position and not implement any future regulatory action to sunset or phase out these credit provisions. As acknowledged by EPA in the Proposed GHG Rule, these credits are an important source of emissions reductions, which cannot be measured properly on 2-cycle testing. These credits represent concrete improvements in fuel consumption and GHG emissions that manufacturers have worked hard to achieve.

Reducing or removing the credits available for such improvements would be disruptive to product planning and would discourage further innovation. EPA and NHTSA should continue to recognize these real-world achievements and should allow continued use of these credits to further incentivize increasing efficient and advanced technologies through model year 2026 and beyond. [EPA-HQ-OAR-2021-0208-0529-A1, p. 8]

Nissan opposes EPA and NHTSA's proposal to update the menu technology definitions, with respect to Active Engine and Transmission warm-up menu credits and passive Cabin Ventilation menu credits. The proposed change would no longer allow systems that capture heat from the coolant circulating in the engine block prior to the opening of the thermostat to qualify for the Active Engine and Active Transmission warm-up menu credits. It would also require a separate alternative application process for seeking Cabin Ventilation credits for the open dash vent system. Making such modifications to meet the new proposed definition for these credits would require sufficient time to develop and implement the relevant technology. For example, making changes to the coolant flow paths in the cylinder head and block would likely require casting changes, full design review activity, and durability testing. These are long lead-time activities and would also drain critical resources needed for electrification efforts. Additionally, eliminating the availability of credits for these currently accepted technologies would also impact the stringency level for manufacturers that have already included such credits in their fleet development and compliance planning. Manufacturers need sufficient lead time in their planning process; the design process for model year 2023 vehicles began years ago and was based on an understanding of the current credit technology definitions. The agencies should consider appropriate lead time requirements in implementing such definition changes, which should not take effect until at least the next rulemaking cycle (model year 2027+).

If EPA chooses to adopt the menu technology definition update as proposed or at a later time, EPA should continue to allow reduced credit value for the technologies meeting the current definitions. The proposed approach would likely increase the number of alternative methodology applications by OEMs seeking partial credits for Active Engine and Transmission warm-up technology credits and Cabin Ventilation credits. Allowing partial credits on the menu for the technologies meeting the current definitions would streamline the application process. [EPA-HQ-OAR-2021-0208-0529-A1, p. 8-9]

Commenter: Rivian Automotive, LLC

Maintain Current Cap on Off-Cycle Credits. Rivian questions the need to expand the off-cycle credit program in a proposed regulation that aims to quickly cut emissions from the transportation sector and accelerate the pace of electrification in the light-duty vehicle fleet. First, some of the technologies and innovations rewarded—such as "stop-start" engine technology—can only apply to ICEs by definition. As the light-duty fleet electrifies, these credits will become valueless. In this context, raising the maximum credit cap is both counter-intuitive and unnecessary. More fundamentally, however, analysts have raised concerns about the environmental integrity of the off-cycle credit program. As ICCT has noted, one of the "most disconcerting findings" of its examination of off-cycle crediting is that the credited technologies "are still largely without validated real-world benefits."7 For this reason, among others, the

Union of Concerned Scientists opposed a provision in the “California Framework” to raise the off-cycle credit cap in a manner identical to that proposed by EPA.8 Evidence suggests that not only are the real-world benefits of many off-cycle technologies less significant than claimed by automakers but, since its inception, the provision has failed to ensure “additionality,” often creating windfalls by awarding credits to automakers for technologies that were already installed. Raising the cap on off-cycle credits is not necessary and doing so would lessen the environmental benefits of the proposed rule. [EPA-HQ-OAR-2021-0208-0274-A1, p. 4]

Commenter: Securing America’s Future Energy

Using Off-Cycle Credit to Promote Safety and Efficiency. In the 2012 Rule, EPA decided to categorically bar safety technologies from receiving credit under the off-cycle program.[58] EPA’s regulation at 40 C.F.R. § 86.1869–12 (‘CO2 credits for offcycle CO2–reducing technologies’) contains a limitation that restricts the eligibility of safety technologies for off-cycle credit:

Off-cycle credits may not be approved for crash-avoidance technologies, safety critical systems or systems affecting safety-critical functions, or technologies designed for the purpose of reducing the frequency of vehicle crashes. Off-cycle credits may not be earned for technologies installed on a motor vehicle to attain compliance with any vehicle safety standard or any regulation set forth in Title 49 of the Code of Federal Regulations.

This provision should be reversed whether EPA plans to use these off-cycle credits or not. New technology can both increase fuel economy and enhance safety benefits simultaneously. The rise of autonomous vehicle technology can lead to dramatic increases in vehicle safety while simultaneously driving fuel economy improvements. While these technologies are under development and the extent of their benefits is still emerging, test results offer the promise of substantially increased efficiency and improved safety through vehicle- and system-level improvements. Yet because these technologies are so new, there is neither sufficient deployment nor adequate understanding of the degree to which these innovations can improve vehicle efficiency and decrease emissions. SAFE estimates, based on independent fuel efficiency modeling, that an 18–25 percent system-wide fuel economy savings can be realized by using existing driver assist and connected vehicle technology, and that thousands of lives can be saved annually.[59]

Fortunately, the off-cycle credit program within the EPA’s regulations to limit greenhouse gas emissions from light-duty vehicles provides a mechanism that could be used to accelerate the real-world testing, and eventual incorporation, of these technologies into the fuel economy program—not only resolving the safety-fuel economy issue once and for all but, more importantly, saving thousands of additional lives while providing further reductions in fuel demand. EPA should allow automakers to earn compliance credits (for 3–5 years) as part of a research program to deploy autonomous and connected vehicle technology, collect data about the technology’s performance, and share the data with regulators so that they can together evaluate the effectiveness of this emerging technology. To the extent that the testing demonstrates improvement in efficiency, lower emissions and increased safety, regulators can use the data to support permanently accounting for such efficiencies in future compliance periods.

The auto industry should have multiple pathways available to meet EPA's emission standards, especially pathways that both save lives on our roads and reduce emissions. Allowing safety technologies to be eligible for credit does not mean the program will suffer from tradeoffs between safety and emissions (or fuel economy) as NHTSA has already demonstrated over the history of the SAFE program the ability to balance these priorities.

SAFE appreciates that although vehicle safety is not within the scope of the Clean Air Act, EPA does regulate emissions and the ability of the auto industry to cost effectively institute advanced technology with the bonus of saving lives. In short, connectivity, autonomy, and electrification are inexorably intertwined, and EPA should evaluate each of them, instead of looking at them piecemeal. Overlooking this opportunity is a lost opportunity to reduce emissions, support the auto sector, and preserve good jobs. EPA should reverse the limitation that restricts the eligibility of safety technologies for off-cycle credit. [EPA-HQ-OAR-2021-0208-0527-A1, p. 15-16]

Commenter: Stellantis

In MY2019, several OEMs were at or approaching the off-cycle cap.2 EPA's proposal to expand the cap will give OEMs certainty to invest in the additional technologies needed.

The EPA rule will take effect early next year, after the MY2023 has begun. EPA is proposing to redefine three technologies for MY2023 that would, at least initially, zero the benefit the agency previously acknowledged. Changing technology on vehicles to accommodate new definitions requires lead time to be implemented and therefore should be proposed during the next rulemaking cycle.

Additional Off-Cycle Technology Flexibilities Needed. Stellantis appreciates both EPA and NHTSA's recognition of the important role off-cycle technologies play in reducing real world CO_2 and fuel consumption and therefore the need to incentivize innovation and implementation of that technology with more flexibility. Expanding the current credit caps is helpful for OEMs (including Stellantis) that have invested in technology on vehicles today, but cannot acknowledge its benefits because of the current cap. Expanding the cap would also incentivize OEMs to innovate and implement new fuel saving technology. There are some process fixes that could further help manufacturers implement the needed technology.

Stellantis Supports a 15 g/mi Off-Cycle Menu Cap Without Linkage to Redefinition. Stellantis supports the agencies' move to modify the off-cycle predefined technology menu cap from 10 g/mile to 15 g/mile. This is an important step to incentivize the early adoption and continued application of GHG-reducing technology in Stellantis' fleet. The increased cap will improve the business case for adding fuel-saving technology to our vehicles from the preapproved menu. See Appendix B for more details supporting the cap being increased in MY2020 to 15 g/mi with existing, approved technologies. [Appendix B can be found at docket number EPA-HQ-OAR-2021-0208-0532-A1, p. 33-45]

This cap increase should not be coupled with the proposed MY2023 technology definition changes to the existing active engine and transmission warmup and passive cabin ventilation categories. MY2023 product designs are already finalized. Recall MY2023 can start as early as January 02, 2022 - just a few months after the close of the comment period for this proposed rule. This contradicts the agencies' typical 3-year lead time allowance for hardware changes. As EPA has noted, they do not believe any of the current passive cabin ventilation21 or active engine and transmission warm up systems22 meet these proposed re-definitions. A redesign of powertrain components (engine and transmission warmup) and HVAC systems (passive cabin ventilation) to accommodate the new definitions proposed is not possible in this MY2023-2026 time frame.

The agencies have recognized many times that the vehicle design process typically takes several years, which pushes implementation of newly defined technologies beyond the period of this proposed rule. Therefore, if the agencies have concern with their existing definitions, the time to implement new technology definitions would be in the next rulemaking cycle (i.e., MY2027+) allowing automakers to plan for and implement fleet wide technology changes.

Technology Redefinition Disregards Proven GHG Saving Technologies and Increases Stringency. The current off-cycle menu definitions for the three technologies that EPA and NHTSA are proposing to modify, recognize their reduced GHG emissions and fuel usage. The advanced engine warmup, advanced transmission warmup and passive cabin ventilation systems, as applied today, all lower GHG emissions in the fleet. These approved technologies and the GHG benefits they provide are threatened by the agencies' proposal to immediately revise technology definitions.

While the new definitions for engine and transmission warmup using exhaust heat, instead of coolant heat, may provide an even larger benefit, the current technologies have provided GHG benefit that were quantified in previous rulemakings. In addition, the agencies now propose to change passive cabin ventilation systems to match unrealistic laboratory test properties with holes cut into the floor and windows opened without regard to commercial feasibility (e.g., rain and snow intrusion, occupant security and theft concerns, etc.) See Appendix B for supporting data on each of these three technologies.

Stellantis met with EPA OTAQ staff regarding the design of our Passive Cabin Ventilation system and reviewed testing results that showed both convective flow with a computational fluid dynamics model and temperature change, without open windows or sunroof. This design and results were accepted by the agencies as meeting the definitions of the credit by providing both an inlet of fresh air through the outside vent via software activation of the vent door and an exit through the body exhausters. Now the agencies' position has shifted to requiring additional parameters of automatic window or sunroof activation. These new requirements should be only considered under a new active cabin ventilation method in the next rulemaking cycle.

The agencies' proposed technology redefinition for active engine warmup, transmission warmup, and passive cabin ventilation alter the stringency of this rulemaking by immediately disqualifying existing systems from taking credit in the MY2023. MY2023 begins in less than 4 months from the time these comments are being submitted. Redevelopment of these systems to meet new or modified definitions requires additional time to accomplish on the order of 3 years or more.

We instead look forward to working with the agencies to define what higher credit values should be for these new credit categories and new names for these advanced menu technologies. In addition, we have proven the technology under the existing definitions provide GHG benefits and therefore should retain credit.

Gaining Credit for New Technology Outside the Menu Cap is Difficult. The agency is proposing to remove menu credit for technologies that impact OEMs as soon as MY2023. Recovering this lost credit outside of the menu is infeasible since the alternative methodology off-cycle application submission process can take a year or longer with uncertain outcome. There are a large number of off-cycle industry applications awaiting action by agency staff. While some of this is certainly due to COVID-19 challenges, the overall lack of movement is concerning. OEMs have yet to be asked technical questions on many applications, and, when responses have been requested and supplied, it is unclear of what happens next.

One improvement that would certainly help would be to set up a system to make the alternative methodology application process more transparent. It would be helpful if EPA could report the nonconfidential status of all off-cycle alternative methodology applications on a quarterly basis to industry.

We propose that a notice of availability be published in the Federal Register for all off-cycle alternative methodology applications after 90 days if the agency has not yet completed the review of the application for completeness, and if applicable, notify the applicant of additional information being required. This review and communication back to the applicant is required to happen within 30 days of submission. Automatically publishing the application after 90 days (three times the length of the required review period) will allow the public comment period to begin, and will help this process function as intended.

Stellantis is willing to solicit industry to partner with EPA to help identify and implement process improvements to evaluate and decision applications more quickly, if deemed helpful to the agency. [EPA-HQ-OAR-2021-0208-0532-A1, pp. 15-18]

Off Cycle & Air Conditioning Efficiency Menus Should Fully Recognize GHG Technology. The agencies need to be flexible and innovative when adding technologies to predefined menus (that could have been approved via the alternative methodology), the cap needs to be adjusted for this new technology. Both the agencies and industry want to standardize this process as much as possible. Using a pre-defined menu versus duplicative alternative methodology applications saves everyone time and resources. Adding more and more technologies to a menu, without adjusting the cap serves no one and dis-incentivizes innovation. For example, EPA recently added High Efficiency Alternators to the predefined menu but did not adjust the cap, so therefore the proposed increase to 15 g/mi is an important step to addressing this necessity.

As the agencies review new applications for credit, some of these technologies should properly be applied to the off-cycle menu as electrical load reductions. Specifically, the efficient AC compressor clutch from Denso and brushless blower motors should be added to achieve an additional 0.6 g/mile in total as originally applied for by many OEMs in April 2020. Greater detail on this subject is covered in Appendix B. [EPA-HQ-OAR-2021-0208-0532-A1, p. 17]

Stellantis Supports the Menu Cap Increase to 15 g/mile for MY2020 Without Additional Restrictions. Stellantis agrees with the agencies' move to modify the off-cycle predefined technology menu cap from 10 g/mile to 15 g/mile. This is an important step to incentivize the early adoption and continued application of GHG reducing technology in the fleet. The increased cap will improve the business case of adding additional technology to our vehicles from the pre-approved menu.

Current cap levels are constraining off-cycle technology implementation and the agencies' actions have contributed to these limitations. Alternative methodology applications have so far been approved for high efficiency alternators, advanced AC compressors, and brushless blower motors. Although credits approved through this process are not supposed to be constrained under a menu cap, the agencies have done so, without the caps expanding which is very concerning. Therefore, Stellantis supports the proposed menu cap expansion as one way to address this discrepancy.

Accordingly, there should be an incremental cap increase for each new technology added to a credit menu (or constrained by the cap even if not placed on a menu) which we suggest consideration to be half the maximum credit value of the technology. For example, the advanced compressors have been approved for a credit value of 1.1 g/mi, and this suggested value would result in an increase in the indirect AC menu credit caps of 0.5 g/mi, bringing the fleet caps to 5.5 g/mi for passenger cars and 7.7 g/mi for light trucks. Because the high efficiency alternator credit is a scalable attribute based credit, it is suggested that the off-cycle credit menu cap be raised by 1.5 g/mi, equivalent to an VDA efficiency of 76.5%, bringing the new cap to 11.5 g/mi for example.

Using this structure would stay true to the spirit of the credit menus by allowing a conservative amount of credit to be claimed at the fleet level (roughly half of the per vehicle credit value with 100% fleet penetration) for the convenience of using the menu-based credits. The alternative methodology pathway would still exist for manufacturers wishing to demonstrate a higher credit value per vehicle or to utilize a higher credit value across an entire fleet should the fleet achieve the credit cap. This also creates a very simple and straight forward system for incrementally raising a credit cap in the future once new off-cycle credit technologies become common across industry.

However, it is easy to see how such a system could create additional burden on agency staff with administering such a program. OEMs could have submissions of unique combinations of technologies and credit values which would require agency monitoring of appropriate technology cap limits for each OEM. Therefore, we support simply raising the cap from 10 g/mi to 15 g/mi as a much more streamlined approach to greatly reduce the burden on the agency for administering this program, and allowing all menu technologies approved through the alternative methodology application process to utilize the capped 15 g/mi credit limit.

Stellantis believes that the agencies should move to increase the menu cap to 15 g/mile beginning in MY2020, without any additional requirements. This would allow those OEMs to recover some of the investment of the incremental benefit of the GHG reducing technologies that are deployed in higher volumes than is being allowed by the current cap. This would also recognize the alternative application technologies that were added to the menu without cap adjustments.

Lead-time Concerns with Proposed Re-definitions. In recognition of the agencies' acknowledgement of the CO2 saving off-cycle technologies, Stellantis has invested in all three of the technologies that are now proposed to be re-defined for MY2023 (and optionally for MY2020-2022). Knowing that MY2020-2022 product has already been sold, there is no chance to change or redesign these products retroactively to allow the usage of the additional flexibility of the cap space. Additionally, EPA has acknowledged that no active warm-up systems currently in production meet the new definitions. Therefore, this proposal by the agencies is of no practical use and needs to be changed (i.e., not tied to simultaneous definition changes) to allow the added 5 g/mi cap space. Tying the two requirements together does not recognize an OEM who has been proactive in bringing more CO2 savings than is currently allowed by the 10 g/mi fleet cap.

Accordingly, MY2023 product is already designed and about to launch later this CY (i.e. MY2023 starts January 02, 2022) a few months after this proposed rule completes the comment period, and therefore redesign of powertrain components (engine and transmission warmup) and HVAC systems (passive cabin ventilation) is not possible. If the agencies have concern with their existing definitions, the time to transition to these new ideas would be after this rulemaking period which is short and immediately impacted. Instead, any changes to definitions should be proposed during the next round of GHG/CAFE rulemaking when automakers can plan to develop fleet wide technology changes and the agencies can meet required lead time requirements for new regulations.

The Existing Credit Definitions Provide a GHG Benefit and Should Retain Credit. The existing technologies for active engine warmup, active transmission warmup and passive cabin ventilation all provide a GHG emissions benefit with the current definitions. Stellantis employs these technologies on select vehicles and uses good engineering judgement to evaluate these technologies for credit.

Stellantis runs vehicle-level tests in an 'A to B' format to evaluate whether the active warmup technologies are a benefit to the vehicle prior to applying for the credit. The test vehicle is driven in the 'A' configuration without the technology to establish a baseline emissions value in grams of CO2 per mile. The test vehicle is then driven in the 'B' configuration with emissions lowering technology and the GHG emissions are recorded in grams of CO2 per mile.

Emissions from the 'B' test are subtracted from the 'A' test and with a greater than zero result, the technology is considered a benefit. This alone is not enough to determine if the vehicle qualifies for the active warmup credit. Stellantis also monitors and records fluid temperatures during the test to ensure that heat is flowing in the direction expected.

Active Engine Warmup Vehicle Testing. The active engine warmup credit that Stellantis claims is supported by data showing that the warmup technology is working and that it lowers the vehicle GHG emissions below the baseline. Engine oil temperature rises more quickly with the technology than without it. Two examples of engine oil warmup are given in Figures 9 and 10.

Figure 9 shows the warmup improvement for a midsize SUV with a 4-cylinder engine. The engine oil temperature rises faster with the active engine warmup technology than without. The improvement begins early in the test cycle with temperature separation beginning minutes after key-on and reaches 7°C of temperature improvement midway through the test cycle before convergence towards the end of the test cycle. [Figure 9 can be found on p. 35 at docket number EPA-HQ-OAR-2021-0208-0532-A1]

Figure 10 shows a similar warmup improvement for a B-Segment Crossover vehicle equipped with a 4- cylinder engine of similar displacement but from a different engine design family. The active engine warmup technology again raises the engine oil temperature faster than in the baseline test condition. The improvement begins early in the test cycle and continues throughout much of the test until the traces eventually converge towards the end of the test cycle. [Figure 10 can be found on p. 36 at docket number EPA-HQ-OAR-2021-0208-0532-A1]

The agencies can be confident that the active engine warmup menu credits granted to Stellantis is underpinned with vehicle-level testing and positive test results showing the technology works.

Active Transmission Warmup Vehicle Testing. Similarly, the active transmission warmup menu credit that Stellantis claims is supported by data showing that the warmup technology is working and that it lowers the vehicle's GHG emissions below those of the baseline vehicle. In addition to lower GHG emissions, the transmission oil temperature is required to rise much more quickly than over the baseline. Stellantis provides three examples of the technology on its vehicles in Figures 11 through 13.

Figure 11 shows the active transmission warmup improvement for a minivan class vehicle. The transmission oil temperature rises early in the test and then separates from the baseline test condition achieving a 10°C temperature delta with GHG reducing technology, rather than without it. The temperature delta remains mostly constant relative to the baseline temperature trace. The technology benefit continues throughout the test.

Figure 12 shows an active transmission warmup improvement for a C-Segment Sport Utility Vehicle contented with a 6-speed transmission. The active transmission warmup improvement begins early in the vehicle test cycle with the warmup traces diverging until half way through the test when the transmission oil temperature is 15°C higher than the baseline condition. Trace separation begins earlier than in the case of the minivan and the separation is greater. [Figures 11 and 12 can be found on p. 37 at docket number EPA-HQ-OAR-2021-0208-0532-A1]

Lastly Figure 13 shows the case of an active transmission warmup improvement for a full size SUV with an 8-speed transmission. The active transmission warmup begins immediately with the transmission oil trace and remains nearly constant at 4°C until towards the end of the test when the improvement diverges again for additional benefit. [Figure 13 can be found on p. 38 at docket number EPA-HQ-OAR-2021-0208-0532-A1]

Variation in these test results comes from shift strategy, thermal mass conditions, and other factors. The temperature response seen in these test vehicles shows that the benefit of the active transmission warmup technology is significant, if somewhat variable, and is difficult to improve upon when using a different heat source.

Stellantis, as part of the good engineering judgment it exercises, ensures that transmission test results and lower GHG emissions support each request for the proper amount of active transmission warmup menu credit.

Passive Cabin Ventilation Testing. The agencies' passive cabin ventilation credit is based on 'proof of concept' testing performed by NREL and reported in 2008 in Vehicle Ancillary Load Reduction Project Close-Out Report. The test results show that '…natural-convection-induced flow can be effective with strategically located air inlets' but that their test method had some limitations in implementation, specifically, … 'implementation challenges for this technique include preventing moisture and contamination (such as exhaust products, dirt, and animals) from entering the vehicle.'

The agencies have drawn conclusions that the passive credit ventilation method must be changed based on the flawed conclusions of one test, performed on one vehicle, in uncontrolled environmental conditions. The testing that NREL performed was insightful and valuable from a directional perspective, that setting up the conditions in the vehicle to establish a natural convection cell is possible. Their testing did not conclude that it must be executed that way. The NREL test result of 5.7°C that is referenced in the proposed credit re-definition was achieved by cutting unrealistic holes in the floor of the Jeep test property. NREL understood that their vehicle modifications are not possible on a production vehicle, of which they comment on in the report.

Stellantis' current passive cabin ventilation system sets up the convection cell in the vehicle using the HVAC air inlet door parked in fresh mode and the exhausters in the rear of the vehicle. [EPA-HQ-OAR-2021-0208-0532-A1, pp. 33-39; Passive Cabin Ventilation system figure can be found at docket number EPA-HQ-OAR-2021-0208-0532-A1, p. 39.]

Body leakage from low in the cabin coupled with airflow through the air inlet door stimulates the creation of the convection cell such that a breath temperature difference of 3.4°C is possible in a minivan as shown in Figure 14. [EPA-HQ-OAR-2021-0208-0532-A1, p. 39] [Figure 14 can be found at docket number EPA-HQ-OAR-2021-0208-0532-A1, p. 40]

Similar testing showed that the system is capable of 3.1°C in a large sedan. Test variables were controlled by evaluating the systems in a climate conditioned test cell with simulated solar load to improve upon the test condition that NREL experienced.

In addition, Stellantis met with EPA OTAQ staff in 2016 regarding the design of our PCV system and reviewed testing results that showed both convection flow and meaningful temperature change, without open windows or sunroof. This design and results were accepted by EPA staff as meeting the definitions of the credit by providing both an inlet of fresh air through the outside vent via software activation and a ventilation exit through the body exhausters. Now the agencies' conclusions seemed to have shifted to wanting additional parameters which should be only considered under a new active cabin ventilation method.

Redefining this credit to become more stringent does not recognize that this technology works as intended and provides GHG benefits as designed today. Redeveloping the technology to meet the new definition would require opening windows and the sunroof to achieve greater ventilation. The difficulty with this approach is that it is not reliably possible to secure the cabin against the elements, against intrusion and vermin. Stellantis believes that the agencies should recognize that existing technology and credit definitions meet the needs of industry, customers and its regulators and qualify for the credit amounts intended.

The agencies' proposed re-definitions should instead be considered new types of warmup credits or active cabin ventilation credits that exceed the performance level of the current definitions. We look forward to working with the agencies to define what those higher credit values should be and also the new name for these advanced menu technologies.

Reaching the 15 g/mile Off-Cycle Menu Credit Cap Will Be Difficult to Achieve. The credit values of the Engine Stop Start, Active Engine Warmup, Active Transmission Warmup and Passive Cabin Ventilation off-cycle menu technologies take up most, if not all, of the 10 g/mile cap value. Based on a theoretical 100% penetration of the fleet and a mix of 55% light-duty trucks and 45% passenger vehicles, these 4 credits total to 10.4 g/mile and are slightly over the existing menu cap.

These four core technologies are central to Stellantis' compliance plan and we see many constraints with backfilling any deterioration of those by using the remaining menu credit technologies. Of the remaining technologies that can be readily applied to existing vehicles, there is very limited additional opportunity as shown below, often at high cost. Other technologies that might provide greater benefit would require significant vehicle redesigns that would place their implementation outside the timeframe of this rulemaking.

Menu Technologies Have Limited Additional Opportunities:

Active Aerodynamics. The active aerodynamics additional contribution is limited by vehicle design, and many vehicle systems already have healthy penetrations of Active Grille Shutter ('AGS'). Ride Height and Active Air Dam technologies are packaged with the convenience features of high end accessory packages and penetration is limited based on customer preference.

High Efficiency Alternators. High efficiency alternators are tied to the volumes of the ICE fleet which is declining as electrification increases due to target stringency.

Solar Panels. The technology faces a steep challenge in the innovation phase as the business case currently is cost prohibitive on top of the costs of electrification. Stellantis does not foresee the wide application of solar panels before MY2026.

Waste Heat Recovery. Waste heat recovery systems that convert waste heat to electrical power are available in the marketplace but not applied to the US fleet as per EPA's 2020 Trends Report. Waste heat recovery systems that utilize engine coolant are available, although adoption remains low due to supplemental heat being required elsewhere in the vehicle. The lack of a credit for this technology and the high cost-benefit ratio make this technology unsuitable even for many ICE powertrains.

Solar Thermal Technologies. The opportunities in the Solar Thermal submenu are also limited as the glazing credit makes up the majority of the menu contribution with the remainder tied to customer preference such as solar paint or high end seat ventilation systems.

New Menu Technology Additions Lacking. New menu technology additions last happened with the SAFE 2 rule in 2020. An additional technology related to alternator efficiency was added to the menu without a corresponding increase in the menu cap. Stellantis asks the agencies to add technology to the cap and adjust the menu to avoid cap limitation.

The agencies have several Stellantis alternative methodology credit applications undergoing the review process for the last 18 months. As recommended in the submission, two of these technologies could be applied to the off-cycle menu as electrical load reductions based on the formula given in the 2017 Joint TSD. Specifically, the efficient AC compressor clutch from Denso and brushless blower motors could be added to the menu and achieve an additional 0.3 g/mile in for each technology. This topic will be addressed further below in regards to the AC efficiency menu.

Redefinition Impact on Compliance Plans. Redefining the three core technologies will negatively impact Stellantis compliance for several years, as we and other OEMs per the agencies' review, fail to meet the new credit definitions. The amount of credit loss depends on technology penetration and fleet mix. Assuming an OEM had 100% penetration of existing technologies (and adjusting for different percentage of fleet mix in terms of light-duty trucks and passenger cars), the loss of credit is alarming. Regardless of LDT/PC fleet mix, the average credit loss is around 50% of the newly expanded 15 g/mi cap value as shown in Table 3 below. If this is what agencies intended by the proposed definition changes, then the stringency impact on compliance must be recognized. [Table 3 can be found at docket number EPA-HQ-OAR-2021-0208-0532-A1, p. 42]

Stellantis Supports Combining the Solar Thermal and AC Efficiency Menus. As commented in previous rulemakings, the solar thermal menu credits are ideally combined with the technology on the AC efficiency menu. Solar thermal technologies that reduce AC system load are synergistic with the AC technologies that efficiently cool the cabin. Stellantis urges the agencies to revisit this menu combination alignment. [EPA-HQ-OAR-2021-0208-0532-A1, pp. 39-42]

Commenter: Tesla

EPA Should Eliminate, Not Expand, Off-Cycle Credits In the proposal, EPA increases the quantity of 'on menu' off-cycle credits available to manufacturers and potentially allows the additional credits to be use retroactively starting in MY 2020.182 When combined with other flexibilities, the credit expansion makes the proposed rule in these model years potentially weaker than the Trump Administration's SAFE rule from MY 2020-2022. See Figure 1. Expanding off-cycle crediting also creates asymmetry in the regulation favoring ICE vehicles, diverts R & D investment away from the best emissions reduction technology of electrification, and unnecessarily weakens the stringency of the standard. Tesla also notes that expanded use of 'off menu' off cycle credits will further reduce the standard's stringency.

First, the utilization and increase in off-cycle credit use creates a disparity in the type of vehicles that are rewarded for deploying efficiency technology. Originally created in 2010,183 the off-cycle menu credits consist almost entirely of technologies (i.e., Active Engine Warmup, Active Transmission Warmup, Engine Stop Start) applicable only for use on internal combustion vehicles.184 Subsequently, in its 2012 rules, EPA moved forward the timeline for generating these credits from a proposed MY 2017 to MY 2014.185 As a result, the off-cycle program has its origins in technologies over a decade old and has been rewarding manufacturers for deploying these technologies for more than seven model years. In combination, this means that ongoing off-cycle credits reduce stringency through rewards for many now commonly deployed efficiency technologies that provide, at best, negligible real-world emissions or technology advancement benefits.

Second, previous analysis has shown that manufacturers will increase reliance on off-cycle credits and divert investment and deployment away from the most efficient vehicle technologies.186 Extending and expanding these credit rewards old technology and, to the extent new technologies are deployed to generate off-cycle credits, focuses critical R & D budgets on tweaking legacy ICE platforms rather than directing these budgets to electrification and greater emissions reductions. As such, EPA's proposal, rather than confronting this built-in bias toward ICE legacy technology, enhances the pre-existing bias by increasing the off-cycle cap to 15 g/mile. Again, such perverse incentives should not be extended, much less increased. [EPA-HQ-OAR-2021-0208-0278-A1][pp.22-23]

Commenter: Toyota Motor North America, Inc. (Toyota)

Off-Cycle Credits – A Path to Real-World Benefits. Off-cycle technologies net immediate real-world emissions reductions and should be viewed no differently than emissions reductions achieved over the Federal Test Procedure. Toyota supports robust verification of off-cycle technology benefits and strongly encourages EPA to use a timely and streamlined process as suggested in past Toyota and AAI comments. We agree with AAI's current comments on the broader off-cycle technology program including but not limited to the approval process, credit values, and benefit limits.

Toyota also supports increasing the maximum credits earned under the technology menu from 10 g/mi to 15 g/mi. Please see the AAI comments for additional details. We understand the refined definitions for passive cabin ventilation, active engine warm-up, and active transmission warmup technologies are intended to better account for the real-world benefit of these technologies. The proposed changes affect program stringency because previously approved credits for these technologies that will no longer be available have already been incorporated into compliance plans. We request the revised definitions be effective starting with the 2025 model year at the earliest to provide adequate lead time for appropriate countermeasures and compliance plan adjustments.

Passive cabin ventilation, engine warm-up, and transmission warm-up technologies that meet the current definitions provide environmental benefit albeit less than under the proposed revised definitions. Once the new definitions become effective, existing passive cabin ventilation, engine warm-up, and transmission warm-up systems designed to meet the original definitions should still be granted some level of credit based on their real-world performance. [EPA-HQ-OAR-2021-0208-0531-A1, p. 11]

Commenter: Union of Concerned Scientists (UCS)

Off-cycle credits. The off-cycle credit program was introduced to capture reductions in greenhouse gas emissions that were not captured in the standard two-cycle test procedures. While this program has prompted some innovation, including active aerodynamic improvements and high efficiency alternators, real-world data on the benefits of many of these technologies continues to be scant, even as they become a larger and larger share of the purported reductions of the fleet.

Despite this lack of evidence, EPA is proposing to increase the amount of reliance on off-cycle credits for reductions from the rule by increasing the cap on technologies from the off-cycle menu. UCS strongly opposes the increase of this cap—if anything, the latest evidence indicates that EPA should be reining in the impacts of the off-cycle program, not expanding it.

Evidence of real-world improvement? In its design of the off-cycle program, and in particular the off-cycle menu, EPA cited uncertainty as a major factor in the design of the program.54 Despite some fleets approaching the limit of the off-cycle credit menu, indicating a widespread use of these off-cycle technologies, there has been no systematic study of the impacts of these technologies. What little additional data is available suggests that the program has likely been substantially overcrediting manufacturer improvements.

Researchers at the National Renewable Energy Laboratory (NREL) have published the most extensive look at a number of off-cycle technologies: active seat ventilation, both active and passive cabin ventilation, solar control glass, and solar reflective paint.55 The results of these studies are shown in Table 5, compared to EPA's off-cycle credit menu values. Because there is a discrepancy between values assumed by EPA and NREL for the greenhouse gas emissions associated with air conditioning usage, we have used NREL's observed percentage improvement for the technologies but applied them to EPA's baseline A/C greenhouse gas value, in order to provide an apples to apples comparison with the off-cycle menu credits, which were derived from EPA's assumed A/C values. [Table 5 can be located at docket number EPA-HQ-OAR-2021-0208-0277-A1, p. 29]

While the NREL data suggests that the menu credit may be conservative with respect to the benefit of active seat ventilation, the off-cycle menu has significantly overcredited both active and passive ventilation. The solar control technologies are comparable to the off-cycle credits awarded by the menu.56 While just 16 percent of the fleet received credit for adopting active seat ventilation in MY2019, 70 percent of the fleet received credit for passive cabin ventilation, and an additional 9 percent received credit for active cabin ventilation. This overestimate indicates that EPA has significantly overcredited manufacturers with respect to thermal control technologies.

EPA has also identified three technologies for which manufacturers have been receiving undue credit: passive cabin ventilation, active engine warm-up, and active transmission warm-up. In all three cases, manufacturers have been receiving credit for technologies that are less efficient than the technologies used to estimate the reduction in emissions.57

UCS strongly supports EPA revising the off-cycle menu definitions for these technologies, and we concur with EPA that any manufacturers seeking credit for technologies that do not meet this revised definition must do so through the public comment process outlined in 40 CFR § 86.1869-12(d). In fact, we recommend that the agencies make these revised definitions effective immediately to avoid further unwarranted credits for these inferior technologies. [EPA-HQ-OAR-2021-0208-0277-A1, pp.28-30]

The lack of justification for an increase in the off-cycle credit cap. Given the data to date that indicates manufacturers have received too much credit for off-cycle technologies, it is difficult to imagine why EPA would expand the program's use by increasing the off-cycle cap. In fact, if EPA were to fully adjust its program to eliminate these unwarranted credits, no manufacturer would be close to the 10 g/mi cap on menu technologies, with the vast majority of manufacturers below 7 g/mi with their MY2019 fleets (Figure 12)59 [Figure 12 can be located at docket number EPA-HQ-OAR-2021-0208-0277-A1, p. 32].

Not only would these revisions offset any potential justification for an increase in the menu cap, but it underlines the incredible amount of overcrediting in which EPA's data-light off-cycle menu has resulted. Since the off-cycle menu went into effect with MY2014, 103 million Mg of credits have been awarded—of those, 32.7 million Mg are not justifiable for the reasons stated above, or just over 30 percent. Unfortunately, this problem is getting worse over time, as manufacturers latch onto cheap-to-deploy credits like passive cabin ventilation which result in virtually no greenhouse gas benefits but are awarded significantly under the off-cycle menu (Figure 13) [Figure 13 can be located at docket number EPA-HQ-OAR-2021-0208-0277-A1, p. 33].

Eliminating the increase in credit cap should not be used to justify any reduction in the stringency of the proposal. In fact, modeling by Dan Meszler, an independent consultant, showed that benefits improve significantly when manufacturers must respond to the proposal with powertrain technologies that lead to real-world performance.60 Maintaining the 10 g/mi off-cycle cap while enforcing the preferred alternative increases the net present value of benefits through calendar year 2050 from $140 billion ($86 billion) at a 3 (7) percent discount rate to $170 billion ($110 billion).61 One of the critical reasons for this improvement is a reduction in per-vehicle price increase from $1,044 in MY2026 down to $867. [EPA-HQ-OAR-2021-0208-0277-A1, pp. 31-33]

Timely awarding of off-cycle credits. Credits for off-cycle technologies are awarded under both EPA's greenhouse gas program and NHTSA's CAFE program. In a parallel rulemaking covering much of the same timeframe as EPA's rule, NHTSA highlighted the lengthy delays in manufacturer requests for off-cycle credits.62 Not only do these delays diminish public access to information on manufacturer compliance, but they are indicative of an industry seeking to game the off-cycle credit system, including seeking retroactive off-cycle credits for vehicles sold long ago, credits which were not part of the manufacturer's initial product plans.

EPA has previously iterated that any credits awarded are required to be reported by the next credit reporting deadline and reiterated its stance that credits are generally required to be reported within four months after the end of a model year.63 It is therefore disconcerting that NHTSA has identified ongoing manufacturer reporting issues.

UCS concurs with NHTSA's concern about the effect this has on compliance and the credit market, as well as public oversight and recommends that EPA move forward with the changes to eligibility requirements for non-menu off-cycle technologies put forth by NHTSA in its proposal, adopting them beginning with MY2023. 64 Retroactively awarding credits for off-cycle technologies is a pure windfall for manufacturers and offers challenges for the agencies in their oversight of the off-cycle credit program. Manufacturers seeking approval of novel test procedures should be required to move forward with such requests well in advance of the model year in order to ensure adequate time for the assessment of such processes. Moreover, requiring timely filing for any credits granted under such programs maintains public awareness of manufacturer compliance, which strengthen the integrity of the program and the robustness of the credit trading market. [EPA-HQ-OAR-2021-0208-0277-A1, pp. 33-34]

54 "The fleetwide cap is being finalized because the default credit values are based on limited data, and also because EPA recognizes that some uncertainty is introduced when credits are provided based on a general assessment of off-cycle performance as opposed to testing on the individual vehicle models." (77 FR 62727)

56 Solar control glass is credited as a scalable technology under the off-cycle menu. However, our estimates of the average credit earned by manufacturers for this technology is similar to the single value assessed by NREL researchers

57 "This open dash vent technology [deployed by manufacturers] is not as effective as the combination of vents used by the NREL researchers to allow additional ambient temperature air to enter the cabin and also to reduce the restriction of heated air exiting the cabin" (86 FR

43764). “EPA expects that [the technologies deployed by manufacturers] may provide some benefit. But, as noted above since these system designs remove heat that is needed to warm-up the engine the Agency expects that these technologies will be less effective than those that capture and utilize exhaust waste heat” (86 FR 43765).

59 Values in Figure 8 are based on an imprecise reverse engineering process—EPA would be able to compare with the actual manufacturer-submitted data, to which UCS does not have access. The updated values reflect corrections for the NREL data, thermal control double-counting, and EPA’s revised definitions for active engine and transmission warm-up. While EPA is proposing the complete elimination of credit under the menu for these technologies, with which UCS concurs, for modeling purposes we have eliminated only half of these credits under the assumption that some share of those credits would be awarded credit under the public comment procedure. It is further worth noting that these averages include credits awarded under the alternative methodology process as well, which includes credits for high-efficiency alternators for which EPA claims require an increase in the menu cap (86 FR 43763).

60 To assess this, Mr. Meszler simply reduced the off-cycle cap in the EPA-CCEMS input files to 10 g/mi in all years. This prevents any adoption of credits above 10 g/mi and forces the additional stringency to be made up via improvements in powertrain or vehicle technologies.

61 There are two main reasons for this significant improvement: 1) off-cycle technology costs in the agencies model are significantly higher than the marginal cost of powertrain or vehicle technologies to comply at the same level, so applying with 2-cycle technology in lieu of off-cycle credits reduces the cost of compliance; 2) the agency’s model does not generate real-world benefits for off-cycle credits. Implicit in their modeling is that no off-cycle credits result in real-world fuel savings or emissions reductions—any modeled differences in off-cycle credit deployment result in significant costs with no benefits, drastically skewing the results.

Commenter: Volvo Car Corporation

Compliance Incentives, Flexibilities, Credits. Volvo Car supports the agency’s proposed modifications to the Compliance Incentives and Flexibilities (86 FR 43733). Specifically, extending the advanced technology vehicle multiplier and increasing the cap for off-cycle technologies supports electrification and the introduction of new energy efficient technologies. [EPA-HQ-OAR-2021-0208-0253-A1, p. 3]

To further support the shift towards electric vehicles, Volvo Car proposes that advanced heating, ventilation, and air-conditioning technologies for electric vehicles be added to the list of technologies that qualify for credits. This has a much greater relative impact on electric vehicles compared to vehicles with an internal combustion engine.

One example of this technology is the heat pump which has now been in use on electric vehicles for some time. There is limited time to perform research on this technology for the purpose of this proposed rule, but research can be conducted for future rulemakings. To support the immediate implementation in MY23 and later of these efficient technologies, Volvo Car proposes that EPA develop an interim temporary measure until an appropriate credit calculation is developed and included in the final regulatory text.

Volvo encourages the EPA to investigate the possibility of a temporary credit for heat pump technology as an addition to the list of predefined technologies. Alternatively, this rulemaking should make it clear that MY23 and later vehicles can be included retroactively once a final credit calculation has been included the regulation.

EPA Response

EPA is finalizing an increase in the off-cycle menu credit cap from 10 to 15 g/mile for MYs 2023-2026. EPA's response to comments regarding the increased credit cap and timing is provided in section II.B.3 of the preamble. EPA's response to comments regarding requiring manufacturers to meet the proposed revised definitions in order to access the additional menu credits is also provided in the preamble with additional discussion below.

EPA received a wide variety of comments on many aspects of the off-cycle credits program. EPA proposed and sought comment on only a narrow set of changes: increasing the menu cap and revising the menu definitions for passive cabin ventilation and active engine and transmission warmup technologies. Comments regarding other program elements are outside the scope of this rule but EPA may further consider commenter recommendations, as well as other potential program changes and approaches, as part of a future rulemaking.

Comment topics outside the scope of the current rulemaking include:

- Combining thermal control off-cycle technologies with credits for improving the efficiency of air conditioning systems and increasing their caps. (Alliance, Denso, Hyundai)
- Removing credit caps and instead incorporating technology interaction effects into credit levels (Gentherm, ITB)
- Potential off-cycle credits for autonomous vehicles (ACEEE, ITB Group, SAFE)
- Adding technologies to the off-cycle credits menu (Honda, Gentherm, ITB, MEMA, Stellantis)
- Changing the regulations to allow off-cycle credits for safety-related technologies (SAFE)
- Allowing additional off-cycle credits for EVs or disallowing off-cycle credits for these vehicles (ITB Group, Consumers Report, Volvo)
- Modifying menu credit levels for certain technologies (Gentherm, ITB, UCS)
- Regulatory changes to streamline the program (Honda, DENSO, MEMA, Nissan, Stellantis, Toyota)
- Providing a supplier pathway (AESI, DENSO, MEMA)

CBD et al. commented that EPA should not increase the menu cap, pointing to issues with the implementation of the off-cycle credits program outlined by NHTSA in their recent proposed rule and commenting that increasing the cap will add to the problems outlined by NHTSA. In response, the implementation issues NHTSA discusses in their proposal for the most part concern applications for credits under the "public process" credits pathway and not the credit menu pathway.[26] In the public process pathway, under existing regulations EPA must seek public comment before issuing a determination whether or not to approve the requested credits. This process can be lengthy if there are technical questions that must be resolved but ultimately may result in a more thorough review of a technology that would otherwise have been difficult if not impossible to predict from a generic menu description. EPA also notes that the updates to the menu definitions should generally help the implementation of the credits menu by clarifying the definitions that have previously been the source of delays because either the manufacturer felt that they didn't quite meet the menu description or EPA had to scrutinize whether the technological approaches used by manufacturers met the previous definitions.

CBD et al. recommends that EPA codify provisions that "prohibit, without exception, the submission of any application that has missed any of the applicable deadlines, a change clearly needed to avoid otherwise inevitable additional processing time, expense and delay in determining and reporting compliance results." Other commenters also raised concerns about delays in EPA's consideration and decisions regarding public process applications. EPA did not propose or seek comment on, and therefore is not finalizing any changes to deadlines for the off-cycle credits program. EPA continues to work with manufacturers to clear the backlog of credit applications. In late 2020, EPA notified manufacturers that starting May 1, 2021, EPA would no longer consider any applications for retroactive credits under the public process pathway.

Several automakers and automotive suppliers commented that off-cycle credits represent real-world CO_2 reductions and some of these commenters also commented that manufacturers should be allowed to continue to claim the menu credits without meeting the revised definitions. For example, Toyota commented "off-cycle technologies net immediate real-world emissions reductions and should be viewed no differently than emissions reductions achieved over the Federal Test Procedure." Toyota also commented "we request the revised definitions be effective starting with the 2025 model year at the earliest to provide adequate lead time for appropriate countermeasures and compliance plan adjustments." Similarly, Nissan commented "these credits represent concrete improvements in fuel consumption and GHG emissions" and also commented "Nissan opposes EPA and NHTSA's proposal to update the menu technology definitions, with respect to Active Engine and Transmission warm-up menu credits and passive Cabin Ventilation menu credits" citing lead time concerns with the changes.

Commenters argued that lead time is needed for manufacturers to change their system to meet the new definitions. For example, Stellantis commented "The agencies have recognized many times that the vehicle design process typically takes several years, which pushes implementation of newly defined technologies beyond the period of this proposed rule. Therefore, if the agencies have concern with their existing definitions, the time to implement new technology definitions

[26] 86 FR 49836, September 3, 2021.

would be in the next rulemaking cycle (i.e., MY2027+) allowing automakers to plan for and implement fleet wide technology changes."

As discussed in the preamble section II.B.3, EPA believes correcting the definitions in a timely manner is important to maintaining the integrity of the off-cycle program. EPA believes it would be a fundamental inconsistency in the program to state that the credits represent real-world reductions and also allow a level of credits that is known not to represent real world reductions. EPA does not believe such an approach is reasonable or appropriate. Off-cycle credits are a voluntary way for manufacturers to generate credits but the use of those credits offsets two cycle emissions reductions that would otherwise be required, and as such EPA believes it is critical for the off-cycle program to provide real world emissions reductions. Allowing manufacturer to continue to use the original definitions out into the future despite the known issues with the definitions is inconsistent with the intent of the off-cycle program. In response to lead time concerns, EPA believes the flexibilities provided in the final rule are sufficient to address lead time concerns without continuing to provide off-cycle credits known to not reflect emissions reductions consistent with the menu credit level provided. In addition, manufacturers don't necessarily need to redesign their systems to generate off-cycle credits for configurations not meeting the revised definitions. Manufacturers would, however, need to pursue those emission reductions through the other program pathways which require the manufacturers to demonstrate the emissions reductions of the systems.

Several manufacturers recommended that some lower level of credits should be provided to technologies meeting the original definitions. Most commenters did not provide recommendations on appropriate credit levels or data on which to base the credit levels. JLR suggested a methodology for a revised credit level for passive cabin ventilation based on an NREL study. JLR commented that EPA should use an estimate based on a sunroof open with and without the cabin vents open. EPA does not believe the suggested approach is reasonable because no data is presented on the current technological approach used by most manufacturers of opening the vents without the sunroof or windows open. Most heat is escaping through the sunroof and opening the vents helps facilitate that process by allowing an additional avenue for air to enter the cabin. This methodology provides no insight on the benefit of only opening the vents. Stellantis commented that their designs "provide a GHG benefit" and provides information on their current systems, discussed in more detail below. Stellantis did not attempt to correlate the operation of their systems to the menu credit levels for each technology and also did not quantify a different corresponding credit value for their systems. EPA again notes that manufacturers can pursue credits for their systems through the other pathways available in the off-cycle program if they are able to provide data to support their requested credit levels consistent with the regulations. If EPA receives sufficient information in the future for other technological approaches, it may consider adding new menu credits for those technologies through rulemaking.

ITB commented that passive cabin ventilation has been shown to provide value, but less than the current menu credit, referring to an NREL presentation (NREL Presentation 17TMSS-0056). The NREL presentation estimates a benefit for passive cabin ventilation of 0.2 g/mile, or roughly 10 percent of the menu credit level for passive cabin ventilation. EPA would need to investigate further how this credit estimate was derived and believes it would be appropriate to consider making any further revisions for menu credits through a notice and comment rulemaking to allow stakeholders an opportunity to provide input. However, EPA believes the NREL presentation does illustrate the differences between the menu credit for passive cabin ventilation and the approaches manufacturers have generally used to date to claim those credits and further supports EPA's basis for updating its passive cabin ventilation menu definition. In addition, the presentation cited by ITB is also cited by other commenters who note that it draws into question the menu credit level for active cabin ventilation. Again, EPA would need to consider the study further and propose any necessary changes to the menu credit for active cabin ventilation through additional rulemaking.

EPA also received comments that EPA should consider the real-world benefit of technologies "stranded" by the definition changes. ITB commented, for example, that technologies have been developed and applied based on the original definitions and they should have a place on the menu commensurate with the verifiable real-world benefit the technology provides. Similarly, Stellantis commented that technologies meeting the original definitions all lower GHG emissions in the fleet and those GHG benefits they provide are threatened by the agencies' proposal to immediately revise technology definitions. However, commenters did not provide data demonstrating the real-world emissions reductions of these technologies. Manufacturers wishing to claim credits for non-menu technological approaches may develop data and apply for credits for these technological approaches through the other off-cycle credits pathways.

Also in response to comments regarding technologies being "stranded", manufacturers have already generated credits over multiple model years for these technologies, as the menu credits were first available starting in MY 2014, and so manufacturers have generally had a significant opportunity to claim credits under the original definitions, and will continue to do so through MY 2022. Also, often manufacturers have made only minor or no adjustments to system already in place in order to claim the menu credits, representing only minimal resource investments. For example, for passive cabin ventilation, manufacturers generally only made software changes to ensure that vents were opened when the vehicle was turned off in warm weather. In fact, Stellantis, during the discussions with EPA about their passive cabin ventilation technology indicated that the approach they were seeking credit for was already generally used across their products before the GHG credit was even available but not for any heat removal benefit but instead for control of objectionable odors from the air conditioning evaporator behind the dashboard when the car is parked in hot weather. EPA confirmed with NREL that this technology was already present in the baseline vehicle study they performed before the modifications were made in support of the credit value and therefore was not believed by NREL to be an improvement from vehicles already in production at the time of the study. It was not EPA's intent that the menu credits would be available indefinitely without change. In fact, EPA continually has sought to ensure that credits represent real world reductions within the program structure. The regulations established in the 2012 rule specify that EPA may request data, engineering analyses, or other information that supports a manufacturer's use of the menu credits (see 40 CFR 86.1869-12(b). Manufacturers were encouraged and expected to review the technical materials in the TSD used to support and justify the technology approach and credit size when they were unclear or had insufficient understanding of the regulation description and goals when considering whether their technology approach satisfied the program intent.

Stellantis commented also that “the current technologies have provided GHG benefit that were quantified in previous rulemakings.” In response, when EPA estimated menu credits for these technologies as part of the 2012 rule, the estimates were based on technological approaches consistent with the revised definitions rather than the original definitions.[27] Therefore, EPA does not agree with Stellantis’ characterization. The intent of the 2012 rule definitions was clear and we expected that the technologies would be implemented as specified but in practice there has been substantial confusion and the agency realized in discussions with manufacturers that their interpretation is not meeting the program goals. Therefore, we are revising the definitions to make clear the types of systems that are deserving of the actual menu credit value. In the 2012 rule proposal, EPA clearly indicated that in the case of active engine and transmission warm-up, the technology must source the waste heat from areas not historically considered a viable source of heat in order for the technology to achieve the substantial credit value. The only source of waste heat would typically only be available in the exhaust leaving the engine and essentially released into the atmosphere as unused heat energy. In response to comments and as a flexibility in the 2012 final rule, EPA finalized the ability to use a liquid coolant based loop instead of just the exhaust based heat exchanger approach described in the proposal, however it was premised on the idea that it would harness only unused waste heat and not take the heat already part of the existing internal coolant system design used to warmup up the engine, a fundamental design aspect of every liquid cooled internal combustion engine. The existing internal engine cooling design and the natural transfer of heat to the coolant and oil is inherent and fundamental to all engine designs and the agency believes already fully captured over the 2-cycle tests in addition to not being considered a technology that results in additional off-cycle benefits. Further, using the existing internal engine cooling system without attempting to harness additional lost heat energy does not accelerate the warm-up of the engine oil or the transmission oil from what was already occurring. Accelerating the engine and the transmission warm-up results in the ability to operate the engine at a more efficient fuel air ratio and/or allows the transmission to use more gear and torque convertor options sooner, particularly in colder conditions, is fundamental to this credit size.

Stellantis further asserted that “we have proven the technology under the existing definitions provide GHG benefits and therefore should retain credit. EPA has reviewed the analysis submitted by Stellantis and found that with respect to their previous claim for their passive cabin ventilation technology, while it may provide a release of a small amount hot air when the cabin pressure exceeds the air pressure outside the vehicle, it does not move cooler outside air into the

[27] See “Joint Technical Support Document: Final Rulemaking for 2017-2025 Light-duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards for the Final Rule,” EPA-420-R-12-901, August 2012, for further information on the definitions and derivation of the credit values. See also the discussion in section II.B.3.iii of the preamble for this MY 2023-2026 final rule.

cabin and purge the hot air out of the cabin in any appreciable amount, something that is required to justify the credit size in the agency supporting documentation in the 2012 FRM. For clarity, the regulatory definition states that the technology must create and maintain convective airflow through the cabin by keeping the windows or sunroof open to prevent excessive interior temperatures when the vehicle is parked and getting direct sun loads. This helps prevent a build-up of heat in the interior air and related components (seats, dashboard, etc.) over the time period that the vehicle is soaking with sun loads in temperatures, where it can be expected that the operator will be requesting cabin cooling on subsequent operation therefore reducing the air conditioning loads on the engine or electrical system. This is a technology description capable of achieving benefits consistent with the menu value and feasible in vehicles particularly considering some manufacturers are already implementing or considering this approach. For this reason, EPA proposed and is finalizing a revised definition to more precisely match the intent of the original rule and to justify the menu credit value.

Stellantis commented that the 15 g/mile cap will be difficult to reach with the new definitions in effect. In response, off-cycle credits remain an optional compliance flexibility and no manufacturer is required to use them. Under the menu-based program, EPA does not review manufacturer's menu credit claims but instead relies on the manufacturer to review the technology definitions in §86.1869-12(b)(4) along with the agency descriptions and supporting analysis in the technical support documentation to ensure that they meet the off-cycle technology definitions. It is the responsibility of the manufacturer to ensure that their technology meets both the definition in the regulations and the performance described in the technical support documentation for the off-cycle technology which they are claiming credit.[28] Occasionally, manufacturers have requested assistance when they have questions as to whether their technology approach or implementation meets the description in the regulatory language. The finalized changes to the definitions are to address this significant concern regarding the regulatory descriptions for these three off-cycle menu technologies and provide clarity for all manufacturers going forward. EPA continues to believe the standards are appropriate with the revised definitions in place.

Nissan commented that the off-cycle credits program should remain in place into the future and should not sunset. DENSO similarly commented that it supports the continuation and expansion of the off-cycle program and they "strongly encourage both EPA and NHTSA to also recognize the important contribution the off-cycle program makes to the overall goals of the regulations." Other commenters, including CBD et al., recommended that the program be revised, further constrained, or ended. Regarding the future of the off-cycle credits program beyond MY 2026, EPA plans to evaluate all aspects of the off-cycle program for MYs 2027 and later through a future rulemaking to ensure the goals of real-world emission reductions are being achieved.

[28] 40 CFR 86.1869-12(b) provides that EPA may EPA may request data, engineering analyses, or other information that supports a manufacturer's use of menu credits.

Hyundai commented that it requests that EPA allow manufacturers to pursue approval of menu items using the alternative (public) method when those automakers have data which proves the benefits of their technology exceeds the amount provided by the menu. Hyundai also requested, "for transparency, that EPA clarify and preferably quantify the statement 'new technology that represents an advancement compared to the technology represented by menu credits – that is, by providing significantly more emissions reductions than the menu credit technology – would be eligible for the other two pathways.' If EPA quantifies the word 'significant' this would serve as a guide for manufacturers to the appropriate approval path." Similarly, ACEEE commented that EPA should clarify what a significant reduction in emissions is in order to determine eligibility for off-cycle menu technologies for other credit pathways. ACEEE proposed a definition of at least 1g/mi greater than those currently assigned by the menu. In response, EPA agrees that if a manufacturer can demonstrate that its technology represents a material improvement on a menu technology and can demonstrate an emissions benefit for those improvements beyond the menu credit level, manufacturers can apply for credits through the public pathway. EPA does not believe it should establish a quantitative cut point, but qualitatively, EPA must be able to discern a clear step change in technology improvement with a clearly demonstratable emissions reduction benefit beyond the menu credit level. At this time, EPA prefers not to establish a quantitative cut point such as the 1 g/mile suggested by ACEEE which may be reasonable for some technologies but not appropriate for others. EPA staff expects to work with manufacturers if questions arise regarding the implementation of these provisions.

Tesla commented against expanding off-cycle menu credits, commenting that it "creates asymmetry in the regulation favoring ICE vehicles, diverts R & D investment away from the best emissions reduction technology of electrification, and unnecessarily weakens the stringency of the standard." Tesla commented that its previous analysis has shown that manufacturers will increase reliance on off-cycle credits and divert investment and deployment away from the most efficient vehicle technologies. Telsa commented further that extending and expanding these credit rewards old technology and, to the extent new technologies are deployed to generate off-cycle credits, focuses critical R & D budgets on tweaking legacy ICE platforms rather than directing these budgets to electrification and greater emissions reductions. In response, ICE vehicles will continue to be a large portion of the fleet for several years during the transition from ICE vehicles to EVs and other advanced technology vehicles. EPA expects that off-cycle credits will remain an important avenue for emissions reductions, at least for the MYs covered by this rule. EPA does not believe there is significant asymmetry favoring ICE vehicles associated with EPA's proposal since EVs can generate menu-based credits in cases where EVs are equipped with menu technologies. Also, any asymmetry due to some menu technologies being ICE vehicle specific and not applicable to EVs such as active engine warmup, is at least somewhat offset by the availability of EV multiplier credits which are not available to ICE vehicles.

JLR proposed that EPA include an option for manufacturers to remain at the 10 g/mile (lower) cap with the original technology definitions up to and including MY 2025. JLR commented "this is required as, for technologies which involve significant changes to the vehicle to meet the new definition such as active transmission warm up, there must be a longer lead time for manufacturers to adapt to this change in the regulation." In response, EPA is not including such an option because EPA believes it is important to implement the revised definitions as soon as possible to help ensure emissions reductions, as discussed above.

Regarding AVE comments that off-cycle credits distort the marketplace and it supports EPA moving away from such incentives, the commenter did not elaborate on how off-cycle credits may distort the market. The off-cycle credits program is an optional program for auto manufacturers which provides additional technology choices in meeting the GHG standards; therefore EPA does not believe that the off-cycle credits program distorts the market.

Revised Definitions

With regard to the proposed revised definitions themselves, rather than their implementation, EPA received relatively few comments. Some commenters generally supported updating the definitions. Ford commented that it understands EPA's rationale for revising the definition for passive cabin ventilation. JLR similarly commented that it understands the EPA's proposal to change the requirements around passive cabin ventilation and active transmission/engine warm up. ITB and Gentherm commented that in principle, they agree that menu definitions should be supported by representative data. MEMA also noted conditional support for the revised definitions. UCS commented that it strongly supports EPA revising the off-cycle menu definitions for these technologies, and that it concurs with EPA that any manufacturers seeking credit for technologies that do not meet this revised definition must do so through the public comment process. EPA appreciates this general input regarding the proposed definitions.

Ford and Stellantis raised issues regarding the modification of the passive cabin ventilation definition being based on ventilation through opening windows and/or a sunroof. As noted above, these credits are optional, and manufacturers are not required to use them if they do not have a technological approach they believe to be workable. However, the menu credit level is based on and consistent with cabin temperature decreases associated with opening a sunroof or window to allow hot air to escape, as discussed above. We disagree with Stellantis and other comments that redefining these credits makes the GHG program more stringent. Stellantis states in their comments that they do not believe that the original technology approach by NREL is feasible in their vehicles. However, that approach was the basis for the passive ventilation credit in the original GHG program TSD. The agency believes the proposed and finalized update to the technology description with slight modifications from the original NREL approach in this new rule will provide clear and feasible design approaches that can be readily adopted with minimal or no hardware changes, and will better reflect the intent of the Agency in its original design goals for this off-cycle technology. The definition modifications were necessary to address significant confusion expressed from many manufacturers when attempting to implement some menu-based technologies while also clarifying the original off-cycle design requirements that were the foundation for the credit size. In fact, even with the proposed changes to the definitions for improved clarity, Ford recommended some additional slight changes to the revised definition of active engine and transmission warm-up to further define the technology design criteria expectations for these credits. Upon review of those recommendation, EPA is adjusting the definitions to more closely align with the recommendations from Ford but still maintaining the original design goals for these off-cycle technologies to achieve the expected GHG reduction.

The active engine warm-up description will not require the liquid cooled exhaust manifold based design to be segregated from the engine cooling loop. Similarly, the active transmission warm-up system using the liquid cooled exhaust manifold as the source of heat will not be required to be segregated from the engine coolant loop, although it must continue to be on a loop that is not shared with other heat extracting devices (ie, interior heating) and must allow immediate heat extraction following the start of the engine, consistent with an exhaust gas waste heat extraction design and the original basis for this credit size. Therefore, EPA is finalizing the revised definition as proposed with the exception of these slight changes to the active engine and transmission warm-up technologies. For technologies not meeting the revised menu definition, manufacturers may seek off-cycle credits for other approaches through the other off-cycle pathways.

9. Air Conditioning System Credits

Commenter: Alliance For Automotive Innovation

Auto Innovators recommends that EPA not cap credits for off-cycle electrical load-reducing technologies in MAC systems under the air conditioning ("A/C") efficiency technology menu.

Automakers and suppliers continue to develop technology innovations that reduce electrical energy consumption from various on-vehicle devices. Reductions in electrical energy consumption reduce GHG emissions and fuel consumption associated with alternator load (i.e., electrical generation). Such innovations also reduce stored energy consumption in EVs, improving range and reducing upstream power plant emissions. Whether the electrical load reductions occur in computer modules, electrical actuators, fans, entertainment systems, lights, A/C system clutches, or other areas, the effect is the same – a watt of reduced electrical load provides the same emission and fuel consumption savings benefits by reducing alternator mechanical power consumption.

Recently, EPA has considered alternative method off-cycle credit applications for several electrical load-reducing technologies in MAC systems. These include technologies that reduce A/C compressor clutch electrical (as opposed to mechanical) power consumption76 and brushless fan motors.77 EPA has taken the position that because the electrical load reductions are occurring in the A/C system, credits approved for these technologies should be included under the credit cap on the A/C system efficiency menu (40 C.F.R. 86.1868-12(b)). In developing the credit values for the A/C efficiency menu, EPA did consider improvements to A/C blower motor controls to limit wasted electrical energy. However, improvements to blower and fan motors themselves were not considered for the A/C efficiency credit menu, nor were they included in the research studies EPA relied upon in its determination of the maximum amount of A/C operation-related emissions that could be reduced. Similarly, improvements in A/C system compressor clutch designs to reduce electrical energy consumption were not considered.

Electrical load reductions have the same effect on emissions and fuel consumption regardless of what system they are found in, and were not fully considered by EPA in establishing an estimated maximum emissions benefit for A/C system efficiency improvements. Therefore, Auto Innovators recommends that EPA exclude new electrical load reducing technologies from the A/C efficiency menu credit cap.

Consumer education programs Additional consumer education and advertising campaigns can help promote the purchase of EVs. [EPA-HQ-OAR-2021-0208-0571-A1, p. 6]

Air Conditioning Efficiency Technology Credits. EPA provides credits for technologies that improve the efficiency of air conditioning systems.88 Auto Innovators provides the following recommendations to improve implementation of these credits. If such changes cannot be made in the present rulemaking because they were not formally proposed, EPA should indicate in the final rule what changes it may consider in the future and act expeditiously to propose those changes as soon as possible.

The cap on A/C efficiency technology credits should be increased commensurate with more recent data from the National Renewable Energy Laboratory and the inclusion of thermal control technologies.

The basis for predefined A/C efficiency technology credits was EPA’s estimate of the total fuel usage from light-duty mobile air conditioner usage in the U.S., which EPA estimated to be 14.3 grams CO2 per mile, or 3.9% of total national light-duty vehicle fuel usage. 89

The technologies identified for predefined A/C efficiency credits and the percentage efficiency improvement estimates for these technologies came primarily from the Improved Mobile Air Conditioner (“IMAC”) industry-government Cooperative Research Program conducted through SAE International. IMAC was a partnership between EPA, DOE and 28 corporate sponsors, which published its final report in 2007. The IMAC program demonstrated an improvement of 36.4% in MAC efficiency using best-of-the-best designs at the time for these technologies on a test vehicle, compared to a baseline MAC system using a defined list of typical technologies in production at that time, such as a fixed displacement compressor.90

EPA estimated from the IMAC work that a 40% reduction in emissions was possible when employing the A/C efficiency menu technologies in the study. That reduction equates to a 5.7 g/mile CO2 reduction (0.40 X 14.3 g/mi CO2), which then became the capped credit value for employing the technologies on the A/C efficiency menu in the 2010 rulemaking for MY 2012-2016 vehicles.91 The cap was modified for MY 2017 and later vehicles to separate caps for passenger cars and light trucks. The cap for predefined A/C efficiency technologies for MY 2017 and later is currently 5.0 g/mile for passenger cars and 7.2 g/mile for light trucks.92 [EPA-HQ-OAR-2021-0208-0571-A1, p. 26]

EPA based its MAC efficiency credits on estimates of each technology’s percentage impact on the total fuel usage by vehicle air conditioner systems in the U.S. However, EPA’s 14.3 grams CO2 per mile estimate of baseline air conditioner energy usage (3.9% of total light-duty fuel consumption) was well below the estimates of others, such as researchers from the National Renewable Energy Laboratory (over 6%), as well as longstanding benchmarks used by industry.

This baseline used by EPA, which was as low as half the baseline MAC energy usage estimated by the other major sources, resulted in MAC efficiency credits and an associated credit cap that are far below the actual real-world fuel savings and CO2 reductions that are resulting from these technologies.

More recent estimates of baseline U.S. energy usage for light-duty vehicle air conditioners, using updated and refined models, have continued to significantly exceed the EPA baseline. In a series of studies released in 2017 by scientists from the National Renewable Energy Laboratory, the baseline MAC energy usage was calculated as 30.0 gallons of gasoline per vehicle per year, equivalent to 23.5 grams of CO2 per mile.93 The updated estimate from NREL of 23.5 grams CO2 per mile is 64% greater than the EPA baseline of 14.3 grams CO2 per mile.

The underestimated EPA baseline for MAC energy usage also impacts the credit caps and credit amounts in the off-cycle credit provisions for thermal control technologies, such as solar reflective paint, solar reflective glass, ventilated seats, and active or passive cabin ventilation. These thermal control technologies should ideally have been analyzed and administered in combination with the MAC efficiency technologies from the earliest stages of the light-duty GHG regulation, since they both address energy usage to power the air conditioning system.

Auto Innovators therefore proposes that the MAC indirect credit caps and the thermal control technology off-cycle caps be combined, and that the two lists of technologies be administered under a single set of caps. We further propose that the combined set of caps should be revised to reflect a 64% higher baseline energy usage for air conditioner energy, as shown in Table 1. [Table 1 can be found on p. 28 of Docket number EPA-HQ-OAR-2021-0208-0571-A1]. [EPA-HQ-OAR-2021-0208-0571-A1, p. 27]

There are additional reasons to consider raising the cap on A/C efficiency credits. EPA describes in its proposal to increase the off-cycle credit menu cap that the headroom under the cap has closed significantly for some manufacturers.94 Similarly within the A/C efficiency credit program, some manufacturers have already reached the cap and are no longer able to receive credit for improving their A/C systems further. Manufacturers on average were at 84 percent of the cap in MY 2019.95 This can lead to manufacturers eliminating or avoiding A/C efficiency technologies that put them beyond the cap, as well as suppliers losing incentives to develop new A/C related technologies with real-world benefits. Manufacturers are less likely to invest resources for implementing technologies on vehicles that have already achieved maximum credits.

EPA also mentions that expanding the number of technologies on the off-cycle credit menu without modifying the cap (such as the inclusion of high-efficiency alternator technology) creates additional difficulty for OEMs to get credit due to the limitations of the credit cap.96 The A/C efficiency menu has also been expanded recently (i.e., high-efficiency compressor). In addition to the A/C efficiency menu expanding, the EPA has applied the A/C system efficiency menu credit cap for all A/C efficiency technologies approved under the alternative method off-cycle credit program. In some cases, said technologies provide an electrical efficiency benefit to the vehicle, but are counted toward the A/C efficiency cap because they are part of the A/C system. Inclusion of such technologies under the predefined A/C efficiency technology menu cap leads to additional constraints, further deterring manufacturers from making continuous improvements.

For the reasons listed above, it is reasonable to also increase the credit cap on predefined A/C efficiency technologies.

If the A/C efficiency (or combined A/C efficiency and thermal control technologies) menu credit cap is increased, EPA should not use this as a reason to further increase standard stringency.

As described above, it is unlikely that any given manufacturer will fully utilize all potential flexibilities. Increasing standard stringency under the assumption that every manufacturer will fully utilize every flexibility ultimately results in a de facto requirement to either use that flexibility or commit to even higher levels of fuel economy technologies.

The Life-Cycle Climate Performance ("LCCP") Model (SAE J2766) should be recognized in regulation or guidance as a core method for determining the benefit of new A/C efficiency technologies that are not on the predefined list.

The LCCP model was developed in 1999, building on the work done by Oak Ridge National Laboratory in developing the Total Equivalent Warming Impact ("TEWI") metric. The model was jointly developed for mobile air conditioning use by GM, SAE, EPA, and the Japanese Automobile Manufacturers Association ("JAMA") to become the Global Refrigerants Energy and Environmental-Mobile Air Conditioning-Life Cycle Climate Performance ("GREEN-MAC-LCCP"). GREEN-MAC-LCCP is a spreadsheet-based emissions estimator that accounts for climate data from around the U.S. and A/C system performance and efficiency data of comparative systems per SAE J2765. SAE developed the J2766 standard that the auto industry uses to estimate MAC emissions today.

The LCCP model considers the variables influencing A/C system operation on an aggregate level, focusing on population centers across the country. Emissions levels are determined by averaging conditions and distribution of vehicles across the country. A key benefit of the LCCP model is that it considers factors influencing MAC operation and can be run from a spreadsheet. Special expertise is not needed, and the SAE specification walks the user through the inputs. A new version of the LCCP model, the IMAC-GHG-LCCP model, has also been developed that is easier to use and has updated climate and usage data and expanded system capability.

Multiple EPA-approved alternative off-cycle credit methodologies have relied on the LCCP including applications associated with Denso SAS high-efficiency compressors (which eventually formed the basis for EPA's standardized indirect air conditioning credit for high-efficiency compressors) and Toyota "S-Flow" technology.

The IMAC-GHG-LCCP model is currently undergoing further updates to include enhancements for EVs including vehicles with heat pumps. In addition, updates and improvements suggested by EPA are planned. The original LCCP model development was a collaboration that included EPA. EPA involvement and input to reach an agency-industry consensus in the current update is requested.

A/C technologies granted credit under an alternative method for generating off-cycle credit should not be subject to the A/C efficiency technology menu credit cap if additional benefits are demonstrated.

The off-cycle credit alternative method is a means by which manufacturers can demonstrate the off-cycle emissions benefits of technologies not included in the predetermined list, or by which manufacturers can demonstrate additional benefits beyond those estimated in the predetermined list. This approach should hold whether the technologies are A/C efficiency related or not. However, EPA has instead made all A/C technologies approved under the off-cycle alternative method subject to the cap on the A/C credit menu, regardless to the benefits demonstrated, under the premise that the cap represents the maximum degree of emissions that can be reduced from A/C system operation.

As we describe above in our request for EPA to increase a combined thermal control and A/C system efficiency cap, more recent studies have demonstrated that greater emissions reductions are possible than those first estimated by EPA in its development of the A/C efficiency cap. Of even greater import, manufacturers have demonstrated additional emission benefits for some A/C efficiency technologies even on vehicles that already included enough other technologies from the predetermined list to be constrained by the cap. Table 2 provides several examples where additional emissions benefits were demonstrated beyond the cap.

We therefore recommend that A/C technologies granted credit under an alternative method for generating off-cycle credit should not be subject to the predefined A/C efficiency technologies credit cap if additional benefits are demonstrated. [EPA-HQ-OAR-2021-0208-0571-A1, p. 28-30]

Credits for Reducing Leakage and Impacts of Air Conditioning Refrigerant. Auto Innovators agrees that if EPA were to remove A/C refrigerant-related credits from the program, the standards would need to be adjusted to reflect their elimination.

EPA notes that A/C refrigerant-related credits were accounted for in setting GHG standards, making them more stringent, and if they were removed, the standards would need to be adjusted or increased to reflect their elimination.

In late 2020, the American Innovation and Manufacturing Act ("AIM Act") was signed into law, requiring a general phasedown in the use of hydrofluorocarbons ("HFCs") in the U.S. EPA recently finalized a rule for the allocation and trading of production and consumption allowances. Furthermore, a group of stakeholders has petitioned EPA to reinstate Significant

New Alternatives Policy ("SNAP") rules 20 and 21 under the authority of the AIM Act. If granted, HFC use in new light-duty vehicles would be prohibited.

Similarly, the State of California is considering a prohibition on the use of high-GWP refrigerants (which include HFC-134a) in new light-duty vehicles as part of its ACC2 rulemaking.

If HFCs or high-GWP refrigerants in general are prohibited from use in new light-duty vehicles under state or federal law, there may be calls for EPA to eliminate the credits for reducing leakage and impacts of air conditioning refrigerants. Auto Innovators agrees with EPA that if these credits were eliminated or modified, the standards would need to be adjusted to reflect such changes. Not doing so would result in a change in stringency not considered when the light-duty vehicle GHG standards were set. [EPA-HQ-OAR-2021-0208-0571-A1, p. 32]

95 Calculation by Auto Innovators based on data from 2020 Trends Report (supra note 32), Figure 5.10 (MY 2019 A/C credit data), Table 5.13 (passenger car production), Table 5.15 (light truck production) and 40 C.F.R. § 86.18686-12(b) (credit caps).

Commenter: Chemours Company (Chemours)

In 2010, 2012 and 2020, the EPA promulgated light duty vehicle ("LDV") regulations that included incentives for automakers to increase the efficiency of MVAC refrigerant systems and support the transition away from HFC-134a refrigerants. In the current rulemaking effort, EPA has proposed to keep these provisions intact and to encourage the use of alternative refrigerants like HFO-1234yf within the stringency of the GHG emission standards for Model Years ("MYs") 2021- 2026. Chemours supports these elements of the proposed rule and would note that other vendors to vehicle manufacturers also have a substantial interest in continuing the transition away from the use of HFC-134a. [EPA-HQ-OAR-2021-0208-0232-A1, p. 2]

EPA should address the use of HFC-134a in vehicle segments other than LDVs. Specifically, EPA should take further action to address HFC use in the medium- and heavy-duty market segment. Chemours is not aware of any substantial technical or economic issues that would preclude EPA from implementing a credit system approach in this market segment similar to the approach utilized for LDVs. • Separately, EPA should also pursue actions that would either "reinstate" previous CAA rules to de-list HFC-134a for use in "MVAC" systems or utilize new legal authority to accomplish the same result. Such action may be taken in parallel with EPA's proposed approach to current MVAC leakage and equipment credits. [EPA-HQ-OAR-2021-0208-0232-A1, p. 3]

EPA Should Finalize Regulations that Retain MVAC Leakage and Equipment Credits. A/C Credits are Necessary to Preserve Transition to HFC- 134a Alternatives. The Transition to Low-GWP Refrigerants is Ongoing. While LDV manufacturers have continued to move towards adoption of low GWP alternatives over the last decade, a full transition is not yet complete and therefore, EPA should retain credits for the full MY 2022-2026 period and beyond. Information in the administrative record for the rule indicates that use of low-GWP refrigerants expanded between MY 2013 and MY 2019. EPA notes that "[f]ive manufacturers have implemented HFO-1234yf across almost their entire fleets, with eight additional manufacturers exceeding at least 50% adoption of HFO-1234yf."2 Another six manufacturers have apparently adopted low-GWP refrigerants in at least some of their fleet.

This broad adoption of low-GWP refrigerants is encouraging, but it is evident that the transition to such refrigerants is not complete, nor is there a firm projection as to when a full transition will occur. One reason for this situation is that there are currently no federal requirements that prohibit a vehicle manufacturer from using HFC-134a or another high-GWP refrigerant or blend in newly-manufactured vehicles. Regulations previously promulgated by EPA to disallow use of high-GWP refrigerants in LDVs are not in effect and, thus, there is no external "forcing mechanism" that sets a firm date by which all new vehicles must utilize low-GWP refrigerants.

A major reason for this situation stems from litigation. Specifically, when EPA conducted its Mid Term Evaluation of the 2012 LDV rule in 2016, the Agency presumed that changes in HFC-134a emissions would occur through MY 2021 "at which point the use of HFC-134a in new vehicles [would be] prohibited under the Significant New Alternatives Policy (SNAP)."3 At the time, EPA expected that HFC134a would "be entirely replaced by refrigerants with lower GWPs by model year 2021."4 But this accelerated transition away from HFC-134a did not occur given the D.C. Circuit Court's 2017 decision in Mexichem Fluor v. EPA5 additional litigation on another SNAP rule,6 and subsequent rulemaking by the Agency.

Specifically, in 2018 EPA issued a rule indicating that the Agency would not apply the HFC "de-listings" promulgated in 2015 and 2016 (including de-listings that would have precluded use of HFC-134a in new MVACs) under SNAP.7 This rule thus eliminated any "forcing mechanism' that would drive the transition from the use of HFC-134a to lower-GWP refrigerants in new MVAC units. While a subsequent decision in 2020 by the D.C. Circuit Court vacated the 2018 rule,8 as of the date of these comments, the extent to which Mexichem I or the subsequent unpublished decision in Mexichem II applies or does not apply to refrigerants used by MVACs has not been further clarified by EPA.9

Therefore, EPA should recognize that the planning for a transition away from HFC-134a has been disrupted over the last several years given the uncertainty with regard to how long HFC-134a would be allowed to be used in new MVAC systems. Within this rulemaking, then, EPA should at minimum retain the status quo and extend the availability of MVAC credits for new refrigerants (generally referenced as "leakage" credits) throughout the full period of time that the new rule will remain in effect. EPA should also retain A/C equipment credits which complement the transition to high-efficiency, low-emissive MVAC systems using low-GWP refrigerants.

Manufacturers Still Require Time to Transition to Low-GWP Refrigerants. Similar to other "off-cycle" credits, credits for air conditioning ("A/C")10 allow flexibility for manufacturers to adopt new technologies when it makes the most economic sense for a specific vehicle and/or their entire fleet of vehicles, e.g., when models are undergoing periodic redesign or when entirely new vehicles are being developed and produced. And, as EPA has recognized, planning horizons for vehicle manufacturers generally extend out for five years on average.11 EPA has observed that “approximate trajectory” of these plans for new vehicles will tend to remain in place after they have been established and that vehicle designs utilize a multi-year process for both development and execution.12

In this regard, A/C credits have been available to manufacturers since the 2012 MY and were retained through rulemaking to extend into the production of vehicles through the 2025 MY. A/C credits have been successful in incentivizing many original equipment manufacturers (“OEMs’) to adopt low-GWP refrigerants across many different types of models of LDVs, even while the degree to which each OEM has adopted low-GWP refrigerants has varied.13 While Chemours is not privy to the product plans of OEMs, it is reasonable for EPA to retain A/C credits on the basis that these credits are likely to be part of current OEM product plans for the MYs addressed through this rulemaking. While specific information on product plans is not available, it would seem clear that, having been promulgated in 2010 and retained in 2010 and 2020, OEMs have relied on A/C credits in planning for the overall composition of their fleets. This reason alone would caution against EPA taking any effort to disrupt what may be viewed as settled expectations.

Other Regulatory Programs Are Not in Place. In late 2020, Congress approved the American Innovation and Manufacturing Act (“AIM Act”)14 and EPA is currently in the process of promulgating regulations to address the requirements of this law in 2022-2023.15 These rules, when adopted in final form, will implement provisions of the AIM Act providing for an overall cap on HFC emissions, implemented through an allowance program that constrains production and consumption of HFCs. As proposed, however, EPA’s rules for 2022-2023 would not specifically affect the use of HFC-134a in MVAC systems. Rather, producers and importers of HFCs will be required to “hold” a corresponding number of annual allowances authorizing the production or import of HFCs.16

The AIM Act, however, does allow for regulations that restrict the use of HFCs in a sector or subsector, and any person may petition the EPA to take such action.17 The EPA is currently in receipt of several petitions related to specific end uses of HFCs, including a request that EPA restrict the use of HFC-134a in MVAC systems.18 The AIM Act, however, provides that no rule promulgated to restrict the use of HFCs may take effect prior to one year after the date on which the Agency promulgates a rule.19 Thus, it is currently uncertain when EPA will propose, take final action and provide for the implementation of a rule that would restrict the use of HFC-134a in MVAC systems or when any such rule would take effect.

Until such time as an actual prohibition on the use of HFC-134a in MVAC systems is in place, – if indeed, that is the outcome of the petitions that EPA will consider following promulgation of a final rule to implement the AIM Act – the use of this refrigerant may still occur. As noted below, prior to such restrictions, it would be possible for an OEM to revert to the use of HFC-134a in some or all of the vehicles it produces. Therefore, retaining current A/C credits can serve as a strong counter-weight to such actions. Particularly when paired with more stringent carbon dioxide gram/mile (“g/mi”) standards for LDVs, retaining A/C credits helps to guard against any “backsliding” in the transition to low-GWP MVAC refrigerants by effectively making standards more stringent for OEMs that chose not to use low-GWP alternatives.

A/C Credits Are Integral to EPA's Proposed LDV Standards. A/C Credits Have Grown in Importance Since MY 2012. EPA has provided for A/C credits since the Agency promulgated its first rules to establish GHG standards for MY 2012 through MY 2016 LDVs.20 These credits have been an important part of EPA's LDV standards and their importance has grown as GHG emission standards have become more stringent. As EPA explained in 2010, "it is important to address A/C direct and indirect emissions because the technologies that manufacturers will employ to reduce vehicle exhaust CO2 will have little or no impact on A/C related emissions. Without addressing A/C related emissions, as vehicles become more efficient, the A/C related contribution will become a much larger portion of the overall vehicle GHG emissions."21

For example, EPA projected in 2010 that fleet-wide compliance levels for passenger cars would be 225 g/mi in 2016 and 298 g/mi light duty trucks in the same year.22 In the same rule, EPA estimated that OEMs, on average, would generate 11 g/mi in A/C credits that could be used toward meeting this compliance level.23 In other words, the percentage of fleetwide compliance that could be attributable to improvements in A/C systems and the use of alternative refrigerants constituted approximately 4.9% and 3.7% of the overall standard for passenger cars and light duty trucks in 2016, respectively.

In EPA's 2012 rule, the Agency projected that fleet-wide compliance in 2025 for passenger cars would be 143 g/mi and 203 g/mi light duty trucks.24 In this same rule, EPA calculated that the maximum A/C credits that would be available would be 18.8 g/mi for cars and 24.24 g/mi for light duty trucks.25 Therefore, the percentage of fleetwide compliance attributable to A/C credits that EPA projected for 2025 was estimated at 13.1% for passenger cars and 12% for light duty trucks. Relative to EPA's 2010 LDV GHG rules, then, the share of compliance represented by A/C credits increased between 267% and 324% over 9 years. In the proposed rule, EPA projects a fleetwide compliance level of 142 g/mi for passenger cars and 199 g/mi for light duty trucks in 2026, meaning that roughly the same percentages calculated above for the 2025 MY would remain26 and that the relative "value" of the credits for compliance will therefore continue to be very significant for OEM fleet compliance.

A/C Credits Do Not "Weaken" Standards. In addition to the relative share of compliance attributable to A/C credits, EPA is also proposing to retain its historic treatment of such credits. Specifically, in the proposed rule, the overall stringency of the standards will "take into account the credit-based emissions averaging, banking and trading flexibilities of the current program as well as additional flexibility provisions [EPA is] proposing to ease the transition to more stringent standards."27 This means that if the Agency were to not continue A/C credits, "the proposed standards would need to be adjusted or increased by the amount of the credit to reflect its elimination from the program."28

Prior to the 2020 Safer Affordable Fuel-Efficient ("SAFE") Rule, this stringency adjustment was reflected by the fact that the National Highway Traffic Safety Administration ("NHTSA") developed its fuel efficiency standards by accounting for improvement in A/C efficiency but not with respect to the use of alternative low-GWP refrigerants.29 Thus, while EPA projected in 2012 that its GHG standards would result in a g/mi standard in 2025 that would be equivalent to 54.5 miles per gallon ("mpg"), NHTSA corresponding standards for 2025 were projected to result in an average range of 48.7 to 49.7 mpg.30 In the SAFE Rule, EPA standards were not presented in the form of equivalent mpg standards but rather the stringency of the EPA g/mile standards did account for projections associated with HFC reductions as well as regulations affecting the emission of other non-CO2 GHGs.31 But under NHTSA's regulatory provisions in the SAFE Rule, manufacturers could not claim CAFE-related benefits (in terms of mpg) for reducing A/C leakage or switching to a refrigerant with a lower GWP.32

Bottomline, the SAFE Rule used different nomenclature; while EPA described A/C credits as an "offset" with respect to anticipated reductions.33 Although the description of the resulting EPA standards was adjusted somewhat, the basis of regarding A/C credits from an EPA regulatory perspective remains essentially intact and the existence of A/C credits did not "weaken" the level of the SAFE Rule as reflected in EPA g/mi standards.

In this regard, it is notable that the historic methodology for determining the relative "value" of A/C credits is robust and verifiable. A/C refrigerant credits utilize the relative GWP of different refrigerants, as determined by values established in climate programs, e.g., IPCC Fourth Assessment Report ("AR4") calculations of HFC-134a versus HFO-1234yf.34 Since the amount of refrigerant used in different MVAC systems is known, this allows for an accurate calculation of CO2 equivalent values which are then used with respect to EPA's g/mile standards.

As discussed in more detail below, however, this level of accuracy in projecting GWP and the resulting climate benefits may not be replicated with respect to other "off-cycle" credits which are based on "research, analysis and simulations, rather than from full vehicle testing."35 In some cases, such credits may be generated based on broadly averaged impact.36 By comparison, the level of accuracy involved in A/C credits measured through relative GWP and the resulting increase in g/mi stringency imposed based on these calculations ensure that the credits cannot be considered to dilute or weaken the proposed standard. Rather, to the extent that vehicle manufactures do not use alternative refrigerants, the relative stringency of g/mi standards that apply to their fleet is increased.

Retaining A/C Credits Avoids Sudden Disruption to LDV GHG Program. As EPA observed during the 2012 rulemaking, "[A/C] credits should continue to the present rule since without them, a manufacturer utilizing credits in MY 2016 could suddenly find in MY 2017 that the stringency of the standards are artificially increased due to discontinued A/C credits."37 This same effect could occur in MY 2023 if EPA fails to continue the A/C credits as it has proposed to do. In fact, vehicle manufacturers would have even less time to make adjustments to their product line than they would have had in the 2012 rulemaking. The 2012 rule was published in the Federal Register on October 15, 2012, leaving approximately four full MYs before the new standards became applicable with MY 2017 vehicles. In contrast, the current rulemaking proposes to adjust g/mile standards from their current levels starting with MY 2023, meaning that if a rule is finalized by the end of 2021 or early 2022, there is effectively less than 1 year available before the standards take effect.

As noted above, OEM vehicle planning horizons extend over many years, with five years being considered to be a "rule of thumb" for fleet projections. The development and manufacture of an entirely new vehicle can take longer. Thus, given the relative short timeframe between the finalization of the proposed rule and when the new standards will take effect, it would also be unreasonable for EPA to eliminate or substantially alter the current A/C credit program.

In addition, while an agency may adopt different approaches to regulation over time, where different approaches from past regulation are pursued, “a more detailed justification” for the changes is necessary given that implementation of the previous policy has “engendered serious reliance interests that must be taken into account.”38 With respect to A/C credits, these interests involve not only OEMs but also companies like Chemours and their suppliers who have developed products to address regulatory requirements and policies that promote the transition away from the use of HFCs in MVAC systems.

Retaining A/C Credits is Consistent With the Regulation of GHGs Under the CAA. In 2009, EPA determined that the “relevant” GHG air pollutant from new motor vehicles and new motor vehicle engines was “the combined mix of six key directly-emitted, long-lived and well-mixed greenhouse gases.”39 In this determination, HFCs were cited as one of the six GHGs that EPA identified as contributing to air pollution that endangered public health and welfare and one of four GHGs that EPA identified as being emitted by motor vehicles.

In every rule promulgated by EPA to regulate GHGs under authority of the CAA since 2009, the Agency has not deviated from considering the “air pollutant” that endangers public health and welfare and the air pollutant to be regulated to be the same six GHGs (including HFCs) despite the fact that a source category subject to regulation may actually emit far fewer individual GHGs.40 In 2010, in the first rule to regulate GHGs from LDVs, EPA noted that it has discretion to adopt separate standards for each of the six GHGs identified in the 2009 endangerment determination and that it was “finalizing separate standards for nitrous oxide and methane and a CO2 standard that provides for credits based on reductions in HFCs, as the appropriate way to issue standards applicable to the emission of the single air pollutant, the aggregate group of six greenhouse gases.”41 Two years later, in the 2012 rule, EPA did not deviate from this analysis nor its legal interpretation of the CAA but indicated that the Agency was “adopting a CO2 tailpipe emissions standard that provides for credits based on reductions in HFCs, as the appropriate way to issue standards applicable to emissions of the single air pollutant.”42

Retaining A/C credits based on HFCs, as translated into CO2e values, is therefore consistent with EPA’s approach to regulating GHGs under the CAA, and specifically, with EPA’s prior regulation for HFCs emitted from LDVs. There is no reason for the EPA to deviate from this past practice in the current proposed rulemaking given that the same methodology has been implemented by the Agency with regard to LDVs for nearly 10 MYs. More importantly, there are substantial legal and policy reasons for EPA to maintain this approach in the current rulemaking.

In Massachusetts v. EPA, the Supreme Court held that “[b]ecause greenhouse gases fit well within the Clean Air Act’s capacious definition of ‘air pollutant’ we hold that EPA has statutory authority to regulate the emission of such gases from new motor vehicles.”43 The court further indicated that once EPA made an endangerment finding for motor vehicles, the CAA requires the

Agency to regulate “emissions of the deleterious pollutant from new motor vehicles.”44 While the Supreme Court later “refined” its interpretation of when EPA must regulate GHGs under the Clean Air Act to encompass those that may be “sensibly regulated,”45 HFCs clearly fall within the zone of GHGs that must be addressed under CAA section 202(a).

HFC-134a has a global warming potential (“GWP”) that is 1,430 times the GWP of CO2 and nearly all vehicles that are produced for the consumer market (and most of the commercial market) contain air conditioning systems.46 As demonstrated over the last decade, technology is readily available to allow MVAC systems to move away from high GWP refrigerants to low GWP refrigerants such as HFO-1234yf. Thus, while EPA may promulgate flexible standards to control GHGs from new motor vehicles, it cannot ignore the substantial emissions attributable to high-GWP refrigerants. EPA should therefore “stay the course” and finalize its proposed treatment of HFCs and A/C credits. Having previously addressed HFCs from MVAC systems in prior rulemakings, EPA lacks rationale for eliminating such regulatory treatment absent a showing that such controls (and resulting stringency of the LDV standards) are no longer needed. [EPA-HQ-OAR-2021-0208-0232-A1, p. 3-11]

EPA Should Take Additional Steps to Address HFCs. Chemours recognizes that EPA has proposed changes to GHG emission standards for LDVs within certain MYs and that a final rule is constrained by what the Agency has proposed and logical outgrowths of a proposed rule.65 At the same time, it is important for EPA to address the full scope of issues concerning the use of high-GWP refrigerants in MVAC systems and thus we would respectfully request attention to the following two issues.

EPA Should Address HFC Use in Medium- and Heavy-Duty Vehicles. EPA last revised GHG standards applicable to medium- and heavy-duty vehicles in 2016.66 These standards are applicable through MY 2027 and provide for compliance based on both direct emission testing of engines and modeling of vehicle emissions using the Agency’s Greenhouse Gas Emissions Model (“GEM”). Within GEM, certain default values are provided for the incorporation of equipment on vehicles (e.g., low-rolling resistance tires, aerodynamics, vehicle and transmission types, certain idle functions, accessories).

With regard to A/C systems, in the first rule EPA promulgated to address GHGs from medium- and heavy-duty vehicles (the 2011 Phase 1 GHG Rule),67 EPA adopted a separate standard for tractor-trailers to reduce leakage of HFC refrigerants from cabin A/C systems. Unlike LDV GHG standards, however, this HFC standard was not “linked” to CO2 tractor standards nor otherwise “creditable” to those standards. Instead, manufacturers were able to select from a list of leak-reducing technologies that EPA considered sufficient to meet the standard. In the 2016 Phase 2 GHG Rule, EPA continued this approach for tractor trailers, while extending the HFC direct emission leakage standards to vocational vehicles.68 EPA also took comment on a provision to allow a manufacturer to “deem” compliance with the leakage standard through use of an alternative refrigerant, but this proposal was not finalized.

A large part of EPA’s rationale for not taking further action with regard to A/C refrigerants in medium- and heavy-duty vehicles has centered on uncertainty with regard to manufacturer adoption of new A/C systems. In 2016, EPA indicated that it was "not aware of any significant development of A/C systems designed to use alternative refrigerants in heavy-duty vehicles."69 If this was a significant consideration in 2016, however, Chemours is not aware of such circumstances existing at the present time. Any technology and economic barriers that exist to the adoption of HFO-1234yf MVAC systems in medium- and heavy-duty vehicles are currently comparable to those previously experienced by LDVs. In other words, Chemours is not aware of technical reasons or cost considerations preventing HFO1234yf systems from being widely used in new medium- and heavy-duty vehicles.70

In the 2016 Phase 2 rulemaking, EPA also noted that it had listed two refrigerants as "acceptable" for use in heavy-duty A/C systems (R-744, HFC-152a) and had proposed to list HFO-1234yf as acceptable in heavy-duty A/C systems subject to use conditions.71 But outside of these actions, EPA did not propose or incorporate any additional provisions related to alternative refrigerants, noting only that transitioning to such refrigerants could be advantageous to vehicle manufacturers for "a variety of reasons, including platform standardization and company environmental stewardship policies."72 In the same rulemaking, however, EPA noted that "[a] transition to A/C systems designed for HFO-1234yf which is more thermodynamically similar to HFC-134a than is CO2 requires less significant hardware changes that typically include installation of a thermal expansion valve and can potentially require resized condensers and evaporators as well as changes in other components."73 In other words, EPA recognized that the technical changes allowing for adoption of alternative refrigerants to HFC-134a varied and could pose significantly less challenges for some refrigerants versus other refrigerants.

While the proposed rule addresses only LDVs, EPA should consider utilizing a credit program for alternative refrigerants/leakage in standards that apply to medium- and heavy-duty vehicles in a manner similar to that utilized in the LDV program. In both the Phase 1 and Phase 2 Rules, EPA incorporated emission models to predict the GHG impact of certain technologies, allowing credits to be generated against an overall standard on this basis. These emission models addressed a variety of different vehicle types given that the medium- and heavy-duty sector is almost entirely commercial and that vehicles are primarily designed to reflect the work that will be required of them. While Chemours recognizes that the situation facing medium- and heavy-duty vehicles is different from LDVs, A/C credits could similarly be integrated into the GEM or otherwise be allowed to generate credits. In doing so, EPA could replicate the success of this approach in the LDV sector and help to incentivize the adopting of alternative refrigerants in medium- and heavy-duty vehicles with much lower GWP values than HFC-134a which remains widely in use today.

EPA Should Proceed Under AIM Act to "Reinstate" Significant New Alternative Program ("SNAP") Rules 20 and 21. Chemours recognizes that this proposed rule is being proposed under the authority of CAA section 202 and that EPA has not proposed to take any action under other authorities available to the Agency to address either ozone-depleting substances or air pollutants that have been considered to endanger public health and welfare due to their effect on climate change.

In conjunction with this rulemaking, however, EPA should actively consider petitions that have been filed with the Agency pursuant to CAA section 112 and/or with respect to new legal authority contained in the AIM Act. Such petitions request that EPA “de-list” HFC-134a in certain end uses, making it unavailable for use in new equipment.

As noted previously, SNAP Rule 20 provided for the de-listing of HFC-134a in newly manufactured motor vehicles, beginning with MY 2021. This rule was partially vacated by the D.C. Circuit Court’s decision in Mexichem I, but the Agency has not proceeded to further consider other rulemaking in this area, even while EPA’s previous rule (to not proceed with any action under SNAP Rules 20 and 21) was also vacated.74 Whether or not EPA has sufficient authority under CAA section 112 to proceed, additional petitions have been filed pursuant to EPA’s authority under the AIM Act to effectuate the same result. Thus, should the Agency believe that it is precluded from acting under CAA section 112, EPA would have additional recourse under the new, independent authority granted by the AIM Act.

EPA should additionally promptly consider pending SNAP petitions with the Office of Stratospheric Ozone Protection that would allow for the use of alternative refrigerants in medium duty, heavy-duty and off-road sectors. As noted above, EPA has not addressed HFC-134a in these sectors even while proceeding to address HFCs in the LDV sector. As a result, medium- and heavy-duty vehicles are still using HFC134a as the primary refrigerant for cabin comfort cooling. Taking further action in this area -- under whatever authority is available to EPA -- will not only help speed the transition away from high-GWP refrigerants but provide needed certainty for equipment manufacturers to plan for, design and test new equipment. [EPA-HQ-OAR-2021-0208-0232-A1, p. 14-17]

Conclusion. As indicated in the comments above, Chemours supports EPA’s proposed retention of A/C credits for LDVs and urges EPA to include these provisions, as proposed, in the final rule. Taking such action is consistent with the Agency’s authority under the CAA, the Agency’s long-standing implementation of the LDV program and accounts for the large beneficial impact of alternative refrigerants in addressing climate change. When EPA originally assessed the impact of A/C program credits in 2008, the Agency projected that an air conditioning refrigerant leakage standard could yield 50 million metric ton CO2-equivalent reductions in 2030, increasing to 70 million metric tons CO2-equivalent in 2040.78 These benefits should be fully realized.

At the same time, Chemours believes that EPA can make improvements to the operation of the A/C credit program. In specific, as noted above, there is considerable information which would indicate that the transition to electric vehicle technology may occur at a much faster rate than EPA is projecting. As a consequence, concurrent incentives for the use of alternative refrigerants such as HFO-1234yf may be diminished, delaying the transition away from HFC-134a or potentially creating some incentive to “switch back” to HFC-134a. EPA should reanalyze how it assesses the relative value of improvements in vehicle GHG performance, including PHEV and EV multipliers and imputed tailpipe emissions, so as to not misalign allowed credits with the goal of achieving broadly sustainable reductions in GHG emissions from the LDV fleet.

EPA should further consider other actions where the transition to alternative refrigerants can be accomplished, most notably through implementation of the CAA section 612 SNAP program and the newly-enacted AIM Act. EPA should promptly consider alternatives to "de-list" HFC-134a in MVAC systems in all on-road and non-road vehicles. And the Agency should consider additional rulemaking to address HFC-134a emissions from medium- and heavy-duty vehicles. The latter action could be accomplished either in the context of a follow-on rulemaking to the Phase 2 Rule or a separate regulatory vehicle amending the Phase 2 Rule. [EPA-HQ-OAR-2021-0208-0232-A1, p. 17-18]

10 These comments will generally refer to "leakage credits" pursuant to 40 C.F.R. §86.1867-12 and efficiency credits pursuant to §86.188-12 collectively as "A/C" credits.

25 77 Fed. Reg. at 62,649. In the 2012 rule, EPA kept the standards for MY 2017 through MY 2025 "generally consistent" with those promulgated in the 2010 rule, but explained that "EPA's GHG standard is more stringent in part due to its assumptions about manufacturers' use of air conditioning leakage/refrigerant replacement credits, which will result in reduced emissions of HFCs." Id. at 62,654.

26 As noted above, EPA retained the A/C leakage credits in the 2012 rule for MY 2017 through MY 2025 LDV GHG standards. 77 Fed. Reg. at 62,628 (Oct. 15, 2012). The SAFE Rule, after initially proposing to eliminate the credits, made no change in the amount of EPA A/C credits available. 84 Fed. Reg. at 24,178 (Apr. 30, 2020). Given the lesser stringency for the SAFE Rule standards in MY 2021-2025 versus the standards promulgated in the 2012, however, the relative percentages of A/C credits also decreased for the years in which the revised standards were in effect. EPA, however, is proposing to effectively restore the stringency of the 2012 LDV standards by 2025 as well as retaining the total allowable adjustment for A/C credits (i.e., 18.8 g/mile for cars and 24.4 g/mile for trucks). 86 Fed. Reg. at 43,748, n. 50.

30 Id. at 62,630. It should be noted that these standards were considered to be "augural" since NHTSA lacks authority to promulgate standards for more than 5 MYs, or for the MY 2022-2025 period covered by EPA rules.

33 Id. at 24,188. EPA and NHTSA also retained the same annual percentage increase in the stringency of the standards (1.5%) albeit EPA's calculated g/mile standard was more stringent to account for the "offset" represented by the effects of using alternative refrigerants and reducing leakage.

34 As noted in EPA's initial 2010 rule, the "A/C Leakage Credits that will be available will be a function of the GWP of the alternative refrigerant, with the largest credits being available for refrigerants with GWPs at or approaching a value of 1." 75 Fed. Reg. at 25,427. EPA has used the GWPs consistent with the 100-year time frame values as expressed in the IPPC AR4 Report. See 77 Fed. Reg. at 62,667, n. 107.

35 77 Fed. Reg. at 62,726. EPA has indicated, however, that it has attempted to derive "conservative" estimates of the resulting emission reductions from such off-cycle calculations. Id.

36 For example, some credits are averaged among many different vehicle types. EPA has included a cap on such credits due to "the uncertainty inherent in using limited data and modeling as the basis of a single credit value for either cars or trucks." 88 Fed. Reg. at 43,762.

40 For example, while EPA promulgated standards to address methane emissions from oil and natural gas production facilities, the Agency defined the "air pollutant" being regulated as the same mix of six GHGs. EPA explained that "this is the same pollutant that is regulated by this rule. However, the standards of performance adopted in the present rulemaking address only one constituent gas of this air pollution: Methane." 81 Fed. Reg. at 35,843 (June 3, 2016). Similarly, when EPA promulgated the first GHG standards to apply to airplanes and aircraft engines, EPA first made an endangerment finding concerning the same six well-mixed GHGs and indicating that it was regulating "the air pollutant that is the aggregate of six well-mixed GHGs" while noting that "[o]nly two of the six well-mixed GHGs – CO2 and N2O have no-zero emissions for total civil subsonic airplanes and U.S. covered airplanes." 86 Fed. Reg. 2,136 2,139 (Jan. 11, 2021).

46 Over a decade ago, EPA observed that "[CAA] section 202 HFC emissions are the largest source of HFC emissions in the United States, that these emissions increased by 274% from 1995 to 2006, and that section 202 sources are also the largest source of emissions of high [global warming potential] gases (i.e., HFCs, PFCs or SF6) in the U.S." 73 Fed. Reg. 44,354, 44,431 (July 30, 2008). Overall, EPA noted that emissions of HFCs from motor vehicles represented the second-highest amount of GHGs emitted from vehicles. Such emissions were 40 times larger than methane emissions from vehicles and over 2 times larger than N2O emissions." Id. at 44,505.

70 Chemours is aware that the structure of the medium- and heavy-duty vehicle industry is different from that of LDV manufacturing. As opposed to LDVs, many different companies may be involved in the manufacture of a medium- or heavy-duty vehicle, including independent vendors and "body builders." But this should not preclude address A/C credits given that EPA has already addressed such issues during the development of the GEM model and the system for certifying medium- and heavy-duty vehicles, which assesses and provides "drop down" menu values for various equipment configurations.

Commenter: DENSO International America, Inc. (DENSO)

A/C Efficiency Credit Program. DENSO supports the A/C efficiency credit program and appreciates EPA continuing the program. We would like to request EPA to propose adjustments to the A/C efficiency credit program similar EPA's proposal for the off-cycle credit program, including increasing the cap on the A/C efficiency program credits.

We ask the agencies to reconsider the application of A/C efficiency credit cap to A/C efficiency technologies approved through the off-cycle petition process. New innovative A/C efficiency technologies continue to be developed. There can be situations where the technology provides additive benefits and incremental improvements to the GHG performance of a vehicle. Therefore, we recommend the agency discontinue counting air conditioning (A/C) efficiency credits toward the cap on A/C efficiency credits if earned through the off-cycle petition process.

Technologies that are additive to the technologies in the A/C efficiency and off-cycle menu (i.e., there is no double-counting of benefits) can be empirically verified to confirm the real-world GHG emissions benefit by testing an A/C system or vehicle which includes A/C efficiency and listed off-cycle technologies at the cap limit and then testing again by adding a non-listed, off-cycle technology to demonstrate the additional, real-world GHG emissions reduction. One benefit of the credits program, and the off-cycle non-listed provision, is to encourage the implementation of technology that can provide incremental improvements in actual GHG emissions.

Counting A/C efficiency technology credits obtained through the off-cycle petition process toward the A/C efficiency credit cap significantly stifles the development of such important innovative technologies. Suppliers will have little justification to continue investing in and developing new A/C efficiency technologies and leave manufacturers with little or no incentive to continue to deploy A/C efficiency technologies. We ask EPA to carefully reconsider the proposed implementation of the A/C efficiency credit cap in conjunction with the off-cycle credit opportunities available for new and innovative A/C efficiency technologies.

Support for Increasing A/C Efficiency Cap. Within previous NPRM’s, as well as comments for credit applications, auto industry members have stated concerns with the A/C efficiency menu and the A/C efficiency credit cap. Similarly, there have been concerns raised regarding the off-cycle credit menu/cap.

Within the current proposal, the EPA has mentioned that they are proposing adjustments to the off-cycle credit program (i.e., increased credit cap), however the EPA also states that they plan to leave the A/C efficiency credit program as it is.1 EPA describes several reasons for considering an increase in the off-cycle technology credit cap. Similar reasons exist for increasing the A/C efficiency credit cap.

Technology Synergies: As the EPA mentions in the NPRM regarding the off-cycle credit menu, there has historically been some uncertainty in off-cycle menu technology credit values. The EPA has stated this same concern in the past for A/C efficiency menu items, as well as uncertainty to how these technologies may behave when combined. This lack of understanding has led to hesitancy in increasing the credit cap or allowing OEMs to get credit beyond the A/C efficiency credit cap.

Limited Headroom: The EPA mentions another reason for proposing to increase off-cycle credit cap being that the headroom under the cap has closed significantly for some OEMs. Within the A/C efficiency credit program, most OEMs have already reached the cap and are no longer able to receive credit for improving their A/C systems further, which halts any further potential improvements to the A/C system.

Menu Additions: The EPA also mentions expanding the off-cycle credit menu to include highefficiency alternator creates additional difficulty for OEMs to get credit due to limitations of the credit cap. The A/C efficiency menu has also been expanded (i.e., high efficiency compressor).

Non-A/C Technologies Counting Towards A/C Efficiency Cap: In addition to the A/C efficiency menu expanding, the EPA has seemed to take the position that any technology that touches the A/C system, will be counted against the A/C efficiency cap, whether its efficiency improvement can be recognized on the A/C system or not. An example of this is in recent applications for DENSO LE40 clutch technology. Even though this technology is an efficiency improvement that results in electrical savings to the vehicles, the EPA has stated that if approved, it will count against the A/C efficiency credit cap. Inclusion of such technologies leads to unintended expansion of the A/C efficiency menu.

For the reasons listed above, we request that in addition to changes to the off-cycle credit program, the EPA also considers similar changes to the A/C efficiency program by increasing the credit cap.

Furthermore, in NREL study 17TMSS-0056, the latest A/C energy consumption estimates 23.5 g/mile based on a series of simulations were performed to three vehicle platforms using various US driving patterns. Compared to 11.9 g/mile for passenger car and 17.2 g/mile for light truck, which were baseline A/C emissions impacts previously used by the agencies to determine A/C efficiency credit cap, new baseline A/C emission impact is calculated to 20.3 g/mile for passenger car and 29.3 g/mile for light truck by using the latest A/C energy consumption (23.5 g/mile). Based on the new baseline emission impact and A/C improvement possibility, 42% of which were previously used by the agencies, the increased A/C credit cap would be 8.5 g/mile for passenger car and 12.3 g/mile for light truck. Therefore, DENSO would request EPA to consider increasing A/C efficiency credit cap as supported by this study. These recommendations are explained in more detail here: [Table # can be found on p. 7 of Docket number EPA-HQ-OAR-2021-0208-0282-A1].

Off-Cycle and A/C Efficiency Credits for ZEVs. DENSO encourages EPA to explore how emissions reductions from off-cycle technologies and A/C efficiency technologies could be rewarded when used on BEVs, PHEVs and FCEVs. Many of these off-cycle and A/C efficiency technologies could help in reducing battery use and therefore lower the amount of electricity used to power the vehicle. All technologies and all powertrains should continue to improve. Consequently, technologies that reduce use of the vehicle battery (and reduce amount of battery charging needed) and therefore the electricity used to power the vehicle should be recognized in model years 2027 and beyond. [EPA-HQ-OAR-2021-0208-0282-A1, p. 5-7]

Support Low-GWP Refrigerants Credits and Other Refrigerant Leakage Credits. As a supplier committed to the environment, we support maintaining the Low Global Warming Potential (low

GWP) Refrigerant Credits and other A/C leakage credits. This credit program advances technological leadership, preserves significant technological investments, and allows vehicle manufacturers continued compliance flexibility while offering greater consumer choice. Importantly, the refrigerant leakage credits provide important compliance flexibility, as using these refrigerants is a simple and cost-effective solution to meeting the targets. The credits also provide a great incentive to voluntarily transition to next-generation refrigerant. Therefore, we support continuation of the low GWP refrigerant credits. [EPA-HQ-OAR-2021-0208-0282-A1, p. 8]

Commenter: Gentherm, Inc.

Real-World Benefits of Off-Cycle and A/C Credits. Studies by the National Renewable Energy Laboratory (NREL) and others have confirmed that off-cycle and A/C efficiency credit technologies provide real-world benefits that are not currently captured by two-cycle testing. The analysis is based on energy consumption for vehicles across the United States. We believe that off - cycle and A/C efficiency technologies are more cost effective than other currently available or proposed on-cycle technologies. It is important to note that these credits do not distort the market and do not artificially create financial benefits.

Latest EPA trends report (2020) shows a 74 gCO2/mile national fleet difference between average light vehicle two-cycle emissions (282 gCO2/mile) and adjusted real-world estimate (356 gCO2/mile) for MY2019. Per the ITB Group analysis, if we assume that 9.5 percent (27 gCO2/mile) of the average two-cycle emissions is attributed to exogenous variables like load, grade, wind, rain/snow, tire pressure, etc. that leaves on average 47g of real-world CO2 emissions due to off-cycle (A/C, thermal, electrical, powertrain and other) variables. This gap is due to off-cycle effects resulting from variation in acceleration, thermal, aerodynamic, and electrical losses. Current and future off-cycle technologies, including autonomous and predictive driving, are expected to provide benefits not contemplated in the current 10 gCO2/mile cap. Therefore, the current 10 g/mile fleet level cap is low and should be raised. Gentherm believes that the EPA proposal of a 15 g/mile off-cycle credit cap is reasonable today, but is conservative compared to the 47g real-world vs. 2- cycle gap and may need future adjustment as new technologies are developed. [EPA-HQ-OAR-2021-0208-0216-A1, p. 2]

Expand the Menu List to Add Active Climate Control Seats. Gentherm supports expanding the list of the off-cycle and A/C efficiency menu options, including adding active climate control seats. Our passenger comfort technologies have been independently proven and validated by NREL to reduce fuel consumption and vehicle CO2 emissions. Our engineers working in the United States developed these technologies with the intention of reducing fuel consumption while improving in-vehicle comfort. For example, we invested approximately $500,000 with NREL to validate the emissions benefits of our technologies. After this validation was completed by NREL, General Motors made an additional investment to prepare a submission based on our research and was awarded off-cycle credits. In addition, Hyundai and Kia have received similar approvals from the EPA, and Stellantis (FCA) has a substantially similar pending request for approval of active climate control seats. An important factor to consider in determining if a menu credit is warranted is its commercialization status. Active Climate Control Seat technology is in production for a number of auto manufacturers and other manufacturers should receive the same credit benefits to level the playing field.

Gentherm also recommends extending off-cycle and A/C efficiency technologies to medium- and heavy-duty classes 2b and 3, which utilize such technologies. Expanding the current credit program encourages commercialization of innovative and cost-efficient technologies, while also providing consumers with more choices. [EPA-HQ-OAR-2021-0208-0216-A1, p. 3-4]

Develop a Process for Adding Technologies to the Menu List. We encourage the agencies to create a process to add technologies to the credit menus. An off-cycle or A/C efficiency credit menu approval process would allow for technologies to be added to the menu list once sufficient data is available to the agencies. Although two technologies were added to the menu in the previous “SAFE” rule, more technologies could be added to the menu more rapidly.

We must encourage the development of new technologies, and we believe that the regulations should encourage new technology developments with sufficient data is available to create a menu credit. When technologies are added to the menu lists, industry compliance costs are decreased, and national fuel consumption and exhaust emissions are reduced. A difficult to change menu deters companies from innovating by making the approval more burdensome than if a credit approval menu process was available. We recommend that the agencies develop a process which allows automakers to apply for adding technologies to the menu lists and which should include public review of such submissions.

Gentherm is currently developing several energy conservation technologies. In the future emissions reductions from off-cycle technologies and A/C efficiency technologies could be credited when used on BEVs, PHEVs and FCEVs. Such a pathway will become highly relevant when EV emissions account for upstream CO2 emissions, not only the 0 grams/mile tailpipe emissions. Certain off-cycle and A/C efficiency technologies, particularly cabin heating technologies help reduce the amount of energy used to power a vehicle. Consequently, technologies that reduce EV energy consumption should be recognized when the 0 g/mi electric drive incentive is potentially eliminated after 2026. Gentherm recommends that a program be developed by the agencies to consider developing a set of EV and autonomous technology off-cycle menu credits in preparation for future rule making. [EPA-HQ-OAR-2021-0208-0216-A1, p. 4-5]

Increase Off-Cycle Thermal Control and A/C Efficiency Technology Credit Levels T

he latest estimate of average national CO2 emissions attributed to light duty vehicle air conditioning, per NREL, is 20.8 gCO2/mile for cars and 26.0 gCO2/mile for trucks1 . If the agencies deem that a A/C load reduction cap is necessary, Gentherm supports an increase and combination of the off-cycle thermal control technology and A/C efficiency caps to 14.3 gCO2/mile for cars and 18.5 gCO2/mile for trucks. This cap increase is based on new NREL A/C load estimates and preserves the original cap rationale. These calculations were made by The ITB Group using NREL data and are included in their comment submission to this docket.

The latest NREL A/C load estimates should be used to increase credit levels of certain Off-Cycle Thermal Control and A/C efficiency technologies. For example, General Motors'2 credit approval for active climate control seat was based on a study by NREL that estimated a 17 percent reduction in A/C energy consumption on average across the United States. General Motors scaled their actively cooled seat credit submission to the A/C fuel usage estimates using recognized A/C energy consumption equivalent to 13.8 and 17.2 gCO2/mile for cars and trucks from the augural standards. If one uses the latest NREL A/C national load estimates of 20.8 and 26 gCO2/mile for cars and trucks, then active seat ventilation and active climate control seat credit benefit levels would increase by approximately 51 percent as shown below. [EPA-HQ-OAR-2021-0208-0216-A1, p. 5]

For ventilated seats we propose increasing the credit levels as shown in the table below and in the NREL benefit calculations3. [Table can be found on p. 6 of Docket number EPA-HQ-OAR-2021-0208-0216-A1]

It may be appropriate for other A/C efficiency or off-cycle thermal control technologies to be scaled-up following the same methodology using the latest NREL A/C load estimates, if their credit levels are a function of vehicle A/C fuel usage.

The agencies currently place a VIN specific cap on A/C efficiency technologies and a sub-cap on off-cycle thermal control technologies which affect A/C load. Gentherm recommends that they be converted to fleet level caps for more flexibility and ease of implementation. Improved flexibility across a fleet average would reduce discounting of real-world benefits. [EPA-HQ-OAR-2021-0208-0216-A1, p. 6]

Commenter: Honeywell

We support EPA's recognition of the effectiveness of low-global warming potential (GWP) refrigerants on reducing greenhouse gas emissions and applaud the retention of the mobile air-conditioning (MAC) credits in the propose rule.

Since 2012, owing in large part to strong incentives like the MAC credit, there have been approximately 125 million vehicles built globally with HFO-1234yf (displacing high-GWP HFC-134a). This change has been responsible for a CO2-equivalent reduction in GHG emissions of over 100 million metric tons into the atmosphere – or the equivalent of globally removing 20 million high polluting (20 mpg or 11.76 L/100 Km) vehicles from service for a year.

Again, we thank EPA for retaining this sensible, cost-effective incentive for reducing HFC emissions in the proposed rule. The credit is a critically important tool to keep the transition to low-GWP substitutes on track. [EPA-HQ-OAR-2021-0208-0212-A1, p.1]

Commenter: ITB Group, Ltd. (ITB)

Real-world fuel consumption and emissions levels show that off-cycle and A/C emissions caps are too low. The agencies should recognize and incorporate the latest NREL estimate of national

A/C fuel usage and CO_2 emissions of 20.8 g CO_2 / mile for cars and 26.0 g CO_2 / mile for trucks. For the A/C efficiency technologies cap, we propose a further 1.1 g CO_2 / mile increase for high-efficiency compressor technology. To preserve the original A/C and off-cycle thermal control cap rationale using the new scaling factors referred to above, the following revised credit cap calculations have been made [Calculations can be found on p. 3 of Docket number EPA-HQ-OAR-2021-0208-0222-A1].

The agencies currently place a VIN-specific cap on A/C efficiency technologies and a sub-cap on offcycle thermal control technologies which affect A/C load. ITB recommends that they be converted to fleet-level caps for more flexibility and ease of implementation. Improved flexibility across a fleet average would reduce discounting of real-world benefits.

EPA has approved technologies that exceed the current A/C efficiency and off-cycle thermal control caps. When the caps are reached, vehicle manufacturer adoption of such technologies may artificially slow down. General Motors, for example, estimated that it would not be able to use 55% of the realworld benefit associated with its approved climate control seat technology due to the thermal control subcap1 and the use of other technologies. When the caps are met, alternative technologies may be more costly. Therefore, caps limit manufacturer and supplier investment in otherwise cost-effective off-cycle technologies with high benefits. The ITB Group analyses show that some off-cycle technologies have high benefit/cost ratios. Until the A/C efficiency and thermal control caps are revised, there is a significant risk of artificially higher fuel consumption and CO_2 emissions, if technologies with real-world benefits are not installed in vehicles. [EPA-HQ-OAR-2021-0208-0222-A1, p. 2-3]

Improvements to the Off-cycle and A/C Efficiency Credit Programs. The current off-cycle and A/C efficiency program has some limitations which form the basis for making improvements. In general, there are two types of opportunities. First, reducing compliance and approval costs will reduce unnecessary burdens without affecting program effectiveness. Second, streamlining the credit approval processes will make approval faster and timing more certain, therefore increasing the rate of development and implementation of cost-effective fuel-saving and emissions-reducing technologies. [EPA-HQ-OAR-2021-0208-0222-A1, p. 4]

Commenter: Motor & Equipment Manufacturers Association (MEMA)

MEMA Supports the A/C Efficiency Credit Program. MEMA continues to support the A/C efficiency credit program and appreciates EPA continuing the program. However, MEMA was disappointed that EPA did not propose adjustments to the A/C efficiency credit program, including increasing the cap on the A/C efficiency program credits.

EPA provides the justification that the off-cycle technologies credits cap is being increased because vehicle manufacturers are close to exceeding the cap and there have been technologies added to the off-cycle menu. Similarly, the A/C efficiency program technologies have seen significant technology advancements, many vehicle manufacturers are close to exceeding the A/C efficiency cap, and A/C efficiency technologies have been added to the menu. The A/C efficiency credits are capped at 5.0 g/mi and 7.2 g/mi for cars and trucks, respectively, in

MY2023 and later. Although this cap is based on a general estimate of synergies and interactions of these technologies, the cap justification still lacks an in-depth analysis that suggests CO2 reductions from vehicle air conditioner efficiency technologies greater than the set cap are not possible.

Consequently, there is much work to be done to improve the A/C efficiency credit program. Similar to the off-cycle technologies program, the A/C efficiency program represents real-world GHG reductions and, therefore, should not be viewed as cutting into the effective stringency of the program. MEMA looks forward to working with EPA on improving and expanding the A/C efficiency credit program in the post-2026 program.

MEMA Continues to Support the A/C Refrigerant Leakage Credit Program. MEMA supports the credits currently offered for the use of A/C refrigerant leakage credits as they stand now. This credit program advances technological leadership, preserves significant technological investments, while offering greater consumer choice. Importantly, the refrigerant leakage credits provide important compliance flexibility, because using these refrigerants is a simple and cost-effective solution to meeting the targets. The credits also provide a great incentive to voluntarily transition to next-generation refrigerants.[EPA-HQ-OAR-2021-0208-0249-A1, p. 10]

Commenter: Nissan North America, Inc.

Air Conditioning (A/C) Leakage and Efficiency and Off-Cycle Credits. Nissan supports EPA's proposal to increase the cap on menu-based credits from 10 g/mile to 15 g/mile. Nissan also supports NHTSA's proposal to maintain the A/C efficiency credit program and to increase the cap on off-cycle menu credits in a manner equivalent to the changes proposed by EPA. Additionally, Nissan supports EPA's stated position that the off-cycle credits and A/C credits do not sunset under the current program and are intended to remain a part of the program through model year 2026 and beyond. Nissan urges EPA to maintain this position and not implement any future regulatory action to sunset or phase out these credit provisions. As acknowledged by EPA in the Proposed GHG Rule, these credits are an important source of emissions reductions, which cannot be measured properly on 2-cycle testing. These credits represent concrete improvements in fuel consumption and GHG emissions that manufacturers have worked hard to achieve. Reducing or removing the credits available for such improvements would be disruptive to product planning and would discourage further innovation. EPA and NHTSA should continue to recognize these real-world achievements and should allow continued use of these credits to further incentivize increasing efficient and advanced technologies through model year 2026 and beyond. [EPA-HQ-OAR-2021-0208-0529-A1, p. 8]

Commenter: Stellantis

Additionally, when the agencies add technology to the AC efficiency menu, the cap should be increased by at least the value of the newly placed menu technology. In the case of advanced compressors, the menu credit cap should be increased for cars and trucks by 1.1 g/mi.

In particular agencies should revisit the assumptions that the AC efficiency credit cap is based upon and adjust the fuel consumption value of AC operation. The original NESCCAF, NREL and 2017 NREL studies all noted more fuel was consumed by AC system operation. These studies generally agreed with each other and suggested a higher number for fuel consumption than EPA's Phoenix Study. That Phoenix Study in fact, showed that fuel consumption due to AC system operation was half of the other two contemporary studies. The most recent NREL work concluded that the average value of AC fuel consumption is 23.5 g/mile. In addition, NREL showed that the solar thermal credits benefit from the same increase. Therefore, the agencies need to adjust the AC related menu caps to reflect this updated consumption value. See Appendix B for more details on these recommended cap increases.

Addressing these updated studies will allow increased innovation, deployment of additional GHG reducing technology in the fleet and remove the excess tons of CO2 due to AC system operation that today are being unrepresented with the artificially low menu cap. [EPA-HQ-OAR-2021-0208-0532-A1, p. 18]

AC Efficiency Program Comments. Stellantis appreciates the air-conditioning efficiency program of 40 CFR 1868-12 and feels that significant reductions in GHG emissions are both possible and still needed due to AC operation. Stellantis suggests the following discussion as an ongoing evolution to the credit program related to efficiency improvements.

The AC Efficiency Menu Cap Needs to be Increased. EPA originally populated the AC efficiency menu with technologies evaluated as part of the Improved Mobile Air Conditioning ('IMAC') studies, sponsored by SAE in a cooperative research program ('CRP'). IMAC was made up of representatives from the mobile air conditioning industry, EPA and DOE. IMAC's mission was to evaluate possible reductions in energy consumption and improve the delivery of conditioned air to the occupants.

Vehicle level testing was performed using a baseline system and an improved system. The improved system consisted of technologies that we see on the AC efficiency menu today. The CRP showed in their final report that a mix of technologies demonstrated a better than 36% improvement in fuel consumption. Based upon those results, the agencies developed the AC efficiency menu with the technologies evaluated by the CRP. Individual technologies were scaled to a credit level based on the relative improvement that the technology showed. The agencies established that a 40% reduction in fuel consumption due to these technologies was possible, which is similar to the IMAC study conclusion.

The agencies then estimated that the fuel required to operate a baseline AC system was '14.3 g/mi per vehicle CO2-equivalent impact due to AC use (where 30% of the vehicle fleet is equipped with automatic AC controls, and 70% of the fleet is equipped with manual controls) as contained in the Final Rulemaking to Establish Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards51 what is known as the Phoenix Study.' While the Phoenix Study is somewhat useful for the information it provided, the conclusion that the amount of fuel used due to AC operation is flawed.

Phoenix Study Issues. EPA's Phoenix Study looked at the relationship between compressor engagement as a function of heat index in the RIA document EPA-420-R-10-009. Heat index is an extrapolation of temperature and humidity into one metric that was then compared with compressor engagement. EPA then extrapolated the fuel consumption data for Phoenix, a high temperature and sunny desert climate to the rest of the United States. Each extrapolation involves an error for the variable being considered. The first error is related to the extreme low humidity and high temperature bias in calculating the heat index term to other parts of the country. In Portland, Oregon and Seattle, Washington we have high humidity and medium ambient temperatures whereas in Miami, Florida we have high humidity and high temperatures much of the year.

The second error is looking at the amount of time that the compressor is engaged instead of the compressor power needed to supply air conditioning to the cabin. Compressor power and the torque on the accessory drive determine the amount of fuel expended in operating the AC system. Compressor engagement and compressor torque are both needed to determine fuel consumption due to AC operation.

The 14.3 g/mile AC impact value from the Phoenix Study can be compared to two contemporary studies of emissions due to AC system operation. The Northeast States Center for a Clean Air Future ('NESCCAF') study52 and the National Renewable Energy Laboratory-Office of Atmospheric Programs ('NREL-OAP')53 study performed for the California Air Resources Board both show that AC fuel consumption is higher than the Phoenix Study value. EPA acknowledges that the emission from their study is half that of the other two studies as reported in the RIA.54

Stellantis believes that the agencies should consider the work performed by NREL in 2017 on this subject. The NREL study methodology looks at the factors affecting AC system fuel consumption at the county level which is an improvement over earlier studies. This method accounts for climate and population variation across the country using vehicle registration data, custom vehicle miles traveled based on MOVES data and technology types in the vehicle fleet giving a more granular picture of AC fuel consumption across the country.

NREL reports that the amount of fuel consumed to operate the AC system results in emissions on average of 23.5 g/mile. This is a staggering difference and explains why the Denso SAS compressor, on the AC 17 test cycle, emitted 1.1 g/mi less than what EPA states is possible based on their study.

Stellantis asks that the agencies consider the NREL value of 23.5 g/mile reported at SAE's TMSS Conference in 2017. Using this value and applying the original reduction of 40% fuel saved by improved mobile AC systems would produce new and appropriate higher AC efficiency menu caps.

The new menu cap would become 8.2 g/mile for passenger cars and 11.8 g/mile for light-duty trucks. Stellantis and other OEMs agree that these values are correct and have provided evidence to such in discussions with the agencies. These values are also aligned with the earlier

NESCCAF and NREL studies cited in the original rulemaking that established the AC credit menu.

The Effect of an Artificially Low Menu Cap. Higher GHG emissions due to AC system operation are the result of the artificially low AC efficiency menu cap. Industry has proven the benefit of the Denso SAS compressor such that the agencies have added the technology to the menu but then constrained its benefit under the menu cap of 5.0 g/mile for passenger cars and 7.2 g/mile for light-duty trucks.

The bench testing that was employed to determine the compressor's benefit was confirmed with vehicle level testing that confirmed the benefit. Stellantis performed their vehicle level testing on a Dodge Charger that was equipped with all of the AC efficiency technologies allowed by the menu at 5.0 g/mi. The vehicle level test confirmed the SAS compressor improvement over and above what EPA believes is possible for this vehicle. Other OEMs tested similarly with vehicles similarly contented and obtained the same result.

This level of the cap, which is constraining the benefit of the technology, is likely the reason why the implementation of this advance AC compressor is not widespread. Many OEMs have already contented their vehicle such that they are close to the menu cap. Adding this technology would offer little to no benefit from the agencies. Other technologies submitted on alternative methodology applications and granted credit under the AC efficiency menu are similarly affected.

Electrical Load Reduction Credits Belong on the Off-Cycle Credit Menu. Mobile AC systems are made up of many different components, some of which are electrical in nature. The power to operate these components can be significant such as in the cases of the HVAC blower, the condenser fan and the AC compressor clutch. PWM operation of the HVAC blower is an AC menu credit today because of real world emissions savings over blower operation in the baseline system. The original resistor based elements of blower speed control of the baseline system had to cooled by the AC system to continue operation. The additional cooling power that the PWM system does not need to keep the resistive elements cool is the benefit that put the PWM control on the efficiency menu. The AC menu credit for PWM control is based upon the additional wasted energy it took to cool the resistance based technology.

Similarly, there are other improvements that can be accomplished in the HVAC unit. Brushless blower motors eliminate the contact resistance found in older systems. The energy saved in this case is purely electrical in nature and the benefit is seen in towards the battery and the alternator, not in the AC system. Substituting a brushed motor with a brushless blower into the AC system will not impact AC related emissions. It will however have a great impact on power in the electrical system.

The Denso LE40 High Efficiency Clutch is another electrical device that is used in the AC system. The Denso clutch lowers the amount of power needed to keep the clutch fully engaged when compared to the baseline technology. The power saved with this device is measured at the battery and alternator, not in emissions due to AC operation.

The agencies seem to be concluding that these technologies, because they are AC related, should be added to and capped under the AC menu. Stellantis strongly objects since these benefits accrue to the charging system, similar to the benefits of the high efficiency alternator on the off-cycle menu. The offcycle menu is the correct area for these two technologies. [EPA-HQ-OAR-2021-0208-0532-A1, pp. 42-45]

Commenter: Union of Concerned Scientists (UCS)

EPA's assessment of the benefits of thermal control technologies does not recognize the simultaneous improvements in the efficiency of air-conditioning systems. Therefore, it inherently overstates the benefits of thermal control technologies, whose benefit is related to the reduced usage of the air-conditioning system—if the air-conditioning system has been improved, the emissions associated with the use of that system are reduced. EPA should revise the process for awarding thermal control credits to reflect a manufacturer's improvement in A/C efficiency.

In MY2019, manufacturers were credited with improvements to A/C efficiency of 4.0 g/mi for cars and 6.1 g/mi for trucks; this is compared to baseline emissions of 11.9 g/mi for cars and 17.2 g/mi for trucks, a reduction in emissions of more than one-third. The credit for thermal controls technology should scale accordingly. [EPA-HQ-OAR-2021-0208-0277-A1, p.30]

EPA Response

As discussed in Section II.B.4 of the preamble, EPA is not changing existing program opportunities to earn compliance credits toward the fleet-wide average CO_2 standards for improvements to air conditioning systems. The current A/C credits program provides credits for improvements to address both hydrofluorocarbon (HFC) refrigerant direct losses (i.e., system "leakage") and indirect CO_2 emissions related to the increased load on the engine (also referred to as "A/C efficiency" related emissions). We did not propose to change any of these aspects of the existing program because they continue to function as intended and we do not presently believe changes are needed in the context of standards for MY 2023-2026.

EPA received several comments suggesting potential changes to the A/C credits program. Also, Chemours encourages EPA to take additional actions to address impacts of A/C refrigerants through other statutory authorities, including the SNAP program and under the AIM act. EPA did not propose and did not request comment on these suggestions, and for this reason, these comments regarding other program elements are outside the scope of this rule. However, EPA may further consider commenter recommendations, as well as other potential program changes and approaches, as part of a future rulemaking.

10. Proposed on-Board Diagnostics (OBD) Provisions

Commenters Included in this Section

Alliance For Automotive Innovation
Manufacturers of Emission Controls Association (MECA)
Volkswagen Group of America, Inc. (Volkswagen)

Commenter: Alliance For Automotive Innovation

Auto Innovators supports the proposed change to allow EPA approval of on-board diagnostic ("OBD") systems that meet CARB OBD requirements newer than the 2013 version referenced in current EPA regulations.

EPA proposes to allow certification of OBD systems that meet CARB OBD requirements newer than 2013.112 Auto Innovators supports this update to maintain alignment between CARB and EPA regulations in this highly technical area. [EPA-HQ-OAR-2021-0208-0571-A1, p. 36]

Commenter: Manufacturers of Emission Controls Association (MECA)

MECA supports EPA's proposal to allow manufacturers to alternatively meet EPA OBD requirements if they can show that the vehicle meets newer CARB OBD regulations. This streamlining will provide additional flexibility to manufacturers while reducing costs by producing vehicles with one OBD system (software, calibration, and hardware) for all 50 states. [EPA-HQ-OAR-2021-0208-0261-A1, p.4]

Commenter: Volkswagen Group of America, Inc. (Volkswagen)

Volkswagen supports the change proposed by EPA to 86.1806-17(a) in order to account for future updates to California's OBD regulation and to promote 50 state calibration strategy. In order to help clarify what information could be helpful to in demonstrating that a newer OBD system approved by CARB still meets the intent of the 2013 version, Volkswagen suggests EPA consider issuing future guidance following updates to CARBs OBD regulation. Alternatively, EPA could include comments regarding intent in EPA's subsequent waiver review/approval of modifications to CARB OBD regulatory updates. Either approach could be applicable only to the extent that certain provisions within a future CARB OBD update appear to move beyond the 2013 version. [EPA-HQ-OAR-2021-0208-0237-A1, p.14]

EPA Response

EPA appreciates the commenters' support for the OBD revisions. Regarding the comments suggesting that EPA provide guidance for future CARB updates to the OBD provisions, EPA appreciates commenters' suggestions for how such guidance could be provided and will consider this issue further in the event of future OBD program updates. EPA notes that manufacturers may submit a letter in their application for certification stating the version of CARB OBD the manufacturer intends to use and requesting EPA approval to use that version. 40 CFR. 86.1806-17(c).

11. Natural Gas Vehicle Incentives

Commenter: American Council for an Energy-Efficient Economy (ACEEE)

EPA proposes removing the 0.15 multiplier for natural gas vehicles. ACEEE agrees supports this move. This multiplier does not accurately reflect the emissions of such vehicles. EPA should continue to focus on encouraging the adoption of light-duty zero emission technology, while reducing emissions from petroleum- fueled vehicles. [EPA-HQ-OAR-2021-0208-0251-A1, p.9]

Remove natural gas vehicle multipliers [EPA-HQ-OAR-2021-0208-0251-A1, p. 15]

Commenter: California Air Resources Board (CARB)

[S]hould not provide any multiplier for natural-gas vehicles (NGVs) for any years; [EPA-HQ-OAR-2021-0208-0643-A6, p.7]

CARB agrees that the multiplier for NGVs should be eliminated. These vehicles have not been produced in this sector for some time and the multiplier has not been used. More importantly, these vehicles directly emit pollutants. A production multiplier is unwarranted. [EPA-HQ-OAR-2021-0208-0643-A6, p. 37]

Commenter: Center for Biological Diversity, et al.

EPA should not renew the natural gas vehicle credit program. EPA's determination to end the natural gas vehicle multiplier (at two vehicles for every one built) first applied with the 2012 rulemaking, Proposal, 86 Fed. Reg. at 43,760, is appropriate and well justified. As discussed above, phantom credits in general are no longer needed to incentivize the production of zero-or near-zero vehicles. Natural gas vehicles are not such vehicles, and, as EPA observes, phantom incentives for them does not constitute a pathway for significant greenhouse gas reductions. Id. Commenters also agree that EPA's Proposal to end these multipliers will have no impact on manufacturers, as none are contained in their production plans. Id. Commenters further agree that EPA's Proposal to correct a scrivener's error, aligning EPA's preamble discussion rejecting a requested additional 0.15 multiplier factor in the 2020 Final Rule with the regulatory text, is reasonable, appropriate and well justified. Id. at 43,766. [EPA-HQ-OAR-2021-0208-0651-A1, p. 69]

Commenter: Center for Climate and Energy Solutions (C2ES)

Natural Gas Vehicle Multipliers. C2ES supports EPA's proposed approach to eliminate the multiplier for natural gas vehicles altogether for MYs 2023–26. While they produce fewer emissions than conventional gas and diesel vehicles, natural gas vehicles are not zero-emission vehicles. Incentives under the greenhouse gas emissions reduction program should support decarbonization, rather than fuel switching to another fossil fuel. Additionally, the 2020 EPA Automotive Trends report found no light-duty compressed natural gas vehicles available for sale from vehicle manufacturers. 21 In light-duty applications, this technology is not applied at a significant enough volume to benefit from an additional incentive, including a multiplier. [EPA-HQ-OAR-2021-0208-0287-A1, p.6]

Commenter: Ingevity Corporation

Ingevity believes that it is appropriate to maintain the 0.15 emissions factor for dedicated and dual fuel NGVs for purposes of GHG Compliance and CAFE Compliance in 40 CFR §600.510-12 subsections (c)(2)(vi), (c)(2)(vii), (j)(2)(v), and (j)(2)(vii)(A) for Model Years 2021 and later. If vehicle multipliers remain included for EVs and PHEVs, equivalent multipliers for dedicated and dual fuel NGVs should be retained. Our detailed comments supporting these positions are in Sections I-III below. Our previous detailed comments and meeting materials in dockets NHTSA-2018-0067 and EPA-HQ-OAR-2018-0283 should be considered substantive comments and part of the Administrative Record1. These comments are attached in the Appendix.

Ingevity requests a full and thorough response from EPA to the following key points related to NGVs which were not sufficiently addressed in the NPRM or 2020 SAFE Rule. The final rulemaking should address our comments outlined in (1) – (3) below, with additional details provided in Sections I – III.

(1) EPA's proposed Natural Gas Vehicles Technical Amendment to remove the 0.15 emissions factor is a substantive change to the regulatory text which should be addressed through notice and comment rulemaking. Under the Administrative Procedure Act, 5 U.S.C. § 553(c), EPA has a clear mandate to give interested parties such as Ingevity the opportunity to participate in this rulemaking and to consider the comments received concerning this clear change in a substantive rule. A more detailed comment is provided in Section I below.

(2) EPA has not provided a detailed rationale for removal of the 0.15 factor for GHG compliance in the 2020 SAFE Rule and this NPRM. EPA's conclusions on removing incentives for NGVs are arbitrary, inconsistent with prior views, and fail to consider all the current facts and those raised by commenters in the SAFE Rule. These facts include:

a. Federally certified dual fuel ANG vehicles are available for purchase today, and a growing number of U.S. natural gas utilities and commercial stakeholders are investing in ANG equipped vehicles, including SoCalGas, Atlanta Gas Light, Ozinga Energy and the City of Orlando. Ingevity was recently awarded an Alternative Fuel Incentive Grant (‘AFIG’) by the Commonwealth of PA Department of Environmental Protection. This grant was a 28 vehicle award for which fleet participants included National Fuels, PGW, Peoples Gas, NiSource/Columbia Gas, UGI, Range Resources, Gateway Engineers and others.

b. As discussed in Section II.B, the Alternative Motor Fuels Act of 1988 shows that Congress intended to provide incentives for NGVs to reduce GHG emissions and EPA has not acknowledged or commented on this fact.

c. As discussed in Section II.C, EPA maintains a narrow ‘tailpipe only’ view of GHG emissions, which does not appropriately account for the full lifecycle GHG emissions, where data exist showing that NGVs fueled with RNG provides significant GHG reduction benefits. From a tailpipe perspective, dual-fueled NGVs on the market today can meet and exceed the emission reduction targets proposed in this NPRM. EPA continues to avoid consideration of full life-cycle analyses which show NGVs fueled by RNG have significantly lower GHG emissions than a BEV, that the RFS is successfully causing large volumes of RNG to be used as fuel for NGVs, and the GHG emissions reductions for a NGV can be achieved at a lower cost than for a BEV.

d. As discussed in Section II.D, EPA is inconsistent in their view of RNG vs. renewable electricity when determining which vehicle technologies and alternative fuels should be incentivized. EPA has not considered recent data showing RNG use has significantly increased and has now become the dominant natural gas fuel for transportation in the U.S. For example, in 2020, 92% of natural gas used in transportation fuel in California was RNG, with a carbon negative fuel footprint.

(3) EPA’s removal of the 0.15 emission factor will have significant impacts on the future NGV industry for light-duty vehicles. Because of the stringency of the proposed GHG emission standards, in addition to technology changes, the OEMs will need to consider regulatory compliance incentives. The removal of the 0.15 emission factor for dual fuel NGVs will disincentivize the OEMs from investing in and marketing dual fuel NGVs (especially considering the incentives for electric vehicles) and thus have the impact of precluding NGVs from entering the light-duty market. This is counter to the basic intent of the regulation since NGVs are an affordable technology which can meet and exceed the GHG emission reduction targets proposed by EPA in the NPRM. This restricts consumer choice and creates large barriers for innovative GHG emissions reductions technologies from entering the market.

For NGVs to fill their role in addressing energy security and environmental concerns, certain changes are needed to the current regulatory program. These regulatory changes will help to promote commercialization of NGV technology by providing OEMs attractive and economically reasonable compliance incentives. These same regulatory incentives are already in place for BEVs and PHEVs, and the changes will help undo technological biases in the current rules.

ANG technology allows vehicles to be refueled using an affordable and reliable low-pressure natural gas refueling appliance. ANG allows for a distributed refueling network at users’ homes and businesses, just like electrical recharging equipment has been installed for PHEVs over the last several years. To extend vehicle range, in a manner similar to PHEVs, a dual fuel gasoline/ANG vehicle is the current configuration. The ANG vehicle platform enables light-duty truck fleets to cost effectively utilize RNG as a long-term fuel solution. RNG is the only immediate opportunity for light-duty vehicles to cost effectively achieve a near zero or negative carbon intensity footprint across the full vehicle lifecycle. Even though ANG is a young technology not yet adopted by OEMs, it is a commercially and economically viable solution available now. More than enough information is available to ascertain how changes in this round of rulemaking would affect vehicle design decisions through the 2026 model year. Manufacturers could produce an ANG NGV at a lower cost than an EV and could use up-fitters to meet customer demand at the current monthly sales rates for EVs. But they will do this only if the NGVs can produce attractive and economically reasonable compliance incentives in both the GHG and CAFE programs.

We believe it is appropriate to maintain the 0.15 emissions multiplier for dedicated and dual-fuel NGVs for CAFE and GHG compliance calculations so that NGVs can generate credits in both the CAFE and GHG programs. This not only makes the regulations more fuel and technology neutral as has been EPA policy for decades for other pollutants, but also provides manufacturers an additional compliance pathway for meeting the fuel economy and GHG reduction goals of the NPRM. It also gives consumers more choice. In today's competitive global vehicle market, automakers choose to incorporate alternative fuel technology into their product lines based in large part on regulatory provisions which enable those technologies to generate compliance credits in both the CAFE and GHG programs.

Detailed Comment on EPA's Natural Gas Vehicles Technical Amendment. We believe EPA's Proposed Natural Gas Vehicles Technical Amendment is not a 'clerical error'2. This correction does have significant impacts and should be addressed through notice and comment rulemaking.

In the NPRM, EPA states it 'is proposing narrow technical amendments to its regulations' to correct an 'inadvertent clerical error'2. EPA also stated they are not 'revisiting or reopening its decision regarding the 0.15 factor'2. EPA's proposed technical amendment is to remove the option for NGVs to use the 0.15 emission multiplier factor for MY 2022 – 2026 for purposes of GHG Compliance in 40 CFR § 600.510-12 subsection (j)(2)(v) and (j)(2)(vii)(A). EPA states that 'there are no significant impact associated with the correction of this clerical error'2.

Ingevity disagrees with the characterization of this proposed technical amendment as an action to correct an 'inadvertent clerical error', the statement that EPA is not 'revisiting or reopening its decision regarding the 0.15 factor', and EPA's characterization that 'there are no significant impact associated with the correction of this clerical error'.

First, Ingevity does not agree with EPA's characterization of the inclusion of the 0.15 emissions multiplier for NGVs within the SAFE Rule regulatory text as an 'inadvertent clerical error'. There is an inconsistency between the preamble and regulatory text. The differences are significant and substantive and cannot be explained by any reasonable definition as being caused by a 'clerical error'.

Second, this change would not qualify as a technical correction or a technical amendment. Any technical correction is published before the rule becomes effective, otherwise a change is termed a technical amendment. A technical amendment is published on the presumption that it is minor and non-controversial in nature. Even knowing the previous comments and perspectives on this issue, EPA made no effort to contact Ingevity or other commenters about this change and instead is characterizing this action as a technical amendment with no significant impact. Contrary to EPA's view, this change to the regulatory text is substantive, and if it is to be pursued, it should be in a notice and comment rulemaking. The regulatory text controls where there is a conflict with the preamble. Ingevity had the right to reasonably rely on the regulatory text and was not obligated to mine the preamble to find an inconsistency. The 0.15 emissions factor was the logical outgrowth of the past proposed rulemaking and directly responsive to comments received by the agencies. On a plain reading of the text in the NPRM preamble, it is an abuse of the regulatory process to propose a substantive change to the regulatory text and then state that EPA is not 'revisiting or reopening its decision regarding the 0.15 factor'. This clearly implies that comments will not be considered. Yet, under the Administrative Procedure Act, 5 U.S.C. § 553(c), EPA has a clear mandate to give interested parties such as Ingevity the opportunity to participate in this rulemaking and to consider the comments received concerning this clear change in a substantive rule. EPA/NHTSA issued a technical correction to the SAFE Rule3 in July 2020, which provided the opportunity to make this change if it truly was an error as were the other items covered in that action. However, EPA did not discuss or address the 0.15 emissions multiplier for NGVs in this July 2020 technical correction action. It is inappropriate for EPA to classify this error as a 'clerical error' now after this discrepancy between the preamble text and the regulatory text has remained for more than one year.

Third, Ingevity also disagrees that this amendment will have no significant impacts. As discussed above, the removal of the 0.15 emissions factor will have the impact of impeding the entry of dual-fuel NGVs into the light-duty market. This restricts consumer choice by preventing an alternative, affordable technology which can meet and exceed the GHG reduction targets proposed by EPA in the NPRM4. Ingevity has invested over many years significant resources in the development and commercialization of ANG technology for NGVs through both internal research and outside collaborations. Ingevity's ability to market its ANG technology as well as the integration of the use of RNG into the platform will be significantly curtailed by the EPA's proposed actions. Without NGV incentives in the framework of the GHG and CAFE programs, many of these innovative products and approaches might never be adopted.

It is Ingevity's view that the regulatory text governs over any inconsistencies with the preamble. Legal rights and obligations flow from the published regulations, not the preamble. A change to amend regulatory text, especially one that has substantive impacts, requires notice and comment rulemaking and a fair opportunity for affected parties to participate. While an agency has some flexibility to change its mind regarding a policy choice, the decision has to be rational, based on the agency's underlying authority, and made after consideration of the administrative record before the agency. This is particularly true where the prior policy engendered reliance. EPA cannot accomplish its new goals by denying affected parties the right to comment.

Detailed comments on EPA's rationale for removal of the 0.15 factor for GHG compliance. EPA has not provided a detailed rationale for removal of the 0.15 factor for GHG compliance in the 2020 SAFE Rule and this NPRM. EPA's conclusions on removing incentives for NGVs are arbitrary, inconsistent with prior views, and fail to consider all the facts raised by commenters in the SAFE Rule.

The 0.15 emissions multiplier for dedicated and dual fuel NGVs for purposes of GHG Compliance in 40 CFR § 600.510-12 subsection (j)(2)(v) and (j)(2)(vii)(A) for Model Years 2021 and later should remain in the regulatory text based on the following points which are discussed further below:

EPA's view in the NPRM that NGVs are not a pathway for significant GHG reductions is arbitrary, inconsistent with prior views, and fails to consider all the facts raised by commenters in the SAFE Rule.

The Alternative Motor Fuels Act of 1988 shows that Congress intended to provide incentives for NGVs to reduce GHG emissions and EPA has not acknowledged or commented on this fact.

EPA maintains a narrow 'tailpipe only' view of GHG emissions, which does not appropriately account for the full lifecycle GHG emissions, where data exists showing that NGVs fueled with alternative fuels provide significant GHG reduction benefits.

EPA is inconsistent in their view of renewable natural gas (RNG) vs. renewable electricity when determining which vehicle technologies and alternative fuels should be incentivized.

EPA's sudden reversal in this NPRM to conclude that NGVs are not a pathway for significant GHG reductions is arbitrary, inconsistent with prior views, and does not consider all data and facts raised by commenters in the SAFE Rule.

In the SAFE Rule, EPA stated 'EPA continues to believe that NGVs could be an important part of the overall light-duty vehicle fleet mix, and such offerings would enhance the diversity of potentially cleaner alternative fuels vehicles available to consumers5.' EPA cited data for a 2015 MY CNG Honda Civic which had approximately 20% lower CO2 compared to the gasoline Civic6. Citing this same data for a CNG Honda Civic, in this NPRM, EPA suddenly reverses their position on NGVs stating 'EPA does not view NGVs as a pathway for significant GHG reductions in the future7.' In the NPRM, EPA also concludes without supporting data that 'for more recent advanced internal combustion engines, the difference [GHG reduction for CNG relative to the gasoline engine] may be less than 20% due to lower emissions of the gasoline-fueled vehicles8.' With this statement, EPA arbitrarily assumes that advancements in vehicle technology to reduce GHG emissions from internal combustion engines would not be applicable to NGVs. As one example, the light-weighting of components that have reduced GHG emissions from gasoline vehicles can readily be adopted by NGVs.

Ingevity has obtained GHG emissions test data from a 2019 Ford F-150 that was converted to an ANG dual-fuel gasoline-natural gas vehicle9. This data is in the table below and shows that CO2 and GHGeq reductions of approximately 18-19% are still achievable for a NGV fueled by fossil natural gas. Further, these reductions are for the large light-duty truck segment, for which effective and economically viable alternatives to reduce GHG emissions are extremely challenging10. There are portions of the LDV market for which electric options are not being explored, due to challenges to electrify larger and heavier trucks, such as the Ford F-250. An ANG F-250 is a pathway that is commercial ready. Therefore, NGVs can provide an alternative vehicle technology and fuel solution which exceeds the GHG reduction targets proposed by EPA in this NPRM11, while also preventing significant cost increases to the consumer and providing more consumer choice. Additionally, as discussed in section II.C below, when NGVs are fueled with RNG and the full lifecycle GHG reductions are considered, NGVs offer a solution for significant GHG reductions (>90% relative to the gasoline version) while also increasing utilization of RNG.[The tables can be found on p.7 of Docket number [EPA-HQ-OAR-2021-0208-0227-A1]].

EPA states that ‘it provided a detailed rationale for its decision not to implement a 0.15 factor recommended by comments in the SAFE Rule13.’ In its comments on the 2020 SAFE Rule, Ingevity provided three major factors that warranted the reinstatement of the 0.15 emissions multiplier for NGVs, and EPA provided a limited response to only two of these factors: (1) EPA disagreed on attributing the benefits of renewable natural gas (RNG) to reducing GHG emissions for NGVs on the basis that the Renewable Fuel Standard (RFS) already incentivizes RNG. (2) EPA decided to continue to ignore upstream and full lifecycle GHG emissions for alternative technologies and fuels, thus continuing an inconsistent and favorable treatment of electric vehicles versus other GHG-reducing alternatives. Additionally, EPA has continuously avoided responding to one substantive comment: The fact that EPA has not considered the findings of Congress and the GHG reduction context of the Alternative Motor Fuels Act (AMFA) of 1988 in the 2012 rulemaking, the mid-term evaluation, the SAFE Rule, and this NPRM.

The Alternative Motor Fuels Act of 1988 shows that Congress intended to provide incentives for NGVs to reduce GHG emissions and EPA has not acknowledged or commented on this fact.

First, although EPA cites EPCA as the source of the 0.15 divisor, the source was actually AMFA (1988) that amended Title V of the Motor Vehicle Information and Cost Savings Act. A reading of Congress’ findings in AMFA14 (see Appendix) shows that Congress intended to provide incentives for natural gas vehicles not only to displace gasoline for energy security purposes, but also to reduce greenhouse gas emissions. For example, Congress found: (a) ‘the Nation’s security, economic, and environmental interests require that the Federal Government should assist clean-burning, nonpetroleum transportation fuels to reach a threshold level of commercial application and consumer acceptability at which they can successfully compete with petroleum based fuels; (b) ‘the production and use of compressed natural gas have been estimated in some studies to release less carbon dioxide than comparable quantities of petroleum-based fuels;’ (c) ‘there exists evidence that manmade pollution—the release of carbon dioxide…—may be producing a long term and substantial increase in the average temperature on Earth, a phenomenon known as global warming through the greenhouse effect;’ and (d) ‘ongoing pollution and deforestation may be contributing now to an irreversible process producing unacceptable global climate changes; necessary actions must be identified and implemented in time to protect the climate.'

The purpose of AMFA was specifically to 'encourage the production of … natural gas powered motor vehicles.' EPA acknowledged the GHG reduction potential for fossil and biomass derived natural gas in its follow-up 1991 report to Congress .15 It is our belief that had a GHG standard existed in 1988, AMFA would have provided the same 0.15 factor to Carbon Related Exhaust Emissions (or CREE) emissions as it provided for CAFE compliance purposes to encourage the production of natural gas vehicles and to reduce GHG emissions. To encourage the use of alternative fuels, including natural gas, AMFA established that for fuel economy calculations, the measured fuel economy on these alternative fuels shall be divided by 0.1516. This 0.15 factor for CAFE Compliance remains statutory for dedicated NGVs with no expiration. For dual-fueled NGVs, the statutory 0.15 factor for fuel economy expired after MY 2019, and for MY 2020 and later, NHTSA determined in the 2020 SAFE Rule that for the portion of operation that occurs on an alternative fuel, it is consistent to use the same 0.15 factor that is specified for dedicated fuel vehicles17 In NHTSA's recent NPRM, no change to this 0.15 factor for fuel economy for dual-fueled vehicles was proposed18.

EPA provided the 0.15 emissions factor for GHG compliance purposes from 2010 through 2015 model years, but removed the incentive thereafter. The removal of the 0.15 factor for GHG compliance purposes effectively nullified any benefit of the incentive for CAFE compliance purposes and eliminated the incentive's ability to result in Congress' goal to encourage the production of natural gas vehicles. This 0.15 factor should be maintained by EPA in the regulatory text for both CAFE and GHG compliance. This action is not only justified by AMFA and for the reasons stated earlier, but also because it would provide consistency between GHG compliance and CAFE compliance. In comments to the SAFE Rule and within this NPRM, EPA has provided no response to this key point on the intent of Congress with AMFA to encourage production of NGVs when discussing their decision to remove the 0.15 factor.

The table below summarizes the current application of the 0.15 factors for EVs and NGVs. We note EVs are provided the discretionary use of a 0.15 factor in the Petroleum Equivalency Factor (PEF) for fuel economy compliance and have received this since 200019. Congress mandates that DOE establish a petroleum equivalency factor (PEF), based on four elements, and that EVs utilize this PEF to equate vehicle electricity use and petroleum consumption for EPA fuel economy regulations. When DOE established the current PEF in 2000, they added a discretionary fifth element through rulemaking, which was to divide the PEF by 0.15. DOE did this so that EVs could generate the same amount of CAFE credits as NGVs and alcohol-fueled vehicles. EPA should now use this same discretion and apply the same factor to NGVs for the CAFE and GHG compliance calculation to remain consistent. [The tables can be found on p.9 of docket number [EPA-HQ-OAR-2021-0208-0227-A1]] [EPA-HQ-OAR-2021-0208-0227-A1, pp 2-9]

EPA is inconsistent in their view of Renewable Natural Gas vs. Renewable electricity when determining which vehicle technologies and fuels should be incentivized.

In the 2020 SAFE Rule, EPA argues against adding the 0.15 emissions multiplier for NGVs on the basis that RNG use cannot be assured for the full life of the vehicle. Yet, EPA is proposing to apply a 0 g/mile upstream credit to EVs through MY 2026 when 60% of U.S. electricity in 2020 was produced using fossil fuel, including fossil natural gas23, whereas the penetration of RNG into the NGV fleet is very significant today24,25. The emergence and significant growth of domestic biomethane (RNG) as a low carbon transportation fuel presents a major opportunity for reducing GHG emissions by eliminating methane emissions from the source and using this methane as a transportation fuel in lieu of petroleum-based fuel. EPA should acknowledge that RNG supply has far exceeded their expectations in 2012 and that RNG volumes continue to grow at >30% per year.

NGVAmerica and the Coalition for Renewable Natural Gas reported in 2020 that 53% of all on-road fuel used in natural gas vehicles in 2020 was RNG24. For California, 92% of all on-road fuels used in natural gas vehicles was RNG25. According to data from the California Air Resources Board (CARB) the annual average carbon intensity score of bio-CNG in that mix was -5.845 gCO2e/MJ26. Further, RNG use as a transportation fuel grew 25% over 2019 volumes, increasing 267% over the last 5 years. Therefore, we believe EPA is incorrect to assume that this trend would not continue. EPA claimed there is no assurance NGVs produced in the future would be fueled with RNG, but the data is clear that the RFS and LCFS are driving significantly large volumes of RNG to be used in the natural gas fleets. There remains incentive for NGVs to be fueled by RNG, but EPA is proposing to remove any incentive for an OEM to manufacture an NGV.

EPA has responded to comments on alternative fuels by asserting that providing credit incentives for RNG and other renewable fuels are unnecessary, because these fuels are already covered under the RFS program and emissions benefits have already been quantified 27 Basically, EPA is saying that it should not incentivize vehicles that utilize a fuel pathway covered under RFS, because of concerns about redundant incentives. However, there are two problems with EPA’s logic. First, the RFS program does not stimulate the production of alternative fuel vehicles. This is because neither the automaker nor the vehicle consumer benefits from RFS. In order for automakers to produce vehicles that use alternative fuels in the RFS program, they need to be incentivized in the GHG/CAFE program. This is demonstrated by actions needed to be taken to get dedicated and dual fuel electric vehicles into the fleet, through generous regulatory incentives by EPA supplemented by generous Federal and state tax credit policy. EPA specifically stated the purpose of providing the incentives to electric vehicles was to promote their commercialization. It should be again noted, that Congress’ intention in AMFA for providing the 0.15- divisor incentive was to encourage the production of natural gas powered motor vehicles. Second, EPA contradicts its own logic because it justified 0 g/mile credit incentives and vehicle multiplier incentives for fuel cell vehicles (FCVs), even though hydrogen, derived from biogas, has been included as a renewable fuel in the RFS program since 2014.28 EPA cannot use the RFS program as an excuse to deny emissions credits for one fuel (e.g, RNG) while ignoring the issue for another fuel (e.g., hydrogen). EPA is also currently preparing for a review of the RFS and there are discussions that EPA could grant RFS electricity credits (eRINS), which if granted, would be in direct contradiction to the views EPA has made regarding RNG and the RFS.

Rather than removing incentives for NGVs and discrediting the benefits of RNG, EPA should be encouraging the adoption of NGVs by retaining the 0.15 factor for both CAFE and GHG compliance.

Response to Comment on 2x Vehicle Multiplier Credit Removal. EPA states it is "proposing to end multipliers for NGVs in this manner because NGVs are not a near-zero emissions technology and EPA no longer believes it is appropriate to incentivize these vehicles to encourage manufacturers to introduce them in the light-duty vehicle market."

Ingevity disagrees. First, the NPRM is not a zero-emission standard, and thus it is inappropriate of EPA to judge technology incentives on the basis of this criteria. Second, all comments referenced above support maintaining incentives for NGVs. Based on these facts, it is arbitrary for EPA to remove NGV incentives, as NGVs are a demonstrated cost-effective technology to reduce GHG. NGVs deserve incentives to stimulate market adoption and EPA should be technology neutral in application of incentives.

Ingevity believes if vehicle multipliers remain included for EVs and PHEVs, equivalent multipliers for dedicated and dual-fuel NGVs should be retained. [EPA-HQ-OAR-2021-0208-0227-A1,pp 11-13]

Commenter: National Automobile Dealers Association (NADA)

NADA generally supports the multiplier incentives EPA has proposed but opposes elimination of the multiplier for natural gas fueled vehicles. Moreover, NADA supports such additional compliance flexibilities as will afford OEMs a greater ability to deliver compliant vehicles in a more cost-efficient manner, and to help incentivize the acceptance of new technology and alternative fueled vehicles in the marketplace.38 [EPA-HQ-OAR-2021-0208-0290-A1, p. 10]

38 NADA supports the comments of the Alliance of Automotive Innovation in this regard.

Commenter: NATSO, Representing America's Travel Centers and Truck Stops et al.

Renewable Natural Gas. For example, the Proposal would repeal policies that have removed barriers to natural gas certification and incentivized expanded natural gas vehicle ('NGV') production. RNG should be a meaningful component of the mix of technologies and fuels that the Proposal incentivizes. The latest data available from the California Low Carbon Fuel Standard Program indicates that the average carbon intensity of bio-CNG sold in 2020 was -5.85gC)2e/MJ.2 In the coming years, the carbon intensity of RNG is expected to be even lower as greater amounts of low-carbon dairy gas is produced and used in NGVs. [EPA-HQ-OAR-2021-0208-0570-A1, p.2]

This rulemaking represents an important opportunity to incentivize the production of vehicles that operate on RNG. The Proposal, unfortunately, misses that opportunity. Specifically, the Agency has proposed removing the multiplier incentives for NGVs that it maintains for EVs and hybrid vehicles.3 EPA indicates that 'NGVs are not a near-zero emissions technology' so they should not receive the benefits of a multiplier incentive. 4 These policies should base GHG emissions standards on science and fully account for all of the environmental benefits of NGVs. Doing so would require the Agency to provide a sufficient incentive for auto manufacturers to produce NGVs. The Proposed Rule does not do this. The Associations urge the Agency to maintain an enhanced sales multiplier for NGVs. We further encourage the Agency to expand this sales multiplier rather than to eliminate it. This will allow vehicle manufacturers to receive emissions credits based on the life-cycle emission benefits of NGVs, consistent with the amount of RNG being utilized by them.

Expanding the enhanced sales multiplier for NGVs, or at the very least maintaining it, would augment the Agency's emissions objectives. For example, commercial pickup trucks and work vans operating in rural parts of the country where extended range is essential are a viable RNG opportunity today. Even if that fleet may one day be electrified, it is likely many years in the future, and it is unnecessary to forfeit emissions improvement opportunities in the intervening years. We should be able to do both. [EPA-HQ-OAR-2021-0208-0570-A1, pp.2-3]

Commenter: NGVAmerica

In this rulemaking, the EPA has proposed rolling back regulatory improvements advanced by the previous administration that removed barriers to natural gas certification and incentivized expanded natural gas vehicle production. The regulatory incentives include to be removed include a sales multiplier for natural gas vehicles, and the continued use of the 0.15 emission s factor used for credit calculations. NGVAmerica with these comments indicates that it supports the comments submitted by Ingevity Corporation in regard to EPA's removal of the 0.15 factor. We request that EPA not eliminate these incentives but instead retain them, or alternatively establish a credit an emission credit based on the life-cycle emission benefits of natural gas vehicles, consistent with the amount of renewable natural gas being used by natural gas vehicles.

In previous comments to EPA, NGVAmerica requested that EPA use the 0.15 factor for greenhouse gas emissions to reward manufacturers for RNG use and to create an efficient method of calculating the benefit of renewable natural gas until EPA moves to adopt a well-to-wheels regulatory approach for all fuels, or until EPA is prepared to come up with a detailed assessment and emission factor specific to erx RNG use. A benefit of the 0.15 factor is that it is consistent with the fuel efficiency credits and has been used in the past in EPA's regulations. As we previously pointed out, EPA can incorporate the 0.15 factor by restoring the credit that previously existed but was never used by manufacturers in 2012 – 2015.[8] In fact, that is exactly what EPA did in its previous rulemaking on this matter but is now proposing to undo. Importantly such factors must be in place for sufficient number of years to allow automakers to incorporate them into their production plans, which typically require 2 – 3 years lead-time.

The concept of adjusting the regulatory framework to encourage low-carbon fuels is explained in much greater detail in a recent NGVA Europe study, which we urge EPA to review.[9] The purpose of this rulemaking should be to accelerate the production of vehicles that reduce carbon emissions – it should not be to favor or support one technology over others. EPA famously indicated that electric vehicles are a game changer and therefore warrant treatment that other technologies do not. But low-carbon fuels that achieve carbon neutrality or carbon negative emissions right now are also a game changer, and they too should be supported and encouraged.

Even if electric vehicles become the dominate technology in coming years, there will continue to be applications and uses that are not a good fit for electric vehicles. For example, commercial pickup trucks operated in rural and remote parts of the country requiring extended range could continue to be an excellent niche market for natural gas. There is no reason not to provide an incentive for this type of application, when the alternative is likely that fleets in these areas will continue to rely on petroleum fueled vehicles if not provided a cleaner alternative.

Expanded deployment of affordable and available low-carbon RNG trucks and work vans will meet the administration’s goal of getting more clean replacement vehicles on the road right away, impacting frontline communities sooner. And an established, mature, and varied RNG refueling infrastructure already exists coast to coast. [EPA-HQ-OAR-2021-0208-0214-A1, p.3]

[8] The previous credit was not utilized by manufactures of NGVs because the window of opportunity was too short, and most manufacturers already were oversubscribed for credits as a result of their production of E85 FFVs. [EPA-HQ-OAR-2021-0208-0214-A1, p.4]

Commenter: South Coast Air Quality Management District

While taking no position on the proposed elimination of the multiplier for natural gas vehicles, the provision is emblematic of the 2020 SAFE rule’s arbitrariness.

EPA proposes to end the natural gas vehicle multiplier after MY2022 because natural gas vehicles (NGVs) are not a near-zero emissions technology and EPA does not believe it is appropriate to encourage any introduction of natural gas vehicles in the light-duty vehicle market. 86 FR at 43761. As EPA notes, the last compressed natural gas (CNG) vehicle to be offered was discontinued after MY2015, and EPA further states it is presently unaware---already 16 months forward from the SAFE rule—of any plans to introduce new NGV models. Id. The South Coast AQMD takes no position on the proposal to end the multiplier for NGVs, chiefly because its continuation or discontinuation would not appear to have any meaningful regulatory effect. The plug-in vehicles on U.S. roadways are already an order of magnitude greater than light-duty NGV numbers, and that disparity will only grow. It bears remarking, however, that if the NGV multiplier should remain in place, it will stand as an artifact of the SAFE rule’s arbitrariness. As the proposal notes, EPA had asserted in 2020 that 'NGVs could be an important part of the overall light-duty vehicle fleet mix, and such offerings would enhance the diversity of potentially cleaner alternative fueled vehicles available to consumers.' Id. EPA now merely says it further considered the issue. But EPA would not be wrong to find its 2020 assertion was technically unsupported and unreasoned. In any event, if EPA should not retain the multiplier, EPA could still point out that natural gas vehicle advocates would have technical eligibility for crediting under plug-in hybrid electric vehicles under the existing definitions of § 86.1803-01. Although the District is not aware of any plans to market or develop vehicles that would combine CNG technology with plug-in battery technology, any such innovation should warrant the same incentivization afforded to gasoline-fueled, plug-in hybrid electric vehicles. [EPA-HQ-OAR-2021-0208-0215-A1, p.5]

EPA Response

EPA received comments supporting its proposals regarding natural gas vehicles and also comments opposing them. Environmental and health NGOs commenting on this topic provided generally supportive comments. Natural gas stakeholders provided critical comments, along with NADA. EPA did not receive any comments from auto manufacturers concerning its proposals.

EPA agree with comments supporting the removal of the multiplier incentives for NGVs. CARB comments that these vehicles have not been produced in this sector for some time and the multiplier has not been used. CARB comments "more importantly, these vehicles directly emit pollutants." CBD comments that NGVs are not zero-or near-zero vehicles and that incentives for them does not constitute a pathway for significant greenhouse gas reductions. C2ES commented incentives under the greenhouse gas emissions reduction program should support decarbonization, rather than fuel switching to another fossil fuel. EPA agrees with all of these points.

NADA commented that it supports retaining the multipliers, commenting that additional compliance flexibilities will afford OEMs a greater ability to deliver compliant vehicles in a more cost-efficient manner, and to help incentivize the acceptance of new technology and alternative fueled vehicles in the marketplace. In response, NADA seems generally supportive of more flexibility for manufacturers. However, manufacturers have shown little interest in producing NGVs for the light-duty vehicle market up to this point, even with incentives in place, so EPA does not believe removing the multipliers will have a significant impact on manufacturers. EPA believes that the lack of comments from auto manufacturers is a further indication that removing the NGV multipliers will not adversely impact manufacturers.

Ingevity, a supplier of a natural gas vehicle technology, provided particularly detailed comments. NGVAmerica commented that it supports the Ingevity comments and also provided similar comments supporting NGV incentives. These comments touch on a range of issues. Ingevity argued that EPA should include the 0.15 factor for NGVs. Regarding Ingevity's comment that the removal of the 0.15 factor from the regulations represents a substantive regulatory change that must be done through rulemaking. EPA agrees with this comment and consistent with the comment, proposed the regulatory change through this notice and comment rulemaking allowing interested stakeholders to provide comments prior to finalizing the change.

Ingevity commented that it disagrees with EPA's characterization that EPA proposed regulatory change to correct an error in the regulations. EPA continues to consider the regulatory change as one that is needed to address an error made by EPA in the regulations established in the SAFE rule. In the 2012 final rule, EPA removed the 0.15 factor from the emissions calculations for NGVs for MYs 2015 and later. In the SAFE rule, EPA sought comment generally on incentives for NGVs. EPA received comments from Ingevity and others advocating for EPA to bring back the 0.15 factor for NGVs. In response to comments provided by Ingevity and other commenters for the SAFE rule advocating for its inclusion, EPA made clear in the SAFE rule preamble that it was not revisiting its previous decision and was not including the 0.15 factor in the program for NGVs. EPA provided its rationale for its decision as part of the SAFE final rule.[29] However, in revisions made to the regulations in the SAFE rule to address an unrelated issue, EPA inadvertently revised the regulations such that the 0.15 factor would apply in MY2021 and later. As discussed in the proposal, this was clearly an error, which EPA is correcting in this final rule. In the proposed rule for this action, EPA discussed the error and proposed to correct it. EPA did not propose or seek comment on additional NGV incentives including revisiting its previous decision to not include the 0.15 factor in NGV emissions calculations. In the proposed rule, EPA described the need for a regulatory change to correct the previous error and proposed to correct it, providing an opportunity as part of a notice and comment rulemaking for interested stakeholders to provide comment.[30]

Ingevity commented that the proposed change should not be characterized as a technical amendment or correction. In response, EPA continues to believe it is a correction as described above, since EPA was not seeking to revisit its previous policy decision, but only to correct the regulations to allow the program to be implemented as intended. EPA does not disagree that the correction could have an impact on any manufacturer seeking credits under the previous regulations, but no manufacturers have done so, and EPA did not receive comments from any manufacturers noting any adverse impact of the proposed correction. Ingevity notes a July 2020 correction notice issued by NHTSA and EPA for the SAFE rule, in which EPA did not include the correction for the NGV regulations. In response, the July 2020 notice was a correction notice, not a rulemaking, for the SAFE rule, which only provided clarifications and where no substantive regulatory changes were included. EPA did not include the NGV issue because substantively revising the regulations would require a notice and comment rulemaking, even when those regulatory changes are technical corrections.

Ingevity comments that the regulatory change removing the 0.15 factor will impede the entry of dual-fuel NGVs into the market, preventing consumers from having access to this type of vehicle. EPA disagrees with this comment. Nothing in the regulations prevents manufacturers from bringing NGVs to the market to satisfy consumer demand. For example, manufacturers could offer a mix of different fueled vehicles to consumers as long as the manufacturer meets its fleet average standard obligations. Automakers may offer NGVs, but EPA is not providing an incentive for them to do so, which EPA views as fundamentally different than impeding their entry into the market. Also, in its comments, Ingevity notes that there are NGVs offered for sale by aftermarket converters. If these vehicles grow in popularity, automakers could choose to bring NGVs into the market again.

Regarding, Ingevity's comment that the regulatory text governs any inconsistency with the preamble, EPA generally agrees. Hypothetically, if a manufacturer pursued credits under the

---

[29] 84 FR 25210.
[30] 86 FR 43766.

erroneous regulations even after reading EPA's clear intent in the preamble, EPA would need to correct the regulations to ensure no manufacturers could benefit from EPA's error. However, this is only hypothetical since no manufacturers have pursued such credits and EPA is now fixing the regulatory error through this notice and comment rulemaking.

Ingevity claims that EPA did not provide a detailed rationale for the removal of the 0.15 factor for GHG compliance in the SAFE rule or the current rulemaking. In response, EPA removed the 0.15 factor from the GHG program starting in MY 2015 in the 2012 rule, and in that final rule, EPA provided its rationale for its policy decision.[31] In the SAFE rule, EPA chose not to reinstate the 0.15 factor after reviewing comments on the topic submitted in response to EPA generally seeking comment on the topic of incentives for NGVs. Again, EPA provided its rationale in response to comments in that rulemaking. In the current rule, EPA did not propose or seek comment on the 0.15 factor since it was not revisiting its prior decision, only correcting the regulations to make them consistent with its previous decision.

Ingevity provides data collected on a 2019 F150 converted to run on natural gas to demonstrate that it achieves CO2 reductions similar to that of the 2015 Honda Civic provided by EPA in the proposal as an example of the potential emissions reductions provided by NGVs. EPA appreciates the data submitted. However, the emissions reductions potential of aftermarket conversions is not central to the technical amendment proposed and finalized in this rule.

Ingevity commented that EPA has not addressed comments that EPA should consider the Alternative Motor Fuels Act (AMFA) of 1988. In response, EPA does not accept Ingevity's argument that EPA must follow AMFA due to Congressional intent in 1988. EPA's authority for the GHG program is provided by the CAA which also provides EPA with flexibility to determine the appropriate treatment of alternative fueled vehicles in the GHG program. AMFA only applies to the CAFE program. Congress amended the CAA in 1990, two years after passing AMFA. Yet, Congress did not include any provisions requiring EPA to follow or even consider AMFA's treatment of alternative fueled vehicles under CAFE. EPA does not accept that it is legally compelled to offer the 0.15 factor as an incentive under the GHG program. In fact, the GHG program does not include the treatment of alternative-fueled vehicles specified by AMFA for CAFE for other fuels as well, in addition to natural gas, including electrified vehicles and vehicles capable of running on E85. EPA has adopted these differing provisions through previous rulemakings because it has determined other approaches are more appropriate for controlling GHG emissions from vehicles than those included in AMFA for fuel economy standards. Ingevity speculates that Congress would have applied AMFA to EPA's GHG standards had they existed in 1988. However, EPA's authority for GHG standards predates AMFA and also EPA has had in place GHG standards since first adopting standards in 2010 with no Congressional action on this topic.

Ingevity comments that RFS does not incentivize the production of vehicles that use alternative fuels and that in order for automakers to produce vehicles that use alternative fuels in the RFS

[31] See 77 FR 62816 for EPA's supporting rationale.

program, they need to be incentivized in the GHG program. EPA disagrees with these comments. RFS can and does stimulate demand for alternative-fueled vehicles indirectly, as it has for natural gas heavy-duty pickups and vans, where there are no additional GHG program incentives. Manufacturers do not "need" direct incentives in the GHG program in order to produce vehicles. EPA continues to believe that RNG is appropriately incentivized through the RFS program for reasons discussed fully in the SAFE final rule.[32]

Ingevity also comments that NGVs fueled by RNG have significantly lower GHG emissions than a BEV and that the RFS is successfully causing large volumes of RNG to be used as fuel for NGVs. Along with Ingevity and NGVAmerica, NATSO also comments that EPA should adopt a full life-cycle emissions approach for these vehicles. EPA did not propose or seek comment on such as approach and is not adopting one in this rule (see sections 16 and 26 of this RTC for further comments and responses on the topic of life-cycle emissions). Further, as discussed in the SAFE rule, EPA remains concerned that there is no assurance that NGVs, once sold by the manufacturer would be fueled by RNG. Ingevity's comparison of NGVs fueled with RNG and EVs is somewhat of an apples and oranges comparison. If fossil fuel-based natural gas is used in the vehicles, the environmental benefits asserted by the commenters would not exist and the substantial vehicle incentives recommended by the commenters would result in a loss of environmental benefits. EPA does not believe it is appropriate to attribute most or all of the potential benefits of the production and use of RNG to the vehicle manufacturer. EPA's RFS already appropriately credits RNG use as compared to fossil fuel-based natural gas. Ingevity acknowledges that the RFS program has been effective in increasing RNG use in vehicles. The RFS program provides a substantial incentive for RNG production, and those incentives may lead to even lower fuel pricing and greater demand for RNG as vehicle fuel, and for NGVs in the future. EPA believes that RNG use is increasing because RFS and similar programs successfully link the vehicle operator with the fuel provider. Providing a large direct incentive to manufacturers to produce NGVs misses this important linkage. As an illustration of this point, for many years manufacturers produced FFVs capable of running on both gasoline and E85 in order to claim significant credits under CAFE but these vehicles rarely were fueled with E85 by consumers. EPA is concerned that a similar situation could potentially arise for NGVs since the consumer would have no reason to seek out RNG.

Further, we believe that it is appropriate to provide incentives for electric vehicles and fuel cell vehicles under this program but not for NGVs because of the relative efficiency of these vehicles and their GHG emission impacts if they are fueled from non-renewable sources. Both electric vehicles and fuel cell vehicles have higher efficiency engines than the internal combustion engines they replace, and thus provide GHG benefits even if they are fueled on grid-average electricity and hydrogen produced from reforming natural gas respectively. NGVs, conversely,

[32] 85 FR 25211.

provide little if any GHG benefits compared to conventional ICE vehicles if they are fueled using fossil natural gas.[33]

Ingevity comments that EPA contradicts its own logic because it justified incentives for fuel cell vehicles (FCVs), even though hydrogen, derived from biogas, has been included as a renewable fuel in the RFS program since 2014. In response, the commenter is incorrect, as the RFS program does not currently have a pathway for hydrogen used in fuel cell vehicles. Currently, the RFS program only provides credits for natural gas derived from several qualifying renewable sources. With regard to electricity, while the RFS contains a pathway for renewable electricity to generate credits, EPA has not registered any parties to generate credits for electricity used as transportation fuel until several outstanding technical and regulatory issues are addressed.

NGVAmerica comments that commercial pickup trucks operated in rural and remote parts of the country requiring extended range could continue to be an excellent niche market for natural gas vehicles fueled with RNG and that there is no reason not to provide an incentive for this type of application, when the alternative is likely that fleets in these areas will continue to rely on petroleum fueled vehicles if not provided a cleaner alternative. NATSO commented similarly on this concept. EPA is not weighing in on the potential benefits of such as approach, but again, EPA believes the RFS program is the best avenue to provide such an incentives as discussed above, because there is not a mechanism within the GHG program to ensure the vehicles, after being sold by a manufacturer, would be refueled with RNG.

Finally, EPA notes EVs and FCVs represent still developing advanced technologies with the potential for very large fleet emissions reductions in the future, whereas for natural gas vehicles, the underlying technology is essentially off the shelf technology that has been available for many years as demonstrated by NGV aftermarket conversions. This is another fundamental reason for their different treatment under the GHG program.

EPA appreciates the thoughtful comments provided by the South Coast Air Quality Management District (SCAQMD). While the commenter does not take a position regarding EPA's proposal to eliminate the multipliers for NGVs, they do note that EPA could find that it's previous decision to include them in the SAFE rule was "technically unsupported and unreasoned." Although EPA might not choose to use that phrasing, it is important to note the EPA believes there is a stronger rationale for removing the multipliers than for retaining them, as discussed above. EPA also appreciates SCAQMD comments that nothing in the regulations that prevents manufacturers from producing natural gas fueled PHEVs and claiming multiplier credits for those vehicles.

[33] Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles Phase 2; Regulatory Impact Analysis Chapter 13, USEPA and NHTSA; August 2016.

EPA agrees that hypothetically, manufacturers with an interest in producing NGVs could use this approach and access the multipliers provided for PHEVs.

12. Technologies Considered, Including Their Effectiveness and Costs

Commenter: Agortsas, George

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 189-190.]

Lastly, we have been leaders in the industrialized world in developing technologies and thriving economically from the leadership we've shown over the last 100 years.

I feel that same leadership can be leveraged and can be used to implement technologies. I believe the technologies are available. I don't believe that we have an issue of not having technologies available.

It's about adoption of those technologies as fast as possible to benefit the planet and to benefit ourselves in the end not only from air pollution but also economically.

As we made the transformation when we were industrializing, we can make the same transformation away from a carbon-based economy and we have the ability to do so. All it takes is willpower.

I look to you and our leaders to provide that willpower and provide that leadership so we can accelerate our transition out of a carbon-based economy.

Commenter: American Council for an Energy-Efficient Economy (ACEEE)

A stronger standard is achievable but also necessary to meet the administration's 2030 goals. EPA estimates that EV sales will reach 8% by MY 2026, for the proposed rule, and even less, for Alternative 2. The White House has set a goal of 50% EV market share for new vehicles by calendar year 2030 (White House 2021). Current EV sales are about 4% of new vehicles, as of MY 2020 (EPA 2020a). EPA therefore expects EV sales share to grow by about 12% per year during the proposed rule. Should EV sales follow EPA's projection, fulfilling the Whitehouse goal would require a growth in EV sales share to grow 44% per year between the end of the proposed rule and 2030. This jump in growth is unrealistic. Either EPA is underestimating the rate of EV sales growth during the rule, and therefore pushing standards that may well be achieved with no improvements in ICV emissions, or EPA is planning for a scenario where the administrations goals will be unachievable. The better approach is clearly to plan for a more gradual growth in EV market share. An even annual growth in EV market share, between MY 2020 and 2030, would suggest an annual growth rate of roughly 26% per year, with EVs having a market share of 16% in MY 2026, double EPA's projections. As discussed above over-awarding credits to EVs is not the best way to accomplish this. Setting a higher standard is. [EPA-HQ-OAR-2021-0208-0251-A1, p.13]

Commenter: California Attorney General Office, et al.

The technologies necessary to reduce GHGs from new motor vehicles already exist and, in fact, are in wide use in the market today. [EPA-HQ-OAR-2021-0208-0245-A1, p.1]

Commenter: International Council on Clean Transportation

Indeed, it appears that no technology improvements from EPA's independent evaluations – or from any comments submitted to EPA or new studies over the last 5 years – were included in the proposed rule. EPA notes that the 2016 TSD data is 'a sound and thorough examination of the available technologies.' This basis for EPA's analysis is an overly conservative assessment of the costs of the standards. We encourage the agency to note this and acknowledge the improvements that have been made, both to effectiveness and costs of compliance technologies, in the intervening years. [EPA-HQ-OAR-2021-0208-0522-A1, p. 3]

Commenter: Motor & Equipment Manufacturers Association (MEMA)

MEMA continues to support a transition to cleaner transportation and the goal of economy-wide net-zero emissions by 2050. Consequently, MEMA supports the goals set out in the proposal and supports the proposed standards outlined through MY2026. It is critical that the EPA continues to emphasize and support multiple technological pathways to meet the targets. As EPA acknowledges in the proposal, there are multiple advanced ICE technologies as well as other advanced propulsion technologies that can significantly contribute to meeting these targets and the post-2026 emissions goals. [EPA-HQ-OAR-2021-0208-0249-A1, p. 4]

MEMA supports EPA's approach of performance-based standards that allow a broad spectrum of advanced propulsion technologies. The framework for MYs 2023–2026 encourages a wide range of electrification technologies while also requiring further technology advances and innovation to ICE technologies. This approach, along with continued credit programs, will sustain long-term supplier technological investments.

Looking beyond MY2026, MEMA stands ready to work with EPA to establish a holistic framework for long-term GHG standards that are ambitious but pragmatic and continue to provide multiple technology pathways for compliance. American innovation can drive the industry to meet the nation's goals if provided the freedom of multiple pathways to achieve them.

The following will allow the supplier industry to have increased stability, continued job growth, and sustain important long-term strategic investments:

• EPA's proposed standards that are stringent but achievable through 2026;

• Coordinated programs between EPA, NHTSA, and CARB;

• Continued credit programs, as proposed and structured; and,

• Utilization of a broad spectrum of advanced technologies that continue into the post-2026 program. [EPA-HQ-OAR-2021-0208-0249-A1, p. 16]

Commenter: NATSO, Representing America's Travel Centers and Truck Stops et al.

All fuels and technologies should be treated equally within the context of establishing performance specifications. Once those specifications are set, however, policy should harness the market's ingenuity to identify the optimal means of satisfying them. If the goal is to reduce GHG emissions and improve fuel economy, EPA should not establish unbalanced regulatory incentives that skew the market towards a particular technology. Instead, EPA should provide a level playing field upon which all technologies can compete fairly for market share. [EPA-HQ-OAR-2021-0208-0570-A1, p. 1]

GHG Emissions Standards Should be Fuel-Neutral. GHG emissions standards should not favor one technology over another. Providing one technology a 'leg up' over others will preclude markets from identifying and gravitating to the most attractive, economical option. While it may be tempting to prematurely pick winners and losers from an energy technology standpoint, sound policy must be grounded in science and recognize that the state of technology can change rapidly. What policymakers think is the best solution today may be surpassed by subsequent innovation. Sound policy should not stifle innovation by mandating specific fuel solutions. Instead, EPA should set emissions standards and let the market – guided by consumers – innovate to find the best way to meet those goals.

The Agency's preference for electric vehicles ('EVs') over other technologies is counterproductively undermining meaningful opportunities to improve the transportation sector's emissions footprint. [EPA-HQ-OAR-2021-0208-0570-A1, p.2]

Commenter: St. Julien, Rene

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 212-213.]

The world has seen incredible technological innovations over the past 40 years, many things changing at a speed which was almost hard to keep up with. Who would have thought even a couple of years ago that we could have a virtual meeting like this on Zoom?

Meanwhile, the automotive industry still produces cars and trucks using the same fossil fuel-burning internal combustion engines that were being made in the early 1900s.

About all the auto industry has done is taken the same technology and refined it a little every decade, generally in the areas of comfort, style, and reliability. For the most part, changes in the areas of safety or the environment are rarely made voluntarily and only when the Federal Government mandates it.

It appears that the open market competition has failed us. After 120 years, the extremely complex internal combustion engine should be retired. Tesla's the only car manufacturer that has dared to take on the status quo.

Our culture needs to set its expectations much higher as to what is possible when the best minds get to work. We need to stop wallowing in the past and start getting innovation and competition to accelerate us into a true clean energy future at a much faster rate than past standards have set.

EPA Response

EPA acknowledges all of the comments above.

In response to comments expressing the need to transition out of a carbon-based economy, EPA recognizes the fact that the economy is largely dependent on carbon-emitting energy sources and the need to reduce GHG emissions from such sources. A comprehensive shift from carbon-based energy sources would take longer than the time frame of the current rulemaking, which is intended to revise the SAFE rule standards through MY 2026. As noted in the Preamble and elsewhere, we acknowledge the value of providing an appropriate transition to stronger standards that we plan to develop in a future rulemaking, and we believe that this rulemaking meets that goal.

In response to comments that the standards should provide for a more appropriate transition to electric vehicles, and that setting a more stringent standard is a more appropriate way to do this than providing credits for EVs, in Preamble Section III.B.3 and RIA Chapter 4.1.4, we discuss that the final standards are projected to lead to a greater penetration of EVs than in the NPRM – the final standards are projected to result in 17 percent EV penetration in MY 2026, which is just above ACEEE’s recommendation for EV penetration that year.

EPA disagrees with comments that assert that no technology improvements were included in the proposed rule. Changes to the technology inputs are described in Preamble III.A. The current rulemaking is intended to revise the SAFE rule standards. As explained in Preamble III.A, EPA chose to continue use of the CCEMS model for this rule in order to facilitate comparisons between the analysis presented in this rulemaking and the analysis presented in support of the SAFE FRM, and to more clearly illustrate the influence of some of the key updates to the inputs used in the SAFE FRM. Also as explained in Preamble III.A, EPA made a number of updates to the inputs for the final rule analysis to better represent and characterize the available technologies. We also made additional updates for the final rule analysis, and we conducted several sensitivities covering alternative technology assumptions, including for battery costs, HCR2, and application of mild and strong hybrid technology (see RIA 4.1.5 for a discussion of these and other sensitivities), and we considered the results of these sensitivities in our assessment of the final standards. EPA notes that the final standards are of similar or lower cost compared to the 2012 rule standards and the NPRM. EPA's assessment in the context of this rulemaking is that additional updates to technologies considered or their costs would not have a meaningful impact on the conclusions of the analysis.

As discussed in Preamble III.C, EPA's assessment is that the final standards are appropriate. Coordination between agencies is discussed in Preamble I.A.1, II.A.3 and II.A.8. Our treatment of credit programs in the final rule is discussed in Preamble II.A.4, and responses to comments on that topic are presented in Section 5 of this Response to Comments document.

Regarding response to comments that EPA should consider a broad spectrum of technologies, in this final rulemaking, as with previous rulemakings, EPA is setting performance-based standards that do not mandate or favor a specific technology over another, and that can be met with a broad variety of available technologies. See also discussion on similar comments in Section 12.1.

Similarly, EPA disagrees with the comment that the agency has a preference for electric vehicles (EVs) over other technologies. Electric vehicles are significantly different from conventional vehicles in terms of their effectiveness, cost, and potential for long-term emissions reduction. Under our performance-based standards, EPA's projected penetrations of specific technologies are primarily an outcome of their relative costs and effectiveness. Our projections of technology penetrations are meant to show potential pathways to meet the standards. Ultimately each manufacturer will decide its specific technology pathway to meet the standards, and the pathways chosen by manufacturers may differ from our projections. While we project that a cost minimizing compliance pathway to meet the performance based standards of the final rule will include increasing numbers of EVs and PHEVs, we also project that more than 80 percent of vehicles in a fleet complying with the standards in MY 2026 will use gasoline technologies, including conventional hybrids which run on gasoline.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 26.] Lack of infrastructure. Do we need fast charging stations for we consumers' range anxiety? Absolutely, and I believe the Administration's plans will greatly help.

Are single family homeowners at an advantage now over multifamily and multistory residential dwellers? Absolutely. But with increased investments in infrastructure, incentives for petroleum retailers to install charging stations, local land use incentives and the like, infrastructure can and will be built to meet the needs of consumers.

Commenter: Allergy & Asthma Network, et al.

US EPA must secure a rapid transition to zero-emission technologies. US EPA's documentation provides a thorough discussion of the technological advances and investments, automaker announcements and state policy developments in pursuit of greater deployments of zero-emission vehicles (ZEVS) as called for by President Biden's August 5, 2021 Executive Order.6 This current proposal must be followed by much stronger limits on greenhouse gas emissions from light-duty vehicles through 2030 as well as stringent multi-pollutant standards for heavy-duty vehicles without delay. US EPA must move aggressively to set additional standards to accelerate ZEV deployment in the on- and off-road medium- and heavy-duty sectors. [EPA-HQ-OAR-2021-0208-0296-A1, p. 3]

Commenter: Alliance For Automotive Innovation

Achieving a Net-Zero Carbon Transportation Future. We are confident that electrification can be successful, and that electrification will deliver uninterrupted mobility services that American families and businesses will benefit from. Together with public and private stakeholders, we can be successful in this transformation.

Transforming our light duty fleet to electrification, and creating an ecosystem in which electrification can thrive, is a task that must be accomplished at scale and in a manner that ensures uninterrupted mobility for American families and businesses. This task is not just building great cars and trucks. It starts with securing access to critical raw minerals and establishing a secure network of logistics and processing that will deliver the flow of materials to new factories that will manufacture advanced batteries and electric drive components. Furthermore, we must train our workforce to build, service, and repair electric vehicles. We must also ensure that the vehicles are handled responsibly at end of life and that critical minerals circulate back into the economy. Our service stations will also need to evolve in order to fuel these new vehicles with electrons and hydrogen. Energy producers must also move in tandem to ensure that the new fuels are sourced from renewables and can be delivered affordably and at scale to our consumers and businesses. Automakers are committed to doing our share. Collectively, automakers have committed to investing more than $330 billion to transforming cars and trucks to an exciting, electrified future.[9] We believe electric vehicles powered by clean electricity, renewable hydrogen and other low- and net-zero carbon fuels will help deliver our contribution to our nation's ambitious climate goals.

We will be successful in this endeavor when we are aligned and moving forward together to achieve our shared goal of cleaner, safer, and smarter vehicles. [EPA-HQ-OAR-2021-0208-0571-A1, p. 2-3]

Achieving Electrification Success through Cooperation and Shared Responsibility. Our national success in achieving a zero-emission future is a shared and collective responsibility that will demand immediate and sustained action from many partners. As the President has established an "all of government" approach to addressing climate change, so too must an "all in" approach to transforming America's manufacturing base, workforce, fueling infrastructure and vehicle fleet be established. Necessary actions to support the transition to electric vehicles ("EVs", including battery electric, plug-in hybrid electric, and fuel cell electric vehicles) and to make the proposed GHG standards a success include, but are not limited to:

Supporting American drivers with reliable and convenient EV refueling infrastructure. A 2021 National Academies report on improving light-duty vehicle fuel economy (the "NASEM Report")[10] cites location and availability of charging stations as the number one reason for a consumer to avoid an electric vehicle.[11] EV recharging and hydrogen fueling infrastructure availability and visibility will be critical to promoting EV market growth and supporting manufacturer sales targets to both meet the proposed standards and long-term electrification goals. Home charging will cover some needs, but not all. State and federal governments, together with private sector charging companies, have the opportunity to establish a fueling infrastructure plan that will provide confidence to American drivers that they will never be afraid of running out of fuel. Auto Innovators supports the National EV Charging Initiative.[12] In the long run, over 250 million light-duty vehicles will need to be supported with convenient, affordable, and reliable EV and hydrogen fueling. [EPA-HQ-OAR-2021-0208-0571-A1, p. 4]

Fleet purchase requirements. Over 8 million cars and trucks are owned by fleet operators in the U.S.[14] Fleets represent a significant opportunity for electrification given regular routes and often centralized fueling. Federal, state, local, and private fleets have an opportunity to demonstrate leadership in accelerating adoption of EVs. Recently, Auto Innovators wrote to the California Air Resources Board ("CARB") in support of such requirements as part of CARB's ACC2 rulemaking.15 Fleet purchase requirements are especially logical in jurisdictions that have specific EV sales requirements. Reaching high EV sales goals will require substantial fleet, in addition to retail, market penetration. [EPA-HQ-OAR-2021-0208-0571-A1, p. 5]

Development of a battery and EV recycling system in the United States. As EV manufacturing in the U.S. grows, the demand for critical minerals will also. In addition, as today's EVs are retired, a robust recycling system is required to ensure valuable components of EVs, such as batteries and the metals within them, are reused and recycled. Auto Innovators is actively working with government and recycling industry stakeholders to develop such a system.

Increased research and development investments. EVs remain relatively more expensive than equivalent ICE vehicles. Significant additional research is required to achieve the cost reductions projected and hoped for. [EPA-HQ-OAR-2021-0208-0571-A1, p. 6]

Auto Innovators supports the goal of 40 to 50 percent new vehicle market share for EVs (including battery electric, plug-in hybrid electric, and fuel cell electric vehicles) by 2030, but action is needed today to implement ten specific policies to grow EV sales significantly through model year 2026 and beyond. [EPA-HQ-OAR-2021-0208-0571-A1, p. 7]

Concerning energy savings associated with electric vehicles, there is a tremendous amount of uncertainty and geographic variability related to the future of the electricity grid, and electricity rates. Auto Innovators urges policymakers to consider the possibility that electricity rates may become considerably more expensive as renewable generation is added.

Technology Costs of Electric Vehicles

The Agencies assume significant cost decreases in battery electric and other electric vehicles through 2032. However, several cost factors need to be considered more thoroughly including raw material costs, the effect of potentially higher electricity costs on electric vehicle production, and how variations in battery cell chemistry, form factor, and pack design could affect cost learning assumptions. There are also likely near-term costs to develop the necessary supply chains. We suggest that, at minimum, the Agencies adopt a two-part learning curve for batteries that separates raw material costs from time/volume learning such as that described by MIT Energy Initiative (2019).32

Both RIAs simulate a significant increase in BEV penetration under the revised standards. It is important that the Agencies use plausible estimates of the future costs of electric vehicles.

A crucial assumption of the agency analyses of BEVs is that the manufacturing cost of a BEV declines in the decade ahead due to a continued decline in the cost of producing battery packs and other components of BEVs. A recent study covering 1992 to 2016 found that the real price of lithium-ion battery packs did decline an average of 13% per year when measured according to energy capacity supplied. When energy-density improvements are considered, the annual improvement rate was about 17%.196 Bloomberg New Energy Finance ("Bloomberg NEF") bases its battery-price forecasts on a historical annual learning rate of 18% and aggressive demand forecasts for EVs and lithium-ion batteries (which leads to high production volumes and associated efficiencies). Bloomberg NEF also assumes that battery producers can achieve maximum economies of scale by producing packs for both the stationary energy storage market as well as for EVs. Recently, the Bloomberg NEF annual battery-pack price survey found that prices continued to fall 13% from 2019 to 2020, a period when raw material prices for battery cells were falling due to the EV sales slowdown in China.197 The National Academies ("NAS") acknowledges that, in recent years, the sharp decline in material costs for cathodes was due primarily to a corresponding decline in the constituent metal prices, a trend that "may not be sustainable."198

The traditional method of accounting for possible future changes in battery-pack costs is to apply a learning curve in future years based on production volume, and then make a somewhat arbitrary assumption about when the rate of decline decelerates or stops (technological maturity). NAS did not forecast changes in material prices but nonetheless assumed that pack costs will decline by a rate of 7% per year until 2030.199 EPA did not change battery-cost estimates compared to the final SAFE rule but opined they may be too high without explanation.200 NHTSA, in its RIA, assumes production-volume economies will reduce NMC 822 production costs by up to 8% in the near-term but by less than 1.2% after seven years.201

The underlying literature focuses on learning related to volume of production, but the Agencies and NAS compress numerous unanalyzed issues into a "learning factor". NHTSA, for example, in the SAFE Rule analysis of battery costs202 – which is the basis for NHTSA's current battery-cost analysis – acknowledges that the learning factor is intended as a "proxy" for changes in battery chemistry, changes in energy density, further gains in plant efficiency, and additional economies of scale in production due to higher production volumes.

All unanalyzed factors are seen as contributing to future reductions in battery-pack costs; neither NAS nor the Agencies confront the real possibility that counteracting, unanalyzed factors could work to restrain the future decline in battery-pack costs.

A recent MIT report took an important step toward realistic forecasting by simulating future battery-pack costs using a two-stage model: one stage for the costs of materials, including processing and synthesis, and a second stage for the costs of manufacturing battery packs.203

MIT's second stage (manufacturing) has annual cost declines of 16.5% (+/- 4.5%) per year – like the results of one-stage models – but the first stage on material inputs (including materials synthesis) declines at only 3.5% per year. Obviously, the raw material costs provide a floor on the future costs of battery packs. Even assuming NMC 811 is the dominant battery chemistry in 2030 (which ensures lower material costs due to substitution of nickel for costly cobalt), the simulated pack-level costs in 2030 are not sufficiently low in the MIT two-stage simulation to hit DOE's target of $100 per kWh. In fact, the DOE goal of $100 per kWh by 2030 cannot be met unless material prices remain depressed at 2016 levels.204

NHTSA erroneously refers to the battery-cost estimate from the MIT simulation as an "upper bound";205 in fact, the MIT report supplies both a best estimate and upper and lower cost estimates based on different scenarios with the two-stage model (best estimate of $124/kWh, low estimate of $93/kWh; high estimate of $140/kWh). The two-stage model used by the MIT Energy Initiative is based on peer-reviewed scientific modeling but without recent information (2021) on the resurgence of material prices.206 The Agencies have not yet performed an in-depth analysis of material costs for lithium-ion batteries; indeed, NHTSA acknowledges that it has performed no analysis of future prices of raw materials.207 Current sensitivity cases on the learning rate alone are insufficient. The Agencies should work with National Laboratories, DOE, and others to produce sensitivity cases for raw and processed material costs, material efficiency in battery construction, and other considerations.

To provide proper analysis of the penetration of different battery chemistries, Auto Innovators recommends that the Agencies remove changes in battery chemistry from the near- term learning factor (2021-2032) and analyze it separately and explicitly in the RIAs. The proposed NHTSA RIA assumes that one battery chemistry (NMC 622) is representative of the industry for BEVs, as it was the most common cathode chemistry in 2019.208 Instead of choosing one battery chemistry as representative of the entire industry, as the Agencies do with the Argonne battery model, the Agencies should forecast the penetration of different battery chemistries in the fleet from 2021 to 2032 and estimate applicable costs for each of them. Since alternatives to lithium-ion batteries are unlikely to have significant penetration prior to 2032, the relevant battery designs for 2021-2032 are the five discussed below (NCA, NMC 111, NMC 622, NMC 811, LFP). Those batteries are well enough understood to perform separate cost analyses for each, rather than assume an arbitrary learning curve. The learning curve should focus on production volume and cell yield rather than battery chemistry.

Auto Innovators is also supplying some detailed information and analytic guidance on several other unanalyzed factors that might restrain the future rate of decline in BEV costs. We encourage the agencies to account for these factors as they make forecasts of future production costs of BEVs.

Battery Raw Material Price Impacts and Considerations

Raw material prices can greatly impact the costs of producing electric vehicles. The Agencies should adopt or develop a two-stage learning model for battery costs that accounts for both raw material costs and other volume/time-based learning in place of the single stage learning curve used in the Agencies proposals.

The key raw materials for battery packs are lithium, cobalt, nickel, manganese and natural graphite. The rare earth neodymium is critical for electric motors.209

Could EV producers face rising raw material prices between today and 2032? It is certainly possible. In the first seven months of 2021 alone, the surge in demand for EVs in China, Europe and the U.S. has induced a rapid recovery in depressed material prices. From January 1, 2021, to July 1, 2021, the spot prices for lithium, cobalt, nickel, manganese, natural graphite, and neodymium have changed +91.4%, +63.1%, +15.0%, +10.4%, +32%, and +24.9%, respectively.210 Some of this surge reflects global recovery from the COVID-induced recession.

Electric vehicle users can also incur costs beyond that of the technology itself. While some of these costs are considered, we urge the Agencies to also consider costs such as those for home charging infrastructure, and cost/benefit differences for long-range and short-range electric vehicles. Electrification technologies, especially BEVs and PHEVs, entail a significant change in how motorists engage with transportation and electric-utility systems.

Less than a handful of the dozens of published battery-forecasting models include any formal analysis of global trends in raw material prices.211 None of the published battery- forecasting models have accounted for the surge in material price experienced in 2021.212

The Agencies are currently relying on the Battery Performance and Cost Model ("BatPaC") developed by Argonne National Laboratory. This transparent spreadsheet model provides a peer-reviewed, bottom-up approach to account for cost-input factors. However, BatPaC does not include a formal global model of the market for each raw material used in battery packs. Instead, "the price of raw materials is based on our best estimate at the time of version release".213 No analytic detail is provided to support the best estimate. The versions used by the Agencies does not account for the 2021 surge in raw material prices.

Gauging the impact of raw material prices on the costs of BEVs requires the following information:

- Material intensities of the raw materials in the cathode chemistry (defined as kg/kWh). These intensities were obtained from reprinted Table 3 (Figure VII-1, below) for several of the cathode chemistries (NCA, NMC 111, NMC 622, NMC 811, LFP).

- Raw material prices.

Derivation of the weights of the materials used as a fraction of the raw materials provided (e.g., lithium as a percentage of lithium carbonate, neodymium as a percentage of neodymium oxide).

Figure VII-2: Material intensities of Raw Materials in Cathode Chemistry. Source: Faraday Insights, https://faraday.ac.uk/wp-content/uploads/2020/12/Faraday_Insights_6_Updated_Dec2020.pdf (accessed Sep. 24, 2021).

The summary tables below show the material costs for lithium, cobalt and nickel for three types of batteries: NMC 111, NMC 622 and NMC 811. For LFP battery chemistry, the usage of cobalt and nickel is zero. The summary tables also show the percent increase in battery cost if the raw material costs were doubled. The Agencies are encouraged to perform similar analyses for manganese and natural graphite.

The amount of rare earth neodymium used in permanent magnet motors was assumed to be 3.5 kgs. The summary table below shows the percent increase in electric motor cost if the raw material cost of neodymium oxide were doubled.

In summary, a pre-2032 doubling of raw material prices could substantially erode the “learning-curve” cost-reductions assumed in the RIAs. The RIAs do include a helpful sensitivity analysis that varies the learning curve by +-20% and the battery-back costs by +/- 20%. But this range is not large enough to account for large increases in raw material prices, especially since the prices of several raw materials could rise simultaneously. There is no basis for believing that raw material prices will decline for a sustained period prior to 2032.

Much more careful analysis of raw material prices is necessary in the final RIAs, because 70% of battery-cell costs are material costs (mostly for the cathode followed by the anode, and then the separator). About 50% of the cathode costs are the constituent costs of raw materials, which makes cathode production costs especially sensitive to raw material prices.214 NAS notes that the declines in metal prices from 2011 to 2017 that helped drive down material costs “may not be sustainable.”215 The preliminary material price data for 2021 supports NAS’s cautionary statement. Over time, as EV manufacturing economics take hold, raw materials – and their prices – will account for an increasing share of the overall cost of battery packs.216

The path of raw material prices from 2021 to 2032 (and beyond) will depend critically on how quickly the global supply of raw materials responds to the growth in EV sales and the price signals in the global market.217 The prospects for each raw material are somewhat different but there are reasons to believe the the global supply responses will be sluggish, especially from 2021 to 2032.218 Major advances in battery design, which could overwhelm the impact of raw material prices, are more likely to exert their impact from 2030 to 2050 than from 2021 to 2030.219 Each of the key raw materials is considered below.

Lithium

The earth has plenty of lithium resources, and the recoverable reserves are more than adequate to support a massive expansion of the global electric vehicle sector. The practical limits on lithium development are more binding than the physical limits on resources.

Lithium mining requires substantial volumes of water but over 50% of lithium mining occurs in water-stressed areas.220 The energy requirements are also substantial, but promising reserves are often located in areas with little or no energy infrastructure. And lithium miners need good access to ports with sea-faring capability in order to ship lithium compounds to refineries for processing, prior to their use in cathode production.

Opposition to lithium mining and processing – among both organized environmental groups and local communities – is intensifying in many parts of the world (including the US). Such opposition lengthens the historically long time frames for lithium development projects (about five years in Australia and seven years in South America, based on 35 projects that came on line between 2009 and 2019).221 In countries with little or no experience with lithium mining, project time lines are much longer, an average of 16 years to move from discovery to first production.222 The opposition is understandable because both lithium mining and processing have significant ecological footprints (some temporary, others longer lasting). In some cases, lithium development may also create conflicts with other business sectors such as tourism, ranching, and agriculture. In addition, investors are hesitant to make new commitments to lithium mines because of the historical price volatility and the low prices contained in some long-term projects negotatied when global prices were depressed from 2018- 2020.223

Analysts from Roskell project that, due to rising sales of electric vehicles, the global demand for lithium will rise by a factor of 4.5 between 2020 and 2030. Since supplies are expanding slowly, global supply deficits of lithium are projected toward the end of 2021 and 2022. Without successful new lithium mines, supply deficits will extend until 2030 or later. Even with new lithium mines, prices will rise insofar as the marginal cost of lithium from new mines is larger than the marginal cost of lithium from existing mines. Thus, all signs point to increasing lithium prices, at least until (or if) post-2030 lithium-free battery technologies emerge as viable substitutes for lithium ion batteries.224

Here is a brief status report on lithium development around the world, with an indication of whether significant local opposition has emerged and/or delays have occurred. The importance of lithium processing capability (as well as mining) is emphasized.

1. Sonora Lithium Project, Mexico. Bacaonora Lithium (UK), owned 50% by Ganfeng Lithium (China), is developing a large mine site in an area that has been considered promising for decades. Development activity slowed when the leftist regime in Mexico announced possible government ownership of the Project, but the government is now allowing private ownership to proceed.225 Novel technology will be used to extract lithium from clay soils with the assistance of technical specialists from China. The company has delayed production several times, most recently from 2020 to 2023.

Complicating factors include an uncertain regulatory environment and royalty regime, fears that drug cartels could disrupt the Project, and concerns from community, indigenous, and environmental groups about water shortages and water quality.226

2. Jadar Lithium-Borates Project, Serbia. In July 2017 the Serbian government and the multinational company Rio Tinto announced plans to launch a major underground lithium mine in western Serbia.227 A feasibility study is expected by the end of 2021. The first production is scheduled for 2026. Environmental and grassroots opposition to the project is growing, including street protests in Belgrade involving thousands of protesters.228 A petition calling for a ban of the project garnered 110,400 signatures as of June 10, 2021. The Serbian government has agreed to have a referendum on the project once a comprehensive study of the project is completed.229

3. Piedmont Lithium Project, North Carolina, USA. Piedmont Lithium (Australia) has proposed an open-pit lithium mine and processing plant in western North Carolina’s Gaston County. The company once had a deal to supply Tesla but that deal has been postponed indefinitely, as the company has experienced delays in securing financing, a state permit, and

Gaston County approval. The nearby community is divided about the Project and the Gaston County Commissioners passed a new zoning ordinance in 2021 to ensure adequate County oversight of the mine. The company believes the zoning ordinance will not prevent the Project from moving forward.230

4. Silver Peak Mine, south-central Nevada, USA. Albemarle (North Carolina, USA) owns the only active lithium mine in the U.S. in Clayton Valley, Nevada. In 2021 the company announced plans to double production at the site by 2025.231 Albemarle has experienced conflicts over water rights with other developers in the water-stressed area.232

5. Thacker Pass Project, northern Nevada, USA. Canada's Lithium Americas, with partial backing from Ganfeng (China), plans to launch a new lithium mine from 2022 to 2026 near the border of Nevada and Oregon. In January, 2021, the Bureau of Land Management completed its environmental impact statement on the Project and granted Lithium Americas a permit. A coalition of local and national environmental groups oppose the project but, in the summer of 2021, failed in court to obtain a preliminary injunction against early excavation work at the site.233 In separate litigation, opponents (which also include a nearby rancher) are challenging BLM's permit decision on multiple grounds such as inadequate consultation with local Tribes and failure to protect that the sage grouse, a bird found in the West that is threatened due to habitat loss.234

6. Rhyolite Ridge Lithium-Boron Project, Nevada, USA. Ioneer Ltd (Australia) is developing a major new lithium and boron mine about 220 miles north of Las Vegas. In September 2021, Silbanye Stillwater (South Africa) bought a 50% interest in the project in one of the largest lithium investments in U.S. history. The project is expected to start in 2024, but complications have emerged in the U.S. regulatory system. The U.S. Fish and Wildlife Service, under court order, issued in June 2021 a proposed decision to list a rare desert flower (Tiehm's buckwheat) as an endangered species under the Endangered Species Act. The flower grows on roughly 10 acres within the mine site area. Ioneer believes the mine and the flower can co-exist but a national environmental group, the Center for Biological Diversity, believes the flower cannot be transplanted safely to other nearby soils.235 The Center is litigating a decision of the Bureau of Land Management to provide an exploratory permit but, meanwhile, the State of Nevada has awarded both water and air permits for the proposed project.236

7. Lithium Extraction in the Atacama Desert, Chile. A decade ago, Chile was the leading producer of lithium in the world but mining progress has slowed. In March, 2018, the two major lithium miners in Chile, state-owned SQM and Albemarle (USA), announced major expansion plans in collaboration with the Chilean government and in conjunction with an elaborate plan by Samsung to build three battery plants in Chile to serve the global electric vehicle market. The deal unraveled when a report of the Chilean government alleged that the existing mining operations of the two companies have exacerbated water shortages in the Atacamera Desert.237 Indigenous groups and environmental activists also challenged lithium mining in Chile on the grounds of adverse ecological impacts.238 In 2019, Chile's First Environmental Court ruled in their favor. Meanwhile, China's Tianqi Lithium purchased a 25% interest in SQM, and Albemarle announced a revised plan to enhance yields at its existing lithium mines in Chile,

without an expansion of its ecological footprint. Chilean opponents of lithium mining see the writing of the country's new Constitution as a forum to redefine ownership of water rights in a manner that would allow indigenous groups in the Atacama Desert to exert more control over how their land is used.

8. Lithium Extraction in the Atacama Desert, Argentina. Until 2015, FMC Corporation (USA) was the only company doing large scale lithium mining in Argentina. As Chile's mining sector faltered, two consecutive presidents of Argentina attracted Japanese, Australian, French, Chinese and American companies to make new investments in Argentina.239 The huge new Cauchari-Loaroz Project, by Lithium Americas is scheduled to begin production in 2022.240 There is some opposition from indigenous groups (e.g., the Kolla communities in the Puna region) and some hydrologists are raising concerns about the potential loss of freshwater resources and adverse ecological impacts. Meanwhile, an NGO called Plurinational Observatory of Andrean Salt Flats (Opsal) links environmental and indigenous activists across The Lithium Triange in Chile, Argentina and Bolivia.241 Nonetheless, Argentina's mining sector was making progress until the COVID-19 recession and the temporary slump in lithium prices. Whether Argentina can overtake Chile as a leading global lithium miner remains to be seen.242

9. The Greenbrushes Mine, Western Australia. The world's largest hard rock lithium mine is a joint venture of Tianqi Lithium Industries (China), Albemarle (USA), and IGO (Australia). It is scheduled for expansion, as the Mine is a major supplier of Tesla.243 But the mine is only one of a recent proliferation of lithium projects in Western Australia, where a pro-mining culture is pervasive, where major investments in ports and transport infrastructure support mining, and where access to foreign capital (especially from China) has helped finance new projects. In 2017, Australia surpassed Chile as the world's number one lithium miner.

10. Northern Montalegre region, Portugal. Portugal is the only European country with active lithium mining and the national government believes that the northern Montalegre region, which possesses significant lithium reserves, would benefit economically from a new lithium mining sector. With encouragement from the European Union and the national government of Portugal, several developers (e.g., Savannah Resources of the UK) have made preliminary investments in Portugal. However, the local populations in the region and their politicians have mounted sustained opposition to new lithium mines. Fearing the political backlash, the national government adopted a new mining law that provides more royalties and local safeguards for affected local communities. Opponents have already stopped one lithium project and are opposing another that has entered the public consultation phase.244 The central government has the theoretical power to override local opposition, but it seems unlikely that such a heavy-handed approach will be taken.245

11. Direct Lithium Extraction Technology. Several developers around the world are touting a relatively new technology, direct lithium extraction (DLE) from brines, as an environmentally more benign approach compared to the traditional brine methods used in Chile and the hard rock mining in Australia.246 DOE is also optimistic about DLE.247 More R&D investments are necessary to ensure the DLE is economical and can be accompanied with proper management of large volumes of waste that accumulate rapidly.248 General Motors recently made a significant

investment in a DLE venture at the Salton Sea in California.249 It is too early to judge whether DLE will experience less community and environmental opposition than traditional methods of lithium mining. It may be 2030 or later before this technology has significant market penetration on a global basis.

12. China's Dominance of Lithium Processing. China was once a major player in lithium mining but in recent years has become a large importer of lithium, as China's lithium mines led to significant water pollution and protests among villagers.250 In order to secure a strong global position in the lithium sector, China's industrial planners – in "China 2025" – urged a move up the value chain to processing and manufacturing.251 Banks and lithium/cathode companies based in China have collaborated on acquisitions of majority (or substantial minority) interests in lithium mines in South America, Australia, the U.S. and other countries. More importantly, China has assumed a dominant position in the processing of mined lithium into lithium chemicals that are suitable for cathode manufacturing. Virtually all of the lithium mined in Australia is shipped to China for processing. China is now making large new investments in lithium processing to ensure continued dominance.252 Thus, U.S. and European politicians seeking to avoid dependence on China will need to orchestrate major investments in lithium processing capability in addition to those in lithium mining.

Cobalt

Cobalt accounts for one-fifth of the material in the cathode of a typical lithium ion battery. It has a stabilizing effect, keeping the layered structure stable as lithium ions travel in the lithium ion cell, and prevents cathode corrosion that can lead to battery degradation and battery fires.

Cobalt is also one of the most expensive materials in an electric vehicle. In 2020, the average spot price of cobalt in the U.S. was $16 per pound, down from a peak of $37.4 per pound in 2018, before the temporary slowdown of EV sales in China (2019-2020). Due to the projected growth in EV sales, Roskill forecasts that global demand for cobalt will rise from 141,000 tons in 2020 to 270,000 tons in 2030.253

The rate of growth in cobalt demand from the EV sector is expected to be slower than the rate of growth of lithium demand, as a transition toward lower-cobalt or zero-cobalt batteries is underway.254 However, the transition to lower-cobalt batteries is occurring more slowly than expected.255 The consulting firm, Rho Motion, forecasts that cobalt-free batteries will grow in the next decade but not exceed 20% of the global battery market by 2030.

Cobalt supplies do not readily respond to growth in global demand for several reasons. Cobalt is typically mined as a byproduct of copper, and thus it is the demand for copper rather than cobalt that drives the amount of cobalt that is extracted from mines. In other words, the supply of cobalt is not elastic with respect to price.

Moreover, about 60% of the cobalt mined in the world comes from one country, the Democratic Republic of Congo (DRC). The current political leadership of DRC seeks to renegotiate the mining agreements with companies doing business in DRC.256 Moreover, Chinese companies have purchased a controlling interest in 70% of Congo's copper-cobalt mines.257 Western businesses are reluctant to make investments in DRC because of political instability, violence and uncertainties about regulation and taxes. There is also evidence that child labor is used in DRC's mines, which further discourages investment by Western businesses.258

Given constraints on supply growth, deficits in cobalt supply are projected by 2024, which in turn will cause prices to rise further.259 Experts at RBC predict that cobalt prices will surpass $40 per pound by 2024.260

Global cobalt shortages and rising prices are a distinct possibility between 2021 and 2030. In the post-2030 period, low-cobalt and cobalt free battery chemistries may dominate the battery sector. Efforts to diversify cobalt mining and refining are underway in the US and Europe, but they face formidable barriers to success unless they receive strong support from host governments. Since China operates 75% of the world's cobalt refining capacity, there is also strong interest in cobalt refining outside of China. Some of those activities, and the challenges they face, are reviewed below. The non-DRC mines have difficulty competing on price with the DRC mines; the refineries outside of China have difficulty competing on price with China's refineries.

1. Mutanga Mine, Democratic Republic of Congo. The largest copper-cobalt mine in the world is the Mutanda mine in south-east DRC. The mine was closed for several years as the owner (the multinational Glencore), and the DRC had disputes about tax rates, regulations and other issues. Glencore's current plan is to resume production at the mine in 2022.261

2. Tenke Mine, Democratic Republic of Congo. The second largest DRC mine, Tenke Fungurume, is owned by China Molybdenum. To capitalize on rising cobalt prices, Molybdenum started in July 2021 a trial production to support a planned $2.8 billion plan to double cobalt and copper output in the mine.262 However, progress has been marred by strikes at the mine and a DRC government investigation of the mine and its contracts with the government.263

3. Cobalt Mining in Finland. The rising prices of cobalt, and the EU's prioritization of cobalt mining, has stimulated interest in Finland's cobalt mines: three already operating, one in development, three more in the exploration phase. Several can co-produce nickel, zinc and copper. Given the high labor costs, community resistence to mining, and high environmental standards in Europe, it remains to be seen whether the mines in Finland (and elsewhere in Europe) can be globally competitive.264

4. Expanded Cobalt Refineries in Brazil and Finland. Jervois Global (Australia) is in the process of acquiring the two largest non-China cobalt refineries, one operated by Freeport Cobalt in central Finland and the other the Sao Miguel Paulista nickel and cobalt refinery in Brazil.265

5. New Mine in Northern Ontario, Canada. Fuse Cobalt Inc. (Vancouver) is planning a new mine in the sliver-cobalt producing region of Ontario, based on promising exploratory drilling that began in 1980.266 Progress has been delayed by cobalt's price volatility and financial issues. The nearby location of a new cobalt refinery (see below) could enhance the mine's prospects for competitiveness.

6. Retooled Canadian Cobalt Refinery. First Cobalt Corporation (Ontario, Canada), with financial assistance from the government of Canada and the Ontario government, has plans to launch in late 2022 the first large-scale cobalt refinery in North America. The new refinery already has cobalt-supply arrangements with DRC mines owned by Glencore and China Molybdenum.

New Mine in Utah. Jervois Global (Australia) is planning a new cobalt mine in the state of Utah where both gold and copper are also present.267 This mine has been under construction since 2012, as the project was first authorized in 2009 by the U.S. Forest Service and delays occurred when a change of mine ownership occurred. The current plan is to ship the mine's cobalt concentrate first to a refinery in Brazil and then to a second refinery central Finland, thereby allowing the product to be used by cathode producers.

Nickel

As nickel gradually replaces cobalt in battery designs, the price of nickel will become more important in cathode and battery production. The demand for nickel in the battery market supplements robust demand from the global stainless steel and non-ferrous alloy markets. But battery producers need a special kind of nickel, nickel sulphate, that requires tailored refining techniques.268

China remains a top-ten miner of nickel but in recent years has emphasized investments in Indonesia.269 Other countries engaged in nickel mining are the Philippines, Russia, Canada, and New Caledonia. Australia and Brazil could become major players due to their substantial nickel reserves.

The global supply of mined nickel is somewhat unpredictable because the largest nickel-producing country, Indonesia (>50% of global supply), has experienced chronic governance problems. The country's political culture is sometimes hostile to foreign investment. Even the remote Indonesian island of Wawonii has become a "battleground between villagers and a nickel-mining company backed by Chinese investors."270 The country's political leadership recently lifted a multi-year ban on nickel exports, which had disrupted the global market for nickel.

The processing of nickel for use in cathodes requires a specialized and more costly leaching process compared to the traditional pyrometallurgical process used to supply the stainless steel sector. China's largest stainless steel producer, Tsingshan Holding Group, is investing up to $15 billion in Indonesia to help supply Class I nickel for the battery market.271 China's Ningbo Legend has also started a high-pressure acid leach process for nickel on the Indonesian island of Obi.

The U.S. imports the vast majority of its nickel, as only one domestic mine (the Eagle mine in Michigan) is currently operating. This mine ships nickel concentrates abroad for refining.272 Tesla, to avoid dependence on China and Indonesia, has signed a major nickel supply contract with the company, BHP, which owns a nickel mining operation in Western Australia.273

The price of nickel also has a volatile history. The commodity hit an all-time high of $51,600 per ton in 2007 but the price collapsed shortly thereafter. The price remained depressed as China's stainless steel industry shifted to a cheaper form of nickel (nickel pig iron). Near-term price forecasts for nickel, prepared before 2021, were around $16,500 per ton for 2021 and 2022, with further price increases expected as demand for nickel from the battery market expands.274 In 2021, however, the price of nickel surged past $20,000 per ton, reaching a seven-year high. Growing demand for use in both stainless steel and EV batteries spurred the price surge.275 Thus, the shift from cobalt to nickel introduces new supply-chain complications.

Rare Earths

The permanent magnets in the electric motors of EVs rely on two specific rare earths: neodymium and dysprosium. Neodymium is valuable because of its strength, its high magnetic force, and its ease of use in the manufacturing of motors. When dysprosium is added, it allows the magnet to tolerate higher temperatures.276 Toyota has an R&D program to reduce neodumium use in magnets by 50% but implementation is not expected until after 2030.277

The land-based process of extracting rare earths entails open pit mining, which leaves an ecological footprint. The dust at the mine can be radioactive because a radioactive element, thorium, is often found with rare earths. Consequently, the wastewater from the mine needs to be handled carefully in order to prevent contamination of nearby surface water and ground water.

Until 1984, the U.S. accounted for a majority of the world's supply of rare earths. The Mountain Pass mine in the Mojave Desert (California) was the single largest source of production. The mine closed in 1982 and China ultimately captured a peak of 95% of global production due to accessible reserves, labor cost advantages, permissive environmental regulation, and state support of rare-earth producers. China's Baotou Steel Rare-Earth High- Tech Co operates a large mine near Baotou in Inner Mongolia. The company extracts rare earths as a byproduct of iron ore mining.

In 2011, China and Japan experienced a territorial rights dispute over a fishing incident that occurred in the South China Sea. During the dispute, China introducted several new policies on rare-earth mining and exports: export quotas were reduced; export taxes were increased; and taxes on rare-earth mining companies were increased from $0.50 per kilogram to $8 per kilogram. Provincial and municipal governments also cracked down on unlicensed mining while the central government began stockpiling rare earths at storage facilities under the direction of the Ministry of Land and Resources. At the time, Japan was consuming 20% of the global supply of rare earths, and China was Japan's largest supplier.

The cumulative effect of China's new policies was an explosive spiral in the market prices of rare earths. From May 2010 to June 2011, neodymium spot prices rose from $19 per kilogram to $500 per kilogram.278 The European Union, Japan and the U.S. protested China's actions and won a lawsuit against China in the World Trade Organization.279 However, China relaxed its export restrictions before the final WTO ruling and the global price of neodymium collapsed.280

After several years of a stable global market for rare earths, China again used rare earths in a geopolitical dispute. During the trade dispute, China invoked retaliatory rare-earth tariffs against the U.S.

Since dependence on China for such a crucial raw material is risky, alternative sources of supply are being pursued eagerly, but with only limited success. For example:

1. Reopening of the Mountain Pass Mine in San Bernardino County, California. With encouragement from the U.S. Department of Energy, Molycorp Inc (Colorado) invested $531 million in a modernization of the Mountain Pass Mine, including a plan to construct a separation and processing facility. The mine reopened for three years but, soon after the collapse of rare earth prices, Molycorp filed for bankruptcy. The new separation and processing facility was not finished. And local government officials worried that the mine site could become an abandoned hazardous waste facility. A consortium of investors acquired the mine at auction in 2017 and the new owner, Mountain Pass (MP) Materials (Las Vegas, Nevada), gradually expanded output from 2017 to 2021, reaching about 15% of global output.281 However, the mine still has no separation and processing facility and thus ships the mine's output to China for processing. One of the company's investors, Shenge of China, acts as a distributor. The company has re-established a multi-year plan to do its own separation and processing (2022) and to make its own magnets for automakers (2025). The target dates may be more feasible now that the company has succeeded in going public (2020) and can better access capital.282

2. Expand Production at the Mount Weld Deposit in Western Australia. Lynas Corporation (New South Wales and Malaysia) is developing a large rare earth mine on Mount Weld near Laverton, Australia and a processing facility in Kuantan, Malaysia.283 The plan for the Malaysian plant experienced setbacks due to community fears of possible exposure to radioactive elements that will be separated from rare earths at the facility. The company is currently adding a cracking and leaching plant at Kalgoorlie, Australia that will process the mine output from Mount Weld, before it is shipped to Malaysia for further processing. Separately, through a 2020 contract with the US Department of Defense, Lynas and its US partner Blue Line Corporation are exploring a new US-based rare earth separation facility.284

3. The Dubbo Rare Earths Project, New South Wales, Australia. An agreement between Australian Strategic Materials (ASM) and South Korean investors is developing the Dubbo Rare Earths Project and a new Korean Metals Plant (KMP) that will supply neodymium-iron-boron alloys.285 The agreement includes a Memorandum of Understanding with two regional governments in South Korea to build the rare-earth processing plant. 286

4. Access Rare Earths in Greenland. More than 25% of the world's rare earths are located in Greenland, where the rare earth oxides lack the usual contaminants (thorium and fluorine) that require special processing. Both China and the U.S. have expressed strong interest in Greenland. Progress is slow, because an environmental regulatory system is only under development, exploratory efforts are underway, and the country lacks technical expertise in this area.

In summary, China is the only country with a complete supply chain for rare earths from mining to refining and processing. China currently controls almost 60% of global production capacity and 85% of refining output.291 With the explosive growth in BEVs globally, the demand for rare earths is outstripping supplies, and the prices of neodymium are rising again.292

ESG Constraints on Use of Low-Cost EV Component Suppliers

Automakers and their battery-making partners are under increasing pressure to refrain from using some low-cost suppliers due to environmental, social and governance (ESG) considerations. The battery-price estimates used in the RIAs are industry averages that do not exclude supply chains that fail ESG tests. Here are some examples of ESG considerations that may preclude use of some low-cost suppliers:

- Suppliers in some countries rely heavily on high-carbon sources of electricity (e.g., Australia, China and Indonesia) such as coal;

- Some suppliers of parts (e.g., cathodes) do not know whether their supply chains utilize mines that violate human rights;

- Some suppliers have low costs because they access raw materials from mines that harm nearby communities with water pollution and mismanagement of wastes; and

- Some suppliers operate in developing countries where corruption of corporate and public officials is commonplace.

For the major global automakers that operate in the US auto market, the RIAs should not assume that low-cost suppliers with poor ESG profiles can be utilized in EV supply chains. As an example, global auto makers are now paying a premium price for nickel sourced outside of Indonesia. 293 In addition to ESG considerations, those premium prices may reflect the need to have a reliable source of supply from a country with stable governance that is not heavily influenced by China.294 To assist governments, automakers and battery suppliers examine supply chains for ESG issues, both OECD and the IGF have issued advisory management frameworks that emphasize environmental and social considerations.295 To reflect these cost-increasing considerations in EV production, the RIAs should focus on the cost of supply chains that pass basic ESG tests.

Recycling of Batteries and EV Components

EV battery recycling offers an opportunity to reduce U.S. reliance on foreign nations, and generally on mining, for the critical minerals used in EV batteries while providing national energy security. EV battery recycling is currently in its infancy as there are not a large number of EVs coming out of service. As the EV market becomes more mature, EV battery recycling will similarly grow. The RIAs do not acknowledge that the shift from recycling of engines and transmissions to the recycling of batteries in EVs will impose a net cost on the economy. We encourage the agencies to consider this cost in the final RIAs.

Recycling of automotive parts, including engines and transmissions, is a mature, commercially successful industry.296 In the U.S., almost 100% of automobiles are recycled, which in turn creates $32 billion in annual sales and approximately 140,000 jobs.297 Much recycling of automotive parts will continue with BEVs, because the BEV affects only or primarily the propulsion system in the vehicle. The loss of revenue from recycling of engines and transmissions will nonetheless be significant, as many of the components of engines and transmissions have significant commercial value. The highest value of some engines and transmissions may be in re-use but even recycled materials have significant value, including aluminum blocks, steel parts, heads, intake manifolds and so forth.

The lost revenue from recycling engines and transmissions needs to be compared to the expected revenue from recycling EV batteries. A UK study found that the expected revenues from recycling automotive-grade lithium ion batteries are significantly less than the current costs of recycling.298 This does not mean that the batteries should not be recycled. The overarching imperative for recycling is to reduce the demands on landfills and other non- sustainable waste-management methods.299 Moreover, as the prices of raw materials rise, the revenue generation from recycling valuable raw materials from batteries will improve. And, with future innovations, battery recycling may become an economically more compelling enterprise.300 In the long run (post-2035), recycling of lithium might reduce the global demand for lithium mining significantly, possibly by 25%-40%.301

Electricity Price Impacts on Costs of Battery Production

Electricity is the source of energy for an EV, and thus the price of electricity is crucial in any benefit-cost analysis that includes EVs. Electric utilities may need to raise electricity rates in order to expand and modernize the grid to accommodate EVs. Rising electricity prices certainly raise the cost of using an EV, but they also have an indirect effect on the cost of producing EVs, because the supply chain of an EV is much more energy-intensive than the supply chain for an ICE vehicle.302 At battery manufacturing facilities, for example, large furnaces are required to evaporate the solvents from the coated electrodes; since battery cells are sensitive to moisture, cell assembly must occur in a dry room, which incurs high electricity costs.303

Meanwhile, both state and national policies are shifting electricity generation from fossil fuels and nuclear power to renewables, especially wind and solar. At low levels of renewables, the effect on electricity prices may be minimal. Moreover, the cost disadvantages of renewables are declining over time, but the renewables transition may increase electricity prices at higher levels of renewables penetration and will likely raise them further when investments are made (e.g., in grid-scale energy storage solutions) to address the intermittent nature of wind and solar.304

It is difficult to estimate how much electricity prices will rise in a precise time frame (e.g., 2024-2026) because they are often determined in utility rate-setting processes in each of the 50 states. And the EIA forecasts of future electricity prices do not account for all the policy changes that are underway or will soon be adopted to promote or compel renewables.

One way for the agencies to bound the potential magnitude of rising electricity prices is to undertake a scenario analysis where all of the U.S. – residences and businesses – face the higher electricity prices now experienced by Germany or the State of California, both jurisdictions that have made determined efforts to boost renewables and phase out coal and nuclear power. Germany has the highest household electricity prices in Europe, about $0.30 per kWh.305 In May 2021, the average price of residential electricity in California was $0.21 per kWh, about 7% higher than the price in May 2020.306 In the U.S. as a whole, the average residential electricty price is about $0.13-0.14 per kWh.

The electricity prices paid by businesses need to analyzed separately, as they tend to be higher than the residential rates (in part due to demand charges). The business rate for electricity is appropriate to use when computing the energy costs in the supply chain of battery production. However, since the supply chain for battery producers is global, and electricity prices vary significantly around the world, a detailed analysis of global supply chains is required. In the case of lithium, for example, agencies need to consider the price of electricity where the lithium is mined, where the lithium is processed, where the lithium is used in cathode production, where the battery cells are made, and where battery packs are assembled. As more of the lithium supply chain develops in the U.S., the analysis will be more straightforward.

In this regard, it is reassuring that the Biden administration is seeking $75 million from Congress for a DOE program to advance lithium recycling.307 Without such a program, China may be the country best positioned globally to capture the lithium recycling business, as it already has one battery recycling plant in operation and plans to build several more overseas.308

In summary, for the next decade or so, the shift from recycling of engines and transmissions to the recycling of lithium ion batteries is expected to impose a net cost on the U.S. economy. That cost should be included in the RIAs in conjunction with estimates of how the cost of battery recycling might decline with appropriate supporting policies (e.g., R&D support).

Modeling of Battery Costs in BatPac

To the extent that some manufacturers begin to vertically integrate and technically differentiate on battery systems, Auto Innovators encourages the Agencies to consider costs and specifications that are reasonable for the industry as a whole to inform policy analysis, and not to assume that intellectual property and proprietary production processes that have been the result of billions of dollars of research and development paid by one manufacturer will be readily available to all manufacturers. In the BatPac model, production volume can affect direct manufacturing cost estimates, and Auto Innovators points out that many battery cells vary (size, shape, chemistry) to suit the application. Even battery packs that share cells may require different housings and assembly processes, requiring separate production lines, resulting in economies of scale lower than would be projected if all these parts were the same. Total industry volumes of BEVs are not an appropriate volume assumption for BatPac. Auto Innovators recommends that EPA update their approach to that used in the NHTSA analysis to estimate battery costs for strong hybrids, PHEVs, and BEVs, considering vehicle type and synergies with other fuel saving technologies. That analysis could be improved by using the BatPac results for BEV400s and BEV500s, instead of scaling up BEV300 costs.

User Costs of Electric Vehicles

Compared to many "invisible" technologies used by vehicle manufacturers to comply with CAFE and GHG standards (e.g., fuel efficient technologies that are integrated into the vehicle with little to no consumer visibilty or change to the driving experience), BEVs and PHEVs are a new technology type for many drivers and, as a result, may incur some costs and inconveniences that should be addressed in the RIAs.

First, the RIAs do not incorporate the costs of charging stations for BEVs and PHEVs, and the summary cost tables do not appear to include the expenditures on electricity consumed by BEVs and PHEVs.

Level 1 charging will likely be too slow for many motorists unless their vehicles are only driven short distances on a regular basis, and thus access to a Level 2 charging station at home or at work will usually be a minimum infrastructure for a BEV or PHEV, especially as battery capacity increases to support longer vehicle driving range. The equipment and labor costs for installation of Level 2 charging typically run somewhere between $500 to $2,000, depending on location, i.e., single family home versus multi-family; a small additional charge for maintenance/repair of the charging stations should be added. Level 3 fast chargers can run into the tens of thousands of dollars and are typically confined to business and commercial applications.309,310

At relatively low levels of EV penetration by prosperous early adopters, where home charging is the predominant method of charging, the agencies could offer a simplified analysis based on a simulated national distribution of charging events: 13% Level 1 charging, 68% Level 2 home charging, 14% Level 2 workplace or public charging, and 5% DC fast charging.311 Based on those assumptions and national-average electricity prices, the levelized cost of charging (which accounts for equipment, installation, and use) is about $0.15/kWh (NAS, 2021, 5-126). The estimates of induced electricity consumption in the RIAs, which were used to compute lifecycle emissions, could be multiplied by the levelized cost of charging to provide a rough estimate of electricity and infrastructure costs induced by the assumed low penetration rates of BEVs and PHEVs. Such costs are reasonably attributable to the proposed standards since the standards are designed explicitly to encourage BEV and PHEV offerings, the agencies estimate that the standards will cause more BEV and PHEV penetration, and the proposed standards are a part of a national policy initiative of 50% PEV penetration by 2030. As the country moves beyond early adopters toward higher levels of BEV penetration near the national goal, many targeted urban dwellers and less-prosperous households may lack a home charging arrangement. A more sophisticated analysis will be required at this point.

Second, the Agencies need to estimate the costs to the user of a vehicle that has a shorter driving range than the typical ICE vehicle and that requires a long time to charge compared to five minutes at a gasoline refueling station. A series of stated preference studies have found that are willing to pay a higher purchase price for vehicles with longer driving range and shorter refueling/recharging times. The authors of a meta-analysis of 33 consumer preference studies found that "short-range cars entail important losses for the average consumer."312 This preference was found in Nordic countries, where electric vehicle penetration is relatively high, and in the U.S., where EV penetration is relatively low.313 The magnitude of the preferences are substantial, with one early study showing willingness to pay at purchase of $35-$75 for each mile of added driving range, and $425-$3250 for each hour of reduced charging time.314 The first-generation, short-range BEVs (e.g., the early version of the Nissan Leaf) were not used nearly much as ICE vehicles; their annual mileage was more than 40% less than average ICE vehicles.315 As automakers have extended the range of BEVs from less than 100 miles to 200-300 miles, their perceived disadvantage compared to ICE vehicles has lessened.

Third, the time spent charging an EV needs to be considered. NHTSA – but not EPA – includes an estimate of the time costs of charging a BEV or PHEV during long trips that occur within one day. To be complete, the time cost should include any additional travel time to the charging station, any expected delay in accessing a charging point, and time spent during the charging event. As more EVs are sold in states with cold winters, the burden of extended, outdoor public charging in cold weather should be considered (as California's temperate coastal climate is not representative of the U.S.).

The bottom-up costing method used by NHTSA is defensible, and should be considered by EPA, but both agencies may wish to explore alternative approaches to measuring the hedonic cost to an owner of a BEV that has a shorter range and longer charging time than a comparably- sized ICE vehicle. EPA does provide different technology costs for a BEV200 and BEV300 but does not offer any estimate of the user benefit of the long-range BEV. NAS (2021) makes some logical arguments that consumers should be willing to make some compromises on driving range and charging time, but more behavioral research is needed to determine whether NAS's view is shared by consumers.

In summary, the Agencies need to depart from their historical practice of assuming that CAFE compliance technologies have zero costs to the user (beyond the purchase price). The electrification technologies, especially BEVs and PHEVs, entail a significant change in how motorists engage with the transportation and electric-utility systems.

Potential Impacts of Raw Material Sourcing , Cell Production, and Pack Assembly on U.S. Content

The NHTSA analysis correctly shows that direct manufacturing costs related to batteries are a significant portion of electrification technology costs. Historically, the permitting process for establishing mining operations on U.S. soil and for building new production and assembly capacity is lengthy. As electrified fuel saving technologies are more widely adopted, significant uncertainty remains about how well extrapolating future percent U.S. content from current percent U.S. content will characterize the supply chain, and employment. Particularly for light trucks, production locations, and supply chains may interact with other policies, such as trade and tariff policies, which may materially affect future costs, availability of parts, and the ability of manufacturers to rapidly bring fuel saving technologies to market. The projected future scale of transportation-related production of some technologies (such as batteries), as forecast in the NPRM compliance pathways, often implies an order of magnitude or larger production and throughput than the currently observed global supply, across all industries. Auto Innovators recommends frequent review and update of rule-making input assumptions related to percent U.S. content, based on observed market conditions. [EPA-HQ-OAR-2021-0208-0116]

Commenter: Alliance for Vehicle Efficiency (AVE)

Impact on Manufacturing Supply Chains. AVE urges EPA to consider the costs and risks to OEMs and technology suppliers associated with converting and expanding automotive supply chains to meet future standards as more ZEV vehicles are introduced into the marketplace. To remain competitive, and to meet future standards, OEMs and technology suppliers could experience significant challenges associated with revamping supply chains, training workers, and obtaining the necessary resources.

Global supply chain pressures have already had a dramatic impact on the automotive sector and its ability to manufacture more efficient vehicles. The ongoing semiconductor shortage, which is expected to last well into 2022, has increased the cost of manufacturing, stifled the production of new vehicles, and forced temporary shutdowns of American automotive facilities.21

Critical Minerals: Similarly, EPA should consider the impact of rising commodity prices and the global availability of critical minerals and materials. Demand for steel and aluminum and the critical minerals needed for EVs is growing and will likely impact the price and availability of all types of vehicles. The World Bank recently predicted the global need for critical minerals will quadruple by 2035, far exceeding current supply.[EPA-HQ-OAR-2021-0208-0256-A1, p.9] [Figure at docket number EPA-HQ-OAR-2021-0208-0256-A1, p. 9.]

The industry may face challenges in the critical materials supply chains needed to achieve compliance. This cost and risk analysis would be similar in scope to the analysis EPA already conducts on fuel prices, as incorporated in previous rulemakings.23 These measurements are key indicators that will impact production numbers, the price of vehicles, job growth, and consumer choice, and are a necessary consideration in determining future achievable standards. [EPA-HQ-OAR-2021-0208-0256-A1,pp.9-10]

AVE recommends EPA's regulatory analysis account for the impact multipliers have on technology improvements to internal combustion engines (ICE) and hybrid vehicles. [EPA-HQ-OAR-2021-0208-0256-A1, p. 2]

Charging Infrastructure: EPA acknowledges that developing charging infrastructure for EVs, PHEVs, and FCEVs will increase upfront costs and may possibly be a barrier for consumers purchasing these vehicles.24 EPA should therefore include an additional cost analysis for the infrastructure needs of EV, PHEV, and FCV vehicles for mass market adoption, as well as how the lack of charging infrastructure in certain regions may impact sales. This analysis would likely assist regulators with understanding the need for further consumer incentives. [EPA-HQ-OAR-2021-0208-0256-A1, p. 10]

Commenter: American Council for an Energy-Efficient Economy (ACEEE)

Since the 2012 rule was finalized, electric vehicle technology has progressed rapidly and battery prices have fallen. More people are buying EVs, and automakers are rapidly expanding their EV lineups. However, hybrids and electric vehicles still only represent a fraction of new vehicle sales and are ripe for rapid growth. They can play a considerable role in meeting stricter standards due to their superior emissions performance. Full battery electric vehicles and plug-in hybrids, as well as conventional hybrids, all have significantly lower fuel use and emissions than their conventional internal combustion engine counterparts. The proposed rule assumes plug-in vehicles reach about 8% by MY 2026 but we believe that automakers could reach even higher levels of penetration, leading to greater efficiency of the fleet.

Greater levels of electrification would allow automakers to meet standards based on EPA's Alternative 2, which proposes an additional increase in stringency of 10 g/mi in MY 2026, and the rule can and should advance that outcome. Increasing the share of non-plug-in vehicles that are strong hybrids from 6-7% in 2023 to 18% by MY 2026 and increasing the share of vehicles that are plug-ins to 14% by MY 2026, while maintaining the same growth in efficiency of gasoline-only vehicles as in the proposed standard, for example, would allow automakers to reach this higher standard. This level of ambition is also essential to put automakers on a path to reach long-term electrification goals and set the market up for further electrification post-MY 2026. [EPA-HQ-OAR-2021-0208-0251-A1, p. 12]

The cost to manufacture electric vehicles has also fallen significantly in recent years, making electric vehicles an attractive option for automakers. Many vehicle manufacturers have made announcements about expanding their EV offerings in 2021. Advances in battery technologies, in particular, have played a major role in reducing the cost to electrify, as the cost of lithium-ion batteries has fallen by over 80% since 2012 (IHS Markit 2020). As a result, the market has seen a steady rise in the number of offerings that are hybrids or battery electric vehicles. Plug-in vehicle sales increased from less than .5% in 2012 to 4% in 2020 while hybrid sales increased from about 3% to over 6% in the same period (EPA 2020). These advances mean that automakers have the technology available to them today to allow them to meet more ambitious standards. These advances are not adequately reflected in the proposed rule. Battery cost assumptions in the NRPM are too high and do not consider the manufacturing and technological advancements of the past few years. EPA uses the same cost figures used in the SAFE rule, which are based on 2017 data, effectively inflating the costs of vehicle electrification (EPA 2021b, p. 145). This limits the role stronger standards can play to drive electrification. The incremental cost of hybrids is also higher than it should be, limiting the role of hybridization can play as a compliance pathway. The incremental hybridization costs used in SAFE and in this rule range from $3,000 to $6,000, almost double what is reasonable (NHTSA and EPA 2020; NAS 2021). [EPA-HQ-OAR-2021-0208-0251-A1, pp. 12-13]

Historically vehicle standards have pushed the adoption of numerous fuel efficiency technologies in internal combustion engine vehicles and helped mainstream hybrid technology. Since the MY 2017-2025 rule was adopted in 2012, vehicle technology has continued to advance in no small part due to the efficiency targets set by that rule. [EPA-HQ-OAR-2021-0208-0251-A1, p. 13]

Commenter: American Enterprise Institute (AEI)

The value of reduced vehicle fleet refueling time. EPA at a conceptual level justifies the promulgation of a tightened fuel economy rule in part by asserting that 'vehicle electrification technologies are also advancing rapidly, as battery costs have continued to decline, and automakers have announced an increasing diversity and volume of zero-emission vehicle models.'49 If a reduction in time consumed by necessary refueling of a petroleum-powered vehicle fleet is a benefit of the Proposed Rule, then the time needed to recharge electric vehicles — when the option of doing so at night in, say, a suburban garage is unavailable — is a cost of the Proposed Rule, and EPA should have included this parameter in its analysis. It has failed to do so. [EPA-HQ-OAR-2021-0208-0254-A1, pp. 12-13]

Commenter: California Air Resources Board (CARB)

The agency cites the National Academies of Sciences recently released light-duty vehicle technology assessment. That technology assessment expects battery pack costs of $90- 115/kWh in 2025 and $65-80 in 2030.106 In May 2021, CARB presented its initial assessment of ZEV technology and battery costs to supports its upcoming rulemaking to adopt future standards for ZEVs. This included its draft Modeling Cost Workbook that included an assessment of battery costs and estimated a cost of $100/kWh in 2026 - similar to the estimates of the National Academies.107 Those battery costs fall well below those used in the draft TAR and Proposed Determination Technical Support Document. Costs for non-battery components are also declining due to improvements in design and integration, demonstrated by several vehicle and component teardowns like those available from Munro & Associates, Inc. 108 Costs are declining more quickly than previously expected, making it more likely that those OEM announcements will materialize.

As costs decline, zero-emission technology becomes cost-competitive and even superior to conventional technology. In comparison to conventional vehicles, zero-emission vehicles, especially battery-electric technology, can cost less to drive and maintain, on average. In every state, the cost of electricity is less than gasoline, and is 60% less on average across the nation. Similarly, the average maintenance cost per mile of a battery-electric vehicle is about 60% of a conventional vehicle. [EPA-HQ-OAR-2021-0208-0643-A6, pp. 34-36]

Commenter: California Attorney General Office, et al.

Third, automakers have expanded the hybrid, plug-in hybrid ('PHEV') and battery electric vehicles ('BEV') they are offering in the United States and have plans to further expand those offerings between now and MY2023.128 [EPA-HQ-OAR-2021-0208-0245-A1, p.27]

Commenter: Center for Climate and Energy Solutions (C2ES)

Additionally, federal funding for charging infrastructure is necessary to ensure all drivers will have access to charging equipment, helping to grow consumer confidence in electric vehicles.10 [EPA-HQ-OAR-2021-0208-0287-A1, p.4]

In the near-decade since the release of the 2012 Final Rule, electrification technologies have improved significantly. Between 2010 and 2020, average lithium-ion battery pack prices fell 89 percent.14 At the same time, average battery electric vehicle ranges increased significantly, with the median range of all-electric vehicles reaching 250 miles for MY 2020, according to the U.S. Department of Energy.15 Longer ranges help to eliminate range anxiety among drivers, improving consumer appetite for zero-emission vehicles.

At the state level, there is growing momentum to accelerate the transition to zero-emission vehicles, both through regulatory or legislative actions and incentive structures. Many states have enacted policies providing additional purchase incentives for electric vehicles and funding the expansion of charging infrastructure. Recently, Connecticut, New York, Oregon, and Vermont instituted consumer incentives, including rebates for the purchase of hydrogen and/or plug-in electric vehicles, which augment existing federal incentives.16 [EPA-HQ-OAR-2021-0208-0287-A1, p.5]

In 2021 alone, states including Louisiana, Maryland, Indiana, and North Carolina announced millions of dollars in grants to local utilities and municipalities to install charging stations, many emphasizing expanding access for rural or low income communities.17 [EPA-HQ-OAR-2021-0208-0287-A1, p. 5]

Utilities have also made significant commitments to expanding charging. For example, the Electric Highway Coalition, a collaboration between fourteen utilities across 29 states and the District of Columbia, aims to ensure efficient and effective fast charging deployment plans and to create a charging corridor with a network of DC fast chargers no more than 100 miles apart to facilitate long-distance electric travel.18 Safe, reliable technologies exist to electrify a significant portion of the global passenger fleet by 2035, and there is significant momentum behind the nationwide deployment of charging infrastructure. EPA's performance standards should build upon the stated ambitions of the private sector, holding automakers accountable through the regulatory process to their electrification goals and efficiency improvement commitments—particularly when many of them align with long-term decarbonization. [EPA-HQ-OAR-2021-0208-0287-A1, p.5]

Commenter: Chun, Mark

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 251.]

Let's talk about range anxiety. The majority of households work within a 15-to-30-minutes radius from home. Providing economic incentives for not only new but used CPO EVs would expedite adoption.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 251-252.]

In conclusion, there's 14 Asian and European countries that have ice bans ranging from the Year 2025 to 2050 with an average of 2034 as the target date.

Let's do all we can to incentivize average Joe households by making EVs economical and easy to get started.

Commenter: Connecticut Department of Energy and Environmental Protection

Further, EPA and the federal government must continue to invest in policies that promote technologies and infrastructure to further reduce mobile source emissions. GHG targets in Connecticut, the U.S. and worldwide will not be met unless there are viable alternatives to internal combustion engine vehicles. The federal government must do more to fund national infrastructure for electric vehicles, and electrification of larger applications, like transit buses. [EPA-HQ-OAR-2021-0208-0264-A1, p.2]

Commenter: Consumer Federation of America

Establishing the goal of an all-electric fleet and speeding the transition will require changes in infrastructure beyond the setting of efficiency standards, which the administration has recognized and is working hard to launch in the near term. [EPA-HQ-OAR-2021-0208-0297-A1, p. 24]

Commenter: Consumer Reports (CR)

Support for Higher EV Penetrations

The feasibility of greatly improving greenhouse gas standards beyond the preferred alternative is helped by rapid improvements in the economics of electrification in recent years, and corresponding growing market shares driven by automaker investments. The following subsections describe data that help justify the feasibility of stronger standards. EPA's analysis shows that Alternative 2 can be achieved with EVs accounting for only 6.9% of the fleet in MY2026. Much higher EV penetrations by this date are both likely, and needed, in order to achieve the administration's climate goals. [EPA-HQ-OAR-2021-0208-0602-A1,p.14]

EPA's modeling of both their preferred alternative, and Alternative 2 shows that both can be achieved with strong net benefits at very low EV penetration rates of 7.8% and 6.9% respectively in 2026. This is well below nearly all up-to-date, credible, industry projections. IHS Markit's latest projections expect US EVs (BEVs + PHEVs) to reach 24.3% of the market by 2026.33 Bloomberg New Energy Finance estimates EV penetrations in the US upwards of 15% by

2026.34 UBS estimates that EVs will account for 20% of the global light duty vehicle market by 2025.35 Although the UBS numbers are global, they indicate that if automakers can achieve that level globally, they can almost certainly achieve some high fraction of that level of penetration in the US. These projections by well respected industry experts combined indicate that EV market penetration rates of 15-25% by 2026 are well within the range of what is feasible. Furthermore, hitting EV penetration rates at least at the bottom of this range will be necessary to be on track to achieve President Biden’s goal of achieving 50% electrification by 2030.36 [EPA-HQ-OAR-2021-0208-0602-A1,pp.14-15]

In addition to being feasible, higher EV penetration rates will be highly beneficial to consumers. Consumer Reports has found that all of the best selling electric vehicles on the market as of 2020 will already save consumers thousands of dollars over the vehicle's lifetime, with typical savings between $6,000 and $10,000.37 This analysis also found that many of these vehicles will also save consumers money from the first year of ownership, as savings on fuel and maintenance outweigh the increased monthly payment on a financed vehicle. [EPA-HQ-OAR-2021-0208-0602-A1, p.15]

While consumers are already saving money on EVs today, they will only save more money in the future as the purchase prices drop. The cost of batteries has dropped by almost 90% over the past decade, and prices are expected to continue to fall in the future.38 This continued decline in battery costs is expected to bring the cost of electric vehicles down to the point of cost parity with conventional gasoline vehicles at some point this decade. [EPA-HQ-OAR-2021-0208-0602-A1, pp.15-16]

Estimates of exactly when cost parity for electric vehicles will be achieved vary, but most estimates fall between 2023 and 2028 (see Table 3.1). However, in vehicle classes such as luxury and sports cars, where consumers are willing to pay extra for power and performance, electric vehicles are expected to be cheaper than gas powered vehicles even sooner. This is due to the fact that it’s much cheaper to add additional horsepower to an electric vehicle than to a gasoline vehicle. That extra power also comes with less of a penalty in terms of fuel cost due to the inherent greater efficiency of electric vehicles, and the lack of a need for premium fuel. This is backed up by claims from GM that EVs are already cheaper in the luxury segment.47 It is also reflected in the actions of the rest of the auto industry, with many luxury automakers promising to rapidly increase electrification, and some promising to go all electric by the end of the decade.48 [EPA-HQ-OAR-2021-0208-0602-A1, pp.16-17] [[See EPA-HQ-OAR-2021-0208-0602-A1, p.16 for Table 3.1]]

Commenter: Elders Climate Action (ECA)

ZEV sales targets are needed now –

• to establish benchmarks for all automakers to meet to create a level playing field that promotes competitive market conditions for zero emission vehicles based on performance, reliability and cost;

• to ensure a market for ZEVs that will justify early investment by third parties in the development of supply chains needed for production of batteries and fuel cells;

• to ensure the capacity of the industry to ramp up to 100% of sales to ensure that ZEVs will be available in time to replace 280 million on-road vehicles by 2050;

• for MY 2026 to give the industry enough lead time to develop supply chains, plan the conversion of production facilities and develop marketing campaigns designed to assure public acceptance of their products. [EPA-HQ-OAR-2021-0208-0521-A1, p.3]

For most transportation sources such as on-road vehicles, zero emissions can be cost-effectively achieved by electrification with batteries or fuel cells. [EPA-HQ-OAR-2021-0208-0521-A1, p. 10.]

Commenter: Energy Innovation Policy and Technology LLC

The companion Policy Report finds that achieving the DRIVE Clean Scenario requires a combination of policy and regulatory changes at the federal, state, local, and utility level, including:

• Strengthened EPA tailpipe emission standards that support ZEV sales and reduce overall tailpipe emissions for all ground vehicle classes to 0 g/mile by 2035;

• Continued adoption of state ZEV standards and rules;

• Incentives for EVs and charging infrastructure to help more consumers access affordable new and used EVs and convenient charging;

• Workforce programs that help streamline the transition to EVs and create new jobs;

• Incentives for domestic manufacturing to encourage the production and sale of electric cars and trucks;

• EV-friendly rules, codes, permitting, interconnection, and rates. [EPA-HQ-OAR-2021-0208-0605-A1, pp. 9-10]

Commenter: Energy Strategy Coalition

Our companies and the states in which we operate have made commitments to additional investments to support EVs and this growing market. National Grid, for example, in addition to significant company- and service-area wide initiatives to support EVs, is investing $9 million in Rhode Island, $25 million in Massachusetts with plans to significantly scale up this investment in the coming years, and over $150 million in New York in charging infrastructure, incentives, and other programs to support existing and new EV drivers and to help meet state goals. Austin Energy provides rebates up to $1,200 to support customers to installing EV charging stations in their homes and up to $4,000 for chargers at workplaces. PG&E is investing more than $400 million in infrastructure and programs to support light-, medium- and heavy-duty EVs with incentives and targets for deployment in disadvantaged communities. Seattle City Light has already invested more than $12 million in installing public charging stations and is collaborating with the region's transit system, state ferry system and the Port of Seattle as they electrify their operations in the service territory. Los Angeles Department of Water and Power will invest nearly $150 million in the coming years on a variety of programs, including charging installation and rebates, electrification of ports, buses, and other heavy-duty vehicles, and education and awareness building for customers. Exelon's utilities are implementing EV programs in Maryland, New Jersey, Delaware, and the District of Columbia with approximately $70 million of approved capital to support EV programs and approximately $10 million deployed to date. PSE&G will invest $166 million to support installation of approximately 45,000 chargers in New Jersey. The Sacramento Municipal Utility District is planning to spend approximately $30 million over the next three years in supporting EVs, including charging infrastructure for both residential and commercial customers and in under-resourced communities.

These commitments and activities support a wide variety of programs, including charging infrastructure investments and educational programs that support the expansion of the EV market. These investments reflect the commitment of our companies and the conclusion that, due to both technological and competitive factors, EVs will continue to grow and play a critical part in the U.S. transportations sector. The Proposed Standards help create a business and market environment that supports these investments and spurs others. [EPA-HQ-OAR-2021-0208-0533-A1, p.3]

Commenter: Environmental Protection Network (EPN)

This proposal covers a limited number of near-term MYs, but it must be evaluated in the context of the overwhelming need for a transition to zero-emissions technologies for these vehicles. EPA's goal should be the sale of near-100% zero-emissions cars and light trucks by MY 2035. [EPA-HQ-OAR-2021-0208-0213-A1, p. 1]

Electrification Revolution Offers a Practical Pathway to Zero-Emissions Vehicles. The two leading zero-emissions technologies for car and light-truck applications are battery electric vehicles and hydrogen fuel cell vehicles. Since these technologies emit no tailpipe pollution, life-cycle GHG and criteria emissions are dominated by the emissions associated with the production and distribution of electricity and hydrogen (of course, there are emissions associated with vehicle manufacturing and disposal as well, as with gasoline and diesel vehicles).

Until recently, many believed that there were too many obstacles to battery electric and hydrogen fuel cell vehicles being viewed as a widespread zero-emissions solution.

EPN believes that this is no longer the case, that we are now on the cusp of an 'electrification revolution,' and that battery electric vehicles (hereafter EVs) now offer a practical and economic pathway to zero-emissions for new cars and light trucks over the next 15 years and for the in-use car and light-truck fleet over the next 30 years. This shift is due to three key trends that have completely upended past skepticism about EVs.

One key trend is that widespread decarbonization of the U.S. electricity sector in the next 20 years now appears to be a near certainty. Historically, fossil fuels have been the primary feedstocks for electricity generation in most parts of the U.S. (with some regional exceptions). As long as the electric system is powered primarily by fossil fuels, EVs are not true zero-emissions vehicles, due to fuel production/distribution GHG and criteria emissions. For example, in most regions of the U.S. today, EVs typically yield about a 50-75% reduction in tailpipe plus fuel production/distribution GHG emissions, relative to a similar gasoline vehicle, depending on the electricity sector fossil fuel market share. Accordingly, today EVs are still responsible for 25-50% of comparable gasoline plus fuel production/distribution GHG emissions, plus fine PM, NOx, and other criteria pollutants as well. But the GHG and criteria emissions footprints of EVs are going to rapidly change as the U.S. electricity sector is decarbonized.

Costs of solar and wind power have plummeted over the last decade—utility-scale solar photovoltaic (PV) costs have plummeted by 85% since 2010, and onshore wind costs have declined by 56%.[14] The International Energy Agency has famously stated that, in many places, ‘solar PV is now the cheapest source of electricity in history.’[15] The U.S. Energy Information Administration reports that fully 81% of new U.S. electricity generating capacity in 2021 will be solar, wind, and batteries (which are almost exclusively paired with wind and solar to accommodate their intermittency).[16] Industry experts expect solar and wind (and batteries) to continue to benefit from innovation and scale-related cost reduction in the future.

In addition to the Biden administration’s pledge to achieve a carbon-free electric sector by 2035, many U.S. states have adopted aggressive requirements or targets to decarbonize electric utilities, and many utilities have made voluntary commitments, often going farther and faster than state requirements. The widespread trend toward electric sector decarbonization means that, by 2035, an EV will be essentially a zero-emissions vehicle in terms of tailpipe plus fuel production/distribution GHG and criteria emissions.

A second key trend is the plummeting cost of batteries. A decade ago, the conventional wisdom was that the true cost to produce an EV was tens of thousands of dollars more than a comparable gasoline car, primarily due to the cost of large battery packs and poor economies of scale. This was the single biggest obstacle to mainstream acceptance of EVs.

Battery innovation and economies of scale have led to a near-90% reduction in lithium-ion battery costs in the last decade.[17] EVs that once had cost premiums, relative to their gasoline counterparts, of tens of thousands of dollars are now typically $5,000 or $10,000 more expensive. [EPA-HQ-OAR-2021-0208-0213-A1, pp. 4-5]

A third key trend is the recognition by many automakers that EVs represent the industry’s future. This is a fundamental change from a decade ago when EVs were viewed as niche vehicles with little chance of widespread utility or appeal. In its Notice of Proposed Rulemaking (NPRM), the agency pointed out that there are already about 60 EV/plug-in hybrid electric vehicle (PHEV) models for sale in the U.S., and that this is expected to grow to about 80 models by 2023.[18] Automakers have publicly pledged to spend over $200 billion in the next few years on electrification research, vehicle design, and assembly and battery plants. General Motors has an aspirational goal to achieve 100% zero-emissions vehicle sales in the U.S. by 2035,[19] and Ford is bringing the F-150 Lightning EV pick-up truck to market in 2022 at a $40,000 base price point that will make it competitive with gasoline versions of the best-selling vehicle in the U.S. market.[20] [EPA-HQ-OAR-2021-0208-0213-A1, p.6]

We Will Only Achieve Near-100% New Zero-Emissions Vehicles by 2035 if EPA Requires It. EPN stipulates that, for several reasons, a fast transition to EVs will not be simple or easy. Examples of fast consumer product transitions typically involve innovations with no or minimal tradeoffs, for example, the change from landlines and “flip” cell phones to smartphones, where the latter was a clearly superior product in every way.

EVs offer many important advantages over gasoline vehicles: zero GHG and criteria pollution, lower and more predictable fuel and maintenance costs, the convenience of home refueling for many homeowners, and in the near future the likelihood of lower vehicle prices.

Finally, EPN agrees with statements by some individual automakers and the Alliance for Automotive Innovation that there is a critical need for complementary federal policies to support a fast transition to EVs in at least three areas: the extension of federal tax credits/rebates for consumers who are willing to buy EVs in the next few years, the buildout of a nationwide public refueling infrastructure, and a modernized and more sophisticated electric grid to support widespread EV use. The Biden administration infrastructure bills include all these critical components, which are currently being debated in Congress. None of these programs would fall under the purview of EPA, of course.[EPA-HQ-OAR-2021-0208-0213-A1, p. 6-7]

Analysis of electrification:

1. Battery— cost, range, etc. This analysis appears appropriate. As part of laying a foundation for the future MYs, it is important to discuss expected future progress as well.

2. Charging and Other Infrastructure. This rulemaking needs to lay a solid groundwork for a following, longer-term rulemaking covering the increasingly broad-based and widespread transition to electric power in MYs after 2026. Therefore, issues such as battery technology, range, and cost; charging technology and infrastructure; and other issues such as electricity grid developments all need to be addressed in this rulemaking. Charging technology and infrastructure is also a critical issue for environmental justice communities.

3. EPA has addressed some areas in detail, such as issues related to battery technology, range, and cost. However, the proposal only gives limited attention to the key issues concerning charging technology and infrastructure, as well as electricity grid developments.

4. Recognizing that these issues are of much greater importance in the rulemaking for MY 2027 and later, to the extent practicable, EPA should provide a more in-depth discussion of these

issues in this rulemaking as part of laying the groundwork for the later successful transition to widespread electrification of cars and light trucks. [EPA-HQ-OAR-2021-0208-0213-A1, p, 11]

Commenter: Ford Motor Company

The Transition to Electric Vehicles. Ford is committed to sustainability leadership, and to being fully carbon neutral worldwide no later than 2050. We're pleased to see the Biden Administration making climate change an early and high priority, along with focusing on American manufacturing. We are doing our part and making our most iconic vehicles electric; the Mustang Mach-E, America's best-selling truck for 44 years – the F150 Lightning, and the E-Transit Commercial Van. Critical to a successful transition are federal and state complimentary measures supporting electrification, such as:

- Purchase incentives to accelerate the transition to EVs, and to achieve the President's goal of making half of all vehicle sold in 2030 electric vehicles. This could include a nationwide low carbon fuel standard (LCFS) program, funding consumer EV incentives as in California's Clean Fuels Reward program.

- EV charging infrastructure policy (residential, workplace, and public facilities)

- Policies to support development of EV and battery manufacturing and domestic supply chains, including critical minerals, and development of a battery and EV recycling system in the United States.

- Consumer education programs

- Continued actions and commitments by automakers to improve the availability, variety, and affordability of EVs in the United States. [EPA-HQ-OAR-2021-0208-0294-A1, pp.5-6]

Commenter: Gillet, Victoria

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 289.] Thankfully, you know, I know that these are harmful, but we also know the paths to the solution: electrify everything as quickly as possible, particularly transportation infrastructure, and make the electricity that we need for those electrified systems with local green energy. That transition will save 2,000 or more lives per year just in my home State of Wisconsin, and the benefit will disproportionately be good for those who have had really negative health outcomes in the past.

Commenter: Holiday, Thomas

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 81-82.]

All I would ask is that the automakers have a significant increase in the production of hybrids. In other words, the technical standards of the fleet should mix their hybrids. Instead of a two percent mile hybrid and a five percent strong hybrid, the automakers should voluntarily raise those hybrids 10 percent per mile hybrids, 10 percent of the fleet for strong hybrids. If they do that, they will sell them.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 82-83.]

Because hybrids give us independence from the vulnerability in a developing grid, gives us independence from natural disasters, cyber hacks, disruptions due to evolving demand on the grid, and they get us there right away. So mixing the hybrids in at a lower percentage will advance the high efficiency of every fleet. We need more hybrids and one more thing. Pollution is local, and it's also global. Weather is global, and the global air climate is a world circulation system with winds that transport water, heat, CO2, water vapor, all of the greenhouse gas emissions.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 83-84.]

So it's not a free ride to go straight to electricity and say all of these vehicles that we really have to have, we couldn't handle it. I'm not sure we can handle it by 2026, but if we go to hybrids first and we build up the hybrid arsenal on the roads, I think that it would go a long way.

I just say electrifying American mobility, it starts here. Let's do it right, put the immediate emphasis on hybrid.

Commenter: Holmgreen, Jack

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 41-42.]

The effect is that the plug-in vehicles are actually just replacing gasoline with some other fossil fuels for the most part.

My comment is this. The plug-in vehicle is not adding efficiency unless it is coupled with a requirement that it provides solar, wind, or hydrogen power to charge it. With hybrid models, however, there is an immediate reduction in gasoline consumption and pollution with no burden on the already delicate grid as witnessed here in Texas last winter.

Most plug-ins will charge at home in the evenings when returning from work and this is at peak load period. Some countries are already assessing huge import duties for all-electric vehicles because it is far more efficient to just burn gas in the car than it is to rely on the grid which in many cases is fed pirmarily by coal.

Commenter: Hyundai America Technical Center, Inc. (Hyundai)

How to ensure the success of an electrified market driven by GHG standards. It is Hyundai's view that the 2023 through 2026 Model Year ('MY') GHG standards will require significant electrification not only to meet the proposed standards but also to set the foundation for achieving the future electrification goals.

The Administration's ambitious goals require an all-hands-on-deck approach to ensure the success of an electrified market including coordination between government agencies, utilities, automakers, fuel suppliers, manufacturers and the supply chain, among others.

As stated, the NPRM and planned future electrification are challenging and will require dramatic transformations in many areas:

- Continued growth of consumer acceptance of EVs
- Proportional additions of EV charging and hydrogen fueling infrastructure
- Availability of consistent EV purchase incentives
- Robustness of the supply chain
- Resiliency of the electric grid
- Growth of green electricity and hydrogen and
- Certainty that all 50-states support expansion of the electric vehicle market.

The success of the program depends on the successful coordination of each of the above variables to deliver the unprecedented penetration of EVs. Therefore, it is crucial that each area is proactively monitored on an ongoing basis, with defined targets and metric-based checkpoints to measure progress. Such continuous, proactive monitoring will inform and enable actions to resolve obstacles before they adversely impact the U.S.'s electric vehicle future. [EPA-HQ-OAR-2021-0208-0603-A1, pp.2-3]

Accessible and reliable infrastructure is required to support plug-in EV charging and hydrogen fueling needs and inspire confidence in potential EV customers. It is critical to monitor infrastructure growth to assure it is available to support the ever increasing number of electric vehicles on the road.

Using the Department of Energy estimate5 for number of EVs per charger, nearly two million plug-in chargers are needed to support the number of EVs projected to be on the road in 2030 (assuming 50% new EV sales by 2030). Figure 1 below shows a linear increase in new EV sales from 3% in 2021 to 50% in 2030 in green, with the estimated percentage of overall EVs in the on-road fleet in orange, both referenced off the left axis. The corresponding DC Fast Charge ('DCFC') and Level 2 ('L2') ports required to support this number of EVs is shown in blue and referenced off the right axis. [Figure 1 can be found at docket number EPA-HQ-OAR-2021-0208-0603-A1, p. 5]

An important infrastructure checkpoint is ensuring that infrastructure policies and growth aligns with and supports the Administration's electrification goals.

Beyond having enough charging and fueling stations, installing the chargers and fuel dispensers in optimal locations that match EV density is vital to appropriately serve all EV customers. Priority siting should include corridors (freeways), destinations (malls, restaurants, and parks), and multiunit dwellings (as residents do not own the garage to install a charger). Another consideration is that infrastructure development is on track to meet the needs of all EV drivers. [EPA-HQ-OAR-2021-0208-0603-A1, pp.4-5]

Supply chain resilience and diversity. A resilient supply chain is crucial to moving forward with electric vehicles. As stated by President Biden: ‘We need a strong, diversified and resilient U.S.-based electric vehicle battery supply chain, so we can supply the growing global demand for these vehicles and components.’

We support strengthening the supply chain for critical minerals and all materials needed in the production of electric vehicles. The diversity and resiliency of the supply chain for all materials needed for electric vehicles should be monitored at checkpoints to determine if any weaknesses are identified and address these accordingly. [EPA-HQ-OAR-2021-0208-0603-A1, pp. 5-6]

Electric grid resiliency. The grid is critical to consumer confidence in electric vehicles. Resiliency is needed for a stable grid. Instability can be disruptive to people’s lives and hamper the uptake of electric vehicles. The national electric grid should be evaluated for readiness to accommodate growth in the electric vehicle market and hardiness against extended outages so that any issues can be addressed before widespread expansion of electric vehicles. This evaluation should be ongoing.

Green electricity and hydrogen. The government should promote and monitor continuing progress towards green electricity and hydrogen. Renewable energy is important for U.S. energy security, the reduction of fossil fuel use, and corresponding greenhouse gas reductions.

Full commitment of all 50 states. We recommend that the Federal government work with all stakeholders including the Governors of all 50 states to facilitate and accelerate EV adoption. Every state must be committed to electric vehicle expansion by developing a concrete blueprint to usher in an electric future.

Current levels of state engagement and support for EVs vary widely with some having no EVrelated support and others offering more comprehensive programs, such as California and New York. Examples of state programs to support EVs include financial incentives for EV purchases and infrastructure, highway corridor fast-charging networks, high-occupancy vehicle lane exemptions, vehicle inspections or emissions test exemptions, parking incentives, and support for utility rate reductions.

The Federal government should work with states to develop metrics to assess readiness for high levels of electrification and enhance programs accordingly.

Fleet purchase requirements. Hyundai supports the Federal Government requirement to add electric vehicles into the Federal fleet and acknowledge the Department of Energy’s6 and other agencies' efforts to promote private fleet electrification. The Federal government could further drive the demand for these new advanced technology vehicles by requiring public and private fleets to purchase EVs at a rate proportional to their overall vehicle market share, where permitted by law. Public, private, and government fleets purchase millions of vehicles each year and are critical to achieving electrification goals.

The California Clean Miles Standard7 is an example of a program designed to transition Transportation Network Companies (like Uber and Lyft) by increasing the electric miles driven each year. The government should at a minimum monitor, and should ideally mandate, fleet purchases of electric vehicles to support the transition to EVs.

In summary, the Federal government should spearhead a multipronged task force of leading experts to prepare defined metrics for each of the above checkpoints, continually assess progress, and recommend preemptive measures. Proactive monitoring as proposed above will be critical to identify and address constraints to EV adoption before they can have an adverse impact. [EPA-HQ-OAR-2021-0208-0603-A1, pp.6-7]

Commenter: International Council on Clean Transportation

Full hybrid cost: The agencies have substantially overestimated the costs of full hybrid vehicles. Because of difficulties in deciphering the agencies' multiple and inconsistent hybrid cost components, ICCT analyzed the complete vehicle costs from the agencies' final output files in the Augural standard analysis for the SAFE proposed rule. This revealed the modeled incremental price increase for hybrids was approximately $6,600 per hybrid vehicle in 2017, decreasing to $4,800 in 2025. As analyzed in ICCT's 2015 report on hybrids (ICCT 2015 hybrids),20 this is not a plausible result.

For additional information see:

ICCT 2018 comments pages I76-I77

ICCT 2015 hybrids

Battery cost: EPA used an updated ANL BatPaC model (BatPaC Version 3.1, 9 October 2017) as the basis for BEV, PHEV, HEV and mild HEV battery costs in its 2018 MTE, but these updated costs were not used in the proposed rule.

For additional information see: EPA DRIA page 1-8

Non-battery BEV and PHEV cost: For EPA's 2018 MTE, non-battery BEV and PHEV costs were updated based on more recent teardown data from California Air Resources Board, UBS, and other references,21 22 23 but these updated costs were not used in the proposed rule.

For additional information see : EPA DRIA page 1-8 [EPA-HQ-OAR-2021-0208-0522-A1, pp. 8-9]

Battery cost: Unlike for the other technologies in the agencies' analysis, the vast majority of costs related to the RPE markup are already included in the base costs that the agencies used from ANL lookup tables. In other words, those lookup tables do not provide 'direct manufacturing costs,' they provide total costs, including indirect costs. Thus, EPA erroneously inflated battery costs by applying the retail price equivalent (RPE) markup to base costs that already include indirect costs.

For additional information see: Joint NGO 2020 Reconsideration Petition, pages 88-90 [EPA-HQ-OAR-2021-0208-0522-A1, pp. 10]

Mild Hybrid: 'Suppliers are developing 48-volt systems with higher power outputs (20 - 30kW). EPA should focus on the integration of such higher power 48-volt mild hybrid systems to evaluate potential advancements in launch assist, low-speed electric driving, aggressive fuel cutoff, startstop, and torque assist during driver tip-in. In addition, these higher power ISG systems should be applied to demonstrate further advancements in synergistic technologies such as advanced electric boosting solutions, high energy ignition systems, advanced cylinder deactivation (dampen torsional vibrations), electric accessories (HVAC compressor), and an electrically heated catalyst. The use of heated catalysts will enable fuel economy to be optimized without concern of low catalyst temperatures which may result from aggressive start-stop strategies. Applications of the 48V motor-generator capability should be evaluated in P2, P3, or P4 configurations, opposed to the current P0 geometries.' (Roush 2021 LDV page 11).

'Roush believes that in the 2021-2030 time frame, higher power 48-volt systems (in P2, P3, and P4 configurations) along with complementary fuel-saving technologies enabled by the high power output of the 48-volt architecture will play an important role in increasing the fuel economy of lightduty vehicles. Such technologies or synergies have not been considered by the EPA or ICCT or the SAFE analysis.' (Roush 2021 48V page 9).

Commenter: International Union, United Automobile, Aerospace & Agricultural Implement Workers of America (UAW)

The move towards electric vehicles will reduce CO2 emissions but currently, only roughly 2% of passenger vehicles are electric. This transformation will not occur overnight and will require an all-of-government approach. Electric vehicle targets will have limited success if they are not coupled with an array of policies to support domestic production and give American workers the opportunity to build the vehicles of the future. It is essential that the Build Back Better Act and the Infrastructure Investment and Jobs Act pass into law as they help set up the foundation for future success. Senator Debbie Stabenow (D-MI) and Rep. Dan Kildee (D-MI-5) are leading the charge in Congress to make sure that future jobs will be protected for decades to come. Their provision in the Build Back Better Act ensures that key consumer rebates for electric vehicles (EV's) create incentives for creating and maintaining good paying, union jobs in the United States. We greatly appreciate the Administration's support for this innovative approach. [EPA-HQ-OAR-2021-0208-0749-A1, p. 2]

Commenter: Lombardy, Anthony

As an American, concerned with the building of more radiation producing nuclear plants, and the increasing number of environmentally damaging mining operations, I'm writing to express my opposition to the EPA's proposed GHG emission standards for passenger cars and light trucks. I respectfully urge you to abandon them as soon as possible and keep the current standards that have drastically reduced pollution with the use of cleaner gasoline and diesel powered vehicles. Electric Vehicles have been wrongly called zero-pollution cars and light trucks. The unsafe and environmentally damaging means that will be needed to generate sufficient electricity, and extricating the rare minerals required to manufacture Electric Vehicles and their batteries, will produce an even more toxic environment that pollutes the atmosphere, waters, and land. Even the EPA has given accolades in it's comments on the status of new gasoline and diesel powered vehicles which emit extremely low emissions and provide high mileage rating unthought of in the past. The extremely high voltage & amperage that power Electric Vehicles are dangerous to first responders, service technicians, and the vehicle occupants - not to mention deadly if directly or indirectly contacted. Due to the extreme heat produced by the battery to power the electric motors, and the vehicle‘s many operational functions, as well as cooling the battery itself, the risk of hard to extinguish high voltage electrical fires is much higher compared with conventional vehicles. In addition, the mileage ratings and charging times being touted for Electric Vehicles is for optimum conditions, and with power sapping comfort, operating, and assistance, devices turned off. The current policy by the EPA is the correct course, not the taxpayer subsidized production and purchasing of Electric Vehicles. Improving gasoline and diesel powered vehicles is the correct route to protecting the health, climate, and pocketbooks for all Americans. [EPA-HQ-OAR-2021-0208-0722-A1, p. 1]

Commenter: Maine Department of Environmental Protection

Furthermore, as battery costs have declined and vehicle ranges increased, a number of automakers have announced plans to fully electrify their fleets in the coming years, signaling a rapid shift towards zero emission technologies not only in the United States, but throughout the world. With nearly 40 percent of the national LDV market already subject to the California standards, EPA's 2023 LDV Proposal can help ensure these vehicles and their environmental benefits are available to all consumers coast-to coast. [EPA-HQ-OAR-2021-0208-0225-A1, p.2]

Commenter: Maryland Department of Environment

Maryland, like many states and local jurisdictions, has made substantial investments in EV incentives and EV infrastructure. We support the federal government taking action to increase initiatives and incentives to further deploy EV and other LDV clean technology the key pieces in the widespread implementation of EVs. Based on numerous studies, Maryland views charging infrastructure as being crucial for the widespread implementation of ZEVs. Over the past five years Maryland has invested over eleven million dollars in the installation of public and private chargers throughout the State. These charges are located at private residences, along public corridors, public areas, and at the workplace. It is important to focus on a mix of charger technologies and locations to meet the needs of the consumer. Moving forward the state will continue its leadership role by investing over sixteen million dollars over of the next three years in the installation of public and private chargers located throughout the State. In addition, Maryland has continued to work with private businesses and Utilities to invest in Maryland’s charging infrastructure. As a result of this effort, Maryland is now recognized as one of the top ten states in the country for charging infrastructure.1 Despite all of this work, studies suggest that Maryland will still need significant investment in chargers if it is to support expected 2030 EV sales. Because of this, states will need strong federal programs to provide the additional infrastructure that states will need to support projected EV volumes. [EPA-HQ-OAR-2021-0208-0241-A1, pp.1-2]

Commenter: Merlotti, J.

Besides electrical charging, EV batteries require significant mining of rare earth minerals Lithium and Cobalt - that create harmful environmental issues of their own.

'There is no way there’s enough raw materials being produced right now to start replacing millions of gasoline-powered motor vehicles with EVs,' said Lewis Black, CEO of Almonty Industries Inc, which mines the hardening metal tungsten in Portugal and South Korea. 3/1/21

A shift to green energy will create energy dependence for the US on foreign states – many of which are not allies of the US.

For further reference, please see:

https://www.reuters.com/article/us-usa-mining-insight/to-go-electric-america-needs-more-mines-canit- build-them-idUSKCN2AT39Z

https://interestingengineering.com/clean-evs-and-dirty-lithium-mining-business

https://www.nbcnews.com/business/autos/amid-clean-energy-push-u-s-swapping-fossil-fueldependence- n1270851 [EPA-HQ-OAR-2021-0208-0189-A1, p. 3]

Second, renewable energy is complementary to fossil fuels, not a replacement. The only feasible way for the US to produce enough non-fossil fuel or 'green' electrical energy for EVs would be to develop more nuclear energy plants (which has no current momentum). Solar and wind simply cannot supply the needed energy for the current electrical demand and mass scaling of EVs.

Reduced Refueling Time

The EPA states a significant saving in refueling time – when the opposite is generally true for EVs vs ICE.

The proposal assumes access to garages or carports for overnight/pre-drive charging. There are ~280M vehicles in the US and 140M Homes. Only 63% of homes (140M x 63%) or 88M homes have a garage or carport. This implies only 88M/280M = 31% of vehicles in the US have access to garage or carport for pre-drive charging – leaving the majority of EVs nearly 70% in need of public charging stations for simple commuting. With minimum recharging times up to 30 minutes to 1.5 hours for fast/high power charges, this will create a net increase, not decrease in 'refueling' time for the average consumer.

Then, as for long distance driving, range for EVs is dramatically impacted. These known facts negatively impact refueling time. For reference, see:

https://www.caranddriver.com/shopping-advice/a32603216/ev-range-explained/

The EPA needs to clearly define their claim of reduced refueling time for EVs

Cost savings risks and other risks for EVs. Where is the risk/impact/cost of battery fires in this EPA proposal? For reference, see the massive recall by Chevrolet on their Bolt:

https://www.wsj.com/articles/gms-chevy-bolt-recall-casts-shadow-over-ev-push-11630246736

Where are the power efficiency impacts of operating EVs in hot/cold climates in this EPA proposal? (>80 and <60 Fahrenheit)?

For reference, see:

https://www.wired.com/story/electric-cars-cold-weather-tips/

The EPA should ask for NHTSA assistance to recommend acceleration governors for EVs do to the much faster acceleration 0-50 for an EV and the risks associated with slower ICE vehicles at intersections and merging traffic, and/or increased motivation for racing.

For reference, see:

https://www.caranddriver.com/features/g36420161/evs-compared-gas-powered-vehiclesperformance/

The EPE needs to include high cost ($5K to $6K minimum) of EV battery replacement and/or associated faster depreciation for the many consumers that own vehicles more than 8 years. Most used EVs will be purchased by lower income households that can’t afford an expense of this magnitude.

There are many additional costs/risks the EPA does not address in this proposal – that need to be included for a comprehensive proposal – especially for such a massive endeavor as proposing to change the power source for the US motor vehicle fleet. [EPA-HQ-OAR-2021-0208-0189-A1, pp. 4-5]

Commenter: Metropolitan Mayors Caucus

At the same time, public awareness of the climate crisis, as well as technological advances in fuel efficiency and transportation electrification has quickened [EPA-HQ-OAR-2021-0208-0504, p.1]

Commenter: Minnesota Pollution Control Agency (MPCA) and Minnesota Department of Transportation (MnDOT)

Transportation is also a sector where strong technology solutions already exist to achieve significant near-term emission reductions. Our country needs to act to take advantage of the opportunity to shift towards electrification and biofuels and be a global leader in the development, production, and use of clean vehicle technology. [EPA-HQ-OAR-2021-0208-0211-A1, p.2]

EPA's proposed standards can be achieved with very little electrification and do not reflect the commitments auto manufacturers have made to aggressively electrify their fleets. The 2012 standards were found to be reasonable and achievable during EPA's Midterm Review and electric vehicle (EV) technology has only gotten better and more affordable since then. EPA notes in its proposal that the technology needed to achieve these emissions standards is widely available and currently in use, and that the standards will only require broader and quicker penetration of existing technologies. The MPCA and MnDOT agree with this assessment. An industry's technological readiness for achieving a standard should serve as a backstop for a standard [EPA-HQ-OAR-2021-0208-0211-A1, p.3]

Commenter: Moore, Kenneth

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 323.]

While the purchase costs of electric vehicles is currently higher than fossil fuel vehicles, that's about to change. With increased production and advances in better e-technology, the range and purchase costs of electric vehicles will soon be on part with fossil cars and trucks.

Commenter: Motor & Equipment Manufacturers Association (MEMA)

MEMA Supports Continued Investments in Supply Chain and Technology Improvements. MEMA supports investments to strengthen and improve the U.S. manufacturing supply chain. MEMA strongly encourages continued analysis of potential challenges for the U.S. manufacturing supply chain for the transition to higher levels of vehicle electrification. This is particularly important for the resources needed to manufacture, recycle, and dispose of (or repurpose) electric vehicle batteries. We support further investments in developing our limited domestic material processing capacity. MEMA generally supports investments and requirements for battery recycling as this would be a force for progress in technology development and strengthening the critical U.S. supply chain if implemented correctly and thoughtfully. Over the long-term, the U.S. must create greater sourcing of these critical components and technologies for the domestic market and the U.S. supply chain. Increasing and diversifying supplies of components and materials in the U.S. are vital to domestic vehicle parts manufacturers. MEMA supports policies that will create a more sustainable supply chain in the U.S. and encourages a virtuous cycle of recycling and repurposing.

Along those same lines, as the markets for these advanced vehicle technologies continue to grow and strengthen, the technologies should also continue to improve. These technologies must be required to continue to innovate and provide cost-effective emission reduction solutions. It is important that performance standards are set to ensure continuous improvements in these advanced technologies (e.g., lower emissions over the full lifecycle, battery performance, range requirements and deterioration limitations). Setting performance standards will provide protections and incentives for consumers that invest in the technology. This will ensure and sustain supplier technology investments. [EPA-HQ-OAR-2021-0208-0249-A1, p. 15-16]

Commenter: National Association of Clean Air Agencies (NACAA)

EPA touts in this proposal the 'proliferation of recent announcements by automakers [that] signals a rapidly growing shift in investment away from internal-combustion technologies and toward high levels of electrification. These automaker announcements are supported by continued advances in automotive electrification technologies, and further driven by the need to compete in a global market as other countries implement aggressive zero-emission transportation policies.' By way of example, EPA cites announcements made this year by General Motors, Volvo, Volkswagen, Honda, Ford, Fiat, Stellantis and Mercedes-Benz (see 86 Fed. Reg. 43,729-30). [EPA-HQ-OAR-2021-0208-0255-A1, p. 4]

Clean Technology. NACAA supports LDV clean technology, investments in building the infrastructure needed to support this clean technology and steps taken to facilitate this clean technology. States and localities across the country are investing considerable resources to proactively pursue policies and programs to advance and support deployment of clean vehicle technologies in order to achieve their clean air, GHG emission reduction and public health goals. Such state and local initiatives fully support NACAA’s request that EPA can and should include in the final rule aggressive steps to support the widescale deployment of ZEVs.

By way of example, the Drive Clean Louisville team plans for and explores opportunities for electric vehicles and clean fuel transportation within the local government and community through the development of grant funding opportunities and policies focused on reducing tailpipe emissions from light- and heavy-duty mobile sources throughout the metropolitan area. Strategies include ones to increase cleaner alternatives to fossil fuels and/or engines that incorporate the most effective emission control technologies. Among the specific projects under this program is the Green Fleet Challenge, under which the Louisville Metro Government seeks to collaborate with local businesses and organizations to collectively increase the number of battery electric vehicles (BEVs) or plug-in hybrid vehicles (PHEVs) in their respective fleets (for larger entities, Louisville is asking partners to match the local government fleet at least one-to-one), These efforts will help Louisville achieve its goals of reducing GHG emissions by 80 percent by 2050 and attaining the ozone NAAQS to protect public health.5

The state of Minnesota is supporting the growth of electric vehicles through a variety of investments and outreach and education efforts. To date, the Minnesota Pollution Control Agency (MPCA) has dedicated the full 15 percent of funds allowed under the Volkswagen settlement fund to electric vehicle (EV) charging infrastructure and has allocated $13.2 million of its VW settlement funds to heavy-duty vehicle electrification. In 2019, the MPCA offered $170,000 in grants for EV charging stations at businesses that wanted to electrify their fleet vehicles. The Minnesota Department of Transportation (MnDOT) also launched a Clean Transportation Pilot Program, offering $2 million annually to support innovative projects that reduce GHG emissions, including potential electrification projects. In fall of 2019, MnDOT began offering an EV incentive through the MnPASS program, which allows transit buses, motorcycles and vehicles with two or more occupants to use express lanes for free during peak travel times; solo motorists are allowed to pay a fee to use these lanes. This pilot program will also give Minnesotans who purchase or lease a new or used BEV or PHEV a one-time credit ($250 for a BEV and $125 for a PHEV) for use in MnPASS lanes. The Minnesota Public Utilities Commission (MPUC) opened a docket to discuss EV programs and potential effects for Minnesota. MPUC directed utilities to develop EV pilot programs and rates that encourage charging EVs during hours when electricity demand is otherwise low. The MPUC process and development of utility programs is ongoing. Finally, many groups around the state are working to educate consumers and support local governments and businesses in converting their vehicle fleets. Drive Electric Minnesota is a public-private partnership working to educate Minnesotans about the benefits of EVs and support EV-friendly legislation in the state. This partnership also supports Communities Charging Ahead, which helps local governments plan for and advance electrification in their communities. The Twin Cities Clean Cities Coalition and Midwest Electric Vehicle Opportunities: Learning, Events, Experience (known as Midwest EVOLVE) puts on ride and drive events around the state to help familiarize people with EVs. The American Lung Association of Minnesota has also been working actively to educate light-duty EV customers and plan ride and drive events for heavy-duty and medium-duty EVs.

Ventura County Air Pollution Control District (VCAPCD) operates several programs and participates collaboratively in others with nearby counties to support EV adoption and infrastructure deployment. In-house programs include 1) the state-sponsored Carl Moyer Memorial Air Quality Standards Attainment Program, under which incentive funding (50 to 75 percent of eligible costs) is provided for publicly available EV charging stations and workplace charging; 2) AB 923 DMV Fees, under which local DMV fees added for vehicle registration can be used to fund incentives for EV infrastructure similar to the Carl Moyer Program; 3) the Community Air Protection Program – another state-sponsored program – this one targeting disadvantaged and low-income communities using the Carl Moyer Program guidelines for EV infrastructure incentives; and 4) the Clean Air Fund – a 100-percent local program funded by an endowment that generates approximately $30,000 per year – that in the past has provided funding for several EV charging stations in locations owned by the City of Thousand Oaks, some public (e.g., in parks, the municipal center) and others for the city fleet. Collaborative programs in which VCAPCD participates include 1) Electric Drive 805 (of which VCAPCD is a founding partner and steering committee member), a coalition dedicated to achieving a rapid, equitable transition to plug-in electric vehicles to reduce pollution from cars and trucks in the region; 2) the California Electric Vehicle Infrastructure Project, which offers incentives for the purchase and installation of electric vehicle charging infrastructure at publicly accessible sites throughout California; and 3) South Central Coast Incentive Project, for which VCAPCD is a funding partner with other air districts and community choice aggregate clean power suppliers in Santa Barbara and San Luis Obispo Counties.6,7,8

New Jersey provides the most generous EV purchase incentives in the country for passenger vehicles. The Charge Up New Jersey program offers an incentive of up to $5,000 for the purchase or lease of a new EV with an MSRP of less than $55,000. Both pure BEVs and PHEVs are eligible for the rebate. Zero-emission vehicles are exempt from the New Jersey state sales tax, so state residents will save 6.625 percent on the purchase or lease of a new or pre-owned pure BEV. It Pay$ to Plug In, the inaugural EV charging station grant program of the state's Department of Environmental Protection, has funded over $10 million in charging stations: $5.4 million for DC fast chargers and $4.6 million for Level 2 chargers. In addition, the New Jersey Board of Public Utilities established minimum requirements for utility filings regarding light-duty, publicly accessible EV charging infrastructure. Thus far, two of the state's four utilities have approved programs: $20.7 million for Atlantic City Electric and $166.2 million for Public Service Electric and Gas.

More examples are provided in an April 21, 2021 letter to President Biden, in which a bipartisan coalition of Governors from 12 states – California, Connecticut, Hawaii, Maine, Massachusetts, New Jersey, New York, New Mexico, North Carolina, Oregon, Rhode Island and Washington – describes actions taken within their respective states to move 'quickly towards a zero-emission transportation future [that] will protect the health of all communities.'9 [EPA-HQ-OAR-2021-0208-0255-A1, pp. 5-7]

As many states and localities continue to make significant investments and put forth bold efforts to ready the market to deploy LDV clean technology, we look to and encourage the federal government to step up and increase such efforts as well, and to use this rulemaking to, at a minimum, adopt EPA's Alternative 2, augmented with a MY 2026 standard that is 10 grams/mile more stringent, so that, together, we can create a pathway that will not only reduce air pollution and protect public health and the environment, but also create high-paying jobs, spur economic development and contribute to fuel security in our nation. [EPA-HQ-OAR-2021-0208-0255-A1, p.7]

Commenter: National Coalition for Advanced Transportation (NCAT)

The Electric Vehicle Market Has Grown and Will Continue to Grow. Electric Vehicle Sales and Investments. Sales and Growth: Electric vehicle sales in the U.S. have continued to grow dramatically. Over two million electric vehicles (battery electric vehicles and plug-in hybrid electric vehicles) have been sold cumulatively in the U.S. from January 2010 to the present. 18 Nearly 375,000 electric vehicles have been sold in 2021 as of August. 19 In the last year, electric vehicle sales have “skyrocket[ed].”20 A total of 43,721 electric vehicles (28,460 battery electric vehicles and 15,261 plug-in hybrid electric vehicles) were sold during the month of August 2021 alone in the United States, which captured 4% of total light-duty vehicle sales that month. 21 The share of electric vehicles in new car sales grew dramatically to 4.4 percent in 2020, substantially higher than 2.5 percent in 2019.22 This increase in electric vehicle sales has continued despite low gas prices, and even as car sales generally declined due to the pandemic.23

Projected sales: President Biden’s recent Executive Order on Strengthening American Leadership in Clean Cars and Trucks set a goal that 50% of all new passenger cars and light trucks sold in 2030 be zero emission vehicles (including battery electric, plug-in hybrid electric, or fuel cell electric vehicles). 24

It is clear that electric vehicle sales have and will continue to increase, and that many projections are underestimates.25 Even the very conservative U.S. Energy Information Administration (EIA) predicts that battery electric vehicle sales will increase faster than any other type of vehicle sales, growing by 6% per year on average with 200- and 300-mile range vehicles reaching almost 2 million vehicles (combined) per year in 2050.26 EVAdoption predicts that by 2030, electric vehicle sales will be nearly 30% of all new car sales nationwide and nearly 57% in California.27 In the nearer-term, IHS Markit estimates that electric vehicles will double their 2020 market share by the end of 2021, and make up 10% of new car sales nationwide by 2025.28 The Goldman School of Public Policy at the University of California, Berkeley has summarized the estimates of some of these projections and others, showing that electric vehicles will likely be between 5% and 35% of new vehicle sales by 2035. [Figure 3 can be found on p. 7 of Docket number EPA-HQ-OAR-2021-0208-0239-A1] [EPA-HQ-OAR-2021-0208-0239-A1, p. 5-6]

Declining Electric Vehicle Costs. Declining Battery Costs: Electric vehicle battery costs have continued to decline, reducing the cost of electric vehicles relative to other vehicles.71 Bloomberg New Energy Finance finds that the cost of lithium-ion batteries fell 89% from 2010 to 2020—with a 13% drop in just 2020 alone.72 This trend is expected to continue due to advances in battery chemistry and the opportunities presented by economies of scale as the battery market grows.73

Declining Purchase Price: Electric vehicles are rapidly moving toward purchase price parity, in part because of declining battery costs. Between 25% and 40% of a battery electric vehicle’s total price is typically attributable to the battery. 74 UBS75 and BNEF76 both predict that by 2025, battery prices will have dropped so much that battery electric vehicles will no longer cost more to manufacture than conventional fuel vehicles. The Goldman School of Public Policy predicts this price parity in the mid to late 2020s.77 By 2022, there will be at least six electric vehicles models priced below $30,000. 78 [EPA-HQ-OAR-2021-0208-0239-A1, p. 12-13]

Significant Investments in Electric Vehicle Charging and Related Infrastructure. The number of public and private electric vehicle chargers has increased dramatically. There are now more than

44,000 public charging stations across the U.S. with over 108,000 ports.86 Notably, this includes nearly 20,000 DC fast chargers nationwide.87 On average, the number of public chargers increased 30% from 2015 to 2019 in the top 50 most populous metropolitan areas.88 This trend of charging infrastructure build out is only accelerating. For example, Shell announced plans to build 500,000 charge points globally by 2025.89 Tesla's global network has grown to include over 3,000 Supercharger Stations with more than 27,000 individual connectors, as of August 1, 2021.90 In 2020, Tesla opened 743 new Supercharger locations around the world, which is an average of two new locations every day. Tesla's charging network also includes over 14,000 Destination Charging locations and over 28,000 Destination Charging connectors.91 Electrify America plans to invest $2 billion in charging infrastructure through 2026.92

Utilities are investing significantly in the build out of infrastructure related to electric vehicle charging. "Throughout 2020, approved utility investment in transportation electrification increased three times over the amount approved in 2019" and almost $3 billion in utility electric vehicles programs have been approved through February 2021.93 Utilities have long-term planning horizons for considering investments in improvements to the electricity grid to support transportation electrification. In addition to preparing the grid to support increased electric vehicle adoption, utilities across the country have been planning and implementing significant transportation electrification infrastructure programs. As an example, in August of 2020, the California Public Utilities Commission (CPUC) approved NCAT member Southern California Edison's Charge Ready 2 program, a $437 million program that will fund the installation of approximately 38,000 charging ports.94 This program builds upon Southern California Edison's initial $22 million Charge Ready pilot in 2016, supporting the installation of 1,300 light-duty electric vehicle charge ports. NCAT member Exelon is part of the Electric Highway Coalition, a partnership among 14 U.S. utilities to create a seamless network of rapid electric vehicle charging stations connecting major highway systems, across the country from the Atlantic Coast through the Midwest, South and into the Gulf and Central Plains regions. Through approved programs at its utilities, Exelon will enable the installation of more than 7,000 residential, commercial and/or utility-owned charging ports across Maryland, D.C., Delaware and New Jersey.95 [EPA-HQ-OAR-2021-0208-0239-A1, p. 13-15]

Benefits of Electric Vehicles to the Electric Grid. Electric vehicles will provide substantial benefits for the management of the electric grid. By improving utilization of the existing power grid and spreading fixed costs over a larger base of sales, electric vehicle use can benefit not just electric vehicle owners, but other electricity consumers as well. For instance, transportation electrification can benefit all customers by putting downward pressure on electricity rates, as fixed costs are spread over a larger base of kWh sold.

Although electric vehicles are expected to increase the demand for electricity,109 they are also a valuable grid resource that can be used to help manage the time and intensity of energy consumption, which helps lower electricity bills and helps avoid otherwise necessary upgrades to the electric grid, and will likely—in the future—facilitate storing energy and transferring it back to buildings or the grid.110 Many utilities are switching to time of use (TOU) rates that price energy based on the day, time, and season.111 As of March 2020, about half of U.S. investor-owned utilities had optional TOU rates.112 These can be used separately or in addition to residential TOU rates to incentivize electric vehicle customers to charge at off-peak times when it is cheaper and also beneficial for the grid.113 Another form of smart charging involves vehicles being plugged in but not charging until they receive a signal from the grid indicating that demand has declined.114 These technologies have benefits for electric vehicle consumers and grid managers, but also for all customers whose rates could decline as electric vehicles help to shift demand.115 California recently undertook a major study of vehicle-to-grid integration—encompassing TOU rates and using electric vehicle batteries as distributed energy resources—and is now working to implement the report's 92 policy recommendations in order to realize the benefits of electric vehicle integration.116

Electric vehicle charging is also increasingly connected to and supported by renewable energy. TOU rates can be coordinated with renewable energy availability, like in Charge Forward, NCAT member PG&E and BMW's pilot program that helped consumer to delay charging to align with renewable energy.117 NCAT member Southern California Edison also introduced a TOU rate connected to renewable energy availability, 118 and has implemented demand response programs through its Charge Ready infrastructure programs that demonstrate how electric vehicle charging load can be shifted to absorb midday excess renewable generation that may otherwise be curtailed. 119 NCAT member EVgo, a fast-charging network, powers its 800-charger network using 100% renewable energy.120

Several utilities including the Sacramento Municipal Utility District (SMUD) have active Vehicle-to-Grid (V2G) research and development projects planned or in progress including both electric school buses and light duty electric vehicles. V2G figures prominently in SMUD's 2030 Zero Carbon Plan pursuant to which SMUD is planning to eliminate its fossil fuel based generation assets by 2030 and could expect over 250 MW/400 MWh of energy storage from V2G. [EPA-HQ-OAR-2021-0208-0239-A1, p. 17-18]

Commenter: NATSO, Representing America's Travel Centers and Truck Stops et al.

The Proposal Does Not Acknowledge the Consequences of GHG Emissions Standards that Favor EVs over Other Technologies

GHG emissions standards that favor EVs over other technologies have led to unintended consequences that ultimately run counter to EPA's regulatory objectives. For example, the 2012 Final Rule5 encouraged regulated utilities to aggressively pursue offering EV charging on the backs of lower-income Americans. Regulated utilities are seeking to convince public utility commissions that they should be able to charge all of their ratepayers – regardless of income – a higher dollar figure on their monthly electric bill in order to underwrite the utilities' investment in EV charging stations. Unfortunately, the cost burden will hit hardest on those least able to afford it. Individuals who struggle to pay their monthly bills should not be required to underwrite investments that the private sector is willing and better equipped to make. EV drivers – who today have above-average incomes and drive cars that cost much more than average – can and should pay the costs of charging their vehicles.

Absent more meaningful guardrails around regulated utilities' ability to own and operate EV charging stations, it is reasonable to believe that the Proposal would perpetuate this activity throughout the country. There is no public policy rationale for pursuing this approach with respect to refueling, as it will only decrease transparency and competition, increase costs, and stifle innovation. And, this model of utilities adding charging stations funded by ratepayers will stunt the growth of such infrastructure because the private sector will have no way to compete and therefore not invest. Because the private sector cannot operate electric charging competitively with infrastructure underwritten by ratepayers, the private market will not build new infrastructure in states using that model. The result will be fewer, not more, EV charging stations. This undermines EPA's regulatory objectives.

The Proposal does not sufficiently acknowledge the costs that all ratepayers will inevitably absorb in order to underwrite their regulated utility's investment in EV charging stations. A competitive, private recharging market will lower the overall costs that consumers pay for electricity as a transportation fuel. The retail fueling industry provides approximately 150,000 locations across the country for drivers to currently refuel. This refueling capacity drives aggressive price competition that, in turn, keeps prices low for consumers.

The overarching structure of the wholesale and retail electricity market is not designed for – and thus incompatible with – the retail fuels market. If the regulated utilities' practice of charging all of their ratepayers more money to underwrite the utilities' investment in owning and operating charging stations were to become the prevalent model, the country will risk replacing one of the most price-transparent and price-competitive consumer markets in the world (retail fuel pricing) with one of the least price-transparent and price-competitive markets in the United States (utility electricity pricing).

Because the Proposal's cost analysis limits the discussion to costs that EV drivers will bear, it understates the true public costs of refueling EVs. In reality, many American businesses and individuals will subsidize those costs through higher electricity bills, and the amount of that subsidy will be unnecessarily high because it will be divorced from the competitive forces that keep prices down. [EPA-HQ-OAR-2021-0208-0570-A1, p.4]

Commenter: New Mexico Environment Department

Increasing standard stringency drives technology innovation in the automotive industry and creates jobs in electrifying the transportation fueling system. EPA's Regulatory Impact Analysis acknowledges the available and planned capacity of the automobile industry to advance GHGe-reduction technology. Five automobile manufacturers that account for approximately one-third of the new vehicles sold in the United States (US) signed onto the California Framework and already plan to meet the stringency of Alternative 1. Additionally, this year many automobile manufacturers, including General Motors, Volvo, Volkswagen, Honda, Ford, Fiat, Stellantis, and Mercedes-Benz, announced their planned shift to greater investments in automotive electrification technology and to strategically increase production of zero-emission vehicles. [EPA-HQ-OAR-2021-0208-0205-A1][p.2]

Commenter: New York State Department of Environmental Conservation

Over the past five years, New York and two dozen other states in the U.S Climate Alliance have led the way with policies and programs to support the electric vehicle transition. New York is investing more than $1 billion in zero emission cars, trucks and buses and zero emission vehicle (ZEV) fueling infrastructure over the next five years, including an $85 million competition to deploy innovative clean transportation strategies in communities overburdened by vehicular emissions. [EPA-HQ-OAR-2021-0208-0238-A1, p.1]

Commenter: NGVAmerica

We support electrification where it makes sense and even anticipate that in the near future an increasing larger share of heavy-duty natural gas vehicles will employ hybrid electric powertrains.[7] Significant investments are being made to bring natural gas/hybrid powertrains to market. Light-duty natural gas fueled vehicles could someday employ similar hybrid-electric powertrains as hybrid vehicles become more prolific. [EPA-HQ-OAR-2021-0208-0214-A1, p.3]

Commenter: Northeast States for Coordinated Air Use Management (NESCAUM)

The Northeast states have a long history of taking actions to reduce GHG emissions and air pollution from the transportation sector. Seven of NESCAUM's member states have exercised their authority under Section 177 of the Clean Air Act to adopt California's Advanced Clean Car standards, including requirements for automakers to deliver increasing volumes of ZEVs. Together with California, the states that have adopted or are in the process of adopting these standards represent approximately 40 percent of the national LDV market. Transportation electrification is a critical component of state plans to reduce emissions from cars and trucks to meet their climate and air quality goals. In addition to state efforts to advance the ZEV market, strong federal standards are needed to accelerate the transition to ZEVs. [EPA-HQ-OAR-2021-0208-0259-A1, p. 3]

Zero-emission technologies have advanced rapidly since EPA established its MY 2017 and later standards in 2012, and the pace of innovation has only accelerated since the 2018 mid-term evaluation. Battery costs continue to decline, and the number of ZEV and plug-in hybrid electric vehicle (PHEV) models offered for sale in the United States is rapidly increasing. As EPA discusses in its proposal, the proliferation of announcements by automakers of their intention to electrify their fleets signals a rapidly growing shift in investment away from internal combustion technologies and toward zeroemission technologies. [EPA-HQ-OAR-2021-0208-0259-A1, p. 3]

The automakers' electrification plans are supported by continuing technological advancements and driven by the need to compete in a global market in which other countries are implementing aggressive zero-emission transportation policies. Likewise, California is currently developing new ZEV requirements for passenger vehicles beyond MY 2025. The new requirements are expected to put market growth on pace for all new vehicle sales being ZEVs or PHEVs by 2035. Several states, including NESCAUM states, are watching this development closely and considering plans to follow suit. In fact, New York recently enacted legislation setting a goal for all new passenger cars and trucks sold in New York State to be zero-emission by 2035.4 [EPA-HQ-OAR-2021-0208-0259-A1, p. 3]

Commenter: Noyes, James

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 262-263.]

There's obviously a very strong drive to move toward electrification, but as everyone is aware, there are very significant technology and cost barriers there, and there's also the very long life of internal combustion engines that are on the road. We've seen in California very aggressive programs to electrify the state that are having effect, but, frankly, they're having effect slowly with still the large dominance of the internal combustion engine.

Commenter: Ohio Attorney General Office, et al.

The proposed rule considers as a benefit 'reductions in energy security externalities caused by U.S. petroleum consumption and imports.'[68] On one hand, that is a concern of the Administration’s own choosing, as the United States produced more energy than it consumed in 2019 for the first time in [62] years, [69] and remained a net exporter in 2020.[70]

Regardless, the proposed rule entirely fails to mention the additional risks to the transportation sector, even if certain risks are alleviated in the energy sector. China dominates the lithium-ion battery market, and is poised to capture a greater share with time.[71] China is home to three-quarters of the global manufacturing capacity for lithium-ion batteries, while the United States has only 12 percent.72 Not only does China own the final manufacturing process, but China also 'controls 80 percent of the world’s raw material refining in the lithium-ion battery supply chain, 77 percent of the world’s cell capacity, and [60] percent of the world’s component manufacturing.'[73] This is not merely a problem of manufacturing, which through various incentives could theoretically be on-shored. China controls [90] percent of the supply of rare-earth magnets, which work to power electric vehicles.[74] Dependence on China for our transportation is a national security threat—one that cannot be overcome overnight. The EPA failed to consider whether the proposed timeframe to change our vehicle fleet will create an overreliance on China, given the current lack of manufacturing and raw materials in United States control. Such failure renders any final rule arbitrary, but more importantly, dangerous. [EPA-HQ-OAR-2021-0208-0258-A1, p.10]

Commenter: Peavler, Jean

This would also make us even more dependent on China, as around 80% of the manufacturing capacity for electric vehicle batteries is in China. A vast majority of the chemical processing and refining for the raw materials (cobalt and lithium) used in these batteries is also performed in China. We are already too dependent on China and need to decrease this, not increase it!

We would also be even more dependent on the electric power grid, which is vulnerable to cyber attacks as well as power plant failures. [EPA-HQ-OAR-2021-0208-0395, p. 1]

Commenter: Piper, Edward

More fuel efficent CAFE requirements incentivize vehicle manufacturers to make battery powered vehicles. These high energy density batteries have all the energy components internally in the battery in a small confined space (as compared to internal combustion engines or fuel cells which have air as one of the reactants). In the event of malfunction or damage this energy can be released in a castastrophic way more difficult to control than a burning liquid hydrocarbon fuel. [EPA-HQ-OAR-2021-0208-0520, p. 1-2]

Commenter: Plug In America, the National Association of Electric Vehicle Drivers

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 78.]

We are on track for EV sales to roughly double from last year to something around four percent market share for 2021. Thus, an aspiration to achieve eight percent EV market penetration by 2026 is just simply too cautious.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 79.]

For more than a decade American automaker Tesla has taken the world by storm showing true American leadership and, as noted in the proposal, many other automakers are now moving forward and have committed to reach 50 percent market share EVs by 2030.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 80.]

In his call for a $174 billion package of support to electrify transportation, President Biden has shown the same level of transformational vision. We would challenge EPA to be no less visionary. This will enable us to assert American leadership in tomorrow's energy and transportation technologies, to create millions of good-paying jobs across numerous industries, and to reclaim our skies and to protect future generations from the devastation of climate change.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 81.]

Just one quick question. In your testimony you said that for 2021 that some data was indicating that for the U.S. we were on target to hit a four percent share this year.

That's information in your public testimony. Could you provide some additional information on that? That would be very helpful. Thank you.

Yes, sure. We're a little bit over three and a half percent right now but it's accelerating. So the numbers I've seen are close to four percent by the end of the year, but, yes, I can share that.

Commenter: Price, Heather

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p p.294-295.]

So, in terms of health and air quality, electrifying our vehicle fleet is really the only solution that we have. And as we clean up our electrical grid, then everything, right, this really does get at the root of the climate crisis and how we're going to address it. It means electrifying everything using zero carbon sources of electricity, such as wind and solar. It means electrifying our vehicle fleet and coming up with ways of recycling the batteries because, yes, there are issues with batteries and with the pollution there. But one of the issues also with batteries, people talk about, oh, recycling. Well, the elements that are in those batteries are there. So, the elements within those batteries are always there. They're transitioning between redox states, but they're not going into the atmosphere the way that, say, when you burn toxic fossil fuels and those go into the atmosphere either as methane or as carbon dioxide, depending on fuel source.

Commenter: Roush Engineering

Attached are two reports Roush Engineering recently completed for the Center of Applied Environmental law and policy that we believe are relevant to the proposed rulemaking, particularly with respect to continuing improvements in effectiveness and cost compliance technologies.

• CAELP Report 1 - Gasoline Engine Technologies (09.24.2021)
• CAELP Report 2 - 48V and BEV costs (09.24.2021 [EPA-HQ-OAR-2021-0208-0210-A1, p. 1]

Commenter: Schrier, Paul

As an American consumer, I stand against the proposed rule change that would make finding affordable vehicles even more difficult because of the following reasons:

Perhaps most telling is problems galore with EVs themselves, which are being recalled due to vehicle fires, sudden losses of power, and failures to start. Within the last year recalls by General Motors, Hyundai, and Ford involved 132,500 electric vehicles and cost a combined $2.2 billion.

Unsurprisingly, these issues have resulted in a lack of consumer confidence. After all, who wants to buy a vehicle that might burst into flames at any moment, or refuse to start when youre already fifteen minutes late to work? [EPA-HQ-OAR-2021-0208-0466, p.1]

And to top it all off, the United States doesn’t currently have the resources or processing capability to make EV batteries -- meaning Bidens push for EVs will primarily benefit China, which is leading the race as one of the largest and fastest-growing EV markets in the world. [EPA-HQ-OAR-2021-0208-0466, p. 1]

Commenter: Shevelew, Jonathan

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 116-117.]

To encourage manufacturers to continue to invest funds and resources into reducing the emissions from fossil fuel-based engines is an absurd approach with diminishing returns, especially when we've already accepted the fact that these types of engines will disappear.

Commenter: Southern Environmental Law Center

In addition to lower fuel costs associated with more efficient internal combustion vehicles, stricter emission standards will also encourage manufacturers to make EVs more widely available—which will help drive the market closer to the Biden administration’s goal of having 50 percent of all new light-duty vehicles sold in the U.S. in 2030 be zero-emissions vehicles.

Owning an EV saves the typical driver between $6,000 and $10,000 over the lifetime of the vehicle as compared to a gas car due to reduced fuel and maintenance costs.[36] [EPA-HQ-OAR-2021-0208-0244-A1]

Commenter: Stabnau, Angela

I am Not a supporter of electrical cars. There is NO disposal facility and no way of recycling the battery. ExampleFORD mach e - 6 months after driving the battery went dead. No longer chargeable. Label on battery states "Do Not throw in garbage." There are No COREs on these smart car batteries. Call FORD - they have no suggestions of Recycling. There is No where on Planet Earth willing to take these. There is No current plan. No ones talking about it. The parks involvement in these vehicles would be contributing to the poisoning of our planet. Thank you for your consideration. [EPA-HQ-OAR-2021-0208-0712-A1, p. 1]

Commenter: Stellantis

An ‘All of Government’ Approach is Needed to Accelerate Electrified Future

The auto industry, labor and Federal and State governments have critical roles to play in transitioning the market to achieve the ambitious targets set forth at the White House. The current electric vehicle market represents 2.5% of total industry sales.3 The EV market must grow to three to five times todays levels in just four years to achieve even the conservative electrification rates of 8- 13% EPA4 and NHTSA5 modeling suggests is needed by MY2026 in these draft rules.

Stellantis is committed to doing our part to reduce CO2 and electrify our fleets. In turn, we are relying on a commitment from the Biden Administration and U.S. policymakers to provide the full suite of supportive policies included in the Build Back Better Plan. Infrastructure and affordability are just two of many critical policies necessary to create EV market 'tailwinds.' While EPA is not directly responsible for all of these needed actions, the proposed rules require increased electrification, and increasing electrification cannot happen without growing the EV market. The market policies outlined below (and more deeply explored in Appendix A) are needed to grow the EV market: [EPA-HQ-OAR-2021-0208-0532-A1, pp. 3-4; Appendix A can be found at docket number EPA-HQ-OAR-2021-0208-0532-A1, pp. 21-32]

Expand and Scale the Charging Network to EV Volumes Required by Proposed Rule – Availability and accessibility of an electric vehicle refueling infrastructure are critical to address consumer concerns over range limitations and re-fueling access – a key barrier to EV market growth. Stellantis estimates nearly 850 thousand additional chargers, costing at least $7.6 billion, will be needed through MY2026 to support the number of EVs required to meet EPA's proposed GHG standards. These numbers significantly increase beyond MY2026. State and federal governments, together with charging companies and utilities need to establish a comprehensive charging infrastructure plan to meet these needs and provide confidence to American drivers. [EPA-HQ-OAR-2021-0208-0532-A1, p. 4]

Develop Domestic Battery Supply Chain (Raw Materials, Manufacturing, and Recycling) - At present, most critical minerals necessary for the production of advanced EV motors and batteries are mined and processed outside of the U.S. As the domestic demand for EV grows, the demand for critical minerals, new technology manufacturing facilities, and battery recycling will grow. Developing a U.S. national policy on recycling (recognizing the greater North American supply chain) offers a strategic chance to lessen this risk while avoiding end-of-life landfill waste for batteries.

Increase Research & Development - EVs remain more expensive than equivalent ICE vehicles. Federal research funding is needed primarily in battery technology to accelerate advancement in electrified vehicle technology with the goal of achieving cost and functional parity with today's ICE vehicles. The Department of Energy should expand research on alternative lower cost substitutionary materials to achieve the needed cost reductions. [EPA-HQ-OAR-2021-0208-0532-A1, p. 4]

Meeting the Proposed Rule Requires Unprecedented Increases in Electrification

Establishing a pathway to first meet the stringency proposed by EPA and then grow further to meet 2030 electrification goals of the Biden administration will require significant growth in electrification from today's levels - more than both EPA or NHTSA predict in their draft rules. EPA in its Regulatory Impact Analysis projects a 7.8% market penetration of plug-in hybrid and full battery electric vehicles (EVs) by MY2026 in response to the proposed GHG requirements.10 NHTSA in its own analysis projects a higher EV market penetration of 13% by MY2026.11 This is a three to fivefold increase of EVs, respectively, from calendar year 2020 sales of 2.5%.12 Third-party sources, such as IHS Markit, believe automakers will need to achieve even higher EV market penetration rates of 17% by MY2026 to meet the proposed compliance requirements, assuming an available market and the necessary supporting measures and polices are realized.13

Stellantis believes EPA has overestimated the potential for ICE improvements on a pathway that is focused on significant EV growth. Unlike the mid-term evaluation where conventional ICE technology was seen as the dominant lever in achieving compliance, we now see a post-MY2026 environment focused on high levels of electrification to accommodate President Biden's Executive Order as well as the pending California Air Resources Board ZEV rule requiring 70% electrification in 2030 and 100% electrification in 2035 (Executive Order N-79-20). So, even if manufacturers could achieve these proposed M2023-2026 standards with conventional ICE technology, it would make little economic sense to pursue a duplicate ICE investment path only to abandon it a few short years later to meet 2030 electrification goals.

The rate of improvement called for in proposed rule (10% in MY2023 and 5% per year to MY2026) significantly outpaces historical improvements achieved with ICE technology. Eleven of 14 major automakers have fallen behind EPA's 2019 standards even as they have been adding technology since 2012. To meet these proposed requirements, significant market penetration of strong electrification (e.g., hybrid, plug-in electric, or fuel cell technology) is needed.

In comments to the SAFE rulemaking, The Auto Alliance supported this conclusion in finding that only 2.5% of MY2018 vehicles would meet the MY2025 standards per the 2012 final rule and all the vehicles meeting the MY2025 standards were equipped with hybrid, plug-in electric, or fuel cell technology.14 In recent analysis performed by IHS Markit for the Alliance for Automotive Innovation, only 11.6% and 5.1% of MY2020 vehicles achieve the proposed MY2023 and MY2026 GHG footprint standards, respectively.15 Of the 5.1% of vehicles that met MY2026 standards all were electrified products (i.e., none were non-hybrid ICE models).

If the only MY2020 vehicles that achieve the proposed MY2026 GHG standards are hybrid, plug-in electric, or fuel cell technology, and a compliant fleet can be thought of as a 50/50 mix of vehicles above and below the target, it's reasonable to project that a compliant fleet in MY2026 will have a market penetration rate of 20 to 50% of models equipped with hybrid, plug-in electric, or fuel cell technologies, depending on the technology mix. This market penetration rate is significantly higher than the 8-13% modeled by the Agencies16 and will increase the cost of compliance. [EPA-HQ-OAR-2021-0208-0532-A1, pp. 9-11]

Expand and Scale the Charging Network to EV Volumes Required by Proposed Rule

Nationwide EV charging infrastructure that is accessible, reliable, and deployed in a timely manner is necessary for broad market adoption of electric vehicles. The 2021 National Academies report on improving light-duty vehicle fuel economy cites location and availability of charging stations as the number one reason for a consumer to avoid an electric vehicle.36 Without comprehensive charging infrastructure, there can be no EV market.

While residential charging at home is the predominant means of charging, public and privately shared charging is essential for owners or renters who have no access to off-street charging, or who live in multi-unit dwellings, have long work commutes, or travel for extended distances.37 Accessible charging must also consider the needs of all types of consumers. An August 2021 report published by Mobilyze.ai highlights the following observations:38

1) 'the majority of early EV adopters have access to dedicated off-street parking at home, where they do the majority of their charging today,'39

2) 'dedicated off-street parking at an owned residence only exists for an estimated 47% of vehicles in the United States,'40 and

3) 'only 9.7% of residents from the top 50 most populous U.S. cities have convenient access to public charging near where they live.'41

Consumer acceptance of EV's demands that charging is simple, fast, affordable and accessible to all types of vehicle owners. Chargers must be strategically placed along interstate corridors to meet consumer needs for long distance commutes and extended travel where higher number of fast, higher power Direct Current Fast Chargers (DCFC) will be needed to minimize recharging times.

Careful planning will be necessary for high powered public chargers to ensure accessibility while also considering other factors such as grid upgrades to meet the power demand, feasibility with getting electrical power to the location, and all the while minimizing implementation cost and time.

Understanding the criticality of a robust charging infrastructure to building an EV market, it is important to quantify the growth needed given the proposed rule and the longer term goals of the Biden administration. The large increase in light-duty vehicle EVs is shown in Figure 6, which estimates a 7 million (MY2026) and 29 million (MY2030) EV cumulative car parc based upon the 7.9% EV sales penetration in MY2026 EPA says is needed to meet the proposed rule and President Biden's executive order calling for 50% EV sales by 2030. The growth rate anticipated by these projections is exponential from today's levels and will require and equally exponential growth in charging infrastructure to accommodate. [EPA-HQ-OAR-2021-0208-0532-A1, pp. 23-24; Figure 6 can be found on p. 24 of Docket number EPA-HQ-OAR-2021-0208-0532-A1]

To determine the number of chargers needed nationally to accommodate the growth anticipated, federal regulatory agencies should look to the most successful North American EV markets such as California and its California Energy Commission (CEC), for policies used to forge a broad public EV charging infrastructure network. The California CEC recently published an EV charging infrastructure assessment report highlighting the need for increased shared private and public EV chargers. This report shows that California, the most successful EV market in the nation, currently has a ratio of 1 charger per 6.9 EVs on the road.42 This ratio is critical since it provides insight from the nation's leading EV market on the amount of charging infrastructure that is needed for the rest of the country.

As stated above, achieving EPA's stated 7.9% EV sales rate would mean approximately 7 million EV's on the road by MY2026. Using the CEC ratio of 1 public charger for every 6.9 EVs on the road, Figure 7 demonstrates that approximately 970K privately shared and public chargers would be needed nationwide to support 7 million EVs by MY2026 (a 850K or 8x increase compared to today). If an EV sales rate of 50% is assumed by MY2030, approximately 4.2 million chargers will be needed to support a 29 million EV car parc, a 35-times increase from today. [EPA-HQ-OAR-2021-0208-0532-A1, p. 25; Figure 7 can be found on p. 25 of Docket number EPA-HQ-OAR-2021-0208-0532-A1]

Figure 8: EV Charger Gap further highlights the large gap between the DOE's count of EV privately shared and public charger ports installed today (121,000 ports43) and what is needed to support the future EV car parc. [EPA-HQ-OAR-2021-0208-0532-A1, p. 26; Figure 8 can be found on p. 26 of Docket number EPA-HQ-OAR-2021-0208-0532-A1]

As a result, significant federal funding will be required to accomplish the kind of growth needed in charging infrastructure. Analysis shown in Table 2 below estimates the cost of meeting the growth in charging infrastructure estimated above. [Table 2 can be found on p. 27 of Docket number EPA-HQ-OAR-2021-0208-0532-A1]

The above analysis shows a low end estimate of $7.6 billion in EV charging infrastructure funding is needed to support EPA's expected EV penetration rate (7.9% sales) in MY2026 based upon a 7 million EV car parc, and $36 billion needed to support a (50% EV sales target) 29 million EV car parc by MY2030.

This estimate could greatly increase, as demonstrated by the high end estimate, due to changes in assumptions such as the DC fast charger power level demanded, percent of DC fast chargers needed, installation costs, and other factors.

The installation cost variability is due to factors such as ease of getting electricity from the grid to the charger location site, site power level needed (sub-station upgrades), retrofit versus new construction, and the number of chargers per site, etc. Similarly, if future demand increases towards higher cost DC fast charging to reduce charging times over lower cost Level 2 chargers, further infrastructure funding may be needed.

This analysis highlights the significant financial funding lift that will be necessary to ensure an EV charging ecosystem for current and future EV owners – an increase in public, workplace, and privately shared chargers of 8-times in MY2026 and 35-times in MY2030. Stellantis supports the continued efforts by the federal government to help fund a long-term comprehensive charging infrastructure plan that includes charger installation funding and associated incentives. Recent examples of U.S. legislative funding activities under development are the Infrastructure and Build Back Better bills, which include funding for charging infrastructure and tax credits for alternative refueling properties.

Federal agency leadership is needed to help coordinate public and private stakeholders such as state agencies, utilities, electric vehicle supply equipment (EVSE) manufacturers to achieve the significant growth outlined above. Permitting and building codes for new and existing construction will need to be streamlined to ensure the make-ready ground work is laid for EV chargers. Given the exponential market growth anticipated, federal and state plans for charging infrastructure growth need to include all costs. Today, charger installation and permitting remains a significant challenge, and it is not uncommon for site upgrades required to accommodate charging infrastructure to be at least as costly as the actual EV charger itself. Funding should be allocated for the upkeep and maintenance costs of EV charging equipment throughout its lifespan, to maintain a robust network.

Implement Fleet Purchase Requirements

Fleet purchase requirements can help to ensure a robust market for electrified vehicles. In order to have a substantial increase in electrification, three factors must be satisfied: a robust supply of EVs, adequate infrastructure, and market demand. Industry as a whole, including Stellantis, has committed to broad electrification of our fleets. Besides infrastructure, one of the biggest unknowns is the rate of market adoption of EVs. A purchase requirement would help create additional certainty during this relatively rapid transition to electrification.

In California there is a proposed Advanced Clean Fleets (ACF) rule which will compel government and big businesses to purchase some medium and heavy-duty ZEV vehicles as they replace their fleet. We think a similar approach to fleets could be implemented for light-duty vehicles too. Fleet applications are generally more suitable to early electrification because of the centralized charging points, where it is easier to predict and plan for the total infrastructure needs. The Alliance for Automotive Innovation (AAI) recently requested CARB to expand the ongoing ACF rulemaking to include light-duty vehicles, stating:

‘In addition to providing a known and stable market for ZEVs, public and private fleet purchase requirements significantly increase consumer awareness as people use and see ZEVs in use. For example, rental cars offer potential EV buyers a risk-free opportunity to experience and drive EVs. Moreover, since the rental car fleet typically turns over much faster, these EVs will move into the used vehicle market quickly, further expanding EV penetration in all communities – including underserved communities.’44

President Biden’s EO14008 directs the Federal government to use its buying power to purchase ZEVs specifically, noting:

‘By providing an immediate, clear, and stable source of product demand, increased transparency and data, and robust standards for the market, my Administration will help to catalyze private sector investment into, and accelerate the advancement of America’s industrial capacity to supply, domestic clean energy, buildings, vehicles, and other necessary products and materials.’45

Further, EO 14088 establishes the National Climate Task Force, which is tasked with revitalizing the Federal Government’s sustainability efforts with a plan to procure:

'…clean and zero-emission vehicles for Federal, State, local, and Tribal government fleets, including vehicles of the United States Postal Service.'46

To remove the ambiguity of implementation, the EPA under the direction of the National Climate Task Force (EPA Administrator Reagan is a member) could craft a purchase mandate.

We also believe large commercial fleets such as transportation network companies (TNCs) and rental car companies could also be well suited to electrification, potentially under a ZEV purchase mandate.

Develop Domestic Battery Supply Chain (Raw Materials, Manufacturing, and Recycling)

Stellantis supports recycling policies that will avoid EV battery end-of-life landfill waste in addition to creating sustainable supply chains for battery manufacturers. The United States does not currently produce enough EV battery raw materials and therefore is at risk to being impacted by changes to supply chains controlled by other countries. Developing a U.S. national policy on recycling offers a strategic chance to lessen this impact and risk.

This is also true for retired EV batteries from vehicles that still retain significant capacity for other usages in the energy grid chain. These secondary-use batteries can lessen the risk to national energy security and trade by keeping that raw material in usage until recycling at end-of-life from that new capacity.

However, an end-of-life battery policy requires federal leadership to develop unified requirements across the country. This policy would promote the growing segment of vehicles and accommodate the anticipated increase in volumes of these vehicle batteries coming to market and starting to accumulate mileage. Already, states have individually begun debate on different approaches to battery requirements that would cause confusion for the customer base and for the dismantlers operating effectively under the current business model. EPA and NHTSA, in consultation with other agencies, are urged to act to avoid a patchwork state approach and exercise clear leadership.

Increase Research and Development

Stellantis is investing billions of dollars to create 4 full BEV platforms with the ability to scale up to 2 million vehicles per platform per year utilizing high energy dense and efficient batteries, optimizing segmentation for full market coverage and utilizing cross shared components and systems.

Stellantis platforms will be designed for interchangeability of battery cell chemistry, electric drive motors, power inverters and software control. Hardware and software will be designed with upgrade capability throughout the lifecycle (in-house software with Over-The-Air capability). This flexibility will enhance competitiveness, cost, efficiency, weight, and capabilities.

Stellantis currently has or is completing several key technology joint ventures, ranging from epowertrain and e-transmission operations to battery cell chemistry and production and digital cockpit and personalized connected services. These partnerships will provide Stellantis the opportunity to leverage not only in-house competencies, but also the expertise of the partners in order to bring new technology and solutions to market more rapidly, while optimizing capital allocation to further enhance Stellantis' competitiveness in the marketplace.

Stellantis is doing its part, committing billions to develop cutting-edge EV technology. Federal research funding is also needed; supporting DOE grants, national lab projects, and USABC etc. This will accelerate precompetitive advancement in electrified vehicle technology with the goal of achieving cost and functional parity to conventional ICE vehicles today. Achieving cost and functional parity is critical to removing customer barriers to adoption, such as range anxiety and the significant incremental cost increase. Several examples of needed research are:

• Alternative lower cost battery materials
o Increased battery energy density
• Extended battery durability
• EV battery design for re-use & recycling
o Reduced EV recharge times (fast charge capability)
• Improved electric motor efficiency

Similarly, federal funding is needed to help the automotive industry transition their facilities to manufacture electrified vehicles and their associated components. Stellantis supports federal manufacturing incentives such as the Section 48C Advanced Energy Investment Tax Credit included in the Build Back Better bill, providing advanced energy investment credit at $2.5 billion per year over a ten-year period. [EPA-HQ-OAR-2021-0208-0532-A1, pp. 27-30]

Commenter: Tesla

Under Section 202(a)(2) Electrification Is the Most Cost-Effective, and Fully Developed Light Duty Vehicle Technology that Provides the Greatest Degree of Emissions Reduction and Should Form the Basis for the Standard's Level of Stringency

A. EPA Fails to Fully Analyze and Recognize EVs as the Best Emission Reducing Technology Deployed Today

In 2010, EPA set MY 2012-2016 light duty vehicle GHG standards and recognized that the new technologies would occur in the future including the initial commercialization of electric vehicles.96 Similarly, in 2012, the agency set standards that would result in annual sales of strong hybrids, plug in hybrids and electric vehicles being up to 7% of the market.97

Unfortunately, EPA ignores the rapid cadence of technological development and deployment since setting standards in 2012 and yet again states, 'The feasibility of the proposed standards does not rely on dramatically increased penetration of electric vehicles into the fleet during the 2023–2026 model years.'98 By not including EVs into the feasibility analysis the result is a dramatically weaker rule that under deploys commercially available technology that can cut millions of tons of CO_2 and does not fully comport with EPA's statutory obligations. As the agency is aware, despite the SAFE rule's recent dramatic rollback in the existing standards' stringency, the role of electric vehicles in the market is far beyond a level of initial commercialization. However, in the proposal, EPA fails to account for the rise in electrification technology that has occurred over the last decade. While EPA points to a handful of manufacturer statements (and there are many more) on near term electrification plans,99 the agency's proposal fails to consider the depth and pace of electrification technology deployment that has already occurred. The cadence of EV sales accelerated even during the pandemic, while other vehicle sales decreased.100 This market growth has continued through the first half of 2021 as EV sales doubled compared to 2020 and now stand at 7% globally101 – a trajectory of growth far greater than EPA's expected penetration rate (including PHEVs) of under 8% by MY 2026.

More directly, EPA makes numerous omissions as to the role electrification can play in establishing the stringency level of proposed standards. As previously mentioned, EPA utilizes a MY 2017 baseline that omits a significant and exponential increase U.S. EV sales.102 Moreover, the Agency's RIA states emphatically:

It is important to note that our conclusion that the proposed program is technologically feasible is based in part on a projection that the standards will be met largely with the kinds of advanced light-duty vehicle engine technologies, transmission technologies, electric drive systems, aerodynamics, tires, and vehicle mass reduction already in place in vehicles within today's fleet. Furthermore, the proposed standards do not rely on a significant penetration of electric vehicles into the fleet during the 2023-2026 model years.103

Similarly, the agency does not attempt to account for the new full electric pick-up trucks set to come on the market, such as the Tesla Cybertruck and others, in the near term.104 Even more troubling is the willful refusal to revisit admittedly over-estimated battery costs in the agency's analysis where the agency states:

Likewise, the battery costs used in the SAFE FRM were considered too high by EPA. However, given that significant levels of vehicle electrification will not be necessary in order to comply with the proposed standards (past analyses by EPA have estimated BEV penetrations of less than 5 percent, in general), we did not consider updating vehicle electrification costs to be of paramount importance for this proposal, although we may update battery and other vehicle electrification costs for the final rule.105

Despite this assertion the agency analysis still suggests, 'we believe it is likely that an even higher percentage of the industry-wide light-duty vehicle fleet could be electrified during the time period of our proposed MY2023 and later standards.'106

Thus, in combination, despite being the most efficacious emissions reduction technology, the agency refused to analyze fully the role EVs can play in terms of setting near term compliance levels simply because it was 'not necessary for compliance.' The agency has its analysis backwards. EPA must look at the technologies at hand to establish its level of stringency not set a compliance level and then exclude the full contribution of readily available technologies. Moreover, embarking on a path that ignores electrification reinforces that in proposing these standards the agency has chosen not to utilize the technology forcing authority present in Section 202 of the Clean Air Act,107 and leaves American technological ingenuity on the cutting room floor. [EPA-HQ-OAR-2021-0208-0278-A1][pp.11-13]

B. EPA Should Utilize Greater Near Term EV Deployment in Setting the MY 2023-26 Standards Under the Relevant Factors Required by Section 202(a)(2)

Over the last decade, EPA has underestimated the role that EVs should play in setting the stringency of the standards. In 2010, 'EPA did not project reliance on the use of any plug-in hybrid or battery electric vehicles when projecting manufacturers’ compliance with the 2016 standards.'108 In 2012, EPA and NHTSA stated: 'At this time we do not estimate whether the number of people who will choose to purchase EVs at private-market prices will be more or less than the number that auto makers are expected to produce to comply with the standards.'109 Yet, when looking at technological feasibility under the standards the EPA acknowledged in its 2012 standards rulemaking that:

[T] the agency is not limited in determining the level of new standards to technology that is already being commercially applied at the time of the rulemaking. It can, instead, set technology forcing standards, i.e., ones that make it necessary for manufacturers to engage in research and development in order to bring a new technology to market. There are certain technologies that the agency has considered for this rulemaking, for example, that we know to be in the research phase now but which we are fairly confident can be commercially applied by the rulemaking timeframe, and very confident by the end of the rulemaking timeframe.110

Rather shockingly, with Tesla now the most valuable automobile manufacturer and having deployed almost two million EVs globally, EPA fails to set technology forcing standards. This is at odds with experience and logic. As a leaked draft of the upcoming IPCC, Working Group 3 report states, 'The vast majority of GHG emission reductions by 2050 in the transport sector are projected to come from electrification of the light duty vehicles. These technologies are now commercially available.'111

In its proposal EPA lays out a number of factors it utilizes when assessing the 'requisite technology' that will support establishing a level of stringency in the standard. When analyzing feasibility and these factors, it should be clear that electrification technology – which is already commercialized – should form the basis for the agency implementing a far stronger standard than proposed. In considering all these factors, the agency should reconsider the stringency level because EVs are now proven beyond any doubt and meet all the elements.112

(1) Electric Vehicles Are the Most Effective Vehicle Technology for Reducing Emissions.

EPA has long considered, in other contexts, electric vehicles to be the most effective technology, stating over a decade ago, 'From a vehicle tailpipe perspective, EVs are a game-changing technology.'113 In discussing electric vehicles in the proposal the EPA also finds that 'the GHG performance for these vehicle types is significantly better than that of conventional vehicles.'114

Recently, in a detailed study, the National Academies of Sciences deemed EVs the greatest opportunity to improve the energy efficiency of light-duty vehicles — i.e., passenger vehicles and light trucks — over the period of 2025-2035, as well as to reduce greenhouse gas pollutants from this sector.115 Additionally, study after study shows EVs are a superior technology for reducing air pollution and GHG emissions on their lifetime.116 On well to wheels analysis including upstream emissions, the DOE has repeatedly found EVs to be far superior in emission performance than ICE technology.117 Moreover, as the carbon intensity of domestic electricity generation continues to decline, EV emission performance becomes better and better over time.118 [EPA-HQ-OAR-2021-0208-0278-A1][pp.13-14]

As EPA notes in its technical review, it failed to complete a review of battery cost for EVs, asserting it was unnecessary given the agency does not rely on significant EV penetration for MY 2023-26.124 As per the EPA's discussion, we agree battery costs in the SAFE rule were too high. UBS reports that leading manufacturers are estimated to reach battery pack costs as low as $67/kWh between 2022 and 2024.125 Recently, others have also projected costs significantly lower than EPA's past projections. BNEF's recent estimate is that pack prices go below $100/kWh on a volume-weighted average basis by 2024, hit $58/kWH in 2030,126 and could achieve a volume-weighted average price of $45/kWh in 2035.127 The National Academies of Sciences found high-volume battery pack production would be at costs of $65-80/kWh by 2030128 and DNV-GL has predicted costs declining to $80/kWh in 2025.129 In short, had the agency rightfully determined that EVs offer the best compliance technology near term and revisited battery pack costs, it would have found dramatically decreasing costs battery costs that further support that EV deployment will accelerate rapidly near term and represents the best possible emissions reduction technology. [EPA-HQ-OAR-2021-0208-0278-A1][p.15]

Commenter: Toyota Motor North America, Inc. (Toyota)

EPA has Underestimated the Level of Electrification Needed to Meet the Standards

A Big Jump in A Few Years

The proposed GHG standards present a formidable challenge in attaining the levels of electrification being projected for compliance. EPA estimates the share of BEVs, FCEVs, and PHEVs will need to grow from an average of 2.4 percent1 today to 8 percent (NHTSA is projecting 12 percent for its proposed CAFE regulation) by 2026. Efforts to build the market must start now to more than triple the share of these technologies in just four years. For perspective, it's taken conventional hybrids 20 years to eclipse 3 percent of the U.S. market, even though hybrids require no new infrastructure, have no range anxiety issues, can be refueled virtually anywhere, and require no behavioral changes. [EPA-HQ-OAR-2021-0208-0531-A1, p. 3]

As described below, Toyota believes the task is even greater than projected by EPA because more electrification will be needed to comply with the proposed standards, which overestimate the likely contribution of ICE vehicle improvements and thus underestimate the level of BEV, FCEV, PHEV, and conventional hybrid volumes likely needed for compliance. [EPA-HQ-OAR-2021-0208-0531-A1, p. 4]

Commenter: U.S. Chamber of Commerce ('the Chamber')

Bolster U.S. supply chains for strategic minerals to ensure affordability and implementation feasibility

The COVID-19 pandemic has led to disruptions of supply chains for U.S. businesses across a broad range of sectors, products, and services. The supply chains in multiple sectors, including the automotive sector, continue to be severely impacted, illustrating the need for a holistic and coordinated government response to ensure the affordability and feasibility of implementing ambitious climate policy.

Nowhere is this need more evident than in the growing challenges associated with securing reliable and affordable resources necessary for the manufacture of electric vehicle batteries. The automotive sector is not the only industry sector that relies on high-capacity batteries – other sectors do as well, including cloud computing and data centers, renewable energy storage systems (RESS), telecommunications and aerospace, and consumer devices. Lithium-ion batteries are deployed in both the stationary storage and transportation markets and are the major source of power in consumer electronics and telecom applications.3 High-capacity batteries are also used in a variety of aerospace applications in order to ensure safety, reliability, and performance. The cumulative demand, plus the surge forecasted to meet demand for these strategic minerals from ambitious climate policies, is expected to increase by five times4 for some minerals over the coming decades due to strong demand in the U.S. marketplace and around the world.

Ensuring a secure and resilient supply chain for strategic minerals and other battery components will be particularly important in the years ahead to ensure affordability and to avoid bottlenecks that could potentially disrupt any dramatic increase in the sale of electric vehicles (EV). For example, because batteries are metal-rich products that comprise approximately 30 percent or more of the cost of an electric vehicle, the cost and availability of those metal inputs are key to accelerating the manufacture and sale of EVs in the years ahead.

As it stands today, however, the U.S. is highly dependent for such inputs on a handful of foreign countries, including China, where the production and processing of strategic minerals used in high-capacity batteries is concentrated.5 As outlined in China’s 13th Five-Year Plan, China has pursued aggressive investments in high-capacity battery development, temperature adaptability, recovery and disposal.6 According to a recent DOE report, China currently has nearly 80 percent of the world’s lithium-ion battery manufacturing capacity,7 and as shown in the graphics below from Benchmark Mineral Intelligence, this manufacturing dominance is accompanied by similar dominance in mining, processing, and refining of key inputs such as lithium, cobalt, nickel, and graphite. Moreover, BMI recently reported that of the more than 200 lithium-ion 'megafactories' planned between now and 2030, 149 will be in China, while only 11 are planned for North America.8 [EPA-HQ-OAR-2021-0208-0524-A1, pp. 3-4] [Graphics can be found at docket number EPA-HQ-OAR-2021-0524-A1, p. 4]

Securing stable supplies of cobalt and nickel is a top concern for high-capacity battery development, and is also relevant for smaller lithium-ion batteries used in a range of consumer devices. According to one report, the Clean Energy Ministerial target of 30 million global EV sales by 2030 would require 314 kilotons of cobalt per year—more than three times the current global cobalt demand for all uses.9 Similarly, nickel mining capacity coming online through 2025 is insufficient to meet battery production needs, leading to further constraints in the nickel supply chain.7

Copper is another resource of concern when it comes to the future of electric vehicles as markets simultaneously demand more data centers and consumer devices. Because an electric vehicle requires approximately four times as much copper as a conventional vehicle, total copper demand for the EV sector is expected to increase more than six-fold by 2030 as the pace of deployment accelerates.10 With copper prices continuing a multi-year rise and now nearing alltime highs, establishing expanded domestic mining and processing capacity is clearly of importance. Batteries used in data centers and for consumer electronics devices have similar dependencies on cobalt, copper, and other critical components.

The significance of securing supplies of these high-capacity battery inputs is extremely important for the success of any significant increase in EV penetration. The Alliance for Automotive Innovation notes that automakers and suppliers will invest $330 billion by 2025 to expedite the transition to EVs.

As EPA considers revising the greenhouse gas standards for light duty vehicles, the agency and the federal government at large should consider how to address supply chain concerns related to strategic minerals and should incorporate consideration of these supply chains issues in the agency’s regulatory benefit-cost analysis and decision-making. [EPA-HQ-OAR-2021-0208-0524-A1, p. 5]

Commenter: Valero Energy Corporation (Valero)

In addition to providing for increased production of renewable fuels and improvements in vehicle efficiency, EISA's statutory purposes include enhancing energy independence and security, consumer protection, and promotion of research and deployment of GHG capture and storage options. The proposed rule undermines each of these objectives:

• By subsidizing accelerated electric vehicle adoption through the extension of multipliers and ignoring the upstream GHG emissions associated with generation of electricity and production of batteries, the rule fails to address the energy security consequences of encouraging greater dependence on electric vehicles that rely on batteries requiring rare earth and other metals sourced substantially outside of the United States and its sphere of influence.14 [EPA-HQ-OAR-2021-0208-0601-A2, pp.6-7]

• Regarding consumer protection, although EPA concludes that the prohibitive up-front costs of electric vehicles will eventually be offset by fuel savings from improved efficiency, this conclusion is inconsistent with the findings of comprehensive assessments by Arthur D. Little Consulting and an April 2021 Report by Argonne National Laboratory.15 Further, the preamble acknowledges that consumers will be impacted by higher vehicle purchase costs and that this may particularly impact consumers' ability to obtain credit. Although EPA projects that the proposed rule will result in doubling the current electric vehicle fleet in a four-year period, the preamble omits any consideration of harm to consumers resulting from increased costs and diminished reliability resulting from increased electricity demand. It does not appear that EPA has considered the findings of a recent IEA report noting that there are insufficient mineral resources or processing capability to supply the need for electrification of the transportation sector. 16 EPA should evaluate whether such scarcities have the potential to result in significant price increases to consumers as well as shortages of batteries and vehicles. [EPA-HQ-OAR-2021-0208-0601-A2, p.7]

Commenter: Volvo Car Corporation

Electrification and US Govt Role

According to consumer research studies, US customers still have some hesitancy with respect to electric vehicles. Several factors play into this hesitancy including cost, range anxiety, low gas prices, lack of infrastructure, and/or lack of awareness of the benefits. So it is clear policymakers and automakers need to continue to educate consumers and pursue policies that incentivize and encourage EV purchases.

It is essential that the US government pursue policies that encourage and develop the US electric vehicle market via federal and state incentives. Also, government support for infrastructure development is critical. If incentives and infrastructure are not in place, the US will not grow the EV market and US EV production and thus the US will likely risk achieving the broader climate change goals.

Volvo Cars supports the Administration’s goals of increased electrification. To accomplish this important goal, we believe EV incentive policies should be non-discriminatory, provide equal treatment for all manufacturers and afford all consumers the broadest choice of vehicles for all models and price points. Volvo Cars is very concerned about the recent Senate Finance Committee and House Ways and Means Committee action on EV incentives. These proposals severely limit consumer choice and thus adoption of EVs, and so we believe this would significantly hinder the Administration’s climate change goals.

Volvo Cars is encouraged by the current plans to add electric charging stations. This is a great initiative to support wider adoption of EVs in the US. Such an initiative would also create economic stimulus and support the US economic recovery following the COVID-19 pandemic. [EPA-HQ-OAR-2021-0208-0253-A1, p. 3]

Commenter: Weck, Will

Hello, my name is Will Weck. I'm here today as a private citizen, and I appreciate you giving me the opportunity to comment on this proposed rule. I am a political science student at Belleville West High School in Belleville, Illinois. As a Senior, that also means that I have the privilege to drive a car, but with the new proposed legislation, my little Mazda could be the last gas-powered car I ever own.

I would like to begin with recognizing the merits that I find factual. America is witnessing a changing climate, and that can mainly be contributed to overall warming of the planet due to carbon emissions. Sure, significant action needs to be taken and taken soon to protect our environment for our generation and those to come, but that shouldn't be accomplished by devastating humanity and the American market.

For over a century, American auto manufacturers have been building vehicles powered by gasoline, but these new regulations on carbon emissions cannot simply be achieved by reengineering motors for fuel efficiency. Instead, cars will be built lighter, cheaper, and with smaller, less powerful engines, creating quality and safety problems all around. Consumers will not be satisfied with these changes, but at the same time, according to 2020 auto sales stats, backed up by Forbes, electric cars only made up 2% of new car sales. Clearly, America is not ready to pull the plug and go all-in on electric. This leaves many consumers who prefer gas-powered large SUVs and trucks with fewer options, since most will have to be phased out with the new regulations.

Take the new Ford F-150 Lightning, for example. This was designed to be the replacement for its gas powered equivalent, the F-150, which is expected to be phased out by 2030. Not only is American infrastructure not prepared for a full sweep of electric vehicles, but American companies and corporations aren't all going to be ready to fit the bill to outfit their fleet with electric vehicles and their garages and parking lots with chargers.

I support American business, and the freedom of choice. I urge you to reconsider this rule and instead focus on offering electric vehicle incentives, while leaving gas and diesel options for those who are not ready to change. [EPA-HQ-OAR-2021-0208-0507, p. 1-2]

Commenter: World Resources Institute (WRI)

ZEV Market Share Projections and their Consequences

The ZEV market share is increasing rapidly in the United States as battery prices fall and as OEMs introduce a much wider range of ZEV models in all market segments, including forthcoming pickup truck and SUV offerings. Even with the currently relatively limited model offering ZEV market share reached 10.7% in California during the first two quarters of 2021.1

These developments are reflected in President Biden's Executive Order of August 5, 2021, setting a national goal that 50 percent of all new passenger cars and light trucks sold in 2030 be zero-emission vehicles. This Executive Order also indicates that the administration will be pursuing a variety of policies to promote electric vehicles independent of this rulemaking.

Despite the very dynamic nature of the ZEV market, EPA chose not to update the battery cost assumptions used in its compliance modeling even though EPA considers the assumed battery costs to be too high.

Likewise, the battery costs used in the SAFE FRM were considered too high by EPA. However, given that significant levels of vehicle electrification will not be necessary in order to comply with the proposed standards (past analyses by EPA have estimated BEV penetrations of less than 5 percent, in general), we did not consider updating vehicle electrification costs to be of paramount importance for this proposal, although we may update battery and other vehicle electrification costs for the final rule.2

This is a fundamental error. While EPA is correct in observing that "significant levels of vehicle electrification will not be necessary in oder to comply with the proposed standard," this in no way obviates the need for EPA to properly evaluate likely ZEV penetration in order to determine whether a more stringent standard is appropriate.

Indeed, based on the admittedly flawed battery price assumption used, EPA projects that the fleet-wide ZEV market share would only be 7.8% in MY2026 under the proposal—less than the ZEV market share in California today. This projection is dramatically lower than the ZEV market share projections made by independent analysts using up-to-date battery cost data. The table below compares EPA's fleetwide market share projections to those made by Bloomberg New Energy Finance3 assuming current policies, and two projections from the Rhodium Group,4 one based on current policies (RhG–C) and one based extended tax credits and charging infrastructure investments (RhG–I) similar to those proposed by the Biden administration and currently under active consideration in Congress.

EPA's flawed battery price assumptions and resulting underestimate of ZEV market penetration rates have a dramatic impact on the emissions rates that would be required of ICEVs under the proposal as well as the alternatives considered. [EPA-HQ-OAR-2021-0208-0207-A1, p. 2-3]

Commenter: Wyman, Stephen

EPA regulations must push existing technologies to the fore, highlighting GHG reducing methodologies that have existed for decades, yet are somewhere between scarce and unknown in vehicles available today.

First: FSHEV (Full Series Hybrid Electric Vehicles) like: Nissan's Note E-Power; GDLS' (General Dynamics Land Systems) RST-V (Reconnaissance, Surveillance and Targeting Vehicle; a.k.a., Shadow)... This technology can scale from the smallest to the largest of vehicles in use today.

Second: The, "skateboard," undercarriage that allows larger battery capacity unobtrusively. This technology is to be applied to the Ford F-150 Lightning as well as being planned for use in a variety of BEV (Battery Electric Vehicle) platforms. The skateboard can also be used in: buses, truck trailers, train cars and RVs (Recreational Vehicles).

Third: Regenerative braking could be applied to all axles and the associated motor/generator could also help heavy vehicles climb hills; move train cars around the railroad yard and tractor trailers around shipping and receiving docks. [EPA-HQ-OAR-2021-0208-0307, p. 1]

EPA Response

EPA acknowledges all of the comments above.

In response to comments on the need for charging infrastructure, or that EPA should conduct a cost analysis for future infrastructure needs or otherwise provide a detailed discussion of infrastructure issues in this rule, EPA disagrees with commenters' statements that inadequate charging infrastructure will act as a critical constraint toward meeting the levels of EV penetration projected under this final rulemaking, and accordingly believes that a more detailed or quantitative analysis of this issue by EPA is unnecessary for this rule. EPA understands that charging infrastructure and fast charging capability is a relevant issue to the adoption of EVs. While policies and incentives to promote infrastructure are largely outside EPA's authority and are outside the scope of this rulemaking, EPA supports the Administration's goals to advance infrastructure in this area and concludes that existing infrastructure and rates of expansion are sufficient. EPA agrees with NCAT's observation in its comments that charging infrastructure has been growing rapidly in recent years, with over 100,000 public charging ports available today. A recent National Renewable Energy Laboratory report found that the amount of public and workplace charging is keeping up with projected needs, based on Level 2 and fast charging ports per plug-in electric vehicle.[34] We note that the Infrastructure Investment and Jobs Act includes up to $7.5 billion to advance EV charging infrastructure,[35] and that this infrastructure is rapidly being prepared for implementation.[36] In addition, EPA acknowledges the many comments received—including from C2ES, EEI, Energy Strategy Coalition, Maryland Department of Environment, NACAA, NCAT, and NY State Department of Environmental Conservation—describing current and planned charging investments across many states by

[34] Brown, Abby, Alexis Schayowitz, and Emily Klotz. 2021. *Electric Vehicle Charging Infrastructure Trends from the Alternative Fueling Station Locator: First Quarter 2021*. Golden, CO: National Renewable Energy Laboratory. NREL/TP-5400-80684. https://www.nrel.gov/docs/fy21osti/80684.pdf, last accessed December 2, 2021.

[35] This includes $5 billion for a National Electric Vehicle Formula Program and $2.5 billion for grants for electric vehicle charging infrastructure, hydrogen fueling infrastructure, propane fueling infrastructure, and natural gas fueling infrastructure. The Infrastructure Investment and Jobs Act (Public Law No: 117-58) is available at: https://www.congress.gov/bill/117th-congress/house-bill/3684, last accessed December 2, 2021.

[36] Beggin, R., "Biden administration announces EV charging network plan," The Detroit News, December 13, 2021.

government, utilities, and other parties. EPA also notes that many electric vehicle owners can charge at home and thus are not dependent on the development of public infrastructure for the bulk of their charging needs. Given the evident rate of activity to address EV infrastructure needs, EPA believes that the outlook for deployment of charging infrastructure is consistent with growth in projected needs during the time frame of the rule and sees no reason to expect that this trend will change.

Nonetheless, EPA acknowledges that additional charging infrastructure may be needed in the coming decade while noting the ongoing progress towards installing new infrastructure and the significant uncertainty associated with estimating the ultimate need. For example, Hyundai commented that about 2 million chargers would be needed in 2030 to support a rate of 50% new EV sales. Stellantis projected a need more than twice as high at approximately 4.2 million chargers. This difference mirrors the wide range of estimates in the literature. A white paper from ICCT compared a dozen recent studies of public infrastructure needs. It found that the ratio of EVs to public chargers varied by more than a factor of 10 across the studies: from about 12 to 129 EVs per public charger—including the authors' own estimate of 24.[37] EPA notes that the above referenced estimate from Stellantis assumed a ratio of 1 charger for every 6.9 EVs , which resulted in a relatively high projection of total chargers needed. This ratio was based on a California-specific assessment of future public and shared private charger needs that EPA notes may not be applicable to the nation as a whole.

Future charging needs will depend on many factors including the level of EV adoption, geography, vehicle characteristics, and charging and driving behavior. EPA understands that access to charging may become a relevant environmental justice issue, if EV penetration increases and charging infrastructure or home charging capability is not equally distributed, although it is as yet uncertain and thus difficult to establish to what extent such inequities may develop. Given the level of activity, investment, and progress in EV charging infrastructure to date and planned, EPA does not expect that charging infrastructure will act as a significant barrier to achieving the levels of EV penetration projected during the 2023-2026 time frame of this final rule. EPA plans to continue to study the market needs and associated costs and availability of charging infrastructure and consider the findings in the context of a subsequent rulemaking.

Regarding comments on other aspects of EV infrastructure, several commenters discussed the importance and challenges associated with residential charging access. While many electric vehicle owners can charge at home, EPA recognizes and agrees that home charging can be dependent on the ability to install a charger and/or park in a location with sufficient electrical access, that this capability varies with different types of housing, that charging access can be

[37] Gordon Bauer, Chih-Wei Hsu, Mike Nicholas, and Nic Lutsey, "Charging Up America: Assessing The Growing Need for U.S. Charging Infrastructure Through 2030", July 2021, The International Council on Clean Transportation, https://theicct.org/publications/charging-up-america-jul2021, last accessed December 2, 2021.

incentivized, and in any case is likely to be implemented in response to growth in consumer demand. While EPA understands that not all potential BEV buyers have a way to charge at home, we believe that the projected penetration of BEVs under this final rule is not likely to result in major shifts toward this category of potential customers.

NATSO raised a concern that the proposal may incentivize utilities to further invest in EV charging infrastructure and pass those costs onto ratepayers, including those with lower incomes. As noted above, we recognize that utilities are one of the groups investing in charging stations along with state and local governments, the federal government through the Infrastructure Investment and Jobs Act, OEMs, dedicated EVSE companies and others. EPA considers it to be outside the scope of this rulemaking to take a position on which entities own and operate charging stations or how those costs are borne.

In response to comments that penetration of EVs was underestimated in the proposal, that a more rapid transition to zero-emission technologies is needed, and that EPA did not properly credit the degree to which EVs can contribute toward meeting a stringent standard, EPA notes that the final rule analysis projects a higher penetration of EVs than in the proposal, and this updated projection is in better agreement with estimates from industry analysts. As described elsewhere in the Preamble and this document, we believe that this projected level and rate of penetration is achievable and appropriate within the time frame of the rule. Regarding Stellantis' comment that 20 to 50 percent of vehicles would have to be hybrid or plug-in vehicles in order to meet the proposed standards, EPA disagrees, based on the analytical modeling results presented in RIA 4.1.4 by which we project cost minimizing compliance pathways, and notes that the projections of EV and hybrid penetration in this final rule are higher than in the proposal.

In response to comments that the current proposal must be followed by stronger limits on GHG emissions, EPA agrees that further reductions in GHG emissions from the light-duty vehicle fleet are possible beyond MY 2026 and is planning to follow this final rule with a subsequent multi-pollutant rulemaking that will include not only light-duty vehicles but also medium duty class 2b and 3 vehicles (see the Preamble to this final rule at I.A.2). EPA believes that the final standards provide for an appropriate transition to a stronger future program.

In response to comments on the potential for automakers to reach higher levels of EV and HEV penetration than we projected and that EPA failed to account for the current pace of electrification, we recognize the widespread investments made by OEMs on electrification, the rapidly increasing pace of electrification, and the potential for growth in EV penetration during the time frame of the rule. We agree that vehicle standards have historically driven the adoption of advanced GHG-reducing technologies and have considered the progress that has been made to date as we considered the appropriate level of stringency of the final standards. The analysis for the final standards, which are more stringent than the proposed standards, projects a significantly higher penetration of EVs than in the proposal. We believe that this level of penetration is appropriate and will build upon the penetration rate already achieved, as well as the stated ambitions of automakers to continue to increase the electrification of their fleets. In the final rule, our projections of EV penetration align more closely with industry projections, and provide for an appropriate transition to stronger standards. EPA continues to monitor current trends in light duty electrification and decarbonization of electricity generation and recognizes the importance of continued GHG reductions in the electricity generation sector as the share of EVs grows in the light duty fleet.

EPA received several comments related to the need for complementary policies and incentives and an “all of government approach” to support increased market penetration of EVs, including, among other areas: public charging infrastructure, supply chain development, workforce training, fleet purchase requirements, EV and battery recycling, end of life issues, economic and purchase incentives, consumer education, grid infrastructure, state and local measures and federal engagement with such measures, and other measures to address the cost and risk of making a transition toward EVs. In response to these comments, EPA notes that many of these policies and incentives are outside of EPA’s statutory authority to control and are outside the scope of this rulemaking, but we continue to monitor developments in each of these areas. EPA supports the goals of the Administration to address these areas individually and as part of an all-of-government approach, including recent passage of the Infrastructure Investment and Jobs Act as previously noted. Many commenters described the investments the auto industry and other segments of the transportation and utility sectors have made and continue to make in these areas. EPA appreciates these efforts and believes that efforts like these will contribute to resolving these issues over time. As stated in RTC 2.2, the level of EV penetration we project during the time frame of this rule is consistent with recent independent market forecasts. EPA believes that the projected level of penetration is also consistent with trends already underway, such as the current level of sales and sales growth that is taking place under the current status of infrastructure, incentives, and other complementary policies, and with the measures currently underway and planned by the industry as mentioned above and by other commenters. As discussed in Preamble III.C, EPA believes that the level of EV penetration anticipated in the final rule is reasonable and achievable, given the multitude of product announcements from vehicle manufacturers, as well as the effect of existing programs, such as the California Framework.

In response to comments on the need for metric-based checkpoints to evaluate the state of progress on infrastructure and other issues described above and to signal the need for preemptive actions to ensure progress, EPA notes again that such measures are outside of EPA’s statutory authority to control and are outside the scope of this rulemaking. EPA also notes the Administration’s initiatives in these areas as described above, as well as the progress in these areas described by other commenters.

In response to comments on the development of a supply chain supporting the manufacture of EVs, please see responses on this topic in RTC Section 19. As described in that section, EPA believes that a wide range of actions cited in that section, including investments and partnerships by the automotive industry and investments and initiatives by the federal government (for example, the recently passed Infrastructure Investment and Jobs Act that provides significant funding to the Department of Energy to promote supply chain development),[38] indicate that the automotive industry has recognized the need to establish a supply chain for electrified vehicles and is taking appropriate action to address this business need. EPA also believes that the abovementioned federal investments and initiatives indicate that the federal government is taking appropriate actions to support its development. EPA believes automakers are taking appropriate and sufficient steps, and the standards adopted in this rule will encourage continued attention to the need for adequate supply chains. EPA will continue to study the impact of critical material cost and availability, changes to the supply chain, employment, and similar issues and will consider our findings as we undertake a subsequent rulemaking.

In response to comments on the demand, cost, and availability of critical minerals and materials and that EPA should conduct a risk analysis on this issue, EPA acknowledges that critical minerals and materials can affect the cost and/or production capacity of batteries and other electrification components, and that uncertainties regarding critical minerals may affect their future projected costs as demand grows. On the other hand, the industry is reacting rapidly to meet anticipated demand (see related discussion in RTC Section 19). It is uncertain at this time whether future costs of critical minerals can be reliably forecast using the data available today. We have included a sensitivity in the analysis supporting this final rule that examines the impact of higher and lower battery costs. EPA recognizes and supports efforts by the Department of Energy and the Administration to pursue initiatives that can reduce the risk associated with these materials by building the domestic supply chain and developing domestic sources for these materials. During the time frame of this rule, our assumptions for future battery costs in this final rule are consistent with projections by the Department of Energy, leading analysis firms and general industry consensus. Where future costs beyond the time frame of the rule are used to determine annualized costs, we have remained conservative with respect to some projections due to these uncertainties. While we project a relatively modest penetration of electrified vehicles during the time frame of the current rule, we plan to continue to study the impact of critical material cost and availability, changes to the supply chain, employment, and similar issues and consider our findings in the context of a subsequent rulemaking.

In response to comments on the energy security and environmental impacts of an increased penetration of EVs, EPA responds to most comments on the energy security topic in RTC Section 19. In further response to similar comments in this section, EPA first notes that the use of imported materials or minerals to build vehicles is not a direct analogy to the issue of energy security associated with use of imported petroleum, because the minerals used in production of batteries, motors, and other components are not an energy source that is consumed to power the vehicle, but rather, once supplied, remain with the manufactured vehicle for its useful life. EPA expects in many if not the vast majority of cases these materials can be recycled from old vehicles and reused, and the motivation for recycling becomes particularly strong if the materials

[38] Department of Energy Fact Sheet: “The Bipartisan Infrastructure Deal Will Deliver For American Workers, Families and Usher in the Clean Energy Future,” November 9, 2021. Accessed on December 6, 2021 at https://www.energy.gov/articles/doe-fact-sheet-bipartisan-infrastructure-deal-will-deliver-american-workers-families-and-0

are in short supply. With regard to the environmental impacts of mining, EPA notes that the mining of virgin materials for any manufactured product can have environmental impacts. EPA believes that over the long term, recycling could dramatically reduce any environmental impacts that may accompany the mining of materials used in electrified vehicles, as the need for virgin materials will be reduced. EPA understands that some materials necessary to the production of electrified vehicle components are currently sourced from other countries. As described in RTC Section 19, EPA notes that the Administration has identified a goal to advance domestic production capacity for these minerals and components, and also notes ongoing work by the Department of Energy to ensure that these materials can be recycled efficiently. We also note that the issue of dependence on imported materials and minerals is not unique to EVs, but also affects conventional vehicles, which use an array of imported and strategic materials, such as platinum and palladium for catalysts, computer chips for engine control and entertainment systems, and other parts and materials that are sourced from other countries. Materials like these were imported for use in other industries long before the recent growth in their use in electrification. While some battery chemistries include cobalt which carries environmental and other impacts depending on how it is sourced, cobalt content is being rapidly reduced and can be eliminated entirely by use of other chemistries that are already gaining market acceptance. While increased demand for critical minerals can cause costs to increase, at the same time the increased value of these materials favors their recycling, and there is little evidence to suggest that minerals that have significant market value will not provide similar incentives for recycling as other materials in the automotive sector, thus reducing demand on production from mining operations. See also our response to comments on energy security and electrified vehicles in RTC Section 19.

In response to comments suggesting that the final rule constitutes a wholesale shift of our transportation infrastructure to EVs and/or overreliance on the electric power grid, EPA disagrees with this characterization. We project that over 80 percent of new vehicles in a fleet complying with the standards in MY 2026 will remain powered by gasoline, with a much greater share of the on-road vehicle stock remaining gasoline powered as well. Similarly, regarding comments suggesting that the rule will mandate electric vehicles, or that GHG emission standards favor EVs over other technologies, EPA disagrees with these characterizations. Again, while we project cost-minimizing compliance pathways that include electrified vehicles, we also project that more than 80 percent of vehicles complying with the standards in MY 2026 will use gasoline technologies. Ultimately, the decision of which technologies to deploy to meet these performance based standards rests with the manufacturer. Similarly, EPA disagrees with comments suggesting that we are proposing to change the power source of the US vehicle fleet, as we project that more than 80 percent of the fleet will continue to be powered by gasoline during the time frame of the rule.

In response to comments recommending that ZEV sales targets be established, see our response to a similar comment in Section 2 of this Response to Comments document. Our modeling for this final rule projects that electrified vehicles will play an increasing role in meeting the final GHG standards, and we believe that the final performance-based standards do in fact support the transition to more EVs in the fleet, including, for example, commenters' call for the creation of competitive market conditions, early investment in supply chains, and similar issues.

In response to comments that the standards should encourage hybrid vehicles over electric vehicles, or gasoline and diesel vehicles over electric vehicles, or that any specific technology should be favored over others or brought to the fore, EPA's final standards are performance based standards that do not mandate a specific technology. Projected penetrations of specific technologies are primarily an outcome of their cost and effectiveness, and ultimately their implementation in the market is the result of manufacturer decisions that may differ from our projections. To the degree that multipliers may encourage EVs, EPA believes that it is appropriate to encourage EVs because of their inherent benefits as a game-changing technology that can potentially eliminate tailpipe criteria pollutants and GHG emissions. Our ABT program in combination with performance-based standards allows manufacturers the greatest flexibility to produce a variety of vehicles to meet consumer demand at the least cost while achieving significant emission reductions. While we project that cost minimizing compliance pathways for manufacturers to meet the performance based standards of the current rule will likely include EVs and PHEVs, we also project that more than 80 percent of new vehicles in a fleet complying with the standards in MY 2026 will use gasoline technologies, including conventional hybrids which run on gasoline. Automakers are free to choose the technologies that they feel best support their compliance with the standards and market demand.

In response to comments that call for standards that ensure continuous technology advancement, the final rule contains performance-based standards that call for significantly greater year-over-year increases in stringency than the SAFE rule. Based on our technical analysis, the standards finalized in this rule will significantly drive technology adoption and bring about significant emissions reductions while appropriately balancing our consideration of statutory factors such as cost, technology availability and lead time.

In response to comments on the impact of multipliers on penetration of other technologies, our analysis for this final rule considers the impact of multipliers in modeling a potential compliance pathway for the industry, which includes consideration of the impacts on penetration of ICE and hybrid vehicles as well as other available technologies. See the discussion of the overall analysis in Preamble I.C and III.A, of flexibilities and multipliers in II.B, and penetration rates in III.B.3.

In response to comments that the battery costs in the proposal were too high, we have reduced battery costs significantly in the analysis for this final rule, and they are now in better agreement with industry consensus for the time frame of the rule. Regarding comments about appropriate battery learning curves, we have also made changes for the final rule. For a full discussion on battery costs and learning see Preamble III.A and RIA 2.3.4 and 4.1.1.2. As the industry evolves and matures, EPA continues to study and update costs for all forms of electrification, including hybrid vehicles, and expects to employ updated costs as they become available for future analyses . See also our detailed responses to other specific comments on battery costs in Preamble III.A.

In response to comments stating that hybrid vehicle costs "are double what is reasonable" (ACEEE) or are "not a plausible result" (ICCT) or are otherwise too high, commenters have not indicated what they consider reasonable or plausible, provided new data to support that position, or explained why they find the existing costs in the NPRM analysis to be not reasonable or plausible. ICCT suggests that this conclusion was based on analyzing incremental total vehicle costs from the output files of the SAFE proposed rule analysis, but does not provide detail showing how these incremental vehicle costs were determined, and it is not clear that the results would be the same for the 2021 EPA NPRM analysis. While ICCT cites a 2015 study that provides estimated direct manufacturing costs for hybrid components, it is not clear whether the commenter's method of deriving an incremental hybrid cost from a total vehicle cost in a CCEMS output file from the SAFE NPRM analysis accurately represents what was assumed for direct manufacturing costs of non-battery components in input files for the 2021 EPA NPRM analysis. Similarly, ACEEE also makes reference to incremental costs, and cites the 2021 NAS report, but does not explain the implication that the direct manufacturing costs in the NAS report would contradict the incremental vehicle costs referred to by the commenter. In considering cost and other inputs for the analysis for the final rule, EPA carefully considered a range of potential updates (see Preamble III.A). This included consideration of whether a potential update to a specific category of technology costs was likely to have a significant influence on the conclusions of the analysis, whether significant new cost information had become available, and whether a potential change could be implemented within the analytical framework of the analysis. For example, many of the comments received on battery costs cited specific data and forecasts that were readily comparable to the direct manufacturing costs that had been used in the analysis, the comparison suggested that updating these costs would have a significant effect, and the update could be reasonably implemented within the framework of the analysis. With regard to non-battery costs, we concluded that, in comparison to the effect of the reduction in battery cost, and also considering that battery costs for hybrids had also been thereby reduced, the impact of further changes such as to non-battery costs for hybrids or EVs was not likely to have a significant impact. We also performed a low battery cost sensitivity case, which would capture a significant degree of the effect of a reduced electrified vehicle cost from other sources such as lower non-battery costs. With regard to hybrid vehicle and EV non-battery costs, we believe the analysis of non-battery costs performed for the SAFE final rule was sufficient for the purposes and time frame of the final rule, and that the potential magnitude of changes to hybrid, stop-start and non-battery costs likely would not be sufficient to change the fundamental findings of the analysis for this final rule with regard to relative penetrations of hybrid vehicles and electric vehicles. EPA notes that the projected penetration of EVs under the final rule is consistent with projections of EV penetration from leading independent organizations, suggesting that the costs that were used as inputs to the analysis were on the whole appropriate. We acknowledge, however, that advancement of technology and cost reduction in electrified vehicle non-battery components continues to take place, and we intend to further update technology costs in analyses for future rulemakings.

In response to comments that EPA should consider an increased focus on higher power 48-volt mild hybrids, particularly in P2, P3, or P4 configurations, and other synergistic mild hybrid technologies, EPA understands that suppliers are currently working to develop such systems and agrees that they show promise for further reducing emissions if adopted by manufacturers. In future analyses EPA may consider these technologies as they begin to enter production applications and empirical data on their cost and effectiveness becomes available.

EPA continues to study updates in full, mild, and stop-start hybrid costs, and non-battery costs, and expects to update these costs in a subsequent analysis for a future rulemaking as new information becomes available.

In response to comments on accounting for the cost of refueling time, our analysis of the cost of refueling time can be found in Preamble VII.C. While the means of refueling and the time necessary differ between liquid fueled and electric vehicles, today the vast majority of BEV charging events take place at home in an unattended status and there is a time saving due to avoidance of a separate trip to a refueling station. In the final rule analysis we have modeled the vast majority of BEVs as 300 mile BEVs, with very limited penetration of shorter range BEVs, which is likely to reduce the number of charging events needed in the modeling as well as the likelihood of frequent need for public charging. While we understand that not all potential BEV buyers have a way to charge at home and would thus need to rely on public charging if they purchase a BEV, EPA believes that the projected penetration of BEVs under this final rule is not likely to result in major shifts toward this category of potential customers. Further, as the penetration of BEVs has been relatively limited to date, there is currently very little data on which to estimate the degree to which buyers will utilize public charging in the future and hence little basis for quantifying the cost of charging time needed by those buyers. Further, refueling a conventional vehicle requires active attention during the refueling process, whereas charging an electric vehicle does not require the vehicle to be actively attended, even at a public charging station; therefore placing a valuation on the time required for public charging is subjective. EPA expects to continue studying these issues to account for the relative cost of refueling time as effectively as possible.

In response to comments relating to total cost of ownership for EVs, and that total cost of ownership of EVs is lower than for ICEVs, our analysis includes the effects of fuel cost savings (discussed in VII.C of the Preamble and Chapters 6 and 10 of the RIA). Other comments relating to fuel cost and cost of ownership differences between EVs and gasoline fueled vehicles are addressed in Section 17.1 and 17.2.1 of this Response to Comments document.

In response to comments that additional cost reductions for EVs call for additional research, EPA agrees that EV cost reduction is a very active area of ongoing research in the industry, and notes that this activity has resulted in significant cost reductions to date, and promises to continue reducing costs in the future.

In response to comments that reference cost parity, while the date of cost parity is not a metric that bears directly on our analysis, we agree that cost parity is rapidly being approached in some vehicle market segments and that this trend is likely to continue.

In response to comments on the impact of EVs on the reliability of grid electricity, EPA disagrees that the penetration of EVs anticipated under the final rulemaking will have a negative impact. For example, a DOE study[39] has concluded that "sufficient energy generation and generation capacity is expected to be available to support a growing EV fleet as it evolves over time, even with high EV market growth." EPA understands that increased penetration of EVs would lead to increased electricity demand. On the other hand, the impact of this electricity demand on the grid infrastructure will depend on several factors, such as the time of day when vehicles are charged, and the advent of vehicle-to-grid (V2G) services. Most currently produced EVs allow the user to conduct charging at off-peak times, such as at night, when rates are often cheaper and added electricity demand is easy to accommodate; for these reasons, home EV charging already often occurs during off-peak hours, and many EVs already allow the user to schedule charging for specific times of day. Even with a mix of charging times, studies indicate that sufficient excess capacity exists for the levels of fleet penetration anticipated in this final rule. While higher levels of EV penetration might occur after the time frame of the rule, during that time frame it is likely that V2G services will begin to be available. V2G technology may even improve grid reliability by allowing EVs to charge when electricity demand is low, and drawing on them when demand is high and the vehicles are not in use. V2G could thereby promote grid reliability and enable increased utilization of renewable energy sources, such as wind and solar, at the same time. EPA also agrees with the NCAT's comment that time of use (TOU) rates and the use of managed (or "smart") charging could also produce many of these benefits by shifting charging to off-peak times or times when excess renewables would otherwise need to be curtailed.

In response to comments on safety and reliability of EVs, and electrical safety and fire risk, EPA finds no evidence that the nature of an electric vehicle necessarily leads to lower reliability, greater safety risk to service or emergency personnel, or a greater probability of a fire. The smaller number of moving parts in an EV is consistent with a potential for greater reliability and lower maintenance costs. Reliability issues are a common occurrence with all new technologies, and where they have been seen to occur with EVs, EPA sees no evidence that these issues are not being addressed as part of the normal course of product development. Regarding electrical safety, all vehicles sold in the U.S. are required to pass Federal Motor Vehicle Safety Standard (FMVSS) standards. For example, this includes FMVSS No. 305, "Electric-powered vehicles: Electrolyte spillage and electrical shock protection." In addition, for all commercially produced vehicles, manufacturers routinely publish guides to emergency responders to show where mechanical means may be used to access the interior of the vehicle after a crash without disturbing airbags or other hazardous components, including high voltage pathways. In regard to fire safety, EPA sees no evidence that EV fires are more frequent on a per-vehicle or per-mile basis than for gasoline powered vehicles. While some manufacturers have recalled electric vehicles due to specific fire risks, there is also evidence that these were caused by specific defects in manufacturing, that are being recognized and addressed by the manufacturers. EPA also disagrees with comments that batteries are inherently unsafe, that they contain all of the reactants necessary to combust, or that they generate large amounts of heat during operation

[39] Department of Energy, US DRIVE, Grid Integration Tech Team and Integrated Systems Analysis Tech Team, Summary Report on EVs at Scale and the U.S. Electric Power System, November 2019.

sufficient to jeopardize the safety of the vehicle. Electric vehicles and their battery systems are designed to maintain appropriate temperature operation and are safeguarded against usage that would cause excessive heat generation. Battery chemistries being used in electrified vehicles lack the necessary oxygen to combust without exposure to air. Additional comments and responses related to vehicle safety are discussed in Section 21 of this Response to Comments.

In response to comments on the need for battery recycling and/or the current availability of recycling, EPA disagrees with comments suggesting that EV batteries must be disposed of in landfills, that no one is considering how to recycle them, or that they otherwise are not of value for reuse or recycling. Many companies are actively pursuing business models on the recycling of materials in batteries or the reapplication of modules and cells for other purposes. EPA notes comments from the Alliance that it is actively working with government and stakeholders in the recycling industry to develop a robust system for battery recycling. Currently, the growth and visibility of battery recycling companies has been limited due to the fact that there does not yet exist a sufficient rate of used automotive traction batteries being generated by the in-use vehicle fleet because most EVs on the road have not yet reached the end of their useful life. Second-life applications, in which cells, modules, and batteries from old vehicles are used in other applications such as stationary energy storage, are likely to create additional market demand for decommissioned vehicle batteries. Further, the Department of Energy has an active research program on lithium-ion battery recycling, for example, the ReCell Center[40] and the Federal Consortium for Advanced Batteries (FCAB).[41] The recently passed Infrastructure Investment and Jobs Act provides more than $7 billion to promote the supply chain for batteries,[42] including funding for battery processing and manufacturing research, battery recycling research, and for local governments to establish or enhance battery collection, recycling, and reprocessing programs. See also our response to comments on supply chain development in RTC Section 19. Based on EPA's understanding of battery recycling and the research and commercial activity and investments surrounding it, EPA believes that it is premature and ultimately incorrect to conclude that EV batteries will not be recycled. EPA continues to study these issues and the development of the battery recycling industry.

In response to comments concerned with EV range and efficiency in extreme weather, EPA understands that cold and hot weather operation can increase EV energy consumption due to use

[40] Argonne National Laboratory, "DOE launches its first lithium-ion battery recycling R&D center: ReCell," February 15, 2019. Accessed on December 6, 2021 at https://www.anl.gov/article/doe-launches-its-first-lithiumion-battery-recycling-rd-center-recell

[42] Department of Energy Fact Sheet: "The Bipartisan Infrastructure Deal Will Deliver For American Workers, Families and Usher in the Clean Energy Future," November 9, 2021. Accessed on December 6, 2021 at https://www.energy.gov/articles/doe-fact-sheet-bipartisan-infrastructure-deal-will-deliver-american-workers-families-and-0

of cabin heating and cooling, and that power demand for heating can have a greater relative impact on energy consumption in EVs than in conventional vehicles where the engine generates waste heat that is available for cabin heating. For earlier EVs, with limited range and battery capacity, energy consumption associated with interior climate control had a significant effect on the vehicle utility (range). However, most recent EVs have a substantial amount of battery capacity and range and as such the increased energy consumption associated with interior climate control has a smaller impact on vehicle utility. EPA continues to study this issue because we recognize that EV energy consumption is an important factor for the environmental performance of an EV and we may consider these issues in a future rulemaking.

In response to comments that EPA neglected to account for the cost of battery replacement and depreciation for EVs, EPA disagrees that battery replacement will typically be necessary or that depreciation of EVs must be greater than for other vehicles. Based on current experience with vehicles in use in the field, and consultations on this topic that EPA has conducted with experts, stakeholders, and manufacturers, EPA finds no evidence that battery replacements will typically be necessary for EVs during their useful life, and therefore did not include the cost of battery replacement in the cost of EVs. While some early generation EVs have shown lower resale value than comparable conventional vehicles, EPA also notes that this is a commonly observed effect for relatively new technologies in a rapidly advancing field in which new models rapidly improve upon their predecessors. Vehicles from some manufacturers such as Tesla have in fact shown a below average rate of depreciation, suggesting that high depreciation is not inherent to all electric vehicles. Based on these observations EPA does not see evidence to suggest that EVs as a mature technology will necessarily experience higher rates of depreciation than that of conventional vehicles.

In response to comments stating that electric vehicles are not zero emission due to upstream emissions, EPA understands that electric vehicles consume electricity which currently is derived from a variety of sources, including from fossil fuels that generate GHG emissions at the power generating plant. However, due to rapidly declining costs and improved technologies, the share of renewable energy on the grid has been growing rapidly in recent years and we believe that it will continue to grow rapidly in the future. Studies have shown that even in areas where the grid is powered largely by fossil fuels, EVs have a net emissions benefit, which only increases as the grid gets cleaner.[43] Regarding comments that the need for clean energy for EVs will result in construction of additional nuclear power plants, EPA sees no evidence that new nuclear power plants will play a significant role in serving increased electricity demand. While some forms of renewable energy, such as wind and solar, are intermittent in nature, the utility industry is actively developing technology to manage this capacity, including energy storage and vehicle-to-grid technology. By enabling increased use of renewable energy for transportation, EVs offer the potential to go much farther toward net reductions in GHG emissions than gasoline vehicles. Although EVs are currently assigned 0 grams per mile in compliance calculations, the associated

[43] Bieker, G., “A Global Comparison of the Life Cycle Greenhouse Gas Emissions of Combustion Engine and Electric Passenger Cars,” ICCT Report, 2021.

upstream emissions are included in our GHG inventory calculations (see Preamble section IV and Chapter 5 of the RIA), and we find that the net GHG reductions offered by EVs are significant even when upstream emissions are taken into account, and even without assuming that the bulk of the energy feedstock is renewable.

In response to comments on increased acceleration of EVs, EPA does not regulate vehicle acceleration levels, and disagrees that EVs must necessarily have dangerous levels of acceleration. The acceleration rate that is designed into a vehicle is the result of manufacturer design decisions and customer demand. There is no inherent reason that EVs cannot be designed with the same level of acceleration as conventional vehicles. Regarding the opposite comment that vehicles meeting the standards will be lighter, cheaper, and with less powerful engines, there is no evidence to suggest that this will be the case. The weight, size, power, and acceleration of new vehicles has continued to increase even as emissions standards have continued to increase in stringency over the last decade. Automakers are free to consider consumer demand for these attributes and select the technologies that best allow them to be preserved while complying with the standards.

In response to comments on the overall consideration of relevant costs and risks in its analyses, for example that there are “costs/risks the EPA does not address in this proposal,” EPA is aware of the issues related to vehicle electrification and takes them into account by evaluating their relevance and impact in the context of a rulemaking and considering evidence available in the literature and through its own analyses. Costs are discussed in Preamble I.D, Preamble III.B, Preamble VII.I, and Chapter 6 of the RIA, and impacts on emissions are described in Preamble IV and V and Chapter 5 of the RIA.

In response to comments that EPA should consider the costs and risks to OEMs and technology suppliers in adapting supply chains to meet the standards, particularly with respect to ZEVs, EPA does consider the impact of its rulemakings on various segments of the industry, including suppliers. EPA has considered the significant activity, investment, and progress that is occurring in public and private contexts to prepare the manufacturing base for EV production at the levels of penetration anticipated during the time frame of this rule, and considers this activity to represent an appropriate market response to the anticipated need to meet the standards.

In response to comments from the Alliance suggesting that electricity rates may become more expensive as renewable generation is added, and citing rates in Germany and California as evidence, EPA disagrees with this assertion. Electricity rates are a result of many factors including national, regional, and state policies and conditions, regional costs of feedstocks, and many other economic and policy factors, all of which must be taken into account when considering the basis for observed electricity rates. The cost of renewable energy capacity is declining faster than other sources and its levelized cost is already highly competitive with or significantly less costly than other sources of new generating capacity,[44] and despite recent increases in commodity costs, renewable energy capacity continues to grow faster than other sources.[45] While integration of renewables with the grid is a consideration that could affect electricity costs at high levels of renewables, EPA does not expect that this rule will drive higher levels of renewables on the grid than utilities are already anticipating, and as noted previously, the grid is generally expected to be capable of serving near term electricity needs for an increase in EVs.[46,47] As the commenter indicates, "it is difficult to estimate how much electricity prices will rise in a precise time frame (e.g. 2024-2026)," which is within the time frame of this final rule. EPA agrees that making such an estimation based on the factors the commenter describes is difficult and uncertain; this applies not only to predicting electricity rates paid in the future for charging EVs on a largely renewable grid, but also to the commenter's later suggestion that it should also be considered when modeling the impact of electricity cost on the cost of future battery production. EPA disagrees that modeling today's rates observed in just one country (Germany) and just one state (California) would be a valid way of identifying the potential future increases in electricity costs due to large increases in renewable energy, or to support or quantify such a relationship.

In response to the Alliance comments on the influence of variations in battery cell chemistry, form factor, and pack design on battery costs, EPA understands the influence of these factors and has considered the latest BEV battery formats and chemistries in the analysis that led to reduction of battery costs in the final rule analysis. See additional discussion in Preamble III.A and RIA 2.3.4 and 4.1.1.2. Regarding commenter's observation that there may be near-term costs to develop supply chains, commenter offers no data to quantify this consideration. EPA generally considers the cost of keeping up with advancements in technology as part of the indirect costs represented by the RPE markup, as well as the normal cost of doing business in a competitive industry that is already increasingly shifting to electrification as discussed in the Preamble and elsewhere.

In response to comments from the Alliance on the potential impact of increased raw material costs on battery costs, EPA agrees that mineral and material costs pose uncertainties for predicting future battery manufacturing costs as demand for these commodities grows. EPA is familiar with the cited 2019 MIT study and has considered its findings in characterizing future

---

[47] CNBC, "'We could handle it right now' - AEP chief says U.S. power grid can sustain influx of EVs," November 12, 2021. Accessed on December 2, 2021 at https://www.cnbc.com/2021/11/12/we-could-handle-it-right-now-aep-chief-says-us-power-grid-can-sustain-influx-of-evs.html

battery costs beyond the time frame of the rule, as discussed in RIA 4.1.1.2. Further response to this comment can be found in Preamble III.A. Regarding use of a two-part learning curve, although this may be one way to address the impact of material costs, it still would require data for future costs and learning rates for those costs, both of which are uncertain at this time. Because it is difficult at this time to quantify the effect of material costs or their potential to limit battery cost reductions in the mid to long term, EPA believes that the use of a lower bound in the primary battery cost case as described in RIA 4.1.1.2 is, at this time, an appropriate modeling means to acknowledge the potential constraints of material costs on battery cost reduction, until better information becomes available; we also note that we performed a lower battery cost sensitivity that omits this lower bound. EPA has consulted with DOE and Argonne National Labs on these issues and finds support for the interim use of the lower bound we have selected for use in the current analysis. EPA continues to study this issue to identify an appropriate way to represent how material and mineral costs influence the potential for future reductions in battery cost in the face of uncertain inputs.

In response to the Alliance suggestion that EPA should forecast the penetration of different battery chemistries, EPA monitors trends in battery chemistries in consultation with the Department of Energy and Argonne National Laboratory, including through participation in the continued development of the ANL BatPaC model. We note that manufacturers are increasingly seeking to reduce cobalt content. Since the relative use of costly minerals such as cobalt is a dominant factor in the cost differences between different chemistries, and because we expect that near term and future choice of cathode chemistry will largely be reduced cobalt varieties, EPA believes that separate modeling of all currently known chemistries is unnecessary. Additional discussion responsive to comments on the basis of learning curves can be found in the discussion of the learning assumptions RIA 4.1.1.2.

EPA acknowledges and appreciates the extensive status report provided by the Alliance on mineral production across the world.

In response to the Alliance comments that EPA should account for the cost of home charging infrastructure, as described previously, for the current rulemaking EPA has chosen to continue using the CCEMS model and the cost structure that was employed in the EPA proposal and SAFE final rulemaking, and has made changes only to a limited number of inputs that we believe would have a significant influence on the conclusions of the analysis. In comparison to the influence of battery costs, charger cost is relatively small. Costs of home charging infrastructure, proportions of usage of Level 2 vs. Level 1 charging, and the cost of EVSE equipment continue to evolve, and costs for EVSE equipment are expected to continue to decline. EPA plans to study these trends as they stabilize so that they can be better established in a future analysis. Regarding the comment on “expenditures on electricity consumed by BEVs and PHEVs,” these are not infrastructure costs but fuel costs, and are discussed in Chapter 6 of the RIA. Regarding cost/benefit differences between long- and short-range EVs, we believe these differences are minimized by our choice in the final rule updates to model primarily BEV300 with very limited penetration of BEV200.

In response to Alliance comments on the modeling of material costs in BatPaC, and the statement that it does not account for the 2021 surge in raw material prices, EPA understands that material prices are volatile. However, EPA disagrees that temporary spikes in prices are relevant to the modeling conducted for this analysis. Material cost inputs to BatPaC attempt to represent a reasonable longer term perspective, and do not try to represent transitory price surges or collapses that happen to be active at the time of publication. The default inputs published in a given edition of the model do not simply represent spot prices for these materials at the time of publication, but represent the expert model developers' best attempt to balance between reported prices and expert opinions of trends that could impact future prices.

EPA appreciates the Alliance's analysis of the contribution of material costs to battery pack costs, which is generally consistent with EPA's understanding. As stated previously, EPA believes that NMC811 and other low-cobalt and cobalt-free cathode chemistries are more relevant than higher cobalt chemistries when considering a near- to mid-term time frame. Table VII-4 in the Alliance comment indicates that for NMC811, doubling the price for lithium, cobalt and nickel in combination would result in a 19.5 percent cost increase. While recognizing that this hypothetical doubling of material prices is not based on any empirical data or forecast, EPA notes that the associated 19.5 percent increase in battery cost is within the range of the higher battery cost sensitivity, which models a more than 30 percent increase in battery cost from the primary case during the time frame of the rule.

EPA also appreciates the Alliance's analysis of the contribution of rare earth costs to permanent magnet motor costs. EPA did not perform a sensitivity on permanent magnet motor rare earth costs because it is a relatively small portion of total battery and non-battery costs for an electrified vehicle. While the commenter mentions that "the average electric vehicle uses between 2 and 5 kg of rare earth magnets," EPA notes that this represents current industry practice under today's magnet prices and availability, and does not necessarily reflect the quantities that will be used in advanced designs that continue to reduce reliance on these materials. For example, the Chevy Volt shifted to ferrite magnets for one of its motors, and Tesla and other manufacturers have shown that induction motors, which use no magnets, are another viable alternative. From a cost modeling perspective, increasing the resolution of our costing methodology to include explicit representation of magnet costs would also call for an accounting for lower-cost, advanced designs that minimize or eliminate the use of magnets. EPA continues to study and update the cost of non-battery components, and is also conducting a new teardown project to better determine the magnitude and direction of non-battery costs for electrified vehicles based on the newest and most advanced designs.

In response to Alliance comments that environmental, social and governance (ESG) considerations could impact critical material prices, EPA agrees that some manufacturers may choose to represent these considerations in their material acquisition policies, but notes that there is little to no data to quantify the extent of this practice in the future or how it would affect material prices collectively across the industry, and the commenter did not provide such data. As noted previously, our high battery cost sensitivity models a more than 30 percent increase in battery cost from the primary case, which could represent additional costs such as potential ESG costs which at present are too uncertain to quantify.

In response to the Alliance suggestion that EPA does not acknowledge the net cost to the economy from "the shift from recycling of engines and transmission to the recycling of batteries in EVs," EPA disagrees with this characterization of how battery recycling will evolve, and also with the presumption that it will represent a net cost. EPA believes that the relatively modest projected market penetration of EVs during the time frame of the rule is unlikely to cause engine recyclers to be compelled to rapidly shift their business to battery recycling and thereby experience a cost of retooling or retraining; instead, over a longer term, the recycling of batteries and cells could as likely generate new entrants to the recycling industry, pursuing new business opportunities and creating new jobs and thus could generate a net benefit. In any case, during the time frame of this rule, the vast majority of vehicles being scrapped will continue to be vehicles with engines and transmissions. As to the potential difference in the value of materials recovered, this depends on the battery chemistry; although some chemistries have more valuable mineral content than others, all contain significant quantities of copper and aluminum. The economics of battery recycling remains uncertain and difficult to quantify with any certainty, given the early stage of development of the industry and the aforementioned uncertainties regarding future mineral prices. As mentioned, EPA continues to study the development of battery recycling technology.

In response to the Alliance's suggestions that EPA should account for the net cost to society of charging infrastructure development, supply chain adaptation, shifting of recycling from engines to batteries, and similar comments, EPA notes that these impacts are separate from the technology costs experienced directly by consumers and auto manufacturers and are not within the scope of this rule's technology cost analysis.

Similarly, regarding the suggestion that EPA should estimate convenience costs to EV users such as the cost associated with a vehicle that has a shorter range than a conventional vehicle and takes longer to charge, these are also currently outside the scope of our analysis. EPA understands that BEVs present some differences in consumer behavior, and is studying how to represent consumer acceptance in our technology and compliance modeling. EPA is studying the issues surrounding consumer acceptance and willingness to pay, and although we recognize that such issues currently lack well-established and accepted methodologies by which they can be quantified appropriately, we hope to be able to further consider these issues in a future analysis. EPA agrees with the commenter's statement that "[as] automakers have extended the range of BEVs from less than 100 miles to 200-300 miles, their perceived disadvantage compared to ICE vehicles has lessened." In the same vein, we also believe that our decision to model primarily the longer-range BEV300 reduces the importance of many of these issues. Regarding the comment on the cost of time spent charging, this was addressed in a previous response above.

In response to Alliance comments on the applicability of technology assumptions to all manufacturers, and appropriate production volumes for developing battery costs, and modeling of BEV400 and BEV500, see Preamble III.A.

In response to Alliance comments on impacts of raw material sourcing, cell production, and pack assembly on U.S. content, EPA acknowledges the comment but it is outside the scope of this rulemaking, as EPA GHG standards are not related to domestic content.

EPA acknowledges the report placed into the docket by Roush concerning 48V and battery electric vehicle costs. EPA notes that the sources cited in the report are largely known to EPA, and thus have been considered in its ongoing costing analyses.

In response to comments from Valero that the rule undermines the statutory purposes of EISA such as consumer protection and energy security, EPA considers these comments largely out of scope because EISA pertains primarily to Corporate Average Fuel Economy (CAFE) standards issued by NHTSA and this rule concerns GHG standards issued by EPA under authority of CAA 202(a). Response to comments on energy security and critical minerals, in addition to the responses found in this section, may be found in Section 19 of this Response to Comments document. We address comments regarding fuel savings and consumer impacts in Section 17.

Commenter: Alliance for Vehicle Efficiency (AVE)

AVE supports performance-based credits to incentivize rapid adoption of emission-reducing technology in ICE vehicles.

President Biden's January 25th Executive Order asks EPA '…to immediately commence work to confront the climate crisis.'5 In this regard, AVE recommends EPA enact standards that will advance adoption of all GHG-reducing vehicle technologies to accelerate faster adoption of CO2 goals and climate benefits.

In 2012, however, EPA chose to focus on incentivizing specific technologies that had the potential to transform the light-duty sector at the expense of near-term carbon reduction.

'EPA believes that these temporary regulatory incentives are justified under CAA section 202 (a) as they promote the commercialization of technologies that have, or of technologies that can be critical facilitators of next-generation technologies that have, the potential to transform the light-duty vehicle sector by achieving zero or near-zero GHG emissions and oil consumption, but which face major near-term market barriers. However, providing temporary regulatory incentives for certain advanced technologies will decrease the overall GHG emissions reductions associated with the program in the near term. EPA believes it is worthwhile to forego modest additional emissions reductions in the near term in order to lay the foundation for the potential for much larger ‘game-changing’ GHG emissions and oil reductions in the longer term.'6

AVE’s recommendation is a logical response to the President’s proclamation and the Administration’s further acknowledgement below on the need for more investment in ICE vehicles:

“There are going to be a lot of gas-powered cars on our roads for a long time, so, there's simply no way to meet our climate goals with EVs alone.' - Transportation Secretary Pete Buttigieg July 8, 2021, speaking to the Bipartisan Policy Center.7

In the Proposed Rule, EPA acknowledges the challenges of bringing zero or near-zero emissions vehicles to market. EPA also acknowledges the challenges and costs associated with adopting specific emission reducing technologies to a significant percentage of an OEMs’ fleet. As indicated in EPA’s 2020 Trends Report, '…it has taken, on average, approximately 15-20 years for new technologies to reach maximum penetration across the industry.'8 EPA further states that the revised standards would result in significant benefits for public health and welfare, primarily through substantial reductions in both GHG emissions and fuel consumption and associated fuel costs paid by drivers, and the benefits of the proposed standards would be far in excess of costs.'9

AVE believes that with performance-based credits, EPA can send a strong signal to automakers to add more GHG-reducing advanced technologies to all vehicles and subsequently accelerate the additional public health benefits these technologies will bring.

Furthermore, over-reliance on credit multipliers to meet the Proposed Rule’s standards could reduce the real-world benefits that zero and near zero technologies can bring to the environment. Multiplier credits may make adoption of advanced technologies for ICE vehicles a more attractive compliance pathway. AVE is concerned, however, that, in the interim, ICE vehicles may see fewer innovations in emission-reducing technology added to future models should OEMs focus primarily on maximizing technology specific credits to reach future compliance standards. [EPA-HQ-OAR-2021-0208-0256-A1,pp.3-4]

The chart below identifies the lengthy timeframe to achieve significant penetration for new emission reduction technologies. Performance-based standards would likely accelerate penetration of advanced technologies for all types of vehicles (ICE, hybrids, PHEV, EV) and would bring an immediate and substantial improvement to the U.S.’s efforts to reduce carbon. [EPA-HQ-OAR-2021-0208-0256-A1, p.5] [Chart can be found at docket number EPA-HQ-OAR-2021-0208-0256-A1, p. 5]

EPA's Proposed Rule makes note of announcements from automakers signaling "a rapidly growing shift in investment away from internal combustion technologies and toward high levels of electrification."10 EPA does not, however, cite recent announcements that indicate several OEMs will not be making new investments in ICE architectures.11 EPA should account for the environmental impact of these decisions as OEMs will likely sell over 50-60 million ICE vehicles during the 2023-2026 model years.

As such, AVE recommends that in their regulatory analysis, EPA also account for how multipliers may impact near-term technology improvements to ICE and hybrid vehicles.

With well over 16 million ICE vehicles sold per year, and with each currently emitting 4.6 metric tons of carbon annually,12 even a mere 5% improvement in ICE performance would lead to reduction of approximately 3.75 million tons of additional carbon emissions per year – 15 million tons from 2023 to 2026. [EPA-HQ-OAR-2021-0208-0256-A1, pp. 5-6]

Commenter: BorgWarner Inc.

Technology Neutrality

We strongly urge EPA to define "zero emissions" as less than one gram of CO_2 per kilometer to allow for technologies that could make a timely real-world difference in CO_2 emissions. For example, hydrogen combustion is an advanced technology that has been under development for some time and could be more rapidly deployed in high volumes to make an impact on the environment. This technology can be readily adapted from existing systems and therefore, could be a used as a bridging strategy to significantly decrease CO_2 during the transition to electric and fuel cell vehicles. [EPA-HQ-OAR-2021-0208-0260-A1, p. 2]

The U.S. should consider legislation to transition to the 5-cycle test. The 5-cycle test is currently used by all manufacturers and better reflects the overall real-world gains that might not be evident from the 2-cycle test. EPA and NHTSA have long recognized that the 2-cycle fuel economy results are greater than most drivers achieve. The development of the 5-cycle procedure for estimating "label" fuel economy offers more accurate estimates, but still may not capture all technologies, for most drivers. Use of the 5-cycle test would also help eliminate or substantially reduce credit adjustments. [EPA-HQ-OAR-2021-0208-0260-A1, p. 3]

Commenter: Consumer Federation of America

First, there are likely to be at least 100 million gasoline vehicles sold before the transition is complete. They are likely to be on the road for a quarter of a century. Therefore, it is important to make sure that they are as efficient as possible. Doing so can 'help' the transition because setting high standards on the gasoline part of the fleet will speed the adoption of electric vehicles, and a significant amount of the gain in efficiency – vehicle design and operation – may be applicable to the electric portion of the fleet. [EPA-HQ-OAR-2021-0208-0297-A1, p. 24]

Commenter: Fuels Freedom Foundation

Automakers have made great strides in advancing spark-ignition engine technology, and have done so without the well-documented GHG emission reduction potential of fuels with properties to facilitate engine performance, such as high-octane fuels that are the standard in other parts of the world. ICEs deploying advancements such as high-compression engines burning high-octane fuel are for the nearterm lower in upfront cost and less disruptive to the consumer behavior, making them a viable pathway to facilitate large-scale GHG emissions reductions within and beyond the MY2023-2026 timeframe. And, critically, ICE evolution complements rather than supplants the maturation and growth of EVs and other alternative vehicle technologies.5 [EPA-HQ-OAR-2021-0208-0231-A1, p. 2]

Commenter: International Council on Clean Transportation

EPA also acknowledges that the engine maps in the proposed rule are outdated and that it has more up-to-date baseline and future engine maps within its OMEGA model. Despite this, EPA declined to incorporate these updated engine maps. EPA claims that the inclusion of these maps will not make a material difference (see DRIA 2021 page 4-3), but EPA's argument boils down to saying it doesn't matter that the outdated maps understate efficiency, as the difference between baseline and future efficiency is still roughly the same using either the outdated maps or the new maps. ICCT does not see how this is possible, as baseline technology efficiency maps (i.e. nonturbocharged and non-HCR engine maps) within the updated OMEGA model are unchanged. Thus, EPA's argument is valid only if there is no additional penetration of turbocharged or HCR engines from the baseline to 2026, i.e. if the proposed standards are completely ineffective in improving vehicle technology. [EPA-HQ-OAR-2021-0208-0522-A1, p. 3]

Outdated engine maps: The engine maps that are included in the agency modeling are severely outdated. For example, all base naturally aspirated engine maps are based on an unidentified 2013 or older vehicle, all turbo (non-Miller cycle) maps are based on a vehicle whose specifications match that of the 2011 MINI R56 N18 / BMW N13 engine, the hybrid Atkinson cycle map (for PS and PHEV) is based on the 2010 Toyota Prius, and the HCR1 map is based on the 2014 Mazda SkyActiv 2.0L engine. Essentially, EPA is assuming there will be no efficiency improvements in any of these technologies through at least 2026, or for 12 to 16 years from the model year of the vehicle used to generate the maps. As just two examples of how absurd it is to assume no improvements in any of these engine technologies for at least 12 years, the turbocharged engine introduced by Honda in 2016 was significantly more efficient than the engine used to generate all the turbocharged maps in the proposed rule and the 2018 Camry hybrid improved fuel economy by 15% (XLE/SE) to 25% (LE) compared to the 2017 Camry hybrid.10 And these (unincorporated) improvements were already in the market by 2016 and 2018 – still 8 to 10 years before 2026.

Miller Cycle effectiveness: EPA DRIA (page 2-13) acknowledges that VW is already using Miller Cycle engines as the base engine in the Passat, Arteon, Atlas, and Tiguan and that a hybridspecific version of this engine with CEGR and VGT is under development by VW that demonstrates a peak BTE of 41.5%. The fact that Miller cycle is already included on the standard engine for many of VW's most popular vehicles supports that Miller cycle is a cost-effective addition to turbocharged engines. Yet there are no Miller cycle applications in 2026 beyond the specific Mazda and Volvo models that already had Miller cycle in 2017.

For additional information, see: ICCT 2018 comments page I71

Turbocharging effectiveness: EPA added a 2nd generation turbocharged downsized engine package based on EPA benchmark testing of the Honda L15B7 1.5L turbocharged, direct-injection engine to its 2018 MTE, which was not used in EPA's proposed rule.11

For additional information see: EPA DRIA page 1-8

HCR engine effectiveness: EPA added an engine map in its 2018 MTE for Atkinson (ATK2+CEGR) technology based on EPA benchmark testing of the MY2018 Camry 2.5L A25A FKS engine. However, EPA's proposed rule continued to use developmental engine test data and GT-POWER engine modeling within the 2016 TSD.12

For additional information see:

EPA DRIA page 1-8 I

ICCT 2016 Camry

ICCT 2018 comments

Cylinder Deactivation on Turbocharged Vehicles: The modeled benefit of adding cylinder deactivation to turbocharged vehicles is less than 25% of the benefit from adding DEAC to a basic engine. While adding DEAC to a turbocharged engine has smaller pumping loss reductions than for naturally aspirated engines, DEAC still has significant pumping loss reductions and has the additional benefit of enabling the engine to operate in a more thermal efficient region of the engine fuel map. The agencies also failed to provide even the most basic information supporting their effectiveness estimates for TURBOD.

For additional information see: Joint NGO 2020 Reconsideration Petition, pages 62-64

Engine downsizing and secondary mass reduction restrictions: While EPA did not address this issue in the RIA for the proposed rule, the agencies have previously taken the position that the assumption that an engine should always be resized in response to tractive load changes was 'impractical'.13 Instead, the engine is 'only resized when mass reduction of 10% or greater was applied to the glider mass'.14 This reflects a lack of understanding of how manufacturers design engines. Engines are commonly shared across a variety of models and trim levels, with a wide variety of weight and roadload. Further, different models can have different target performance levels. Thus, the idea that somehow the existing 'baseline' engines are perfectly designed for every vehicle is absurd. In reality, most versions of the vehicles into which a single engine is used do not precisely meet their performance targets. Generally this means that performance exceeds the target, as the engine is sized to ensure that the worst case application still meets its performance target. Which in turn means that a modest amount of load reduction can justify the use of a smaller engine. The complexity issue is also not a real factor, as engines are only downsized during periodic complete redesign cycles. Finally, only downsizing engines for large changes in tractive load artificially increases the overall performance of the fleet, the consumer benefits of which the proposed rule does not address. Due to the large uncertainties in when and how to downsize engines for the variety of vehicles, the only acceptable solution is to always model the appropriate amount of engine downsizing to maintain performance.

For additional information see:

Joint NGO 2020 Reconsideration Petition, pages 124-125

2019 Supplemental Comment of H-D Systems15 [EPA-HQ-OAR-2021-0208-0522-A1, pp. 4-6]

Miller Cycle cost: EPA erroneously included the cost of the Atkinson Cycle engine in its cost estimate for Miller Cycle. Most of the cost of the Atkinson engine is due to increased scavenging to maintain performance and extend the efficiency region. However, for the Miller cycle, this performance function is duplicative of the 24-bar turbo system with a variable geometry turbocharger added in the Proposed Determination to maintain performance for the Miller cycle.17 Thus, Atkinson cycle costs are valid for naturally aspirated engines, but these costs should not be applied for the Miller cycle.

For additional information see: ICCT 2018 comments page I71

Advanced cylinder deactivation cost: FEV's 2016 teardown analysis for ICCT found advanced cylinder deactivation cost to be based on variable valve lift (VVL) technology plus NVH improvements. The agencies' cost estimate is over 5 times higher than FEV's calculated costs. The rationale for especially high agency costs is unclear, but their costs appear to account for fingerfollower de-lashing on a fixed block of cylinders (half the cylinders of a V6 or V8), which is not needed for dynamic cylinder deactivation. These findings are corroborated by EPA's communications with NHTSA and other officials, as shared in interagency emails and posted in the rulemaking docket. EPA indicates that the agencies' assumed cost for ADEAC is 2 to 4 times the cost of industry-quoted costs for the version of the technology in production in MY2019. 18 This is troubling that the assumed agency cost would so wildly diverge from important information, and that the agencies would choose not to share this clearly applicable information other than buried in interagency dialogue.

For additional information see:

ICCT 2018 comments pages I71-I72

FEV 2016

Turbocharging cost: The agencies have overestimated turbocharging costs by hundreds of dollars per application of the turbocharging package. Much of this may be due to the agencies not appropriately downsized engines to maintain constant vehicle utility and performance. Compared to FEV's 2016 engineering teardown analyses, as well as EPA's detailed technology benchmarking analysis for the 2016 TSD, the agencies greatly increased turbocharging costs in the SAFE rule and, hence, in the proposed rule. Based on the FEV teardown and EPA analysis, turbo-downsizing costs for 18-bar turbocharging range from a -$391 (i.e., a benefit due to moving from 6 to 4 cylinders) to a cost increase of $315 (for shift from I4 to I3) and $376 (for shift from V8 to V6).19 The agencies current cost assessments for 18-bar systems range from $638 to $1,052 for the same configurations. (Table 1) [EPA-HQ-OAR-2021-0208-0522-A1, pp. 7-8; The tables can be found on p. 8 of Docket number EPA-HQ-OAR-2021-0208-0522-A1]

New comments on technology

Roush has released two reports commissioned by CAELP to assess the current state-of=the-art in light-duty engines and powertrains (Roush 2021 LDV)24 and to assess the cost and effectiveness of 48-volt mild-hybrid systems and Battery electric vehicles (Roush 2021 48v).25 Statements from Roush's executive summaries are copied, below. In addition, ANL made a presentation at a 2020 webinar in Europe that supports many of the Roush comments and recommendations (AVL 2020).26 References to additional information in the Roush reports and AVL webinar are included below each of the following summaries.

Roush's recommended near-term areas of focus (2025) are as follows:

Naturally Aspirated Engine: 'Based on a review of published data, information from major automotive suppliers, and proprietary knowledge of potential product plans, Roush recommends that EPA focus on Atkinson cycle engines with higher geometric compression ratio, lower bore-tostroke ratios, and increased cooled EGR dilution. For consistent ignition and acceptable burn rates these engines should have some combination of a) Intake, cylinder head, and piston design improvements for high in-cylinder turbulence; b) High energy ignition systems such as high energy spark plugs, plasma ignition, prechamber ignition, etc.; and c) In-cylinder fuel reforming technologies such as Direct EGR or pilot fuel injection during negative valve overlap.' (Roush 2021 LDV page 11). Additional information can be found at:

- Roush 2021 LDV Section 2.3 pages 23-25 on higher compression ratios and higher Miller/Atkinson ratios.
- Roush 2021 LDV Section 4.0 pages 31-35
- AVL 2020 slide 24: BSFC for Lambda=1

Turbocharged Engines: 'Future turbocharged engines should contain increased use of the Miller cycle with a smaller bore to stroke ratio, higher geometric compression ratio (with higher Miller ratios), and higher EGR dilution rates. Therefore, Roush recommends that EPA focus on Miller cycle engines with advanced boosting technologies such as variable geometry turbochargers, electrically assisted turbochargers, or a combination of a turbocharger and an electric supercharger. Similar to naturally aspirated engines, for consistent ignition and acceptable burn rates EPA should focus on future turbocharged engines which contain combinations of a) Intake, cylinder head, and piston design elements for high in-cylinder turbulence; b) High energy ignition systems such as high energy spark plugs, plasma ignition, passive prechamber ignition, etc.; and c) In-cylinder fuel reforming technologies such as Direct EGR or pilot fuel injection during negative valve overlap.' (Roush 2021 LDV page 11). Additional information can be found at:

- Roush 2021 LDV Section 2.3 pages 23-25 on higher compression ratios and higher Miller/Atkinson ratios.
- Roush 2021 LDV Section 5.0 pages 36-38 • Roush 2021 LDV Section 9.0 pages 48-49
- AVL 2020 slide 24: BSFC for Lambda=1
- AVL 2020 slide 27: E-Turbocharger waste heat recovery
- AVL 2020 slide 62: WLTP % CO2 reduction and slide 63: cost per % FC reduction [EPA-HQ-OAR-2021-0208-0522-A1, pp 10-11]

Full Hybrid Powertrains: 'The torque provided by the electric motor partially decouples engine output from the driver pedal. This effectively makes the hybrid system an energy management tool that can optimize engine speed-load demands to maximize the time spent in the high-efficiency parts of the engine operating map. Accordingly, low load engine operation is minimized by using the electric drive. EPA should focus on the expanded application of energy management capabilities in full hybrid powertrains to also minimize operation under the low-speed high torque areas of the engine which are prone to knocking by torque augmentation with the electric motor. The instantaneous torque capability of the electric motor can effectively support transient torque demand. This will allow both naturally aspirated and turbocharged engines that are part of a hybrid powertrain to be optimized for a narrow operating range incorporating higher compression ratios and increased EGR dilution (maintaining stoichiometric operation), thereby prioritizing efficiency over peak torque at low engine speeds and transient response, while maintaining good drivability.' (Roush 2021 LDV page 12). Additional information can be found at:

- Roush 2021 LDV Section 7.0 pages 41-44
- AVL 2020 slide 24: BSFC for Lambda=1
- AVL 2020 slides 25-26: Dedicated Hybrid Engine Efficiency Roadmaps (45% Lambda=1, 51% ideal)
- AVL 2020 slides 35-42: WLTP CO2 reduction potential of various hybrid configurations
- AVL 2020 slide 43: Relative comparison of attributes for three powertrain architectures
- AVL 2020 slide 62: WLTP % CO2 reduction and slide 63: cost per % FC reduction

Roush also made several project recommendations, with estimated GHG reductions:

Future Pickup /Full-Size SUV GHG Reduction: 'Two powertrain configurations are recommended for study and could support future rulemaking. The first option synergistically combines available technologies (without a major redesign of the underlying engine architecture) to give maximum fuel economy benefit for a relatively low cost, hence high effectiveness. It combines a naturally aspirated DI engine with advanced cylinder deactivation and a 30kW 48V P2 mild hybrid system. The 48V hybrid system is used to actively smooth out crankshaft torque pulsations to enable aggressive cylinder deactivation strategies (advanced deac – like the Tula

Skipfire System). Such a system will also enable start-stop, electric creep, regen braking, slow-speed electric driving, and a heated catalyst. Depending on system integration factors Roush estimates a reduction in GHG emissions of 20% or more, compared to a baseline naturally aspirated directinjection V8.' (Roush 2021 LDV page 13). Additional information can be found at:

• Roush 2021 LDV Section 13.1 page 65

Compact SUV GHG Reduction: 'A 30kW 48-volt P2 system mated to a low bore-to-stroke ratio miller cycle engine with electrified boosting, advanced cylinder deactivation, cooled EGR and a heated catalyst can provide a fuel economy benefit close to a full high voltage hybrid powertrain at a much lower cost. The 48V electric motor can supplement the engine torque under low- speed high load conditions, thereby avoiding this knock-prone area of the engine map. Also, the use of an advanced boosting system, combining a turbocharger and a 48V electric supercharger, will reduce engine backpressure (larger turbine) and improve scavenging, reduce combustion residuals, and reduce the propensity for knock. This combination enables the use of a higher compression ratio, thereby increasing engine efficiency. A combination of a high-energy ignition system (high energy spark plug/ plasma ignition) and fuel reforming by pilot fuel injection during NVO can be used to increase cEGR tolerance at low loads. The initial part of such a project should include engine and combustion modeling, followed by prototype engine testing. The overall GHG reduction potential will require modeling and optimization of engine design, calibration parameters, and boosting system sizing and control. Roush estimates a reduction in GHG emissions exceeding 30% is possible compared to a level 1 (NHTSA) turbocharged engine.' (Roush 2021 LDV page 14). Additional information can be found at:

• Roush 2021 LDV Section 2.3 pages 23-25 on higher compression ratios and higher Miller/Atkinson ratios.
• Roush 2021 LDV Sections 2.4 and 2.5 pages 26-28 on low bore-to-stroke ratio benefits
• Roush 2021 LDV Section 13.2 page 66

Effect of Negative Valve Overlap (NVO) fuel reforming on EGR tolerance on an engine: 'Incylinder fuel reforming by using pilot fuel injection during NVO has shown to significantly improve cooled EGR (cEGR) tolerance, combustion stability, and engine efficiency. Such a system can have wide application in turbocharged and NA engines across different vehicle segments with minimal hardware requirements. Depending on the base engine, Roush estimates an efficiency improvement, and the corresponding reduction in GHG emissions, in the range of 5 to 10% is possible and low cost, therefore correspondingly high effectiveness.' (Roush 2021 LDV page 14). Additional information can be found at:

• Roush 2021 LDV Section 10.0 pages 50-52
• Roush 2021 LDV Section 13.3 page 66

Benchmarking a production passive prechamber engine for knock resistance and EGR tolerance: 'Prechamber combustion systems are one of the most promising technologies for improving the dilution limit of engines, thereby improving system efficiency. It can also enable extremely fast burn rates increasing the knock tolerance of turbocharged engines, allowing higher compression ratios and the associated efficiency improvements. The Maserati Nettuno engine in the 2021 Maserati MC20 will be the first application of a passive prechamber engine in production. However, the primary objective in the MC20 is high performance. It would be very valuable to study the effect of the system on knock tolerance, burn rates, dilution tolerance (EGR and air), and emissions. The effort should focus on quantifying possible efficiency gains in a non-performance application.' (Roush 2021 LDV pages 14-15). Additional information can be found at:

- Roush 2021 LDV Section 13.4 page 67
- AVL 2021 slides 29, 31, and 33

Evaluation of production-intent high energy ignition systems: 'High energy volume ignition systems can enable combustion of dilute (cEGR or air diluted) in-cylinder mixtures resulting in a step-change in engine efficiency compared to conventional spark plugs. Such systems can be a drop-in replacement for a spark plug, thereby representing a cost-effective GHG improvement option. Such systems should be evaluated for maximum efficiency potential, in conventional, 48V mild hybrid, and full HV hybrid applications. Roush estimates that systems such as plasma ignition can support good combustion stability with high amounts of cooled EGR, thereby achieving engine efficiency improvements in the range of 5-10% over a baseline turbocharged DI, dual VVT engine. Microwave ignition systems, on the other hand, have the potential to achieve levels consistent with prechamber ignition systems. This would enable lean-burn engines with low engine-out NOx emissions which can achieve brake thermal efficiency which exceeds 45% in light-duty vehicle applications, compared to a level of 36-38% for a baseline turbocharged DI, dual VVT engine.' (Roush 2021 LDV page 15). Additional information can be found at:

- Roush 2021 LDV Section 11.0 pages 53-62
- Roush 2021 LDV Section 13.5 page 67 [EPA-HQ-OAR-2021-0208-0522-A1, pp. 11-14]

Atkinson Cycle engine restrictions (HCR0, HCR1, HCR2)

We applaud EPA for allowing HCR2 technology to be used in their modeling for some segments of the fleet, especially given NHTSA's refusal to do so. Comments have been previously submitted that provided extensive justification for HCR technology benefits beyond HCR1 and it is good to see EPA responding positively to these comments. For example:

Joint NGO 2020 Reconsideration Petition, pages 64-68

ICCT 2018 Camry study

ICCT 2018 comments, pages I2-I12

However, EPA also argued in the DRIA that Atkinson Cycle engines (HCR0, HCR1, HCR2) cannot be used on V8 engines or pickup trucks, ‘The restriction within the analysis of HCR technologies to naturally aspirated engines with cylinder counts of 6 or less during compliance modeling was a means of restricting Atkinson Cycle from application to trucks and other applications having a specific need for additional torque reserve (e.g., trailer towing or high payload applications).’ (DRIA page 2-13)

NHTSA in its proposed rule elaborated on this point, stating that:

‘Pickup trucks and vehicles that share engines with pickup trucks are also excluded from receiving HCR engines; the duty cycle for these heavy vehicles, particularly when hauling cargo or towing, are likely unable to take full advantage of Atkinson cycle use, and would ultimately spend the majority of operation as an Otto cycle engine, negating the benefits of HCR technology.’ (NHTSA NPRM page 49662)

These arguments are backwards and wrong. Engines in pickup trucks and high-performance vehicles are sized and powered to handle higher peak loads. This means larger engines that operate at lower loads relative to their maximum capacity on the 2-cycle – and during most realworld driving. According to supplemental tables for the 2020 EPA FE Trends report found online, pickups have 18% to 19% higher power to weight than cars and truck SUVs (Table 2). Which in turn means that pickup trucks and high-performance vehicles will spend more time in Atkinson Cycle operation than lower performance vehicles on both the test cycles and in the real world, not less. [Table 2 can be found on p. 15 of Docket number EPA-HQ-OAR-2021-0208-0522-A1]

As acknowledged by the agencies, these engines have the ability to switch between Otto cycle and Atkinson cycle. Thus, the specific need for ‘additional torque reserve’ is met by switching to Otto cycle. NHTSA’s claim that these vehicles ‘would ultimately spend the majority of operation as an Otto cycle engine’ is ludicrous. Given the high output of these engines, the vehicle would have to be driven on a race track to spend most of the time in Otto cycle. The one exception is towing, which does impose constant high loads on the engine. However, even pickup trucks spend relatively little time towing. Strategic Vision data finds that ‘75 percent of [pickup] truck owners use their truck for towing one time a year or less’.27 Thus, only 25 percent of pickup trucks tow even occasionally. This means that the large majority of pickup trucks spend the vast majority of driving at low loads relative to the engine’s capability, where Atkinson Cycle engines are very effective.

Note that Atkinson Cycle engines have been used on the Toyota Tacoma pickup V6 engine since 2017, illustrating that Atkinson Cycle engines are cost-effective for use on pickups and the claim that an Atkinson Cycle engine that switches to Otto cycle on demand cannot provide the additional torque reserve is not accurate.

The only legitimate concern with Atkinson Cycle engines for pickup trucks and high-performance vehicles is compression ratio. The HCR engines evaluated by EPA have very high compression ratios, which can raise combustion temperatures and necessitate a modest reduction in peak power. However, combustion temperatures can be lowered with cooled EGR and any remaining peak performance effect can be handled by modestly decreasing compression ratio.

Based on a 2014 paper by Speth et al.,28 the brake efficiency improvement for increasing compression ratio from 13:1 to 14:1 is 0.9%.29 Modeling with Autonomie found that the fuel-consumption reduction, if performance is maintained, is 1.32 times the brake efficiency improvement. So, increasing the compression ratio from 13:1 to 14:1 would reduce fuel consumption by 1.19%.

In summary, HCR technology is likely to have higher benefits on pickup trucks, due to the higher power-to-weight of the engines used on pickup trucks. Any concerns with compression ratio can easily be handled by determining the compression ratio reduction needed to maintain performance during Otto Cycle operation and analytically adjusting the HCR0, HCR1, and HCR2 modeling output efficiency for pickup trucks and high-performance vehicles. Thus, all restrictions on HCR engines should be removed. Further information is contained in previously submitted comments: Joint NGO 2020 Reconsideration petition pages 68-73 ICCT 2018 Camry study ICCT 2018 comments, pages I2-I12 [EPA-HQ-OAR-2021-0208-0522-A1, pp. 14-16]

10 Up to 10% of the fuel economy gain might be explained by modest roadload and mass reductions, but a large amount is clearly due to improvements in engine and powertrain efficiency.

29 This is extrapolated from the modeled results, as the benefits of increasing compression ratio decrease as the baseline compression ratio increases. For example, the paper found that increasing the compression ratio from 10.5:1 to 11.5:1 would improve brake efficiency by 1.9%, or more than twice the 0.9% benefit of increasing from 13:1 to 14:1.

Commenter: National Propane Gas Association (NPGA)

Today there is innovative demonstration and deployment of dual-fuel engine vehicles that blend propane and dimethyl ether (DME), which combines clean emission profiles and propane infrastructure without the significant financial requirements necessary to proliferate other, less mature alternative energies. [EPA-HQ-OAR-2021-0208-0252-A1, p.2]

Bi-Fuel Engine Technology

In addition, bi-fuel engine conversions offer the emission reduction advantages and extend vehicle mileage. A bi-fuel engine typically uses either gasoline or autogas through the same internal combustion system.36 A bi-fuel autogas vehicle is equipped with two fuel tanks, injection systems, and fuel lines to store both autogas and gasoline.37 Bi-fuel engines increase the driving range of the vehicle, which can be a more valuable feature for rural fleet vehicles.38 Bi-fuel autogas engines also provide flexibility in fueling infrastructure as well as the option for fleet vehicles to switch fuels depending on other factors. The advantage of doubling the driving range is most attractive to police fleets and national parks.39 Further, state government fleets convert light- to heavy-duty vehicles to bi-fuel autogas engines as part of state disaster plans.40 In fact, the U.S. Department of Energy Clean Cities program has developed initiatives to increase bi-fuel autogas vehicles throughout multiple states as an asset for emergency response.41 The availability, emissions profile, and comparatively low cost combined with simple infrastructure and advancing technological research distinguish autogas in the alternative fuel marketplace. [EPA-HQ-OAR-2021-0208-0252-A1, pp. 4-5]

The multiplier incentive program should include provisions for alternative fuels, including autogas, to achieve the agency's ambition for effective GHG emission reduction. [EPA-HQ-OAR-2021-0208-0252-A1, p. 5]

Commenter: Olmstead, Thomas

As laid out in The 2020 EPA Automotive Trends Report Greenhouse Gas Emissions, Fuel Economy, and Technology since 1975, there are numerous technologies manufacturers can use to improve fuel economy and reduce GHG emissions including Turbo, GDI, CD, seven or more speeds, CVTs, stop/start, alternative fuel vehicles, and many more, but not all manufacturers have fully adopted the technologies: [Table ca be found at docket number EPA-HQ-OAR-2021-0208-0190-A1, p. 2] If all of the manufacturers used these technologies, fuel economy and GHG emissions would be reduced. [EPA-HQ-OAR-2021-0208-0190-A1, pp. 1-2]

Commenter: Roush Engineering

Attached are two reports Roush Engineering recently completed for the Center of Applied Environmental law and policy that we believe are relevant to the proposed rulemaking, particularly with respect to continuing improvementss in effectiveness and cost compliance technologies.

- CAELP Report 1 - Gasoline Engine Technologies (09.24.2021)
- CAELP Report 2 - 48V and BEV costs (09.24.2021 [EPA-HQ-OAR-2021-0208-0210-A1, p. 1]

Commenter: Shevelew, Jonathan

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 118.]

It's imperative that we push them harder by making the financial penalties so severe that not investing in the transition would be a disastrous business decision for them. The costs associated with transitioning their products to ZEVs needs to be less than the penalty for not doing it.

EPA Response

In response to comments on the impact of technology multiplier incentives on near-term ICE and HEV technology improvements (AVE), we did not conduct a separate analysis of the impact of multipliers on near-term technology improvements to ICE and HEVs. We have set fuel neutral, performance-based standards and increased the level of stringency for the final rule which will result in additional emissions reductions. We acknowledge that if an OEM chooses to implement significant levels of BEVs, then the given OEM's ICE vehicles and or HEVs would not be required to improve as much as part of the fleet-wide average standards as an OEM that chooses a non-BEV path. For the final rule we have adopted a narrower set of advanced technology multipliers, limited the multipliers to two model years (2023 and 2024), reduced the numerical value of the multipliers, and maintained the 10 g/mile multiplier credit cap as originally proposed. Please see Preamble section II.B.1 for additional details regarding the advanced technology multiplier incentives and changes made to the incentives for the final rule. Also, see section 6.1 within this Response to Comments document for our response to similar comments regarding the multiplier incentives.

With respect to comments on defining "zero emissions" as less than one gram of CO2 per kilometer to allow for H2 internal combustion engines (H2-ICE) (BorgWarner), we have set fuel neutral, performance-based standards and manufacturers are free to choose specific fuels, including hydrogen, as part of their compliance plan for meeting the revised GHG standards. Changes to what constitutes "zero emissions", e.g., the definition of Light-duty Tier 3 Bin 0 or any other changes to the Light-duty Tier 3 Standards are outside of the scope of this rulemaking. We did not propose or seek comment on changes to the definition of the Tier 3 Bin emissions compliance level or how EPA defines "zero emissions" as a means of achieving the proposed GHG standards.

Regarding comments that EPA should consider legislation to transition to the 5-cycle test (BorgWarner), legislative changes are outside the scope of the rulemaking. Changes to the test cycles used for demonstrating compliance with the light-duty vehicle GHG standards are also outside of the scope of the rulemaking. We did not propose or seek comment regarding changes to the test cycles used for determining light-duty GHG compliance.

With respect to comments received regarding the ability of manufacturers to achieve additional GHG reductions using advanced high-compression internal combustion engines and high octane fuels (Fuels Freedom Foundation), engines with high geometric compression ratios (e.g., 13:1) using the over-expanded Atkinson Cycle are already mass-produced and widely available within U.S. light-duty vehicle applications, in particular passenger cars and cross-over utility vehicles from both Toyota and Mazda, all with minimum specified octane requirements of 87 AKI (e.g., regular grade fuel) and thus are using widely available grades of gasoline. EPA does not anticipate manufacturers pursuing strategies relying on higher octane fuel beyond the use of widely available, higher octane grades of gasoline (e.g., 89 AKI or 91 AKI) in the MY 2023-2026 timeframe but nothing in this rule would preclude such strategies. To the extent the commenter is suggesting EPA set a minimum octane standard, that issue is beyond the scope of the rule. We did not propose or seek comment on setting a minimum octane fuel standard as a means of achieving the proposed GHG standards.

In response to comments related to the inclusion of outdated engine efficiency maps within the CCEMS analysis relative to previous EPA analyses using OMEGA and that this results in understating incremental improvements in powertrain efficiency (ICCT), the commenter's assumptions are incorrect since they did not take into consideration the powertrain efficiencies of the baseline technologies already within the light-duty vehicle fleet (e.g., naturally aspirated GDI) used within CCEMS and OMEGA and thus are incorrect with respect to the inference that we used the wrong incremental powertrain efficiencies in the CCEMS analysis. The incremental differences between technologies such as GDI relative to Turbocharging levels 1 or 2, or GDI relative to HCR0 or HCR1, are comparable between CCEMS and OMEGA. In other words, the relative differences between control cases and no-action cases are comparable between the two analytical approaches. This is because the incremental effectiveness between baseline and added powertrain technologies (e.g., turbocharging/downsizing, HCR0, HCR1) are comparable between OMEGA and CCEMS despite differences in individual brake thermal efficiency maps for some of the underlying data. Similar to OMEGA, CCEMS continues adding powertrain and other technologies until the standards being assessed are met. When doing so, the technology penetrations and per vehicle costs are comparable between previous analyses using OMEGA and the analysis for this rule using CCEMS as long as specific technologies are not excluded or restricted within either of the models (see RIA Chapter 1.2.2)

In response to comments that EPA erroneously included Atkinson Cycle costs within the cost estimates for Miller Cycle (ICCT), the costs that EPA included for Atkinson Cycle reflect the use of a rapidly changing, high-range-of-authority camshaft phasing system for the intake camshaft. This is used both for load control via varying of trapped air/fuel charge and to limit the maximum effective compression ratio for knock control. A similar system is used by Mazda in their boosted Miller Cycle engines, while VW has used an alternative valvetrain control system (translating to different lobes on the intake camshaft) in some applications. We believe that such a level of valvetrain control is necessary for non-hybrid, light-duty vehicle applications of Miller Cycle both for knock control and for prevention of low-speed preignition, and thus such valvetrain costs are included within our costs of turbocharged/downsized engines, and do not constitute a double-counting of costs. Such systems can also significantly improve part-load off-boost efficiency of Miller Cycle engines by allowing load control via camshaft phasing.

With respect to the comment that turbocharged engine costs within the CCEMS analysis for this rule are significantly higher than previous analyses (ICCT), we acknowledge that the costs for turbocharged engines within the analysis for this rule may be a high estimate. For this reason we believe our cost estimates may be somewhat conservative and we intend to update turbocharged engine costs within analyses for future rulemakings.

Comments regarding the NHTSA proposed rule (ICCT) regarding Atkinson Cycle and its application to light-duty pickup truck applications are incorrect. Neither EPA's proposed nor final rule addresses whether Atkinson Cycle engines have the ability to "switch" between Otto Cycle and Atkinson Cycle, although EPA believes such operation would be inconsistent with the design of currently available implementations of Atkinson Cycle as well as previous EPA benchmarking data of non-HEV applications of Atkinson Cycle engines from Mazda and Toyota. Atkinson Cycle engines operate over-expanded throughout the entire speed-torque operational range and, based upon detailed EPA benchmarking and engineering analysis, do not "switch" to Otto Cycle.[48] We disagree with comments that non-HEV pickup truck applications with significant trailer towing capability can apply Atkinson Cycle (ICCT). Some pickup truck applications require significant torque reserve, such as for trailer towing requirements which include trucks with high rated gross-combined vehicle weights (GCWR, i.e., combined truck payload + trailer capacity). Many of these applications exceed 18,000 lbs. GCWR. Non-HEV applications of Atkinson Cycle engines, which EPA has extensively benchmarked, would not have sufficient torque reserve for such applications without either a) a significant increase in per-cylinder engine displacement, which has potential negative implications for both brake-thermal-efficiency and criteria pollutant emissions or b) the use of strong hybridization. For non-HEV applications, turbocharged/downsized engines and Miller Cycle provide sufficient torque reserve to allow high GCWR and trailer towing and are thus a more suitable technology for such applications. Electric hybridization can also be used to supply sufficient torque reserve for such applications, depending on its specific design characteristics (motor torque output, battery energy reserve, etc.)

In response to comments regarding the incremental effectiveness of advanced engine technologies such as HCR and Turbocharging (ICCT), we disagree that our input assumptions on incremental effectiveness are too low. The incremental effectiveness of HCR1 technology package within CCEMS is consistent with the incremental effectiveness of the Toyota A25A-FKS engine benchmarked by EPA, which itself is nearly identical to the 2-cycle incremental effectiveness of the previously tested EPA developmental engine referred to by the commenter.[49] The incremental effectiveness of the TURBO1 technology package within CCEMS is consistent with the incremental effectiveness of the Honda L15B7 engine.

In response to comments regarding Miller Cycle engines for dedicated-hybrid-electric applications (ICCT), we acknowledge that such applications might be suitable for future vehicle and truck applications requiring high torque reserve. EPA plans to initiate a future rulemaking to establish multi-pollutant emission standards over the longer term, for MY 2027 and later (see the Preamble to this rule at section I.A.2). EPA will again review GHG emission-reducing technologies, including Miller Cycle and other potential dedicated hybrid engine applications, as part of the regulatory impact analysis for the MY2027 and later light-duty GHG standards rulemaking. Other technologies, such as negative valve overlap and higher power 48V P2 hybrid systems (as suggested by ICCT and Roush), merit further investigation. EPA will again review GHG emission-reducing technologies, including negative valve overlap and higher power 48V

[48] See Figures 22 and 23. Kargul, J., Stuhldreher, M., Barba, D., Schenk, C., Bohac, S., McDonald, J., Dekraker, P. Benchmarking a 2018 Toyota Camry 2.5-Liter Atkinson Cycle Engine with Cooled-EGR. SAE Technical Paper No. 2019-01-0249, 2019, doi:10.4271/2019-01-024.

[49] See Table 7. Kargul, J., Stuhldreher, M., Barba, D., Schenk, C., Bohac, S., McDonald, J., Dekraker, P. Benchmarking a 2018 Toyota Camry 2.5-Liter Atkinson Cycle Engine with Cooled-EGR. SAE Technical Paper No. 2019-01-0249, 2019, doi:10.4271/2019-01-024.

hybrid systems as part of the regulatory impact analysis for the MY2027 and later light-duty GHG standards rulemaking.

In response to comments recommending the use of dedicated EGR systems[50] or more advanced versions of Miller Cycle or other internal combustion technologies not included within our analysis (ICCT), the report on internal combustion engine technologies cited within the comments and also submitted separately by Roush did not include a detailed cost analysis for such internal combustion engine technologies, and thus no clear conclusion can be drawn regarding these technologies on per-vehicle cost of compliance. As discussed in section VI.A, VI. B of the preamble to the final rule and Chapter 2.3 and Chapter 4 of the RIA, EPA has demonstrated a reasonable cost and technologically feasible pathway to meet the final standards even without more advanced, and in some cases, more expensive, ICE technologies. Our technology assessment is consistent with several manufacturers' public statements that they are choosing to deemphasize the further development of ICE technologies to focus their resources on vehicle electrification (e.g., MHEVs, HEVs, PHEVs, and BEVs).[51,52] Consistent with EPA's LD GHG program, manufacturers may choose whether or not to implement these more advanced ICE technologies as part of their preferred pathway in meeting the final GHG standards. EPA will again review further advancements to ICE technologies in our planned future rulemaking for standards for MY 2027 and later. The updated battery costs used within the final rule CCEMS analysis better reflect recent improvements in battery chemistry, topology and manufacturing (see RIA Chapter 2.3.4 and RIA Chapter 4.1.1.2). These updates to battery costs used in CCEMS for the final rule analysis reduced Li-ion battery costs by an approximate average of 25 percent. A result of these changes is a projected trend between model years 2023 and 2026 of increased technology penetration of electrified technologies such as BEV/PHEV, HEV, and MHEV along with a projected trend of increased penetration of relatively inexpensive ICE technologies such as HCR1. In addition, the analysis shows a trend in the opposite direction of decreased penetration of more expensive ICE technologies such as turbocharging/downsizing. The inclusion in the analysis of more advanced, and likely more expensive, ICE technologies such as dedicated EGR and more advanced versions of Miller Cycle would likely not reverse a general projected trend towards increased electrification, considering recent cost reductions for automotive lithium-ion batteries and the anticipated battery cost reductions through 2026, and thus would likely not lower the cost of compliance of the final and alternative standards that were analyzed.

[50] E.g., internal combustion engines that use one or more cylinders primarily for fuel reformation rather than for extracting work.

[51] Motavalli, J. Phasing Out Internal Combustion Engines? It's Already Happening. Autoweek, April 30, 2021. https://www.autoweek.com/news/a36292118/phasing-out-internal-combustion-engines/

[52] Plumer, B. Tabuchi, H. 6 Automakers and 30 Countries Say They'll Phase Out Gasoline Car Sales. The New York Times, November 11, 2021. https://www.nytimes.com/2021/11/09/climate/cars-zero-emissions-cop26.html

Comments related to other alternative fuels such as propane Autogas or bi-fuel DME/propane Autogas (NPGA) are outside the scope of the rulemaking. We did not propose or seek comment on providing multiplier incentives for propane Autogas or bi-fuel DME/propane Autogas as a means of achieving the proposed GHG standards and we do not believe multiplier incentives for these fuels are appropriate for the same reasons we do not believe multiplier incentives are appropriate for natural gas vehicles (including that these fuels are not near-zero emissions technology which warrant incentives).

The comment regarding increasing civil penalties (Jonathan Shevelew) are beyond the scope of this rulemaking. Civil penalties for violations of motor vehicle emissions standards assessed pursuant to 42 USC §752.[53]

Platform Level Technologies (aerodynamics, mass reduction)

In reviewing the agency's modeling of Honda's fleet, we noticed significant increases in adoption of aggressive aerodynamic and mass reduction improvements. While Honda continues to seek opportunities for emissions reductions in these areas, we believe these agency estimates are overly optimistic given the short regulatory window, limited time for technology implementation across our fleet, and natural asymptotes associated with vehicle design. For example, agency modeling of aerodynamic improvements in Honda's fleet climb from 4% in

[53] Title 42 - The Public Health and Welfare Chapter 85 - Air Pollution Prevention And Control Subchapter II - Emission Standards For Moving Sources Part A - Motor Vehicle Emission and Fuel Standards, §7524. Civil penalties.

MY2020 to over 12% in MY2026, as shown in Figure 5 [Figure 5 can be found at docket number EPA-HQ-OAR-2021-0208-0565-A2, p. 13.]

This represents a tripling of fleet average aero improvement over one product redesign cycle. While aerodynamic improvements to Honda's fleet have and will continue to occur, they are progressing at a pace well below those modeled by the agency. Part of this can be attributed to market and customer demands, which continue to show preference for larger vehicles, creating a natural limitation for design. Since roughly 70% of vehicle drag is a function of size and shape – functional attributes of the vehicle and the category to which it belongs – major development efforts would be required to yield further improvements that avoid packaging compromises or changes to fundamental attributes that customers seek.

Mass reduction is another area where agency modeling anticipates further emissions reduction opportunities. While Honda continues to make improvements in this area as well, it is important to note that ongoing efforts to improve vehicle safety and meet future crashworthiness targets often involve countermeasures offsetting such mass reductions. As such, we believe the agency's estimates regarding mass reduction opportunities across the fleet are overly optimistic in the proposed rule's timeframe.

In summary, Honda believes the above platform technologies are, or will soon be, reaching the point of diminishing returns given safety requirements and other key design considerations. As such, agency modeling assumptions may be incorrectly prioritizing these technologies and the remaining benefits they can deliver beyond a MY2017 base year vehicle. [EPA-HQ-OAR-2021-0208-0565-A1, pp. 13-14]

Commenter: Attorney General of Missouri et al.

The EPA's proposed rule goes to some effort to highlight the hoped-for positive outcomes of the mandated rush to adopt supposedly more environmentally friendly fuel-cell technologies. As discussed above, there are many examples of negative externalities that must be taken into account. [EPA-HQ-OAR-2021-0208-0288-A1, p.16]

Commenter: Bay Area Air Quality Management District

A primary area for innovation is zero emission technologies. Zero emission vehicles (ZEVs) have significantly lower greenhouse gas emissions, especially in states with cleaner grids such as California. And due to the fact that ZEVs emit zero criteria pollutant emissions from their tailpipe, they also provide important local air pollution benefits. Continued innovation in ZEV technology will further drive down costs, foster greater economies of scale, and bring larger volumes of battery electric and fuel cell electric vehicles into those communities that need clean vehicles most. [EPA-HQ-OAR-2021-0208-0283-A1, p. 3]

Commenter: Center for Climate and Energy Solutions (C2ES)

Hydrogen fuel cell electric vehicles and other zero-emissions technologies represent a powerful, if nascent, opportunity to expand options for decarbonizing transportation, particularly in medium- and heavy-duty applications. Federal policy support for zero-emission vehicles should also include investments in research, development, demonstration, and deployment to accelerate these technologies. [EPA-HQ-OAR-2021-0208-0287-A1, p.4]

Commenter: Ghost Locomotion, Inc.

The vision of an electric consumer vehicle mass market is within sight. The proposed standards, combined with the President's Executive Order and automakers' electric vehicle commitments, make it possible for the majority of new light-duty vehicles offered for sale in the United States soon to be electrically driven.

As automakers roll out increasingly electric fleets, they will also be equipping these cars with more autonomous capabilities. Although higher-level autonomous driving may affect various of the regulatory elements analyzed in the proposals, scant attention is given to the impact that a progressively more autonomous fleet may have on these analyses.

It is axiomatic that well-designed autonomous driving systems can operate more quickly and more accurately than human drivers, and are not subject to fatigue, distraction or other driving impairments. The safety promise of an autonomous future will begin when Level 4 autonomous systems are deployed for personal transportation.[1] Level 4 systems will not abdicate responsibility to the driver at the last minute nor defer to a driver with slower computational abilities and response times, but instead will retain responsibility for making driving and fallback decisions.

The marriage of electrification and autonomy, however, is endangered. Current systems generally operate either only semi-autonomously or with such compute complexity that use of the ADAS or ADS systems shrinks the available power supply in electric vehicles, substantially diminishing the available battery range. According to one industry analyst: ‘In general, most assisted driving system developers agree that battery electric AVs will lose about 40-50% of the range available from the base vehicle.’[2] Yet, emerging ADS technology can solve this dilemma and conserve battery power with more efficient algorithms and general purpose sensors, requiring substantially less computing power.

To meet the aggressive goals for EV deployment, the EV market will need to extend beyond consumers who choose them solely or mostly for environmental reasons. They must also meet the growing consumer demand for autonomy — with drivers able to safely rely on the autonomous system for highway driving. If autonomous operation unduly limits range, electric vehicles will be less consumer-friendly and less likely to proliferate at a pace necessary to meet the current EV goals. High-level autonomy free of additional range anxiety will likely spur demand for electric vehicles.

Ghost Locomotion Inc. (‘Ghost’) appreciates the opportunity to provide input into how technology, such as that being developed by Ghost, will affect the driving environment envisioned in the proposals.[3] A high-autonomy and low-compute system can:

• Provide autonomy without undue battery drain, particularly if coupled with a credit system such as that proposed by Ghost below.

• Reduce fatalities even beyond those expected due to the rebound effect and mass reduction; and

• Allow consumers to redirect time typically spent driving and put it towards other productive use.

Ghost Technology

Ghost is developing a unique Level 4 autonomous driving system. Ghost technology is centered around a revolutionary approach to crash avoidance. The Ghost approach tracks the motion of clusters of pixels in a scene to determine the relative distance and velocity of the object to the vehicle. Based on this information, and other information collected about the environment, Ghost technology makes next step driving decisions.

Unlike other systems, the Ghost approach is not dependent on a pre-set classification of images and is not subject to the error conditions of mis- or not recognizing objects. The Ghost system does not need to know what an object is in order not to hit it. As a result, it can manage many of the edge cases other systems cannot.

Preserving Battery Range

Current systems offer either high autonomy or low power draw, but not both. The Ghost system uses more efficient algorithms and general purpose sensors. The resulting compute efficiency requires significantly less energy than robotic-based and/or other compute-intense systems now in use. More efficient autonomous driving capability protects battery range, an essential precursor for a successful marriage between electric drive and autonomy.

That the market for autonomous and electric vehicles will grow together is clear.[4] One estimate projects that 7% of the total automotive market will have autonomous capability by 2023, and that more than half the total market will have Level 3 and higher capability by 2030.[5] At the same time, the proposed regulations support the President's vision and automakers' commitments to substantially expand their electric-drive offerings by 2030. Autonomy and electric vehicles offer a 1-2 punch, encouraging consumers to modernize their vehicles, accelerating both the safety benefits offered by autonomy and the environmental benefits offered by electric power.

The technology paths, however, are not necessarily compatible. Operating in autonomous mode can strain the power supply and result in a significant drain in available range. Tesla, for example, has estimated an approximate 25% range reduction when operating in driver-assist mode.6 A study by Nature Energy suggests that, with regard to certain LiDar systems, aerodynamic drag can also contribute to battery drain, particularly for suburban driving.[7]

The agencies should consider ensuring that electric vehicle range is maintained through a credit program aimed at encouraging low-compute and high-autonomy systems. The credits could be expressed similarly to how the agencies value off-cycle credits or alternatively could be applied through a multiplier. The program could, for example, offer credits for higher-level autonomous systems operating at 120 watts or below, with additional credit opportunities should the systems be able to operate at wattages below that level (e.g., 75 watts or 50 watts). To reflect how systems are used in the real world, wattage should be measured when the system is operating with full redundancy, and not when redundancies are in standby mode.

Such a credit program would acknowledge the impending linkage between autonomous and electric vehicles and support systems that allow consumers to take advantage of autonomy without losing benefits associated with their electric vehicles. By recognizing and potentially encouraging systems that draw less power the agencies can help catalyze a driving environment devoid of both motor vehicle fatalities and motor vehicle emissions.

An advanced AV credit system would be consistent with the agencies' proposed consideration of expanding the off-cycle credit program.[8] Flexibility and opportunities for credits can spur technological innovation, new investments, and greater deployment of EVs. Indeed, CARB's Zero Emission Vehicle (ZEV) program has played a key role in Tesla's success.[9]

Fewer Fatalities

Ghost's breakthrough approach to crash avoidance has the potential to substantially reduce crash occurrence on highways, including those attributed to mass reduction and those associated with the rebound effect resulting from better fuel efficiency.[10]

Much of the benefit tied to autonomous driving results from minimizing human error. Ghost believes that crash avoidance is more than a by-product of autonomy. It is an essential capability and necessary foundation for any autonomous driving system, just as the central nervous system in humans is designed to instantly react and move the body out of harm's way when an object is rapidly approaching. It is indeed the missing link to the success of autonomous driving systems.

The data is clear that driver assistance features or additional sensors alone cannot solve our motor vehicle safety problems. More comprehensive crash avoidance must be deployed to avert the vast majority of motor vehicle fatalities. In a 2019 article updating an earlier study, researchers at Carnegie Mellon University suggested that if all light duty vehicles in the fleet were equipped with three current driver assistance systems — forward collision warnings, lane departure warning and blind spot alert — it ‘could prevent or reduce the severity of as many as 1.6 million crashes, including 7200 fatal crashes,’ with the highest reduction for fatal crashes associated with Lane Departure Warning.[11] While that is substantial progress, with more than 35,000 motor vehicle fatalities annually, it is not alone sufficient to meet the safety need.

The safety impact analyses in the proposals point largely to crash protection considerations. The additional fatalities estimated are largely due to the increased on-road exposure and/or possible crash incompatibility due to mass reduction in certain vehicles. As more advanced crash avoidance systems deploy into the fleet, the relationship between exposure and crash risk may need to be reconsidered and adjusted. Trailblazing crash avoidance will upend this dynamic, minimizing risk associated with exposure and also reducing any impacts from mass reduction or longer vehicle retention.

Productive Time Recouped

The agencies have long recognized time as a significant private benefit. The proposals monetize the productive time recaptured as part of the cost/benefit analyses.

NHTSA estimates these savings by calculating the amount of refueling time avoided—including the time it takes to find, refuel, and pay—and multiplying it by DOT's ‘value of time of travel savings estimate.’ EPA similarly considers ‘the costs of time spent refueling ... calculated as the total amount of time the driver of a typical vehicle would spend refueling multiplied by the value of their time. If less time is spent refueling vehicles under the proposed standards, then a refueling time savings would be incurred.’[12]

Level 4 autonomy represents another opportunity to recapture time. With Level 4 operation, the autonomous driving system operates all aspects of the dynamic driving task within its Operational Design Domain and retains responsibility to manage unexpected or emergent conditions. Only with Level 4/5 operation is a driver able to focus their attention on a task other than driving. With education and experience, consumers will increasingly demand the ability to redirect their commuting time and put it to use in other productive ways. This evolution is likely to occur during the time frame encompassing the useful life of the vehicles subject to the proposals, and while it may be too speculative at this point to quantify the value of the time saved, the agencies should nonetheless recognize this as a benefit of Level 4/5 autonomy.

The Energy Efficiency Gap

According to NHTSA's proposal, automakers maintain that consumers tend to value the benefits of better fuel economy over a period of approximately 30 months, even though the actual benefits may extend further.

Ghost maintains that consumers will value the benefits of autonomous driving for much longer, and indeed for as long as the autonomous driving system is able to be updated and remain competitive within the market. A critical aspect of software-centric autonomous driving will be its ability to update the software systems on an ongoing basis. The speed with which the systems can be updated means that the reliability and performance of these systems can be regularly enhanced. As a result, while consumers may not readily recognize the longer-term financial benefits of a more fuel-efficient vehicle, they should continue to acknowledge the ongoing benefits of a self-learning and self-improving autonomous driving system.

Conclusion

The advent of reliable, safe, and low-compute Level 4 autonomous driving will have a profound impact on how consumers in the United States use their vehicles. In the coming decades, vehicles are likely to be both electrically driven and autonomous. The result should be fewer crashes, less congestion, and more time recouped. It is possible to achieve these results without unduly draining battery range — thus allowing for a fully compatible electric and autonomous future which can not only eviscerate motor vehicle emissions but motor vehicle fatalities as well. [EPA-HQ-OAR-2021-0208-0242-A1, pp. 1-7]

[1] The Levels of Autonomy are defined by SAE J3016_202104.

[3] Ghost's founders have a history of successfully developing highly secure software systems. CEO John Hayes previously founded Pure Storage to store and protect critical customer data for Fortune 500 companies. Pure Storage is now publicly listed on the New York Stock Exchange. CTO Volkmar Uhlig architected the L4 Pistachio Microkernel, which protects biometric data on billions of Apple and Android devices worldwide. Ghost was founded in 2017 and, in addition to its primary location in Mountain View, California, includes a software formal verification team in Sydney, Australia and a radar development team near Dallas, Texas.

[4] Steps such as the recent enactment of SB 500 in California — mandating that future Level 3-5 autonomous driving systems be installed only on electric vehicles — represent this movement. Other states are likely to follow California's path. Market analysts, moreover, opine that the pace of vehicle development and refresh may become shorter with electric vehicles than what has become traditional with regard to ICE vehicles. See Robinet (IHS Markit), "Preparing for the new, faster EV product cadence," SAE International (Aug. 30, 2021). See also https://www.ucsusa.orgiaboutinews/california-bill-requires-all-new-self-driving-vehicles-be-zero-emission-2030.

[10] Mass reduction can increase or reduce safety risk, depending on whether weight is removed from smaller/lighter vehicles (increasing crash incompatibility) or from larger/heavier vehicles (reducing crash incompatibility). The rebound effect results in higher risk exposure by virtue of more time spent traveling on the roadways. NHTSA estimates that the proposed standards will result in an additional 1822 fatalities: 115 associated with mass reduction, 584 due to the increased exposure arising from the rebound effect of consumers driving more in response to better fuel efficiency, and 1123 attributed to delays in vehicle turnover mostly associated with the increased cost of the new motor vehicles and the fewer safety features incorporated into older ones. (NHTSA NPRM, 86 Fed. Reg. 49602, 49742 (Sept. 3, 2021). For its part, EPA estimates an additional 2288 fatalities, with 1952 (about 85%) associated with increased driving and the remainder with increased fatality risk. (EPA NPRM, 86 Fed. Reg. 43726, 43793 (Aug. 10, 2021).

[12] See NHTSA Draft Technical Support Document, pp. 388 and 415-416; EPA NPRM, pp. 204). Recaptured time does not include time that is otherwise recouped — such as using the restroom or buying snacks at the gas stations. Nor does it include routine trips to the gas station (e.g., every Sunday evening) because that time has already been institutionalized into the

consumer's regular activities. This analysis may become more complex with regard to electric vehicles, as some owners can charge at home overnight, others at shopping malls or grocery stores, and yet others may need to take the time to charge at other publicly available stations.

Commenter: Ingevity Corporation

In this NPRM, EPA maintains a narrow 'tailpipe only' view of GHG emissions, which does not appropriately account for the full lifecycle GHG emissions and the GHG reduction benefits of alternative technologies and fuels.

The purpose of EPA's GHG regulation is to reduce GHG emissions, and, given the long survival period of CO2 in the atmosphere, there is little difference on the effect of GHG emissions whether they are produced during the production of the vehicle and battery, from the tailpipe, or during the production of electricity. The problem is that EPA's well-to-wheels analysis inherently tipped the scale in favor of electric vehicles by ignoring the substantial amount of energy used to produce lithium ion batteries. Many studies are now being made on lifecycle emissions, and there are wide estimates in the magnitudes of upstream emissions.

EPA's exclusive recognition of battery electric vehicles as 'game-changing' technology and making electric vehicles the sole beneficiary of valuable 0 g/mile CO2 credit incentives have been based on a narrow well-to-wheels (tailpipe only) view of emissions. However, in 2016, Argonne National Laboratory issued a report evaluating the full life-cycle (or cradle-to-grave) emissions of several fuel pathways, including fossil natural gas and battery electric vehicles .21 The study finds that BEVs are expensive to operate and do not provide significantly larger GHG reductions than gasoline hybrid electric vehicles (HEVs) that operate at half the cost. The study also finds that CNG vehicles, utilizing fossil natural gas, provide 70% of the GHG reductions at 20% of the cost of avoidance in comparison to BEVs .22 The table below summarizes these findings. [The table can be found on p.10 of Docket number [EPA-HQ-OAR-2021-0208-0227-A1]]. [EPA-HQ-OAR-2021-0208-0227-A1, p,10]

The Manufacturers of Emission Controls Association (MECA) recently completed a comprehensive scientific analysis for cradle-to-grave (full lifecycle) greenhouse gas (GHG) emissions for traditional ICE vehicles, HEVs, PHEVs, and NGVs (including NGVs fueled by RNG). As shown in the table below, the results show a NGV crossover SUV operating on RNG has 92% lower emissions than a similar ICE version operating on gasoline and 67% lower emissions than a BEV operating on the 2030 California energy grid. Such analyses confirm that EPA's 'tailpipe only' view is limiting and restricts alternative, and in some cases more effective and lower cost, GHG reduction technologies from being adopted by OEMs and consumers. Ingevity believes the EPA should adopt a full-lifecycle approach as it is the most appropriate and effective method to evaluate alternative vehicle and fuel technologies to achieve real-world GHG reductions. [The tables can be found on p.11 of Docket number [EPA-HQ-OAR-2021-0208-0227-A1] [EPA-HQ-OAR-2021-0208-0227-A1, p.11]

Commenter: International Council on Clean Transportation

Direct Injection (GDI) cost: ICCT submitted direct injection cost data in our 2018 comments based on a 2016 FEV teardown cost study (FEV 2016)16, which found costs to be about 26% lower than the agencies assessment. The FEV teardown study costs were ignored and have not been incorporated into EPA's proposed rule.

For additional information see:

ICCT 2018 comments pages I69-I70

FEV 2016

Cooled Exhaust gas recirculation (CEGR) cost: ICCT submitted CEGR cost data in our 2018 comments based on a 2016 FEV teardown cost study, which found CEGR costs (DMC) in to be roughly $100 less than the agencies assessment after applying learning to 2025. The FEV teardown study costs have not been incorporated into EPA's proposed rule. Supporting FEV's teardown cost analysis, CEGR costs in EPA's 2018 MTE were changed to a single EGR loop from a higher cost low-pressure/higher pressure dual loop system, but its updated CEGR costs were not used in the proposed rule.

For additional information see:

ICCT 2018 comments page I70

FEV 2016

EPA DRIA page 1-9

HCR cost: DMC costs for HCR in the SAFE rule, which are unchanged in EPA's proposed rule, were about $200 more than in EPA's 2016 TAR. This is a clear case where the agencies appear to have not used the best available data from EPA, which extensively analyzed this technology and its associated cost, nor have the agencies justified how they increased the associated costs in this proposal.

For additional information see: ICCT 2018 comments pages I70-I71 [EPA-HQ-OAR-2021-0208-0522-A1, pp. 6-7]

Commenter: National Corn Growers Association (NCGA)

Describing use of these new technologies, EPA notes that as of MY 2020, more than half of light-duty gasoline spark ignition engines now use direct injection (GDI) engines and more than a third are turbocharged.[6] However, further advancements from these and additional engine technologies such as higher compression ratios and greater downsizing are limited by current fuel formulations in the marketplace. [EPA-HQ-OAR-2021-0208-0246-A1, p. 2]

Commenter: Nissan North America, Inc.

Autonomous and Connected Vehicle Credits. Nissan strongly believes that autonomous and connected vehicles are the future of the industry, and an important tool in increasing consumer and pedestrian safety. Continued investment by both the industry and the government is critical to the development of this technology. Nissan encourages EPA to work with NHTSA to establish a federal regulatory framework to incentivize manufacturers to develop technologies that offer environmental benefits, including awarding credits to manufacturers for producing vehicles with safe and proven connected or automated technology. The Proposed GHG Rule and Proposed CAFE rule make no mention of autonomous vehicles or the potential positive impact such vehicles could have in the pursuit of vehicle emissions reductions. [EPA-HQ-OAR-2021-0208-0529-A1, p. 10]

Commenter: South Coast Air Quality Management District

The District believes EPA should reasonably count on that acceleration, not merely because of the urgency of the needed GHG reductions, but also because the advanced state of zero emission technology already makes it unwise to bet against aggressive rates of adoption. Even as the air quality planning jurisdiction of the South Coast Air Quality Management (which includes the entirety of Orange county and parts of Los Angeles, Riverside and San Bernardino counties) itself has more on-road electric vehicles and higher electric vehicle market share in new sales than any other state, the buyers in this area are just keeping pace with the electric vehicle adopters in major markets in European countries and China. [EPA-HQ-OAR-2021-0208-0215-A1, p.3]

EPA Response

We acknowledge the comments supporting increased introduction of ZEVs as a means of reducing GHG emissions (Bay Area Air Quality Management District, Ghost Locomotion, South Coast Air Quality Management District) and agree in general with comments regarding criteria pollutant and GHG emissions reduction potential, decreasing costs, economies of scale, and increased pace of new ZEV model introduction. We have also included updated Li-ion battery costs within our analysis for the final rule to better reflect recent advances in BEV technology (see RIA Chapter 2.3.4 and RIA Chapter 4.1.1.2).

Regarding the establishment of a credit program for higher-level autonomous vehicle systems (Ghost Locomotion) or other types of automation and connected technologies (Nissan), this is outside the scope of the rulemaking. We did not propose or seek comment on establishing autonomous and/or connected vehicle credits to comply with the GHG standards.

With respect to comments regarding a “mandated rush to adopt fuel cells,” we neither proposed nor are adopting any mandates for fuel cells in light-duty vehicles. Furthermore, use of fuel cell technology is not required to meet the final standards and our modeling of light-duty vehicle GHG compliance under the final standards did not project any penetration of light-duty fuel cell technology into the light-duty fleet during the timeframe of the final standards(see RIA Chapter 4).

Regarding a comment on life cycle emissions of BEVs vs. HEVs and CNG (Ingevity), the commenter cites a study on life cycle emissions by Argonne National Laboratories to posit that EPA somehow "tipped the scales" with respect to advanced technology multipliers for BEVs. We disagree with this comment. The cited study relied on outdated data with respect to road load reduction, Li-ion battery energy density, and the energy sources either currently used within the U.S. electric grid or near-term electric generation energy source trends. As a result, the cited 2016 ANL study predicts average conventional internal combustion engine (ICE), CNG, HEV, BEV90, and BEV210 life cycle GHG emissions to be approximately 350-450, 320-370, 240-345, 250-300, and 250-440 gCO_{2e}/mi, respectively. A more recent analysis based on more recent vehicle data from the 2020 EPA Trends Report, and more recent energy source data from the 2020 International Energy Agency - World Energy Outlook, shows life cycle BEV GHG emissions of 100-160 gCO_{2e}/mi, less than half that of the older ANL study despite an assumption of increased BEV range within the more recent study.[54,55,56]. The commenter (Ingevity) also cites a MECA analysis of natural gas vehicle GHG emissions, however only provided isolated data tables without either a copy of the study or a citation that would allow review of the study's methodology. Such a review would be crucial for determining whether or not the study included a full accounting of factors of critical importance to NGV life-cycle GHG emissions, such as fugitive methane emissions during extraction, refining, compression, and end-use. The GHG life-cycle emissions for BEVs within the table from MECA analysis also conflict with the life-cycle emissions from ANL study also cited by the commenter (Ingevity). BEV life cycle emissions within the table from the MECA analysis are only one-third to one-half of those cited within the ANL analysis. EPA's decision to not include the emissions associated with battery production, as the commenter recommends, is based on our current assessment of existing LCA studies, and the degree of uncertainty in the study results relative to magnitude of the impact on overall emissions. EPA is not making any determination here about the potential value of LCA for informing standards in the future, and we will continue to monitor further developments in LCA studies on the impacts of battery production.

With respect to comments regarding road-load reductions (Honda), we disagree that the projected levels of mass reduction within our GHG compliance analysis are overstated and/or too high. Our GHG compliance analysis for the final rule summarizes mass reduction expressed as an industry average fleet reduction in curb weight within RIA Chapter 4.1.4.1, Table 4-31. The compliance analysis had a 5% curb weight reduction for the "no-action scenario" and a 5.2% curb weight reduction for the final rule for MY2023. For MY2026, the compliance analysis had a 5.4% reduction for the "no-action scenario" and a 6.3% reduction for the final rule. We assume a level of mass reduction already exists within the current fleet and continues to exist

---

[54] Bieker, G. (2021) A Global Comparison of the Life Cycle Greenhouse Gas Emissions of Combustion Engine and Electric Passenger Cars. ICCT.

[55] U.S. EPA. The 2020 EPA Automotive Trends Report - Greenhouse Gas Emissions, Fuel Economy, and Technology since 1975. EPA-420-R-21-003, January 2021.

[56] International Energy Agency. (2020). World energy outlook 2020. http://www.iea.org/weo

within the “no-action scenario” with a small, further decrease in fleet average mass for the final rule versus the “no-action scenario”. The incremental decrease in fleet average curb weight between the no-action case and the final rule is approximately 0.2% in 2023 and less than 1% for MY2026 and is feasible within the timeframe of the rulemaking. Our modeled projections represent one set of compliance pathways, but manufacturers are free to, and certainly will, make their own compliance decisions about product mix, use of credits, pace of technology development and adoption, etc. With respect to aerodynamic improvements being optimistic (Honda), the percentages cited in the comments are relative to a MY2015 fleet average drag coefficient (C_d) baseline by vehicle class, not an absolute reduction in drag force or drag coefficient of their existing vehicles and thus include aerodynamic reductions already incorporated from previous vehicle design cycles reflecting approximately a decade of improvement through MY2026, not merely improvements through MY2026 from today.

Regarding comments on the costs of GDI, CEGR, and HCR (ICCT), we acknowledge that the costs from the FEV teardown studies and the EPA Technical Assessment Report may be more appropriate than the higher estimated costs used within our CCEMS analysis. We will update the costs for these specific technologies within our analyses for future rulemakings.

With respect to comments that further technological advancements with respect to higher compression ratios or greater engine downsizing are limited by current fuel formulations in the marketplace (NCGA), the full comments stated that “Higher octane fuel is an essential tool for automakers to meet revised standards, but higher octane must also be clean octane to meet emission reduction goals. Clean octane from today’s ethanol is 50 percent lower in GHG…” and thus the implication within the comments is that reformulating the fuel should be accomplished via increasing octane levels using ethanol. Such a change to gasoline is outside the scope of the rulemaking. We did not propose or seek comment on high octane fuel or requiring the use of ethanol to increase octane as means of achieving the proposed GHG standards. Higher octane fuels (e.g., “premium” fuel with an anti-knock index of 91 or higher) are already widely available within the marketplace and manufacturers already have the option to demonstrate light-duty GHG compliance using premium (i.e., higher octane) E10 certification gasoline if premium grade fuels are required by the manufacturer for specific vehicle models.

The Environmental Protection Agency Proposed Rule to Revise Existing National GHG Emissions Standards for Passenger Cars and Light Trucks Through Model Year 2026 is fatally flawed methodologically, and in particular cannot satisfy a standard benefit/cost test even assuming the quantitative estimates provided in the Proposed Rule and the accompanying Regulatory Impact Analysis. It does not provide a reliable guide for the estimation of the magnitude of an assumed greenhouse gas externality in the passenger car and light truck sector, and it does not and cannot provide a rigorous basis for an updated analysis in support of the future promulgation of greenhouse gas policies generally. Accordingly, the Proposed Rule is inappropriate; it must not be finalized in its current form, and any such finalization must reflect a very substantial revision of the underlying analysis. Any such updated analysis based upon the same or similar methodologies and assumptions similarly will be fatally flawed. [EPA-HQ-OAR-2021-0208-0254-A1, p. 1]

Accordingly, the Proposed Rule is analytically deficient, as it is based upon a benefit/cost framework fundamentally incorrect. It cannot be viewed as appropriate, and should not be finalized in its present form. [EPA-HQ-OAR-2021-0208-0254-A1, p. 2]

The EPA Calculation of Net Benefits is Fatally Flawed The Proposed Rule calculates a net economic benefit of the Proposed Rule in present value terms between $86 billion and $140 billion through 2050.13 This calculation is fatally flawed for several reasons:

• The use of purported 'global' rather than domestic benefits is illegitimate. [EPA-HQ-OAR-2021-0208-0254-A1, p. 5]

The Proposed Rule cannot satisfy any plausible benefit/cost test even under the assumptions and quantitative findings presented in the Proposed Rule and the accompanying RIA. The future climate effect of the Proposed Rule — a maximum of 0.0013 degrees C by 2100 — would be effectively zero. The annual increase in global real GDP would be a maximum of 0.075 percent, a figure that cannot be statistically significant given the normal variation in global GDP growth.

Fuel savings — roughly double the asserted environmental benefits of the Proposed Rule — are not a legitimate 'benefit' of a rule aimed at a purported environmental externality. 'Fuel savings,' asserted by the EPA to be roughly twice the purported environmental benefits of the Proposed Rule, are illegitimate as an economic benefit, as the purported environmental benefits of reduced fuel use are reported separately, and thus there remains no further divergence between the market price and the social cost of petroleum fuels. The EPA fails to consider the adverse consumer effects of a forced reduction in fuel consumption.

The asserted 'energy security' externality of petroleum consumption and imports is fundamentally incorrect. The asserted health benefits of reduced emissions of particulate matter are not consistent with the available scientific analysis, and represent double counting given other regulatory efforts under the Clean Air Act to reduce ambient particulate concentrations to levels that 'protect the public health' 'with an adequate margin of safety.' The EPA analysis of the value of refueling time savings for a vehicle fleet characterized by lower per-mile fuel consumption should be combined with a similar analysis for the time costs of recharging a larger fleet of electric vehicles. EPA fails to do so. The use of asserted global rather than domestic environmental benefits of the Proposed Rule is illegitimate, and would yield important inefficiencies. The discount rate analysis presented in the Proposed Rule and the RIA is not correct because the use of resources for future environmental improvement is an investment by definition.

The use of different discount rates for the asserted benefit and cost streams yielded by the Proposed Rule is illegitimate. The interests of future generations — the intergenerational equity question — is served by a bequest of the most valuable possible capital stock, an outcome dependent upon the use of a correct and consistent discount rate by the current generation. Accordingly, the Proposed Rule is analytically deficient, as it is based upon a benefit/cost framework fundamentally incorrect. It therefore is not appropriate, and should not be finalized in its present form. [EPA-HQ-OAR-2021-0208-0254-A1, pp. 16-17]

Commenter: California Air Resources Board (CARB)

In the Absence of California's Standards, More Stringent Standards Would Reduce Greenhouse Gases and Ozone-Forming NOx Pollution in the State

To illustrate the significance of this proposal, CARB staff have estimated its criteria and GHG emissions benefits in California if the state were not able to enforce its own GHG and ZEV standards. Besides the proposed standards, staff also analyzed the impact of the more stringent Alternative 2. The impacts of the preferred alternative, or a hybrid of Alternative 2 and the preferred alternative varying by model year, would be similar – and all would aid significantly in protecting public health and meeting state and federal air quality standards. This analysis, shown in the enclosed Emission Analysis in Support of Comments on Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards, acknowledges that California currently does not have a waiver of preemption from U.S. EPA for its light-duty vehicle GHG emissions and zero-emission vehicles (ZEV) standards. 13

U.S. EPA's proposal would revise current federal GHG standards beginning in model year 2023 and increase in stringency year-over-year through model year 2026. The preferred alternative would increase in stringency from model year 2022 to 2023 by 10 percent, followed by a nearly five percent stringency increase in each model year from 2024 through 2026. This is far better than the Final SAFE Rules, which become only 1.5 percent more stringent each year.14 U.S. EPA is not proposing to revise GHG emissions standards for model year 2021 and model year 2022. [EPA-HQ-OAR-2021-0208-0643-A6, pp. 9-10]

Comprehensive Emissions Estimates Consider the Fuel Lifecycle.

The emission estimates of reductions from the standards may be comprehensively described as well-to-wheel, or WTW, emissions that reflect the lifecycle of motor vehicle fuel from the production, distribution, and the use (e.g., combustion) of the fuel. These stages may be divided into two categories: well-to-tank (WTT) and tank-to-wheel (TTW). The WTT emissions are described as 'upstream' and are those associated with fuel extraction, processing, production, and distribution to refueling stations for consumers. The TTW emissions are described as 'downstream' and are from the vehicle tailpipe and evaporative emissions from the vehicle's fuel system.

These estimates reflect the upstream (WTT), downstream (TTW), and total (WTW) criteria and GHG emission reductions from EPA's GHG emission standards for vehicles of model years 2023 and newer if they applied in California and CARB's greenhouse gas emission and zero-emission vehicle standards did not. These estimates are quantified for the years by when the South Coast air basin must meet the National Ambient Air Quality Standards (NAAQS) for ozone as well as key milestones years for California's GHG emission reduction goals. CARB estimated the emission benefits of U.S. EPA's proposed GHG emission standards for passenger vehicles using the latest version of CARB's emission inventory tool, EMission FACtor 2021 (EMFAC2021).15

Figure 1, below, shows fleet average CO2 emission rate assumptions embedded in EMFAC2021, the U.S. EPA's preferred alternative (identified as the Proposal) and Alternative 2 scenarios, and U.S. EPA's 2012 National Program GHG emission standards that were replaced by the Final SAFE Vehicles Rule. The reduction factors can be calculated by dividing the U.S. EPA proposed standards by the EMFAC2021 standards for model years 2023 and later. Table 1 lists the ratios of GHG standards between U.S. EPA's preferred alternative (proposed) scenarios and default EMFAC2021 estimates. The GHG reduction factors in Table 1are computed between U.S. EPA's preferred alternative and California's standards and do not reflect emission credits for air conditioning systems or 'off-cycle' technologies whose emission benefits are not recognized by the federal test procedures. [EPA-HQ-OAR-2021-0208-0643-A6, pp.10-11] [Figure 1 can be found at docket number EPA-HQ-OAR-2021-0208-0643-A6, p. 11] [Table 1 can be found at docket number EPA-HQ-OAR-2021-0208-0643-A6, p. 11]

The Numbers: Avoided GHG and NOx Emissions in California

Staff analysis showed that absent CARB's GHG and ZEV standards, U.S. EPA's preferred alternative federal GHG standards for passenger vehicles will reduce, in tons per year (tpy) and tons per day (tpd), upstream oxides of nitrogen (NOx) emissions of:

• 25 fewer tons per year NOx, or 0.07 tons per day, in calendar year 2023,

• 411 fewer tons per year NOx, or 1.19 tons per day, in calendar year 2031,

• 609 fewer tons per year NOx, or 1.76 tons per day, in calendar year 2037.

To consider this in context, NOx emissions in the South Coast air basin are approximately 278 tons per day as of calendar year 2021 for all mobile sources (annual average).16 These emissions must be reduced to 141 tons per day to meet the 1997 ozone NAAQS of 80 parts per billion (ppb), which has a deadline of 2023. To meet the 2008 standard of 75 ppb, which has a deadline of 2031, NOx emissions must be reduced to 96 tpd. A significant portion of the reductions described above will occur in the South Coast air basin because of its high concentration of people, vehicles, and refineries; they are a significant part of the solution to meeting the air quality standards in California.

Every reduction is needed to meet these health-based standards. Other regions in California are also in non-attainment with federal standards for ozone, and reductions of all sizes are likewise needed there, although the South Coast air basin faces the most significant ozone air quality challenge in the country.

In addition, the U.S. EPA's preferred alternative standards for passenger vehicles would reduce, statewide, GHG emissions by:

• 8.5 million metric tons in 2030, and
• 16.8 million metric tons in 2045.

Based on EMFAC2021, a typical passenger vehicle emits about 4.3 metric tons of CO2 per year. The statewide decreases in GHG emissions are equivalent to:

• 2.0 million passenger vehicles in 2030,
• 3.9 million passenger vehicles in 2045.

In comparison, in the absence of CARB's GHG and ZEV standards, U.S. EPA's more stringent Alternative 2 would reduce, statewide, WTT NOx emissions by:

• 33 tons per year NOx, or 0.09 tons per day, in calendar year 2023,
• 449 tons per year NOx, or 1.29 tons per day, in calendar year 2031, and
• 658 tons per year NOx, or 1.90 tons per day, in calendar year 2037;
and statewide GHG emissions by:

- 9.3 million metric tons in 2030, and
- 18.0 million metric tons in 2045.

These statewide GHG emissions reduction from Alternative 2 would be equivalent to emissions from:

- 2.2 million passenger vehicles in 2030, and
- 4.2 million passenger vehicles in 2045. [EPA-HQ-OAR-2021-0208-0643-A6, pp. 11-12]

Commenter: Elders Climate Action (ECA)

Needed GHG Reductions Cannot Be Achieved Without Zero Emission Standard.

The emissions reductions likely to be achieved by an approximation of the regulatory policy proposed by EPA in this rulemaking was investigated in a modeling analysis performed by the Rhodium Group: "Pathways to Build Back Better: Investing in Transportation Decarbonization" (May 13, 2021).30 Assuming that EPA would restore the Obama GHG emission standards with a one-year delay, the analysis estimated that the regulation would reduce GHG emissions from the transportation sector 22% by 2031. Public investments such as the tax credits proposed for enactment as part of the current Build Back Better reconciliation bill was estimated to increase the share of ZEVs sold by 2031 to achieve a 24-26% reduction in GHG emissions from the sector. Adding a 90gr/mi standard for CO2 emitted from future vehicles is estimated to increase ZEV sales as a share of total LDV sales in the range of 53% to 61% (Fig. 9) contributing to a 27-28% reduction in transport emissions by 2031 (Fig. 10).

A ZEV sales mandate for the years 2026-2030 is not investigated with respect to GHG emissions reductions, but the report includes an estimate that ZEV sales would need to reach 99% of total LDV sales by 2030 to achieve a zero emission fleet by 2045 (Fig. 2). Assuming the electric power sector achieves zero emissions by 2035 as President Biden has proposed, the LDV portion of the transport sector could achieve zero emissions by 2045 if a zero emission standard applies to all new LDVs by 2031. [EPA-HQ-OAR-2021-0208-0521-A1, p. 11]

Commenter: Environmental Defense Fund (EDF)

Accordingly, EDF modeled the costs and benefits of EPA's proposed GHG standards using available versions of EPA's Optimization Model for reducing Emissions of Greenhouse Gases from Automobiles ("OMEGA") model, both to show the OMEGA model's projected costs for the Proposal, and to assess the effect of the modeling assumption in the Proposal that automakers would incur costs associated with application of off-cycle technologies achieving 10 g/mi in MY 2020-2022 and 15 g/mi in MY 2023-2026 (the maximum allowed under the respective rules).

Key findings

OMEGA modeling confirms the feasibility of the agency's Proposed Standards using EPA's own analytical tools, as well as the feasibility of increasing the stringency of the MY 2026 standard by 10 g/mile particularly where those reductions are delivered through additional ZEV deployment. [EPA-HQ-OAR-2021-0208-0688-A1, p. 24-25]

Approach

Model

EDF conducted modeling using two versions of OMEGA that are publicly available: the latest public version 1.4.56 (referred to hereafter as PD OMEGA), which was published in early 2017 and used to project technology costs in EPA's 2016 Draft Technical Assessment Report and Proposed Determination; and version 1.4.59 (referred to hereafter as FOIA OMEGA), which was the latest operative version as of mid-2018, and was provided to EDF in mid-2020 pursuant to a FOIA request and ensuing litigation.50

PD OMEGA is fully documented by EPA and has been used to support the mid-term review of the original MY 2022-2025 GHG standards. It includes a slightly broader range of GHG control technology relative to FOIA OMEGA, particularly the inclusion of Miller cycle engines.

The GHG effectiveness estimates for control technology in PD OMEGA are based on EPA's Lumped Parameter Model (LPM), which accounts for overlap between the GHG control effectiveness of individual control technologies. The LPM estimates are supported by EPA's Advanced Light-Duty Powertrain and Hybrid Analysis ("ALPHA") model, which is a full vehicle simulation model. EDF also has access to a version of PD OMEGA which includes cost and GHG control effectiveness adjustments made by ICCT.51 These adjustments were developed based on direct interactions with automakers and technology suppliers. PD OMEGA utilizes a MY 2015 vehicle fleet as its baseline vehicle fleet, which is now fairly dated.

FOIA OMEGA utilizes a 2016 vehicle fleet as its baseline, one year newer than PD OMEGA. Its GHG effectiveness estimates for control technology are based solely on EPA's ALPHA model. ALPHA is a full vehicle simulation model which allows the effect of control technology to be assessed on a second-by-second basis during actual on-road driving simulation. In general, FOIA OMEGA's technology costs are identical to those in PD OMEGA, except in one case: Its costs for cooled exhaust gas recirculation are much lower than those in PD OMEGA and very close to those estimated by ICCT. However, FOIA OMEGA omits the consideration of Miller cycle engines, presumably due to the contemporaneous lack of an engine map for ALPHA assessment (such a map is now available). Miller cycle engines are an important aspect of mild hybrid systems. EPA highlights the benefits of Miller cycle engines in the Draft RIA for the current Proposal (pp. 2-11ff). Thus, its absence in FOIA OMEGA (and in the CAFE model used by EPA for its current Proposal) significantly raises the average cost of meeting GHG standards in the range being evaluated here. There is also no updated documentation for FOIA OMEGA. Only the model itself and the pre-processing spreadsheet were provided to EDF as part of EPA's response to the FOIA request. [EPA-HQ-OAR-2021-0208-0688-A1, p. 26-27]

Off-Cycle Control Technologies and Multiplier Credits

We evaluate both the reference and the EPA's Proposed Standards case using two approaches to off-cycle control technology. The 2020 Rule provides manufacturers with a menu of off-cycle control technologies and their individual credits, and manufacturers are allowed up to 10 g/mi off-cycle credits from the technologies listed in the menu. The California Framework Agreement includes up to 15 g/mi off-cycle credits from the technologies listed in the menu. Starting in MY 2023, the EPA Proposal also allows up to 15 g/mi off-cycle credits.

One approach assumes that manufacturers only have access to 3 g/mi off-cycle controls, which is how OMEGA applies off-cycle controls notwithstanding the higher levels allowed by the various standards described above. The cost of these 3 g/mi is contained in PD OMEGA and FOIA OMEGA and applied whenever it is necessary and cost effective to comply with the GHG standards, as is the case with all other control technologies. The remainder of the requisite GHG reductions is accomplished using 2-cycle tailpipe control technology. [EPA-HQ-OAR-2021-0208-0688-A1, p. 27]

Since PD OMEGA and FOIA OMEGA both internally considered the application of 3 g/mi offcycle control, we only added 7 g/mi under the 2020 Rule's standards, for a total of 10 g/mi of off-cycle control, as allowed under these standards. Under the California Framework emissions reductions and EPA Proposed Standards, we added 12 g/mi off-cycle control outside of the model, for a total of 15 g/mi off-cycle control. By comparing the projected technology cost using the two approaches, we can evaluate the cost effectiveness of the external off-cycle controls relative to other available control technology.

We only evaluated the technology cost of the 10 g/mi alternative in 2026 under the first approach to off-cycle controls. That is, off-cycle credits are limited to the 3 g/mi level included in the PD OMEGA and FOIA OMEGA input files. No additional off-cycle credits are considered, as these controls were not found to be as cost effective in the analyses of the Proposed Standards.

OMEGA does not allow the simulation of advanced technology vehicle multiplier credits. Thus, we model both the California Framework reductions and EPA's Proposed Standards with no advanced technology vehicle multiplier credits. [EPA-HQ-OAR-2021-0208-0688-A1, p. 28]

Table 8 presents technology costs with and without an external addition of off-cycle controls (in the latter case, 7 g/mi under the 2020 Rule standards and 12 g/mi under the California Framework Agreement and EPA's Proposed Standards.) Technology costs are presented for cars and trucks separately, as well as for the entire new vehicle fleet. The car/truck splits of the MY 2015 and MY 2016 baseline fleets differ, and both differ from the current mix of vehicles. Because of this, we show fleetwide costs resulting from the OMEGA and CAFE models as well as a second fleetwide cost using the new car/truck sales split from AEO2021 (40% cars). [EPA-HQ-OAR-2021-0208-0688-A1, p. 29] [Table 8 can be found on p. 29 of Docket number EPA-HQ-OAR-2021-0208-0688-A1]

Relative Cost Effectiveness of 2-Cycle Versus Off-Cycle Controls

EDF's OMEGA analysis confirms that EPA over-estimated the technology cost for the Proposal by assuming manufacturers would add up to 15 g/mi off cycle controls at an inflated cost of $76 per g/mi in both its reference case and control case. In the final rule, EPA should decrease the assumed cost of off-cycle controls and re-evaluate the level of off-cycle controls applied.

EPA added off-cycle controls to each of their runs of the CAFE Model used in the Proposal. Ten g/mi off-cycle controls were added to the 2020 Rule's standards (and the standards for MY 2020). Fifteen g/mi off-cycle controls were added to the reductions under the California Framework and EPA's Proposed Standards. These off-cycle controls were assumed to cost $76 per g/mi. The CAFE Model adds the cost and effectiveness of these off-cycle controls before it begins its process of evaluating and adding 2-cycle emission control technology. (As an aside, the CAFE model's fuel-savings calculations do not reflect that these off-cycle controls reduce fuel consumption.)

Table 9 demonstrates the impact of imposing these off-cycle controls on the projected technology costs of the 2020 Rule's standards, the California Framework Agreement, and the Proposed Standards. Fleetwide costs (cars and trucks, Framework and non-Framework manufacturers) are shown in all instances for simplicity. [Table 9 can be found on p. 30-31 of Docket number EPA-HQ-OAR-2021-0208-0688-A1]

Starting with the 2020 Rule's standards for MY 2026, the assumption that manufacturers will apply 7 g/mi off-cycle controls at a cost of $534 increases total compliance costs by over $400. In other words, achieving the additional 7 g/mi of GHG control via 2-cycle technology only costs about $100 across the three models. Since manufacturers are applying a significant level of offcycle controls currently, the $76 per g/mi GHG assumed in the CAFE modeling must be too high.

Moving to the emissions reductions expected in MY 2026 for automakers that entered into the California Framework Agreement, the application of 12 g/mi off-cycle controls at a cost of $916 increases total technology costs by $500 using EPA technology costs and $700 using ICCT technology costs and effectiveness. Again, achieving the 12 g/mi of GHG control via 2-cycle technology only costs a fraction of the assumed cost of off-cycle controls ($200-$400 versus $900).

Finally, under EPA's proposed MY 2026 standards, the application of 12 g/mi off-cycle controls at a cost of $916 increases total technology costs by $430-$450 using EPA technology costs and $670 using ICCT technology costs and effectiveness. Again, achieving the 12 g/mi of GHG control via 2-cycle technology only costs a fraction of the assumed cost of off-cycle controls ($250-$500 versus $900). Accordingly, we encourage EPA to lower its projected costs of adding off-cycle technologies. [EPA-HQ-OAR-2021-0208-0688-A1, p. 30-31]

EDF used OMEGA to project the technology cost of standards for MY 2026 that were 10 g/mile lower than the MY 2026 levels proposed. OMEGA modeling confirms the feasibility of such standards. Using EPA's technology costs, compliance with the 10 g/mi alternative would cost $502-$529 more per vehicle than EPA's projected cost for the Proposed Standards. Using

ICCT's technology costs and effectiveness values, the fleetwide average cost of the 10 g/mi alternative relative to EPA's projected cost for the Proposed Standards is only $245 per vehicle.

Both sets of additional costs are lower per g/mi of GHG control than the off-cycle controls assumed by EPA in its modeling.

Because available OMEGA input files use dated, and thus inaccurately high, costs for vehicle electrification, the model does not convert many, if any, vehicles powered by internal combustion engines (ICEVs) to ZEVs under the range of standards evaluated here, despite dramatic changes in the marketplace and automakers' announced plans to introduce new ZEV models. Accordingly, EDF has also conducted an analysis of the role of vehicle electrification outside of the model for this scenario. Our analysis shows that BEVs are likely to be the most cost-effective pathway to compliance with GHG emission standards in the 2026-2028 timeframe. Vehicle electrification could enable compliance with the 10 g/mi alternative at very low to negative costs.52

Table 10 presents the projected incremental technology costs of EPA's Proposed Standards and the 10 g/mi more stringent MY 2026 alternative versus the reference case. Due to the outdated high costs for vehicle electrification assumed in both versions of OMEGA, the projected levels of vehicle electrification in these OMEGA runs was very low. The cost of complying with the 10 g/mi alternative using battery electric vehicles (BEVs) is addressed in the last section below. [Table 10 can be found on p. 32-33 of Docket number EPA-HQ-OAR-2021-0208-0688-A1]

As can be seen in Table 10, the two OMEGA models with EPA technology costs and effectiveness project roughly similar costs for the 10 g/mi alternative relative to the reference case ($1,306-1,416), as well as relative to the Proposed Standards ($502-$529). Based on these models, compliance with the 10 g/mi alternative is only $246-$356 more than EPA's projected cost for the Proposed Standards ($1,306-$1,416 less $1,060). As with the Proposed Standards, the FOIA version of OMEGA projects slightly higher costs than PD OMEGA. We again attribute this to the absence of Miller cycle engines in this version of OMEGA and possibly the difference in the baseline fleet used in the two model versions.

As was the case with the Proposed Standards, projected compliance costs are much lower with the ICCT technology costs and effectiveness values. The fleetwide average cost of the 10 g/mi alternative relative to the reference case decreases to $730 per vehicle and only $245 compared to the Proposed Standards.

One important factor in all the OMEGA-based costs shown in Table 10is that they include a maximum of 3 g/mi off-cycle credits. EPA's estimate of the cost of 1.5-3 g/mi of off-cycle emission control embedded in the PD and FOIA OMEGA input files is only $50-56 per g/mi, one-third less than the $76 per g/mi 2020 Rule estimate utilized by EPA in this Proposal (taken from the 2020 Rule analysis). Still, even at this lower cost, PD OMEGA projects that only 1% of vehicles receive the lower 1.5 g/mi level of off-cycle controls and 10% receive the higher 3.0 g/mi level of control.

At the same time, as shown in the 2020 Trends Report, manufacturers have already qualified for an average of 5 g/mi off-cycle controls for cars and nearly 10 g/mi for trucks in MY 2019. Manufacturers only add off-cycle controls if they are cheaper than 2-cycle tailpipe controls. This indicates that the cost of off-cycle controls must be far less than even that assumed by EPA in the OMEGA model versions we are using and that in fact the models undervalue off-cycle control compared to 2-cycle emission control technology. Since the overall cost of compliance was less in MY 2019 than it will be in MY 2026, had we added additional off-cycle controls at costs competitive in MY 2019, the compliance costs projected here would be much lower than shown. At the same time, the incremental costs of the 10 g/mi alternative over the Proposed Standards is still much less than the cost of off-cycle controls assumed by EPA in its analysis of the proposed rule. As described above, EPA projected in its Proposal that manufacturers would add 15 g/mi off-cycle emission controls at a cost of $76 per g/mi. PD OMEGA using ICCT technology costs and effectiveness levels projects that an additional 10 g/mi of GHG control would cost $250, or $25 per g/mi CO2. This is only one-third the cost of off-cycle controls which EPA assumed all manufacturers would deploy. PD OMEGA and FOIA OMEGA with EPA costs and effectiveness values project that an additional 10 g/mi of GHG control would cost $500-$530, or $50-$53 per g/mi CO2. This is two-thirds the cost of off-cycle controls which EPA assumed all manufacturers would deploy. Thus, the incremental cost of the additional 10 g/mi of GHG control is far more cost effective than technology which EPA assumed the industry would employ under the Proposal.

As mentioned above, the battery costs assumed in all of the OMEGA input files are many years out of date and therefore much too high. As a result, even FOIA OMEGA adds fewer than 1% ZEVs to the fleet in the above compliance simulations. The potential for electrification to further facilitate compliance with the 10 g/mi scenario is addressed below. [EPA-HQ-OAR-2021-0208-0688-A1, p. 31-34]

The results are shown in Table 11. The average cost shown is weighted 40% cars, 26% CUVs, 22% SUVs and 11% pickups, which was the vehicle split in the U.S. developed by ICCT. The 40% car fraction is consistent with AEO2021. The BEV300 costs shown include indirect costs and can be taken as representative of a typical retail price equivalent cost though do not account for any consumer tax incentives. Negative numbers in this table reflect that the cost of an ICEV exceeds the cost of a BEV300. [Table 11 can be found on p. 35 of Docket number EPA-HQ-OAR-2021-0208-0688-A1]

As can be seen, the average cost of a MY 2026 BEV300 exceeds the average cost of a MY 2026-compliant ICEV by less than $1000; the costs reach parity in MY 2027; and the BEV300 is $350 cheaper than the MY 2026 ICEV in MY 2028, again without considering any consumer tax incentives.

BNEF projects vehicle cost parity in Europe are even earlier, ranging from MY 2025-2026 depending on market segment.55 Again, focusing on the fleetwide average cost of a BEV300 is conservative, as the highest selling BEVs in the U.S. thus far are cars and CUVs, although Ford has announced that it will produce a BEV version of its popular F150 pickup in the spring of 2022.

Even at $971, a BEV300 is far more cost effective than additional ICEV emission control. In the Proposal, EPA projected a fleetwide GHG level of 171 g/mi under the proposed 2026 standard. Thus, a manufacturer would only need to sell 5.8% more BEVs under the 10 g/mi alternative than the proposed standard to comply with the former. On a fleet average basis, these BEVs would cost $57 per vehicle, much lower than the $245-$529 shown in Table 10. [EPA-HQ-OAR-2021-0208-0688-A1, p. 35]

Commenter: International Council on Clean Transportation

Off-Cycle credit cost: The agencies use an arbitrarily and unrealistically high estimate of off-cycle credit costs in their compliance modeling. In the 2016 TSD, EPA did not assess 'particular off-cycle technologies or their costs and credits,' but used an OMEGA sensitivity run for two-cycle technologies as a proxy. Specifically, EPA used the OMEGA model to estimate the average cost to comply with the previous standards (with a then-projected CO2 target of 199 grams CO2 per mile in 2025) under the 'Perfect Trading' run (which treats the entire U.S. Fleet as one manufacturer). In that case, EPA found that the cost per g/mi reduction was $34. EPA also then made a second increment of off-cycle credits available in the model. To calculate the cost for these credits, EPA increased the price premium from 30 percent to 60 percent. EPA did not offer any justification for using projections of the cost to comply with the 'Perfect Trading' sensitivity run or for the 60% cost premium. In fact, the use of off-cycle credits for compliance demonstrates that off-cycle credits are more cost-effective than test cycle technologies, not less.

For additional information see: Joint NGO 2020 Reconsideration Petition, pages 50-56 [EPA-HQ-OAR-2021-0208-0522-A1, p. 9]

Off-Cycle credit cap revision

EPA revised the off-cycle credit caps from 10 g/mi in the SAFE rule to 15 g/mi in the proposed rule. This would be fine if off-cycle technologies were treated the same as on-cycle technologies when determining the next incrementally most cost-effective technology to add to a vehicle. However, the model used by EPA for the proposed rule arbitrarily forces manufacturers to add off-cycle technologies to the 15 g/mi cap before evaluating the addition of on-cycle technologies. These off-cycle credits are valued at $78/g/mi, or almost $400 for the 5 g/mi increase in the cap. Even Tesla is charged this $400 cost premium, which can be seen in the Tesla valuation in Table 4-16 of the DRIA. [EPA-HQ-OAR-2021-0208-0522-A1, p. 16]

As many on-cycle technologies can reduce CO2 emissions at far less cost, arbitrarily forcing high cost off-cycle credits on manufacturers increases the cost of complying with the proposed rule by well over $200 per vehicle. This should be fixed in the final rule by (1) revising the cost for off-cycle credits to a reasonable level and (2) revising the model to treat off-cycle technologies the same as on-cycle technologies, i.e. both should be evaluated for inclusion based on their relative cost effectiveness. If EPA lacks the time and resources to fix this in the final rule, at a minimum EPA should acknowledge that this overstates the costs of complying with the standards and commit to fixing it in future rulemaking. [EPA-HQ-OAR-2021-0208-0522-A1, p. 16]

Commenter: New York State Department of Environmental Conservation

We have known since 2016 that standards comparable to those EPA is proposing can be met with existing technology. In that year, the Draft Technical Assessment Report on the Midterm Evaluation of Light-Duty Vehicle Greenhouse Gas Standards and CAFE Standards for MY 2022-2025, conducted in collaboration by EPA, National Highway Traffic Safety Administration, and California Air Resources Board (CARB), concluded that the MY2022-2025 standards could be achieved using 'advanced gasoline vehicle technologies with modest penetrations of lower cost electrification and low penetrations of higher cost electrification.' GARB also noted that emerging technologies likely to be available in the 2022-2025 timeframe could perform better, or be lower cost, than the technologies modeled in the assessment and that vehicle manufacturers have a history of outpacing agency expectations and are likely to continue to do so. [EPA-HQ-OAR-2021-0208-0238-A1, p.2]

Commenter: Securing America's Future Energy

Reevaluate Baseline Market Expectations

In the analysis supporting the rule, EPA assumes an even split of the vehicle market between cars and trucks.[63] EPA's own analysis indicates that trucks already represented 60 percent of the market for new light-duty vehicles in 2019, a share that has been growing steadily for years.[64] This reflects the fact that the three domestic automakers have narrowed their selection of sedans to just a handful of cars in contrast to a full line of crossovers, SUVs, and pickup trucks.[65]

Because the emission reductions achieved by the rule are a function of the ratio of cars to trucks that automakers sell, overestimating the market share of cars versus trucks will overstate the potential benefits of the rule. While that will not affect the actual stringency of the rule, it would result in EPA overstating the likely effect of the rule in public pronouncements, suggesting that the rule will achieve greater emission reductions than are reasonably likely to happen. EPA should adjust its assumptions to more accurately reflect market forecasts. [EPA-HQ-OAR-2021-0208-0527-A1, p.17]

Organization: **Stellantis**

Agency Modeling Compounds Stringency Increase of Redefinition

Since the agencies' Regulatory Impact Analysis (RIA) assumed manufacturers earned 15 g/mi of off cycle credit, and did not assess the actual ability to achieve 15 g/mi, this action acts as a de facto stringency increase. While the RIA applies 15 g/mi to all manufacturers from MY2023-2026, it is not possible to achieve this cap for several reasons.

First, electric vehicles cannot claim many of the 'ICE-specific' credits and with a growing number of EVs from all manufacturers, this becomes a growing constraint. Second, manufacturers will lose their ability to claim many existing off-cycle credits without product redesigns that are outside the scope and timing of this rule as noted by EPA in the proposed rule:

‘At this time no manufacturer has introduced an exhaust waste heat exchanger to be used to warm up the engine or transmission. The systems in use are engine-coolant loop-based and are taking heat from the coolant to warm-up the engine oil and transmission fluid.’ 23

Per EPA’s acknowledgement above, manufacturers would need to redesign their products to claim the warm-up credits and the same is true of passive cabin ventilation. It will take many years of lead time for these new designs to be developed, validated, and introduced across the fleet. The active warm-up and passive cabin ventilation credits represent a large portion of currently claimed off-cycle credits (worth as much as 8.7 g/mi) that will no longer be available in MY2023 with existing technology.

Consequently, the 15g/mi contribution assumed in the RIA from off-cycle credits cannot be achieved. This needs to be reflected in the modelling, so that other offsetting technology levers (e.g., electrification) can be pulled to more accurately reflect the technology and cost needed for fleet compliance.

EPA Response

In response to comments about our benefit-cost analysis, EPA follows applicable guidance and best practices when conducting its benefit-cost analyses, including OMB Circular A-4, EPA’s Guidelines for Preparing Economic Analyses. For information on EPA’s estimates of monetizing GHG reductions see Section 14.1 of this Response to Comments document and Chapter 3.3 of the RIA. We consider our analysis methodologically rigorous and a best estimate of the projected benefits and costs associated with the final rule.

We address comments regarding fuel savings in Section 17.

We address comments pertaining to energy security in Section 19.

EPA agrees with the commenters that the initial analysis fleet is important. In the analysis for the final rule, EPA has updated the initial analysis fleet from a MY 2017 based fleet (having a 50/50 split of cars and trucks) to a MY 2020 based fleet (having a 44/56 percent split of cars and trucks).

EPA agrees with EDF, ICCT, Stellantis and other commenters that the off-cycle costs and the off-cycle modeling approach used in the proposed rulemaking could be improved. In response to the comments, EPA has made updates to the off-cycle credit modeling approach for the final rule. In addition, Stellantis argued that the 15 g/mi off-cycle credit cap could not be achieved and that our modeling should reflect that. While EPA believes that some OEMs may in fact use the opportunity under the off-cycle credit cap to reach the 15 g/mi cap for MY2023-2026, our modeling analysis does not project usage of off-cycle credits greater than 10 g/mi. This is discussed in RIA 4.1.1.1 where we describe our updated cost estimates for each gram per mile of off-cycle credit and our updated modeling approach.

The Need for Updated Tools and Modeling Inputs

EPA uses many outdated datasets, assumptions, and tools in its analysis supporting the GHG NPRM. Its choices significantly lower the projected challenges of meeting the proposed standards and inflate the projected benefits. These older inputs are used despite new data, based on credible information, like recently submitted greenhouse gas compliance data. This is readily available within the U.S. Federal Government, as demonstrated by NHTSA's CAFE NPRM, which was signed on the same day as the GHG NPRM.

The GHG NPRM states that:

[I]t is notable that, although each analysis is based on projections from the then-available fleet data forward to model years 2025 or 2026, the results of each of these earlier analyses, as well as the updated analysis we have performed for our proposed standards, have all produced very similar results in several key metrics. For example, the estimated projected cost to manufacturers to implement similar standards in 2025–2026 has remained fairly consistent since 2012.143

Auto Innovators does not agree that updated analysis produced similar results. Key metrics, such as the portion of the fleet that must be electrified to comply with standards, have changed with reasonably updated assumptions.

EPA should make use of the most recent version of CCEMS.

EPA uses the version of CCEMS developed for use in the SAFE final rule with some modifications to its inputs.144 The Department of Transportation has developed a more recent version of CCEMS, which it used for the CAFE NPRM.145 It is unclear why the Agencies did not coordinate and use the same version of CCEMS. By using an older model, and older data, EPA ignores many recommendations highlighted in the peer review of modeling tools for GHG policy analysis.146

The baseline fleet should be updated from MY 2017 to MY 2020.

The EPA analysis begins with a MY 2017 fleet,147 even though a reasonable representation of manufacturer compliance positions and vehicles is available with the MY 2020 fleet.148 While some updates to the characterization of tire rolling resistance, aerodynamic drag, and other fuel saving technologies may yet need additional characterization to more accurately reflect the technologies used in MY 2020, the MY 2020 fleet is preferred over the MY 2017 fleet as a baseline for compliance modeling. Using the MY 2020 fleet will account for important shifts in consumer preferences related to fuel prices, and adoption of fuel-saving technologies (like advanced engines, and electric vehicles), as well as significant changes to the mix of vehicles sold at an industry level. These changes substantively affect the benefit-cost analysis, and the projection of actions manufacturers may take to comply with a rapid increase in stringency of GHG and CAFE standards. Analysis using a MY 2020 baseline fleet will also highlight the importance of electrification in meeting standards and lay bare the risks for the industry as adoption of electrified technology moves beyond the “innovator” stage, to “early adopters” and “early majority” consumers. Use of electrified vehicle technology is a key metric for policy analysis, as highlighted in President Biden’s Executive Order targeting 50% electric vehicle sales share in 2030.149,150 [EPA-HQ-OAR-2021-0208-0571-A1, p. 47-48]

Off-cycle credit assumptions should be reconsidered.

Technologies that earn off-cycle credits are an important pathway for manufacturers to comply with GHG and CAFE standards. The EPA analysis assumes that manufacturers earned 10 g/mi, or even 15 g/mi by MY 2020,151,152 but compliance data shows that this was not the case.153

Furthermore, the costs for off-cycle technologies used in today's study are based off an average technology cost from an older EPA compliance pathway study, conducted around the time of the Draft Technology Assessment Report. An analysis with compliance pathways that rely significantly on a rapid adoption of off-cycle technologies, at a cost pegged to the output average technology cost of older studies, would be expected to skew the results of the current analysis towards those of the older analysis. Also, it is important to recognize that many off-cycle technologies on the credit menu are specific to vehicles with ICEs, and these may not be applicable for battery electric vehicles, or plug-in hybrid vehicles. As manufacturers introduce significant numbers of battery electric vehicles in their production plans to meet GHG/CAFE standards, especially towards the MYs 2026-2030 timeframe, EPA does not describe what off-cycle technologies might be recognized to earn 15 g/mi at a fleet level, with a raised cap and greater EV penetration.

Auto Innovators encourages EPA to update how off-cycle technologies are modeled to better address these topics above. Auto Innovators encourages EPA to update the number of off-cycle credits assumed in the analysis so that it more closely aligns with what manufacturers have actually earned in MYs 2018-2020 and are likely to earn (particularly with the proposed revised definitions) in MYs 2021- 2026. This update to inputs is more realistic (though imperfect) and will likely highlight the significant amount of electrification needed to comply with rapidly rising GHG and CAFE standards, including in the near-term.

Modeling of HCR2 engines should be reconsidered.

For this NPRM, EPA has resurrected highly optimistic effectiveness estimates for future Atkinson cycle engines based on a speculative engine map, and has used the results as "HCR2" technology. This usage diminishes the integrity of the analysis and distorts discussions of technological feasibility and economic practicability of future standards. While some commenting organizations have purported that EPA's 2016 characterization of HCR2 is a reasonable characterization of engines in the market today, like Toyota's 2.5L on the Camry and RAV4,154 or Mazda's 2.5L on the CX-5,155 history has shown that the HCR2 assumptions used in the analysis significantly and unreasonably overestimate the real-world fuel saving capability of state-of-the-art Atkinson engine technology in these applications. The EPA HCR2 engine map assumes engine accessory drive improvements ("IACC") and engine friction reduction ("EFR") have already been used to the maximum extent possible, so reapplying these technologies again in the modeling (as the EPA analysis does) incorrectly double-counts the potential effectiveness of these technologies. EPA incorrectly states that HCR2 technology, as modeled, exists in the fleet and is widely available for adoption. Tables 3, 4, and 5 [Tables 3, 4, and 5 can be found on p. 50-51 of Docket number EPA-HQ-OAR-2021-0208-0571-A1] below compare existing vehicles with advanced high-compression ratio engines to the modeled results for such vehicles, demonstrating the optimistic and speculative nature of the HCR2 technology modeling. [EPA-HQ-OAR-2021-0208-0571-A1, p. 49-50]

EPA projects that manufacturers will broadly apply HCR2 technology to improve fuel economy, and this is no surprise given the unrealistically high projected effectiveness estimates, and relatively low cost in comparison with other technologies. Moreover, EPA projects that many manufacturers should have already applied very advanced configurations of HCR technology between MYs 2017 and 2022 to a greater extent than is observed in the fleet as actually produced.

Table 6 shows the technology penetration rates of HCR2 in the EPA analysis, by manufacturer, in the "Safe-to-Proposal" alternative published in EPA's NPRM, and the DOT 2020 baseline. Note, projected HCR0 penetration rates, also significant in the EPA analysis for many manufacturers, are not included in this table for brevity. [EPA-HQ-OAR-2021-0208-0571-A1, p. 51] [Table 6 can be found on p. 52 of Docket number EPA-HQ-OAR-2021-0208-0571-A1]

Batteries and Electric Vehicles

Batteries

Automotive-grade batteries will play a prominent role in many important fuel-saving technologies, and Auto Innovators encourages the Agencies to regularly review assumptions about batteries and high-voltage automotive systems.

Auto Innovators appreciates DOT's and DOE's continued collaborative effort to refine the BatPac model assumptions, considering battery chemistries, battery cell sizes, and battery pack architectures. Auto Innovators encourages continued benchmarking, teardown, and technical review of production systems, and the use of information to inform technical specifications of packs and estimates of current direct manufacturing costs that likely reflect the commercial state-of-the art as demonstrated by production vehicles. Given high levels of investment in research and development, and production processes, and the considerable uncertainty of what approaches will succeed or fail, it is possible that NHTSA's estimates of battery pack direct manufacturing costs (after learning factor) will be meaningfully low, or high in the MY 2027 timeframe and beyond.

EPA appears to use previous generation assumptions and battery costs from the SAFE Final Rule record, despite updated battery pack assumptions, and direct manufacturing cost assumptions being available for use in the DOT analysis.

To the extent that some manufacturers begin to vertically integrate and technically differentiate on battery systems, Auto Innovators encourages the Agencies to consider costs and specifications that are reasonable for the industry as a whole to inform policy analysis, and not to assume that intellectual property and proprietary production processes that have been the result of billions of dollars of research and development paid by one manufacturer will be readily available to all manufacturers. In the BatPac model, production volume can affect direct manufacturing cost estimates, and Auto Innovators points out that many battery cells vary (size, shape, chemistry) to suit the application. Even battery packs that share cells may require different housings and assembly processes, requiring separate production lines, resulting in economies of scale lower than would be projected if all these parts were the same. Total industry volumes of battery electric vehicles are not an appropriate volume assumption for BatPac. Auto Innovators recommends that EPA update their approach to that used in the DOT analysis to estimate battery costs for strong hybrids, plug-in hybrids, and battery electric vehicles, considering vehicle type and synergies with other fuel saving technologies. That analysis could be improved by using the BatPac results for BEV400's and BEV500's, instead of scaling up BEV300 costs.

Battery electric vehicles should be carefully considered in the GHG analysis

More battery electric vehicles have been stated as a policy objective by some state governments, and by executive order. The market is emerging, and there is considerable uncertainty around the types of battery electric vehicles consumers may adopt, their costs to build, their costs to charge and operate, and how they will be used. Policymakers should carefully consider what complementary programs may be needed to unlock to the projected benefits of this technology.

The EPA proposal considers battery electric vehicles with limited range (BEV200, BEV300), and in response to rapid increases in stringency, the analysis assumes a very large portion of the market may adopt vehicles with less range than comparable internal combustion engine vehicles. The DOT analysis considers that longer range battery electric vehicles (BEV400, BEV500, in addition to BEV200, BEV300) will be required to attract "early adopters" and "early majority" to these alternative fuel vehicles. BEV400 vehicles are already on the market and are necessary to meet the demands of some of the earliest battery electric vehicle adopters. Auto Innovators encourages EPA to include BEV400 and BEV500 in their analysis tool, and to adopt DOT phase-in caps from the CAFE NPRM in place of the phase-in caps used in the EPA proposal, as the EPA proposal likely overestimates the number of consumers who would accept BEV200's, especially given today's charging infrastructure. Even if there are more charging stations, rapidly adding energy to a small pack is difficult, and pack size may limit charge rate.160 Longer range means battery packs with more storage capacity, and more capacity generally means additional cost of equipment. Battery electric vehicles with larger packs are even more expensive relative to their internal combustion engine counterparts than their lower range siblings, taking longer to pay back the upfront investment based on fuel savings alone, which policymakers should carefully consider when designing consumer incentive programs and analyzing regulatory policies. Auto Innovators encourages the Agencies to regularly review assumed phase-in caps, and the market acceptance of vehicles with limited electric range for some segments (i.e., trucks and SUV's) as the market for battery electric vehicles and charging infrastructure mature.

Both the EPA and DOT proposals assume that EVs will be driven like their ICE counterparts, but early data suggest this is not the case. In each agency's analysis, benefits like fuel savings accumulate as miles are driven. The benefits of EVs could be overestimated (perhaps significantly so) if multi-vehicle households shift their mileage towards ICE vehicles and drive the EVs less than projected. The Agencies should review the data used to create vehicle miles traveled (VMT) assumptions, and study how EVs are accumulating miles over time relative to comparable ICE vehicles, and how these differences trend as the market for EVs matures. Coordinated policies and programs (like charging infrastructure) will be important to realize the benefits as projected with the current VMT schedules in the modeling tools, and to entice drivers to choose EVs for all kinds of trips, in all kinds of driving conditions.

Approach to Fuel Cost Savings

Energy savings associated with EVs.

In both EPA and DOT analysis, a large portion of the projected benefits are attributed to fuel savings, either from using less energy to travel the same number of miles, from switching to a lower cost fuel (electricity), or from a combination of both. At this time, there is a tremendous amount of uncertainty related to the future of the electricity grid, and electricity rates (both residential rates including transmission costs, and whatever rates that may be offered to consumers at public vehicle charging infrastructure). Researchers and scientists from National Renewable Energy Laboratory ("NREL") have highlighted challenges with integrating variable renewable energy generation into the electric grid beyond 30% generating capacity, with challenges including higher transmission costs, and costly overhead associated with storage and standby generation.161 Notably, states with higher portions of renewable electricity generation like Hawaii, California and Massachusetts also have some of the highest electricity rates in the country.162,163 Studies from the NREL have outlined how renewable power sources, such as solar, could be integrated into the electric grid to meet the nation's ambitious emissions goals, and these studies acknowledge that costs increase when the timing of electricity generation and electricity demand are not synchronized.164 Without public charging infrastructure, many EVs will be charged at night, at residences, when solar arrays are not generating electricity. EPA inputs estimate the cost of delivered electricity ($/kWh) as $0.122 in 2021, and $0.133 in 2040. DOT inputs estimate the cost of delivered electricity ($/kWh) as $0.121, and $0.120 in 2040. States with a larger percentage of renewable electricity generation typically have end-use rates 1.5 to 2.5 times higher than those assumed by the Agencies, with delivered costs ($/kWh) increasing as more renewable generating capacities are added. (Increases in transmission costs and increases in standby generating costs partially offset or exceed cost reductions of solar and wind generation). As the U.S. electricity generating industry transforms towards renewables, Auto Innovators urges policymakers to consider the possibility that electricity rates may be considerably more expensive relative to gasoline than projected in the GHG NPRM and CAFE NPRM analyses (as indicated by higher electricity rates in states that are already working toward renewable electricity generation), and this could significantly erode projected fuel savings and consumer demand for EVs. As the penetration rate of EVs increases, the projected electricity rates will become an important modeling input for assessing costs, benefits, and consumer adoption of EVs. Auto Innovators encourages policymakers to consider the possibility that electricity rates may double from 2021 to 2040 (in 2018$ terms) when considering policies for light-duty vehicle GHG and CAFE, and to use real-world data to inform an electricity price forecast.

Fuels and Benefit-Cost Analysis

Both EPA and DOT recognize fuel savings as significant in the benefit-cost analysis. These fuel savings accumulate to consumers based on assumed prices of fuel, fuel efficiency for combinations of technologies, and travel over the lifetime of the vehicle. Each analysis recognizes that independent of regulations, consumers will adopt fuel saving technologies that pay back quickly.165

Fuel prices vary significantly across the U.S. California has some of the highest gasoline prices in the country, often 50% higher than in other states with large automotive markets.166 Many manufacturers' sales vary significantly by region. Some manufacturers have higher sales concentrations in California and Section 177 states than other manufacturers, and this may affect corporate strategy and the incorporation of fuel-saving technologies on vehicles. Auto Innovators encourages policymakers to consider the importance of regional factors carefully before exporting California policy as a baseline for federal standards.

Both the EPA and DOT analysis use—and have used—forecasts from the U.S. Energy Information Administration for fuel prices in their central analyses. Over the last decade (as shown in Figure 4 below), these fuel price forecasts have significantly overestimated the national average price of gasoline, which has in turn overstated the projected benefits of increases in stringency and improving fuel economy for consumers in the near term. Over the last decade, the long-term price outlook for gasoline has steadily declined as well, both in the EIA forecasts, and in private sector forecasts. [Figure 4 can be found on p. 59 of Docket number EPA-HQ-OAR-2021-0208-0571-A1]

Interestingly, DOT included a sensitivity case for gasoline prices, as forecast by Global Insight. This is a credible source, alongside the EIA forecast. Both forecasts have a similar trajectory and values from 2022-2029, but they depart significantly in 2030 and beyond. Gasoline prices are volatile, and difficult to predict. Both EPA and DOT show U.S. consumption of gasoline decreasing significantly in the long term, as fuel efficiency of light duty vehicles improves in response to stringent alternatives, and as the fleet transitions towards electrification. Auto Innovators encourages policymakers to review the assumptions underlying the EIA gasoline price forecast, including assumed domestic consumption of fuel, and the extent to which plug-in vehicles are assumed to be adopted, and review the extent to which those assumptions are consistent with the policy objectives for light-duty vehicle electrification as stated in recent executive orders. If the EIA Central Case gasoline forecast assumes fewer than 50% plug-in vehicles by 2030, Auto Innovators encourages use of the Global Insight gasoline price forecast in the Central Case for both EPA and DOT analysis. To the extent that gasoline prices may remain low in the long-term (perhaps reflecting depressed demand for gasoline, as shown in both of the Agencies' analysis), consumers may require additional incentives to transition towards plug-in vehicles.

Many of the projected benefits of the proposal are backloaded, taking years for consumers, and society, to realize payback on fuel-saving technologies. If gasoline prices do not increase significantly in the 2030 and beyond timeframe, this would have significant bearing on the benefit-cost analysis, and the projected benefits of the proposed rule. Policymakers should carefully consider this possibility given the trends of fuel price forecasts over the last decade, and consumption projections.

Tools and Inputs for Compliance Modeling

Compliance modeling tools should simultaneously consider all federal and state regulations that significantly affect light-duty vehicle GHG emissions, fuel economy, and related technology mandates.

Auto Innovators supports the use of a compliance modeling tool that is capable of simultaneously modeling individual manufacturer compliance at the fleet (manufacturer, domestic car, import car, and light truck) level with the multitude of GHG and fuel economy regulatory requirements in the U.S. (including EPA GHG regulations, NHTSA CAFE regulations, CARB GHG regulations, CARB zero-emission vehicle regulations, and the California Framework Agreement). This is the challenge that manufacturers face in developing compliance plans—numerous similar, but not fully coordinated and harmonized regulations, all of which product plans must account for. While no presently available vehicle regulatory compliance modeling tool fully considers all of these requirements, the CAFE Compliance and Effects Modeling System ("CCEMS") comes closest for the time being. Therefore, we support use of CCEMS by EPA for modeling compliance, and urge the Agencies to jointly develop a tool that is more fully capable of considering all requirements.

The consumer-facing costs of the EVs should be included and shown as part of the anticipated increased costs of future vehicles.

Fully accounting for the costs of EVs in assessing the technology costs of GHG and CAFE regulations is becoming increasingly important. Simply assuming that other regulations such as the California ZEV mandate will create specific outcomes in isolation from EPA's own regulatory efforts— e.g., including them in a baseline or reference case—is a flawed approach. As noted above, manufacturers must plan simultaneous compliance with all regulations, and the technology decisions made for compliance with one also affect compliance with the others. Conducting the analysis in a way that assumes the costs of meeting other related regulations are incurred separately from compliance with the proposed GHG regulations will lead to under-reporting of expected vehicle cost increases associated with meeting the multitude of related standards simultaneously. We recommend that cost increases associated with the technology required to meet all of the related GHG, fuel economy, and technology-forcing regulations at minimum be shown as part of the consumer-facing costs (expected per-vehicle cost increases) over the regulatory period.

Insofar as the revised standards cause a reduction in engine-out emissions due to less combustion of gasoline, the amount of tailpipe emissions will not decline proportionately. The structure of the Clean Air Act and the EPA/CARB regulations define limits on tailpipe emissions of criteria air pollutants in terms of grams of pollution per mile. Vehicle manufacturers and their suppliers seek to fully comply with those standards on a least cost basis, since any unrequired expenditures on emissions control could place an individual vehicle manufacturer or supplier at a competitive disadvantage. If engine-out emissions are reduced due to the revised CAFE/GHG standards, vehicle manufacturers can adjust the design of their catalyst systems to reduce compliance costs while maintaining compliance with the gram-per mile standards. One way vehicle manufacturers and suppliers do this is by reducing the use of expensive coatings on the catalyst. Thus, from a technical point of view, the benefits of reduced engine-out emissions are not experienced in public health terms but in savings to manufacturers/suppliers and consumers in the costs of emissions control. Insofar as the Agencies seek to claim benefits from reduce engine-out emissions (due to greater fuel economy), they should estimate the savings in catalyst costs that result. While complex catalyst systems can add $200 to $400 to the cost of manufacturing a new vehicle, the incremental cost savings from the changes in coatings to catalysts will be only a small fraction of the total cost of the system. For the entire fleet, those savings will be a small fraction of the purported public health benefits that are currently claimed in the RIAs.

Coordination Between the Agencies' Analysis

While DOT and EPA use similar tools to conduct analysis, EPA is using an old version of inputs, with a few meaningful tweaks, to conduct the analysis. The differences are notable (Table 9). [Table 9 can be found on p. 61 of Docket number EPA-HQ-OAR-2021-0208-0571-A1] [EPA-HQ-OAR-2021-0208-0571-A1, p. 55-60]

Forecasts for conventional fuel prices are also uncertain. Despite recent rises in the price of gasoline, historically forecasts have overestimated the national average price of conventional fuels. We urge the Agencies to review the assumptions underlying the Energy Information Administration ("EIA") gasoline price forecast, and if the EIA gasoline price forecast assumes fewer than 50% plug-in vehicles by 2030 (the goal set by the Biden Administration), Auto Innovators encourages use of the Global Insight gasoline price forecast in the Central Case for both EPA and NHTSA analysis. Policymakers should carefully consider the possibility that gasoline prices will not increase significantly past 2030, and the impacts that would have on longer-term projections of private benefits from fuel savings. [EPA-HQ-OAR-2021-0208-0116]

Commenter: Alliance for Vehicle Efficiency (AVE)

• AVE urges EPA to consider the costs and risks to OEMs and technology suppliers associated with converting and expanding automotive supply chains to meet future standards as more ZEV vehicles are introduced into the marketplace. [EPA-HQ-OAR-2021-0208-0256-A1, p. 2]

Fleet Mix: AVE urges EPA to incorporate real-world sales data as forecasted by IHS Markit (below) to account for the historical changes in fleet mix since 2012. In 2012, EPA modeling predicted significant reductions in light truck sales:

"Between MY2008 and MY2025, the agencies' forecast [for light-duty truck sales] showed declines from 17.8% to 5.8% for Chrysler, from 14.5% to 12.0% for Ford, from 26.8% to 27.8% from General Motors, and from 58.3% to 44.5% for the aggregate of these three manufacturers."25 [EPA-HQ-OAR-2021-0208-0256-A1, p. 10; Table can be found at docket number EPA-HQ-OAR-2021-0208-0256-A1, p. 10]

IHS Markit predicts an additional 23% increase in light truck sales from the end of 2021 to 2026. Real-world modeling in the Proposed Rule will assist manufacturers with future planning to reflect consumer's vehicle choices.

Post-2026: As indicated in President Biden's August 5, 2021, Executive Order, EPA will soon embark on setting standards beyond 2026. As EPA looks to increase the stringency of these standards, the agency must foster innovation for multiple technology pathways that demonstrate feasibility and maximize the environmental benefits of all available technology. As technology solution providers, AVE members will help the U.S. reach its climate goals. [EPA-HQ-OAR-2021-0208-0256-A1, p. 10]

The U.S. light-duty marketplace of today is quite different from that of 2012 when EPA and NHTSA issued joint emissions and fuel economy standards. The challenges of the global marketplace have forced OEMs and technology suppliers to change the way they operate and invest in advanced vehicle technologies. Performance-based standards that reflect real world data, including LCA and upstream emissions, provides industry the best opportunity to compete globally while offering consumers reasonably-priced vehicles that will meet the U.S.'s carbon reduction goals.

EPA should also consider adjusting future standards to reflect the global pressures facing OEMs and technology suppliers if the United States is going to continue leading the world in producing advanced vehicle technologies for the next generation of vehicles. A single technology solution will not accomplish our goals and EPA should set standards that encourage as many solutions as possible.

AVE encourages EPA to use this rulemaking as an opportunity for regulators to provide certainty across the automotive industry, foster more U.S. jobs and innovation, and solidify the United States' position in the world as a leader in mobility innovation. [EPA-HQ-OAR-2021-0208-0256-A1, pp. 10-11]

Commenter: American Enterprise Institute (AEI)

• The EPA analysis of the value of refueling time savings for a vehicle fleet characterized by lower per-mile fuel consumption should be combined with a similar analysis for the time costs of recharging a larger fleet of electric vehicles. EPA fails to do so. [EPA-HQ-OAR-2021-0208-0254-A1, p. 2]

Commenter: American Honda Motor Company (Honda)

Base Year Fleet

The agency requests comment on its use of a MY2017 base year fleet, and whether it would be more appropriate to update the base year in the final rule to one reflecting the most recent year of final compliance data. The agency notes a history of seeking to use the most recent base year data available, though it suggests that base year selection has only modest impact on model results for the projected fleets:

When performing compliance analyses, EPA will often attempt to utilize the most recent base year data that is available as finalized compliance data, which at the time of this analysis was for

MY2019. It is important to note that because the model applies technologies to future vehicles for all alternatives being analyzed, including the ‘‘No Action’’ scenario, the vintage of the base year normally will not have a significant impact on the model results for projected fleets.19

It is Honda’s belief that selection of the base year fleet can have meaningful impact on modeling results, at least at an OEM-based level of granularity. Fundamentally, the base year defines the sets of technologies already applied in the market, and thus sets constraints regarding 'technology walks' to further emissions reductions. In other words, it defines the low-hanging fruit that are available for providing further improvement to the fleet. By selecting an overly dated base year fleet, the agency’s modeling could erroneously assume application of technology that, in reality, did not occur. Use of a MY2017 base year permits the modeling to apply 'imagined' technology to model years that have already passed, ignoring actual technology application decisions and potentially widening the gap between simulated results and what is achievable with the current vehicle fleet.

Figure 4, at right, illustrates this point at an industry level.20 Starting with a 2017 base year fleet, the agency projects technology application and market shift such that the simulated fleet in 2020 averages 222 g/mi, a 38 g/mi reduction over 3 model years (2018-2020). However, the actual 2020 fleet achieved 246 g/mi, 24 g/mi higher than what was derived via the NPRM simulations using the 2017 base year fleet. Figure 4 can be found at docket number EPA-HQ-OAR-2021-0208-0565-A2, p. 10]

This can also impact OEM-specific fleets. Consider, for example, the agency’s modeling of HCR1 and HCR2 engines in Honda’s fleet. As a result of the use of a MY2017 base year fleet, the computer model brings these engines into Honda’s fleet beginning in Model Year 2018. However, in reality, this did not occur. We are concerned that incorrectly modeled technology application choices can result in overly optimistic scenarios yielding fleet performance and credit banks that would not be possible had the base year been updated. Ultimately, this leads to greater potential for divergent findings between the agency’s estimated compliance costs and those facing a manufacturer.

Honda would like to better understand the agency’s position regarding baseline fleet selections and welcomes further dialogue on the topic. In the meantime, in response to the agency’s request for comment on this topic, we support use of a more recent baseline fleet, such as the MY2020 fleet utilized by NHTSA in its proposed rule. Doing so should have the added benefit of helping further align core agency assumptions, an important element of regulatory harmonization. [EPA-HQ-OAR-2021-0208-0565-A1, pp. 9-11]

Commenter: BorgWarner Inc.

Vehicles Sales Mix Assessment

We strongly encourage EPA to update their impact assessment based on the most-current actual and projected sales mix of trucks and cars, instead of the 50/50 split used in the analysis to date. The actual U.S. sales mix in 2020 and 2021 was 76% light trucks / 24% cars and 78% light trucks / 22% cars, respectively. Similarly, the 2022 forecast is 80% light trucks / 20% cars. The projected sales mix in 2026 is 83% light trucks / 17% cars. i Since the sales mix can dramatically impact modeling and conclusions in the regulatory rulemaking process, using real-world data is critical when setting meaningful and realistic standards. [EPA-HQ-OAR-2021-0208-0260-A1, p. 3]

Commenter: California Air Resources Board (CARB)

ZEV-Only Manufacturers Should be Fully Considered in Credit Modeling.

ZEV-only manufacturers effectively never have a need for the credits they earn under the GHG emission standards, as they can only over-comply. Such ZEV-only manufacturers earn significant credits per vehicle under the GHG standards given the large difference between the standard and the zero or near-zero emission level at which their vehicles are counted.

Further, the annual EPA Automotive Trends Reports show that ZEV-only manufacturers are active sellers of credits in the marketplace and many of the other manufacturers of conventional vehicles have been active purchasers of such credits. This history supports recognizing that future credits earned by ZEV-only manufacturers will likely be purchased and used by other manufacturers and should be included in subsequent modeling runs to better reflect likely compliance. Additionally, even though financial details of credit transactions are not disclosed, this history of credit purchase and usage shows that such credits are being acquired at lower cost than otherwise would be expended by the purchasing manufacturer to comply. Accordingly, U.S. EPA should endeavor to model the credit market as it exists, including that credits generated by ZEV-only and other manufacturers are sold to lower the overall compliance costs of the standards, rather than only modeling each manufacturer’s credits and compliance strategy in a silo. [EPA-HQ-OAR-2021-0208-0643-A6, pp. 33-34]

Zero-Emission and Electrification Technology Supports Alternative 2.

CARB agrees with U.S. EPA that more stringent standards can be met with advanced gasoline vehicle technologies already in vehicles on the road and zero-emission and electrification technologies that continue existing manufacturer trends.93 In addition to conventional technologies, U.S. EPA correctly recognizes the breadth of public announcements, resource commitments, and projections to incorporate zero-emission technology extensively, and in many contexts exclusively, into vehicles.94 The Revised 2023 and Later Model Year Light Duty Vehicle GHG Emissions Standards Draft Regulatory Impact Analysis (DRIA) in section 2.3.3, beginning at page 2-13, discusses manufacturer plans for zero-emission technologies, investments, and vehicle models.

CARB reaches the same conclusions based on the information it has reviewed. The trend towards zero-emission technology is well underway. In 2020, 8% of new vehicle sales in California were ZEVs and PHEVs. As CARB explained in its comments to U.S. EPA on its proposal to restore California’s waiver for its GHG and ZEV standards, manufacturers are expected to increase ZEV production. Manufacturers have invested heavily in zero-emission technology, reduced its costs, greatly improved its capability, and made tangible, public commitments to new vehicles. Nationally, between August 2020 and August 2021, sales of vehicles with zero-emission technology, whether battery-electric, fuel cell, or plug-in hybrid, went from 2.1% to 4.0%,[95] and were 5% of sales in July 2021.[96] Scrutiny of credits generated by ZEV-only manufacturers indicates that current sales of ZEVs are higher than U.S. EPA estimates, which further supports the feasibility of the proposed standards and Alternative 2 specifically.

Accordingly, CARB recommends that U.S. EPA utilize a newer baseline than the 2017 model year used in the analysis for the proposal. Notably, Tesla is the largest ZEV-only manufacturer and is listed in the baseline market input files used by U.S. EPA as having nationwide sales of less than 50,000 vehicles. However, Tesla has substantially increased sales since 2017 with the expansion from two to four vehicle models, including the more popular Model 3. In the 2020 model year baseline market input file used by NHTSA in its recent proposal to revise the fuel economy standards for model years 2024 through 2026, Tesla's nationwide sales are listed as nearly 200,000 vehicles, an approximate four-fold increase.[97] Tesla also has publicly announced plans for production of a roadster model and a truck application and U.S. EPA has also recently certified models from both Rivian and Lucid Motors adding support for including some representation of growth in sales (and corresponding credits) from ZEV-only manufacturers in future modeling analysis.

Looking ahead at other manufacturers, the annual alternative fuel vehicle projections submitted to CARB to assist with infrastructure planning predict increasing ZEV sales. These reports include three- to five-year future model year sales projections for battery electrics, plug in hybrids, and hydrogen fuel cell vehicles. Based on this data, new vehicle sales in California of ZEVs and PHEVs are projected to reach 25% by 2023.[98]

This prediction is corroborated by manufacturer projection they will increase their number of available models to at least 82 by model year 2023. Ford Motor Company, General Motors, and Stellantis announced on August 4, 2021, in support of this proposal, a goal for 40-50% US ZEV sales by 2030.[99] Ford followed up with plans to double its production target of the Lightening full-size electric pickup truck.[100] Nissan has announced 40% of their US sales will be BEVs by 2030.[101] Audi also recently announced its new corporate strategy, 'Vorsprung 2030', which states that the company will introduce its last new combustion engine product in 2026, and completely phase out its internal combustion engines by 2033.[102]

Sales are also expected to increase because vehicles will better meet consumer needs and at lower costs. Several start-up manufacturers have product releases imminent that are pushing vehicle range even higher with greater vehicle utility. Rivian’s R1T pickup truck and R1S SUV are expected to start shipping in September of this year.[103] Lucid’s Air sedan is expected to ship in the second half of this year.[104] The company has also shown a concept SUV based on the Air’s platform that is planned to go on sale in 2023.[105] Those vehicles reflect 'clean-sheet' design approaches that take full advantage of the integration and design opportunities that a dedicated BEV platform can provide. The Rivian models have options for over 400 miles of range and the Lucid Air will offer over 500 miles.

U.S. EPA also requested comment on how it should treat California's GHG and ZEV standards here.80 For the reasons explained in its comments on that proceeding, CARB urges EPA to quickly reverse its SAFE 1 actions. Assuming EPA does so before it finalizes these standards, it would be reasonable for EPA to model compliance, manufacturer costs, and development of technology to meet its final standards from a no-action baseline that includes California's greenhouse gas emission and zero-emission vehicle standards in those states in which they would then be in effect. [EPA-HQ-OAR-2021-0208-0643-A6, pp. 29-30]

Commenter: Center for Biological Diversity, et al.

Relative to the 2020 Final Rule, EPA has made several improvements to its modeling of GHG standards, making its analysis more reasonable and accurate. These include allowing high-compression ratio level 2 technology (HCR2) to be used in modeling automakers' potential compliance pathways under the standards, Proposal, 86 Fed. Reg. at 43,769,74 as well as using global social cost of carbon values instead of domestic values, id. at 43,769.75 However, EPA's modeling and analysis still includes inputs, assumptions, and methodologies that overstate the costs and understate the benefits of more stringent GHG standards. [EPA-HQ-OAR-2021-0208-0651-A1, p. 29-30]

EPA's simplified calculation of consumer costs likely understates the net consumer benefits of stronger GHG standards.

In the 2020 Final Rule, EPA's consumer benefit calculations incorporated several costs and several benefits which do not appear to have been incorporated into the consumer impacts calculations in the Proposal. On the cost side, in addition to price increase/technology cost, EPA previously included increased financing costs, increased insurance cost, increased taxes and fees, implicit opportunity cost, and lost consumer surplus. See, e.g., 2020 Final Rule, 85 Fed. Reg. at 24,991, Tbl. VII-80 et seq. On the benefit side, in addition to fuel savings, EPA previously included a mobility benefit and refueling benefit. See id. In the NPRM and RIA, it appears that EPA identified and calculated several of these costs and benefits. See, e.g., DRIA at 6-7 (identifying as non-emission benefits drive value, refueling time, and energy security benefits); DRIA at 3-15 to 3-26 (quantifying annual energy security benefits of the Proposal). EPA should provide an explanation for why these costs and benefits were not incorporated into the consumer impact calculations for the Proposal.

EPA's exclusion of several categories of costs and benefits in this Proposal understates the benefits of more stringent standards. This is because, based on the numbers in EPA's prior modeling, the omitted benefits were consistently larger than the omitted costs. See 2020 Final Rule, 85 Fed. Reg. at 24,991, Tbl. VII-80 et seq. For example, at a 3 percent discount rate, EPA calculated total increased financing and insurance costs and increased taxes and fees from MY 2021 through MY 2026 to be -$323/vehicle under the 2020 Final Rule. 85 Fed. Reg. at 24,991, Tbl. VII-80. By comparison, EPA projected the total mobility and refueling benefit under the 2020 Final Rule to be -$489/vehicle. See id. Assuming the relative magnitude of these impacts is similar for the Proposal, exclusion of these costs and benefits will, on net, decrease projected consumer benefits. [EPA-HQ-OAR-2021-0208-0651-A1, p. 49-50]

Commenter: Center for Climate and Energy Solutions (C2ES)

Base Year Fleet

EPA should use the MY 2019 data as a baseline rather than the MY 2017 base year fleet used in the proposal to ensure the standards accurately reflect the higher levels of zero-emission vehicle proliferation in the current light-duty market. Data from MY 2019 is available and reflects the implementation of the standards set in the 2012 Final Rule prior to the implementation of the SAFE rule. In particular, the increased market proliferation of electric vehicles as well as the improvements in costs of zero-emission vehicles should be considered. From 2017 to 2019, plug-in electric vehicle sales increased 67 percent in the United States, as more models became available and costs fell. Despite a small decrease in overall sales from 2018 to 2019, due largely to the discontinuation of a popular model, increased model choice is clearly linked with significant year-over-year growth in sales, and given automaker commitments to greatly expand the number of zeroemission model offerings through 2025, this more recent data indicates a strong upward trend in the U.S. electric vehicle market.24 [EPA-HQ-OAR-2021-0208-0287-A1, p.7]

Commenter: Consumer Federation of America

• In the EPA's proposed revision to the SAFE 2 rule, it has corrected numerous errors made by the Trump administration. These corrections include fixing the valuation of greenhouse gases and other pollutants, returning the rebound rate to 10 percent, lowering the discount rate and updating the availability of technologies. [EPA-HQ-OAR-2021-0208-0297-A1, p. 2]

In comments CFA2 has submitted to the agencies previously, we noted over three dozen (41) errors that took more than a decade to correct, as shown below in Table 1.1. The Table also shows that the Trump administration, in its SAFE 2 rule, reintroduced over two dozen (28) of these errors. The impact of reintroducing these errors into the standards was dramatic. A benefit-cost ratio calculated by CFA shows the standards in place before the Trump administration to be 5-to-1, but subsequently has been reduced to a mere 1.1-to-1. Reversing many of these errors through this proposed rulemaking and taking into account key changes (like the projected price of gasoline) has restored the cost-benefit ratio to about 2.2-to-1. [EPA-HQ-OAR-2021-0208-0297-A1, p. 3; Table 1.1 can be found at docket number EPA-HQ-OAR-2021-0297-A1, p. 4]

Doubling the benefit-cost ratio is an important step in justifying the rule, but there are a number of areas we think EPA could have gone further with superior assumptions and methods for modeling the impact of standards. Before we turn to those points of difference, it is important to stress what EPA has gotten right. In the next section, we discuss three ways in which the Trump Administration got the big picture wrong and EPA got it right: compliance with broad statutes governing energy efficiency/emissions, the Administrative Procedure Act, and the overall approach to regulation. [EPA-HQ-OAR-2021-0208-0297-A1, p. 5]

Estimating the cost of increasing fuel economy has been a matter of great debate for decades. As noted above, empirical analyses that look at actual costs show that regulators overestimate the cost by a factor of two, and automakers overestimate it by much more than that.

David Greene, one of the leading experts on fuel economy, recently conducted a review of the literature. He concluded that an estimate of 27 percent of increased auto costs, or about $150 for every mile per gallon improvement, was too high. He gave two reasons for this.13 First, backward-looking analysis of cost increases that included used vehicles (as his analysis did), were double-counting the cost of increasing fuel economy because the sellers of vehicles were capturing a significant part of the capitalized value of better fuel economy equal to about 20 percent of the estimated cost of efficiency) in their sales price. This factor alone would lower the estimate to 21.6 percent of the increase in price or about $120 for each 1-mile improvement in the MPG. Second, real-world experience showed that there was a learning process in which costs fell as automakers gained more experience with increasing fuel economy. Over the redesign cycle of vehicles (e.g., five years) this learning rate would lower the cost by about 10 percent. Thus, one might argue that the appropriate numbers would be about 20 percent per year and $108 per MPG, as shown in Table 4.1 [EPA-HQ-OAR-2021-0208-0297-A1, p. 14; Table 4.1. can be found at docket number EPA-HQ-OAR-2021-0297-A1, p. 15.]

There is a third factor that is implicit in Greene's analysis. The distribution of the cost of vehicles is skewed. The much more expensive vehicles purchased by upper-income households are likely to include a larger amount of costs incurred to upscale the vehicles, rather than for fuel economy. In a subsequent analysis, Greene estimated the cost of improving fuel economy directly with an econometric model that corroborated the above concerns. The simple adjustment to a constant 20 percent of total cost moves the estimate much closer to the empirical evidence offered by Greene, which suggests that costs are about two-thirds of what was found in the literature review—about 18 percent or $99/MPG.

EPA's analysis of the cost of the National Program currently yields an estimate in fuel savings that is similar, $97/MPG. This estimate reflects considerable technological progress over the early years of the National Program, which is consistent with the historical pattern. A recent study by the ICCT offers an estimate of going forward costs of improvement close to the rate of the national program (national program = 3.3%, ICCT = 4% per year). The ICCT study also includes continuing technological progress.

Cost Whiplash

The whiplash of the current rule is depicted in Figure 4.1. The reasons for the whiplash are the severe constraint on technology choices imposed by the model and the very high markup assumed. By imposing constraints on the use of technologies, ignoring emerging technologies and assuming many more electric vehicles would be necessary, NHTSA has adopted a price that is far above EPA's estimates and those of independent third parties, as shown in the upper graph of Figure 4.1. Greene's analysis suggested that a 2 percent per year was a reasonable cost estimate. Over the redesign cycle of vehicles (e.g., five years) this learning rate would lower the cost by about 10 percent. Thus, one might argue that the appropriate numbers would be about 20 percent per year and $108 per MPG. [EPA-HQ-OAR-2021-0208-0297-A1, p. 15]

Automakers also regularly state that compliance costs are higher than what regulators estimate, when in fact, they comply with efficiency standards at a lower cost than the regulators' estimates. New car prices, for the most part, have since the Great Recession failed to match the rate of inflation, all the while increasing in fuel economy. While new vehicle prices are indeed rising, this is due to the switch from cars to trucks and SUVs, which have a higher MSRP.

CFA analysis has further shown that after factoring in inflation, a full 27 percent of the 'all-new' 2017 vehicles went down in price and increased their fuel economy by 1 to 10 MPG compared to their 2011 counterpart14. This is without considering that fuel economy technology is only one of the many different improvements that increase a vehicle's MSRP, such as safety technology, convenience items, and design changes that are equal or higher drivers to increased vehicle costs. When using historically supported evidence, the best estimate of fuel economy technology costs is about $100 per MPG of improvement. Using this estimate, 94 percent of the 'all-new' 2017 saw a net positive benefit for the drivers, as the fuel savings exceeded the cost of fuel efficiency technology over the first five years of ownership defined and defended by the TAR. [EPA-HQ-OAR-2021-0208-0297-A1, pp. 16-17]

MACROECONOMIC BENEFITS

Importance In our earlier comments to the EPA, we demonstrated that the benefits of reduced emissions achieved through greater efficiency have substantial macroeconomic benefits that are inextricably linked to the reduction in the cost of driving. EPA considers the macroeconomic benefit of improved energy security, but not the benefits that flow from consumer pocketbook savings. The social cost of carbon reflects some of the benefits foregone by reducing emissions, but not all. In fact, a 2010 agency memo placed in the record calculated a substantial macroeconomic benefit which roughly equaled the consumer pocketbook savings.20

We again call on the agency to recognize this benefit, which is as measurable and certain as many of the other benefits it counts. The need to acknowledge these benefits is more significant than ever.

First, the Biden administration has correctly made the case that a vigorous response to climate change based on efficiency and a shift in power sources (from petroleum to low-emissions electricity) will be good for the economy. The benefits come directly from the jobs needed to create the new technologies and indirectly from the re-spending of the energy savings. These are precisely the same benefits that are identified in the general literature on energy efficiency savings. It is inconsistent to claim the external benefit of emissions reductions for security or public health purposes and not for macroeconomic purposes.

Second, over time, the macroeconomic benefits may become the single largest category of benefit, embodied in an industrial revolution – a shift from coal and oil to clean electricity – as large as the last such revolution (from wind and water to fossil fuels). From the consumer/economic point of view, the decarbonization of the economy may become the 'secondary' benefit.

Increasing the benefit-cost ratio dramatically makes the case for the proposed rule all the more compelling. Therefore, we will repeat the earlier argument.

Econometric models that use general flows of resources between economic activities have been used to assess the impact of increasing efficiency. In a sense, the coefficients in the macro models are representations of the relationships in the economy through which the micro-level effects flow. Simply put, when the cost of driving declines, consumers have more money to spend on other things. These other things tend to be much less energy-intensive than driving. This flows through the economy and stimulates economic growth and increases job creation. No matter the level or approach, the evidence strongly supports the conclusion that there is a positive impact.

Increasingly, research shows that energy savings from energy efficiency improvements can deliver more comprehensive benefits across the whole economy, such as increases in employment, GDP, trade balances, energy security, etc.…

One way to look at the macroeconomic impacts is to separate them into:

The cost and effects derived from investing in energy-efficient goods and services, and the effects derived from the energy savings (or reduced costs) from realizing an improvement in energy efficiency…

Increased energy efficiency can lead to more competitive production for 'business consumers' or energy, while for final consumers, increased efficiency mainly leads to a demand shift from energy consumption to other goods. For the consuming sectors, it is relatively straightforward to observe how investment in energy efficiency and energy savings can lead to increased spending and economic activity with second-round effects such as employment, government revenue, and price effects (if other investment and spending is not crowded out). There are likely to be positive income effects, unless household wage demand increases as the labor supply becomes more competitive.21

One way to gain an appreciation of the impact of energy costs is to consider how transportation costs are dealt with in the economy and models of the economy. The economic reality of the flow through to consumers of transportation fuel costs is reflected in the way econometric models describe the growth of the economy. Such models are built on input/output tables, and transportation costs are a significant input in the models. In building these models, the pass-through of transportation costs is assumed since transportation plays a fundamental role in the overall cost of production.

Transportation is an economic factor of production of goods and services, implying that relatively small changes can have substantial impacts on costs, locations and performance…

Transport also contributes to economic development through job creation and its derived economic activities. Accordingly, a large number of direct (freighters, managers, shippers) and indirect (insurance, finance, packaging, handling, travel agencies, transit operators) employment are associated with transport. Producers and consumers make economic decisions on products, markets, costs, location, prices which are themselves based on transport services, their availability, costs and capacity.22

Typically, the more places that are touched by a sector, the larger its multiplier. Because most economic models are built on the flow of goods and services through the economy, they depend on the geographic scope and nature of activity within the economy being modeled. Transportation is generally seen as a central input to measuring broader economic activity. In modeling the impact of higher fuel economy with these econometric models, it is important to understand certain market factors. As the cost of transportation declines, demand for transportation increases because the demand for goods and services increases due to their lower costs. In addition, as the population and economy grow, the need for commercial transportation increases as well. Nevertheless, the fuel savings from greater efficiency are much larger than the increase in consumption. The net effect is to reduce expenditures on fuel as a percent of total output. In fact, the reduction in energy consumption may be so large that the absolute level of consumption is lowered. This has a positive effect on the economy.

In 2010, NHTSA noted one of the important externalities of reduced consumption, the downward pressure on prices, is a consumption externality. 23 Derived from an auto standard, it provides a comprehensive discussion of the macroeconomic benefits that we find in all efforts to apply these models. 'Lower prices allow for additional purchase of investment goods, which, in turn, lead to a more comprehensive capital stock. These price reductions also allow higher levels of government spending while improving U.S. competitiveness, thus promoting increased exports relative to the growth-driven increase in imports. As a result, GDP is expected to increase because of this rule.24

The EPA reviewed the literature on the macroeconomic impact of reduced energy consumption.25 It ran econometric models driven by pocketbook savings. The analysis models three effects on impacts of the rule that trigger adjustments in the economy – increased cost for vehicles, decreased consumption of gasoline, and a reduction in the price of petroleum. It does not model the impact of reduced pollutants (carbon and non-carbon) or other changes (like reduced fueling time). It found a very substantial multiplier effect increasing the GDP by just under 1 percent, or $340 billion, by 2050. Discounting the incremental growth of the economy at 3 percent, which is the discount rate used as the base case in this paper, the total is just under $100 billion, and it is reached by 2030. This is slightly larger than the total consumer pocketbook savings.

This combination of effects—price increases for vehicles and lower demand and world oil prices—would impact all sectors of the economy that use light-duty vehicles and fuels as intermediate inputs (e.g., delivery vehicles) to produce final goods. Households would also be impacted indirectly as consumers of final goods and directly as consumers of fuels and light-duty vehicles.

However, it is important to note that these potential impacts do not represent additional benefits or costs from the regulation. Instead, they represent the effects on the U.S. economy as its direct benefits and costs are transmitted through changes in prices in the affected markets, including those for vehicles and their components, fuel, and the various resources used to supply them.26

Estimating the Size of the Macroeconomic Benefit

These impacts, as discussed in the EPA memo, are an indirect effect of the rule, a genuine externality. This approach has become quite common with detailed analyses of energy efficiency across a range of activities (autos, appliances, buildings, industries),27 sectors (e.g. energy, manufacturing, service, particularly as it impacts the use of labor),28 and with a variety of analytic approaches (qualitative, econometric).29 These efforts to model the economic impact of energy efficiency have proliferated with different models30 being applied to other geographic units, including states31 and nations.32 The results differ across studies because the models are different, the impact varies according to the size of the geographic unit studied and because the assumptions about the level and cost of energy savings differ. These differences are not an indication that the approach is wrong. On the contrary, all the analyses conclude that there will be increases in economic activity and employment. Given that different regions and different policies are being evaluated, we should expect different results.

The rule of thumb – an approximate doubling of the economic impact – that emerges in the literature reflects the observation on jobs.33 Similarly, in a study of 52 examples of increases in industrial productivity, where the benefit was monetized, the productivity savings were 1.25 times as large as the energy savings.34 Table 6.1 shows examples of the multiplier, with the GDP impact expressed as a multiplier of the value of net pocketbook savings. [EPA-HQ-OAR-2021-0208-0297-A1, pp. 19-22; Table 6.1. can be found at docket number EPA-HQ-OAR-2021-0297-A1, p. 23.]

In this analysis, we take a very cautious approach to estimating the induced macroeconomic benefits of efficiency. We apply the multiplier to 90 percent of the pocketbook savings. The benefits excluded from the multiplier effect (10 percent of pocketbook, other values, such as driving, reduced fueling time, public health, and environmental) are 25 percent larger than the total of the technology costs. This ensures that we do not double count the indirect effect, although that might have an induced multiplier effect of its own.

We also do not include a separate impact of the consumption externality, the effect that U.S. consumption has on lowering the market price of energy. In petroleum, this number is substantial. Agencies have estimated it but have not included it in their cost-benefit analysis. Where they have presented the calculations, it is equal to about one-fifth of what we call the macroeconomic multiplier.35 In the appliance sector, this effect has been modeled by considering the impact of reduced electricity demand on the price of natural gas.36

We do not apply the multiplier to the value of environmental, public health, and other externalities. Although these have been monetized in the traditional cost-benefit analysis, that monetization does not generally include macroeconomic multipliers. Since it could be argued that these costs are reflected in the model coefficients that are a representation of empirically observed real-world relationships, out of an abundance of caution, we do not apply the multiplier to these benefits, which is the traditional approach.

While we have chosen to add the rebound effect back into the pocketbook savings, we do not add it into the macroeconomic effect since the rebound effect spends the money on consumption, meaning no change in the multiplier. To err on the side of caution, we assume the lowest value in the table and set the multiplier equal to the net pocketbook savings. Macroeconomic models measuring the outcome in the change in GDP yield a 're-spending' effect that clusters around 90 percent.37 [EPA-HQ-OAR-2021-0297-A1, p. 22]

Commenter: Consumer Reports (CR)

Model Shortcomings

Consumer Reports recognizes the limited time EPA has had to develop the analysis for this proposal, and that EPA has consequently relied heavily on the models and assumptions developed to support the SAFE rule. However, the use of these models and assumptions results in EPA significantly undercounting the benefits from this proposal. The following sections highlight some of those issues, and provide recommendations on how to improve the analysis to support strong standards. [EPA-HQ-OAR-2021-0208-0602-A1, p.19]

a. Consumer Valuation of Fuel Economy and the Energy Efficiency Gap

Consumer Reports and others have contributed significant input into both the previous regulatory record, and legal record around past rulemakings, regarding the treatment of consumer valuation of fuel economy and the energy efficiency gap. We continue to stand behind the argument that there is a market failure in the automotive market, and that automakers will not deploy cost effective fuel savings technologies that consumers want unless driven to do so by regulations. EPA itself within the RIA concludes that an energy efficiency gap does indeed occur stating: "it appears that markets on their own have not led to adoption of a number of technologies with short payback periods in the absence of the standards."53 [EPA-HQ-OAR-2021-0208-0602-A1, p.19]

EPA also explores if the energy efficiency gap might be caused by low consumer valuation of fuel economy, or as a result of the market and automaker decisions. Consumer Reports has decades of experience doing survey work to understand what consumers want, and we assert that this market failure rests firmly in the hands of automakers.54 The exact reason is unclear to us at this time, but some combination of the potential explanations outlined on pages 8-5 and 8-6 of the RIA is plausible. [EPA-HQ-OAR-2021-0208-0602-A1, p.19]

EPA goes on to state that: "It appears possible that automakers may operate under a different perception of consumer willingness to pay for additional fuel economy than how consumers actually behave."55 Yet despite this statement, EPA uses the same 2.5 year payback period to both estimate consumer valuation of fuel economy in their sales model, and assumes that automakers apply all technology with a payback period of less than 2.5 years within the baseline of their analysis, despite specifically recognizing that automakers have not done this in this in the past. [EPA-HQ-OAR-2021-0208-0602-A1, p.19]

Consumer Reports recommends that EPA appropriately reflect the energy efficiency gap in their future modeling for this and future rulemakings. Although there is uncertainty in the exact numbers with respect to what, if any, technology automakers will deploy in the absence of standards, and the exact amount of fuel savings consumers value, the record and literature clearly show that these values should be very different. EPA should attempt to model automaker behavior based upon their past historical actions with respect to the application of technology within the baseline. EPA should also update their consumer valuation of fuel economy assumptions in their sales model to more appropriately match the literature on consumer willingness to pay. [EPA-HQ-OAR-2021-0208-0602-A1, pp.19-20]

b. Modeling of Off-Cycle Credits

EPA assumes that all automakers apply 15 g/mi of off-cycle credits starting in MY2023 regardless of the cost effectiveness of these technologies relative to other compliance options. EPA also uses an average cost of $78 per g/mi improvement in emissions which seems very high.56 Given that the standards require an average of 49 g/mi in total emissions reductions, complying with entirely off-cycle credits would cost automakers $3,800 per vehicle, while EPA's modeling finds that the average cost of compliance in MY2026 is only $1,044.57 [EPA-HQ-OAR-2021-0208-0602-A1, p.20]

While CR has not directly examined the CAFE model used by EPA directly, a close examination of table 4-16 of the RIA also provides some details as to the impact of these assumptions. Tesla jumps off the page as having compliance costs that average around $390 per vehicle despite being an all-electric vehicle manufacturer that easily complies with the rule with no additional credits. When comparing Telsa's compliance costs with the average automaker compliance cost for MY2026 of $1,044/vehicle we see that they are modeled to be spending 37% as much as the average automaker just to add 5 g/mi of off-cycle credits. While Tesla may indeed make a financial decision to use the off-cycle program to generate additional credits (see section 3.c.iii of this comment for discussion of why EPA should consider not allowing this) to sell to other automakers, they will only do so if they can make a profit doing it. If we assume that all automakers are modeled to be spending a similar amount on off-cycle credits, this implies that the average automaker is spending 37% of their compliance budget on 5 g/mi of improved performance and 63% of their compliance budget on an average of 44 g/mi of improved performance. While the presence of Automakers who agreed to the California framework agreement complicates this analysis, and it is not perfect for that reason, it is nonetheless clear that assumptions surrounding off-cycle credits are having a significant effect on the cost analysis in ways that imply completely irrational behavior by automakers. Either off-cycle credits have significantly lower costs to automakers than assumed by EPA, or automakers will choose other compliance pathways that avoid using these expensive credits. [EPA-HQ-OAR-2021-0208-0602-A1,p.20]

The most obvious way to address this modeling issue would be to simply not expand the off-cycle credit limit to 15 g/mi as Consumer Reports has recommended in section 3.c.iii. However, if EPA does continue to include expanded off-cycle credits, they should do significant modeling sensitivities around their assumptions related to these credits and their effect on the overall cost-benefit analysis. [EPA-HQ-OAR-2021-0208-0602-A1,p.21]

c. Battery Costs

EPA notes that: "The battery costs used in the SAFE FRM were considered too high by EPA. However, given that significant levels of vehicle electrification will not be necessary in order to comply with the proposed standards (past analyses by EPA have estimated BEV penetrations of less than 5 percent, in general), we did not consider updating vehicle electrification costs to be of paramount importance for this proposal, although we may update battery and other vehicle electrification costs for the final rule." Consumer Reports recommends that EPA update their battery costs to be more in line with the current state of the electric vehicle market. This has the potential to have a significant impact on the cost-benefit analysis of the rule, especially with regards to the ability for EPA to push further, and set a stronger standard than the preferred alternative that is more in line with the administration's climate commitments. [EPA-HQ-OAR-2021-0208-0602-A1, p.21]

d. Maintenance and Repair Costs

EPA has not historically quantified the change in maintenance and repair costs from changes in the vehicle fleet driven by greenhouse gas standards. However, the growing percentages of battery electric and plug-in hybrid vehicles in the fleet means that strong standards are likely to contribute significant consumer savings in the form of reduced repair and maintenance costs. Two recent studies, one by Consumer Reports,58 and one by Argonne National Laboratory,59 have attempted to quantify the change in maintenance and repair costs for vehicles with different powertrains. Although both studies use different methods, and place slightly different numbers on the specific costs, they both come to the same general conclusion that vehicles with electrified powertrains are likely to provide significant lifetime consumer savings from lower maintenance and repair spending. Consumer reports for example concludes that both BEVs and PHEVs are estimated to save $4,600 over the lifetime of a vehicle when discounted to the present value at the time of purchase, with a discount rate of 3%. Applying these savings to the preferred alternative, which EPA's modeling estimates includes 7.8% EVs, would result in over $5B of additional present value consumer benefits for MY2026 alone. Given the magnitude of these benefits, and the inevitable growth in electrification of the fleet, it is imperative that EPA capture this important consumer benefit in their cost benefit analysis. [EPA-HQ-OAR-2021-0208-0602-A1, pp.21-22]

e. Use of AEO2021 energy prices

While the use of energy price data from the DOE's Energy Information Agency's (EIA) Annual Energy Outlook (AEO) in cost-benefit analysis is standard practice, 2020 was an extreme outlier given the COVID-19 pandemic. Because of this, EIA's AEO2021 is heavily influenced by this outlier event which shut down the entire global economy and crashed energy prices. However, energy prices have rebounded sharply as demand has recovered quicker than supply. The result is that current gasoline prices are now much much higher than the AEO projections, and in fact AEO2021 projects that gasoline prices won't even reach their current levels of $3.19 a gallon60 until 2044. One possible solution is that EPA could instead use energy prices from EIA's AEO2020 which was performed prior to the pandemic. Although the prices projected in AEO2020 are still well below current gasoline prices, they are at least closer. At a minimum EPA should acknowledge that the use of these energy price projections developed in the middle of a pandemic causes them to likely underestimate future consumer savings from this rule. [EPA-HQ-OAR-2021-0208-0602-A1, p.22]

Commenter: DENSO International America, Inc. (DENSO)

Updated GREEN-MAC-LCCP Model

DENSO requests EPA to consider updating their modeling with the updated IMAC-GHG-LCCP. Because the GREEN-MAC-LCCP has been updated recently by SAE CRP, and developed into IMAC-GHG-LCCP, leading to the notable change of higher occurrence of warmer days across US. Therefore, CO2 reduction benefits of the related cooling technologies compared with baseline systems may be affected by the IMAC-GHG LCCP. [EPA-HQ-OAR-2021-0208-0282-A1, p. 7]

Commenter: Environmental Defense Fund (EDF)

III. EPA's own analytical tools confirm the feasibility and cost effectiveness of the MY2023-26 standards EPA utilized NHTSA's CAFE model to project the costs and benefits of its Proposed Standards. EDF previously filed comments describing the tendency of this model to over-estimate compliance costs and under-estimate benefits.46 [EPA-HQ-OAR-2021-0208-0688-A1, p. 24]

As discussed in more detail and shown in table 8, below, using the technology costs and effectiveness contained in the version of OMEGA (v.1.4.56) used in EPA's mid-term review of the MY 2022-2025 standards conducted in 2016-201747 (PD OMEGA) and the more recent version of OMEGA (v.1.4.59) that EPA provided to EDF as required by the Freedom of Information Act (FOIA OMEGA), see NRDC v. EPA, 954 F.3d 150 (2d Cir. 2020), the OMEGA model projects compliance costs per vehicle $173-$259 lower than the CAFE model on a common fleetwide basis. Incorporating estimates of technology costs and effectiveness from the International Council on Clean Transportation (ICCT) into PD OMEGA further reduces pervehicle costs by $434-$574. As discussed further below, the two versions of the OMEGA model available include a maximum of only 3 g/mi off-cycle credits. OMEGA's cost per g/mi reduction of off-cycle controls is only two-thirds of the cost per g/mi reduction that EPA assumed in its recent Proposal. In the modeling runs we conducted, and which are described below, OMEGA projects that only 10 percent of industry-wide new vehicle sales will achieve the full 3 g/mi reduction using off-cycle technologies. At the same time, manufacturers have already added 5 g/mi of off-cycle controls to their cars and 10 g/mi to their trucks, per EPA's 2020

Automotive Trends Report. This indicates that these off-cycle controls are readily applicable and of low cost. While the level of off-cycle technology assumed by EPA in its CAFE modeling is reasonable, its assumed cost is out of proportion to the cost of 2-cycle emission control technologies.48 This resulted in EPA projecting compliance costs that are inaccurately high. Because of the interaction between compliance costs and vehicle sales in the CAFE model, this error affects sales, as well.

EPA's assumption that non-Framework manufacturers will apply 10 g/mi off-cycle controls under the 2020 Rule at a cost of $706 inflates total compliance costs by over $400 per vehicle. The assumption that (1) automakers that executed agreements with California and (2) all manufacturers under the Proposal would apply 15 g/mi off-cycle controls at a cost of $1143 inflates total compliance costs by $500 per vehicle using EPA's technology costs and $700 per vehicle using ICCT's technology costs and effectiveness.49 This impact is greater when using ICCT technology costs and effectiveness because the difference between these lower ICCT costs and the unreasonably high EPA costs for off-cycle control is greater. [EPA-HQ-OAR-2021-0208-0688-A1, p. 25]

In EPA's 2016 Draft Technical Assessment Report (EPA-420-D-16-900) and Proposed Determination on the Appropriateness of the Model Year 2022-2025 Light-Duty Vehicle Greenhouse Gas Emissions Standards under the Midterm Evaluation (EPA-420-R-16-020) ("Proposed Determination"), EPA premised off-cycle control costs on the cost of 2-cycle tailpipe CO2 controls on the assumption that off-cycle controls would be cost-competitive since manufacturers were requesting the ability to apply these controls. The off-cycle control costs EPA assumed for this Proposal are clearly not consistent with this approach. We conclude that EPA should decrease its estimated cost of off-cycle controls to reflect manufacturers' use of these controls through MY 2020 and confirm that the results of CAFE modeling are consistent with this use. [EPA-HQ-OAR-2021-0208-0688-A1, p. 26]

Modeling conducted with each version of the model supports our primary conclusion that the CAFE model EPA used to assess its proposed GHG standards significantly over-estimates the cost of compliance with those standards. [EPA-HQ-OAR-2021-0208-0688-A1, p. 27]

Cases

The reference case for our analyses is a combination of the 2020 Rule standards and the voluntary GHG emissions reductions reflected in the California Framework Agreements. The latter applies to five manufacturers which have signed an Agreement: BMW, Ford, Honda, Volkswagen and Volvo. The 2020 Rule standards apply to the remaining manufacturers. These inputs are the same as those modeled by EPA in its CAFE model runs. The technology cost for the combination of the 2020 Rule's standards and the Framework emissions reductions was determined using the same approach taken by EPA. The total annual cost of the 2020 Rule's standards for the non-Framework manufacturers was added to that of the California Framework emissions reductions for the Framework manufacturers and divided by total vehicle sales.

We also project the total technology costs for two sets of “control” scenarios. The first is EPA’s proposed GHG standards. The incremental technology cost for EPA’s proposed GHG standards is the total cost less the cost of manufacturers meeting the combination of the 2020 Rule’s standards and the emissions reductions achieved due to the California Framework.

The second control scenario is EPA’s MY 2026 alternative that is 10 g/mi more stringent than the proposed MY 2026 standard. While EPA did not report along with the Proposal a separate evaluation of the costs and benefits of this alternative, we modeled this alternative as consisting of increasing the stringency of the Proposed Standards for MY 2026 by 10 g/mi for both cars and trucks across the full range of footprint values. [EPA-HQ-OAR-2021-0208-0688-A1, p. 27]

The second approach includes this 3 g/mi off-cycle control internal to OMEGA and adds 7-12 g/mi off-cycle control outside of the OMEGA model runs, at a cost of $76 per g/mi off-cycle control (the cost per g/mi used by EPA in this Proposal). In this second approach, the 2020 Rule’s GHG standards are numerically relaxed by 7 g/mi and a cost of $534 added to the OMEGA-projected cost to reach the total technology cost for the 2020 Rule’s GHG standards. Similarly, EPA’s proposed GHG standards and the emissions reductions required by the California Framework Agreements are numerically relaxed by 12 g/mi and a cost of $916 added to the OMEGA-projected cost to reach the total technology cost for the 2020 Rule’s GHG standards. This second approach is analogous to the approach embedded in the CAFE model used by EPA in this Proposal. The level and cost for off-cycle controls is specified in the model’s input files and applied prior to any additional technology needed to meet the GHG standards. Using this approach, EPA’s Proposal adds 15 g/mi off-cycle controls at a cost of $1145 per vehicle in MY 2026. [EPA-HQ-OAR-2021-0208-0688-A1, p. 28]

Proposal Cost Findings

EDF used three sets of technology costs for the reference case and the two control scenarios:

1) PD OMEGA with EPA technology costs and effectiveness

2) PD OMEGA with ICCT technology cost and effectiveness adjustments, and

3) FOIA OMEGA with EPA technology costs and effectiveness

The incremental cost of the Proposal is compared to that estimated by EPA using the CAFE model with 15 g/mi of external off-cycle emission control. As we did not include the effect of the advanced technology vehicle multipliers in our OMEGA modeling, we show EPA’s projected costs also with no multipliers. However, had we included these multipliers, projected costs would be lower.

The incremental cost of the 10 g/mi alternative is compared to the cost for the reference case and the Proposal, as EPA did not project the impact of the 10 g/mi alternative on technology costs. [EPA-HQ-OAR-2021-0208-0688-A1, p. 28]

This OMEGA analysis shows that the CAFE model greatly over-estimates the technology costs of the Proposal. This supports the feasibility of the EPA standards as the OMEGA model projects technology costs are far less than estimated by EPA in the Proposal. EPA should recognize that the CAFE Model greatly over-estimates compliance costs when projecting technology costs for the final rule. [EPA-HQ-OAR-2021-0208-0688-A1, p. 30]

Commenter: Kreucher, Walter

CAFE IS NO LONGER AN EFFECTIVE POLICY TOOL

In all the cases the Agencies evaluated in the notice of proposed rulemaking, the predicted fleet average fuel economy continues to increase by 17 – 22 miles per gallon above the standard (or in the case of CO2 by 40 to 50 grams per mile below the 2026 standard) without any increase in stringency beyond the 2026 Model Year standards. Thus, we are led to the conclusion that either the assumptions the Agencies makes are wildly optimistic, and thus arbitrary and capricious, OR the need for CAFE standards is obviated by the low cost of technology, high fuel prices, and strong consumer demand for energy efficient vehicles. If the latter is the case, CAFE is no longer an effective policy tool and the statutory standards laid down in EISA are sufficient going forward. If the former is true the rule must be withdrawn in its entirety. THE EPA BASES ITS CO2 TAILPIPE STANDARDS ON MARKET PENETRATION OF ZEVS Both the EPA Greenhouse Gas proposal and the NHTSA CAFE proposal rely on the current market penetration of electric vehicles which both agencies acknowledge are driven by state mandates. Further, as pointed out in the Regulatory Impact Analysis, there will be a de minimus impact on climate as a result of the proposals. [EPA-HQ-OAR-2021-0208-0199-A1, p. 2]

ELECTRIC VEHICLES ARE MORE COSTLY THAN THE AGENCIES PREDICT

NHTSA claims that the ‘analysis projects continued cost learning over time and shows battery electric vehicles reaching price parity with conventional vehicles in the 2030s for most market segments – after which market adoption of BEVs accelerates – although other estimates show price parity occurring sooner.’8 This assumption is arbitrary and capricious. The 2021 Model Year9 EPA/NHTSA Fuel Economy Guide contains information on twentythree battery electric vehicles. None of the battery electric vehicles saved the customer money using the methodology employed by the National Highway Traffic Safety Administration and EPA for calculating the cost and benefits10 of technology. Based on MSRPs, the average net cost premium for an electric vehicle was $22,400 MORE than its gasoline counterpart11.

THE DRIVING RANGE FOR AN ELECTRIC VEHICLE IS LOWER THAN PREDICTED BY THE AGENCIES

The EPA reports the estimated driving range for electric vehicles. These estimates should be viewed with caution as they represent the maximum driving range under ideal condition of 72°F with all accessories including the heater and the air conditioning system in the off position.

AAA published a study12 where they tested six electric vehicles at 20° with the heater turned on.

• The range decreased by an average of 42% compared to the range listed in the EPA mileage guide.

• AAA tested the vehicles at 95° with the air conditioning turned on. The range decreased by an average of 39%.

• AAA tested the vehicles under normal acceleration rates and driving speeds. The driving range decreased by an average of 51%.

Further, electric vehicle manufacturers recommend charging their vehicles to only 80% of capacity13 to avoid the risk of battery fire. This reduces the driving range even further.

THE AGENCIES HAVE CORRUPTED THE INTENT OF CAFE

Based on published EPA information14, Tesla is credited with a CAFE fuel economy of 763 miles per gallon equivalent for its passenger car fleet in 2019 and 445 miles per gallon equivalent for its light truck fleet. This allows Tesla to generate OVER $67 billion in CAFE credits since 2017. Tesla generated more CAFE credits in 2019 than it earned in revenue selling its vehicles.

One might congratulate Tesla for its benevolence in generating these credits.

HOWEVER, one must take a closer look at what this actually means. The CAFE MPG established by EPA equates to an eye-popping on-road driving range of over 2200 miles. Even the Agency does not believe their own CAFE numbers because they say in their Mileage Guide owners can expect about 330 miles on a full charge (average of all Tesla models for the 2021 model year). AAA, in their 2019 study, says this range is closer to 200 miles on a full charge (165 miles at 80% charge) under typical driving conditions. Thus, the real-world on-road driving range is less than 7% of the range granted Tesla for CAFE purposes.

EPA manipulates the CAFE values for electric vehicles by assuming the 0.1515 petroleum equivalence factor applies to electric vehicles plus the Agency factors in additional credits for air conditioning efficiency and off-cycle operation. The Agency has done this in an arbitrary and capricious manner that is not grounded in reality to promote a costly technology.

It should be noted that the CAFE Model uses a much lower fuel economy for electric vehicles thus artificially increasing the benefits to air quality and other societal benefits by requiring additional electric vehicles.

The Agencies further propose in the rulemaking to modify these generous credits to add a vehicle multiplier for EVs and FCVs. Under the proposal, each vehicle counts as 2.0 for MYs 2022-2024, and 1.75 for MY 2025, subject to a cap on all vehicle multipliers. A clear indication that even they do not think the standards are achievable. [EPA-HQ-OAR-2021-0208-0199-A1, pp. 6-7]

THE PREDICTED FUEL SAVINGS WILL NOT OCCUR NOR WILL THE REDUCTIONS IN EMISSIONS

The Agencies predicts a modest drop in fuel usage and emissions as a result of the proposal. In reality none of this will occur. Because of the ‘Tesla-like’ CAFE fuel economies EPA arbitrarily assigns to electric vehicles AND the Agency proposed multipliers to EV sales, only a relatively small (less than 10% of what is predicted by the analysis) handful of costly, electric vehicles will be necessary to meet the proposed standards. Mitsubishi will need to produce less than 1000 battery-electric vehicles (BEVs) to meet the 2026 Model Year standard. Many manufacturers will have met these goals in 2021 under the current rules. [EPA-HQ-OAR-2021-0208-0199-A1, p. 8]

Commenter: Michalek, Jeremy and Whitefoot, Kate S.

Benefit-cost analysis: EPA analyzes three alternative options for rules and estimates their costs and benefits but then selects a proposed rule that has lower net benefits than one of its alternatives. We discuss concerns with this choice and recommend that EPA choose the option with the highest estimated net benefits. [EPA-HQ-OAR-2021-0208-0300-A1, p. 2]

Modeling vehicle scrappage effects: EPA is adopting the model of vehicle scrappage effects used in the SAFE rule’s FRIA in the new proposed rule to estimate the effects of the policy on externalities via induced changes in used vehicle scrappage rates. We provide a working paper summarizing an empirical analysis that we are conducting that is able to reject some of the assumptions made in the prior literature and in the SAFE PRIA and FRIA, and we provide recommendations for the range of assumptions that appear to be consistent with empirical evidence. [EPA-HQ-OAR-2021-0208-0300-A1, p. 3]

Vehicle Scrappage

EPA’s PRIA for the proposed rule considers effects that the regulation of new vehicles may have on the scrappage of used vehicles as well as resulting effects on vehicle miles traveled and associated externalities. EPA has chosen to use a model from the final regulatory impact assessment of the SAFE rule. The SAFE FRIA used a scrappage model that was substantially modified after extensive criticism of assumptions made in the SAFE PRIA.

‘Note that the scrappage model received many negative comments following the SAFE NPRM, but the FRM version of he model incorporated changes such that it no longer generates the inexplicable sales and VMT results of the NPRM version’ (PRIA p 5-10)

EPA notes in the PRIA for 2023 and later model years that

‘EPA’s project to review new vehicle demand elasticities is also reviewing the literature on the relationship between new and used vehicle markets and scrappage.’

To support this review, we are attaching a working paper from Carnegie Mellon researchers Connor Forsythe, Akshaya Jha, Jeremy Michalek and Kate Whitefoot investigating the externality implications of the scrappage effect of policies like the LDV standards by empirically identifying the effect of policy-induced changes in fleet size on fleet travel distance and highway gasoline consumption. Figure 1 from that paper is shown below. [Working Paper can be found at docket number EPA-HQ-OAR-2021-0208-0300-A2, and Figure 1 can be found at OAR-2021-0208-0300-A1, p. 10]

Economic theory, originally proposed by Gruenspecht (1982) and others suggests that regulation of new vehicles can put upward pressure on new vehicle prices, which puts upward pressure on used vehicle prices, because they are (imperfect) substitutes. Increased used vehicle prices may lead owners with vehicles near the point of scrappage to sell, rather than scrap, those vehicles, keeping them on the road longer. More vehicles on the road may result in more vehicle travel, which has associated externalities, including air emissions, congestion, crashes, and noise. Prior work has found empirical evidence of all of the elements of this effect linking new vehicle regulation to travel-related externalities except for the effect of vehicle scrappage on fleet travel and fuel use (Figure 1).

In lieu of empirical evidence for this link in the chain, modelers in the academic literature and in government, including EPA's SAFE PRIA, typically make the assumption that vehicle travel is attached to the vehicle, so that if a vehicle is scrapped the travel associated with that vehicle will disappear, rather than shift to other vehicles or modes. Our study tests this assumption by leveraging the staggered removal of safety inspection requirements across US states as an instrument to identify the effect of policy-induced changes in fleet size on fleet-wide travel distance and fleet-wide fuel consumption. We find that removal of safety inspections in US states increased fleet size by 3-4%, on average, and we use that change in fleet size to identify the effect of fleet size on fleet travel distance and highway gasoline consumption. Though our estimates contain uncertainty, we are nevertheless able to reject several assumptions made in the SAFE PRIA and FRIA as well as the academic literature.

Figure 4 summarizes our preliminary empirical findings in relation to assumptions made in the academic literature and in regulatory impact assessments. These results reject the assumptions made in the SAFE PRIA as well as the gasoline consumption assumptions made in the SAFE FRIA, which are being used in the current proposed rule. Potential reasons that these prior assumptions are not consistent with our empirical findings include (1) when vehicles are scrapped, travelers may shift some of their travel needs to other vehicles and/or (2) vehicles selected for scrappage due to policy changes are systematically different from other vehicles of the same age and class (e.g.: driven less frequently). [Figure 4 can be found at docket number EPA-HQ-OAR-2021-0208-0300-A1, p.12]

We cannot reject the assumption in the SAFE FRIA, adopted in the proposed rule, that changes in fleet size have no non-rebound effect on fleet-wide travel distance. However, we do not endorse the assumptions in the SAFE FRIA and the proposed rule because the assumptions lack grounding in theory or evidence and have some implications that are difficult to defend. The SAFE FRIA assumes that non-rebound fleet VMT is constant regardless of fleet size, which can lead to implausible predictions of VMT per vehicle when fleet size changes substantially. The FRIA assumptions appear to be an attempt to patch the issues with the SAFE PRIA and avoid the implausible predictions about fleet VMT implied by that model, but this patch makes its own assumptions about VMT that are difficult to justify and have questionable implications.

Given our findings, we recommend that EPA's regulatory impact assessment consider a range of potential assumptions for the effect of policy-induced changes of fleet size on fleet travel distance, fleet gasoline consumption, and associated externalities. On the low end, our analysis cannot reject the possibility that policy-induced vehicle scrappage delay has no effect or a negative effect on fleet travel and gasoline consumption, though we expect the effect is likely nonnegative in practice, so using a lower bound of zero for sensitivity analysis may be reasonable. On the high end, our analysis does reject common assumptions that the travel associated with vehicles scrapped early is foregone when the vehicle is scrapped. It appears that at least some of the associated travel likely shifts to other vehicles in the fleet, and our analysis cannot reject elasticities up to 0.64 for fleet travel distance and 0.33 for highway gasoline consumption, so these may serve as reasonable upper bounds for sensitivity analysis. [EPA-HQ-OAR-2021-0208-0300-A1, pp. 10-12]

Distinguishing between transfers and costs

EPA should appropriately account for transfers between manufacturers and suppliers within the cost-benefit analysis. Some of the costs incurred by manufacturers in response to the regulations are transfers between manufacturers and suppliers. Specifically, a portion of profit losses by manufacturers due to higher vehicle component costs may be realized as profit gains by their suppliers. Historically, EPA's cost-benefit analysis has treated these transfers as regulatory compliance costs on the automotive industry, which effectively ignores suppliers altogether in the cost-benefit analysis. While we believe that EPA should consider the feasibility and economic costs of the regulation on manufacturers when setting the standards, transfers within the automotive industry (such as transfers between manufacturers or transfers between manufacturers and suppliers) should not be treated as costs for the purpose of calculating the net benefits of the regulations. [EPA-HQ-OAR-2021-0208-0300-A1, p. 5]

Omitting regulatory flexibilities from the cost-benefit analysis

When evaluating the costs and benefits of the regulations and alternative options, EPA should consider all provisions of flexibilities available to manufacturers, including off-cycle, averaging, banking, and trading of credits. NHTSA was prohibited by Congress from considering certain credits in their cost-benefit analysis, such as off-cycle credits and trading credits across manufacturers. However, EPA is not subject to these restrictions. Ignoring these flexibilities overestimates the compliance costs of the regulations and presents a distorted picture of which regulatory alternative has the highest net benefits. The cost-benefit analysis should represent the proposed regulation and alternatives as accurately as possible and therefore should include all credit provisions. [EPA-HQ-OAR-2021-0208-0300-A1, p. 6]

Commenter: National Coalition for Advanced Transportation (NCAT)

Modeling inputs relating to electric vehicles tend to underestimate electric vehicle penetration and overestimate electric vehicle cost:

As explained in the Proposed Rule, EPA chose to continue to use certain model inputs from the modeling conducted several years ago for the 2020 Rule, including the continued use of MY 2017 as the base year fleet and use of the electric vehicle battery cost data from the 2020 Rule modeling effort.156 However, electric vehicle penetration has grown significantly since that time, see Section IV, A above, and battery costs have continued to decline dramatically, see id. EPA even acknowledged that the agency may consider updating the battery costs for the final rule, noting that EPA's latest assessment suggests they could have been lower. 157 There was a 13% drop in electric vehicle battery cost in just 2020 alone.158 EPA's approach was very conservative in light of these older model inputs relating to electric vehicles. [EPA-HQ-OAR-2021-0208-0239-A1, p. 23]

Commenter: Peterson, Doug

The cost benefit analysis itself is hopelessly flawed, greatly underestimating the benefits of climate mitigation by ignoring benefits that are outside the realm of quantification. How are we to assign monetary value to the extinction of countless animal species? What is the dollar amount associated with the pain a family feels when their loved ones die in a wildfire, or drown in the basement of their flooded apartment? With so much uncertainty about the extent of the misery that climate change will inflict on future generations, and how long that misery will endure, how are we to quantify their future misery and include it in our so-called cost benefit analysis? The people who will suffer the most from climate change have yet to be born, and they have no way of participating in this rulemaking process. Their valid arguments, and those of innocent wildlife, can only be voiced by advocates like myself, and I protest in the strongest terms that the undeniable value of their well-being has been excluded from the EPA's cost benefit analysis. The limitation of the analysis to the historical period that ends in 2050 is an obvious flaw, ignoring the well-established scientific view that the severest harms of climate change will endure well beyond that date, perhaps for centuries. The geographic limitation of the analysis is also a central flaw; the analysis is restricted to U.S. costs and benefits. But the harms generated by our carbon dioxide are projected beyond our national borders, causing severe harms to innocent, vulnerable foreigners, many of whom have very small carbon footprints. From a moral standpoint, the cost benefit analysis has no validity whatsoever, greatly underestimating the large, unquantifiable benefits of climate change mitigation.

Perhaps the greatest unquantifiable element left out of the EPA's invalid utilitarian calculus is the staggering weight of our nation's moral indifference. The cost benefit analysis ignores the profound harm caused by our unwillingness to fulfill our obligations under the Paris Climate Agreement. The international effort to defeat climate change can only succeed if we can build trust with the international community, convincing other nations that we finally intend to contribute our fair share 5 to the global effort, that the unprecedented tragedy of the commons currently taking place is one that we acknowledge and abhor. The notion that our nation is leading the global effort against climate change borders on being delusional; we have been dragging our heals. If the world looks to the United States and sees that we still have no intention of surrendering one iota of comfort and convenience, all hope is lost. The EPA's cost benefit analysis places no value on that loss, and I reject it out of hand for its simplemindedness, an immoral manifestation of our habitual scientism. The well being of planetary life is beyond quantification; it is priceless. The Clean Air Act was signed into law as an expression of our nation's collective belief that our shared environment is extraordinarily precious, and the EPA fails to implement the will of the American people when it sidelines its core mission in deference to immediate economic concerns. The only way for the EPA to adequately regulate carbon dioxide is to enforce an effective regulatory framework that quickly achieves real reductions that are visibly significant in the eyes of the international community. If unquantifiable benefits that our society values were somehow monetized and included in the cost benefit analysis, and the analysis was revised to include future benefits beyond 2050, and the analysis included benefits accruing to people outside our national boundaries, the benefits would increase by many orders of magnitude, dwarfing the upfront costs. But they cannot be monetized, and the cost benefit analysis is poppycock. This kind of quantitative analysis is entirely inappropriate for assessing the efficacy of any climate change mitigation strategy because it excludes significant, valuable benefits that cannot be quantified. It is also a very poor tool for balancing tangential concerns outlined in the Clean Air Act with the EPA's core mission. By excluding benefits that are unquantifiable, cost benefit analysis systematically devalues benefits that are at the very heart of environmental preservation while overvaluing immediate economic concerns. It is inherently invalid and misleading, warping the EPA's view of its priorities. A more compassionate, comprehensive analysis that acknowledges the real limitations of quantitative accounting leads to the conclusion that the immeasurable benefits of restraining tailpipe carbon dioxide far outweigh the precise costs. [EPA-HQ-OAR-2021-0208-0692-A1, p. 4-5]

Commenter: Rivian Automotive, LLC

Reevaluate Baseline Market Expectations

EPA's calculations are built upon outdated baseline market data. Specifically, EPA used the MY 2017 base year fleet, a baseline that remains unchanged from the analysis underpinning the SAFE Rule. The agency states that the vintage of the base year will "not normally have a significant impact" but that certain broad shifts in the market, such as in the average vehicle power-to-weight ratio, can affect the incremental costeffectiveness of technology application in the modeling.13 Rivian questions whether the significant growth in the BEV market in the later years of the last decade—a trend that would not be visible in the MY 2017 data—would not also constitute a "broad market shift" and thus have impacts on the model runs that ought to be reflected. For example, could greater BEV volumes in the base year fleet affect credit-trading and technology application decisions in the model? If nothing else, greater BEV volumes in the base year fleet would imply greater growth potential and higher penetrations of this technology by the end of the regulation window and could support greater stringency than the agency currently proposes. While we understand that this proposal was developed on an expedited timeline, rulemaking documents acknowledge that finalized compliance data through MY 2019 was available during the analysis and development phase. We encourage incorporation of the most recent base year data for the final rule in accordance with typical practice. 14

The agency also appears to assume a 50/50 car/truck market share split despite the overwhelming popularity of trucks in the current market.15 In fact, EPA's own reporting of actual market data shows that trucks had already achieved a 60 percent market share by MY 2019 and this has only continued to climb.16 Assuming a 50/50 split nonetheless would have the effect of unreasonably overweighting cars in the calculation of projected fleet average compliance targets, potentially overstating those targets and thus the rule's final benefit. 17 EPA should clarify the market share split it assumes in its calculations and better convey its rationale. [EPA-HQ-OAR-2021-0208-0274-A1, p. 5-6]

Commenter: Toyota Motor North America, Inc. (Toyota)

EPA has Overestimated the GHG Performance from ICEs

Toyota has provided extensive information, in public comments and under CBI, on the effectiveness of CO2 reduction technologies including those for advanced gasoline engines.2 The data has consistently documented that even advanced ICE-only powertrains will fall short of the proposed standards and that while future advancements are possible, a point of diminishing returns is in part driving the transition to electrified powertrains, including conventional hybrids. EPA notes manufacturer plans and announcements of "a rapidly growing shift in investment away from internal-combustion technologies and toward high levels of electrification".3

EPA projects roughly 87 percent of the 2026 model year fleet will continue to be conventional gasoline powertrains. We are confused by EPA's statement that "the standards can be met largely with the kinds of advanced gasoline vehicle technologies already in place in vehicles within today's new vehicle fleet …". 4

This position is at odds with findings from the most recent evaluation of U.S. fleet performance conducted by IHS Markit using manufacturer-supplied data. This baseline study assessed the percentage of 2020 model year vehicles capable of meeting the proposed GHG standards. As Figure 1 illustrates, only electrified powertrains (HEV, PHEV, BEV and FCEV) can attain the proposed targets for the 2024 model year and later passenger cars and 2025 MY and later light trucks. Most gasoline engine technologies modeled by EPA are already being used in the 2020 model year fleet. A more widespread adoption of top-performing gasoline engine technologies through 2026 model year will not result in fleet compliance. [EPA-HQ-OAR-2021-0208-0531-A1, p. 4] [Figure 1 can be found on p. 4 of Docket number EPA-HQ-OAR-2021-0208-0531-A1]

Modeling Assumptions Are Critical

The performance discrepancy is due to overly optimistic technology effectiveness assumptions and a reliance on unproven technologies being added to an older baseline fleet. For example, HCR2 Atkinson engine technology has returned to EPA's compliance modeling. 5 EPA now defines HCR2 as "the addition of dynamic cylinder deactivation and cooled EGR within nonHEV Atkinson Cycle engine applications".6 However, the cost, technology effectiveness, and underlying engine map used for modeling HCR2 technology appears identical to that used for the SAFE 2 Final Rule which is represented by the simulated and experimental effectiveness of the 2014 2.0L SKYACTIV engine with the addition of cooled Exhaust Gas Recirculation (cEGR), 14:1 compression ratio (CR), and cylinder deactivation. 7,8 There is still no U.S. production vehicle that incorporates this definition of HCR2 technology because the 14:1 CR requires higher octane than currently available in U.S. regular grade gasoline. Further, there are more cost-effective pathways than combining cylinder deactivation with Atkinson cycle engines which have inherently low pumping loss characteristics.

EPA compliance modeling applies HCR2 engine technology to over 40 percent of Toyota's fleet by 2026 model year. For example, Camry receives HCR2 along with engine friction reduction (EFR) in 2024 model year. The resulting 51.7 mpg fuel economy is about a 9% improvement over Toyota's current generation Camry powered by a 2.5L Atkinson engine which has a worldbest 40% thermal efficiency.9 The modeled CO2 and fuel economy are closer to hybrid Camry performance and are unreasonably large for the technologies involved. First, cylinder deactivation is the only practical distinction between HCR2 and Toyota's 2.5L Dynamic Force Atkinson engine. NHTSA's evaluation has determined applying only cylinder deactivation to Atkinson cycle engines (HCR1) nets an incremental improvement of roughly 2 percent. 10 Second, the 2.5L Dynamic Force engine already encompasses EFR as explained in past comments under CBI. 11 Finally, IACC and EFR benefits appear to be double counted on top of ERF already being included in the Camry 2.5L Atkinson engine. This is because IACC and EFR are both fully included in the simulated HCR2 engine map, yet both technologies are added again in the CAFE Model runs.

EPA modeling sequentially adds enhanced technology to a 2017 baseline fleet until compliance with the proposed standards is achieved. The 2017 model year fleet is outdated because it fails to capture more recent state-of-the-art technologies in the U.S. fleet and requires the CO2 reduction effectiveness of those technologies to be assumed or simulated. An example is Toyota's 2.5L Atkinson engine technology which has been in the market since 2018 model year. The Camry example above could largely be avoided using a more recent baseline. A 2020 model year baseline fleet is more appropriate and provides a more accurate performance assessment, and with fewer product redesign cycles available, there is less chance for technology effectiveness errors to propagate through the fleet. The 2017 baseline has resulted in more Atkinson technology being assumed in the 2018 through 2021 model year fleets than really exists in the market. 12 The Focus is on Successful Outcomes Pointing out these ICE limitations in no way diminishes Toyota's general support for the proposed standards, but rather is intended to stress that compliance will require a more substantive shift to electrified powertrains, including conventional hybrids. We need to begin working together now to chart a path for near-term market readiness and growth of electrified powertrains. [EPA-HQ-OAR-2021-0208-0531-A1, p. 5-7]

Commenter: Union of Concerned Scientists (UCS)

Modeling future compliance with limited lead-time

Modeling assumptions

It is likely that manufacturers have product plans in motion that are built largely around achieving the standards set in 2012. In that case, lead-time is not an issue at all—industry will have been preparing for compliance with standards already that are stronger than the agency's proposal. And in fact, this may be exactly what market analysis of those product plans indicates (§ I.a.).

However, a more conservative assumption is to assume that manufacturers have responded to the weakened rules. One subset of manufacturers entered a voluntary framework with the state of California in order to provide more long-term certainty so they could plan investments accordingly ('Framework OEMs'), while another subset of manufacturers responded to the short-term incentives of the severely weakened rule and would have put planned investments on hold ('SAFE OEMs'). A conservative assessment of manufacturer flexibility would be to assume the same 18-month lead-time requirement from NHTSA's CAFE regulation.18 This is conservative because if manufacturers have already responded in MY2021 to a rule finalized in March 2020, that is a much faster timeline and would suggest that manufacturers could respond to a rule finalized in December 2021 by MY2023 at the latest. However, by adopting the conservative 18-month assessment of lead-time, we assume that if EPA's rule is finalized by the end of the year, manufacturers' product plans for MY2023 would not be able to be affected, while MY2024 could be.

The modeling behind the scenarios below is described in greater detail in Appendix A [Appendix A can be found at docket number EPA-HQ-OAR-2021-0208-0277-A1, pp. 41-57] One key factor in our modeling is that, unlike the Volpe model used by EPA, the algorithm underpinning manufacturer compliance in our modeling prefers for manufacturers to utilize banked credits before adding any additional technology, and manufacturers can purchase credits from any manufacturer with a lower marginal cost of compliance. For this set of runs assessing the question of lead-time, we simulated manufacturer compliance beyond MY2020 starting from finalized data on credits through MY2019 and used mid-model year data to represent the MY2020 fleet, correcting for actual fleetwide sales volumes. Compliance was then projected forward under the assumption that Framework OEMs had planned to comply with the voluntary agreements through MY2023, while SAFE OEMs had planned to comply with the SAFE rule through MY2023. Then, in MY2024 (as in all Volpe modeling), new technologies may only be applied to the portion of the fleet that is designated by Volpe for a refresh or redesign cycle in that Model Year. Notably the redesign cycles identified in the Volpe model inputs are generally slower than the rate anticipated in Murphy 2021.

Owing to the large credit banks manufacturers would seek to maximize the utilization of in any scenario, which can only be applied towards fleet debits, OEMs generally have greater debits than credits until MY2024-2026 timeframe, at which point they are in approximately annual compliance (i.e. net-positive credit generation). Industrywide for MY2020-2026, this tracks with approximately a 4.5 percent annual reduction in credited CO_2 improvements for Framework OEMs (i.e. including any relevant credit provisions such as EV multipliers or increased off-cycle credits) and 2.4 percent annual improvement for SAFE OEMs. These are slightly higher than the respective rates of stringency increase in the respective annual curves in order for manufacturers to shift from annual debits to annual compliance.

As noted above, our modeling allows manufacturers to deviate from this baseline compliance pathway beginning in MY2024. Because of the periodic refresh and redesign cycles faced by a manufacturer, it is unlikely that a manufacturer can fully redesign its entire fleet in a given year in response to a change in regulations. By matching the fleet to the compliance trajectory projected through MY2023, we best reflect the steps which are feasible for a manufacturer in the years afterwards, even limited by any such potential product cycle constraints. There are a number of additional strategies for compliance that cannot be mimicked by our modeling (see § I.d. for details), so we consider limiting improvements in this way a conservative constraint on how manufacturers could respond to a rule finalized for MY2023-2026.

For our modeling, we have considered the use of credit flexibilities with slight modification from those proposed by EPA, to be more consistent with our arguments on those flexibilities below. For the EV multipliers, we have only considered OEMs use of these credits in the MY2023-2025 timeframe—because the EV share prior to the rule going into effect is small, we assume that manufacturers will utilize the cap in later years when their EV share is greater. This is a conservative assumption, particularly with regards to lead-time, since a manufacturer selling EVs in MY2023 may wish to take full advantage of the cap in that year because of the large change in stringency. Additionally, we have not modeled the use of hybrid pick-up credits at all, and manufacturers in our model do not exceed the 10 g/mi off-cycle cap until MY2023. [EPA-HQ-OAR-2021-0208-0277-A1, pp.6-8]

18 The 18-month lead-time underpinning the rule’s ability to affect MY2021 stems from the National Highway Traffic Safety Administration’s fuel economy program under the Energy Policy and Conservation Act. It should be emphasized that EPA has no such requirement under the Clean Air Act, and this 18-month lead-time acts as a surrogate for action for manufacturers, since if manufacturers respond to the regulation on a slower timescale, they will not have been able to significantly alter their product plans in response to the SAFE rule, and thus there would be no lead-time issue, as already noted.

Commenter: Zero Emission Transportation Association (ZETA) and EVHybridNoire (EVHN)

ZETA members, including Rivian, Tesla, and Lucid, among others in the EV industry, have created over 250,000 American jobs and are scheduled to produce and accelerate the delivery of a variety of EVs during the implementation of the new rule.4 Some of these automakers and models are debuting in the next two years, so the EPA’s MY 2017 baseline used in the impact analysis of the proposed standards neither accounts for these new entrants nor the large deployment of EVs post-MY 2017 like the Tesla Model 3. Because of this, electric vehicles and trucks will make up a larger portion of the new vehicle market in MY 2023-2026 than projected. [EPA-HQ-OAR-2021-0208-0275-A1, pp.2-3]

EPA Response

In response to comments about modeling inputs from the Alliance For Automotive Innovation, Honda, Rivian, and others, EPA notes that we have updated inputs used in the FRM analysis. We are using a MY 2020 based fleet and have updated the banked credits information based on the most recent data. These and other modeling updates for the final rule are discussed in Preamble III and in RIA 4.

EPA disagrees with comments that we should use the most recent version of CCEMS and believes that the version we have used is appropriate for analyzing the costs and benefits in this rulemaking, including for our final program. We discuss this in Preamble III and in RIA 4.

In response to the off-cycle costs used in the NPRM, EPA notes that we have updated the costs of off-cycle credits using more recent data in the modeling inputs. This is discussed in RIA 4.1.1.1. Further, we have updated our approach to modeling off-cycle credits in the FRM analysis as detailed in RIA 4.1.1.1.

In response to comments on modeling of HCR2 technology, its use and its effectiveness value in the NPRM analysis, we have removed HCR2 from compliance pathways in our primary analysis model runs. Instead, we include a sensitivity that allows HCR2 to play a role in compliance pathways for MY 2025 and later, with the updated modeling results showing very little use of HCR2 technology in the MY 2023 through 2026 timeframe. See RIA 4.1.5.1 and Table 4-38. We discuss HCR2 technology in more detail in RIA 2.3.2 and 4.1.1.3.

In response to comments on battery costs, EPA has updated our battery costs for the final analysis. We discuss battery costs in Preamble III.A with more detail in RIA 2.3.4 and 4.1.1.2. Preamble III.A also includes specific responses to the Alliance's comments regarding intellectual property and proprietary production processes, total industry volumes of battery electric vehicles as a battery production volume assumption, and including BEV400 and BEV500 as technology options. We also address comments on battery cost in section 12.1 of this document. In response to comments on EPA relying on BEVs with short range (BEV200), EPA agrees in part and has limited the penetration of BEV200 technology in the final analysis to a level we believe is more realistic by setting the phase-in at 0.13% per year and beginning that low phase-in in MY 2020. As a result, very few of the BEVs in our final analysis are BEV200 (<2% in MY 2026).

In response to comments from the Alliance citing the uncertainty of future electricity rates and suggesting that electricity rates may become more expensive as renewable generation is added, please see our response in Section 12.1.

In response to comments on miles driven by BEVs versus ICE vehicles, EPA agrees that this is an important issue to consider. Based on the data and studies available to us (no new data was provided by the commenter), we have not reached any conclusions about systematic differences in use between these vehicles. We have also not reached a conclusion regarding the extent to which any differences that may exist today might persist in the future. We do not believe it is appropriate to make any analytical changes at this time regarding the VMT assumptions for BEVs and ICE vehicles for standards through MY2026 addressed in this rulemaking, but we intend to continue to study this issue.

Regarding comments on future fuel prices compared to today's prices and today's projections of future prices, EPA will continue to track such trends and to rely, as we have historically done for light-duty GHG rules, on experts at the Department of Energy’s Energy Information Administration to project future energy prices. Importantly, we have included in our sensitivity analysis, an assessment of the impacts of the standards with both lower oil prices (i.e., lower gasoline prices) and with higher oil prices (i.e., higher gasoline prices). See RIA 4.1.5.1, Tables 4-37 and 4-38.

Regarding comments on modeling of all federal and state programs simultaneously, rather than our approach to model our GHG program in isolation, see earlier statements in this Section 13 where we noted that EPA follows applicable guidance and best practices when conducting its benefit-cost analyses, including OMB Circular A-4, EPA’s Guidelines for Preparing Economic Analyses, and the Interagency Working Group (IWG) on Social Cost of Greenhouse Gases Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimates under Executive Order 13990. We therefore consider our analysis methodologically rigorous, performed in accordance with OMB guidelines, and a best estimate of the projected benefits and costs associated with the final rule. Further, EPA has included in its no action scenario both the GHG standards set in the SAFE 2 final rule and the voluntary agreements for national GHG emissions targets between California and five automakers (the California Framework Agreements). In each of the action scenarios analyzed, EPA considered the GHG program in isolation since EPA is only setting LD GHG standards in this rulemaking.

The Alliance for Auto Innovators comments claim a possibility that vehicle manufacturers may de-content conventional vehicle emission aftertreatment systems to save costs as the result of increasing stringency of GHG standards and reduced fuel consumption, and note that it would be inappropriate to claim benefits from reduced engine-out emissions. The EPA analysis does not assume tailpipe emissions of criteria pollutants will decrease with decreasing fuel consumption, and we believe that benefit-cost analysis conducted for this FRM appropriately reflects the emissions resulting from the final standards.

Regarding comments from the Alliance for Vehicle Efficiency suggesting that EPA use projected sales data from IHS Markit and pointing out shortcomings of past EPA projections, the commenter states that "Real-world modeling in the Proposed Rule will assist manufacturers with future planning to reflect consumer’s vehicle choices." CCEMS projects a future fleet based on data from EIA about the future fleet and on algorithms within the model that influence future fleet mix based on fuel consumption projections and costs. EPA acknowledges the commenter’s statement that manufacturers make use of its models or modeling results in their future planning with respect to consumer's vehicle choices.

Regarding comments that EPA should set standards that encourage as many solutions as possible, and that a single technology solution will not accomplish our goals, EPA agrees and has set performance-based, fuel-neutral standards directed at resulting insignificant GHG emissions reductions rather than mandating specific technologies.

The American Enterprise Institute claims that EPA failed, in the NPRM analysis, to consider the time-related costs of electric vehicle charging. This is not true. While we inadvertently did not mention that fact in the description of our analysis inputs in the proposal, we have corrected that oversight in the final preamble at Section VII.C. The CCEMS model input files used by EPA in support of the NPRM included all relevant factors used in the modeling (see any parameters input file at EPA_CCEMS_PostProcessingTool, Docket ID EPA-HQ-OAR-2021-0208-0133). The fact that EPA does include those impacts in the analysis is clear by the greater magnitude of the "Refueling Time Savings" in the FRM analysis relative to the NPRM analysis as shown in Preamble Table 45 (the negative time savings constitute a cost and since the magnitude is greater in the FRM analysis than it was in the NPRM analysis, then costs are greater for the FRM's final standards due to the higher BEV penetration in the FRM than in the NPRM).

Regarding comments from the Consumer Federation of America, Drs. Michalek and Whitefoot, and Mr. Peterson regarding our benefit-cost analysis, we note that our benefit-cost analysis follows the practices of OMB Circular A-4 and the Guidelines for Preparing Economic Analyses. EPA has been developing tools to examine the macroeconomic impacts of rulemakings but these tools are still in development; see https://www.epa.gov/environmental-economics/cge-modeling-regulatory-analysis).

The California Air Resources Board suggested that ZEV-only manufacturers be fully considered in credit modeling. EPA agrees with this comment and has conducted a sensitivity analysis which reflects this recommendation. CCEMS does not allow for credit trading across manufacturers. Instead, any credits earned and/or banked by a manufacturer are usable by that manufacturer only. Therefore, in the CCEMS modeling a pure BEV manufacturer (e.g., Tesla) that earns many credits each year, retains all of the earned credits since those credits cannot be traded or sold to another manufacturer within the modeling constraints. While that does not impact Tesla's average cost per vehicle calculated within the model, it can impact costs per vehicle of other manufacturers since, rather than purchasing credits from Tesla, the model simulates that they must add technology to achieve compliance. While we recognize there is uncertainty in the credit trading market in any given model year, EPA's annual manufacturer Trends reports indicates that there is a robust credit market and we believe it is more likely that most credits will not go unused. For that reason, for both the proposed and final rules we assessed a sensitivity case that allows for such trading -- our "perfect trading" sensitivity -- where we remove all manufacturer identifying data from the input files and treat the entire fleet as produced by a single manufacturer. That way, Tesla's credit sales, and the sales and purchases of other manufacturers, can be better reflected. We present our sensitivity results in several places: RIA 4.1.5.1 for cost per vehicle and technology penetration rates, and RIA 10.4 for benefit-cost analysis results.

In response to a request for comment, CARB suggested that if EPA's SAFE1 waiver action were reversed prior to this final rule, then it would be reasonable for EPA to include the California GHG and ZEV programs in the No Action case. EPA has not included the California GHG or ZEV programs in the No Action case for this final rule, as described in Preamble III.A and RIA 4.1. EPA applied the California Framework Agreement nationwide targets to the five participating manufacturers as part of the No-Action case in its compliance modeling.

Other commenters questioned why EPA had not included certain consumer-related costs and benefits as was done in the SAFE 2 final rule. As noted earlier, EPA follows applicable guidance and best practices when conducting its benefit-cost analyses, including OMB Circular A-4, EPA's Guidelines for Preparing Economic Analyses. EPA does not believe it is necessary to characterize certain costs and benefits as private (consumer) and others as societal (social) costs and benefits. In the past, EPA has considered financing costs, taxes, insurance, etc., when calculating consumer-oriented impacts such as payback periods and lifetime costs/savings, but has never included those costs in its final benefit-cost analyses.

In response to comments from Consumer Reports on the fuel economy gap, we discuss these issues in detail in Section 17 of this document and in Preamble VII.A. and RIA 8.1. We agree with the comment that our off-cycle credit modeling approach was not optimal in the NPRM. We have updated our approach as discussed in RIA 4.1.1.1. This commenter also suggests that we update our battery costs, which we have done as discussed in Preamble III.A with more detail in RIA 2.3.4 and 4.1.1.2. This commenter also states that EPA generally does not include repair and maintenance costs in GHG rules. In fact, EPA included maintenance cost impacts in the 2012 final rule and the analyses we conducted during the midterm evaluation, but maintenance costs were not included in the SAFE rulemaking and, likewise, were not included in the NPRM for this rulemaking. We also did not attempt to include those costs in our final analysis because we do not have a good method to incorporate recent studies into CCEMS. That said, we intend to study this issue for future analyses and appreciate the studies the commenter has referenced in their comments. As for fuel prices and the AEO report used, we have chosen to continue with the AEO 2021 report as it remains the most recent report. We have conducted sensitivities that include the high oil and low oil prices and present those results in RIA 4.1.5.1.

Regarding the DENSO comment that we update our modeling with the updated IMAC-GHG-LCCP (Improved Mobile Air-Conditioning Greenhouse Gas Life Cycle Climate Performance software). We considered the comment but decided it was not necessary to do so for the final rule analysis since EPA did not propose and is not finalizing any changes to the air conditioning credit elements of the GHG program. We address Life-cycle Analysis comments in section 16 of this document.

Regarding comments from Walter Kreucher, many of the comments are difficult to understand and many do not appear specifically directed at this rulemaking or the EPA GHG program, but as far as EPA can determine pertain to the CAFE program. Mr. Kreucher may be implying that EPA based its "CO2 Tailpipe standards on market penetration of ZEVs" and that our RIA stated that there will be a de minimis impact on climate as a result of the proposal. Neither of these statements is true of EPA's NPRM. We did not conduct climate modeling for this rulemaking and did not make such claims on climate impacts. However, we have estimated climate benefits and present those estimates in Preamble VII.I and RIA 10. Mr. Kreucher also claims "average cost premium (including fuel cost and the social benefits) of an electric vehicle was $22,400 above the cost of its gasoline counterpart." The commenter did not provide an explanation for how this value was determined, but even if were true with respect to price, we note that the highest selling EVs tend to have performance and utility features which are not available in any ICE vehicles of the same class. It is therefore difficult to compare BEV vs. ICE prices on an equivalent basis. Any apparent price premium could imply higher costs to manufacturers, but it could also imply that electric vehicles are more desirable to consumers and that supply and demand is driving up their prices, or that EVs are sold in more expensive market segments than most new vehicles. The latter would say nothing of their costs. In addition, there are often federal and state tax incentives for consumers in purchasing zero emissions vehicles that can directionally reduce the prices paid by consumers. We believe, as discussed in Section 12 of this document, Preamble III.A and in RIA 2.3.4 and 4.1.1.2, that we have estimated electric vehicle costs, including our updated analysis of battery costs, as accurately as possible. With respect to comments on advanced technology multipliers suggesting that EPA does not think the proposed standards are feasible, EPA disagrees with this comment. The multipliers are meant to promote earlier introduction of BEV and PHEV vehicles in MYs 2023 and 2024 and to provide flexibility in light of lead time. We believe the standards could be achieved at a reasonable cost even in the absence of the multipliers, although the multipliers serve as an incentive for EVs.

In response to the Michalek and Whitefoot comments, we note that EPA is not obligated under the Clean Air Act to set standards based on maximizing net benefits. With respect to the scrappage modeling, we address this issue in more detail in Preamble III.A where we state that EPA is maintaining the assumption of constant non-rebound total fleet VMT for this FRM and will continue to review these and other modeling approaches for future analyses. Further, we have generally characterized the flexibilities available to manufacturers in our benefit-cost analysis where appropriate (see Preamble III and RIA 4).

NCAT commented that they believed our battery costs in the proposal were too high. EPA has updated those costs based on public comments and the most recent data, which has resulted in a lowering of battery costs for the final rule as discussed in Section 12 of this document, Preamble III.A and in RIA 2.3.4 and 4.1.1.2.

Toyota commented on our use of HCR2 technology and that the technology was inappropriately modeled. As we discuss in RIA 2.3.2 and 4.1.1.3., we have revised our approach to modeling the HCR2 technology and for the final rule we do not allow the technology within the modeling for our primary analysis. HCR2 is now modeled as part of a sensitivity analysis for model years 2025 and later (see RIA Chapter 4.1.5). The comment that HCR2 assumes use of a compression ratio of 14:1 is incorrect. The effectiveness of HCR2 is based upon a geometric compression ratio of 13:1, use of cooled EGR, and addition of dynamic cylinder deactivation (see RIA 2.3.2), and thus the incremental CO_2 effectiveness would be comparable to the incremental effectiveness of Toyota's current production A25A-FKS engine except with the addition of dynamic cylinder deactivation.[57]

13.2. Projected Technology Packages and Manufacturer Compliance Costs

Commenter: Alliance For Automotive Innovation

Auto Innovators provides the following comments on EPA's modeling of potential manufacturer compliance pathways, including technology benefits and costs, in the spirit of ensuring a robust assessment of the actions manufacturers may take for compliance, their associated costs, and other considerations. Given the limited time provided for comments, we have necessarily abbreviated our review. Auto Innovators may submit additional supplemental technical comments in response to EPA's analysis and to that of other stakeholder submissions.

In the GHG NPRM, EPA states that:

In our design and analyses of the proposed program and our overall updated assessment of feasibility, EPA also took into account the decade-long light-duty vehicle GHG emission reduction program in which the auto industry has introduced a wide lineup of ever more fuel efficient, GHG-reducing technologies. The technological achievements already developed and applied to vehicles within the current new vehicle fleet will enable the industry to achieve the proposed standards even without the development of new technologies beyond those already widely available. Furthermore, in light of the design cycle timing for vehicles, EPA has basis to expect that the vehicles that automakers will be selling during the first years of the proposed MY 2023-26 program were already designed before the less stringent SAFE standards were recently

[57] Kargul, J., Stuhldreher, M., Barba, D., Schenk, C., Bohac, S., McDonald, J., & Dekraker, P. (2019). Benchmarking a 2018 Toyota camry 2.5-liter atkinson cycle engine with cooled-EGR. SAE International journal of advances and current practices in mobility, 1(2), 601.

adopted. Further support that the technologies needed to meet the proposed standards do not need to be developed, but are already widely available and in use on vehicles…140

Auto Innovators encourages EPA to rethink the assumption that the compliance modeling is reasonable in the context of policy analysis and projected response to major regulatory reform and considering significant events since 2017.141
